As is generally the case where forests exist in the tropics, parasites and fungi abound, and of these there are interesting examples in the collection. The hush-ropes, which winds in fustoons from tree to tree, is one of the most remarkable of these; some of them have all the appearance of a manufactured rope. Its mode of propagation is peculiar. The seed is deposited by birds on the upper branches of trees, where it takes root and subsists upon the sap, gradually growing downwards till it reaches the ground, on reaching which it takes root and gains new vigour. Of fibrous plants there is great variety, some of which are spun into ropes by the natives. Specimens of this native manufacture are shown, and this variety of plants may yet become extensively used in the making of that class of goods, as the fibres are long and tough. The cotton plant, which is indigenous to the colony, was, at one time, extensively cultivated, and formed a staple industry of the country; but America has now the chief hold of the market as regards that article. It is shown in different stages as manufactured into hammocks and fabrics for clothing, &c., by the natives. The cocoa-nut tree is also put to various uses, and several examples of the inner bark of trees, also used by them, appear as if they might be more extensively utilised. Examples are shown of Gum Animi obtained from the locust-trees, which is of fine amber-colour, and is used in making the finer kinds of varnish. It is scarce and of great value, some of the purer blocks fetching as much as 200l. a ton. The blocks take the form of stalactites, and are produced when the tree receives any slight injury from insects or otherwise, and their formation progresses slowly year by year. This secretion is formed in the interior of the tree, and, of course, cannot be got at until the wood is cut open. Amongst the exhibits are specimens of india-rubber and gutta-percha, which latter is used for covering submarine cables. Samples of the Cassava from the root of the Manioc, which forms a staple article of food of the natives, and a large assortment of medicinal barks, are submitted for inspection. There is a model of the "banah," or woodland hut of the natives, formed by driving poles into the ground, the spaces between which are left open, and are covered by a roof of palm-leaves. It is divided within into two apartments, and from the roof rafters hammocks are swung, under which fires are lighted to keep off damp and insects. In its construction the fibrous substances found in the woods are used for lashing the timbers together, and the scanty furniture is made of wicker-work. A canoe scooped out from a block of cedar, and another formed of bark, are characteristic examples of native boat-building. A model of the punt raft used for floating timber down the rivers is sent for exhibition. As the rivers are tidal for nearly 100 miles they afford great facility for the transit of the timber to the places of shipment, of which Georgetown is the chief. The forests are so extensive and luxuriant that there is no need to supply what is taken away by fresh planting, and as yet nature sufficiently makes up for the outtake, which is confined to no particular period of the year. As a precautionary measure, however, Government has appointed superintendents to overlook the traffic, and it is proposed to establish a School of Forestry with the view of utilising the abundant products to the best advantage.

### BRITISH ARCHÆOLOGICAL ASSOCIATION.

THE forty-first annual meeting of this Association, to be held at Tenby, will extend from Tuesday, September 2nd, to Thursday, the 11th, inclusive. The president is the Right Hon. the Lord Bishop of St. David's. The following is an outline of the intended proceedings of the Congress:—

**Tuesday, September 2.**—Members and visitors to assemble at the Town-hall, at 2 p.m., for the reception of the Bishop of St. David's, president, officers, &c., of the Association, by the Mayor and Town Council of Tenby; afterwards the President will deliver the opening address. At its close the party will proceed to the examination of the ancient town walls and towers and ruins of the castle, together with the old buildings of the town, under the guidance of Mr. Edward Laws, hon. local secretary of the Congress, and then inspect the many objects of antiquity preserved in the museum. During the afternoon the parish church will be visited.

**Wednesday, September 3.**—Leave by special train at 9 a.m. for Pembroke, where carriages will be in receipt of the Bishop of St. David's, president, the hon. Colonel Lambton, and the Mayor of a long harrow. After leaving Brownslade the party will be driven to Castle-Martin, where the church will be examined, and described by the vicar. Afterwards, under the guidance of Mr. Edward Scott, the drive will be continued to Newton Tonnage, where a cromlech, close by the high road, will be examined and commented on, and the party will proceed to Angle, and afterwards to Rhos Crowther, where the Edwardian house of Jestinton (now called Eastington), will be commented on, and the old parish church, which will be explained, and its history given by the rector. Evening meeting and discussion of papers. (No papers are to exceed twenty minutes in reading.)

**Thursday, September 4.**—Leave by carriages at 9 a.m., and drive to Manorbere Castle, which will be examined and commented on by Mr. E. P. Loftus Brock, F.S.A., and then the party will walk to the church close by, which will be described by Mr. George Patrick. Afterwards the party will walk to the cromlech overlooking the bay, which will be described by Mr. Edward Laws. Thence the party will return to Manorbere Castle, and after luncheon will take carriages to Hodgeston Church, and the drive will be continued to the remains of the Bishop's Palace at Lamphay, returning to Tenby in good time for the evening meeting at the Town-hall, at 8.30, where papers will be read and discussed.

**Friday, September 5.**—Leave by special train at 9.30 a.m. for Pembroke, where carriages will be in readiness to proceed direct to the Stack Rocks and thence to St. Govan's, where the chapel will be described and examined. The carriages will then proceed to Bosherston Church, which will be described by the Rector, and thence to Stackpole Court, by the permission of the Earl of Cadwor. Afterwards a visit will be paid to the prehistoric village on Stackpole Warren, where the tumulus or barrow opened by the occasion will be examined and described by Col. Lambton and others. The party then will drive direct to Pembroke in time for the special train to Tenby at 6.30 p.m. An evening meeting will be held at the Town-hall at 8.30, for the reading and discussion of papers.

**Saturday, September 6.**—Leave by carriages at 9 a.m. for the Castle House Hotel, and proceed to Gunfriston Church, which will be examined and described, and thence to St. Florence Church, which will be described, and its history given, by the Rev. E. J. S. Rudd, as well as the remains of the old Flemish House close by. At about 10.30 a.m. the carriages will proceed to Carew Castle, which will be examined and described by Mr. Thomas Blashill, and afterwards the ancient interlaced Cross, outside the Castle wall, will be inspected, and then the church examined, and explained by the Vicar and Mr. Loftus Brock. Luncheon will be partaken of at 2 p.m. in the Castle-grounds. At 3 p.m. the party will be driven to Upton Castle, where the disused church or chapel in the grounds, near the ruins of the castle, will be visited. Evening meeting at the Town-hall, Tenby, at 8.30.

**Monday, September 8.**—Leave by special train for Pembroke at 9 a.m., and then walk to the Castle, which will be examined and commented on by Mr. Loftus Brock and others. Afterwards, the party will return by the Church of St. Nicolas at Monkton, with the remains of the interesting Monastic buildings in the churchyard, which will be described by the Vicar. The Prior's House, now the residence of the Vicar, will then be visited and described. Luncheon will be partaken of at the King's Arms Hotel, Pembroke, at 2 p.m., and at 3 p.m. the party will return by the Church of St. Nicholas for the closing meeting of the Congress, at the Town-hall. It is proposed that a conversation shall take place at the Assembly-rooms at 8.30 p.m.

Three extra days have been arranged for, viz.:—  
**Tuesday, September 9.**—Members and visitors to start by train for Haverfordwest, whence by carriages will be made to Glamorgan and Pilton Castle, the seat of Mr. Charles E. G. Phillips, V.P., taking any object of antiquarian interest on the road there.

**Wednesday, September 10.**—Leave the Castle Hotel by carriages, and drive to St. David's, taking certain antiquarian remains on the way, and halting at Roeb Castle, and taking the tumulus at Pointz Castle. On reaching St. David's, luncheon will be partaken of at the Crown Hotel and other inns, where accommodation will be arranged for the night. At 2 p.m. a visit will be made to the cathedral, where, under the guidance of the Dean of St. David's, an examination of some of its principal features will be made. After service, a further investigation will be made of the monuments, effigies, &c., and then a visit paid to the remains of Bishop Gower's Palace, &c.

**Thursday, September 11.**—Members and visitors to proceed after breakfast to St. David's Head, and there examine the stone circles, stone avenues, and cromlech, and other prehistoric monuments. Return to St. David's by the reputed site of the supposed Roman city of Menapia, and inspect the ruins of St. Justinian's Chapel on the seashore. Afterwards leave St. David's by carriage, and return to Liverpool, thus bringing the Forty-first Annual Congress of the Association to an end.

**MASTERS AND MEN.**

**Scott Masons.**—At general meetings of the operative masons of Edinburgh and Leith, held on Saturday afternoon, two delegates from Glasgow reported that the strike there was still continuing. They stated that three weeks ago 2,500 men came out for an advance of wages to 8d. per hour. Fifty-eight employers agreed to pay the sum asked, and had employed 1,050 hands. Upwards of 1,000 had left the city, and had found employment throughout the country, and the strike roll was now reduced to 275.

**North Wales Slate Quarries.**—The men employed at the Maenollen Slate quarries, one of the largest industries in North Wales, who struck work a fortnight ago against a reduction of 6 per cent. in wages, on the 29th inst. resumed work upon the masters' terms. The slate trade in North Wales keeps very flat.

**AN ARCHITECT'S CLAIM FOR PROFESSIONAL SERVICES.**

NORMAN V. THE LEZANT SCHOOL BOARD.

MR. GIFFARD, judge, on Monday last, gave his decision at the Stonehouse county court in the case of Mr. A. Norman, architect, v. The Lezant School Board. Mr. Norman claimed 30l. 9s., which he made up as follows:—Surveying Kenna school buildings and the master's house and reporting in what respects they were not in accordance with the specifications, 6l. 6s.; measuring the work in detail and making estimates of cost, conformably to the contract, 7l. 7s.; numerous attendances and correspondences as arbitrator, 12l. 12s.; umpire's fee, 2l. 2s.; expenses, 2l. 2s. The first item of 6l. 6s. and last of 2l. 2s. were paid into court, the defendants contending that this was all Mr. Norman was entitled to. It appears he was instructed to make a report on the buildings in question, and named as his price 6l. 6s. and expenses, which was accepted. Circumstances afterwards arose calling for further services on his part. He therefore claimed for further remuneration.

His Honour gave a verdict for the plaintiff with costs, and remarked that in his opinion there was nothing in the course Mr. Norman took inconsistent with his duty, and he was fairly entitled to remuneration for his time and labour.

**DISSENTING CHURCH-BUILDING NEWS.**

**Chatham.**—The memorial-stones of a new Bible Christian Chapel and Hall in the Luton-road, Chatham, have been laid. The buildings consist of a chapel and hall with class-room, vestries, lavatories, &c. They are situated on a commanding corner site, the chapel having a square buttressed tower at the angle of the building, with turret on opposite side, large rose-window in centre of arched recess, and double-entrance porch, while the side elevation is divided into five bays with double windows and buttresses between. The elevation of hall is of similar design to side of chapel, to which it is joined by vestry buildings and choir and organ recess over. The style adopted is Early English, the materials being red bricks with white stone dressings and slated roofs. Mr. J. Kingwell Cole, of Mount-street, Grosvenor-square, is the architect, and Mr. C. E. Skinner, of Chatham, is the contractor.

**Forest-hill.**—The new Bible Christian Church of St. James, situated in the Stanstead-road, Forest-hill, was formally opened on the 1st inst. The church, with its spire, 120 ft. in height, is in the Early English style. It has a double entrance in the front. There is sitting accommodation for 500 persons. The organ, built by Mr. Hunter, of Clapham, is fixed in the chancel

in the rear of the choir-stalls. In front is the rostrum, which is of stone. The contract price for the erection of the church and adjoining hall is 7,800l.; but the building of the hall will not be immediately proceeded with. The architects are Messrs. James Tolley & Son, of 66, Cannon-street; and the builders are Messrs. J. M. Macey & Sons, of Battersea. The gas-fitting work has been supplied by Mr. Dodson, of Fetter-lane; and the heating and cooling apparatus by the *Jolus* Water-spray and General Ventilating Company.

**The Student's Column.**

**HINTS FOR THE STUDY OF THE HISTORY OF ARCHITECTURE.—IX. THIRTEENTH-CENTURY GOTHIC.**

**W**E have now taken note of the various styles that had come into existence previously to the development of the Pointed Gothic style, which reached its culminating perfection, in the opinion of the best authors, in the thirteenth century.

Rosengarten, with pardonable national prejudices, heads his chapter v. (page 287), as "The Pointed Style, called also the Gothic or German Style." We have seen, however, that the Germans developed and clung to a round-arched Gothic style, of which they may well be proud, and which they may well be content to call a German style. The Italians developed a Pointed Gothic style which has beauties of its own, and in some individual instances,—such as the Campanile at Florence, designed by Giotto in 1324 (see Fergusson, page 788; Rosengarten, page 361; Prof. Roger Smith's "Gothic and Renaissance," page 121),—their work is unrivalled; but they were half-hearted in their appreciation of the style. In Sicily there is some Gothic work, such as Palermo Cathedral, but as nearly all the styles of the known world met in that small island, they all exhibit a mixed character, highly interesting, but decidedly adulterated. Spain is now known, through Street's special work on the Gothic architecture of that country, to contain some very fine examples of this style. The north-east of Europe displays its local peculiarities, as at Lubeck. Norway has its Trondhjem Cathedral, Sweden its Upsala, Holland its Dordrecht, Belgium its Malines, and we in England have a series of buildings, which are certainly unsurpassed for quiet beauty and lovely proportion by any other Gothic work in the world; but it must be admitted that the main problems of the Pointed Gothic style were worked out in France, and that it spread from that country, more or less directly, into all the others that cared to adopt its principles.

Before describing the fully-developed style, it will be well to accompany Fergusson, who, starting on p. 293 of his Handbook, and from the time of Charlemagne, 768 to 813 A.D., goes steadily through the various districts of France, in which the several local peculiarities are distinctly recognisable. He begins with Provence at the south-east, where the Romanesque influence is strongly marked in such churches as Notre Dame des Doms at Avignon (mentioned in the former article on Romanesque), and which led to the Classic frieze-like result in the porches of St. Trophime at Arles. He proposes his theory that the pointed arch was introduced in order to reduce the weight over the apex of the continuous tunnel vaults, which were immediately covered with their external tiles, without an outer wooden roof; other authors attribute the introduction of the pointed arch to the Crusaders, who became acquainted with it in Syria in the twelfth century; but there can be no doubt that the real origin of the pointed arch was a constructional one, and that it arose in the first instance from the tendency of large round arches to sink at the crown. Thus in Furness and Kirkstall abbeys all the large arches of the nave arcade are pointed, though the small arches in the same buildings are round. Mr. Fergusson then takes the adjoining district of Aquitaine, which, as we have seen before, contains the remarkable Church of St. Front at Perigueux, copied from the Byzantine example of St. Mark's at Venice, except that the arches and domes are pointed; this he considers easier of construction than with round arches; whereas Scott, in his Academy Lectures, holds the contrary opinion. Thence follow other domed churches,

but all on the plan of a Latin cross, instead of the Greek cross. [These churches are illustrated by Verneilh, in his "Architecture Byzantine en France," 1851, 1 vol. quarto.] He then mentions the typical Church of St. Sernin at Toulouse, and points out the aisle continued around the apse and chapels forming out of the aisle, which constitute a *chevet* as distinguished from the simple apse. He next takes the district of Anjou, north of the latter, in which we get the remarkable church at Loches, with its row of octagonal domes like squat spires, and the domed church at Fontevrault, where our Plantagenet kings, Henry II. and Richard I., were buried. Then he illustrates the Church of Notre Dame at Poitiers, the west front of which shows the local love for sculpture. Next he takes Auvergne,—a purely volcanic country, whose inhabitants long retained their original characteristics unchanged, and whose style of architecture is distinct, and early reached perfection. This district may be studied in an excellent paper by Street, illustrating the churches of Le Puy. It was also visited by members of the Architectural Association, under the direction of the late Mr. Sharpe, with the result of a finely-illustrated work on the subject. After remarking the Frankish style as exhibited by a church called the Basse Gueuro at Beannvais, not unlike a Roman basilica, he goes on to Normandy and treats of the difficulties of vaulting the nave of a church without having recourse to a pointed arch. Here the subject is brought home to us by the churches at Caen erected by William the Conqueror, who introduced the Norman style into England in 1066 A.D.

The next district, Burgundy, is remarkable for its abbey churches, that of Cluny, now destroyed, having been one of the largest in Europe, measuring 580 ft. in length. It was begun in 1089 by St. Hugues, and dedicated in 1131, and was lacking in the contrivances of groined vaulting, which provided clear-story windows, and must therefore have shared the upper darkness common to churches without such means of lighting. The church at Tournus has the peculiarity of a series of barrel vaults, at right angles to the direction of the nave, an example, perhaps, worth imitating for many reasons. At Autun the fluted Corinthian pilasters are rather startling, until we look about and find them accounted for as being inspired by old Roman work in the town. The church at Vezelay is remarkable for the progress in vaulting exhibited in the nave, and afterwards the porch or narthex required by the rules of the monastic order to which it belonged (no connexion with the Classic "orders").

Fergusson concludes his topographical arrangement with Frankish architecture, Frankia being the central province of which Paris is the head, and he then goes on to describe the features of those fully-developed cathedrals of which a surprising number were erected in the thirteenth century, including the end of the twelfth,—that is, from the revival of the national power, under the guidance of the great Abbe Suger, about the year 1144.

It should here be mentioned that England was again indebted to French influence in two more leading examples, at Canterbury Cathedral, from the design of William of Sens, in 1175, and at Westminster Abbey, where French arrangements are strongly marked in the portion built in 1269. We had, however, developed a style of our own, known as Early English (and not to be confused with the upholsterers' abominable misuse of that title), of which Salisbury Cathedral, built between 1220 and 1258, is a well-known example.

For those who can read French, no better author can be consulted than Viollet-le-Duc. His "Lectures" and his "Habitations of Man" have been translated into English; but not his finest, most exhaustive, and most practical work, "Dictionnaire raisonné de l'Architecture française du XI<sup>e</sup> au XVI<sup>e</sup> Siècle," or, rather, the translation has only been begun. In vol. i., under the word "Architecture," is a long essay from p. 116 to p. 452, which deals not only with the subject generally, but afterwards with the Ecclesiastical, Civil, and Military divisions of it in complete detail.

He demonstrates that the development of Pointed Gothic architecture is entirely a question of stone vaulting. At first continuous tunnel vaults were used over the nave, supported at their springing on each side by half tunnel vaults over the upper story of the side aisles, and he instances the Church of Notre Dame du Port, Clermont-Ferrand, in the south

of France. This church is also illustrated by Rosengarten on page 266, and shows how this arrangement precludes the introduction of light into the upper part of the nave. On account of this difficulty the naves of some churches had a wooden roof only above the level of a range of clerestory windows, as at the original church of St. Remy at Reims. The aisles of these churches were often covered with groined vaults (that is to say, the intersection of two vaults at right angles to each other) which admitted of windows being continued up to their apex; but the early builders were not able to construct a groined vault over the width of a nave. Moreover, such a vault is most easily applicable to a square plan, and, if the bays of the aisles were square it follows that the wider naves consisted of oblong bays; that is to say, the arches from side to side, and which were strengthened by transverse ribs, were wider than the arches from pier to pier, which were strengthened by small ribs.

What was to be done? If they all sprang from the same level, the web wall arches would only reach part of the way up the transverse arches and would look ridiculous (though this system is adopted in Renaissance buildings, such as our St. Paul's Cathedral, and is there well managed). If the transverse arches were bodily raised above the clerestory the want of abutment would bring the whole church to grief. At Amun Cathedral they reduced this danger by adopting a pointed tunnel vault over a clerestory, but such churches have either fallen or been subsequently supported by flying buttresses, and still their tunnel vault is dark.

In the nave of Vézelay Abbey church a new departure was made at the beginning of the twelfth century by building a groined vault which rose from the apex of the wall ribs up to the level of the apex of the transverse ribs. This construction, or "domed groining," as it is sometimes called, was also used in the Rhemish churches. An improvement was effected in the porch or narthex of this same church at Vézelay (of which a section is given by Fergusson on p. 655), so far as the appearance of the vault is concerned, but at the sacrifice of clerestory windows again, so that not much had been gained. Viollet-le-Duc next discusses the possibility of getting the crowns of the wall ribs up to the same level as those of the transverse ribs, so that the wooden tie-beam roof may sit comfortably above them without any waste of space, with the result that down goes the springing line of the transverse ribs! That would not do. He says that it was after many hesitations that, towards 1220, the crowns of these two sets of ribs were arranged so as to reach the same level. Now the groins came to be strengthened by diagonal ribs. By comprising two bays of vaulting and making these diagonal ribs a semicircle, their height agreed pretty comfortably with that of the transverse ribs. True, this arrangement produced six spaces and gave the wall ribs a squint-eyed appearance; but it was followed for many years, and goes by the name of *hærpertie* vaulting.

The height of these great diagonals was felt to be a nuisance, for Viollet-le-Duc insists that the builders of those days did not wish to give their naves any loftier proportions than were required for the necessary fitting on of the side aisles; and that, at last, it occurred to them to treat each bay of the nave with its own diagonal ribs, of consequently less altitude and forming four spaces or *quadrupartite* vaulting. This subject is more clearly explained in the lectures at the Architectural Association by means of a model; but it is also very fully described and illustrated in Scott's Academy Lectures, Nos. 14 and 15, in vol. ii.

Willis's paper on the construction of the vaults of the Middle Ages in vol. iii. of the Loan Collection of the Transactions is a recognised standard work on the subject, and deals with English examples. An excellent means of studying a building book in hand, is afforded by Scott's "Gleanings from Westminster Abbey," and also by Willis's "Canterbury Cathedral." While Rickman's "Gothic Architecture" is a valuable companion in a visit to any part of our island. Parker's "Glossary," in three vols.; Bloxam's handy little pocket volume, Paley's "Gothic Mouldings," De Caumont's "Abécédaire" (for France), and Smith's "Gothic and Renaissance" (for all countries), are also portable friends in need.

Of larger works on Gothic architecture there is nearly no end. Pugin's "Specimens," his

"Examples," Pugin & Britton's "Normandy," Britton's "Cathedrals," Sharpe's "Parallels," Turner's "Domestic Architecture of the Middle Ages," are all most useful; while of monographs on particular buildings, Neale's "St. Albans," Christian's "Skelton," and hosts of others will be found in the Institute Library. Last, but not least, the early volumes of the "Architectural Association Sketch-book" were far more devoted to Gothic work than the recent ones have been. While recognising the fact that there are many beautiful buildings in England that are not Gothic, it must not be forgotten that our Early English, Decorated, and Perpendicular styles are thoroughly national and are more at home in our climate and in the midst of our lovely scenery than Italian work can ever be; and that, in assimilating the juices of the latter we need not loosen our hold on the stem and branches of the former.

### Miscellanea.

**Prizes for Designs for Furniture.**—The Council of the Society of Arts are trustees of the sum of 400l., presented to them by the Owen Jones Memorial Committee, to expend the interest thereof in prizes to "Students of the Schools of Art, who in annual competition produce the best designs for household furniture, carpets, wall-papers and hangings, damasks, chintzes, &c., regulated by the principles laid down by Owen Jones"; the prizes to "consist of a bound copy of Owen Jones's 'Principles of Design,' a bronze medal, and such sums of money as the fund admits of." The prizes will be awarded on the results of the annual competition of the Science and Art Department. Competing designs must be marked "In competition for the Owen Jones Prizes." No candidate who has gained one of the above prizes can again take part in this competition. The next award will be made in 1885, when six prizes are offered for competition, each prize to consist of a bound copy of Owen Jones's "Principles of Design," and the Society's Bronze Medal.

**A New Smoke-consuming Locomotive.**—An engine of a novel type has recently been constructed by the Brooks Locomotive Works for the Chicago Locomotive Improvement Company. The head-light is placed where the stack generally is, while the stack is at the rear of the boiler and close to the cab. The boiler is one of the largest manufactured (what is known as a 60-in. shell), and the smoke, gas, &c., traverse it twice, along the bottom and over the back on the top to the stack. This makes such a good combustion that the finer particles of fuel, the gas, and the smoke are almost entirely consumed, and when the engine is going at full speed it is impossible to see any smoke. The smoke stack itself is very small, being not more than 7 in. to 8 in. in diameter. The patentee, Mr. Charles B. Coventry, claims among the advantages of this invention that it gets a steady even draught, reduces the waste of fuel to a minimum, and throws no cinders, sparks, or fire. The locomotive is peculiar in appearance, but it is said that it does its work well. It weighs 40 tons, which is 10 tons heavier than the largest engine at present on the Dunkirk, Alleghany Valley, and Pittsburgh Railroad.—*Iron.*

**Royal Victoria Hall and Coffee Tavern.** This hall (long known as the Victoria Theatre), will re-open this Saturday, August 30. The programme for the coming season comprises "Variety" entertainments and lectures. In this connection we note that Mr. Malden is engaged to deliver a course of lectures on "Egypt and the Soudan." On each Monday André's Alpine Choir with soloists will appear, and on Wednesdays an assault-at-arms is included in the plan. The managers are evidently striving energetically to provide cheap amusements for the people, and we hope they will succeed in attracting large audiences.

**Eastbourne Fine Art Exhibition.**—We learn that in order to meet the wishes of exhibitors, the committee have decided upon a change of date, and to hold the above exhibition from the 24th of September to the 3rd of October, all exhibits to be sent in on the 22nd of September, 1884.

**Parcel Post Accommodation at St. Martin's-le-Grand.**—The roofs over the yards at the General Post-Office, St. Martin's-le-Grand, mentioned by us a fortnight ago, are glazed on Mr. T. W. Helliwell's patent system.

**A South Kensington Exhibition for 1886.**—The principal Indian Princes and Chiefs have been sent invitations to join the Royal Commission for the Exhibition of India and the Colonies, to be held in 1886. Among them may be named the Nizam, Scindiah Holkar, the Maharajahs of Mysore, of Bhowuggur, of Cashmere, and of Oodeypore. The Governor General, the Governors of the two Presidencies of Bombay and Madras, the Political Agents, the Secretary of State, and some members of the Indian Council, Mr. Godley, Sir Owen Burne, Sir George Birdwood, Sir Philip Cunliffe Owen, Mr. Pedder, and other gentlemen connected with India have also been invited.

**Enlargement of the London School Board Offices.**—The offices of the London School Board on the Thames Embankment are now undergoing a very considerable enlargement by the erection of a new block of buildings having a frontage to the Embankment of 60 ft., and extending from the present offices to the newly-erected Fitzalan Chambers, which have just been built by the Law Land Company. The elevation of the extension will be uniform with that of the existing building. The accommodation provided by the enlargement will contain (besides numerous general offices) a new committee-room. The building is being erected from the designs of Mr. E. R. Robson, architect to the Board. The contractors are Messrs. Higgs & Hill.

**Tunbridge Wells.**—On Saturday last the Marchioness of Abergavenny laid the foundation-stone of a new convalescent home, which is about to be erected on a site adjoining Hawkenbury Church, near Tunbridge Wells. It was about fourteen years ago that Mrs. Thomas Ladds first established a similar institution on a small scale at Frant Forest. The new building, which will be of the Domestic Gothic style of architecture, will cost about 1,900l. It will be of red brick, and the walls will be hollow throughout. There will be accommodation for twenty-eight beds. The architect is Mr. J. Ladds, of Chapel-street, Bedford-row, London, and the builders are Messrs. Benle & Son, Frant-road, Tunbridge Wells.

**New Gas Tubing.**—We have received from Mr. Fletcher, of Warrington, a specimen of his new elastic rubber tubing, which is stated to be perfectly gas-tight and free from smell. The tubing is made of two layers of rubber, with pure soft tinfoil vulcanised between. This tube is "the result of many years' experiments." Irrespective of the well-known fact that extremely thin layers of rolled or beaten metal are perfectly gas-tight, the tube has been in practical use for some time, and has been thoroughly tested for months under continuous and heavy pressures of gas.

**Errata.**—By two vexatious errors which occurred in our last, the signatures of two of our correspondents were incorrectly given. The printer had been directed to substitute "R." for the "H." incorrectly printed as the initial letter in Mr. Herbert Carpenter's signature, so as to make it read correctly as "R. Herbert Carpenter," but in "correcting" the "R." was somehow substituted for the "H." which was the first initial of the writer of the letter about the curious floor at Croydon, whose signature should have been printed as "E. G. Carpenter."

**Gilchrist Engineering Scholarships.**—These scholarships, in connexion with University College, London, are given by the Gilchrist Trustees. They consist of an entrance scholarship, value 35l. per annum, tenable for two years, and a senior scholarship, value 80l. (half payable at the time of the award and half in the succeeding June), to be awarded at the close of each session. The examination for the entrance scholarship will be held this year on the 25th September and following days.

**Scandinavian Antiquities.**—Dr. Phené, F.S.A., has been for some time investigating the museums and private collections of antiquities in Scandinavia, and also the Ship Mounds of Norway, and the stone monuments of Denmark and Sweden, in continuation of his researches in Iceland and the Northern American Continent.

**The New Council Chamber at Guildhall.** The opening of the new Council Chamber at Guildhall will (according to the *City Press*) take place about the 25th of September. The building has cost about 40,000l. We gave a large view of the interior nearly a year ago.

**Disinfection and Deodorisation.**—We have received certain papers from Messrs. Forensis & Baynes as to a patent automatic disinfecting and deodorising apparatus, which can be used in connexion with water-closets, urinals, water-carts, &c., and which is so designed that any given quantity of a disinfecting fluid can be mingled with the water and be automatically delivered whenever either of the appliances referred to comes into use. Mechanically the arrangement is ingenious, and wherever the regular mingling of a fluid disinfectant with any water becomes necessary it will be useful. But our doubt as to the value of this and allied appliances is twofold. If a water-closet, for example, be foul, its filth will certainly not be "disinfected" by means of such an arrangement. Disinfection must be regarded as meaning the destruction of matter capable of conveying infection, and in the present state of our knowledge as to what constitutes the poison of the infectious fevers we cannot speak of disinfection apart from the destruction of all the organic matter in which the infection may lie hidden, and it is certain that no occasional flushing with water containing a certain quantity of any of the ordinary so-called "disinfectants" attains this end. Then, again, if a water-closet does really stand in need of such occasional chemical flushings, it may be taken for granted that the apparatus is in fault, being one permitting the retention of contents or being otherwise favourable to foulness. The remedy is to get rid of the faulty contrivance, not to attempt to deal with it by disinfecting fluids. In so far as the apparatus facilitates deodorisation it may have important uses, especially in connexion with urinals and street watering, but even then we should prefer to see the removal of the conditions which lead to offensiveness, rather than the attempt, however successful, to deal with them by an ingenious method of deodorisation.—*Lancet.*

**A New Patent Safety Cage for Collieries.** At a meeting of the Bolton and District Colliery Managers' Association, held on Monday, Mr. J. Lindley, of the Clifton and Kearsley collieries, exhibited his model clip cage to prevent accidents arising from overcropping or the breaking of the winding rope. In case of overcropping, the cage is suspended, releasing the central pin, which slips out of the jaws, and the cage remains suspended instead of being dashed through the head gear. The apparatus to prevent the cage falling down the shaft through breakage of the rope, consists in connecting the lower ends of the top rods to a pair of levers mounted on each side of the cage, the other end of the levers being forked and connected to opposite ends of a pair of links, which are fastened to the ordinary wooden or iron guide rods. As soon as the cage is released from the rope the inner arms of the levers rise and force the links together. The inner side of the forks being provided with wedge projections, which come in contact with similar projections on the sides of the links, the cage remains suspended, wedged fast to the guide rods. The meeting approved the principle of the cage.

**Accidents in Summer.**—The remark is often made that accidents in the summer time rarely occur; in the short days of winter, darkened by fogs, and the roads made dangerous by frosts and floods, accidents are looked for as a matter of course. The growing taste for athletic pursuits, and the increasing risk to those who engage in them, have, however, brought the two seasons more into unison as regards liability to accidents, and no more striking evidence of the truth of this statement can be found than the statistics of the Railway Passengers Assurance Company. In the week ending the 12th of August, notice of injury to 210 insurers was received, and no fewer than five fatal cases were reported; the injuries were caused by accidents at lawn tennis and cricket, when bathing, boating, riding, and driving, bicycle and tricycle riding, &c.

**Health Exhibition Library.**—The catalogue of the Health Exhibition Library, which has just been brought out, but is to be regarded as still "under revision," owing to the influx of new publications, presents a long array of titles of books relating to hygiene, forming a collection which visitors to the exhibition are to have the opportunity of consulting, and two rooms in the Albert Hall have been set apart as a library and reading-room. The collection consists entirely of voluntary contributions.

**Roman Remains in London.**—Mr. Roach Smith, in a letter to the *Times*, says:—The destruction of the remains of London Wall has brought to light some unexpected and important evidence of the fortunes of Londinium which do not yet seem to have been adequately attended to. Many years since I noticed that the foundations of the Roman wall on the river side were largely constructed of materials which had previously been used in public buildings, and near Tower-hill some fine sepulchral monuments have been made to serve in the same ignominious capacity. More recently, during the further demolition of the wall, it has been ascertained that it was in part constructed with the materials of anterior buildings to an unsuspected extent, some of the bastions being largely composed of them; and now, in the curtain wall near Castle-street, in Bevis Marks

additional sculptured stones with fragmentary inscriptions are being disinterred, luckily under the supervision of a few active members of the London and Middlesex Archaeological Society. They will make a valuable addition to those in the Guildhall Museum. These remains confirm the opinion I published many years ago on the comparatively late date of the circumvallation of Londinium known to us as London-wall.

**The New Sewerage Scheme for Sheffield.** At a meeting of the Sewerage and Rivers Committee, Mr. Wm. Todd, of Sheffield, was appointed clerk of the works in connexion with the sewerage scheme. There were 108 applications.

**The Iron and Steel Institute.**—The autumn meeting of this Institute is to take place in the city of Chester, on September 23rd and three following days.

**COMPETITIONS, CONTRACTS, & PUBLIC APPOINTMENTS.**

*Epitome of Advertisements in this Number.*

**COMPETITIONS.**

Nature of Work.	By whom required.	Premium.	Designs to be delivered.	Page.
Municipal Hall and Offices, Bombay .....	Municipal Commissioners, Governors of Longton Endowed School ..	Rs. 5,000, 3,000, 2,000..	Nov. 6th	ii.
School Buildings .....	do	Not stated .....	Not stated ..	ii.

**CONTRACTS.**

Nature of Work, or Materials.	By whom required.	Architect, Surveyor, or Engineer.	Tenders to be delivered.	Page.
Making Roads .....	Wandsworth B. of Wks. Brentford Local Board ..	Official .....	Sept. 2nd	xxii.

Nature of Appointment.	By whom advertised.	Applications to be in.	Salary.	Page.
Assistant to Surveyor's Office of Works .....	Civil Service Com. ....	Sept. 5th	Not stated .....	xviii.

**TENDERS.**

For new station, Upper-street, Islington, for the London Salvage Corps. Mr. Wimbale, architect:—

Dove House .....	£13,675 0 0
Scrivenor & Co. ....	13,615 0 0
Grover .....	13,334 0 0
Bird .....	13,239 0 0
Greenswood .....	12,903 0 0
Lavrance & Sandell ..	12,771 0 0
Morter .....	12,737 0 0

For pulling down and rebuilding Nos. 1, 3, 5, and 7, Great Portland-street, Nos. 37 and 39, Great Castle-street, and premises in rear of Oxford-street, for Mr. Peter Robinson. Mr. A. E. Hughes, architect. Quantities by Messrs. Carden & Sandell:—

Higgs & Hill (accepted) ..	£37,740 0 0
----------------------------	-------------

[Full list published by us a fortnight ago.]

For rebuilding No. 321, Strand, W.O. Mr. T. E. Knightley, architect. Quantities by Messrs. Batterbury & Huxley:—

Kiddle & Sons .....	£3,900 0 0
J. & J. Greenwood .....	3,739 0 0
C. Wall .....	3,668 0 0
Wm. Brass .....	3,467 0 0
Patman & Fotheringham ..	3,385 0 0
Ashby Bros. ....	3,245 0 0

For new sugar-boiling and confectionery works at Lincoln, for Messrs. Poppleton & Son. Mr. James Whitton, architect. Quantities supplied:—

Harrison & Sands .....	£2,347 0 0
Kendall .....	2,769 15 0
Simpson & Goy .....	2,766 0 0
Horton .....	2,745 0 0
Morgan .....	2,693 11 0
Martin & Sims .....	2,649 0 0
Baines .....	2,616 10 0
H. S. & W. Close .....	2,643 0 0
Middleton .....	2,617 18 0
Knight .....	2,600 0 0
Bradley & Noble .....	2,596 0 0
Wright .....	2,589 0 0
Crosby & Sons (accepted) ..	2,465 0 0
J. M. Harrison .....	2,487 0 0
J. B. Harrison .....	2,484 0 0
J. & H. Woodhouse .....	2,380 0 0
Codd & Escherger .....	2,165 0 0

For completing five houses, Gascony-avenue, Kilburn, for Mr. Geo. Gladman. Mr. Chas. J. Gladman, architect:—

Falkner .....	£1,275 0 0
Pryor .....	1,176 0 0
Barnet .....	1,050 0 0
Barnes (too late) .....	1,232 2 9

For alterations and additions to No. 173, High-street, Brentford, for Mr. Geo. Stone. Mr. Chas. J. Gladman, architect:—

Gibson .....	£384 10 0
do .....	365 0 0
do .....	258 15 0
Barnes .....	244 3 10

For alterations and repairs to No. 34, Baker-street, for Mr. Arthur Canton. Mr. Chas. J. Gladman, architect:—

D. D. & A. Brown .....	£417 0 0
J. Brown .....	375 15 0
Langridge & Sons .....	300 0 0
J. Styles & Son .....	295 0 0
Falkner .....	257 0 0

For the erection of a 4-quarter brewery, at Vauxhall, for Barrett's Screw Stopper Bottling Co., Limited, Messrs. H. Stoper & Co., architects, 24, Southwark street, S.E. Quantities by Mr. F. E. Morris, Cost-keeper:—

Main Building only. Table with columns for item name and cost. Items include Balbs Bros., Thos Hooper, R. & E. Evans, Raham Bros., Thos. Watson, J. Rider Hunt, Chas. Oldridge & Sons, W. W. Lerdou & Sons, Bea Cook, Chas. Manning, G. Howard, O. T. Gibbons, R. W. Priestley, Jones Bros., Chas. Elyton, Edwin Stafford, Scharian & Williams, C. Ansell, W. P. Croker, E. C. Howell & Sons, D. D. & A. Brown, F. Higgins, J. Allen & Sons, G. Stephenson, J. Tyerman, J. Dickson, Stephens & Bastow, Chas. Dickinson (accepted).

For alterations and additions to Lucton Foundation Schools, near Kingland, Herefordshire, Mr. F. R. Kempton, architect, Hereford. Quantities by Mr. F. Downing:—

School. Sanatorium. Table with columns for item name and cost. Items include Jones & Sons, Sedgley, near Dudley, Benj. Waale, Ludlow, D. D. & A. Brown, London, Hucksion & Warwick, Hereford, Bowers & Co., Hereford, Richard Yates, Shifnal, John Wood & Co., Westminster, Henry Welch, Hereford, William Cullis, Hereford, Horsman & Co., Wolverhampton, Thos. Collins, Tewkesbury, Chas. Claridge, Banbury, Edwards & Grosvenor, Leominster, and Ludlow, Tressane & Son, Shrewsbury, Page & Son, Leominster.

For branch stores and dwelling-houses for the Denton and Houghton Co-operative Society, Limited, Denton, near Manchester. Mr. T. Cook, architect, Victoria-buildings, Manchester. Quantities by the architect:—

Table with columns for item name and cost. Items include Sandam & Thomson, Fairfield, Turner, Knutsford, Rome, Manchester, Macfarlane & Co., Manchester, Butter & Carson, Manchester, Houghton, Goolley, Robinson & Parkes, Hyde, W. Brown, Salford, Warrington, Newton Moor, Holland, Fiddleton, Williams, Manchester, Whitell, Manchester, Burgess & Gault, Manchester, Hayes, Hulse, Shaw Cuzner, Shalybridge, Aughton, Dukinfield, Clayton, Denton (accepted), Robinson, Hyde, Stover, Denton.

For erection of additional schoolrooms and infant mistress's residence, at the Quarry-hill Board Schools, for the Gray's Thurock School Board. Mr. E. Clerk Allam, architect, Romford. Quantities supplied:—

Table with columns for item name and cost. Items include B. Stafford, Old Kent-road, G. D. Senger, Gravesend, Thompson & Tweed, Burdett-road, Wm. Wood, Chelmsford, G. Mower, Hackney, Jas. Welch, Stratford, S. W. Hawkins, London, Aldridge & Jenvey, Camberwell, H. J. Carter, Grays (accepted).

For the erection of a shop and lakehouse at William-street, Grays, for Mr. J. R. Banks. Mr. E. Clerk Allam, architect:—

J. Brown, Grays (accepted).

For rebuilding premises at the corner of Long Acre and Mercer-street, for Mr. Fredk. Kingwell. Mr. Albert E. Kingwell, architect, Victor House, Theobald's-road. Quantities supplied:—

Table with columns for item name and cost. Items include G. Kirk, W. & H. Salmon, Lawrence & Son, Pickersill Bros., Martin Wells & Co., Kirk & Randall, Green (accepted).

For painting, &c., at the Workhouse and Infirmary, for the Guardians of the Parish of St. Leonard, Shore-ditch. Messrs. Lee & Smith, architects. Quantities by Mr. Walter Barnett:—

Table with columns for item name and cost. Items include Coombe, Shurmer, Green, Maskall, Barton, Giblin, Flaxman, Hayworth, Wythe (accepted), Harter, Ware, Deacon, Lawson.

For constructing 1,278 ft. lineal of 50 ft. road and 153 ft. lineal of 40 ft. road, kerbed with 12 in. by 6 in. granite kerb, and the requisite water-drainage, on the Surbiton Estate, No. 2, of the National Liberal Land Company, Limited. Mr. Geo. Pooley, surveyor, 29, Charing-cross, London, S.W.:—

Table with columns for item name and cost. Items include W. William Carter, Austerly, John Stickley, Surbiton, Samuel Chafin, Rotherhithe, James Blomfield, Tottenham, William Nicholls, W. accepted.

For the erection of three houses at Dorling, for Mr. G. Whitford. Mr. F. C. Dyer, architect, 53, Gracechurch-street, E.C.:—

D. Duhhin (accepted).

For Kettering Sewerage Works. Mr. R. W. Johnson, surveyor and engineer, Kettering:—

Contract No. 1.—General Works. Table with columns for item name and cost. Items include Cooke & Co., Battersea, Corrie & Co., Lichfield, E. Barton, Rothwell, Sanders, Northampton, Dickson, St. Albans, C. & F. Henson, Kettering, F. Barton, Kettering, Geo. V. Henson, Kettering.

Contract No. 2.—Ironwork.

Table with columns for item name and cost. Items include Wright Bros., Leicester, Cave, Northampton, Cart & Paul, Leicester, Mohb, Northampton, Saloon, Kettering, Studd & Co., Kettering, Gimson & Co., Leicester.

For making new road, to be called Franche Court-road, leading out of Burnwood Lane, Wandsworth, and sewer, for Mr. John Mossor. Mr. Richard M. Hiscock, architect and surveyor, Wandsworth:—

Table with columns for item name and cost. Items include G. & R. Neal, J. A. Neal, J. Nobbs, G. Butler, W. Hampton (accepted).

For making a new road and sewer, leading out of Garrat-lane, Wandsworth, for Mrs. Diana Keach, of Garrat. Mr. Richard M. Hiscock, architect and surveyor, Wandsworth:—

Table with columns for item name and cost. Items include G. & R. Neal, J. A. Neal, G. Butler, W. Hampton (accepted).

For the erection of a portion of premises in Baldwin and Queen Charlotte streets, Bristol, for Messrs. C. T. Jelleries & Sons. Mr. Frank Wells, architect:—

Table with columns for item name and cost. Items include A. J. Beavan, A. Knass, H. A. Furse, J. Wilkins, W. Church, C. Clark, Fishponds, R. J. Crocker, Stephens & Bastow, J. E. Davis, Eastbrook & Sons, E. & T. Hatherly, W. Cowlin & Son (accepted).

For the enlargement and decoration of Lewinsdale House, Weston-super-Mare, for the Rev. Wm. Wheeler Aldridge. Messrs E. H. Lingen-Barker & Fredk. T. H. Chambers, architects:—

Table with columns for item name and cost. Items include Theophilus Palmer, Edwin Bryant, Thomas Lye, Underhay & Pine, Charles Addicot (accepted).

For new stables, &c., at Lewinsdale House, Weston-super-Mare, for the Rev. Wheeler Aldridge. Messrs. E. H. Lingen-Barker & Fredk. T. H. Chambers, architects:—

Table with columns for item name and cost. Items include John Palmer, Theophilus Palmer, Edwin Bryant, Thomas Lye, Underhay & Pine, Charles Addicot (accepted).

Accepted for altering and rebuilding the Bridge of Hope Mission-rooms, St. George's-in-the-East. Mr. E. M. Whitaker, architect:—

Table with columns for item name and cost. Items include The Building, Fitting, and Furnishing Company, Limited (formerly Theobald's-road), The Building, Fitting, and Furnishing Company, Limited.

Accepted for office fittings at the Equitable Fire Insurance Office, No. 69, Lombard-street:—

Table with columns for item name and cost. Items include The Building, Fitting, and Furnishing Company, Limited, The Building, Fitting, and Furnishing Company, Limited.

Accepted for shop-front and fittings, for Mrs. Swindley, No. 21, Church-street, Kensington:—

Table with columns for item name and cost. Items include The Building, Fitting, and Furnishing Company, Limited.

The 'Falcon,' Clapham.—In our last (p. 275) we gave a list of tenders for alterations at the Falcon public-house, Bedford-road, Clapham. We are asked to say that the accepted tender was that of Mr. Benjamin Cook, of Farrington-street, and not 'Cook Bros.'

Colleges, Shacklewell Estate.—The name of the successful competitor for this work, and for that mentioned immediately following it in our last (p. 282), should have been printed 'Dales,' not 'Dale.' Correspondents should be more careful in writing names. We wish week have to exclude a list of tenders altogether on account of illegibility.

Special Notice.—Lists of tenders frequently reach us too late for insertion. They should be delivered at our office, 46, Catherine-street, Strand, W.C., not later than four p.m. on Thursdays.

TO CORRESPONDENTS.

C. C. H.—Major K.—E. S. F. (photograph received).—A. W. (proof sent).—J. (photograph received).—W. T. (drawing received).—L. & L.—J. H. L.—H.—W. P. B. (next week). All statements of facts, lists of tenders, &c., must be accompanied by the name and address of the sender, not necessarily for publication. We are compelled to decline pointing out books and giving addresses. NOTE.—The responsibility of signed articles, and papers read at public meetings, rests, of course, with the authors. Letters or communications beyond average news items which have been duplicated for other journals, are NOT DESIRED.

PUBLISHER'S NOTICES.

CHARGES FOR ADVERTISEMENTS. SITUATIONS VACANT, PARTNERSHIPS, APPOINTMENTS, TRADE AND GENERAL ADVERTISEMENTS. Six lines (about fifty words) or under, 4s. 6d. Terms for Series of Trade Advertisements, 6s. 6d. Advertisements on front page, Competitions, Contracts, Sales by Auction, &c. may be obtained on application to the Publisher. SITUATIONS WANTED. FOUR Lines (about thirty words) or under, 2s. 6d. Each additional line (about ten words) 1s. 6d. PREPAYMENT IS ABSOLUTELY NECESSARY. \* Stamps must not be sent, but all small sums should be remitted by Cash in Registered Letter or by Money Order, payable at the Post-Office, Covent-garden, W.C. to DOUGLAS FOURDRENIER, Publisher. Addressed to No. 46, Catherine-street, W.C. Advertisements for the current week's issue must reach the Office before THREE o'clock p.m. on THURSDAY. The Publisher cannot be responsible for DRAWINGS, TESTIMONIALS, &c. left at the Office in reply to Advertisements, and strongly recommends that all the COPIES ONLY should be sent.

TERMS OF SUBSCRIPTION. 'THE BUILDER' is supplied by post from the Office to residents in any part of the United Kingdom at the rate of 19s. per annum, FAVORITE TO countries within the Postal Union, also for Special Advantages payable to DOUGLAS FOURDRENIER, Publisher, No. 46, Catherine-street, W.C.

SPECIAL.—ALTERATIONS IN STANDING ADVERTISEMENTS. MENUS or ORDERS to DISCONTINUE same, must reach the Office before TEN o'clock on WEDNESDAY mornings.

PERSONS Advertising in 'The Builder,' may have Replies addressed to the Office, 46, Catherine-street, Covent-garden, W.C. Free of charge. Letters will be forwarded if addressed to the Office, and sent, together with sufficient stamps to cover the postage. All communications regarding literary and artistic matters should be addressed to THE PUBLISHER, and not to the Editor.

Best Bath Stone. WESTWOOD GROUND, Box Ground, Combe Down, Corsam Down, And Farleigh Down.

RANDELL, SAUNDERS, & CO., Limited, Corsam, Wilts. [Adv.]

Box Ground Stone. Is the Best for Use in all Exposed Positions, being a well-known and tried Weather Stone. 50,000 feet cube in stock. PICTOR & SONS, BOX, WILTS. [Adv.]

Doubling Freestone and Ham Hill Stone. Of best quality, in blocks, or prepared ready for fixing. An inspection of the Doubling Quarries is respectfully solicited; and Architects and others are CAUTIONED against inferior stone. Prices, delivered to any part of the United Kingdom, given on application to CHARLES TRASK, Norton-sub-Hamdon, Ilminster, Somerset.—Agent, Mr. E. WILLIAMS, 73, Charlotte-street, Portland-place, W. [Adv.]

Doubling Free Stone. For prices, &c., address S. & J. STAPLE, Quarry Owners, Stone HAM HILL STONE, and Lime Merchants, BLUE LIAS LIME, Stoke-under-Ham, (Ground or Lamp), Ilminster. [Adv.]

### The Two Designs for the Decoration of St. Paul's.

On the 5th of July last we published a coloured plate showing a reduction of the general design by Mr. Poynter for the decoration of the dome of St. Paul's, and two plates, giving on a larger scale the subjects painted by Sir F. Leighton and Mr Poynter respectively for the larger and smaller circular spaces between what may be called the ribs of the design. The design from which our coloured illustration was taken was then expected to be in a few days exposed to public view in its place in the dome; but unforeseen difficulties in the fixing of the immense cartoon appear to have led to repeated delays, and it was only about the commencement of this week that the scaffolding was so far removed as to render it possible to form an idea of the effect of the cartoon *in situ*. Since that design was published we learn that there has been "another Richmond in the field." Mr. Hugh Stannus has been for some time engaged in working out a design of his own, the cartoon for which is also now fixed in position on the opposite side of the dome. We publish in this number a fac-simile of a line drawing kindly furnished to us by Mr. Stannus, showing his design so far as it can be shown without the aid of colour; and in another column will be found his own statement, at some length, as to his views and intentions in the design. Mr. Poynter's description of the motive and working out of his design will be found in the *Builder* for July 5th, under the heading "Illustrations." Both designs are professedly based, in general scheme, on the grand sketch left by Stevens, of whom Mr. Stannus, we believe, was a pupil; and both may be said to have to some extent the same object,—that of reducing the lines of Stevens's design into more strictly architectural form, and rendering it more in accordance with architectural fitness and expression in regard to the arrangement of the substructure.

It is only fair to Mr. Stannus to say at once that the drawing he furnishes, and for which we are not responsible, does no justice to the effect of his design as seen in the coloured cartoon; and those who are interested in the experiment and are within reach should visit St. Paul's and make their estimate from the cartoons themselves. It is also as well to explain that the larger and smaller intermediate circles are purposely only roughly

filled in with indications of pictorial subjects, because, as we understand him, Mr. Stannus regards those as out of his jurisdiction and to be filled up, as in the other scheme, by Sir F. Leighton and Mr. Poynter. He has designed certain accessory figures in the base of each compartment and in the lunettes in the drum, and of these it is not, perhaps, necessary to say much. They are not likely to be executed as designed; but that does not affect much the main *raison d'être* of Mr. Stannus's design, which, as he himself says in his description, is an architect's design rather than a painter's, and is intended really to suggest a different method of treating the architectural detail and arranging and dividing the space.

The other cartoon, of course, stands on different ground. Though grouped in accordance with what may be regarded as the architectural lines of the structure (concerning which a word anon), and though it was intended, as explained in the description given,—mostly in Mr. Poynter's own words,—(p. 11, *ante*), to reduce to more architectural continuity the rather ragged lines of Stevens's composition, it is essentially a painter's design, and as such is to be judged. Of the very fine character of some of the work there will be no question, we surmise, raised anywhere. We must humbly confess that the large circle, painted by the "P.R.A.," the picture of "the sea giving up her dead," does not strike us as happy, even with some alterations which appear to have been made in it since it was first painted. Its effect is, as we heard it put, somewhat "gruesome." There is no suggestion in it, to our thinking, of the rising of imprisoned souls to a vision of immortal life, which surely would have been the most suitable idea to have suggested in the centre and crowning portion of a great Christian church. It suggests rather the slow and painful ascent of corpses from the waves, as if dragged up perpendicularly by some unseen but relentless force. The idea is not an inspiring one, and we fear the design will not find many favourites. Of Mr. Poynter's figure subjects, two portions at least are equal to anything he has ever done, and may, in fact, rank among his very finest productions. The seated figure of the prophet, and that of the angel beside him, recall Michelangelo, certainly; but, they recall him in a way in which modern painting has not often succeeded in recalling the manner of the great Florentine. They are in his spirit, but are no plagiarisms. In this respect they carry on also the spirit of Stevens, whose powerful figures they supersede, and who may he said to have been Michelangelesque or nothing. The painting in the lunette above, of "Christ in Judgment," has less of the Michelangelesque and more of the modern artist. As we saw it in Mr. Poynter's studio, it appeared

a grand design, and one which to a remarkable degree solved the difficult problem of combining decorative effect with life-like delineation of the figure. The aspect of the face of Christ, stern and passionless, the foreshortening of the outstretched right hand, the drawing and grouping of the other figures in the composition, the cherubim who fill up the space in subordination to the principal figure, go to make a very powerful work, impressive in feeling as well as in drawing and composition. But now comes the moral of the tale: how are all these qualities to be recognised by the spectator who, with aching muscles, throws his head back to gaze up at this apparently small lunette far up in the dome? The fine points of the work are quite lost; only the main disposition of the figures can be realised. The small scale to which the work is reduced is the more emphasised by the larger size of the circular subject underneath it and somewhat nearer the eye; and the proper relative importance of the two subjects thus seems reversed; the incident of the rising of the dead from the sea becomes the most important and strikes the eye most, while the figure of Christ in judgment, which certainly should be the predominant one, is placed in a smaller and less important section of the design, and thus becomes dwarfed into a secondary position. In regard to this, Mr. Stannus's arrangement of the spaces appears to afford better opportunities for the painter. The two sets of circles are more distinct in size, and thus the large lower circle could be employed for the principal subjects, and the small ones above merely for subsidiary related subjects or decorative figures. That is not the idea suggested by Mr. Stannus; but that is the use to which we should put his scheme when it came to filling in the framework with painted subjects. The main subjects would then have more space and be nearer the eye. Whether Mr. Poynter's lower figures of the prophet and the angel, at the base of the segment, tell any better from below, it is not easy to say, as on Tuesday, when we looked at them, the scaffold still partially hid the base of the cartoon. They will probably tell the best, however, from their vigorous action and their more favourable position in regard to the spectator on the floor.\* But in regard to the upper lunette, the result appears to us to be, what we feared from the first, the consigning of very fine work to a position in which it is quite lost.

When we leave the consideration of the pictorial subjects, and come to regard the effect of each design as a whole and in relation to the architecture, we can then consider them on equal ground. The idea in both is

\* Of course from the Whispering Gallery the subjects can be seen well enough; but then one can hardly regard them as painted to be seen from there.

that of dividing the dome into eight compartments by eight ribs or more solid and architecturalised portions of the design, and eight interspaces corresponding to the division which is in some sort suggested by the architecture. Considering them in this light, the contrast between the painter's and the architect's design comes out very characteristically. If it be regarded as an object to divide the dome up into ribs and spaces, Mr. Poynter's design fails in emphasis. The rib portions are not sufficiently homogeneous (though far more so than in Stevens's design), nor do they assert themselves with sufficient prominence to keep the spaces in subordination. There is a want of leading lines about the whole; or, rather, the leading lines are not sufficiently brought out. It may have been Mr. Poynter's object to avoid this,—to break up the whole so as to escape having too prominent a division between ribs and spaces. But half measures are not satisfactory in such a case. Either you wish the dome to be a "rib-and-space" design, or you do not. If you do intend that, do it thoroughly and with no shirking. If the ribs are to be architectural lines, supposed to have relation to the structure, let them be strong and clearly defined, as architectural lines should be. Now from this point of view Mr. Stannus's arrangement meets the case the better of the two. He has not only emphasised his rib-lines and kept them simpler and more homogeneous, but he has suggested further strengthening them by treatment in relief; and this is strictly logical if the rib-and-space treatment be accepted. Supposing that we wish this architectural division of the dome, Mr. Stannus's is a frank acceptance of it worked out in a frankly architectural manner. His lines are everywhere stronger and more decisive; and he has acted well in stopping the design somewhat below the opening of the lantern, and strongly emphasising the horizontal circle there (more so in the cartoon than this drawing shows). In the conventional scroll-work running round the drum of the dome, which both designs exhibit nearly in the same position, Mr. Poynter shows more elegant, graceful, and original detail, more distinctly painter's work; Mr. Stannus shows larger and broader and more strictly architectural detail, more in keeping with the building; but also, from its large scale, rather tending to dwarf the architecture. If the whole of the substructure were decorated in the same key and in the same style, Mr. Stannus's dome design would be a thoroughly architectural finish in the ordinary sense, locking the whole design of dome and substructure together with its firmly-knit lines. But,—and this is a very formidable "but,"—it would sensibly and materially lower the apparent height of the dome. It does so already, even in ordinary colouring; so much so that it is difficult to believe that it is not actually lower than Mr. Poynter's, though both of them, we presume, are fixed in the same manner against the internal surface of the dome; and how much more would it do so if executed with the harder surface and stronger colour of mosaic!

And this brings us to the very central question affecting the whole scheme. Is it, after all, the right thing to divide the dome up into compartments in this formal manner? We spoke advisedly of such an arrangement as having reference to the "substructure," but what about the dome itself? The reply of those who wish for this rib-and-space division, of course, will be that Wren has so divided the dome structurally by his interposition of solid piers between each set of three windows. In other words, Wren knew that the dome wanted both lighting and buttressing, and he arranged for both, and he showed the buttressing externally also. But because counterforts are thus provided for the dome without interfering with its light, is it, therefore, any less in itself a dome, viz., a homogeneous spherical roof? Certainly not, and there is not a hint of dividing it internally into gores or sections, architecturally speaking. Thornhill treated his paintings so, it is true, and we may observe in passing that it is a question, if this architectural division of the dome he adopted,

whether Thornhill's design is not, saving its Brobdingnagian rococo ornaments, the most effective in its general idea of all the three schemes that are at present to be seen on the concave of the dome. But we assert, in the face of all three, that this is not the true way to decorate a dome internally. A dome is essentially an undivided concave vault. To divide it into so many ribs is not only to contradict its real construction (whatever may be the arrangement of its substructure), but to lose all its effect of grandeur and mystery by dividing it up into measurable slices. Mr. Poynter's design, irrespective of its pictorial value, reduces the height, and what may be called the special expression of the dome, less than Mr. Stannus's, because its rib-divisions are incompletely emphasised, and are, therefore, less forced upon the eye. Sweep them away altogether, then, and instead of pretending to divide up the dome into ribs and spaces, treat it as what it is, one great homogeneous concave; fill it with a host of angels, or some such suggestive treatment, which would give a grand total effect, and would suggest a grand idea, without making the hopeless attempt to place a number of isolated and differentiated individual figures in a position where it is impossible they can ever be really seen, or their special expression appreciated. Do not throw away fine painting by placing it where it can never be seen; and do not throw away the whole real grandeur and mystery of a dome by cutting it up into sections like an orange. That appears to us to be the summary of the moral to be derived from the study of the two cartoons now hung in St. Paul's Cathedral.

#### PROPOSED FORTH AND CLYDE SHIP CANAL.

PROMINENT engineering tendency of the age is the construction of short-cuts for ocean navigation and traffic. The magnificent success of the great Suez project, persisted in through much evil report and infinite discouragement, has been the chief incentive, and now all over the globe schemes of a kindred description are found in various stages of inception and progress. The days of canal making for purposes of inland traffic intercommunication merely have long since gone by, this class of work having been rendered all but obsolete by the greatly superior contrivance of the steam-worked railway. The railway cannot do everything, however. It is confined somewhat strictly within its legitimate domain of dry land, and cannot in any appreciable degree invade that of ocean navigation, although in mere coasting traffic it stands a powerful rival. The sea-going steamer may, on the contrary, by means of the ship canal contrivance, be made to affect the railway supremacy to a serious extent, there being, it may be said, no physical limit to the piercing of dry land for these waterways, except that of expense alone. In this sense, the operation of canal building, once so active and of late so dead, promises a vigorous revival, with results of a thoroughly revolutionary character so far as the channels of ocean-borne traffic are concerned. The Manchester proposal, for the time in abeyance, is that which has elicited the most earnestness and vigour within our own borders. Its almost realised success, so far as the Parliamentary stage is concerned had previously revived discussion upon the subject of ship canals generally, including one to connect the Tyne and Solway, but more particularly an older and much more momentous project, that, viz., of cutting the strikingly narrow neck of land between the estuaries of the Forth and Clyde, and thereby transforming the one island of Great Britain into two. This is a scheme which even an uninformed glance at the map will show to be rather a fascinating one.

From Lizard Point in Cornwall, the most southerly stretch of England, to Dunnet Head in Caithness, the most northerly projection of the Scottish mainland, the distance, as the crow flies, is about 600 miles. The Orkney

and Shetland groups of islands stretch in all about 150 miles still farther to the north, terminating in the Scaw of Unst, which is thus in a straight line distant about 750 miles from the most southerly point in England. With all vessels of any pretensions to size making from the North Sea into the Atlantic, it becomes a question whether passage is to be made southward through the English Channel or northward *via* the Pentland Firth. This alternative does not hold good, however, in certain exaggerations of unfavourable weather, and sometimes, especially in the case of sailing vessels, the longer though open route, right round the north isles, is preferred before crowded Channel and dreaded Pentland alike. On the east coast, nearly 200 miles from the most northerly point of the mainland, the estuary of the Forth cuts about due west into the land, presenting on the map a wedge-like indentation, sixty miles long or thereabout. Almost directly opposite, on the west side, the Firth of Clyde breaks the coast-line with rather more of irregularity, projecting its inner waters in the direction, generally speaking, of the higher reaches of its eastern *ris-a-ris*, from which it is thus separated by a comparatively narrow isthmus. If this isthmus were adequately cut, as has been proposed, the east and west ocean and deep sea traffics would unquestionably be revolutionised, whatever might be the financial fortune or misfortune accruing to the promoters.

It is a neck of land of singularly low elevation, as compared with the ruling cross sections of Scotland, which elsewhere are all very hilly when not positively mountainous. The Romans marked it as a pass of great natural weakness, and drew across it seventeen centuries ago a defending earthwork, whose vestiges at numerous points and stretches from sea to sea are still plainly traceable. Generally speaking, it bears the appearance of a valley of trifling width, bounded on the north by hills of some elevation, and on the south by grounds of a very moderate rise. Except in the neighbourhood of Falkirk, the population is sparse, the small towns of Kilsyth and Kirkintilloch, with a few insignificant villages, comprising the whole, exclusive of the purely agricultural element. The River Kelvin, which falls into the Clyde at Glasgow, occupies the bottom of the depression over more than half its course; while the Carron in its lower reaches with its affluent the Bonny Water, whose united streams reach the Firth of Forth at Grange-mouth, take up a similar position over the smaller eastern half. One of the Edinburgh and Glasgow turnpike routes accompanies the valley much of its way. The Kelvin Valley Railway, with extensions and connexions, scores it from end to end; and lastly, there is the Forth and Clyde Canal, which, in its small way, makes the most alike of narrowness of isthmus and moderation of summit level. This canal is quite complete of its kind, and was really at one time a ship canal of the period, accommodating the craft which then carried on the trade between the North of Europe and the West Coast, and for a while, indeed, existing in the highest reputation. The "Great Canal," as it was then termed, has outlived its greatness owing to the enormous strides in navigation of all kinds during the past half-century; but as this concern would have to be "reckoned with" (bought up most likely) in the event of a new enterprise, its record may here be briefly summarised.

In the year 1767 Parliament was applied to unfruitfully for permission to construct from firth to firth a ditch canal, 4 ft. deep, but general attention being thereupon aroused and becoming intensely interested, the scheme at once developed to the scope of a ship canal of 7 ft. depth, under the auspices of a powerful company. Operations commenced in 1768, and in the year 1773 the canal was navigable from Grange-mouth to Kirkintilloch. Three years subsequently the neighbourhood of Glasgow was reached, but it was not until 1790 that finished junction was made with the Clyde at Bowling. The Clyde at Glasgow, and for many miles below, was a trifling stream

in those days, capable of accommodating nothing larger than the smallest of sailing craft, and then only at high water. But for this radical defect the canal might have terminated in the river immediately below the city, to the saving of at least ten miles of additional excavation in carrying the work down to Bowling Bay. At various epochs the depth of the canal was increased slightly, but this being a movement necessarily limited in a finished lockage work of the kind, it has long since ceased. Rising from the tidal water at Grangemouth, the work mounts in the course of ten miles and a half, by means of twenty locks in all, to its summit level of 156 ft. This level is maintained unbroken for sixteen miles, descent to the Clyde being effected over the remainder of the course by means of nineteen locks. The length of the work from sea to sea is thirty-five miles. The locks measure 74 ft. by 20 ft., and the waterway when full affords a draft of rather over 9 ft. The original capital involved stood at 150,000l., but 70,000l. had afterwards to be borrowed privately, in addition to 50,000l. lent by the Government, sums, however, which were fully redeemed subsequently. As testifying to the amount of general, or rather national, interest surrounding the inception of the undertaking, it is worth noting that at the first general meeting of proprietors, held at the St. Alban's Tavern, St. Alban's-street, London, on the 14th of March, 1768, the Duke of Queensberry and Dover presiding, there were present four dukes, one marquis, four earls, and three baronets, besides a powerful residuum of

and *vice versa*. Middlesbrough pig-iron for the Glasgow market follows this route chiefly; but is invariably trans-shipped at Grangemouth into steam barges or horse-tracked craft, by means of which, also, a rather languid traffic in general merchandise is carried on.

When the Forth and Clyde Canal was projected the City of Glasgow was a place of barely 30,000 inhabitants. The Clyde was a paltry stream so far as navigation was concerned, though of some consequence in connexion with the salmon fishing industry. Smeaton, the engineer, had some years previously surveyed and reported upon it to the Navigation Trustees, with the result that an engagement with a Chester contractor was entered into for the deepening of the below-bridge channel. Under these operations the river became so scoured that by the year 1775 vessels drawing almost, but not quite, 6 ft. of water could come up from the sea,—a result which was at that time regarded as partaking of the nature of an achievement. Glasgow in our day, with the suburbs which its mushroom-like growth has gradually absorbed, possesses a population of, in round numbers, 700,000. The Clyde, from Greenock upwards, has since that time undergone so stupendous an excavation, carried on from year to year unceasingly, that the largest ironclad of the navy may now be piloted right up into the harbour itself, in all ease and security. The Clyde below Glasgow and until deep-sea water is reached is, in point of fact, only nominally a river, being in reality an inland ship canal of nearly twenty miles in length,—and a ship canal, too,

its name, is at least practically straight stretching at a very gentle rise east-north-east past Kirkintilloch and Kilsyth, and pointing throughout right across the isthmus on the line of its narrowest section. Our supposititious map line keeps about the centre of this valley all the way, joining, about four miles distant from the Kelvin elbow mentioned, the course of the Forth and Clyde Canal, which at construction was made to hold rather more to the south than the levels demanded, and that for the purpose of passing Glasgow at a moderate distance only, a navigable cut to the northern suburbs of that city being also part of the scheme. The existing canal, once thus caught up, is not left again to any appreciable extent, as, after passing the head-springs of the Kelvin, it traverses the east-going and now descending valley of the Bonny Water, and soon thereafter enters upon the flat low-lying carse land through which the Carron tediously seeks its way for some distance above its entrance into the sea at the port of Grangemouth, the point at which also the present artificial navigation ceases. On the line thus rapidly overrun in description there are no hilly ranges to be cut; hardly anything even of the nature of a difficult ridge to be pierced, if difficulty be here measured by the best resources of modern engineering. But unquestionably the cutting of the isthmus for a tidal deep-water lockless canal, even under natural and artificial conditions of so singularly favourable a kind, must prove a work of extraordinary labour and outlay. The existing canal reaches its summit level at 156 ft., and remains at that for sixteen

untitled shareholders. At that time there were only two canals in operation within the British Islands, though many schemes were in projection; but this of the Forth and Clyde stood alone in its quality as a navigable arm of the sea, through which, when the wind proved favourable, masted craft might freely pass by the impulse of their own canvas alone. And the idea was in some limited sense realised too, before steam stepped in and revolutionised the conditions of navigation generally. During the long war, traffic from the west of Scotland round the north and south points of Britain became all but extinguished, the canal securing nearly the whole of that portion of it still braving the risks of capture; but when peace was restored, the inevitable restrictions imposed by draught of water and dimensions of canal locks gradually told, and accordingly in the year 1816 we find many ships, slightly larger than the canal capacity, making the round passage to the Continent, and the governor and council of the company stretching every nerve in the way of possible enlargement of works and easement of traffic, in order to arrest, or at least impede, so threatening a tendency. The hassle was a losing one for the latter from the first, though this was not generally apparent till the advent of steam navigation and the gradual introduction of those giant changes which have been effected through its agency. The canal has for many years been in the possession, and under the management, of the Caledonian Railway Company. Small coasting sloops and schooners occasionally use it on an emergency, and fishing-boats, from as far away sometimes as St. Ives in Cornwall, employ it as a short cut from eastern to western herring-grounds

of the very foremost grade; measured, that is, by depth of water and width of channel. This magnificent artificial waterway cuts into the land in an easterly direction with an inclination southwards, and in any scheme for piercing the Isthmus between the two Firths with a view to large-ship unimpeded navigation, these great Clyde works must be held as presenting, already in an entirely completed state, about one-third of the ambitious channel aimed at. Taking the Ordnance Survey sheets, it is seen that under the vastly improved conditions noted, a straight line drawn between the two points of deep-sea navigation which most closely approach each other, namely from the mouth of the Carron at Grangemouth to the Clyde about two miles and a half below Glasgow, stretches a distance of about twenty-five miles only. It is not necessary to go down now to Bowling or elsewhere for deep-water, deep-water having already been carried artificially up, even much higher than necessary for the particular purpose under review. The straight line thus hypothetically drawn, pursues throughout, with a fidelity which is rather striking at first glance, the base level of the crossing valley or depression already described. A short distance from the Clyde, whose margin at the point struck presents an exceedingly moderate rise, the Bowling arm of the old canal is crossed, and immediately after the river Kelvin is caught up at a great elbow of its course, round which it turns to the south-east in seeking a rather tortuous outlet higher up the Clyde at Glasgow. The Kelvin, which is not in any sense at all a navigable stream, is, generally speaking, straight in its course above this elbow. The valley through which it flows, and which bears

There is here provided a kind of basis for calculating the amount of excavation which the cutting of a tidal waterway would necessitate. Yet is there room for a very liberal discount in the calculation; for it is found that over these sixteen miles the old canal, to preserve its level unbroken, has often to pass incidental depressions either by a deviation of track at the expense of increased length, or by embankment at the cost of massive works. Indeed, the old waterway, in its summit level section, is so far from taking advantage of the lowest levels procurable, that it is very frequently carried over, rather than under, roadways, railways, and watercourses. In the case of a tidal canal starting, as such a work must inevitably do, with a wholesale and uncompromising scheme of excavation throughout, a straighter, and therefore shorter, route might be embraced, and the benefit could be freely taken of whatever incidental depressions of surface the surveyors might encounter. The value of the land along the central valley is not very great. Much of the area was of old time mere morass, and part of it is still comparatively worthless moss. The arable portions take generally a very moderate standing as to market value, and the principal wealth consists in the minerals, which are worked almost unbroken from sea to sea. The mineral interest especially, and probably all the others except railways alone, would hail the prospect of a ship canal with the greatest ardour, and he prepared severally to concede the requisite facilities on terms most equitable, not to say most favourable. The roads and railways intersecting the route, for which swing or other opening bridges would have to be provided, are not numerous. The intersecting traffic is already partly mured

to the drawback, the Scottish Central Railway and the Great North Turnpike having been all along served in this way, though the Caledonian Railway and many minor roads are made to pass underneath.

It has been proposed,—perhaps hardly in serious mood, however,—to carry the canal by a wide half-circle round into Loch Lomond and thence through the Endrick and Forth valleys to the deep water of the eastern Firth. Over and above the almost fatal necessity of lockage impediments militating against a proposal of the kind, there are other disabilities, such as tedious length of route, barrenness of borders, &c., to which it would be difficult to reconcile likely promoters; and the idea has, therefore, been generally dismissed as beyond the pale of serious discussion. The central valley is the only likely route for a ship canal connecting the two estuaries, and if not made there it may safely be asserted that it will be made at no other crossing. The existing canal would be of immense assistance in aiding the progress of the new works, and even although it had to be bought and paid for bodily, as a preliminary to the starting of operations, the works scire afterwards rendered might more than square the outlay. The advantages to be gained in a national point of view by the cutting of this isthmus for a ship canal of really first-class proportions are so prominent as to forcibly indicate the realisation as a suitable and proper undertaking for Government itself, rather than any mere syndicate of private investors. It has been pointed out, and not without justice perhaps, that were this country at war with any coalition of foreign naval powers, the ability to send ironclads from coast to coast within the space of a few hours would be almost equivalent to a doubling of the actual national fighting material afloat. In a large measure, too, the canal would furnish a solution of the east coast harbour-of-refuge problem, so far as Scotland is concerned; for traffic, instead of running the gauntlet south or north along the dangerous coast line would, as a matter of course, make for the Forth,—then as now the only available natural harbour of refuge on the Scottish line; and then, in addition, affording a safe and swift passage across to the western seas. Ocean traffic in foreign bottoms from the Baltic and North of Europe generally would take advantage of the short cut when bound west, while Glasgow, which at present sends large fleets constantly both round north and round south to the Continent, would of itself be answerable for no small part of the revenue necessary to make ends meet. The British Government is not entirely new to the canal business. The Suez investment has turned out successful beyond the dreams of the most sanguine at the time the purchase was made. The Caledonian Canal, finished on a national basis in the year 1822, and connecting West Highland waters with the Moray Firth, is not susceptible of so complacent a review, however. It was meant really to be a ship canal, serving all the uses of commerce and for all time to come. Its locks were constructed 170 ft. long, 40 ft. wide, and offering quite a generous draught of water, but it can hardly be said ever to have been accepted as other than a wondrous effort of civil engineering, and a noble monument to the genius of Telford. Tourist steamers have it now almost entirely to themselves, and they are abundantly patronised for the scenery is of the grandest; but as a through traffic route it has never taken any place, and it is chiefly useful to the Government and the nation as a standing warning against the repetition of costly, yet still but half-hearted, schemes of the kind. The existence of locks seems to be fatal to the permanent cultivation of a sea-to-sea navigation on any scale, and the histories of the Forth and Clyde and Caledonian canals are in this respect one and the same. The latter, constructed at a later date, resolved to avoid the mistakes of the former, and in size of locks and draught of water it really made a formidable step in the desired direction; but the Caledonian now is where the Forth and Clyde was so long as three-quarters a century ago, and that is practically and hopelessly out of the competition in the matter of through sea-going

traffic. The lesson of the Suez Canal is to be taken to heart in all future projects of the kind. Finished as it is, and rejoicing in an enormous revenue, it is still essentially elastic in its conditions of construction, and may from time to time be deepened or widened to suit the exigencies of traffic, and that without suspending navigation for an hour. If the Scotch project is conceived on similar principles it will most likely prove a great engineering success, and remain so permanently.

## NOTES.

**T**HE subjects of the principal papers in the Health and Art Sections of the forthcoming Social Science Congress seem likely to be very well taken up this year, and in a manner worthy of the importance of some of them. In the Health Section the question "What is the best method of dealing with (a) town sewage, (b) the products of house and street scavenging, and (c) the products of combustion" is to be treated of by Mr. E. Pritchard, C.E., Mr. Lawson Tait, and Captain Douglas Galton. The only fault to be found with the "question" is that it perhaps attempts to deal with too many and too complicated subjects at once. Any one of the sub-divisions would be enough for a good day's work; but it is, perhaps, thought that some new light may be thrown on some practical relation between them. The second question in the same section, "What are the best means, legislative or other, of securing those improvements in the dwellings of the poor which are essential to the welfare of the community?" is well worded, as the latter part of the sentence seems intended as a fence against demonstrations of ill-judged and sentimental philanthropy on behalf of a class. "The welfare of the community" is the only solid ground which can be taken for public action on such a subject. The paper on this question is to be read by Mr. John Hanmer, hon. secretary of the Mansion House Council on the Dwellings of the Poor. In the Art Section the very practical question, "Ought elementary instruction in drawing to be made an essential part of national education?" is to be dealt with by Mr. J. P. Seddon, from whom an exposition both sound in its matter and trenchant in its style may be confidently expected, and from whom we should have no difficulty in predicting an affirmative answer to the question, on which Mr. C. G. Leland and Mr. Rowland Hamilton will also contribute papers. "What is the value to the ear, the mind, the health, and the disposition of the young produced by class instruction in music?" is the second question in the Art Section, on which a paper will be read by Lady Macfarren, from whom we shall expect to hear a decisive attack on the false so-called teaching "by ear" or by a music-made-easy method which has been far too much countenanced by our educational legislators. Mr. Manby Sargison follows on the same subject. Concerning the third question:—"How can a love and appreciation of art be best developed among the masses of the people?" we have already expressed an opinion that such vague and large questions are of little practical value; but Mr. Walter Besant is to take it up, and we have no doubt the author of "All Sorts and Conditions of Men" will, at any rate, have something that is interesting to say, and give much pleasure to his listeners, even if no further result is attained.

**W**E gave, on August 23rd, in a "Note" the names of nine of the architects who had been selected from among those who had sent in sketches in competition for admission among the number who were to be asked to furnish designs for the Liverpool Cathedral. It was understood that twelve were to be selected for special consideration, and we now learn that among those thus selected were Messrs. Carpenter & Ingelow, whose name was omitted from no fault of ours. There is still no official statement published, and there are conflicting rumours on the one hand that

twelve, on the other hand that only ten, were selected. If the latter is the case, we have now given all the names. From these, according to a statement in a Liverpool paper, which we have not yet seen contradicted, four architects have been finally invited to submit designs,—Messrs. Pearson, Bodley, Brooks, and Emerson. These are a very good four, no doubt, but this is a very limited competition for so important a thing as a new cathedral, and a larger number might very wisely have been invited. We cannot help adding that it would have been more fair to the competitors if a correct official statement of the result had been communicated to them and to the architectural press, instead of leaving the truth to be discovered by a system of cross questions and crooked answers. There can surely be no mystery about it, and those who have been selected had a right to expect that their names should be made known.

**T**HE sceptics who doubted the wisdom of the Transatlantic trip of the British Association must surely be sufficiently answered by the accounts which have come across of the entire success of the meeting, both in a scientific and a social sense. It may be true that the practical importance of the work of the Association in advancing science is relatively less than it formerly was. There are so many more channels now for the communication of new ideas and new discoveries in science, that any one who has made a real step in any branch of scientific research may be sure of finding a hearing among the minority at least who are qualified to understand his work. But the great advantage of the annual meeting is that it tends to bring the scientific and the popular mind *en rapport* (to the benefit at all events, of the latter) and to quicken and extend general public interest in scientific discovery. In this light it may be regarded as an educational influence of a kind which nothing else exactly supplies the place of. The idea that the excursion to Canada would be a precedent for further excursions beyond the boundaries of these islands is not one to be regarded with distrust or dislike. The headquarters of the British Association will always be Great Britain; but that it should take advantage of the greatly increased facilities of travel and intercommunication in these days to extend its meetings occasionally to distant parts of the English-speaking world, is really a consummation to be wished, and a probable benefit, one way or another, to all concerned.

**M**R. H. J. LANCHESTER, A.R.I.B.A., has suggested the construction of a new low-level bridge across the Thames between London Bridge and the Cannon-street Railway Bridge. This, he claims, would materially relieve London Bridge, for Southwark Bridge is, as he points out, too far west to be of any service in relieving congested traffic near London Bridge. He might have added that the gradients of Southwark Bridge are too severe for any but the lightest traffic. But the construction of the bridge now suggested by Mr. Lancashire involves the question of approaches. On the south side he suggests that a new street should be made, commencing in the High-street, Borough, crossing Southwark-street nearly at right angles, and passing through the Borough Market (which would have to be re-arranged) right up to the south end of the proposed new bridge, "which is to be carried over the Thames at a low level into Upper Thames-street, at a point 100 yards east of the Cannon-street Railway Station. At the junction with that street a square is to be formed of sufficient size to allow this traffic to pass readily east and west into Thames-street." The proposed bridge would no doubt in some degree facilitate traffic between Thames-street and Billingsgate and the southern suburbs. It is not suggested as in any way providing for traffic across the river at any appreciable distance eastward of London Bridge, for the accommodation of which Mr. Lancashire favours our view, that well-designed steam-ferris should be fairly tried before deciding upon bridge-building below London Bridge.

IN the South Annex of the Health Exhibition is a model illustrating a design for the Utilisation of Tidal Power, a problem the solution of which has long exercised many ingenious minds, but which has not, we believe, been ever turned to useful account. In the tide, however, there exists an enormous reservoir of power capable, without question, of being profitably employed. That Mr. Maynard Walker's patent is an ingenious application of it is very apparent, but that it is an economical adaptation to the disposal of sewage from cities and large towns is not so clear; for though its action may be automatic, and the working expenses in consequence practically nothing, yet the works necessary to render it available cannot be erected except at so large a capital outlay as to make the interest amount to a very heavy item in comparison with that chargeable on the first cost of steam-pumping machinery, the working expenses of which would probably fall short of that interest. The economical application of Mr. Maynard Walker's system to some of the other purposes enumerated in the exhibitor's prospectus is quite possible, and especially in the accumulation or storage of power for the generation of the electric light, where a comparatively small storage area is required. The economical limit of its application, however, is a matter of very simple calculation. One indicated horse power being represented by 33,000 foot pounds, or, in round numbers, by 530 cubic feet of water raised through 1 ft., the same power would be obtained by 26.5 cubic feet raised through 20 ft., a volume requiring a cistern of 5½ square feet, with a depth of 5 ft. The comparative economy with that of a steam-engine to do the same work would depend on the number and cost of cisterns to be erected in order to furnish the amount of power required, a calculation which any engineer could make in a few minutes.

FROM Dr. Airey's report to the Local Government Board, dated August 6th, on the sanitary state of the Borough of Burnley, we learn that the main drainage scheme has been completed, and the work of connecting the houses with the sewers, and cutting off the old drains that discharged into the rivers and canal, has been generally accomplished. The cleansing of the rivers has been greatly aided by the paving of their channels. The following particulars in regard to the treatment of the sewage, extracted from the report, will be of interest at the present moment:—

"The sewerage outfall is by the side of the River Calder, about two miles below Burnley. Here the sewage is treated by General Scott's process for the manufacture of cement. Lime is added, and lime-sludge precipitated in a series of settling tanks, from the last of which the effluent water escapes to the river. After heavy rain the volume of the sewage is greater than can be dealt with at the tanks, and the surplus goes into the river unaltered. On the day of my visit everything at the tanks was in very proper order, but I was led to suspect that this was not always the case, and that it often happened that the main object of dealing with the sewage so as to prevent its polluting the river was not attained. The lime-sludge is recovered from the settling-tanks and dried by heat previous to being turned to a slag in a lofty furnace. The slag is crushed to powder in a powerful mill, and the powder makes a good commercial cement. The process is by no means a remunerative one. It is worked by a company to whom the Burnley Corporation pay 1,400*l.* or 1,500*l.* a year. Complaint of nuisance from the fumes of the furnace is made by some residents in the neighbourhood.

"Should the question ever arise of disposing of the sewage in some other way, it would be well to consider whether it might not be dealt with by irrigation. The position of Burnley in relation to the lower valley seems favourable for it, and the experience of the neighbouring town of Blackburn is encouraging."

VISITORS to the Health Exhibition, who really go there to study sanitary matters (if any do), will find some useful hints in regard to the portions representing the "Sanitary Arrangements of Dwelling-houses," in a pamphlet by Mr. Mark H. Judge, published by the Sanitary Assurance Association. It suggests what should be the desideratum in regard to various sections of house arrange-

ment, and gives some information as to the objects to be found in the Exhibition in connexion with each subject mentioned. The pamphlet arose out of a Report to the Council of the Association.

IN Mr. Lovegrove's annual report of the Surveyor's Department for the Hackney District we note the mention of an experiment in rendering a roadway more durable under special conditions. On the western side of Stamford Hill it had been observed that, what with waterwash and the action of skidded wheels, this part of the road was difficult to keep in repair. Hot tar was, therefore, mixed with the granite at the wharf and carted to be laid on the road and rolled in. The success was only partial, but the surveyor thinks it would be more successful in future if the granite was first heated to thorough dryness before mixing. In the same report are some statistics as to the wear of asphalt under traffic. A sample laid down an inch thick in Broad-street in 1877 is now ¾ in. thick. The surface generally is in good condition, but in some of the narrower parts it is worn through to the concrete. The degradation from 1 in. to ¾ in. is noted in several places where the asphalt was laid two years later, in 1879. Material laid down seven months since, at the same thickness, is not degraded at all. The asphalt in all these cases was the Linnier Company's Compressed. In regard to concrete paving, a sample of the Eureka Concrete, laid near the Stoke Newington Station, shows both longitudinal and lateral cracks. Mr. Lovegrove believes, however, that this defect will be avoided by the improved method of laying in alternate panels, which has been tried in the Kenton and Oakfield roads with success, no cracks having developed in these cases.

THE state of the Lower Thames has found a defender in Mr. Chas. A. Cameron, Vice-President of the Royal College of Surgeons, Ireland, who, according to a letter in the *Times* of Thursday, has, like some other people, gone down in a steamboat "to see and smell the Thames in a leisured manner." Mr. Cameron smelt smells, but to him they all seemed to come from the banks of the river, and not from the water. He enjoyed his run through Barking Creek, and perceived not the slightest smell of sewage. Mr. Cameron's experience is certainly at variance with that of which many other observers have given evidence, but perhaps this may be accounted for by the fact that he went in a steamer "kindly placed at his disposal" by a member of the Metropolitan Board of Works, who is specially concerned with the sewage. No doubt the sewage is better behaved than to make itself disagreeable under those circumstances.

THE Vicar of Combe, Woodstock, communicates the following experience on "restoration" to the *Times*:—

"A few years ago a clergyman, who was also an archaeologist, visited an ancient village church. On entering, he saw in the midst of it a man, who was on his knees, howling low and facing the altar. The clergyman, of course, thought he had lighted on an instance of religious fervour, and that, moreover, expressed in an unexceptionable manner,—an instance which was highly exemplary, especially in these degenerate days. But, on getting a close view of the being in the reverential attitude and in the eastward position, the clergyman, also an archaeologist, found, to his horror, that the supposed devotee was earnestly and vigorously wrenching out of the stone floor a fine old brass, and in doing so knocking it to pieces. 'The surprised and grieved beholder exclaimed, with some excitement, 'What are you about?' Without looking up, and without desisting one moment, the rustic,—a workman employed there,—quietly answered, 'We be a restorin'.'"

This is an unquestionably good restoration anecdote,—too good to be true, some people may think; but we must protest against this sort of lively anecdote being put forward as an indication of the evil deeds of restoring architects. Granting the correctness of the facts, did the "clergyman, also an archaeologist," ascertain whether the man was acting under orders, or whether he was not a stupid fellow exceeding his instructions?

MR. WHEATLEY brings to a conclusion, in the September number of that admirable periodical the *Antiquary*, a short series of interesting papers on "The Adelphi and its Site," which are well worth the attention of those who are interested in London records. The article for this month contains an illustration of the old deserted tavern "The Fox under the Hill," once much frequented, and which still stands on the land under the terrace. Mr. Wheatley concludes with a remark which should be taken to heart by architects and those who are concerned in promoting building in London. It is to the genius, he observes, of the Adams that we owe it that a site little different in regard to distinguishing character from the sites around, should have become a recognised district with a distinct name. The genius of the Adams, and the artistic value of their style, have been of late somewhat exaggerated; but still it was genius, and by the impress of it the brothers redeemed an ordinary city building locality from commonplace, and gave it a name and a permanent interest. The moral is, Go thou and do likewise.

#### ARCHÆOLOGICAL PROGRESS IN CYPRUS.

THE excavations of General Cesnola have not exhausted the possibilities of Cyprus, and surely if Englishmen are to excavate anywhere this island is the natural field for their labours. A committee, consisting of Englishmen and Cypriotes, was formed in 1882, by Sir Robert Biddulph with the object of establishing a local museum at Leukosia. Under the auspices of the committee, excavations on a small scale and supported by private subscriptions have been carried on in the years 1883-1884. It is a little surprising that these excavations have had to be conducted by a German, Herr Max Ohnefalsch-Richter, and that the report appears this month in a German periodical, the *Mittheilungen*, of the German archaeological institute at Athens.

The site chosen was the village of Voni, the ancient Chytrai, and the find has been a large one. It speedily became evident from a multitude of inscriptions that the excavators had lighted on a sanctuary of Apollo. The architectural remains are insignificant, but there is evidence that on the remains of the old Pagan shrine a Christian church had been raised, into the walls of which a mass of fragments of ancient sculpture was built. The sculptural find was a very rich one, as many as 133 statues are already catalogued. They were found, for the most part, near the east front of the building scattered among a *débris* of ashes, bones, inscribed stones, fragments of terra-cotta, glass lamps, &c. As is usually the case in Cyprian remains, considerable monotony prevails,—a few types appear in endless replicas. The statues cover a wide area as to date: within a few square yards we have representatives of Egyptian, of Oriental, of Greek, and of Roman styles. The majority of the statues have been intended to stand against a wall; the back parts are unfinished; the front frequently picked out with colour. Three types, which all occur in several replicas, are of special interest. First, a statuette of Herakles, with lion-skin over his shoulders, and a horn in the left hand. Herakles, it will be remembered, is a hero always at home in Cyprus, and indeed in every Phœnician settlement. He frequently appears on Cyprian coins. Second, a male standing figure draped, holding in his left hand Iustration twigs; in his right a figure of Nike. This little figure of Nike is interesting because its pose is like that of the famous Nike of Paenios. The statue may possibly represent Apollo in his aspect of the Victory-bringer (Nikephoros). Third, the statuette of a boy seated with one leg tucked under him, and holding a dove. Probably this type represents Adonis, who is frequently connected with the worship of Apollo as with that of Aphrodite.

Together with the statues were found a large number of dedicatory inscriptions, with the names of worshippers and a record of their offerings to Apollo. In one instance, on the statuette of a female figure, a quadrangular tablet is engraved, bearing a well-preserved inscription in Cypriote characters.

While so much new work is going forward, it is satisfactory to learn that steps are being taken to render the Cyprian material already amassed by the Cesnola excavations permanently accessible to archaeologists. If anything could console us as a nation for the loss of the Cesnola collection, which in a moment of national niggardiness we allowed to slip through our fingers, it is the proposed publication of a pictorial atlas illustrating the collection. The publication of such an atlas has been undertaken by the firm of Osgood & Co., Boston, under the auspices of the trustees of the Metropolitan Museum of Art, in which the collection now lies. It will be complete in three volumes, one of which is to appear this autumn: each volume is to contain 150 plates, some in colour by the chromolithographic process; some in heliotype from photographs. Only 200 copies will be printed, after which the plates are to be broken up. The total cost is to be 150 dols. The accompanying text promises to be second only in value to the plates. There is to be a general introduction, by Professor Curtius, and from him, if from any one, we may look for a brilliant and suggestive exposition of the historical significance of the Cypriote antiquities. Volume I., which is to contain objects in marble, alabaster, and stone, large and life-size statues and statuettas, busts, heads, bas-reliefs, votive offerings, and sarcophagi, is to have a special preface by Dr. Samuel Birch, of the British Museum. Vol. II. is to contain bronzes, silver and gold ornaments, rock crystal, glass, and engraved gems, and is to be prefaced by the writer, who has already contributed so much to the elucidation of the Cesnola antiquities. Mr. A. Murray, of the British Museum. Vol. III. is to contain terracotta statues, heads, busts, horsemen, chariots, lamps, vases, inscriptions. Every one who is following M. Perrot through his delightful history of Phœnicia and its dependencies which is issuing weekly from the press will rejoice that the preface to this third volume is to be by his hand. In addition to these prefaces each object is to be fully described in accompanying letter-press, and so far as possible explained. The promise of the work is very great; its execution we shall hope to notice later.

#### THE BRITISH ARCHÆOLOGICAL ASSOCIATION.

THE British Archæological Association opened their forty-first annual meeting at Tenby, on Tuesday last, under the patronage of H.R.H. the Prince of Wales, and the presidency of the Bishop of St. David's.

A better president it would have been impossible to select than the joint author of Jones and Freeman's "History and Antiquities of St. David's," and the sole author of "Vestiges of the Gael." Thirty-four years ago the Bishop of St. David's, then the Rev. W. B. Jones, drew attention to the fact that an immense number of place-names all over Wales refer to Gaels; from this and other evidence he deduced a theory that the Gaelic or Irish branch of the Celtic family preceded the Kymric or Welsh. This has been abundantly confirmed by ethnologists and philologists; and it is now pretty well established that the Gaels were the vanguard of the Aryan race, and preceded their Kymric cousins, not only in Wales, but over the continent of Europe. It was the "Vestiges of the Gael" that paved the way to this interesting discovery.

The members of the Association assembled in the Town-hall at two o'clock, when they were received by the Mayor (Mr. W. H. Richards) and the members of the Town Council. His Worship, in the name of the Corporation, expressed the pleasure they all felt in welcoming the British Archæological Association and their Right Rev. President to the ancient borough of Tenby. He then withdrew, making way for the President, who delivered his opening address, of which we here append a considerable portion, which we take from the report in the *Times*:-

I suppose we may, with sufficient accuracy for our present purpose, make a rough five-fold division of material antiquities according to date. I think it will not be inconvenient to classify them as primeval, Roman, post-Roman, mediæval, and post-Reformation, the last being, no doubt, a very awkward term, but I do not know how to express the notion better. The name, however, is inimportant,

and the more so that I do not intend to refer to any memorials of that period. I have already said that the division is a rough one; the distinction of periods is not clearly defined, and they sometimes overlap one another. For it is plain that certain antiquities, which we call primeval, may date from or even after the Roman occupation of Britain. Some of the early Christian monuments, which we call post-Roman, may have had their origin during that occupation, although I do not suppose that any of them did. It is very hard to say where we are to place the beginning of the middle age, although it is perhaps not so hard to distinguish between the decay of Roman and the development of Mediæval art, while the latter did, as a matter of fact, linger on in some places even into the seventeenth century. Still, I think we must be content with the classification which I have made, for lack of a better. In primeval remains, Pembrokeshire is unusually rich; but, although the district in which Tenby stands is not without them, they are most abundant in the northern and north-western parts of the county. They may be divided into villages, fortresses, sepulchral remains, and early roads or trackways. A good specimen of the first class was discovered not many years since on Stackpole Warren, and to this the attention of the Association will be directed at its present meeting. Fortresses occupy many of the peninsular headlands of the Pembrokeshire coast, and many eminences in the interior. Some of them are of great size and complexity, and show considerable military skill. In some cases we have the fortress and village combined. Perhaps the best example of this combination in South Wales is visible in the well-defined village fort on St. David's Head, where the foundations of the circular houses, forming a considerable group, are defended by a system of concentric walls, of which the masonry forming the face is in some places well preserved. Of primeval remains, intended originally as places of sepulture, most conspicuous are the cromlechs. In this class of antiquities the county is particularly rich, as regards both their number and the importance of individual examples. The great cromlech at Pentre Iwan, in Kemes, which ranks very high among those which are known to exist, the cromlech at Longhouse, in Dewisland, that at Dol Willim (not in Pembrokeshire, indeed, but just beyond the limits of the county), and that at Burton, in Rose, ought to be mentioned specifically. The stone circle is commonly associated with the cromlech, as part of the same arrangement. Antiquities of this class are most abundant in the northern part of the county, in the neighbourhood of the Preselly range, of the Pencar hills, and the St. David's rocks. I do not learn that at any place in Pembrokeshire there have been found stones with those mysterious markings, which have so greatly puzzled archæologists, which appear to be widely diffused through various parts of the world. Of sepulchral remains of another class,—barrows, tumuli, carneddau, and so forth,—I believe there is good store in the county. Two in the immediate neighbourhood, viz., Carew and Norchard Beacons, were opened immediately after the Cambrian meeting in 1851, and the results are given in the "Archæologia Cambrensis" of that year. Another, situated on Stackpole Warren, will, it is hoped, be examined during the present meeting. Of ancient roads I have not much to say. One seems to run along the ridge of the Preselly Mountains, and its course is marked in the Ordnance Map. I traced another in the neighbourhood of St. David's, and what I found there may be read in the history of that place. I have little enough to say about Roman things. I do not know that there is any trustworthy evidence that the Romans ever got into Pembrokeshire at all. We find material traces of them in Cardiganshire and in the upper part of Carmarthenshire; and, although I am not aware that any Roman remains have been found there in modern times, I suppose there is no doubt that Carmarthen occupies the site of a Roman town. But I see no certain evidence of Roman occupation further west than that place.

Well, then, what about Menapia, the site of which is to be visited by the Association, or by what remains of it, on the 11th inst.? When I last went to look for Menapia it was supposed to be under I do not know how many feet of blown sand, so I have no doubt it is quite safe, if it ever existed. But what is the evidence of

its existence? Richard of Cirencester, or the ingenious person who wrote under that name. On the whole it would seem most likely that the name of Menapia is simply modified from that of Menevia, the Latin name (and, no doubt, a Latinised form of the ancient Celtic name) of the place of which I have the honour to be hishop. The Ordnance Map finds a place for another station of Richard's,—"Ad Vigesimum," but does not indicate any actual remains. Nor have I ever seen any trustworthy evidence to show that anything of Roman make has been at any time discovered in the county.

After speaking of the period between the Roman and the Mediæval, and of its monoliths and incised crosses, the Bishop observed,—I come now to Mediæval architecture, and begin, of course, with sacred buildings. I may safely say that there is no real Norman church architect in Pembrokeshire, or, with one exception, in the three south-western counties of Wales. The sole exception, so far as I am aware, is the fine chancel arch of St. Clears, in Carmarthenshire. Probably, during the period in which this style was in vogue, our churches were very poor and small, while the country was unsettled and a battleground of races. There is nothing of this date even at St. David's. Of course, it exhibits alterations, additions, and insertions of various dates down to the beginning of the sixteenth century, and its history, as it has to be read in the traces of these numerous changes, presents an interesting, and at the same time a difficult, problem to the archæologist. But I cannot dwell upon these points in detail at present, nor have I any right to anticipate what will, no doubt, be brought before some of you more fully on the spot. I will only say this, that while the cathedral church of St. David's takes a low rank in point of actual dimensions among the minsters of this country, I know of nothing in the world so impressive. The wild country which surrounds it, the sense of isolation, the neighbourhood of the sea, and the consciousness of its being on almost every side of you, the marvellous picturesqueness of the ruined buildings in the midst of which it stands, undoubtedly enhance the influence of the impression which it produces when it is first seen from without. But the effect of the exterior, which must be admitted to depend in some degree upon these accessories, is far less imposing than the first view of the interior on entering by the south porch, above all, in the low light of the evening. The complicated richness of the Romanesque mouldings, the deep and solemn colouring of the native stone, the strange and fantastic details of the flat ceiling and its pendants, and (now) the painting, gilding, and mosaic dimly visible within the darkened choir, combine to render this one of the most striking architectural views in this country, or anywhere. But, again, I must not anticipate. The chief conventional churches in Pembrokeshire, at all events of which any remains exist, are St. Dogmael's, Monkton, Pill, and Haverfordwest priories. Of these two only come within the scope of the Association at present, Monkton and Haverfordwest. The former, the nave of which is in use as the parish church, and the choir of it is intended to restore, is utterly unlike anything I ever saw in the way of proportion. It is a long aisleless choir attached to a long aisleless nave, and having a large chapel to the north of the choir, forming, however, a distinct building. In fact, it looks like three churches in contact, and perhaps it really was so; for although it is most difficult to say exactly how the opening from the nave into the choir was managed, there are symptoms which incline me to believe that it was little more than a doorway, so that the choir and nave would have the appearance of being (what they, no doubt, were, as regards their use) two distinct churches. At Haverfordwest the ruins do not give any certain indication of what the church was like; but I should infer from what I have seen that it was a cruciform church of the thirteenth century, certainly without aisles, and probably with a central tower. This was a not uncommon Welsh arrangement for important churches,—witness the abbey church of Talley, and the minister of Llanbadarn-fawr, in Cardiganshire. The two most important parish churches in the county, architecturally, are St. Mary's, Haverfordwest, and St. Mary's, Tenby. The former is quite one of the most interesting churches in Wales, and nowhere,

perhaps, in the principally is there better detail. The latter is striking, but of a somewhat unusual type in Wales. Its ground-plan and arrangements partly resemble some of the larger Cornish churches. None of the churches which I have mentioned, with the single exception of Monkton Priory, exhibit the characteristic features of Pembrokeshire parish churches. This singular type is found, as a rule, only within the English-speaking districts of the county, and I believe no specimens of it are found within those districts on the shores of St. Bride's Bay. Their main features are tall and slender towers, generally diminishing as they rise, a general rudeness of masonry, and internally much vaulting, with side-chapels and squints, and many holes and corners, and a general effect of cavern-like obscurity. Then we come to another class of antiquities, both numerous and conspicuous in this district. Pembrokeshire is a perfect paradise of castles. Not to mention others, three remarkably interesting ones are within easy reach of this place. — Manorbier, which is, perhaps, the most picturesque of the Pembrokeshire castles, especially when looked at in connexion with its surroundings. Carew, which is the most complete, and which (like Kenilworth) contains portions which mark the castellated manor-house rather than the castle, properly so called, and Pembroke, the Queen of South Welsh castles, and certainly one of the most impressive masses of building I have ever seen. One more castle must be specially mentioned, both on account of its inherent interest and because some of those who hear me are to pay a visit to it next week. I mean Picton, which presents the unusual feature of a Medieval fortress (for it was a real fortress, and not a mere castellated manor-house) remaining in the occupation of the ancient family which owned it down to the present time. Considering that it is at this time a convenient mansion, to which a large addition was made early in the present century, there has been far less destruction of its original features than could have been expected to be the case. Of domestic remains of the Middle Ages there are, in addition to minor buildings and fragments to which I need not now refer, but which are numerous, two great habitations of my predecessors, one undoubtedly, and the other (in part, at least) very probably, the work of Bishop Henry Gower. The palace at St. David's is quite one of the best pieces of Medieval Domestic architecture in the kingdom. Its style and arrangements are peculiar to itself and to two other buildings commonly attributed to the same prelate, while it presents to the archaeologist the unusual spectacle of a great Medieval house, partially ruined indeed, but otherwise left very much as it was built. It dates from the early part of the fourteenth century, and exhibits few, if any, traces of later addition or change. I suspect the secret of this to have been that my predecessors never found St. David's a convenient or perhaps a very comfortable place to live at, so that they did not care to adapt it to the requirements of their own times.

Sir James Picton returned thanks to the Bishop for his excellent and learned address, but took exception to his views on the Roman question. Mr. Morgan seconded the motion.

Mr. Lambert then gave a short but lucid paper on the Maces of Tenby, Pembroke, and Haverfordwest. Those of Haverfordwest were the oldest, dating back to 1630; one, however, was a recent copy. Pembroke owned two, made in 1632. Tenby's were of the date of 1660, and bore the crown, which was added after the Restoration. All of them were in a terribly dilapidated condition, mended apparently by a tinker with tin. Battered, bruised, and broken, he begged his worship the Mayor to entrust the Tenby insignia to his care, and promised, in case he would do so, to have them restored in a fitting manner.

When the proceedings in the Town-hall were concluded the party, under the guidance of Mr. Edward Laws, hon. local sec., adjourned to the gardens of the White Lion Hotel, whence a good view of the interior of the town walls may be obtained. Formerly Tenby had four gates. Three have disappeared, including the northern or Carmarthen gate, which Leland commended as "the most excellent as circled without, with an embattled hill open roofed tower." The west gate, which still remains, was built on much the same plan. It is a semi-circular bastion, pierced with four arches, and in the wall which closes it in behind is the gate-

way. These arches were each defended by a portcullis, "*en solido ferro*," as Leland says. The bulk of the tower is out of all proportion to its elevation, and it was never roofed. The battlements have been walled up in order that a narrow chamber made in the wall, and running round it, might be covered. This is, of course, modern work; formerly it was the alure, and afforded a defence for archers or musketeers, for whom loops are provided. Any tyro can see at a glance that the fortifications of Tenby were erected at different times; the walls on the northern and western sides are in a fair state of preservation, though somewhat disfigured by modern doorways, &c. In these are eight towers, six circular and two rectangular; in the wall to the north of the western gate is a niche of Decorated work, and on the southern side a tablet inscribed A° 1688 ER 30, showing that the Armada scare stirred up the local powers to repair their walls. The fortifications on the eastern and southern sides ran along the top of the cliff, and were, therefore, not of such a substantial kind as those undefended by nature. These have almost disappeared, though one circular turret remains on the southern side. Oddly enough, the fortifications on the Castle-hill are comparatively flimsy; a round tower and sallyport defended the entrance. Its little keep, which crowns the apex of the hill, is partly round and partly square; it seems rather to have been intended as a watch-tower than a fortification, and appears to have formed one of a chain. Of these, one on the Burrows still exists; another stood behind the cemetery; a third is to be seen at Ivy Tower, about five miles away. Although Roman coins as early as Domitian have been found in Tenby, and the Welsh recognised it as Dinbych y Piscoed, or Fish Littlefort (to distinguish it from Denbigh in North Wales), and the Norseman honoured it as Danely the Danes town, we do not get much satisfactory information concerning its early days. In 1108 a small detachment of immigrant Flemings were sent to this place by Henry I., and in all probability they were the builders of the earliest portions of the wall. In the year 1150 Meredith and Rhys ap Gwilyf took Tenby, and put its inhabitants to the sword, in revenge for a poisoning fray in Amroth woods. Five years afterwards a new batch of Flemings were sent by Henry II. to take the place of the slaughtered men; these were annihilated by the sons of the Lord Rhys in 1183, and after that the church and town lay ruinous for sixty years, a few men-at-arms being its only inhabitants. Then Warine de Mountcheusy, who had married the heiress of the Earls Marchal of Pembroke, rebuilt walls and church, and bestowed great store of plate and jewels on the latter. In 1457 Jasper Tudor reconstructed the walls, building a footway, 6 ft. broad, on the inner side, so that the sentinels might patrol the town; and he gave the defences to the mayor and corporation for ever. These good folks repaired the walls, as has been seen, in the Armada year. In 1643 Tenby received Lord Carbery, the Royalist Lieutenant-General of South Wales, rather sulkily, but Langhame and Poyer, the Parliamentary leaders from Pembroke, retook it after a severe fight in 1644. It remained in their hands until, dissatisfied with the treatment they received from the Independent party, they ran up the Royal standard on Pembroke Keep and Tenby Castle Hill. This brought down Cromwell on Pembroke and Horton on Tenby, who took the places and dismantled them both.

After viewing the walls and tower, the Association passed down Froy-street (debatting by the way whether this place was named after the *Four-de-llys*) to a ruinous building now used as a cellar, which once formed the chapel of a Carmelite convent, founded in 1399 by one John de Swyemore. In it a female skeleton was dug up some few years ago, and in one corner is a sort of tomb, evidently made up with fragments from other tombs and portions of the building; on this is inscribed the date, 1730, and the builder's name, James Eynon, who seems to have been a joker, for he goes on to dedicate his hogus tomb to King Hezekiah.

The entrance to this convent was through an archway facing the west door of the church. This archway is clearly Tudor.

At this point the Association were taken in charge by the Rev. George Huntington, rector

of Tenby, who conducted them over St. Mary's Church. The tower is capped with a spire, an unusual circumstance in Pembrokeshire. This is evidently a later addition, being Decorated, and built of Caen stone. The tower springs from the south aisle of the chancel. There is no clearstory, but the mullions of its windows were discovered in the chancel wall some years ago during repairs. A flight of ten steps leading up to the altar has a very good effect. The south porch has openings east, west, and south. The outer wall of the north choir aisle is askew. This has rendered it necessary to build pointed arches at the east end of the church and broad segmental ones at the west.

Remains of the old church, destroyed by the Welsh in 1188, may be detected by an examination of the plinths of the pillars. On the eastern side of the north door is a tomb, on which there is a female effigy, clad in a flowing robe, with short sleeves, under a cinquefoiled canopy. A chin-cloth, or barbe, covers the head. This tomb is believed to be not later than the first half of the fourteenth century, and is considered to be the oldest in the church, but that of Thomas White, the friend and protector of Henry Tudor, is, without doubt, the most interesting. It is situated at the east end of the south aisle, under the arch which divides it from the chancel. On it lie two male recumbent figures, which are clad in fifteenth-century costume; their hats hang over their left shoulders, to their girdles hang gypcières, their feet rest on talbots, their heads on peacocks. Thomas lies to the east, his brother John to the west. The church is undergoing a restoration (Mr. J. P. Seddon, architect); this work will not in any way affect the interior of the building, but greatly improve the exterior, as a tumble-down brick vestry will be replaced by stonework, though the general appearance is not enhanced by a hideous brick chimney.

Mr. Loftus Brock, Secretary of the Association, gave an excellent and lucid description of the church, showing how it had grown from a small cruciform edifice into its present lordly proportions. This, he considered, took place when it was rebuilt by Warren de Mountcheusy.

Colonel Bramble then led the party round and examined and expatiated on the numerous and interesting monuments.

After leaving the church the members examined some curious old buildings in Crackwell-street, which gave a notion of what Tenby was in the sixteenth century; its most noticeable feature seems to have been a want of elbow room, land "within wall" being very valuable. This led apparently to great overcrowding of buildings, and probably of their occupants. The expedition ended up on the Castle Hill, many of the party entering the little local museum, in which a very creditable loan collection proved an additional attraction; the more so as Mr. De Gray Birch gave a thorough and exhaustive discourse on the seals and charters of the three boroughs of Haverfordwest, Pembroke, and Tenby; these he considered to be invaluable. He especially drew attention to an impression of a seal of James I., attached to a Tenby Charter, of which only one other copy is known to be in existence. He much regretted the neglected condition in which he found these invaluable documents.

The report of the proceedings will be continued in our next.

#### Value of Building Sites at Rotherhithe.

What have for several years been known as the St. Helena Gardens at Rotherhithe are now being converted into a building estate, and last week forty-seven of the plots on the estate were let by auction on building leases, at the St. Helena Tavern, on the estate, by Mr. F. J. Bisle. The property is situated in Engenia-road, near the new railway stations, and in the immediate neighbourhood of Southwark Park. The plots were let in eight lots, several of the lots containing six plots, and the remaining lot five plots. Each plot contained a frontage of 15 ft. 6 in., and they were offered on leases direct from the freeholder, for a term of ninety-nine years from June, 1882. There was a large attendance, and the whole of the lots were readily disposed of at prices varying from 25l. to 27l. each, representing an annual ground-rent for each plot of about 4l. 10s. At the same time nineteen houses on the estate, in various stages, and partly finished, were offered for sale, and realised 930l.

## Illustrations.

## ACCEPTED DESIGN FOR THE NEW WAR OFFICES.

**W**E give this week the Park view and the two principal plans of the accepted design for the proposed New War Offices, by Messrs. Leeming & Leeming. The competition having been obviously in the main a competition of *plans* rather than of design,—for on no other supposition can the presence of some competitors among the selected nine, and the omission of others, be reasonably accounted for,—we may call attention to the fact that the plans are now first published on such a scale that their arrangement is intelligible and the lettering of the rooms legible.

The following tabular statement of the classification of rooms, as supplied to the candidates, will serve more or less as a key to the plans of all the sets:—

## THE WAR OFFICE.

- A. Staff.
- B. Surveyor-General's Department.
  - B. 1. Director of Artillery.
  - B. 2. " " Supplies.
  - B. 3. " " Contracts.
- B. 4. Inspector-General of Fortifications.
- C. General (or Secretary of State's) Department.
  - C. 1. " " " "
  - C. 2. " " " "
  - C. 3. " " " "
  - C. 4. " " " "
- D. Finance Department.
  - D. 1. Finance Department.
  - D. 2. Auditors.
- E. Military Department.
  - E. 1. Military Secretary.
  - E. 2. Adjutant-General and Quartermaster-General.
  - E. 3. Intelligence Department.
  - E. 4. Deputy Adjutant-General R.A.
  - E. 5. Deputy Adjutant-General R.E.
  - E. 6. Army Medical Department.
  - E. 7. Military Education Department.
  - E. 8. Commissary-General's Department.
  - E. 9. Principal Veterinary Surgeon's Department.
- F. Miscellaneous.
  - F. 1. Army Purchase Commission.
  - F. 2. Judge Advocate General.
  - F. 3. Pay Office, Commissariat and Transport and Ordnance Store Corps.
  - F. 4. Pay Office, Army Hospital Corps.
  - F. 5. Army Sanitary Committee.

## THE ADMIRALTY.

- A. Board-room Suite and Secretary's Department.
  - A. 1. Board-room Suite.
  - A. 2. Military Branch.
  - A. 3. Intelligence Branch.
  - A. 4. Naval Branch.
  - A. 5. Civil Branch.
  - A. 6. Legal Branch.
  - A. 7. Registry Branch.
  - A. 8. Record Office Branch.
  - A. 9. Copying Branch.
- B. Hydrographer's Department.
- C. Transport Department.
- D. Victualling Department.
- E. Controller's Department.
  - E. 1. Director of Naval Construction.
  - E. 2. Engineer-in-Chief.
  - E. 3. Director of Naval Ordnance.
  - E. 4. Store Branch.
  - E. 5. Dockyard, Ship, Gunnery, and Registry and Copying Branches.
- F. Accountant-General's Department.
  - F. 1. First Division.
  - F. 2. Second Division.
  - F. 3. Third Division.
  - F. 4. Fourth Division.
  - F. 5. Fifth Division.
  - F. 6. Sixth Division.
  - F. 7. Greenwich Hospital Division.
  - F. 8. Auditors.
- G. Director of Contracts Department.
- H. Director of Medical Department.
- J. Director of Works Department.
- K. Naval Reserve Department.
- L. Royal Marines Department.
- M. Inspector of Naval Schools Department.

As will be seen, Messrs. Leeming place the Secretary of State and the First Lord's rooms as "pendants" to one another at the extreme angles of the Park front on the first floor, with their respective staff members grouped about them. The other departments appear conveniently grouped, and the plan has the merit of being geographically simple and easy to find one's way in. Its defects are narrow courts, and rooms with insufficient window accommodation placed at the ends of the rooms. The main design is unquestionably picturesque in general effect and grouping, but it is not a great building, and none of the improvements in detail

which are quite possible, and some of which have been suggested in these columns already, will make it so. But there,—we have given up having great buildings now, especially for Government purposes.

The view is engraved by Mr. J. D. Cooper.

## THE DECORATION OF ST. PAUL'S CATHEDRAL.

THE accompanying sketch shows the modification I propose in the design by Alfred Stevens for the decoration of the cupola of St. Paul's Cathedral, together with my own designs for the decoration of the subjacent parts of the dome.

The full-sized cartoons are now fixed in the dome itself on the south side, opposite to the modification of Stevens's design by Mr. E. J. Poynter, R.A., which is on the north side. The storiation,—which was arranged by Mr. Edmund Oldfield, M.A., one of the sub-committee appointed on the 9th of June, 1877, to make preliminary arrangements for the decoration,—has been fully explained before in connexion with Mr. Poynter's work, illustrated on the 5th of July last. The two modifications may be described as a Painter's version and an Architect's version. Each version shows two "ribs," with the space between, and covers about one-sixth of the cupola. As I understand the case, it is not a competition between persons, but an experiment to ascertain treatment. Omitting minor details, there is not scope for much originality in either version, and it is rather a question of suitability.

The sketch shows about half of the dome, in order that the articulation of the whole may be better understood.

*Principles.*—The endeavour has been, as far as possible, to avoid the *rococo* elements, borrowed from the Louis XIV. style by Grinling Gibbons and the other carvers who were employed on the fabric; and, while keeping to the pure Italian practised by Stevens, to introduce no new element not in accordance with Sir Christopher's views as seen in his works and shown by engravings and other documentary evidence. Further, to use no architectural feature not suitable to the interior of a roof, and no painted perspective such as would suggest recession, and cause loss of the surface, but to preserve the "pattern-effect" of Stevens's design, and to arrange such a modification as, while providing for the storiation, should satisfy the architectural and other requirements.

*Distance.*—The most favourable point of view is at the commencement of the barrel-vaults under the dome-supports: from this position the whole of the opposite side of the cupola is visible. And at this point the nearest part of it, *i.e.*, the base, is over 200 ft. distant. The minuteness resulting from this may be judged if the engraving be held at a distance of 16 in. from the eye.

*Scale.*—To suit the great distance, the architectural work has been kept simple, and the initial modulus of the figures large. The sitting figures typifying the early Churches, together with that of John himself, would be, if upright, 16 ft.; the attendant angels are 12 ft. 6 in.; the figures in the lower series of visions would also be 12 ft. 6 in.; the demi-figures in the lower rank of rib-roundels, and the figures in the upper series of visions, would be 10 ft.; the demi-figures in the upper rib-roundels, and the Elders, would be 9 ft. Thus a gradual decrease in modulus will prevent the decorative work having the effect of "dragging the cupola down." (The Apostle in the roundel of podium is, I now find, too large; but that is a matter of detail which would be easily corrected.)

*Divisions.*—To ignore architectonic considerations, and decorate the cupola with one picture, as has been suggested, would be, not decoration, but articulation of the surface; the disastrous effects of which may be seen at Parma and several other churches which were decorated in the Decadence. Unless the cupola were decorated with one subject covering the whole 16,000 square feet, there must be a series, the several pictures of which would be axial with the architecture below; and hence subdivision becomes necessary. In addition to this logical necessity, there is the further advantage which should not be lost sight of,—that it brings the cupola into scale with the rest of the building.

*Circles.*—Stevens's base of subdivision is the circle; the fact, that every plane section of a

sphere is a circle, being the key to his design; and to him is due the credit of first seeing and using this apparently self-evident fact. In addition to being the typical shape for cupola decoration, the circle is a perfect and mysterious shape, well suited to contain "visions," as to give the simplicity and sublimity consonant with religion. The circular frames intersect with the vertical lines; and, being as strongly pronounced as they are, take away the preponderance of the vertical element. The figure compositions in them will be designed by Sir Frederick Leighton and Mr. Poynter, and hence they are only smudges of colour.

*Ribs.*—I have deviated from Stevens in the treatment of the "ribs" between the circles. They are treated, not as constructed features built up in several stories, but merely as continuing decoratively the eight solid bays of the peristyle; for which a precedent may be found in the semi-dome over the altar, where Wren has applied ribs over the pilasters dividing the surface. The decreasing "gores," resulting from this "rib" treatment, do not extend so far upward as the eye of the cupola, but are stopped below the annular frieze of the Twenty-four Elders, where the radius of the cupola changes, according to Mr. Penrose's discovery; and they are not so small as the much-criticised divisions of St. Peter's. The strong lines of colour in the latter are further avoided by gliding the ribs. They will, therefore, have just sufficient emphasis to steady the vision-circles, and to assist in defining the profile of the cupola, without destroying its perfect homogeneity. They contain representations of some of the imagery used by John:—the candlesticks (more properly lamps), the eighth being the typical branched one; the stars, the eighth being the sun and moon; and the martyrs' palms.

*Pattern.*—In connexion with the subdivision it will be noticed how the masses and colour of the roundels, thrones, and siebes, being in regularly set-out positions, make a pattern which "runs" not only over the cupola, but also through the peristyle and podium, and thus suggests the unity which existed in the older domes before peristyles had been interpolated between the spandrel panels and the cupola.

*Thrones.*—The axial thrones form one of the most characteristic features of Stevens's design. The details in my version are studied from the window-dressings in the clearstory; and I have connected them with the attic pedestal for simplicity of design.

*Attic.*—This pedestal was proportioned in height to the order of the peristyle, and broken over the pilasters; and the cupola design was thus "tied" to the existing architecture, by Stevens.

*Angels.*—The Seven Churches, judging from the reproofs and promises to each, may be taken as typical of Christendom. The "Aggelloi" represents the sorts and conditions of men written to by John; and there seems great fitness in placing them round the base between the Lower things and the Consummation. The attendant angels would not be individualised, but rather considered as messengers, directing, or hearing symbols of the Promises:—the Tree of Life, the Safety from the second Death, the New Name, the Power over the Gentiles, the White Garments, the Pillar of God, and the Grant to sit on the Throne.

*Elders.*—The annular frieze round the eye of the cupola contains the twenty-four Elders, who "surround the Throne." Those on the west side would be represented as sitting on golden thrones, and from them on each side round towards the east they would be singing the song and casting themselves down and "worshipping." Thus they avoid continuing the vertical lines of the ribs, but would instead give a composition sweeping round the circle. *Cherubim.*—Cherubim and Seraphim are introduced floating in space; they carry the idea of Praise through the design, and are useful, decoratively, in helping to define the roundness of the cupola.

*Lantern.*—On the ceiling of the lantern at the top of the cone, I would suggest the vision of the Throne. I say "suggest," because it is impossible to depict it. I would use a dark blue ground for the "darkness which surrounded the throne"; on this and over the four windows at the cardinal points I would place the "four living creatures"; between them and over the four intermediate windows the words of their hymn,—"Holy," "Holy," "Holy," and "Amen";

**I.B.A. Architect.**

**58, Wellington Buildings  
Chelsea, S.W.**

and between and below the eight windows I would represent the "lightning which came from under the throne." Thus the visible portion of the cone would be decorated; and by placing the living creatures on the domical portion, the distortion of "sotto-in-su" would be avoided.

**Peristyle.**—The peristyle is treated as an integral portion of the dome, with the object of "carrying-down" the cupola treatment; to this end the pilasters have applied ornaments, similar in character to those above, or adapted from other ornaments in the cathedral. Mr. Penrose has designed those on the north side; and I am responsible for the treatment of those on the south side. The inscription which I suggest is taken from chap. xxii, verse 6, of the Apocalypse.

**Podium.**—The manner in which the eye, on entering the cathedral, runs along the apse, ignoring the Crux, has been pointed out as a defect. The podium, which is the only portion of the dome visible at this point, gives an opportunity for remedying this by making an important central feature, which may arrest the eye, and suggest an axial line of something above. This is attempted by the axial roundels set in the belt or chain of rich colour that appears to enclose the cupola, and serves as a connecting-link between the golden colour above and the graver colour beneath. A typical Apostle is introduced: the demi-figures at the other cardinal points would be typical representatives of the "Prophetarum Laudabilis Numerus," the "Martyrium Candidatus Exercitus," and the "Sancta Ecclesia per Orbem Terrarum"; and the intermediate roundels would be occupied by angels with the Sanctus. One half of the cartoon is shown with a tablet and portion of the sentence from the Te Deum, "Te laudat gloriosus Apostolorum chorus"; and the other shows another experiment with simple ornament. I am responsible for this design; the podium treatments on the north side are by Mr. Penrose.

**Stone Surface.**—In the colour treatment the aim has been to retain the unpolished stone for all constructive features up to the level of the podium, and only to introduce the mosaic and marble inlay in panels; and the gilding on enrichments as now existing from the time of Sir Christopher. It might be washed (not scraped), and treated with a silicate that should keep it in the beautiful pale yellowish brown which is its normal colour. Any treatment by painting or removing its patina would take away all that adds dignity of colour, and would destroy the indefinable charm of mystery and space. For these reasons I would take the stone as the key of the colour scheme, and avoid the "white and gold" used in assembly-rooms, &c.

**Gold Ground.**—The glorious golden ground, too class suggested by S. Marco, is another of Stevens's most valuable suggestions. It is the only ground which will "tell" in the normal colour of the dome; and the figures should, as far as possible consistent with the composition, silhouette upon it. The tint (at the commencement of the cupola, and in all other parts) should be that of "old gold," because more beautiful in colour, and more in accord with the old stone, and also because, if the colour of new oil-gilding be taken, the mosaic remaining unchanged while the gilding became redder, in course of time the harmony would be lost. In the cupola the tint of the gold ground should be gradually modified to sea-green gold as it ascends.

**Decorative Colour.**—The colour of the corative work should be on very simple hues, so as not to lose dignity and breadth. It should be more neutral, and the chiaroscuro more solid, in the lower parts of the cathedral; and gradually gain in fulness of colour and lose in solidity, as it ascends to the podium. This should be the richest band of colour in the whole building. Below there should be the gradual crescendo in richness on the stone-colour and neutrals; and above the cupola would "lose colour" in a gradual crescendo, till it became almost golden. We should not take away the splendid variety of Wren's crowning work.

**Mosaic.**—The cartoons have been designed and painted as if for execution in mosaic; and an attempt has been made to observe the technical limitations of the material, and to attain the necessary simplicity and directness of composition shown at Sta. Maria Maggiore, Apollinare Nuova, Galla Placidia, and in the middle-period work in S. Marco.

**Relief.**—In my version I have shown the possibility of applying mouldings in actual (low) relief to the surface of the cupola: a practice which has been often done in Italy with the bappest effect, *teste* the small transept cupolas of St. Peter's. They have been made by Messrs. George Jackson & Sons in their "Bibbus plaster." They are very easily fixed, and, by giving true lines they materially simplify the setting-out of the mosaic, and make more manageable sizes for the cartoons. I am solely responsible for this suggestion of applying actual relief; but I wish it to be clearly understood that it is by no means a *sine qua non*, as the design might as readily be executed entirely in mosaic; the relief would, however, give a more architectonic character by having a real potential value instead of mere chiaroscuro.

**Galleries.**—On the right-hand side of the sketch a suggestion is submitted for treatment of the quarter galleries, while the left-hand side shows their present form. On my return from Italy in December, 1878, fresh from studying the finest domes, I was more than ever struck with the unfortunate effect of these. It has been often alluded to by architectural critics, and various expedients have been suggested. After much consideration on the spot I arrived at the solution shown, which embodies five suggestions:—(a.) To carry the panelled arch-face over the galleries, with inner archivolts resting upon the stone breast-forward under the railing; the panels to agree in treatment with the first rows of coffering in the adjacent barrel-vaults. I would strongly object to any tampering with Sir Christopher's construction; but this suggestion does not cut away a stone; it is added to the existing construction, and could be made, if desired, to give additional strength, both really, and (what is of importance) apparently. It would take away four or five available seats in each gallery; but it would destroy the eight axes and make only four, thus emphasising the Crux. It also gives opportunity for uniting the colour treatment of the four arms of the barrel-vault with each other, by the colour picked in the coffers of the arch-faces and in those of the vaults.

(b.) To add festoon ornaments, in gilt gesso, to the attic under the railings, in order to disguise the hard cutting lines which come down upon the curved pediments, and to lead the eye pleasantly to the horizontal lines. There are many precedents for this in Wren's work.

(c.) To add a thin baluster column and garland, of gilt bronze, in each arch, for the purpose of "taking the eye across" and (apparently) filling up the void: this would not obstruct the view of any one in the galleries, as the garland would be above the line of sight. This intention—to take away the effect of the gaping void,—has been often achieved by the expedient of a gilt grill in the opening; but I venture to think the above is a better method.

(d.) To remove those portions of the ornamental cornice projecting inwards, in order that the cornice and frieze of the main order may be carried from the horizontal over the curves without interruption, and to affix an inscription (John v. 33) in gilt bronze letters to that portion of the frieze on the four oblique faces; this is suggested because, by its easy division into four portions, it gives unity to the supports of the dome.

(e.) To sub-panel the four semi-domes under the galleries. At present each of these has a superficies of about 360 ft., while the spandrel-panels have only 240. They are thus more important by reason of their largeness than their adventitious existence would justify. I would therefore propose to cut off a row of horizontal panels, of the same height as the above-mentioned frieze, which should be axial with the arches below, as shown; and also to make a margin round the remaining space, leaving the best-seen portion for the pictures. By this expedient these soffits would be brought into scale with the rest of the building. The divisions may be executed either in mosaic or with relief mouldings. These pictures might be either scenes from the life of St. Paul, or, if a cycle of events from his life reserved for some position nearer to the level of human life, with some of the "great company" of angels who are ever singing the song of the redeemed, and are come down to lead our lower anthems. These five suggestions were not asked for; and I am solely responsible for having devised them and for having shown them on the sketch. They might be tried experimentally very cheaply by

chiaroscuro painting on thin boarding. It is with all admiration for the great genius who raised the pile, and in all humility that I venture to publish them, and to suggest that experiment might be made to determine if they be emendations or not.

**Time.**—In conclusion, for the information of those who take an interest in the work, I would beg to say that the best time for seeing the two versions of Stevens under equal conditions is when the sunlight comes through the windows on the west side of the peristyle, about five o'clock each afternoon, in a week's time.

HUGH STANNUS.

#### PROPOSED MISSION-HOUSE AND PORCH, ST. AUGUSTINE'S, HAGGERSTON.

We give an illustration of these intended buildings, from the drawings of the architect, Mr. R. A. Briggs. As no principal porch was designed when the church was built some years ago, it has been thought advisable that one should now be added.

The Mission-rooms will be used for parochial meetings, &c., and on Sundays the classes for girls will be held.

A sexton's house is provided, with a shop on the ground-floor, where hooks will be sold. The present entrance under the clergy-houses will still be retained, but the inner court will be widened.

The Mission-house will be built of red Suffolk bricks and Portland stone dressings.

#### THE PRIVATE BILL LEGISLATION OF THE SESSION, AND PUBLIC WORKS.

An analysis of the private Bills which have been passed during the session just ended shows that about two-thirds of the entire number of Bills promoted have received Parliamentary sanction, the total number presented being 294, of which 203 were successful. The railway projects embraced about one half the total number of Bills of all kinds, being 149, for the construction of 1,045 miles of new railway, at an estimated cost of 60,968,195*l.* But in addition the Money Bill of the Mill, Barnsley, and West Riding Junction Railway and Dock Company, which was presented at a late period of the session, brings up the aggregate estimated cost of the whole of the Bills promoted to 62,468,195*l.* Of this class of Bills, 82 have been passed, being a little in excess of one-half of the whole, the capital expenditure sanctioned by the Bills amounting to 20,438,700*l.*, for the construction of 315 miles of new railway and other works. It should, however, be stated that 40 of the Bills sanctioned are in respect of extension of time, abandonment, or arrangements, leaving 42 Bills having reference to the actual construction of works. Ten of these successful Bills were promoted by companies to be incorporated for the construction of entirely new lines of railway, 123 miles in length, at an estimated outlay of 5,612,000*l.* The most costly of these is the Barry Docks and Railway project, involving an expenditure of 1,600,000*l.* for making a dock, with a lock, basin, an entrance channel, and breakwater, between Barry Island and the mainland of Glamorganshire, and for the construction of thirty-three miles of railway. The next in order of the new lines in amount and mileage is the new railway from Preston to Lytham and Blackpool, the estimated cost of which is 680,000*l.* for the construction of twenty miles. Amongst the other new lines is that from the Kingsbury extension of the Metropolitan Railway at West Hamstead to the Hendon Station of the Midland line, a length of four miles, at an outlay of 240,000*l.* The additional powers obtained by several of the great companies involves the expenditure of a very large amount in new works, that of the Midland Company being 1,600,000*l.*, which includes the construction of thirteen miles of new railway; the London and North Western Company, 1,437,500*l.*; the Manchester, Sheffield, and Lincolnshire, 1,066,000*l.* for the construction of twenty-eight miles of new railway; the North-Eastern, 660,000*l.*, for twelve miles of new railway; the London and South-Western, 660,000*l.*; the Caledonian, 634,000*l.*, for the construction of eleven miles of new railway; the London, Chatham, and Dover, 626,000*l.*, for seven miles and other works; the Great Western, 600,000*l.*, for twelve miles; the South-Eastern, 430,000*l.*; and the Lancashire and Yorkshire,

420,000. The Mersey Company have also obtained powers for expending 400,000. in the construction of two miles of additional lines in Birkenhead. The powers obtained by the Metropolitan District Company enable them to expend 180,000. in forming a short junction line at Hammersmith, and also in the construction of a subway from the South Kensington Station to the Royal Horticultural Gardens. The Session has been remarkable for the rejection of an unusually large number of railway Bills connected with the metropolis.

Of the thirty tramway Bills promoted for the construction of 173 miles of tramways in different parts of the country, at an outlay of 3,747,910., the number sanctioned is fifteen, or exactly one half of the Bills applied for. In these Bills the construction of seventy-seven miles of tramway is sanctioned, at an outlay of 2,003,300. Seven of these Bills are in respect of tramways to be constructed within the metropolitan area, and include the West Metropolitan Company's Bill for the construction of tramways in the parishes of Acton, Hammersmith, and Norwood, fifteen miles in length, at the cost of 350,000.; the London Southern Tramways Bill for the construction of tramways, five miles in length, in Lambeth, Newington, Clapham, and Brixton, at an outlay of 150,000.; the North Metropolitan Company's Bill for the construction of six miles of additional tramways in East London, at an outlay of 125,000.; also Bills promoted by the London, London Street, North London, and Lea Bridge, Leyton, and Walthamstow companies for constructing fifteen additional miles of tramway, at an estimated cost of 127,000. The South Eastern Metropolitan (a new company) have likewise obtained powers to construct four miles of tramway in Greenwich, Deptford, and Lewisham, at a cost of 75,000. Amongst the successful Bills under this head is one for constructing ten miles of tramway in the neighbourhoods of Manchester, Bury, and Rochdale, at a cost of 750,000.

Twenty of the successful Bills were in respect of gas and water supply, six being in connexion with gas and fourteen with water supply. The Bills sanctioned for the construction of new waterworks authorise the expenditure for that purpose of 853,900.

Seventeen Bills relating to piers, docks, and harbours were passed. Amongst them were Bills for the construction of piers at Gravesend, Folkestone, Ventnor, and Weston-super-Mare; also a Bill promoted by the London and St. Katharine's Dock Company for the construction of a new entrance to the Royal Albert Dock at Galleon's Reach; together with a Bill promoted by the North Sea Fisheries and Harbour Company, empowering the company to make a tidal harbour, dock, piers, and other works at Sutton, in Lincolnshire.

Nineteen town improvement Bills likewise received Parliamentary sanction, under which the several corporations and local authorities are authorised to widen existing streets, and construct new streets, with increased powers over the construction of buildings. The powers obtained by the Brighton Corporation under their Bill are of a very comprehensive character. They are authorised to construct a running wall, promenades, piers, and landing-places, with tidal, swimming, and other baths. They are likewise empowered to erect shelter arcades, conservatories, and other works on the seashore, in connexion with the construction of lifts for carrying passengers up the face of the cliff, from the seashore to the Marine Parade. The Bill likewise authorises the corporation to erect a wholesale provision market, new municipal offices, and an arcade or bazaar. It also transfers to the Corporation 103 acres of land known as Tenants' Down, to be laid down as a recreation-ground for the use of the public. The Dewsbury Bill empowers the Corporation to erect a new town-hall, municipal offices, court-house and gaol, and museum, together with the construction of public baths, and a public park. The Birkenhead Bill enables the Corporation to widen thirty-one streets, and to form other new streets; also to purchase and take down 131 insanitary houses.

**Appointments.**—The Haverhill Local Board has appointed Mr. F. Kemp to fill their vacant office of Surveyor and Inspector of Nuisances; and the Town Council of the borough of Eastbourne have appointed Mr. W. T. Vale as clerk of the works to their new Town-hall and Municipal Buildings.

#### THE FIFTH INTERNATIONAL CONGRESS ON HYGIENE.

THE present congress has been, perhaps, a little less brilliant, but certainly more business-like than its predecessor, held at Geneva two years ago, and which was fully described in these columns. Much good work has been done, and resolutions voted that will not fail to influence Continental Governments. The Governments of Belgium, Bavaria, Brazil, Spain, Austria, France, Italy, Roumania, Germany, Servia, Turkey, Switzerland, and Bulgaria, the Argentine Republic, and the United States of America, have all sent special delegates. The French were as usual the best represented, and the English last on the list. This was all the more to be regretted on this occasion, as we have been strongly attacked and accused of sacrificing the health of Europe to the promotion of our commercial interests. The Dutch themselves, fortunately, were not so bitter against the English, and though on certain occasions they might advocate the establishment of quarantines, they, nevertheless, recognised how exaggerated the present outcry has been.

As affecting the preservation of health, almost every word said at the congress may be considered of interest by our readers; but the subjects that had a specific and direct bearing on the interests represented by this journal are far more limited. We will not reproduce the speeches of welcome, the eloquent harangues on the great mission of sanitary reformers. These we will leave to the imagination of the reader, or to those who choose to read the official report of the congress when it is published. Suffice it to say that all that could tend to make foreigners welcome, and to inspire them with a high and disinterested sense of their duties, was uttered with much feeling at the opening of the congress by its president, Dr. de Beaufort, Senator, and Dr. Overbeck van Meijer, its honorary secretary. These sentiments were repeated in the evening at a reception given by the Municipality of the Hague to its visitors.

On the following day the congress set to work in real earnest. The first section, after a stormy debate, invited the Dutch Government to take the initiative in convoking an international congress on the cholera question. This congress, it was further suggested, should appoint a permanent commission on epidemics, and proceed to codify in an international sense the laws affecting hygiene. To this latter proposal it was insinuated England would never submit, for fear her commercial interests might be compromised; and there being no Englishman present, it was the Russian delegate who took up our cause and sought to defend the honour of England. The Count Paul de Suzor, of St. Petersburg, objected that England, on the contrary, of all European nations, had made the greatest sacrifices for the preservation of public health. It had in spite of the cost, drained all its principal towns, and at the present moment if Englishmen could calmly contemplate the progress of the cholera, it was precisely because they had been such zealous promoters of public hygiene.

In the fourth section on the same day, Dr. H. Napias, Inspector of Factories, and delegate of the Municipality of Paris, read a lengthy and studious report on the duties of the State with respect to the health of the working-classes. Opening a voluminous manuscript, he remarked that he took his appointment as reporter to the congress on such a subject as a reward for his past labours. His object was to give some indications that might serve as a basis for industrial legislation of an international description. M. de Fréycinet had laid down the axiom that all industries are insalubrious. Two centuries previously Italian reformers had argued in the same strain. The position, the air, the dust, the whole surroundings of the workshop, were unwholesome. The State was, therefore, bound to step in and see that what was had in itself should not be made worse by neglect. In 1848 the Chamber of Commerce of Ronen had protested against unlimited freedom in such matters, and denounced the immoral effects of unconstrained competition. But at the same time it must be recognised that it was a manufacturer who first proposed a law on the subject, and that such motions had received the warmest support from M. Waddington and others, whose interests might be supposed to lead them into

the opposite camp. The more enlightened among the employers recognised that it was their duty to limit the number of killed and wounded in the army of labour.

Dr. Napias then reviewed with admirable brevity and completeness the legislation of the different countries, rendering high homage to what had been done in England. The Austrian law watched the health, working hours, salary, and apprenticeship of the working classes. The German law affected the health of workshops, and limited the labour of children. The Belgian law only regulated unwholesome manufacturing, and the work of children, except in mines, was not restricted. The Danish law only touched unwholesome industries; though Article 5 stipulated that manufacturers must submit to the health authorities. In Italy each province had a law of its own, principally to protect the work of women and children. In Portugal, Spain, Roumania, and Sweden, the law related to the outside of the factory, the harm it might do to the neighbours, and little was said of the workmen who toiled within. But Servia has given us an admirable law protecting workmen, which, with the legislation of Switzerland, deserves to be universally studied. In France, the law is drawn up to protect children; and, if a factory is unwholesome, the employer only need send the children away to legalise his position. Fortunately, the Consultative Commission of Hygiene and the Minister of Commerce were now engaged in preparing a better law. All European laws were open to criticism, and each nation should borrow the best clauses from the Acts of Parliament of neighbouring countries. A good law should not only protect the neighbours against dangerous or injurious industries, but the workmen themselves. Workshops should be rendered as wholesome as dwellings, and special precautions taken against special dangers, the Government offering every encouragement to health-saving inventions. With respect to accidents, Dr. Napias would only exercise severity with regard to measures of precaution, which he would render obligatory under harsh penalties. The law should also watch over the lodging of the workmen, which must perform be rendered wholesome. It should be a penal offence to let a tenement unfit for habitation. It is no use reforming the workshop if the workman's home does not receive equal attention. Actually, sanitary authorities were nowhere armed with sufficient powers. At the same time, Dr. Napias thought that the State, having provided the workman with a good general and technical education, and having watched over his health during childhood, owed to the adult nothing else but his liberty.

To this, it was objected, that a large section of the population, that section precisely which caused the greatest difficulty to sanitary reformers, had not received these educational advantages. What with competition and lack of skill, this residuum could only obtain starvation wages, and it was impossible to expect them to pay the high rents charged for healthy dwellings. If the poor man is to live a wholesome life, some one must supply the money this would cost, and the money would only be forthcoming by trampling under foot the rights of property and the freedom of contract. The difficulty could not be overcome except by a law enacting that adult males should not work over a limited number of hours; that all private rooms where work was done should be placed under factory inspection; and finally that a minimum wage must be established, so that all who worked should earn enough to live in a healthy manner. These might be revolutionary proposals, and certainly they produced considerable sensation, but they were presented as the only possible logical outcome of the problem of the housing of the poor.

Several other speakers described various model dwellings, and M. Malberbe, an engineer, delegated from the town of Liège, repudiated all State intervention, claiming that absolute freedom was the true solvent for every difficulty. To this Dr. Napias replied that absolute freedom existed in Belgium, and that was why women and children still toiled below ground in the coal-mines. This concluded the debate on this portion of the proceedings.

At a subsequent meeting it was demonstrated by numerous experiments on animals that consumption is contagious, but that, the virus being principally confined to the sputa of the patients, the chief measures taken should be

adopted with a view to prevent the contamination of clothing and furniture by the expectorations. Spittoons charged with liquid disinfectants should, therefore, be used instead of handkerchiefs. In the same manner the congress insisted on the boiling of milk, the thorough cooking of beef, as cattle often suffered from tuberculosis; and that disinfection should not be limited to dry heat, but that a jet of steam must be introduced into the stove. A great deal was said against the danger arising in the trade of rags, and Dr. Roth, representing the British Society for the Prevention of Blindness, did good service in showing that more than half the cases of blindness now existing might have been prevented if taken in time. This is a question to which the attention of architects will be directed more and more every day. The supply of light to dwelling-rooms will not long remain an optional matter. Rules will ultimately be laid down stating per candle-power the amount of light necessary. Dr. Conn, of Breslau, showed us how the light of the sky could be accurately estimated and compared with the amount of light existing in any part of any room. The complicated but most ingenious instrument employed for this purpose cannot be easily described without a drawing. We shall, however, probably return to the subject, and for the moment it suffices to say that now it is as easy to estimate in a moment the candle-power of light in any place or position as it is to ascertain the temperature. Hence in future it will be as practical to lay down rules with respect to the amount of light to be given as with respect to the temperature that should be maintained, and the facility of verifying as great in both cases.

M. Emile Trélat, in one of the afternoon general meetings of the congress, took up the question of the atmosphere and internal conditions of dwellings. Most of the members of the congress were present, being anxious to hear what the eminent Parisian architect had to say on this important topic; also vague rumours were floating about as to the strange and novel theories M. Trélat was about to propound.

M. Trélat commenced by alluding to Dr. Rochard's admirable lecture on the money value of human life. Dr. Rochard, he remarked, wished to increase the duration of human life by suppressing epidemical diseases. M. Trélat, on his side, proposed to economise life by reducing all lowering causes, all circumstances that tended to debilitate a population. Among these causes he must place in the foremost rank our homes. Our dwellings should shelter us, but they too often proved a mere snare, in which we were slowly poisoned. If we failed to obtain the necessary warmth with the required volume of pure air, our homes became a danger, a menace to our existence. His object, however, was not to deliver a lecture on warming and ventilating, but rather a lecture against what was done in this respect. It would be his painful duty to attack both Pecklét and General Morin, whose memory he revered, but whose science was now out of date. Pecklét had studied how things are burned. In his time very little fuel was used. The whole population was impoverished by long wars. They had large chimney-places, but very small fires. The trouble many people took to light a fire warmed them more than the fire itself. Pecklét calculated that under these circumstances the average chimney absorbed 95 per cent. of the heat coming from the small fires then in vogue; for the chimneys had been built before the war, when people could afford to fill them. Pecklét then conceived the idea of bringing the air in from the outside, and warming it by making it revolve behind the fireplace before it entered the room. This was the foundation of his great success, and the contrivance was all the more appreciated as it allowed the inhabitants to close the windows. Having done this much, it then occurred to him that it would be even still cheaper to warm the air downstairs at one single fire, and then distribute it all over the house by means of fines. Thus the calorifère was invented, and for forty years these doctrines had been followed. For forty years experiments of most minute and difficult nature were made. Dr. Rochard had blamed architects; but why did the doctors let the architects grope in the dark for forty long years? Why did not the medical profession discover at an earlier date what were the sanitary principles that should govern the warming of dwellings? He then

related how various architects had tried model systems of warming and ventilating, and had failed, and condemned the breathing of warmed air, on the ground that it contained less oxygen. Also air-fines soon became dirty, the sun could not reach them, and the dust they contained helped to develop germs.

The most agreeable feeling was that experienced on a cold fine morning, when our bodies were warmed by the direct rays of the sun while we breathed cold air. Our rooms should be fed with cold pure air, taken direct from the outside, and warmed with radiating heat from an open fire-place. The walls should be warm and reflect heat, the windows should be warmed, all solid bodies in the room should receive and radiate heat; but the air that we breathe should not be warmed, and must come in direct from the outside. He remarked with pleasure that many of the English artisans' dwellings had small openings in the wall which allowed the cold street air to enter direct into the room.\* It was astonishing how much cold the human body could stand if it also enjoyed counteracting heat. Thus the bivouac fire enabled the soldier to pass a comfortable night in the open air, and M. Trélat wished that rooms should be treated on the same principle,—a houseless supply of outdoor cold air, with radiated heat to counteract its chilling effects.

As discussion was not allowed at the public meetings these propositions could not be debated; but their general tenor was challenged. The matter was then referred to the second section, but M. Trélat was unable to attend, so that the point at issue is postponed to the next congress, when an attempt will in all probability be made to show that M. Trélat's proposals are not practical. The entrance of air taken direct from the outside during winter would be felt by many to such an extent as to lead the inhabitants of the dwellings thus treated to block up all the openings that supplied the air.

THE LIVERPOOL AUTUMN EXHIBITION.

THE Liverpool Corporation's eighth annual exhibition of pictures opened to the public at the Walker Art Gallery on September 1st is one of uncommon and, we might almost say, historic interest in the annals of English art. Never before has there been brought together under one roof a collection which represents in such an ample and generous manner the leading art institutions of the country. Eight large well-lighted and well-proportioned rooms have recently been added to the gallery, the *total ensemble* of which now may be said to rival that of Burlington House. Of these new rooms some, and of the older ones some, have been severally and separately allotted to the following institutions and societies, viz., the Grosvenor Gallery, the Society of Painters in Water Colours, the Institute of Painters in Water Colours, the Hibernian Academy, the Institute of Painters in Oils, the Dudley Gallery Art Society, the Society of Painter Etchers, the Collection of Architectural Designs, and the Liverpool Academy. Each society or institute appointed its own executive committee to hang and arrange its special room, and in addition to the foregoing there are several spacious chambers devoted to what may be called the Liverpool Autumn Exhibition proper or ordinary.

We cannot attempt to do more than describe the impressions derived from a cursory run through the show. Entering Room A (the largest of the chambers devoted to the autumn exhibition ordinary), the first picture which catches the eye is Mr. C. Van Haanen's "Afternoon Coffee," a brilliant bit of Parisian life depicting a number of girls in varied colours gossiping and refreshing themselves in a dressmaker's work-room. This popular work has been given the place of honour on the far wall, and is for the first time seen to full advantage. Close by, and equally well hung, we come upon "Husband, Children, Home," Mrs. S. Anderson's striking and pathetic representation of a victim to the Ischian earthquake. For dramatic conception there are few pictures in the exhibition to challenge this. On the upper side of the door and well taken care of, is Mr. Frank Goodall's "A New Light in the Harem." As one of the popular works in the Academy, this

\* Not by the will of the English artisan, certainly! Has M. Trélat's credulity been practised upon, or is this a genuine jest?—Ed.

will naturally attract considerable attention, and those who see it are not likely to overlook Wm. Stott's "La Baignade," which bangs just above it, a charming study by one of the younger school of impressionists. Mr. T. B. Kennington's merits have been previously recognised by the Liverpool Corporation, and in the present exhibition his "Lap of Luxury" is given a prominent place on the line. Another young and aspiring impressionist, Mr. Stanhope Forbes, contributes "Preparation for the Market," and no visitor can fail to enjoy "Autumnal Spoils," the restful picture of a girl in a boat picking bolrushes growing in a quiet creek. Before quitting Room A we desire to draw special attention to Miss M. Bernard Hall's "Pauvre Père," a somewhat painful subject powerfully executed, which might fairly have been hung a little nearer the line.

The central feature of Room B (also a portion of the ordinary exhibition) is Frank Goodall's gigantic "Flight into Egypt," which has been judiciously placed on the end wall, and, consequently, looks better than it did in London. We also note a great improvement in Mr. Holiday's "Dante and Beatrice." The artist must have done a good deal of work upon this picture since it was exhibited at the Grosvenor, although even now it is not quite what it might be. The Liverpool Corporation are purchasing "Lorenzo and Isabella" as a sample of Millais's earlier method. In doing so they are securing a very remarkable work, though in an eccentric style; a picture which makes us regret that the painter should not devote his wonderfully developed technical power to works of similar aim and equally intense feeling, instead of squandering it on portraits sometimes little worthy of his genius. They have also bought J. R. Reid's "Rival Grandfathers," from the Grosvenor Gallery Room. The latter promises to be one of the most popular pictures of the Liverpool season.

Room C is devoted to the water-colours of the ordinary exhibition, and contains a good deal of very nice work, notably R. H. Carter's "Nut-brown Maid," and Joseph Nash's gloomy but powerful dead duellist ("Satisfaction"), which attracted considerable attention at the Institute last spring. Immediately beneath "Satisfaction" bangs "La Belle Amour," a charming study by Mr. S. Melton Fisher. The room is strengthened generally by some pleasing landscapes of Cockram's, whose work is made rather a feature of it.

Turning out of Room C we find ourselves in the portion of the exhibition devoted to the Royal Society of Painters in Water-Colours, who really seem to have managed to get together a wonderfully choice collection. Glancing round, one immediately recognises several old favourites. It is years since Boyce has been so strongly represented. He exhibits no less than five pictures, some of them (notably No. 648, "Hilton Castle") being exceptionally fine. Mr. Albert Moore has only one small and somewhat insignificant work in the exhibition (No. 512, "An Alcove"). This seems a pity, as he was appreciated in Liverpool earlier than anywhere else. Amongst other interesting pictures in the Old Water-Colours Room may be mentioned Basil Bradley's "Lost," a vigorous hunting scene in which the hounds are full of life; E. Buckman's pathetic "Home," a weather-worn sailor and his young children standing by the wife and mother's newly-made grave; and Chas. Gregory's "Adrift," some travellers resting in a country churchyard. A large room has been placed at the disposal of the Grosvenor Gallery executive, who exhibit an average collection of works,—mostly well known. On the end wall in the place of honour bangs Calderon's marvellous "Aphrodite." A prominent place has also been given to Gregory's fine portrait of Miss Galoway, and close by we noticed Herkomer's somewhat sinister likeness of the popular war correspondent, Archibald Forbes. Richmond's portraits look well, and Mrs. Jopling's "Ellen Terry" is as attractive as ever.

Mr. G. F. Watts sends a new and decidedly quaint picture under the inexplicable title of "B. C. \* \* \*." A far better name would have been "The First Oyster," for the artist represents two nude figures (presumably Adam and Eve) kneeling on a sandy shore amidst seaweed and shell-fish. Adam has just swallowed an oyster and holds the shell in his hand, while Eve watches apprehensively for the consequences. Mrs. Collier's "By the Tideless, Dolorous, Midland Sea," is on all hands pro-

nounced a remarkable picture for a lady to have painted, as we have already remarked when speaking of the Grosvenor Gallery in May; the flesh tints against the sand are put with a sympathy and subtlety beyond praise. Its only serious fault is a misleading and entirely unsuitable title. We were surprised to find none of Burne Jones's works in this room. Considering how much he owes to the Grosvenor, his absence is scarcely graceful.

The small room set aside for the works of the Liverpool Academy evidences that there are several local artists of more than ordinary promise. In "Freja's Quest" (hung on the line), Miss Jessie McGregor has taken a distinct step; and marked improvement can be claimed for Mr. H. H. Stanton, who exhibits a breezy sea-piece, "Eventide," by Peter Ghent, also shows an advance on former work. Mr. Thompson Jones, on the other hand, fails lamentably to fulfil expectations. His "On the Guidecca" is not the sort of work that should emanate from an artist once considered so promising.

The Royal Hibernian Academy have sent a small collection of moderately interesting work. The President's (Sir Thomas Jones's) large picture of the Archbishop of Dublin attracts most notice, though connoisseurs in Irish heavy who go through the room thoroughly may not improbably prefer the same artist's "Molly Astore," a true daughter of Erin.

The Institute of Painters in Water-Colours have hardly made the most of the material available. Their collection requires inspection before you find out how good it is. During our somewhat hurried glance round, however, we were favourably impressed with "The Downs of Mount Harry," a tender, silvery landscape, by H. G. Hine; and some of Arthur Severn's work, notably a view of Edinburgh from the Nelson Monument, and the "Versailles" of Mr. Fulleylove, one of the most masterly painters of architecture of the day.

The great feature of the chamber appropriated by the Institute of Painters in Oils is Fantin's magnificent series of portraits of the French Impressionists. It is a pity this was not hung on the end wall, as it would then have given size and grandeur to the whole room. We were sorry too, to notice a pleasing landscape of Frank Walton's almost spoiled by being stamped upon by a heavy picture of Hacker's, which is, however, by no means destitute of merit.

In Chamber K we noticed a little landscape by R. A. Brockbank, which calls for a favourable recognition; and in L. I. Starr's "Oh, Sweet New Year," and Henry Schafers's "An Improvment," should not be missed. "Sally in Our Alley," a clever bit of work, by E. Sherrard Kennedy, has been rather cruelly skied; and a somewhat better place might fairly have been given to a carefully-painted portrait of a little girl, by Harold S. Rathbone.

#### VENTILATING APPLIANCES AT THE HEALTH EXHIBITION.

SIR,—In the remarks under this heading (p. 274, ante), it is stated that I show a system of ventilating apartments by "supplying air direct from outside to assist the combustion in the fireplaces." Now this is a mistake, as the fresh air from outside referred to is for the ventilation of the apartment, and is let in near the fireplace, so that while ventilating the room by the admission of fresh air, such may be done without persons sitting round, or near, the fire feeling a cold draught at their backs.

W. P. BUCHAN.

#### A PERIODICAL QUESTION.

SIR,—Can any of your correspondents kindly suggest anything that will rid a house of beetles, crickets, and cockroaches? I have some cottages troubled with these pests, and I am at a loss to know how to get rid of them. I shall feel greatly obliged for any practical suggestion.

F. H.

**A Day's Outing.**—In connexion with Hampton's Home for the Blind and Aged Cripples, Wehher-row, Waterloo-road, an excursion, in which some 150 sightless ones (representing nearly all branches of the building trades) with their guides took part, came off last week, under circumstances most favourable. The locality chosen by the authorities of the home was the ground attached to North Lodge, Morden, which the proprietor (Mr. T. North, of London-road, Southwark), kindly placed at the disposal of the excursionists.

#### PROVINCIAL NEWS.

**Birmingham.**—The town of Birmingham is now in possession of several arcades. They are all noteworthy, but without exception are in the Classic or Renaissance style of architecture. A new arcade, however, has been commenced (for Mr. C. Ede) in the Early Gothic style, situated in the important thoroughfare of Snow-hill, and nearly opposite to the entrance of the Great Western Railway Station. A number of old and dilapidated buildings will have to be demolished to clear the site. The arcade will run between two streets, viz., Snow-hill and Slaney-street, but at present it is not contemplated to open a public entrance into the latter street, a private entrance for the shopkeepers only being formed. The frontage to Snow-hill will consist of large shops, four stories high, divided by a bold Gothic arched entrance. Into the elevation towards Snow-hill, buff glazed bricks, Minton's tiles, parti-coloured stone, ornamental red brick-work and terra-cotta, ornamental metal work, &c., will be introduced. A large enriched centre gable, filled in with panelling, tiles, &c., will emphasise this front. The elevation to Slaney-street will be of a plain Gothic character. The shops in the arcade will also be of a somewhat plain design, glazed white brick facings, gauged brick arches, moulded brick cornices, bay-windows, &c., being introduced. The architect employed is Mr. J. Statham Davis, of Birmingham.—New Assembly-rooms for Edgbaston, at the corner of the Hagley and Francis roads, are approaching completion. The building, which is being erected for a limited liability company, is expected to be ready for use in a month or six weeks. The architects are Messrs. Osborn & Reading, of Bennett's-hill, Birmingham. The principal frontage of the new building is in Francis-road. The entrance will be through an enclosed vestibule, communicating with ladies' and gentlemen's cloak-rooms on either side, and opening into a spacious entrance-hall, from which a broad central staircase leads to a suite of rooms, consisting of a hall-room, 70 ft. by 40 ft., a drawing-room (with a smaller drawing or card room adjoining), wide galleries, refreshment-room, and other apartments. The hall-room has a gallery for musicians and a stage, with green-room, dressing-rooms, and other accommodation. The room will, therefore, be available for private and other theatrical performances, concerts, and other entertainments. On the ground-floor, in addition to the entrance and the apartments appertaining to it, there are an ante-room and a supper-room, with serving-room, butler's pantry, and other accessories. The basement contains kitchen, larder, scullery, pantry, beer-cellar, heating-chamber, hakehouse, and other offices, besides apartments for the custodian and attendants. The building, with furniture and other contingencies, is estimated to cost 11,200*l.*, making, with the amount paid for the site, 16,500*l.*

**Bristol.**—Plans have been prepared for the erection of a parsonage-house in connexion with St. Matthew's Church, Moorfields, by Mr. Vincent W. Voisey, F.R.I.B.A.

**Withington (near Manchester).**—A Local Government inquiry has recently been held at Withington by Mr. J. Thornhill Harrison, M.Inst.C.E., one of the Inspectors to the Local Government Board, in reference to an application from the Withington Local Board for sanction to borrow a sum of 16,700*l.* Mr. Joseph Swarbrick, Assoc. M.Inst.C.E., Engineer and Surveyor to the Board, explained the nature of the works proposed to be executed, and stated that they consisted of works of private and public street improvements, and works of the sewerage and sewage disposal; and that 4,787*l.* of the amount required was for additional works at the sewage farm at Chorlton-cum-Hardy, the total cost of the works upon which had been about 12,500*l.*

**Oakham.**—The new swimming-bath for Oakham school has been opened, and will no doubt be found to be a great boon to the boys, who now number over 120. It is situated within a short distance of the cricket ground, is 80 ft. long by 30 ft. broad, the depth graduating from 3 ft. 6 in. to 6 ft. It is lined with blue brick, with a smooth concrete floor; and the boarded enclosure includes a large dressing-shed, water-closet, &c. There is a wide asphalted pathway all round the bath, and the water is brought in by iron pipes from a neighbouring spring, and is always flowing through the bath,

which is fitted with filter and proper sluices for cleansing purposes. The cost has been about 500*l.*, and the works have been carried out by Mr. Dean, builder, of Uppingham, Mr. R. Winter Johnson, of Melton Mowbray, being the architect.

#### SCHOOL-BUILDING NEWS.

**Sheffield.**—New Board schools at Huntsman's Gardens, Attercliffe, have just been opened by the Mayor of Sheffield. The school is on an entirely different plan from any previously built in the town. The Sheffield School Board has already in use one school building with a central hall, which is a parallelogram in shape, with class-rooms along the sides and ends. The school just opened has a central hall, but it is of polygonal form, with the class-rooms so arranged around it that they radiate from the eye of the head-master when he is at his desk. There are in the main building, which is a mixed department, twelve class-rooms arranged as above, and capable, by means of movable partitions, of being made to accommodate varying numbers of scholars, as those in the separate standards increase or lessen in number. The class-rooms, however, are square in themselves, in order that the desks may be of equal length; and another important feature is that left-hand lights are obtained for the classes at desks to a much larger extent than is generally the case. The school is fitted up with electric bells, and by an understood code the head master can, from either his private room or his desk in the school, signify his wishes to any of the teachers in the class-rooms and to the caretaker's house. The infants are placed in a separate building, which has a school-room and four class-rooms. In the lower part of the main building is an extensive gymnasium. The contract for the building amounted to 11,412*l.*, and the number of scholars accommodated is 1,250. Externally, the buildings are all of coursed stone, and covered with dark Westmoreland slates. The schools are warmed throughout by low-pressure steam apparatus supplied by Mr. W. Truswell, of Durham Foundry, Sheffield. The stone-carving, &c., is by Mr. Harry Homs, of Exeter; and the electric bells are by Messrs. J. Northam & Co., of Sheffield. The architect was Mr. C. J. Innocent (late Innocent & Brown), of George-street, Sheffield.

**Smethwick.**—New infants' schools are in course of erection in Crockett's-lane, Smethwick, for the Harborne School Board. The contractors are Messrs. Jeffery & Son; and the works are being carried out under the superintendence of the architects to the Board, Messrs. J. P. Sharp & Co., of Birmingham. The contract is about 3,000*l.* Drawings are being prepared for higher grade schools to be erected on a neighbouring site.

**The Beckenham Public Hall.**—A new public hall at Beckenham has just been completed and opened. The building has its main frontage to the Bromley-road, 65 ft. in length, 34 ft. in height to the parapet, and 55 ft. high to the ridge of a high-pitched roof. It is surmounted in the centre by an octagonal tower rising to a height of 74 ft. above the ground line. The principal entrance to the building is surmounted by an elliptical arch, with rich carving. The building, which contains two lofty main floors, with dormers in the roof, is faced with stock and red brick. Each floor has millioned windows, those to the ground-floor being arched and deeply recessed. The return elevation is somewhat plainer in character. The building is approached along an entrance-hall 16 ft. in width and 34 ft. in width. The front portion of the ground-floor is intended to be let as offices. At the rear of this floor is a reading-room, also a billiard-room, besides coffee-room, cloak-room, and other apartments. A staircase, 15 ft. in width, leads to the upper floor, which contains the large public hall, 61 ft. long and 34 ft. wide, at one end of which there is a gallery extending the entire width of the hall, and at the opposite end a platform with space for the erection of an organ. The hall will seat an audience of 600 persons. In connexion with the hall there are ante-rooms, cloak-rooms, and dressing-rooms. In addition to the large hall there is another hall at the extreme rear of the building, 38 ft. long by 23 ft. wide. The cost of the building, which with the grounds, covers an area of 100 ft. by 80 ft., is about 5,000*l.* Mr. G. Vigers, of Frederick's-place, Old Jewry, is the architect, and Messrs. D. D. & A. Brown, of Camberwell, are the contractors.

## The Student's Column.

HINTS FOR THE STUDY OF  
THE HISTORY OF ARCHITECTURE.—X.  
FIFTEENTH-CENTURY GOTHIC.

It might be supposed that, in a history of the typical styles of architecture, there is not sufficient distinction between the Gothic work of the thirteenth and of the fifteenth centuries to call for a separate article on each. Indeed, the change from the one to the other during the intermediate fourteenth century was, in England at least, so gradual, that the builders of that period were probably unconsciously of the distinct results that they were producing.

The main difference lies in this: that whereas the earlier builders devoted their attention to the arrangement of the structural bones of the building, the later ones laboured theirs on its skin.

More than this: whereas a fully-developed thirteenth-century church has very much the same recognisable features in whatever country we may find it (with certain exceptions), the fifteenth-century churches in various countries differ from each other as much as they do from thirteenth-century work.

England exhibits, as has been mentioned in the last article, a thirteenth-century style of its own, and it is remarkable that when French influence was occasionally imported, as in the case of Westminster Abbey, the admixture of English art has produced a far more beautiful result than can be found in any French cathedral. Street, in his "Gothic Architecture of Spain," points out a somewhat similar result at Toledo, where, he says, the problem of vaulting a chevet has been more successfully solved than in any cathedral in France.

As a rule, however, thirteenth-century Gothic is very much alike wherever it may have been built under direct influence from headquarters, even in such a distant country as the island of Cyprus, as may be seen in Mr. Sydney Vacher's numerous illustrations to his "Sydney's paper on that subject," to be found in last year's Transactions of the Institute. Where local peculiarities survive, such as in the triapsal plan of the church at Marburg in Germany (see p. 738 of Fergusson's Handbook), still the construction and details are French.

The Germans, indeed, were determined to outdo France itself by building a huge cathedral at Cologne. This building is illustrated in all the handbooks,—most profusely, of course, by Rosengarten, on p. 306 *et seq.*, and a view on p. 317. Fergusson tells us on p. 740 that it was begun about the year 1270-1275, and the choir completed by 1322. The entire church has only been completed within the last few years; fortunately from the original design, which has been preserved to work from. It has double aisles, and chevet of seven chapels, with transept and western towers crowned with spires,—everything complete and very correct. Surface richness begins to vie with constructional lines, the flying buttresses are pierced by monotonous rows of quatrefoils, the spires are covered with tracery, also pierced,—a treatment which is found in several German examples,—and the upper portions of the buttresses are also smothered with tracery. The change from the skeleton to the skin has set in.

The Germans ran their taste for open-traced spires into the very extreme of tenuity, and insisted upon drawing them out to ridiculous lengths, as in the Sacraments Hauslein at Nuremberg, illustrated by Fergusson on p. 753, where the summit of its spire, being too high to stand upright under the vaulting, is bent round beneath it; a pretty fancy, but one at variance with strict architectural common sense; other spirelets, which have not to keep clear of obstructions, have nevertheless caught the infection, and bend their heads in meaningless fashion, until all notion of structural rigidity has disappeared from this piece of stonework. Simplicity, says Fergusson, is not the characteristic of the German mind. A difficulty conquered is what it glories in, and patient toil is not a means only, but an end, and its expression often excites in Germany more admiration than either loftier or purer art.

Soon the masons set themselves a more intricate task. At Chemnitz (see Fergusson, p. 760) there is a doorway around which the tracery is represented by the stems and branches

of trees, some of the latter being chopped off. Here was another object in life. The idea was followed up in ordinary tracery, and the ends were duly chopped in every conceivable position. A mingling of these two crazes, such as may be found in many German interiors, gives one an uncomfortable admiration for their digestion of difficult problems.

The town-halls for which Belgium is more especially famous, retained, during the fourteenth and fifteenth centuries, much of the propriety of design that had been applied to them in the thirteenth century; the Cloth Hall at Ypres, of which the foundation-stone was laid in 1200, but which was not finished till 104 years afterwards, being a very grand and simple design, and even its elaborate successor at Louvain (1448-63), although somewhat crowded with dormer windows, is free from debasement in detail. A lofty central tower is a feature in most of these town-halls.

The Italians in the fifteenth century had begun to tire of Gothic. They erected two enormous churches at the end of the fourteenth century, St. Petronio at Bologna (only partly finished), and the cathedral at Milan. The former with central naves, not only about 60 ft. across, but square in plan,—a huge dimension, unknown in true Gothic churches; the latter, said to have been designed by a German, but carried out under Italian influence, with a hasty result. The choir, says Fergusson, p. 780, is neither a French chevet nor a German nor Italian apse, but this part of the building, with its simple forms and three glorious windows, is perhaps an improvement upon both the methods of which it is compounded. The Certosa, near Pavia, also of the same date (1396), is internally worse than either. Externally, however, the galleries, of which we saw the beginning in the Lombard style, and other national features, render it a more successful building. When the façade was added in 1473, the Italians had said good-bye to Gothic; it is entirely in the Renaissance style, and the subject of this article is, in Italy, conspicuous by its absence.

Going on to Spain, where some remarkable churches were built during the fourteenth century with the buttresses brought inside to form side chapels and with the side aisles omitted, we find that the Gothic work of the latest period "became extraordinarily florid in its details, especially in the variety introduced into the ribs of the vaulting and the enrichments generally. The great cathedrals of Segovia and Salamanca were neither of them begun until the sixteenth century had already well set in. They are the two principal examples of this florid Gothic" (Smith's Gothic and Renaissance, page 140). The interesting element in Spanish Gothic is the infusion of Moorish (Saracenic) details which were skilfully combined with it. This may be seen in a survival of the cusps which we saw at Cordova in the eighth century, and they sometimes repeated a very satisfying feature of Moorish work, namely, the habit of inclosing an arch within a rectangular frame. The church at Batalha, in Portugal, is an extremely rich example in which this treatment is observed.

In France, after the first few years of the fourteenth century, which had produced the beautiful Church of St. Ouen, at Ronen, architecture was much neglected on account of the wars in which she was engaged; however, we find that she burst forth with pent-up vigour in the fifteenth. Like all other countries, she became florid in her architecture, her particular weaknesses, perhaps, being for "flamboyant,"—or flame-like,—tracery and extravagant dormers. See the Palais de Justice at Ronen illustrated on page 852 of Gwill's Encyclopædia. There is an amount of abandon in the compositions and details of this period that has won the admiration of a no less fastidious critic than Ruskin, who compares it favourably with our more formal English work; nevertheless, it is with something of the comfortable feeling of coming home after a holiday that we now turn to the study of our own styles.

We have already alluded to the Early English period, which is also called the Lancet style from the form of the separate windows, which were, for a long time, used singly or grouped in complets or triplets. Soon they came under the protection of an inclosing dripstone, and then circles and other forms began to peep through the remainder of the inclosed space, and, by degrees, the window lights and these piercings became fused into tracery, such as may be seen

at Westminster Abbey. Perhaps the finishing touch of the system was given by the French designer of this building, for tracery had been used in France long before we adopted it.

The study of tracery is an interesting one, and may be followed in Sharpe's "Windows," From circular and other "geometrical" forms, it gradually became blended into "curvilinear" lines, after which a taste set in in favour of "perpendicular," or rather "rectilinear" lines (often in connexion with depressed four-centred arches), which were not confined to the tracery of the windows, but were spread all over the surface of the buildings from floor to roof, thus fulfilling the distinction, pointed out at the beginning of this article, between the attention to the bones and the skin of architecture.

On the subject of roofs Fergusson repeats with regret that we adopted the double covering,—stone inside and wood over it,—instead of making a thorough job of one or the other; especially as we became so proficient in the construction of open-timber roofs (see Brander's work on these), culminating in that over Westminster Hall (see Gwill's "Encyclopædia," p. 181), 68 ft. internal span and 238 ft. long, erected in the reign of Richard II.

Viollet-le-Duc points out the danger of cracks or settlements in a stone-covered vault, and the convenience afforded by an upper wooden roof in obtaining access to all parts of the back of a stone vault below it for repairs, &c. However glorious the English open-timber roofs were, our stone vaults were no less beautiful. Indeed, while the French seemed satisfied with their plain quadripartite vault when they had got it, the English soon began to introduce intermediate ribs, and gradually made our vaults richer and richer, until it became a question of carving these ribs out of the same stone as the filling-in instead of the filling-in being supported by the ribs.

Then, again, the unequal lengths of these ribs (the diagonal being longest, and the wall-ribs shortest, with ever so many intermediate lengths between them), was felt to be an objection that must be overcome; hence the invention of fan tracery, in which all the ribs are of the same length and curvature. Then came the ingenious contrivances for suiting fan tracery to oblong bays, the culmination of which may be seen in Henry VII.'s Chapel at Westminster. An internal view will be found in Rosengarten (p. 335) and Smith (p. 57). Willis's paper on vaulting contains a hack view of this structure showing the wonderful manner, in which the stones are keyed together.

Another peculiarity of English Gothic, during the whole Middle Ages, lies in the square eastern ends of our churches which were adopted when we had become quite free from French influence: by this means we obtained grand east windows, such as that at Gloucester Cathedral. Lastly, the general external proportions of our cathedrals and other churches are far more beautiful than those built by the French. They, with their frequent double aisles, raised their naves to an immense height. We were content with a low and long proportion, which gives full value to the height of our towers, and which admits of double transepts in several examples. The play of perspective is thus much improved. An excellent idea of our cathedrals may be obtained from a plate in the "Quarterly Papers" of the Institute, in which block models of several of them are represented in perspective to the same scale.

Domestic architecture went hand in hand with Ecclesiastical, houses being designed in the same style as churches (it is reserved for our day to pronounce that one style is fit for the one, and another style for the other), and yet there is no danger of mistaking these Mediaeval houses for churches.

Sculpture became more formal and square in its treatment in the fifteenth century. In connexion with the chancel screens an excellent school of figure-painting on the panels prevailed, especially in Norfolk. Drawings of some of these were purchased by the Institute. Generally the same works may be consulted in fifteenth-century Gothic, as were referred to in the last article: and Burgess's "Architectural Drawings" should have been added to the list.

**Stratford-on-Avon Water Works.**—Mr. E. Willcox, A. M. Inst. C. E., of Sutton Coldfield, has been appointed Resident Engineer for these works.

## BUILDING PATENT RECORD.\*

## APPLICATIONS FOR LETTERS PATENT.

- Aug. 15.—11,313, G. T. Harrap and F. C. Hartin, London, Fans for Ventilating.—11,315, G. H. Jennings, S. Jennings, and J. Morley, London, Controlling, &c., Supply of Water for Sanitary Purposes, &c. (June 28, '84).

- Aug. 25.—11,598, W. Foor, London, Heating Apparatus, &c.—11,599, A. Soward and H. G. Walton, Liverpool, Flushing Apparatus.
- Aug. 26.—11,640, J. Jameson, London, Trap for Pipes.—11,653, J. Robbins, London, Manholes for Sewers, &c.—11,659, H. R. Lake, London, Street and other Pavements or Floorings. Com. by K. Kibb, St. Johann-on-the-Saar.—11,665, J. Atterton, London, Stench Traps.—11,666, J. Edwards and A. Rogers, London, Fireproof Doors, &c.
- Aug. 27.—11,680, W. R. Maguire, Dublin, Wash-hand Basins, Baths, &c.—11,700, C. D. Ahel, London, Stoves or Fireplaces. Com. by C. de Choubersky, Paris.—11,703, J. N. Peake, London, Securing Tiles to Walls, &c.
- Aug. 28.—11,718, R. Stanley, Nunaton, Chimney-pots or Ventilators.—11,727, H. Trott, London, Ball Valve for High and Low Water Pressure.

## SPECIFICATIONS ACCEPTED.†

- Aug. 19.—3,878, J. Smeaton, London, Water Waste-preventing Apparatus for Water-closets, &c.—3,972, C. A. Harvey, Lewisham, Chimney-pots and Ventilators.—10,270, W. Harrison, Sheffield, Spindles for Door-handles.
- Aug. 22.—1,164, W. A. Gill, London, Securing Door-handles to their Spindles.—7,452, W. Sanderson and T. A. Moffitt, Gateshead, Blind Furniture.—8,217, A. J. Bout, London, Manufacture of Parquet Floor-plates, &c. Com. by C. Wittkowsky, Berlin.—10,454, H. Trott, London, Ball-valve for High and Low Pressure Water.—10,460, E. Newton, Hitchin, Trap for Water-closets, &c.
- Aug. 26.—469, E. Verley, J. N. Verity, and B. Banks, Leeds, Leeds, Opening, Closing, &c., Windows, Skylights, Louvers for Church Entrances, &c.—J. E. Doughty and P. Kranich, London, Builders' Stage.—9,061, W. Clutterbuck, London, Ventilating Tunnels, &c.—10,605, G. D. Peters, London, Spring Rollers for Window-blinds.
- Aug. 29.—881, T. R. Shelley, Birmingham, Glazing Conservatories, Roofs, &c.—1,922, E. Edwards, London, Louvers for Church Entrances, &c. Com. by A. Cheneval, Maffs, Belgium.—1,439, J. Parry, Birmingham, Fastener for French Windows, &c.—8,778, J. H. Johnson, London, Heating Apparatus. Com. by E. Körting, Hanover.—8,919, T. F. May, Liverpool, Flue-mouth for the Flues of Dwelling-houses, &c.—10,742, S. B. Goslin and J. J. Brown, London, Water-closet Apparatus.

## ABRIDGMENTS OF SPECIFICATIONS

Published during the week ending August 23, 1884.

5,861, G. Hanl-Smith, London, Sinking or Fixing Colours, &c., into or on Marble, Wood, &c. (Dec. 26, '83. Price 8d.)

This is an improvement on Patent No. 3,610 of 1879 and 5,610 of 1880, in which the article to be treated in a closed vessel, and subjecting it to a heat of about 150 deg. Fahr. Air is also heated in a separate saturator in conjunction with a solution of the colour required, and this highly saturated and intensely heated air is then forced in under a heavy pressure to the vessel in which the article is, and the colour is fixed thereon.

5,897, R. Lofthouse, Manchester, Creating Currents of Air, &c., for Ventilating Purposes. (Dec. 28, '83. 6d.)

Inside a stationary tube is a rotating cylinder, and in the smaller sizes an Archimedean screw-blade or blades are contained within this cylinder, while in the larger size the blades may be outside the rotating cylinder.

5,971, W. Brindle and T. Brindle, Upholland, Dressing, Ornamenting, or Polishing Stone, Concrete, &c. (Dec. 31, '83. 6d.)

The apparatus consists of a rapidly revolving or reciprocating

surface of metal, which is brought to bear against the surface of the stone, &c., while sand and water are placed between the two surfaces.

## Miscellaneous.

**A Memorial of the Landing of St. Augustine in England.**—Mr. John Roddis, architectural sculptor, Birmingham, has just completed a monument to commemorate the landing of St. Augustine in this country and his meeting with King Ethelbert. The spot where this meeting took place is believed to be Cottingham, now known as Cottingham. It appears that Lord Granville, occupying the office of Lord Warden of the Cinque Ports, has become the owner of the land on which these events took place. According to the *Birmingham Post*, in consequence of reading the historical description of the Isle of Thanet, written by Mr. Robert Bnhb, of Minster, in Hitchings and Crowsley's guide to the island, Lord Granville was induced to entertain a plan of erecting a memorial on the spot. He communicated this project to Mr. Buhb, and Mr. Buhb sought the advice of Dr. Freeman, of Birmingham, who is a native of the Isle of Thanet, and is intimately acquainted with its historical legends. Dr. Freeman referred to Mr. Roddis for practical suggestions as to the nature and cost of the memorial, and afterwards engaged in a correspondence with Lord Granville on the subject. In the end it was determined, on the original suggestion of Lord Granville, that the memorial should take the form of a reproduction of one of the famous crosses at Sandbach, near Crewe. Having consulted Messrs. Hardman and Powell, Mr. Roddis prepared his design, which was approved by Lord Granville. The west front exhibits the Christian legend. On the encircled cross at the head of the shaft are four emblems of the evangelists, the lion, the eagle, the man, and the hulk. On the pannelled shaft below are represented the Annunciation, the Virgin and Child, the Crucifixion, and Transfiguration, with demi-figures of saints and angels. On the north side the theme is continued by figures of the twelve apostles. On the south side is a series of fourteen figures of early Christian martyrs. The east front of the circular cross is filled in with rustic ornament, which continues nearly halfway down the shaft, when the design breaks into diamond-shaped panels, filled with figures in the following order:—St. Alban, the proto-martyr of England (A.D. 303); St. Augustine, attended by monks; and Ethelbert, king of Kent. The date of unvailing the memorial will be fixed by Lord Granville.

**The Hospital for Diseases of the Chest, City-road.**—The Hospital for Diseases of the Chest, in the City-road, is at present being greatly enlarged by the erection of a new block of buildings on the north side. The enlarged structure is 73 ft. wide, and is carried to a height of 84 ft., having a ground floor and three lofty floors above. It is faced with stock bricks, each floor having spacious and lofty two-light mullion windows made of Lascelles' patent concrete. The elevation is surmounted by pediment dormers, and at the south end of the structure there is a tower rising to a height of 114 ft., which will form a central feature in the hospital when in course of erection. The ground-floor of the new building will have a large projecting bay window about 18 ft. in height. The two buildings as connected will be approached by a Gothic entrance under the tower. We understand that the sashes of the several windows will be constructed on an entirely new principle, invented and patented by the foreman of the works. The invention consists of the iron framework and glazing of each sash being reversible, so as to open both ways, thus providing increased facilities for cleaning and ventilation. The basement will contain a kitchen, 32 ft. by 18 ft., together with scullery and other culinary offices; also the officers' dining-room; whilst in the rear will be the machinery for a hydraulic lift connected with the several floors. The ground and first and second floors will each contain three wards, 31 ft. by 18 ft., the third and dormer floors being set apart as dormitories for the matron and servants. Mr. J. O. Abbott, of Charing-cross, is the architect, and Mr. W. Brass, of Old-street, is the contractor. Mr. T. Abbott (nephew of the architect) is clerk of the works, and G. Harris the foreman. The estimated cost of the building is about 14,000l.

**The Electric Light at the Law Courts.**—The installation of machines and engines has hitherto been only temporary, being in an iron shed on the waste ground to the west of the building. The permanent plant will be placed in the crypt under the great hall. This change involves a considerable amount of labour, as the existing steam boilers, which were only designed for the ventilation of the building, will have to be removed, as also will nearly all the existing steam and exhaust pipes as well as several large tanks. When completed there will be two 100-horse power Galloway patent boilers, two single-cylinder horizontal engines, each indicating 105-horse power at sixty revolutions, either one being capable of doing the whole of the lighting. The requisite speed for the dynamo, about 1,100 revolutions, will be obtained by two sets of shafting, with friction clutches on the first, so as to allow either or both the engines to be worked, as necessary. Six Crompton-Burgin compound wound 10-unit machines, all coupled parallel, will produce the current for the general illumination, lighting about 650 twenty-candle-power Swan lamps. A small Willans high-speed engine, with electric governors, will drive a 6-unit machine for lighting an all-day circuit of about forty-five lamps. There will also be two Burgin series machines, each lighting a series of three 4,000 candle-power Crompton-Crabb arc lamps, in the central hall. The engines, boilers, &c., are being fitted by Messrs. Galloway & Sons, and the dynamo, cables, switch-boards, &c., by Messrs. R. E. Crompton & Co., who fitted and wired the building, and under whose supervision the lighting was carried on until May last, when it was taken over by the Government, under the control of Her Majesty's Office of Works.—*The Electrician.*

**The Dundee Institute of Architecture, Science, and Art.**—The programme for session 1884-5, includes the following syllabus of papers to be delivered during the session, viz.,—Nov. 20th, Professor G. Baldwin Brown, on "Architectural Art"; Dec. 18th, Mr. Henry Fattullo, on "The Law of Building Contracts"; Jan. 15th, 1885, the Rev. George Mure Smith, on "Church Bells"; Feb. 18th, Professor Carnelly, D.Sc., on "Some Chemical Facts Connected with Plumber Work"; March 19th, Mr. Geo. S. Aitken, F.S.A. Scot., on "Ecclesiastical Architecture"; April 16th, Professor Ewing, B.Sc., F.R.S.E., on "The Sanitary Inspection of Dwelling-Houses"; May 21st, Mr. J. G. H. Spindler on "Art Work in the Middle Ages." The *conversations* will take place early in October, and the business meeting for election of office-bearers, &c., on June 21st. Prizes for designs, &c., are offered, and particulars of the conditions may be had from the hon. secretary, Mr. Charles Ower, architect, 104, Commercial-street, Dundee.

**The Royal Princess Theatre, Edinburgh,** has been reopened, after a thorough overhaul as regards decoration. The mouldings which were used to divide the centre of the ceiling have been taken away, leaving an unbroken circular space, on which is painted a design on a light blue ground, formed by Cupids supporting festoons with musical emblems. The enriched moulding round this panel is bronze and gold, and the remainder of the ceiling is powdered with patera of a brownish tint on a yellow ground, giving relief to the centre. The proscenium-opening and fronts of balconies are also bronze and gold, and on the space over the proscenium are painted two winged figures in the splendours of the arch. The walls of the whole auditorium are covered with a soft blue damask paper, which gives a cool effect to the interior. The work has been done by Messrs. Geo. Dohie & Son, 23, George-street, and Messrs. W. B. Clapperton & Co., Princes-street, respectively.

**The Drainage of Cape Town.**—The *Cape Argus*, just received, contains the report of the three engineers appointed to adjudicate upon the competitive schemes for the efficient drainage of Cape Town. By their unanimous award, the premium of 250l. is accorded to the scheme under the motto "Sanitary," sent in by Mr. Isaac Harpur, son of Mr. Samuel Harpur, the engineer and surveyor to the Merthyr Tydfil Local Board. It would appear from the report of the adjudicators that one of the chief merits of Mr. Harpur's scheme lies in his selection of the outfall. Mr. Harpur is now engaged in superintending, under the resident engineer the reconstruction of the Molteno reservoir at Capetown.

\* Compiled by Hart & Co., Patent Agents, 186, Fleet-street.

† Open to public inspection for two months from the dates named.

**An Electric Lighthouse in Brazil.**—An electric lighthouse has recently been erected on the island of Raza, at the entrance of the Bay of Rio Janeiro. The lighthouse proper is 85 ft. high, and is put upon a rock 230 ft. in height, so that the focus of the light of the apparatus is fixed at an elevation of 315 ft. above the sea. The electric current is produced by a continuous current Gramme machine, working at the rate of 700 revolutions, and feeding a light of 2,000 candle-power. The Gramme machine referred to is worked by a stationary surface-condensing steam-engine, this arrangement being inevitable owing to the want of fresh water. All the fittings are double, so as to prevent interruptions by unforeseen accidents; and, to make assurance doubly sure, an oil-lamp is always kept in readiness. The light is revolving, having two white discs and one red one, succeeding one another at fifteen minutes' interval, and the light is visible at a distance of about thirty-five statute miles.—*Iron.*

**The Sunday Society.**—On Sunday last Grosvenor House was open for the last time this season to the members of the Sunday Society. In July last the Duke of Westminster, as president, authorised the honorary secretary,

Mr. Mark H. Judge, to issue tickets of admission to the members of the Sunday Society and to the Sunday League. Each ticket admitted the bearer on any day in August, between the hours of two p.m. and six p.m., so that it is interesting to note how these tickets were used. The following figures give the highest number of visitors on the different days of the week—Mondays, 23; Tuesdays, 34; Wednesdays, 33; Thursdays, 30; Fridays, 51; Saturdays, 99; Sundays, 494. It is claimed that this result corresponds with the results of Sunday opening wherever it has been tried, whether in this country, the United States, or on the Continent.

**Ulverston.**—The great west window of Holy Trinity Church, Ulverston, has just been filled with stained glass, by way of memorial of the late Mr. Miles Kennedy, of Stone Cross. The window is of three lights, the centre light being 23 ft. by 5 ft. and the side lights of somewhat less dimensions. The subjects selected for illustration are excerpt from the *Te Deum*. The work is in the style of the thirteenth century. Messrs. Powell Bros., of Leeds, are the designers and painters, and the work has been carried out under the superintendence of Mr. J. W. Grundy, architect, Ulverstone.

For proposed system of sewerage, at Dorking, for the Dorking District Local Board. Messrs. Smith & Austin, engineers:—

McCrea & McFarland, Westminster	£21,320	0	0
Jas. Young & Co., Hereford	12,848	0	0

### The Archaeology of Homer.\*

WHEN Dr. Schliemann laid bare the foundations of Hissarlik, high hopes were raised; these hopes we know were, so far as Homeric scholarship was concerned, doomed to disappointment. Something was added to our knowledge of barbarian races centuries before the days of Homer; but no necklace of Helen, no breast-plate of Achilles, could reward the search. Happily this search did not end at Hissarlik; not only Mycenæ but Thera, Ialysus, Sparta, Athens herself, and, farther afield, Syracuse, Etruria, Latium, and the valley of the Po, have yielded up their buried evidence. We are conscious now that questions of Homeric terminology have to seek their answer not merely in textual criticism, but in the added witness of archaeology; that the form of the "aspis" of Æneas, or of the "amphikupellon" from which Telemachos drank, may have to be determined by the hurried relics of some hero's tomb at Cymæ or at Thera.

We are conscious of this, and most of us probably conscious of an unpleasant vagueness in the matter of this archaeological evidence, which makes us timid of opinion. We do not feel any assuring certainty what discoveries are legitimate for our purpose, what again are chronologically *hors de combat*; we know that we may not put our trust in the Troy of Hissarlik; we are not clear why we are allowed to put confidence in Dipydon vases, and other types from Etruria. We have been all waiting till some one should speak with authority on these matters, put in order the mass of scattered evidence, give us at least an approach to some chronological landmarks; in a word, establish some well-defined relation between the literary testimony of Homer himself and the archaeological evidence of recent excavations.

This, in a masterly manner, Dr. Helbig has done in the book before us. His work falls into two parts. His object is to give as full and complete a picture as possible of the Homeric age, the dwellings of the Homeric heroes, their clothing, the jewels and adornments of their women, the arms of their men, the implements and vessels of their households, their decorative art. This is the second

part of his work, but in order to make this picture real and reliable he has first to give a *résumé* of the evidence on which it is based, to summarise the material which has made the drawing of such a picture possible. In summarising this material he is necessarily obliged to pass in review all the excavations which have yielded objects which could in any way illustrate Homeric art or Homeric custom; he must give his opinion as to the date of these objects in order to show whether they may or may not be reasonably connected with Homer; he gives, therefore, incidentally a whole survey of recent archaeological discovery. It is to this survey, rather than to its application in detail to Homeric technology, that we shall turn.

The "sources" (*Quellen*, as the Germans happily call them) of Homeric criticism are, of course, two-fold,—first, literary; second, monumental. As regards the art and industry of Homeric times, the literary sources are necessarily very inadequate. The poet describes what he is sure is familiar to his hearers; he wants just to recall to their minds a picture, to touch its salient points, hit off its characteristic features, not to describe with detailed precision; hence it is often difficult for us, to whom the object, be it beaker, shield, or necklet, is unfamiliar, to recover its outline; we have lost the clue. Works of art of classical date, vase paintings and sculptured reliefs, are of no service if they depict Trojan scenes. They do it in no historical spirit. Trojan heroes are clothed and armed after the fashion of sixth-century garb. The scholars of Alexandria are no help. Aristarchos and Dionysius Thrax, with all their critical acumen, never look for a moment to monumental evidence; indeed, Alexandria was a city barren of antiquities, as Dr. Helbig suggests. Had the ancient school of philology had its seat at Ephesus or Samos, or any site charged with historical association, we might have had some valuable help to archaeological criticism. To gather, then, any just notion of Homeric antiquities we must look for monumental evidences; most happily, however, the Homeric poems themselves give us the clue where this monumental evidence is to be sought.

Very few Ionic towns in Asia Minor have undergone systematic excavation, hut, fortunately, we need not circumscribe our evidence to the strict limits of the scenes that Homer describes. The "Iliad" and the "Odyssey" show clearly enough that the Hellenic people on the east and west of the Ægean were, practically, in character and customs, one. We

may argue, then, from excavations in the West, of the civilisation of the East. This is, then, the first important literary evidence, the oneness of the Hellenic people; the fact that in drawing, customs, dwellings, implements, the Trojans and their allies were one and the same with their foes; a local peculiarity, indicated by an epithet here and there, only confirms the general impression. Further, we learn that one nation, accounted barbarian in classical times, was in Homeric days conspicuous for its advanced civilisation. Priam offered, as part ransom for the body of Hector, the godliest of his possessions, a Thracian drinking cup. Achilles prized above others his splendid Thracian sword. The causes of this early prosperity are not far to seek. There is abundant evidence, archaeological and philological, that Thrace was in close and constant contact by land with Asia Minor, by sea with Phœnicia. We may take it generally that this artistic predominance of Thrace subsided with the rise of colonisation from Greece proper.

A third point, most clearly evidenced by Homer, is that works of art and objects of use were produced rather by individual craftsmen than by local industries; we do not hear in the Homeric poems, as we do in classical times, of Beotian bucklers, of Chalcidian swords. This prepares us for the further important fact that the Hellenes of the Homeric days were a people who imported rather than exported manufactured and artistic objects. They bartered their raw produce for the finished manufactures of the East. This carrying trade between the East and Hellas lay, of course, principally in the hands of the Phœnician. We need only recall for a moment the breast-plate of Agamemnon, gift of a king of Cyprus; the mixing bowl which the king of the Sidonians gave to Menelaos; the gold and amber necklace which the Phœnician trader gave to the mother of Eumaios. Literary evidence then bids us look to Phœnician remains for analogies to those articles of import, descriptions of which occur in Homer; and not only to Phœnician remains found in Hellas, but to those scattered far and wide in the tombs of Etruria and of Latium. Shortly to recapitulate, the poems of Homer themselves bid us look for evidence, not only, as we should naturally presuppose, to the earliest Greek remains, but also to the antiquities of Phœnicia and the North.

Dr. Helbig begins with Phœnician art industry, the no chapter of his work is fuller both of well-ascertained fact and fruitful suggestion. He opens with a polemic against Professor Brunn. It has been supposed by

\* Das Homerische Epos aus den Denkmälern Erläutert. W. Helbig. Leipzig, 1884.

Brunn that the famous silver and bronze bowls, so well known for their curious and mechanical mixture of Assyrian and Egyptian elements, are not the work of Phœnician artists, but of Cyprian Greeks. Brunn believes that the Phœnicians were mere traders, incapable of artistic effort. He further thinks that the freedom of style, the naturalism displayed in some of these bowls, can only be due to Hellenic impulse. Helbig brings a mass of evidence to show, and we think conclusively, that this view is mistaken, and that the Phœnicians were, in the early stages of their art development, abundantly capable of such naturalistic work as we see on these bowls; *à priori*, we should, indeed, expect their work to be nearer akin to Hellenic than to Oriental style. Their civilisation was developed under conditions wholly different from that of Egypt or of Chaldeo-Assyria. The artists of the Nile valley and of Mesopotamia were bound down by a strict despotism, which necessitated a severe conventionalism, which hampered all individual freedom; the Phœnicians, on the other hand, had a land whose physical conditions prevented centralisation, a climate that was variable, a coast-line that invited trade; every impulse was at work that could stir and prompt individual artistic effort. To this *a priori* argument we can add the testimony of fact. Both at Mycenaë and in Cyprus works of art have been found of undeniably naturalistic tendency. Dr. Helbig instances from Cyprus the portrait statue of a man; from Mycenaë, certain figures of Astarte; at Idalium, in Cyprus, a bronze bowl was found, the naturalism of the design of which is surprising, when we compare it to the typical conventional stereotyped forms that appear on vessels of similar workmanship. Clearly there is only one possible conclusion. If the stereotyped work and the naturalistic work be both Phœnician, then Phœnician art must have known two distinct periods and styles. This is precisely what Dr. Helbig holds. He believes that Phœnician art started, as we may believe Assyrian and Egyptian did, in naturalism. That in this stage it came in contact with, and influenced the art of Homer's days; hence the marvellous realistic wonders that Homer describes, the writhing fawn, the lion and the ox, and the like. This period passed; Phœnician art, always dominated by that of Egypt and Assyria, became stereotyped and conventional. This is the style we get in the greater number of the bronze bowls, and this style in its turn influenced Hellenic art in post-Homeric days. When this period set in, Dr. Helbig does not decide; the transition was, of course, gradual.—indeed, in some monuments, *e.g.*, a silver cup from Amathus, we have the two principles, naturalism and conventionalism, at work side by side. This view about the twofold character of Phœnician art plunges Dr. Helbig necessarily into perhaps the most exciting controversy going on at present in the archaeological world. Every one has been in turn puzzled by this phenomenon of early naturalism, succeeded by, and in part contemporary with, conventionalism. We have Dr. Langbehr maintaining that it is due to the influence of the Asia Minor Dorians; Dr. Milehoeffler that it is the outcome of Aryan and opposed to Semitic impulse; and finally Dr. Helbig, whom ourselves we believe to be right, maintaining that the Phœnicians themselves are responsible. Dr. Helbig promises that the battle shall be fought out in his still unpublished work on the early art of the Italian peninsula.

To the testimony of Phœnician we have to add the testimony of archaic Italian and Greek art. The necessity of such evidence scarcely needs demonstration; it is enough to point out that down to the middle even of the fifth century B.C. Greek art went on producing conventional Oriental types, some of which may have been familiar to the art of Homer's days, and that Italian art, being of less independent inspiration, bears the impress of antique convention down to even later days. The trade of Latium and Etruria with Phœnicians, Chalcidians, and Phœcians made the West but the feebler echo of the East: hence we

look for evidence of the art of Homer to types preserved in the wall paintings and tomb slabs of Etruria, and with even more confidence to the remains of the always backward and conservative culture of the countries east of the Apennines, to the graves of Tolentinum or Aufidena. To the evidence of archaic Greek and Italian art we add the testimony of the North; fragments of vases of Corinthian style have been found in an island of the Steinberger-see, an archaic bronze Hydria at Grachwyl in Switzerland; types superseded in the rapid development of the southern seacoast linger on in the hardier North.

Our material thus collected from Phœnicia, from Greece, Italy, and the North, it remains to arrange and date the available material. Dr. Helbig divides his "Fundgruppen" into Eastern and Western. Beginning with the East we have the discoveries at—1. Hissarlik; 2. Thera; 3. Ialysos; 4. Mycenaë; 5. the Dipylon find. We have placed them at once in the order Dr. Helbig establishes, an order which will scarcely now be disputed. He shows that the remains of Hissarlik belong to a period long before the time of Homer, a period when an early and barbarian state of society was as yet almost untouched by Oriental culture. Thera comes next and shows a marked advance; the simple geometrical decorations of Hissarlik pottery develop a more complicated syntax; metal-work appears, but stone weapons prove that the remains are still pre-Homeric. Next Ialysos,—ceramic ornament here approaches the conventional style,—a scarabæus of Amenophis III. is distinct evidence of Egyptian influence, and gives us also as a terminus the sixteenth century. Fourth and of the highest importance comes Mycenaë. The remains here found are still pre-Homeric; they show a condition almost wholly dominated by the East, a richness, a splendour, and in some respects a technical dexterity, which outdoes, though it precedes, the skill of Homer's time. From the civilisation of Mycenaë to that of Homer there is then in the matter of splendour and luxury, a marked decline, although in others, such as by the use of iron and the absence of obsidian, a marked advance. Was there, we naturally ask, between the time of the great impulse from the East and the date currently assigned to Homer, any event which could have caused this difference, this decline? Dr. Helbig unhesitatingly answers there was,—the Dorian invasion. Before the onset of the Dorians, the old civilisations, rich with the traffic of the East, ruled by princes half Oriental, declined, and a new civilisation, ruder, harder, sturper, more indigenous, set in. Such is the civilisation of Homer. It bears the traces, cherishes the memories, of a splendid all-golden, half-Oriental past; but its richest works of art are from the East. Its own conditions of life are simple and Hellenic. The Mycenaë remains fall then, before the tenth century B.C., the date currently given to the Dorian invasion. They touch closely on the times of Homer, but are not identical. Closer, but on the post-Homeric side, comes the find of "Dipylon" vases at Athens. Found though they were at Athens, they were probably not made there. Vases of similar type have been discovered at Melos, Thera, Asia Minor, and North Africa. Their designs are, perhaps, the most Homeric works of art we possess, only the ships that appear, furnished with rostra, make us suspect that their date is post-Homeric. Beaked ships do not, according to Dr. Helbig, appear till the eighth or seventh century B.C.; also the wide distribution of vases of the "Dipylon" style makes us suppose a regular local industry, which seems a post-Homeric notion.

We have been able only to indicate in the roughest way the method employed by Dr. Helbig and some of his conclusions. The arguments he employs it is impossible for us even to enumerate. Nor can we follow him through the second portion of his book, a portion less instructive, perhaps, to the general reader, but of supreme importance to the Homeric scholar. In this second portion Dr. Helbig takes up one by one each detail of Homeric life, and considers what light is thrown on each by the material we have been

considering, how far this corrects, how far it confirms, current literary interpretation. He has provided, in fact, an archaeological handbook for the Homeric scholar,—a handbook so complete and so profusely illustrated, that the ordinary educated public will scarcely need to seek information farther afield. He can learn here all that archeology can tell him of the building and furnishing of the Homeric house, of chariots and ships, of the cut and colour of Homeric clothing, and pins and necklaces and spirals and earrings, of armour and drinking-vessels, and of art proper as seen in the decoration of houses, in the great shield of Achilles, in the images of the gods. Literary scholarship may possibly be at issue with some interpretations offered by Dr. Helbig, but no literary scholar and no teacher of literary scholarship can afford to remain in his ignorance. The book must surely appear before long in an English garb.

#### LONDON WATER SUPPLY.

THE London Water Companies have reason to congratulate themselves on the expenditure which they have incurred in employing three such distinguished analysts as Professors Crookes, Odling, and Tidy to make so complete and thorough an examination of the water which they respectively supply to the metropolis; for the results, as given in their Report\* just published, are satisfactory evidence of the goodness of the article they undertake to supply, and of a progressive improvement in the methods adopted to free the water from those impurities which it is alleged must necessarily be more or less present in river water. It is likewise a satisfaction to the public to be informed, on such distinguished and reliable authority, that the fears with which they have had reason to be exercised, by the Reports addressed to the Registrar-General, and published by him in the Weekly Returns on the Water Supply of the Metropolis, have been groundless. "Moving organisms" is a term sufficient to make poor "Mrs. Brown's" hair stand on end, especially when the advent of cholera is so confidently predicted, coupled with the comforting assurance that its "germ" finds its habitation in water. That fear predisposes the human frame to contract disease more readily than it would otherwise do is a well-observed fact, and therefore as matter of policy, apart from humanitarian considerations, the circulation of reports by even irresponsible individuals is much to be deprecated. Much more is the employment of vague and indefinite expressions in actual official statements prepared for public information by those whose scientific attainments ought to be a guarantee for strictness of accuracy, to be deplored. The protest, therefore, with which the general observations in their Report is prepared against "the peculiar expressions and modes of statement" found in the Registrar-General's Weekly Returns is quite justified.

The presence of colour in water is ordinarily taken to indicate a certain degree of impurity, though, as in the case of peaty water, there is not necessarily any noxious ingredient in it,—but the use of the colorimeter has shown that there exists "a close relationship between the organic carbon present and the colour of the water," and therefore the natural instinct which leads us to prefer a colourless liquid to one at all tinged with colour is not altogether unfounded. It is scientific observation and investigation only that can pronounce as to whether the substance that produces the colour is really harmful or not. "As a general rule," this Report tells us, "the degree of brownish tint in the same supply of water is found to vary with the proportion of organic matter present in the water, and is strikingly illustrated in the diagrams on which the mean Thames water curves are depicted. To this general rule, however, occasional exceptions are presented by individual samples of water; doubtless because the fluctuating conditions affecting the constituent colorific organic

\* "Report on the Composition and Quality of Daily Samples of Water supplied to London during the year 1883." By Drs. Crookes, Odling, and Tidy.

matter of the water and its entire organic matter are not identical, and because the effect of filtration upon the constituent and the entirety are also not identical." The mechanically-suspended substance, which may give the colour in particular samples of water, it is quite possible to remove by the aid of filters,—but the chemical impurity necessitates different treatment. Of the former there are excellent illustrations to be seen at the Health Exhibition, and there are likewise some descriptions of filters capable of absorbing even matters held in solution,—but none of those can possibly be as effective as, or prove a substitute for, air, which the late distinguished Professor Angus Smith demonstrated to be the greatest and most rapidly purifying of all the agencies that could be employed.

Another of the qualities tested was that of clearness, and the results obtained redound to the credit of the water companies' operations; for out of 2,224 samples tested, only 35 were found to be at all turbid, all the rest being "perfectly bright, clear, and well filtered." In three out of five samples recorded as "slightly turbid," the turbidity was confined to the locality from which the samples were drawn, and was dependent on the carrying out of work in connexion with the supply of the neighbourhood. That increased care in the filtering processes has been taken is evident from the proportion of bright samples having increased from 91.4 per cent. in 1881 to 97.6 per cent. in 1882, and 98.3 per cent. in the past year.

But one of the most important results obtained by the analysts was in regard to the amount of free oxygen which the river water was found to contain. It is stated that "practically the water has been found throughout the year to be fully aerated or oxygenated." If so, then the outcry which has been raised against the Thames water as unfit for potable purposes may be utterly disregarded; and if, as the Report asserts, chemists generally "are beginning to make use of the process of free oxygen determination in their study of questions relating both to water supply and to the remarkable self-purifying power of running water which has now become more than ever a matter of positive demonstration," it is to be hoped the controversy regarding the best sources of supply for the metropolis will cease; and common sense taking the place of imaginative theories, will lead to a speedy practical issue in the provision of the requisite quantity, which is the principal question now that the doubtfulness of the quality can be no longer disputed. This is the point, then, to which public attention should be more especially directed; and, as we have before and more than once urged, the most obvious and simplest means of obtaining the supply required for the inhabitants not only of London, but for the greater portion of the Thames basin, will be to store the surplus rain-water where it falls in the upper feeders of the river, whence it can be so conducted, with the full quantity of aeration required, to wherever it is needed.

#### A PALESTINE MUSEUM.

**A** PROPOSAL for the foundation of a Museum devoted to the antiquities of Palestine has recently been attracting attention. A room in the Louvre is now devoted to the display of objects of this class, which, however, in 1879, did not exceed eighty-three in number; to these about 100 more have recently been added, including between fifty and sixty vases and lamps in terra cotta. In the British Museum exist between fifty and sixty similar objects; and a much larger collection, belonging to the Palestine Exploration Fund, is partly in the possession of that association, either in London or in Jerusalem, and partly at the South Kensington Museum. The whole collection, in these several detachments, does not exceed, perhaps, 1,000 objects. It is, however, worthy of remark that the proposal, which is evidently made *con amore*, makes no reference to what, in the eyes of many persons, are the most interesting of all the objects as yet recovered in the Holy Land,—a class of objects

of which the increase may be with the utmost confidence anticipated, if once such a nucleus for discoveries and stimulus to research as a museum would form were established. These are the coins of Palestine, a large number of which, unsorted and unarranged, were among the objects displayed by the Exploration Fund some years ago. These coins are either silver or copper. Gold Jewish coins are said to be in existence; but the fact, if such it be, has yet to be proved. Apart from the Crusading, Byzantine, and Arabic coins, each of which belongs to a separate chapter in the chequered history of the Holy Land, exist coins of undoubtedly Jewish type, coins of the Maccabean and of the Idumean dynasties, and coins of the Roman domination. In speaking of Jewish coins (if not of all classes of reputed antiquities from the Holy Land), it is necessary to allot a comparatively large space to the subject of forgeries. Thus coins exist which to a cursory inspector would appear accurately to fulfil the descriptions given in the Talmud, and which purport to be of the reign of David or of Solomon. Unfortunately, however, these productions bear square Hebrew characters, and thus carry their own condemnation on their faces. The subject of Jewish coins has been discussed at length by M. de Saulcy, and by Mr. Madden, of the British Museum; but a considerable amount of correction has since been applied to views which were hazarded by writers but very imperfectly acquainted with the Talmud.

There exists a class of silver coins, on none of which occurs the name of any sovereign or pontiff, but which bear numbers which have been taken for dates, none of which, however, are higher than four. At least twenty-eight types of this kind of coin in silver are known, besides seventeen in copper. It has been pointed out recently that these coins present all the features proper to the "Jerusalem money" of the Talmud, which was a coinage issued at Jerusalem for the express purpose of the payment of the annual poll-tax, and of the second tithe, as to which, for ritual reasons, the ascertainment of the year of the week of years to which the coin belonged was a requisite. Numbers 1 to 4 would be adequate to denote seven years, by the use of the same coin for the first and fourth, or for the first and fifth years, and so on; and a system not so very different from that of our own Hall-marks may be thus denoted. This explanation avoids the obvious anomaly which, by the attempt to refer all these coins to the same regnal or sacerdotal years, would limit the issue of some 30 per cent. of the known coins to four years out of at least a couple of centuries.

On this view the coins in question may be of various degrees of antiquity; which, in fact, they appear to be. The oldest coins as yet distinctly ascertained are those of the reign of Johanan the High Priest (John Hyrcanus), B.C. 204. Of this prince four copper types exist. These are followed in regular order by the coins of Judah the High Priest (Aristobulus I.), and Jonathan the High Priest (Alexander I.). Their coins, eight in all, bear inscriptions in Aramean characters, somewhat like those of the Moabite stone. There are also four coins of Jonathan with bilingual legends, and six, also bilingual, of Queen Alexandra, Alexander II., and Mattathiah the High Priest (Antigonus). Of the seven kings, Ethnarchs, and Tetrarchs, of the Idumean line, the coins of all have been recovered, viz., those of four of them of Jewish types, thirty-eight in all, and those of the remaining four of Pagan types, forty-one in all, all bearing Greek legends. There are also coins of the Roman Emperors and Procurators after A.D. 70. It is evident that a series of this nature, comprising ninety-seven types, of which twenty-eight are in silver, is in itself matter of no little interest; nor is it very doubtful that it may be considerably extended. Even more interesting than this regnal series are two small copper and one silver coin, bearing the names "Eliashib the Priest," and of "Eliasar the Priest," which remount, if authentic, to 435 and 281 B.C. Here is a very important and interesting starting point for a numismatic collection of the utmost value.

The fauna and flora of Palestine, the gorgeous birds and beautiful butterflies, the little crocodile of the Zerka river, the relics and memorials of the Latin kingdom of Jerusalem, the crests and arms of the crusading nobles, the illustrations of the earliest developments of the pointed arch, and of the stilted or horseshoe arch so gracefully developed by the Saracenic builders, the splendid stained glass of the windows of the Dome of the Rock,—specimens, casts, photographs, and drawings, of all these are attainable. These, which occur to the mind on the spur of the moment, are only a few of the objects the collection of which, mutually illustrative as it would be, would throw so much light on the history of Palestine, and on the study of the Scriptures. Hardly a year would pass, hardly a traveller would visit Jerusalem, without adding to the stores of a museum for the founding of which we can hardly permit the doubt that the requisite funds will be readily forthcoming. Local research, in the present state of our Eastern relations, is arrested. To review and place in order the treasures we have actually gained, with the aim of filling up the gaps, and extending and completing the series, is thus the best work that we can now accomplish. It is difficult to assign the historic value of the discovery of a single authentic coin previously unknown to collectors.

#### NOTES.

**E**NGRAVED mirrors of Etruscan workmanship are already counted by thousands; those of Greek workmanship now known to us number sixteen. An interesting specimen found at Corinth, and preserved in the Bibliothèque Nationale, is published in the current issue of the "Bulletin de Correspondance Hellénique." The mirror itself is engraved, the cover decorated with a design in bas-relief. The engraved design represents Artemis just descending from a rudely-indicated mountain, and standing before Apollo seated on a rock. Apollo is of the type which came in about the time of Scopas, i.e., the long-robed priestly figure, crowned and playing on the lyre. The style and conception of the design is,—as we so often find in works of this sort,—fine; the execution somewhat poor. The bas-reliefs of the cover are much better work. Cast as they were for a number of impressions it was worth the artist's while to take more pains. A winged Eros is seated opposite a winged female figure. There is little doubt that we have in the winged female figure a Nike. The juxtaposition is frequent in the third century B.C., when the love-god began to dominate mythology. In fact, we have in the bas-reliefs of the mirror a charming toilette text in plastic form: "Omnis vincit Amor."

**I**T is a pity that the Trades' Union Congress does not confine itself more to the practical objects for which it was presumably instituted, instead of running off into disquisitions on subjects which have really nothing to do with those objects. Half a day seems to have been spent at the first meeting in discussing the Peers and the Franchise, in the course of which the proceedings were further complicated by the efforts of some irrepressible feminine preachers of women's rights to be instant in season and out of season, or, rather, altogether out of season. Matters were not mended at a subsequent meeting, when much time was taken up in foolish talk about demanding the system of payment to members of Parliament as a step towards the more direct representation of the working classes. It is our rule to abstain from politics, but we cannot help warning the Trades' Union Congress that they are wasting their time and making an absurd figure in discussing such a proposition, which, were it possible to establish it, would at once lower and degrade the whole tone and feeling of representative government to an extent which those who themselves propose it are probably far from realising. The most practical suggestions of the Congress were in regard to the need of more efficient inspection of mines and machinery; and in the line they

take in regard to co-operative labour we are entirely with them. But the Congress will certainly not make its proceedings the more respected in the eyes of even its best friends by spending so much time over ill-judged digressions into subjects wide of its proper objects, and over which much has been said which, to borrow a phrase of Kingsley's, might be catalogued as "pure bosh."

IT is to be hoped that the people of Manchester will not sanction the proposal to raise a sum from the rates towards the expenses of the Manchester Ship Canal Bill. We are willing to assume that the canal will be successful, and that it will be of great commercial advantage to a portion of Lancashire. But the funds of a city corporation are not meant to be paid into the coffers of a trading company, or to aid in its foundation, however advantageous such company may prove to the place. If once the principle is admitted, that the rates of a town may be used for the purposes of assisting a limited company, it will open wide a door to all sorts of applications from companies and promoters,—good, bad, and indifferent. It will cause every kind of improper means to be used in order to influence persons who have a voice in the government of a town, and a place in a city council will have a direct commercial value. It will strike a distinct blow at the purity of municipal life and municipal management. The great railways of England were made with private capital, and if the promoters of the Manchester Ship Canal are unable to raise funds to carry on their campaign, it is obvious that they do not thoroughly satisfy capitalists that their project is a sound one. We should certainly be disposed to say that any Select Committee which found that the scheme was being helped on by the rates of a town would be inclined to feel a prejudice against its commercial value.

FROM a letter in the *Leeds Mercury* it appears that in the competition for the Leeds and County Conservative Club-house, Mr. Corson, who was called in as professional referee, awarded the first prize to Mr. G. B. Bulmer, the second to Messrs. Chorley & Connon, and the third to Messrs. Smith & Tweedale; but that the directors of the Club-house Company have reversed the first and last decisions, and offered Mr. Bulmer the third prize, giving the first to Messrs. Smith & Tweedale. Mr. Bulmer, who writes the letter referred to, refuses under these circumstances to accept the third premium; and on the face of the facts as stated he is unquestionably acting in a very proper spirit in doing so. There is only the question, did the Directors commission Mr. Corson to award the premiums, or only to advise? If the former, they were bound to accept his decision, or else the calling in of a professional referee is a mere farce. But a professional referee is a mere farce. But a professional adviser may be and has been sometimes engaged to report upon designs and assist a committee in coming to a decision, without necessarily being commissioned to make the award. It is very important that all architects who are invited to act as judges in a competition should ascertain clearly first whether they are asked to advise or to award, and if the latter they should not enter upon the office without a clear understanding that the committee or owners will abide by their decision. In any case, the directors in this instance will probably hardly have done a wise thing in overthrowing the decision of Mr. Corson, who is in every sense an exceedingly well-qualified judge.

THE idea of a conference on the subject of industrial remuneration and the distribution of wealth has been started by the offer of a gentleman in Edinburgh, who prefers to remain anonymous, to devote 1,000*l.* to the expense of inaugurating a thorough inquiry into the subject. Trustees have been invited to act on his behalf, and to prepare a plan for giving effect to his proposal, among whom are Mr. Thomas Burt, M.P., Mr. Frederic Harrison, the Earl of Dalhousie, and Sir Thomas Brassey. The inquiry is to be opened on the lines of the

main questions: "Is the present system or manner, whereby the products of industry are distributed as between the various classes and persons of the community, satisfactory?" and "If not, are there any means by which that system can be improved?" The "inquiry" would take the double form of a conference of representative men, to be held, if possible, in January of next year, and of the subsequent publication of a volume containing a report of the discussions, accompanied by special papers and statistics. As to the first part of the question, we should say at once the answer is an "eternal no." The system by which the products of industry are distributed never was satisfactory to all classes of the community, and never will be, in the very nature of things; and if we ever get to the point when it were, the social clock would stand still. "Scipio was not as rich as Lælius, Lælius was not as rich as Crassus, Crassus was not as rich as Lucullus, and Lucullus was not as rich,—as he wished to be." So the world goes, and no conferences will make any fundamental difference in that tendency of humanity, any more than in other tendencies equally broad and simple, so simple that they are overlooked, which lead to the unequal distribution of wealth. However, the idea of the conference is a thoroughly benevolent one, and we have no doubt light will be struck out on some points in the course of the discussions, but we fear they will also give occasion for a good deal of somewhat wild and utopian speculation, and "oppositions of science falsely so-called."\*

THE river and sewage question seems to get more and more persistent. The Cam and the Lea are now the prominent sufferers, next to Father Thames himself. The Lea has at length fairly made his complaints heard, and the Local Government Board, following up a report of their inspector, have called on the Edmonton Local Board to provide other means of disposing of their sewage than into the river. In regard to the Cam it appears that between 1869 and 1871 the University Boat Club have spent more than 4,000*l.* in deepening and improving the river (a poor one at best for their purposes), but has filled up since to a depth of 3 ft. chiefly from sewage deposit. A preliminary step seems to have been at last taken in getting the assent of the University and College authorities to a scheme for apportioning properly the liability for new works as between the University and the town, and it is to be hoped we shall before long hear of some satisfactory practical result.

FROM the *Gazette des Architectes* we learn that it is proposed to institute in Paris a special "service d'hygiène municipale," to unite under the control of one chief, having the grade of "sous-directeur," all the services concerned in the sanitation of Paris. These include the management of the water-supply, of the sewers, the overseeing of "ordures ménagères," and of the cleansing of the public streets, the cleansing of brooks and of the street channels, the sanitary treatment of the Seine, the control of all dangerous or insanitary structures, the medical inspection of schools, of lodging-houses, and of the municipal laboratory, &c.

SOME time ago we mentioned the new refuse destructor invented by Mr. Stafford, the Borough Engineer of Burnley,† and which had been brought into use with great success in that town. We are glad to learn that this invention has been brought into operation at Richmond; not that Richmond is especially in want of it more than other places, but that all progress in the systematic destruction of rubbish is a step gained in a sanitary point of view. The accumulation of *debris* which is done with, which no one wants, and which is left to lie festering in gutters and on roadways, is one of the most serious obstacles to keeping inhabited places in a sanitary condition; and the difficulty increases, of course, with the

density of population. Those who have noted the aspect of East London streets on Sundays, with the roadways covered with what can only be called "garbage" of all sorts, the leavings of Saturday's crowds and street business, must have wished that all this could be burned up by a happy despatch, instead of (at the best) being swept up to fester in a more concentrated manner elsewhere. We hope it will not be long before every parish and district in London will have its refuse-destructor.

WITH the other diversions of the silly season, the game of architect-hating is, of course, revived in the *Times*. The periodical anti-restorationist writes his letter describing the removal of some old tomb, and this is enough hint for an article in which the public are informed that when an architect is called in to restore a church, "he is compelled by the conditions of his profession to make work for himself," and with this noble object proceeds to cut away old ornaments and old glass, and to strip the building of everything that gave it a history. This delightful way of putting it was protested against in a sensible but much too mild letter from "An Architect who loves Old Work," which was duly inserted as a reply to the statements of the "leader-writer." But why do not the scribes of the *Times* proceed to apply the same charitable reasoning to other professions? Why do not they point out how physicians, in the interest of their pocket, will prolong the patient's disease; how solicitors endeavour to beguile every one into lawsuits; and so on? It would be just as logical, and give them more matter to fill their columns when Parliament is up. Probably, however, this sort of thing is the result of pure ignorance rather than of malice *prepens*, if one may judge from the insertion in the *Times* last week of the ridiculous letter from "A Country Architect" (very far in the country we should imagine), who asserted that architects had no means of preventing builders from removing the excavated material from a building site. The simplicity of the "leading journal" in inserting such a letter, and actually founding an article upon it, is only equalled by that of the country architect himself, who must be one of the persons who have eaten largely of that commodity called "flap-doodle," defined by Marryat as "the stuff they feed fools on."

A VERY different specimen of *Times* correspondence is the letter from "An Express Engine-driver" on railway brakes which appeared on Wednesday. It is interesting to have a look into railway experiences from the driver's point of view; and the "Express Driver" has had some experiences. He has twice had his engine run down an embankment, and eight times had crank-axes break under him (those crank-axes again!), and he has had practical trial of the working of four of the brakes most in use, and he declares emphatically for the Westinghouse. With that he feels safe; with the others he is not sure whether they will act or not; but the Westinghouse never fails, and has saved his life and limbs five times. Three others have failed more than once, and did not prevent accidents. This evidence, coming from such a quarter, seems to be practically conclusive of the brake question. As the "Express Driver" very truly says, the drivers not only see danger first, but are in it first, and it is a matter of life and death to them; and, therefore, it stands to reason that what they feel to be safest for themselves, and wish to have adopted, is safest for the passengers, "no matter what chairmen may tell gentlemen at meetings."

Westbourne.—A stained-glass window has been recently placed in Westbourne Church, Hants, to the memory of the late vicar, the Rev. J. Mee. The window is a two-light one, the subjects illustrated being Feeding the Hungry and Visiting the Sick, surmounted by architectural canopies. A brass tablet, with memorial inscription, is placed on the sill of the window. The work was designed and executed by Messrs. Warrington & Co., of Fitzroy-square.

\* We give elsewhere the list of suggested subjects for discussion.

† A short description of it will be found in the *Builder* for June 21 of this year, p. 912.

THE TIMBER OF THE UNITED STATES.

The question of forestry and the best means of cultivating that study is at last beginning to assume the importance that it deserves; and a knowledge of what is taking place in other countries can scarcely fail to be useful, more especially to those who are interested in the preservation of timber for building and ornamental purposes. The Americans have been gradually awakening to the extreme necessity of looking after their forests and checking the reckless waste that they have sustained at the hands of pioneers and settlers. In the early days of the continent, the primeval woods, through which the wandering tribes of Indians tracked their way with such marvellous skill, covered a large proportion of the land; but from the moment that the white man appeared, the work of their destruction proceeded with great rapidity. The first arrivals made their settlement along a heavily-timbered coast, and, for the better part of a century, literally hacked their way towards the interior, until the great plains were reached; and, in fact, it seemed to be the aim of the settler to destroy as much as he could of the American forests. The woodman's axe was the symbol of civilisation, and the State seal of Indiana still bears the figure of a wood-chopper. Indeed, the idea that a forest tree was of any value, except to be used up for posts and rails or burned for peat, is quite of modern origin. If the colonist lived near the borders of a forest that skirted the streams, he cut the trees down for cordwood, as though the supply were inexhaustible, nor did he ever dream of planting groves about his house, which should at once yield him fuel and give him shelter from the fierce winds. This reckless waste, combined with the incessant demand created by the lumber trade, has in many cases entirely altered the appearance of the country, and, worse than that, materially modified the climatic conditions by interfering with the rainfall.

For several years past, however, a salutary change has come over public opinion in the matter of forestry, and many of the States, especially the younger ones, are as earnest about tree-planting and preservation as the earlier inhabitants were careless. Of course the damage that has been done in many of the older States is practically irremediable, but a great deal of good has resulted in those of more recent constitution, in which the public lands of the United States are situated, by the Timber Culture Act, which applies to nineteen States and eight Territories. The purpose of this law, which was passed in 1873, and amended in 1878, is to promote the growth of forest trees on public land. It gives a right to any settler who has cultivated for two years as much as five acres in trees, to an eighty-acre homestead; or ten acres, to a homestead of 160, and a free patent for his land at the end of three years instead of five. The limitation of the homestead laws to 160 acres for each settler is extended in the case of timber culture, so as to grant as many quarter sections of 160 acres each as have been improved by the culture for ten years of forty acres of timber thereon, but the quarter sections must not be immediately contiguous. Unfortunately this law, excellent in principle, has been made comparatively worthless, and its intention avoided; for non-residents and speculators have taken claims under the Act merely for the purpose of selling them to persons who wished to take them as homesteads or pre-emptions. An amendment should be made, so that when there is a filing under the Timber Culture Act, the land should be withdrawn from entry under either the Homestead or Pre-emption Act, and the title should never be perfected, except in compliance with the letter and the spirit of the Timber Culture Act. Since the passage of the original Act, in 1873, there have been 93,246 filings, covering 13,637,140 acres. Of this amount, there have been entered since the amendment of the Act, in 1878, about 11,177,510 acres. Of the first-named acreage, at least one-third has, from various causes, been cancelled or entered under other Acts, leaving over 9,000,000 acres held for the present under the provisions of the Timber Culture Act.

Taking the eastern half of the States, the two great classes of timber which prevail most and furnish the material for the lumber trade, are pine and hardwood. The former consist, for the most part, of the long-leaved pine (*P. Australis*), the short-leaved pine (*P. mitis*), the

white pine (*P. strobus*), the loblolly pine (*P. taeda*), the scrub pine (*P. Bantisiiana*), together with the spruce (*Picea alba* and *P. nigra*). The hardwood comprises, roughly speaking, the hemlock (*Tsuga Canadensis*), white, red, and burr oak, sugar maple, poplar, birch (*Betula papyracea*), tamarack, white cedar (*Chamaecyparis sphaeroides*), yellow cedar (*Thuja occidentalis*), &c. The following table shows what was the quantity of merchantable pine standing in 1880 in sixteen of the principal timber States, together with the amount cut during the year in board-measure feet:—

State.	Variety.	Pine standing.	Pine cut.
Maine .....	Spruce .....	5,475,000,000	439,845,000
Vermont .....	Black spruce .....	755,000,000	205,591,000
New Hampshire.....	" and white pine .....	1,510,000,000	259,584,000
Pennsylvania .....	Hemlock and " .....	1,800,000,000	380,010,000
Michigan .....	White pine .....	35,060,000,000	4,397,201,000
Wisconsin .....	" .....	41,000,000,000	2,097,299,000
Minnesota .....	" .....	6,100,000,000	549,997,000
North Carolina .....	Long-leaved and loblolly .....	5,228,000,000	158,591,000
South Carolina .....	" .....	5,316,000,000	124,492,000
Florida .....	" .....	6,615,000,000	208,054,000
Louisiana .....	Long and short-leaved .....	48,213,000,000	84,591,000
Alabama .....	" .....	21,192,000,000	245,396,000
Georgia .....	Long-leaved .....	16,778,000,000	272,743,000
Arkansas .....	Short-leaved .....	41,315,000,000	129,780,000
Mississippi .....	Long and short-leaved .....	23,275,000,000	115,775,000
Texas .....	" and loblolly .....	67,505,500,000	274,440,000
	Total.....	327,581,500,000	9,927,380,000

This does not, of course, imply that no other timber exists than these kinds, but simply that they form the bulk of the forests. Each State has its various species of trees, according to its geographical situation. Florida possesses a typical tree flora, such as cypress, sweet bay, palmetto, live oak, mastie, &c. Georgia is stated by Dr. Little, in his "Eclectic Geography," to have no less than 230 kinds of wood; while parts of Virginia are timbered from the valleys to the mountain tops with white oak, walnut, maple, tulip-tree, hickory, bass-wood, cherry, chestnut, buckeye, cucumber tree, dogwood, white and black pine, &c.

A most interesting epitome of the timber resources of the southern states is given in a valuable report on the agriculture of Alabama. The list of trees has been compiled by Dr. Charles Mohr, of Mobile, and shows not only the characteristics of the timber of the South but the kinds of soil affected by the various species. The lower pine region, or coast pine belt, includes—(1.) The maritime plain, with saline marshes and flats, and dunes of drifting sands on the islands near the coast. The trees most prevalent here are live oak (*Quercus vivens*), a typical form on inlets and bayous; willow oak (*Q. Phellos*), water oak (*Q. aquatica*), *Vitis incisa*, *Lycium Carolinianum*, and *Yucca aloifolia*. (2.) In the open grassy river swamps and wooded alluvial bottoms, more or less inundated, are red cypress (*Taxodium distichum*), tupelo gum (*Nyssa unijlora*), cotton-wood (*Populus monilifera*), *P. heterophylla*, ash (*Fraxinus viridis*), *P. platycarpa*, hickory (*Carya aquatica*), wahoo (*Ulmus alata*), elm (*U. Americanus*), dwarf palmetto (*Sabal Adansonii*), holly (*Ilex opaca* and *I. decidua*), *Catalpa bignonioides*, *Persea palustris*, &c. (3.) Low flat pine barrens or pine meadows, with pine-pitch (*Pinus Clobensis*), and long-leaved pine (*P. Australis*). (4.) The ever-green glades of the hummock lands and wooded bottoms, more or less peaty, with the open swamp bordering them. Here flourish the bull-bay (*Magnolia grandiflora*), the bay (*M. glauca*), the juniper (*Cupressus thyoides*), loblolly pine (*P. taeda*), *P. Elliottii*, the sour wood (*Ostrya arborescens*), and the prickly ash (*Zanthoxylum clava-Herculis*). The principal timber of the (5) rolling pine lands, which are almost devoid of undergrowth, consists of high-ground willow-oak (*Quercus cinerea*), black-jack (*Q. nigra*), turkey oak (*Q. Catesbii*), mocker-nut hickory (*Carya tomentosa*), and the saw palmetto (*Sabal serrulata*).

The next zone is a region of mixed tree-growth, known as the upper pine regions. The lowland, with its heavily-wooded river valleys and creek bottoms, abounds in the white spruce and loblolly pines, the white cedar, swamp chestnut oak, red and over-cup oak (*Quercus lyrata*), shell-bark hickory, sycamore, red and ash-leaved maple, linden, and umbrella-tree; while the uplands and so-called wooded prairies are covered with black, Spanish, and post oak-

and on the deep rich soils are large poplars, black walnut, ash, and white oak. The forest growth of Indiana and Illinois, and especially those of the Lower Wabash and White River valleys, is hardly surpassed by any other State, both for the number of species contained, and the magnificent development of individual trees. Nearly all the most valuable and largest broad-leaved trees are there found associated, and in a single square mile of wood, seventy-five species of trees, nearly all first-class, were tabulated by Mr. Ridgway. The tallest specimen measured, a tulip-tree, was 190 ft. in height, while individuals of ten other species exceeded 150 ft. Numerous small prairies, which were common in the Wabash basin at the time of its first settlement, have been transformed into woodland, and the area of the forest ground greatly increased.

To the west of the Mississippi lies a vast district, quite different in its tree riches and its requirements. It extends westward as far as the Rocky Mountains, and southward from the British possessions to the warm waters of the Gulf of Mexico, the great river itself being lined throughout its length by forests, which increase in width as the number and size of its tributaries increase in volume. The Missouri is also bordered with forests for the last 200 miles of its course, above that running through a comparatively disforested region. The woods keep up a gallant fight for existence along the streams that flow east, such as the Platte, the Kaw, and the Arkansas, but finally diminish to a thin winding fringe of cottonwood or willow, and the eye for hundreds of miles sees no more, until the pine-covered slopes of the Rockies appear dimly in sight. Iowa, one of the prairie States, was once fairly well wooded, especially on the banks of the Desmoines, but it has been so recklessly maltreated by the settlers, that native timber has almost ceased to exist. In 1875 the forest area of Iowa was estimated at 2,300,000 acres out of a total of 35 millions. Nebraska, when first settled, was almost entirely destitute of timber, the chief bulk being found along the line of the Missouri, composed of willow and cottonwood, a considerable body of the latter existing also at the mouth of the Platte, together with groves of white and burr oak. But of late years Nebraska has shown a most commendable activity in forest operations, having adopted laws which provide that the increased value of lands from live fences, fruit, and forest trees grown thereon, shall not be taken into consideration in the assessment; also exempting from taxation for five years 100 dollars valuation for each acre of fruit planted, and 50 dollars for each acre of forest-trees, together with some other clauses tending to encourage forestry. In this State arose also the institution known as "Arbor Day," which was designated with the object of fixing one day in April, when everybody is expected to keep holiday, and to devote it to tree planting. It is universally observed, not only in Nebraska, but in Min-

nesota, Kansas, and several neighbouring States, and millions of trees are annually planted on that occasion. Between the passing of the Kansas-Nebraska Acts 1854 and 1852, there have been planted in the latter State 244,350 acres of forest trees, while spontaneous indigenous growth is estimated to be equal to half the area planted, since fires have been kept from borders of streams and prairies. Kansas was, at the beginning, more timbered than Nebraska, the Kansas river from its mouth to 135 miles west, the banks of the Neosho, the streams of East Kansas, and the tributaries of the Republican running to the borders of Colorado having been all covered with forests. After the ravages of twenty years the area is estimated at 2,560,000 acres, or 4.92 per cent. of the whole. When the mines of Colorado were first worked, some twenty-five years ago, large bodies of spruce pine and fir covered its mountain sides, and it was estimated in 1870 that nearly one-half had been destroyed by reckless cutting and fires. Within the shadow of these forests rose the head-waters of the Rio Grande, Platte, Arkansas, &c., and as the snow in the deep woods melted slowly, the rise of the streams was gradual and uniform for a long period. Now that these mountains are left peeled and bare, the hill-sides are converted into a bald and black desert, the springs are drying up, and the great rivers now rise with sudden violence, and then sink as suddenly in their dry and diminished beds. Miners and railroad tie cutters have inflicted on these mountain regions the effect of which it is impossible to overrate.

New Mexico has likewise suffered in the same way, although in this territory there are still vast regions covered with pines and piñons; and, further west, in Arizona, along the line of the South Pacific Railway, is found a good deal of iron-wood, one of the hardest woods in existence, which will turn the edge of an axe, and can scarcely be cut by a well-tempered saw. The mountains of Montana were originally covered with forests of spruce, pine, cedar, fir, and balsam. A quantity of this has disappeared, and it has been noticed that, in this territory, timber, once destroyed, is not followed by a second growth. Idaho is remarkable for containing the finest body of red cedar on the continent.

The most characteristic indigenous timber throughout the prairie districts is the cotton wood (*Populus monilifera*), a tree of quick and long growth, living a long time on water alone, planting itself in the most unexpected places and sowed by the wind, although time has proved that on the high prairie it requires very careful nurture. Then come the black walnut, the soft maple, the catalpa, the hickory, the box-elder, and the red cedar. A valuable willow, called the diamond (*Salix cordata*), grows on the banks of the Missouri, and there are also many indigenous oaks, including the chinquapin oak, which grows in profusion on the bluff lands adjacent to the Missouri river, and is an abundant hearer, with nuts almost equal to chestnuts, greedily eaten by swine, deer, and antelope.

On the Pacific side of the Rocky Mountains, are forests of a different type and growth, affording enormous supplies of red wood (*Sequoia sempervirens*), of which in California there were accessible in 1880 over 25,828,000,000 board-measure feet. The chief characteristics of these magnificent Pacific forests are age, height, and exuberance of growth. The nutmeg-tree (*Torreya Californica*) towers in the coast forests to over 100 ft. with a clear trunk of 40 ft. straight as an arrow; the great Washington cedars (*Sequoia gigantea*) are the loftiest trees in the world, rising from 275 ft. to 400 ft. aloft, and sometimes 40 ft. in diameter, with a marvellously clear shaft from 80 ft. to 150 ft., as true and straight as if laid by a plumb-line; the Douglas spruce (*pseudo-tsuga Douglasii*), an abundant tree in Oregon, 200 ft. or 300 ft. in height; the great sugar pine (*P. Lambertiana*), 300 ft. or more,—all these and many others have deservedly contributed to obtain for California the name of the Land of Big Trees. The oaks, sequoias, and junipers, are as remarkable for age and picturesque aspect as some of the others are for height. The western juniper is one of the most venerable trees of all the higher mountain regions of California, venerable as to appearance and for the vast antiquity of the larger trees, which date back to the great Sequoian age, while hundreds and even thousands of miles may be

traversed without meeting with a single perfect tree. All seem to be more or less dismantled, or the top altogether carried away by storms and the ever-recurring snow-slides. When viewing these veterans, we should remember that they have braved the eventful cycles of time, measured by many thousands of years, with a most astonishing vitality. If killed from any cause on one side, the other side still continues its journey of life, externally developing, until the investigator finds it convenient to take bearings in order to find the original centre.

From the foregoing remarks, it will be seen how great has been the neglect and waste throughout the United States of one of the most valuable sources of wealth that the country contains. Not only has reckless cutting, but the loss by fire, to be taken into consideration,—the latter contributing very largely to the national destruction. In 1825, a fire passed from Maine into the adjoining New Brunswick, which destroyed 6,000 square miles of territory, including about a million acres of forest land, although nature repaired the damage with wonderful celerity, and clothed the district with a finer forest than before. What will, perhaps, act most stringently in the matter is, that the price of pine lands in many parts has greatly advanced, and this will materially check the timber trade, the vastness of which may be estimated by the statement that upwards of 5,000,000 ft. of timber, principally white ash, are used in the manufacture of oars alone. Another check, which will be greatly increased as time goes on, is that more and more stone is daily being used for building purposes throughout the American cities and towns, and more especially in the Far West and Pacific States, where at present the greatest waste of timber is to be found.

The demand for wood throughout the States is very large, if only for fuel alone, and notwithstanding the increasing area of the coalfield. But, on the other hand, there are vast regions which are not only destitute of coal, but where the cost of transport would entirely preclude its use. The lumber trade is on a scale that is unknown in any other country, the statistics of the census year showing that there were 25,708 establishments for the production of sawn timber, representing 181,186,122 dollars of capital, and employing 147,556 hands. The amount and character of the produce for the year was as follows:—

Value of logs .....	15,091,356,000	\$139,636,569
Board-measure feet sawn .....	1,761,738,000	into
Laths, numbering .....	5,555,046,000	
Shingles .....	1,218,230,000	
Staves .....	146,523,000	
Sets of headings .....	34,076,500	
Spool and bobbin-stocks, ft. ....	233,268,729	
Value of total product .....		

#### THE BRITISH ARCHEOLOGICAL ASSOCIATION AT TENBY.\*

(From our own Correspondent.)

On Wednesday, the 3rd inst., the party proceeded by special train to Pembroke Station, at which place they found the brakes in readiness. In passing through Pembroke we heard one stranger express great surprise that so small a place was inscribed in such large letters on the map; but when this scoffer came within sight of the castle, with Monkton Priory as a background, he subsided. Passing the ruins we drove through the pretty wooded valley of Coits-water (*coed*, a waddy) past Orleton, the old home of the Owens, now the seat of Mr. M. A. Saurin. Near the road are a cluster of round bronze-age barrows. Passing on we reach Brownslade, the seat of Colonel Lambton, where a large harrow had been opened by the kindness of the colonel. From its shape and construction a careless observer would pass it by as a hewn sand hillock, many of which are to be seen in the neighbourhood, but in reality it is an assemblage of human skeletons (some hundreds) lying two and three deep, all oriented. In the centre was a kistvaen, containing human and animal bones, a small slab of limestone about the size of a sheet of note-paper, on which was roughly described a cup in a circle, and a donkey-capped stone on which a pivot had turned. Among the other skeletons were found two bronze rings and a small stoup cut from red sandstone. In the immediate neighbourhood are the foundations

of a tiny chapel. The place is called Churchways, and the farm Bullbar—Pwly Fur, Fur's Bar. The supposition is that the primary interment was that of a man whose rank or sanctity cast a reflected glory on the many obscure dead who rested round him; these latter were brought from a distance, for the country must always have been very sparsely inhabited. After lunch the party proceeded to Angle, from which a grand view of the Haven was obtained, and from which place Henry II. sailed for the conquest of Ireland. Here a curious castellated building was examined, which is supposed to have been used as a rectory; if so the divine must have indeed been a member of the Church Militant. Thence to Eastington, a fine specimen of an Edwardian house; then on to Rhoscrowther, and home by Pembroke.

Thursday, Sept. 4th. "Demetia (Pembrokeshire), with its seven cantreds, is the most beautiful, as well as the most powerful district of Wales; Pembroke, the finest part of the province of Demetia; and the place I have just described (Manorbier), the most delightful part of Pembroke. It is evident, therefore, that Manorbier is the pleasantest spot in Wales." So said Giraldus Cambrensis in the twelfth century, and though some of our party considered the old chronicler slightly prejudiced in favour of his own home, all admitted there was a good excuse for his somewhat exaggerated extollation. Manorbier has not the proud strength of Pembroke, it lacks the architectural beauties of Carew, the historic associations of Lamphey, and the fairy-like beauty of the Episcopal palace of St. David's, but no Medieval building in Pembrokeshire excites a greater interest. It originally stood in a walled park of some 150 acres, in which were signal towers (part of the chain that extended through Tenly). The castle and its precincts was divided into three wards. The outer ward is entered from the north-east. There are slight remains of the barban, which seems to have been square, a semicircular bastion (see illustration) is nearly complete, although the walls in its immediate neighbourhood have been ruined, most likely in the Parliamentary wars. A deep ditch divides the outer from the inner ward; the digging of this moat appears to have destroyed a square tower adjoining the gate-house. A draw-bridge spans this ditch, working in one of the original sockets, but the other socket is a restoration. Entering the middle ward through the gate tower, on each side are small chambers which have been rendered habitable by the tenant, Mr. J. R. Cobb; to the north will be seen a semicircular tower, still known as the Bull Tower, because the parish bull had his residence there in the last century. On the south is the round tower, which is still covered by its original stone dome; the woodwork has been restored, and it is now inhabited. A building standing due east and west is imagined to have been the kitchen; over it is a room supposed to be the banqueting-hall. Some, however, maintain that they were both chapels, one of earlier date than the other. Portions of Manorbier were erected about 1100. It was no doubt nearly rebuilt in the Edwardian period, and again altered during the Glyndwr rebellion, strengthened in Elizabeth's reign, and dismantled in 1648. Mr. Cobb has laid bare many old foundations, and cleared out the well, in which were found a number of bolts made of lead, resembling clock weights. He also found the keys (Jacobean) lying in the moat, and an episcopal gold ring was among his spoils.

Leaving the castle we sought the church, over which the good vicar, the Rev. A. Wratislaw, conducted our party, and Mr. Loftus Brock gave a lucid and excellent description. Many churches in Pembrokeshire are worthy of note, but not one exceeds Manorbier in interest. The church would seem originally to have consisted of a nave. This was added, and lighted by long Norman windows; then the aisles were added, and arches cut,—one had almost said quarried,—through the walls; the head of one of these windows having been left apparently for a tall-tale. After nave, chancel, and tower were completed, a northern transept was added as a mortuary chapel for the De Barri family. In the chancel lies the effigy of a cross-legged knight in mixed mail and plate armour; on his shield he bears the four bars of the De Barri, and tradition declares him to be the uncle of Giraldus Cambrensis.

After leaving the church a small crom

\* See page 318, ante, and illustrations in this number.

was visited, which Mr. Laws declared was the original "Purr stone," from which the place derives its name of Maen-y-pur. Then to lanch, and on to Lamphay Palace, past the little church of Hodgeston, which was restored through the liberality of the Cambrian Society some years ago. Lamphay Palace lies low. We drove through the park-like grounds of Mr. C. Mathias, passing under a curious arch with a Decorated niche, and then along a shrubbery, in which, by the way, hemp palms were flourishing, and had doubtless unprotected for the last twenty years. We crossed a walled garden and reached the ruin, which consists of two blocks of building, detached from each other, and certain smaller works dotted about. The eastern block, which seemingly contained the residential apartments, is remarkable for its crown of arched parapet, resembling that which surrounds the Palace of St. David's, and has been attributed to Bishop Gower, though the wood is rougher than that which is the glory of St. David's. The western block is little better than a shell of the outlying buildings. The chapel is of most importance, and stands on a small cloister. It has a fine Perpendicular east window in good preservation, and is generally attributed to Bishop Vaughan,—1509 to 1523. Rawlins, when bishop, was visited at this house by Leland, the antiquary. Bishop Barlow was the last ecclesiastic who held it; from him it passed to the Devereux family, and the three Earls,—Walter, Robert I., and Robert II.,—made it their home.

From Lamphay the party made their way home; some turning off at Penally to examine the cross, ruins of St. Terlo's Chapel, and assist at aazaar for the restoration of the church.

On Friday, the 5th, our indefatigable shepherd, Mr. Wright, the Congress Secretary, collected his flock of B.A.A. lambs at Pembroke. After a long drive through a somewhat dreary country we reached the coast, and a line of cliff and crag opened out to view which well repaid us for the journey. Eastward and westward as far as eye could reach stretched the iron-bound coast of Pembrokeshire, carved into a thousand fantastic bays and headlands by the ceaseless roll of the Atlantic breakers which find no land to curb their might between St. Govan's and North America. The immediate object of our search was not, strictly speaking, archaeological; though Norsemen gave their name to the Stack Rocks, they have never been inhabited by man, nor, for the matter of that, ever will be, but they are not tenantless, thousands upon thousands of guillemots (called in the Pembrokeshire dialect eilegugs) come here to breed, arriving in May and leaving in August; unfortunately we were, therefore, too late to see the birds. From the Stacks we drove along the coast, and passing several ancient earthworks (which are said to be Danish, though as all that have been examined contain flint chips they would seem rather to be Neolithic), we arrived at St. Govan's Chapel.

This little church stands across a narrow gully which gives access to the beach. It is a very rude structure built into the live rock, 20 ft. high by 12 ft. broad. The entrance is by a door in the north-west angle, and the exit by the west; both of these doorways are arched. A limestone slab forms the altar, and under the northern wall is a small hot well, which formerly enjoyed a great reputation for curing diseases of the eye. On the left hand of the altar a doorway leads into a sort of grotto in the limestone rock, somewhat resembling a human form; this, no doubt, was the original sanctum sanctorum. From the vaulted arch of the roof, the pointed arches, and the style of masonry employed, Mr. Loftus Brock came to the conclusion that the building is of comparatively modern date, but that it was erected on a site deemed holy when Christianity was first introduced into South Wales. St. Govan finds no place in the Welsh hagiology. Some will have it he is no other than

"Gawain, surnamed the Courteous, fair and strong."

Walwyn's Castle, an earthwork lying between Haverfordwest and Dale, is said by some to take its name from the same hero, while others think the name is derived from a Latinised Irish word Gobanus, which simply means an hermit. Many wonderful tales were told of St. Govan. It is said that when he was pursued by Pagan persecutors he hid himself in his grotto, which miraculously closed around him. Hence the mark of ribs on the limestone, and if (baving full faith in the legend) you get into the cleft,

express a wish, and turn around, your wish assuredly will be granted. These wicked persecutors, not being able to find the saint, stole his bell, which they placed on a stone outside; the bell, like its master, slipped into the stone, and there it remains. If you doubt, hammer the stone and you will hear it ring.

From St. Govan's we drove to Bosherton, where is a rude cross in the churchyard, the Saviour's head only being carved at the intersection of the limbs.

Thence we proceeded to Stackpole Court, the fine seat of the Earl of Cawdor, examined his gallery of pictures, many of which are very good (unfortunately the Hirk's Horn is at Golden Grove). Thence to the Warren, where are some curious prehistoric remains, broken cromlechs, bronze-age harrows, and strange low walls forming circles, lines, squares, &c., which led to a long discussion, but no definite conclusion. Flint flakes and iron slag lie on the surface. In the immediate neighbourhood, cinerary urns, bronze weapons, and a gold fibula, now in the British Museum, have been discovered. Passing by the swannery, which excited great admiration, we drove to the church of Stackpole Eldrud, which lies within his Lordship's grounds. This church was restored by Sir Gilbert Scott, and consists of nave, chancel, and two small aisles on the south side. On the north side of the chancel lies a mailed cross-legged knight, his right hand on his sword, and his left resting on a plain shield. This is believed to represent Eldrud de Stackpole (twelfth century). In the aisle are two other effigies, and a tomb to Roger Lort (1613), a former owner of Stackpole. On the south side of the chancel is a small chantry is preserved the original stone altar, on which is the following inscription:—

CAM . . . . ORISI.  
FILI . . . . FANNCCI.

This seems very early,—perhaps seventh century.

On Saturday we got under weigh in the town of Tenby. Up to this we had been favoured with splendid weather; but on this occasion we were treated to a fine specimen of what Pembrokeshire can do in the way of wind and rain. The local secretary was asked what he thought of the weather, and stated that rain from the south-east usually lasted twenty-four hours. He proved to be right. However, some fifty ladies and gentlemen stood by the programme, and we proceeded. We first passed Scotsborough, a ruined manor-house, once belonging to the Perrots, thence up a terrible hill to Gumphreston, a charming little church, about two miles from Tenby. It consists of nave and chancel, with a tower at the junction, and on the northern side a small mortuary. The date seems early in the fourteenth century. The only entrance is by a west door, under a porch, in which is a very archaic stoup. A stone bench runs along its walls. In the chancel is a fine Decorated piscina. The baptistery consists of a semicircular chamber in the north wall. The tower, a good typical specimen, is 60 ft. high, 20 ft. square at the base, and 14 ft. at the top. On the north-west of the nave are the remains of fresco-paintings, very rude,—apparently instruments of torture are depicted. The bronze sanctus bell preserved at Gumphreston is 8 in. in height, quite plain, but of good workmanship.

Then on to Carew. We stopped to examine the fine interlarded cross before entering the Castle; on it is an inscription that defeated the antiquaries until two years ago, when Professor Sidebotam obtained a photograph, and, after consultation with Professors Sayce and Rhys, deciphered:—

MARGIT  
LUT DE } Margit Decet  
CETT FX } fecit X.

Margit is an archaic form of the modern "Meredit"; "Decet" is a Gaelic name not uncommonly found in old Welsh inscriptions. This translation has effectually destroyed one error; it used commonly to be said that the scroll crosses of Carew and Nevern were Runic. Now Carew, at all events, proves to be early Welsh. Having admired the cross we passed into Carew Castle, which lies on the shore of Milford Haven. Caerw, in Welsh pronounced Car, is the plural of Caer, an earthwork, and that, no doubt, is the derivation of the name. One of these camps forms the site of the Medieval castle; the lines of the other may be discerned across the water. Carew was given as a dower

to Nest, daughter of Rhys ap Tudor (when she married Gerald de Windsor, castellan of Pembroke), by her brother Griffith ap Rhys, Prince of South Wales. Nest was a celebrated beauty. She had previously borne a child to King Henry I. Her descendants took the name of Carew, and still own the castle (Carews of Crowcomb, Devon), but several interlopers have been in possession. Sir Rhys ap Thomas, who raised Wales for Henry VII., added immensely to it, and Sir John Perrot, Lord Deputy of Ireland, did even more. Perrot is said to have been a son of Henry VIII. The western front is a grim Medieval fortress, flanked by two round towers. The northern portion is a grand Elizabethan mansion, with ranges of large windows and oriels running up the whole height. This last was Perrot's work. The inner western portion, of Late Perpendicular, is attributed to Sir Rhys ap Thomas.

From the castle we adjourned to the Parish Church, consisting of nave, chancel, two aisles and north transept, with a well-built lofty tower. The church is Decorated, the tower Perpendicular. In the south aisle is the effigy of a chain-mail clad knight cross-legged, and with his head on one side. Fenton considers that it represents Sir Roger de Melyn, temp. Edward I. There is also a monument to an ecclesiastic. From Carew we proceeded to Upton. This has been rebuilt, and is simply a modern house of a castellated form.

When are we going to Pembroke? had been asked over and over again. We had driven through its dingy streets twice, and admired the frowning towers from afar. But a closer inspection was reserved for Monday, the last day of the Congress (the expedition to St. David's being an extra, and to some extent not official). Although the Mediaeval castle was founded by Gerald de Windsor in the reign of Rufus, some sort of fortification existed on the spot for centuries before his time. Mr. Cobb, in his excavations, found Roman coins of Carausius and Constantine the Great.

Pembroke Castle stands on a limestone rock, from which, indeed, it seems to grow; both are draped with ivy, so that it is difficult at first sight to say which is natural and which is artificial. Beneath is a great cavern, which has been enlarged by man, and faced with masonry. This is known as the Wogan. The most striking features of this magnificent fortress are the flanking towers above the Wogan and the keep. This last seems to stand as a sentry over an inlet of Milford Haven, and from its position assumes an appearance of even greater massiveness than it really possesses. Its chief architectural features are two complets of windows, in one of which are two pointed lights under an obtuse arch, in the other two rounded ones under an acute; a small human head is inserted in both. In a wall near this tower is a blocked door, which looks strangely like Saxon work. Pembroke Castle was the birthplace of Henry Tudor, the founder of the royal line. Here, too, Col. Poyer, the drunken Mayor of Pembroke, held Oliver himself in check for two long months, and then yielded to famine alone. From the Castle we passed on to a curious old building, which used to be known as the Prior's House, but in reality was probably the Shire-hall. This had fallen into a sadly dilapidated state, from which it was rescued by Mr. Cobb, and generously handed over by him to the Vicar of Monkton, who now uses it as a residence; the vaulted roofing is well worth close attention.

The Priory of Monkton next was visited; this building takes a sort of middle position between the ruins and the parish churches. It consists of a nave, and which was intended for the use of the laity, and which still serves that purpose, and a choir, in former days allotted to the ecclesiastics. The monks are gone, and their choir is roofless. A fine southern porch with a vaulted roof of Early English work remains. A little Norman window, which seems to have been the only light on that side, is blocked up; the western window is lost. The choir is roofless; the east window, of which only the opening remains, from its size must have been very fine; the remains of a triple sedilia on the south side must also have been very grand, but the slab has all been removed, and a recess for a tomb on the west side blocked up. There is a large chapel on the north side of the chapel, and the remains of the domestic portion of the monastic buildings may still be traced, with the cloisters that lead to them. This building led to a long debate. Mr. Bowen, the vicar, is anxious to

remove the wall dividing the parish church from the ruined choir; but the feeling of the Association was decidedly against him, as a beautiful Norman arch must in that case be sacrificed, and the chief characteristics of the building irretrievably lost.

On Tuesday last a number of the party went by train to Narberth,—"Arherth, the high grove,"—a place celebrated in the mythology of Wales as the court of mythical kings, now an interesting Irish-looking little town. We examined what small remains are left of the castle founded by Sir Andrew Perrot in the reign of Rufus, and thence proceeded to the picturesque Castle of Llawhaddon. Of the many Medieval fortresses we had seen none surpass Llawhaddon, standing as it does on a wooded hill, overlooking the sparkling river Cleddan (a sword), with the pretty church nestling by its waters. The grand entrance, a view of which will be found on another page, is very striking. On either side are bastion towers; above the arch in which the gate hung is another, whence the portcullis descended, through which is a window with a label moulding. To the right of the gateway are two octagonal towers; the first was divided into two apartments, with little retiring-rooms attached, each having its own garderobe. The interior of the building must have been very magnificent in its day, and contained many splendid rooms. The chapel was erected by Bishop Vaughan; of it but three windows remain. At Llawhaddon the Bishops of St. David's lived as feudal lords; indeed they took their title of Baron from this property, and as such were charged with military service. The castle was terribly mutilated in the last century, being used as a quarry from which material for metalling the roads might most readily be obtained, and its present condition reflects but little credit on its owners, the Ecclesiastical Commissioners. From Llawhaddon we proceeded to Pictou, which is the only castle in Pembrokeshire which was never dismantled. Here we were met by the owners, Mr. and Mrs. Phillips, who most kindly entertained the Association. Pictou would seem originally to have been an oblong flanked by six bastions, three on each side. At the east end was the grand porticulated entrance, now unfortunately replaced by a modern Norman doorway. It was originally moated. Its general appearance has been greatly spoiled by additions made at the beginning of the century by the first Lord Milford, but these, we were glad to hear, Mr. Phillips thinks of removing. After enjoying an excellent luncheon provided by the owner, we quit Pictou, and proceed to Haverfordwest, the county town of Pembrokeshire, a queer old-world place. Its inhabitants boast that Haverford, like Rome, is built on seven hills. To us it appeared they under-estimated the number, or, perhaps, the severity of gradient led us astray; for every street appeared to be a mountain path, except Hill-street, which is flat.

There are the remains of a grand old castle at Haverford, but as this has been completely gutted, and was until lately used as the county gaol, it is of no great interest. The remains of the priory are also little worthy of notice. On the whole, we were glad to get under sail again for St. David's.

On Wednesday the first object of interest we came across during a long dray drive was the little rock fortress of Roch. Balanced, rather than built, on a crag, this little towerlet overlooks an immense range of country; this was clearly the purpose of its foundations, as it lies on the boundary between the English and Welsh speaking peoples. It consists of a D-shaped tower with prolonged sides, and may be of the reign of Henry III. The tower floor was most likely a barrack; a straight stair leads thence past a garderobe to the front floor and chapel. Leaving Roch, we proceed onwards to St. David's, leaving Solva to the left; this little fishing village rather reminded us of South Devon, and was the prettiest thing we had seen on this side of Haverfordwest. Soon afterwards we arrived at the city of holy Dewi, the patron saint of Wales. There may possibly be in America very newly founded cities as small,—such as Eden, described by Dickens,—but for its age I have no hesitation in declaring St. David's to be the smallest city in the world; we were told its population was 600, but, if so, they must pack very closely. The good Bishop had prepared a capital luncheon for us in his little city, and there can be little doubt the British Archaeological Asso-

ciation were the first batch of pilgrims who have enjoyed episcopal hospitality in the halls of St. David's since the Reformation; for Barlow, the first Protestant bishop, hated the place, and is said to have stripped off its leaden roof that he might dower his daughter with the spoil. Barlow was the destroyer, Gower the creator of the palace. It has four fronts, of Early Pointed architecture, with superb decorations, more particularly the staircase porch. The grand entrance was through a beautiful gateway; immediately opposite is a porch, with a flight of steps leading into the great hall. The archway of the hall affords a rare example of an inverted ogee, and above it are two niches. This great room is 96 ft. by 33 ft., and is lighted by side windows with a beautiful circular rose-window at the southern end, with mullions and tracery. At the south-west end of the hall is the drawing-room; further to the west a suite of state bed-chambers. The chapel has a freestone ephe, and is connected to the drawing-room, though it also has a porch and staircase of its own. The parapet of the outer walls, however,—the most remarkable thing at St. David's,—is made out by a succession of small arches resting on octagonal pillars, with ornamental capitals. The arches are built of alternate blocks of purple and yellow stone, and the sweep of each arch is adorned in a similar fashion to the door-frames of the porches. This is the finished result of the 'prentice work we saw at Lamphey, and it is also to be observed in Swansea Castle. Gower was builder of both.

Some of us attended Divine service in the cathedral, others wandering about the little city. The next morning we visited St. David's Head, where the scenery equals that we saw at St. Govan's, though here it is igneous, there limestone rock.

Then back to Haverfordwest, where the forty-first Congress of the British Archaeological Association dissolved, after a most enjoyable ten days' tour. Their pilgrimage, we may hope, was not in vain, for in addition to the pleasure derived certain suggestions were thrown out which we must hope will bear fruit. In the first place, Mr. J. R. Cogh was publicly thanked for the tender care he had bestowed on the castles of Manorbier and Tenby. The castles of Carew and Narberth, on the other hand, were found to be in such a sad plight that it was decided to draw the attention of their owners to their state, while Llawhaddon, which, being held by the Ecclesiastical Commissioners, should be a model, was found to be more neglected than any other edifice visited; they, too, were addressed to take measures for the preservation of an invaluable building which had been committed by Parliament to their care.

#### THE TRADES' UNION CONGRESS.

The seventeenth annual Congress of representatives of the trade unions of Great Britain and Ireland commenced on Monday last at Aberdeen. The chair was taken in the first instance by Mr. A. W. Bailey, chairman of the Parliamentary Committee, who in the course of his address observed that notwithstanding the distance of this year's place of meeting from the centres of trade unionism, no fewer than 140 delegates had already sent in their credentials and subscriptions.

Subsequently, the officers of the Congress were elected, Mr. James C. Thompson (president of the Aberdeen Trades' Council) being elected president, Mr. James Swift (of Manchester), vice-president, and Mr. J. W. Annand (of Aberdeen), secretary. Mr. Thompson having taken the chair,

Mr. Broadhurst, M.P., read the report of the Parliamentary Committee, from which we make the following extracts:—

#### Employers' Liability Act (1880) Amendment Bill.

We regret that little or no progress was made with this measure during the past session. Mr. Burt, not being fortunate enough to secure a first place in the ballot, took the next best at his disposal, but when the day came for second reading, the hills in front of it occupied the whole of the sitting. No subsequent opportunity occurred, so that no debate took place.

The Parliamentary Committee did all that lay in their power to promote the interest of the Bill. They prepared about six thousand petitions, with the corresponding number of instructions to petitioners, and despatched them to the branches of the various trades. The return of these petitions to the members of the House of Commons created a considerable interest, and had we been able to obtain a division, this interest would, no doubt, have been evinced in the list of votes.

We have increasing evidence of the necessity of prevent-

ing employers contracting out of the Act of 1880, and hope that in no longer a period we may be able to do so. The working of this Act continues to progress, and we now give some figures from a Government return made up to December 31st, 1883.

#### Employers' Liability Act: Cases entered in County Courts in 1883.

Number of actions brought.....	343
Number of actions in which damages were obtained 116	
Total amount of damages obtained.....	9,242, 13s. 3d.
Average amount of damages recovered.....	79s. 18s. 4d.
Cases standing over to following year.....	41
Cases withdrawn and settled out of court.....	60

#### Engineers' Certificate Bill.

Mr. John Morley very kindly undertook the charge of the Engineer's Certificate Bill, but no opportunity was obtainable for a debate on it.

There were various other questions which formed the subject of resolutions at the last Congress, but which the committee have been unable to deal with during the year.

#### Canal Boats Act (1884), Amending the Canal Boats Act (1877).

We are glad to note the passing of this amending Act, which has for its object the bettering of the condition of our canal population. The Act of 1877 made provision for registration of canal boats where families lived aboard of them, and also provisions for the education of the children. The working of the Act was left to local authorities, which, in a great many cases, proved to be ineffectual. The amending Act gives increased powers to the local authorities, and the Home Department responsible for the instruction of the children. The Local Government have now appointed an inspector to see to the enforcement of the Act, and we hope that he will be successful in his work, and his efforts much-needed part of the industrial population.

Mr. Burt had charge of the Bill, and your secretary's name was also on the back of it. The reason of this legislation was mainly due to the efforts of Mr. George Smith.

#### Employers and Workmen Act (1875).

Mr. Crawford brought under the notice of the Committee a case in which 1,126 workmen had to take out separate summonses against one employer for the recovery of wages, although the plaintiff was the same in each case.

The Committee brought the incident under the notice of Sir Paresy Hertschell, the Solicitor General, and he and the Lord Chancellor at once agreed to remedy this great hardship, by making new rules under which one summons will be sufficient, if all the names of the complainants are given on it. This will effectively remedy a great evil.

#### Increased Inspection of Industrial Operations.

It will be remembered that at the last Congress resolutions were passed in favour of increasing the number of factory and workshop inspectors, and also of inspectors of mines.

A careful consideration of these resolutions led the Committee to decide to concentrate their efforts in favour of the increase of inspectors for mines. Mr. Burt and the Secretary had had for a day for a motion on the subject, and ultimately Mr. Burt succeeded in getting the first place on July 4th. In the meantime the committee organised a large deputation of the trades, which was very kindly and favourably received by the Home Secretary and Mr. Herbert (the Under-Secretary for the Home Department), on July 2nd.

In the debate on the motion, Sir William Harcourt's statement was so hopeful that Mr. Burt did not take a division on it. On July 25th, in reply to a question put to him by your secretary, Sir William Harcourt said that the Government had decided to appoint a number of additional inspectors. We believe that the number will be about half a dozen or so, and that they will be practical miners. Amongst the conditions required for these posts will be one of the candidates shall have worked underground for at least two years, within five years of his appointment.

We congratulate the trades on this further signal success of their effort for the protection of the lives of the industrial population.

The discussion of the report was adjourned to Tuesday morning.

#### Joiners' and Carpenters' Associations.

In connexion with the Congress, a meeting of carpenters and joiners was held on Monday evening, in the Northern Friendly Society's Hall,—Mr. Samuel Cocker in the chair,—for the purpose of hearing addresses by Mr. Murchie, secretary of the Amalgamated Carpenters' and Joiners' Society; and Mr. Beveridge, secretary of the Associated Carpenters' and Joiners' Society of Scotland.

Mr. Murchie gave an account of the formation and progress of the society with which he was connected. Established in 1850, the society at the end of that year had enrolled 618 members, but the number had now increased to 26,000. At the end of the year 1860 there were twenty-one branches, only two of which were outside of London, and to-day there were 415 branches, 367 being situated in England and Scotland, and others in the United States, Canada, New Zealand, Australia, and South Africa. He spoke of the advantages of the society in the case of losses by fire and theft, and in times of fire and sickness, and illustrated the progress they had made by showing that at the end of 1860 they had only 321l. at their credit, while at the end of 1883 they had 61,617l. 18s. 11½d. They had paid to their members 450,000l. in the form of benefits. It had been said that a large amount of prejudice existed in Scotland among the well-to-do class against such societies, on the ground that they spent money recklessly on strikes. Now, to show that their money was not spent recklessly

in this way, be would mention that the total sum expended on strikes was £6,000, a little over 14 per cent., and fully one-third of that amount had been spent on the formation of boards of arbitration, committees, boards of conciliation, &c. If they admitted that the principle of strikes was wrong they had better return at once to the old condition of things and work for 3d. per hour, for that would be the result, if such an admission were made. He would recommend to their attention the recently-published article of Mr. Howell in the *Contemporary Review*, which dealt with trades' unions, and which contained more information on that subject than anything the speaker had ever read. The article in question stated that six societies between 1876 and 1881 had received from their members no less a sum than 1,784,410l. 17s. 11d., and within that time they had paid out to their members 1,984,003l. 0s. 1d., so that they had given away more than they had received. Mr. Mariche concluded by appealing to non-society men who wished not only to help themselves but their fellow-workers as well to come forward and join the society.

Mr. Beveridge made some remarks on the general question of trades' unionism. One of the most remarkable circumstances of the present day was the energy with which the principle of combination was asserting itself. Everything was being done by societies. Experience had taught men what wonders were accomplished by union, it had shown them that they could do jointly what they could not do singly, and that success in any enterprise whatever lies and depends very much on the hearty co-operation of those interested in it. To what did they owe the Saturday half-holiday, the reduction of hours of labour, and fair remuneration, if not to the hearty co-operation of members of societies such as theirs, backed up by the funds of this and other societies? Some of their non-society friends who might be present might think that they were justified in combining against such contingencies as sickness, accident, or death, but could not see the force of combining for the protection and advancement of trade interests. Why? Because they said that was regulated by the law of supply and demand. That, no doubt, has a very important bearing on the price of labour, but was it through the exclusive operation of that law that wages rose and fell? Had not the will and action of the buyers and sellers something to do with it? He thought they had, and the price of labour depended as much on the will and action of the employers and employed as on the operation of that so-called law. The machinery of trade societies, if properly wrought, would drive oppression from the market-place of labour, and force its way onward for the benefit and well-being of the sons of toil.

Mr. A. C. Telfer, president of the Edinburgh Trades' Council, next addressed the meeting, and he was followed by Mr. Beattie, Alderdeen, and Mr. P. Esslemont.

On Tuesday the President of the Congress, Mr. J. C. Thompson, delivered his opening address, in the course of which he said that, had it not been for the well-directed and persistent policy of the Congress from time to time, they should have been without many of the enactments which were now on the Statute-Book. It was heartrending to find from the newspapers that so large a number were at present unemployed, more particularly in the iron trade. Was it too much to ask employers of labour to wisely consider their modes of dealing with their employed? They should not be in haste to get rid of those who in times past had added by their busy hands and brains to their wealth, and surrounded them with comforts. In times like these, employers were called upon to make the greatest possible sacrifices, Nay, more,—as employers of labour had their privileges, so also had they their duties to perform. While sympathy was a good thing,—and they honestly thought it should take some practical shape in striving to modify at least those seasons of depression,—much lay to their hand in the way of directing the minds of men in certain directions, with the view of relieving the grieved labour market, such as a thorough revision of our land laws. One other thought on the subject of depression. It must be a patent fact to all that in alcoholic liquors they notionally spent by far too much. It did reflect very heavily upon them that so many were living on the bare necessities, sadly lacking the comforts of life, while they had so many

anxious to supply them. At the best their wage would no more than allow comforts of a very common kind, and why there were so many spending their earnings in the direction indicated was most astonishing. It was casting aside the chance of a better and nobler useful life, simply to satisfy the abnormal appetite. Governed, they were not governing. It became them, as leaders of public opinion among their fellows, to urge the principles of sobriety. The relationship between employer and employed seemed to be as strained as ever. Interests that were said to be identical were cycling each other with continued jealousy, taking the catch who could. This working relationship would never consolidate, but disintegrate. Both sides had expressed themselves very strongly that it was ruinous to be so circumstanced, and that it was a great hindrance to the common weal, yet no satisfactory basis was being asked for on the one hand, nor being held out on the other. The present system, it was clear, had not wrought well, as there was distrust all over. Why? Because employers of labour had generally acted on the principle, not of how much they could offer for labour, but how little. "This being the case, new questions arose in the minds of men, and the cry "to be content with thy wage" would never meet them. As every new question thus raised had an ultimatum, it was for men to consider what it might be, and shape themselves accordingly. His opinion was that it must give way to something of a broader kind that would affect and lighten the whole labour community, giving them a grander motive to perform, and that principle was productive copartnership. Such a principle extended would create a living interest, and take away much of the harshness of the burdens that were borne by labour. It was a principle which they would advocate strongly, because, if generally adopted by the employing class, it would disturb the least possible existing machinery; and the more they could take advantage of this the better. Other modes presented greater difficulties, for this reason, that in starting a new movement they had to make headway against the large vested interests which by far too often crushed those new aspiring movements. It was a principle that would likewise distribute wealth more fairly among all classes, and that was a matter to be desired. A great many employers had strong convictions as to the necessity for a principle of strike out and set at rest what was believed to be the goal between labour and capital. He could assure those employers of a co-operative spirit among working men ready to fall in to some such plan; and they looked to them to open the door. In prosperous times they would prosper together; in seasons of depression they would suffer together. The counterfeiter for honest labour would soon disappear. In the meantime, however, they purposed standing truly by their unions, knowing what good they had accomplished in the past; and, wrought now judiciously and wisely, what a great amount of good they would accomplish in the future.

On Wednesday the proceedings commenced with the presentation of a sum of 1,200l. and an illuminated address from the workmen of the United Kingdom and other friends to Mr. Henry Broadhurst, M.P., for his services in the cause of labour, and especially in his capacity as secretary of the Parliamentary Committee.

We defer until next week further notice of the proceedings of the Congress.

#### THE SOCIETY OF ENGINEERS AT THE SIEMENS TELEGRAPH WORKS.

The practice which the Society of Engineers has followed for many years of paying, from time to time, special visits to some of the great works and industries which contribute to the commerce, wealth, and reputation of Great Britain, had a happy illustration on Wednesday, in the selection of the famous establishment of Messrs. Siemens at Charlton, on the banks of the Thames, near Woolwich, where the manufacture of a very fine specimen of an ocean telegraph cable was in full progress, part being put on board the fine steamship *Paradise* (specially built and adapted for the service of cable-laying), and part still being fabricated in the manufacturing machines and passing under electrical test into the store-room, ready for shipment. Some 5,000 miles of the Mackay-Bennett cable have been laid, and the one line is working through from end to end. It

would scarcely accord, however, with either engineering or commercial principles to risk the possibilities of interruption of a single electrical conductor, and the provision of a duplicate line would be certainly dictated by prudence, if not, indeed, deemed an actual necessity. The portion of this duplicate line now nearly finished is about 1,500 miles in length, and will be laid between Newfoundland and the American continent. The shore ends are very stout, and strongly defended by hemp servings and iron-wire sheatings, a diameter of 2 in. being attained by the cable when finished. The deep-sea cable itself is much less protected, having to lie without disturbance on the ocean bottom. It is, of course, hemp-covered and wire-protected, but it is in total diameter only 1 in. over all in its full construction. The finished portions of both shore and deep-sea cables were in process of shipment on the arrival of the party,—which was a very numerous one,—and an inspection of the *Paradise* was the first item on the programme. The ordinary steam-winch of the vessel was employed for hauling the cables on board, and they were at the same time passed forward as they were hauled in through guides into their respective holds, where they were coiled round large central drums or bosses ready for paying out. The deck was one continuous mass of machinery and testing and recording apparatus,—a veritable electrical engineers' establishment on a very extensive scale. The cable in the process of its delivery into the sea is to be hauled by the steam winch out of the hold, and thence it will pass over and under a series of pulleys in order to maintain an easy hold upon it. The required rate of paying out is regulated at the steam winch, which is made to haul faster or slower according to the judgment of the officer in charge, who has the records of speed of delivery and strain always automatically recorded by the instruments around him. The passage of the cable into the sea is illuminated at night by a powerful arc light on each side of the bow.

After this inspection, the manufacturing department ashore occupied long and well-deserved attention, the dimensions and powers of the machines, and the skill and knowledge of requirements shown in their design, being such as are not to be seen in any other class of rope or cable making. First there is the copper conductor in the very heart of the telegraph cable. For this, industrial-rubber has to be prepared for its electrical insulation. This rubber is made plastic, and manipulated with the other ingredients required to form it into sheeting by two heated steam rollers or cylinders. The sheets are then cut into narrow strips by grooved wheels. Following the wire, which has been coated with a solution, the strips of rubber are pressed on to it as it is drawn through the grooved rims of two narrow wheels working one above the other, the excess of rubber being sheared off on each side in the operation. Over the central core hinge machines, each containing a number of reels of hempen thread, wind the threads evenly and closely round, one in one direction from left to right, the other in the opposite way from right to left. As these servings pass on from the machines each serving receives the flow over it of hot insulating material, and then passes through a die which presses the insulating material into the substance of the hemp and gauges the size of the cable in every stage. The steel wires are in like manner coiled spirally over the hemp servings by machines carrying reels of wire of as much length as is practicable, in order to have as few joints as possible. In the smaller wires these joints are made by soldering. In the shorter wires welding is performed. It is a curious feature in these machines that the reels are kept perfectly horizontal, notwithstanding the revolution of the machinery which carries them. The reels are placed in frames hung upon gimballs, which are so actuated by an eccentric ring working on the same spindle as the other revolving parts that the connexion between them is always maintained in a vertical line.

The electric lighting department was also viewed with deserved interest, dynamo machines of many dimensions and capacities being in progress, the smallest susceptible of being put in a space of a 6-inch cube, whilst others were of great size, developing high and powerful currents. One very striking illustration was given by the fusing of an iron wire, 5 millimetres in diameter; the machine which performed the experiment absorbed 40-horse-

power from the steam-engine in the act. The wire being galvanised, a very pretty and remarkable effect was produced by the blazing of the zinc over the red-hot iron long before the fusion of the iron itself took place; the flames of the zinc extending along the whole length of the wire, 18 ft., and rising to a height of 6 in. or 8 in. in the air, with numberless curls of white smoke. Finally, the incandescent wire broke and fell on the floor, dashing pieces and sparks in every direction.

An inspection of the Land Telegraph Department, with its poles, insulators, sending instruments, recorders, transmitters, railway signals, testing instruments, galvanic batteries, and other numberless details connected therewith, terminated the rapid survey of the visitors, who might have been well and usefully entertained for as many days as they spent hours in these remarkable works.

Amongst the members present were Mr. Jabez Church, past-president, Mr. Alfred Williams, treasurer, and Mr. Gandon, Mr. Perry F. Nursey, Mr. Berridge, and Mr. Schönheyder, members of council.

#### PROPOSED ADMIRALTY AND WAR OFFICE.

DESIGN BY MESSRS. F. INGRESS BELL AND ASTON WEBB.

**W**E give this week a view and the two principal plans of this design. In compliance with our request, the authors of the design have sent in the following explanatory memorandum:—

1. "As a primary condition of the problem, we endeavoured to arrange the plan in conformity with the latest sanitary knowledge, feeling it to be of the first importance that the civil servants of the Crown should be enabled to perform their duties under healthy conditions. Accordingly, we resolutely abandoned all small, close, damp, and gloomy courts, and ranged our buildings on the perimeter of the site, around one central courtyard of magnificent proportions, and open on all sides to sun and air. This courtyard would be 250 ft. across both ways in its widest part, the large courtyard at the Foreign Office being about 250 ft. by 175 ft.

2. The privacy of all the office rooms was obtained by removing from their side of the main corridors all staircases, lifts, messengers' lobbies, water-closets, and sanitary and other services,—the water-closets being taken up in vertical series in projecting side-ventilated towers facing the courtyard: their water services, wastes, and drainage all passing away from the site without underlying any portion of the building.

3. Quiet for the rooms facing Whitehall was secured by recessing the frontage to that thoroughfare,—the only arrangement, moreover, by which so great a length of façade could be properly seen from so narrow a street.

4. The proper relation of the heights of the several rooms to their horizontal dimensions was secured by the interpolation of a partial mezzanine. The want of some such expedient for harmonising the dimensions of large rooms and small rooms *en suite* is severely felt at the new Foreign Office, and due warning was taken from this and similar public buildings. That this expedient did not necessarily add greatly to the height of the building is shown by the fact that the height to the parapet is precisely the same in this and in the selected design.

5. By the introduction of large glazed halls at the interior angles of the courtyard, the principle of block corridors on a modified scale was introduced, the areas being glazed and utilised as magnificent entrances to the Admiralty and War Office respectively, and they also enabled us to provide congeries of rooms for subordinate officials in the immediate neighbourhood of their chiefs.

6. Provision was made for the occasional increase of the clerical staff by giving all the rooms a larger area than required by schedule, so that instead of there being a number of normally unoccupied rooms, getting damp and stuffy from disuse, every room would accommodate, when needed, a few additional clerks, 'more room rather than more rooms' being the principle adopted throughout.

A distinctive feature of the plan is the pro-

vision of a central Council-chamber, in which the chiefs of the two great departments of the State and their advisers could confer, where in time of war maps and models could be exhibited, and where, by special telegraph arrangements, the latest movements of troops and war vessels in any part of the world could be recorded. The various branches connected with the 'Intelligence' Departments of both services were accommodated in the neighbourhood of this chamber. In peace time it would be available for lectures. Beneath it a separate entrance to the building enabled officers of the army and navy to have access to the Adjutant-General and Quarter-Master-General's Departments on the one side and the naval lords on the other, without threading their way through the Civil departments of the building; and could also have been used for lectures. Great care was taken to remove the printing establishment and the kitchens and their accessories to the topmost floors, for the sake of quiet to the Office generally, and for immunity from dinner smells.

So far as possible, the traditions of the old offices were preserved. The fittings of the old Admiralty Board-room, designed by Sir C. Wren and executed by Grinling Gibbons, were intended to be re-used in the new Board-room. The justly-admired screen, enclosing the present Admiralty forecourt, was to have been re-erected across the new Admiralty court facing Spring-gardens, and forming a picturesque termination to the Mall, and the excellent statue of Lord Herbert was intended to occupy in the forecourt of the new War Office a similar position to that which it now holds in the present one.

These notes will, it is hoped, show the care and thoroughness with which the whole problem was treated.

It only remains to speak of the style of architecture selected. It was desirable that the building should be dignified and discreetly ornate as befitting its imperial purpose. It was necessary for the proper accommodation of a multitude of varied requirements that the style adopted should not only possess the reserve and gravity of the Classic manner, but also something of the flexibility of Gothic design. The union of the two was thought to be found in the early and pure phase of Renaissance, the details of which we had made our especial study. It had at least the advantage of combining dignity with picturesqueness; and, moreover, both the constructive and decorative schemes were thoroughly sound and rational. Not a single feature was constructed as mere ornament, while the ornament, sparingly applied, was intended to be throughout original in design, appropriate, relevant, and of high excellence as art."

We may add a word of appreciation on our own part of a quality which is certainly not shown in all the designs, viz., the feeling for the artistic as well as the practical element in the plan which this design shows. The interior laying out of the quadrangle lends itself to effect as well as to arrangement, and the three large glazed courts would have formed very striking architectural centres in the interior cosmogony of the building, besides serving their practical purpose as centres of meeting for the internal traffic of the building.

#### "THE GRANGE," BROOK GREEN.

The illustration of the above shows the garden front of Mr. Henry Irving's house at Brook Green,—an old one recently altered and added to under the direction of Mr. Fred. Pinches. Whilst the work was going on, evidences of former alterations, dating probably in the early part of George II.'s reign, were brought to light. Owing to the method adopted of adding a wing on each side of the main and older portion of the house, access to the rooms in the east wing can only be had by going through other rooms. The service accommodation being inadequate, it was found necessary to build out-offices at the back, and also to provide a servants' common room. By removing a partition, and building out a bay window, the entrance-hall has been considerably enlarged, and the old staircase opened up to view. Sundry alterations have been made in removing partitions, enlarging rooms, providing bath-rooms, &c., on the first and second floors. With the exception of adding a porch and bow-window, the front which faces Brook Green has been but very little altered. Unfortunately, owing to damp, it was found necessary to remove the ivy which had grown nearly all over it. An enclosure-wall and carriage-gates have been added, in place of the open railing which formerly existed.

Mr. Irving's desire being to retain the unpretentious character of the house, care has been taken not to introduce any feature likely to give it the appearance in any way of a mansion.

The garden attached to the house is nearly an acre in extent, with a large lawn, and containing some good old trees. Here Mr. Irving is able to get the rest and fresh air which the demands of his profession render so necessary.

The works were carried out by Messrs. Stimpson & Co., under the personal direction of the architect.

#### ST. GEORGES DE BOSCHERVILLE: ENTRANCE TO CHAPTER-HOUSE.

The Abbey Church of which this forms a part is about six miles from Rouen, and is one of the most perfect examples of Norman architecture existing. It will be found more fully illustrated in Mr. Galsworthy Davis's "Architectural Studies in France." A note as to the origin of the church will be found on the drawing.

#### OLD CASTLES AND PALACES IN WALES.

We give views of the remains of Manorbey Castle, the keep at Pembroke, the interior of the bishop's palace at St. David's, and the gateway of the episcopal palace at Llanhaden, which were among the buildings visited by the British Archaeological Association last week. Some particulars of the remains will be found in our account of the Association's Congress at Tenby (see p. 350 of this week's Builder).

**Lavatory Apparatus.**—Mr. H. R. Batson has made provisional application for a patent for improved lavatory apparatus for industrial schools and similar institutions.

### THE GERMAN ARCHITECTS' AND ENGINEERS' CONGRESS.

This annual gathering has just been held, under favourable circumstances, at Stuttgart. The usual preliminary meeting of delegates took place on the 22nd ult., and was attended by forty representatives from eighteen societies in various parts of Germany.

The subject of contracts between employers and professional men was dealt with, and, after much discussion, it was resolved not to act upon the suggestion that the settlement of the question should be postponed until the issue of the Imperial code now in preparation. Consequently, the rules will be finally drawn up within the next few months, after which they will be published. The question of normal regulations for the delivery of iron structures had given rise to preliminary expressions of opinion by fifteen societies, which, in conjunction with the reports of the Association of German Engineers and the Association of German Iron Manufacturers, afforded considerable matter for discussion. The Aix-la-Chapelle Society had, consequently, a short time ago suggested the examination and summarising of these various opinions by a joint commission of the technical bodies interested. The assembly resolved upon recommending the portion of the rules of general application, and upon inviting expressions of opinion from the various local societies. The whole subject will then come before next year's congress for final discussion and settlement. Professor Fränkel, Herr Gerber, Herr Köpke, Professor Häselar, Dr. Schäfer, Professor Winkler, and Professor Weyrauch, are entrusted with the revision of the material now available.

During the last year a collection has been organised for the erection at Dresden of a Semper Monument. The total cost is estimated at 1,000,000, and about a quarter of that sum has now been obtained. In order to second the efforts of the local societies it was resolved at the present Congress to invite subscriptions from bodies of a more general character, such as art societies, &c., in Germany, Austria, and Switzerland.

The Mid-Rhenish Society having brought to a close its researches on the subject of "Typical Forms of Dwelling-houses," the further treatment of the subject was undertaken by the Hanover Society at its own request, with a view to the publication of the materials now ready and still to be obtained. Arrangements were also made as to the publication of the valuable information now collected as to the use of glazed bricks and statistics of building. The business proceedings concluded with the selection of Dresden for next year's meeting, and of Frankfurt for the general assembly of 1886.

The first general meeting was opened by a congratulatory address, in which Herr Von Schlierholz welcomed the assembled visitors, and referred to the progress made by Stuttgart since 1858, when the Architects' and Engineers' Congress last met in that city. After Dr. Holbrecht, of Berlin, had invited the assembly to express their feelings of respect towards the Royal family of Wurtemberg, Herr Adolf Bötticher, of Berlin, gave an address dealing with the most recent investigations regarding the history of building in ancient times. The speaker was particularly qualified for such a task, having personally co-operated in the excavations at Olympia as the official representative of the German Government. His remarks bore special reference to the work done within the last ten years at Tyrins, Mycena, Olympia, Pergamon, Delos, and Pompeii. Mycena and Tyrins were discovered by Schliemann in 1876, and maps of both localities served to elucidate the detailed references made. A plan was likewise shown which represented the interesting palace at Tyrins, which was only discovered this year, and which is being treated by Schliemann in a descriptive work now in preparation. With reference to the Lions' Gate at Mycena, the speaker proceeded to deal with the most recent opinions as to the origin of Doric columns, which he traced back to Egypt, attributing their source to wood architecture, of which various specimens came to light at Olympia. Thus the Herion consisted for the greater part of wood in the oldest times, its wooden columns having been subsequently exchanged for stone pillars. From this and other examples, the speaker argued that the oldest forms of Grecian houses and temples were composed of wood, at least in the upper portions. Reference was also

made to the work carried on by the French at Delos, which seems, however, to have possessed less architectural value than antiquarian interest. In the same manner, the excavations at Pergamon have been more important in their results as to sculpture than architecture. With regard to Pompeian discoveries, Herr Bötticher divided the architecture of that locality into five distinct periods, each characterised by stylistic and decorative peculiarities, which were illustrated by drawings and photographs.

Professor Hubert Stier, of Hanover, gave an interesting account of the German Renaissance, remarking that for half a century one past style has been utilised after another in new buildings, the result being a more intimate acquaintance with the history of architectural forms, and with their adaptation to practical uses. The speaker remarked that his father had incorporated the German Renaissance style into his classification of the subject as early as 1854, but the first incentive to its general adoption was given by the patriotic feelings which the events of 1870 and 1871 aroused throughout the German nation. The influence of the German Renaissance was not only felt in architecture, but also extended to furniture, tissues, weapons, metal work, and various other branches of artistic industry. The weak point of the style in question would, however, seem to be its deficiency in monumental character, and to this circumstance the speaker attributed the fact that in ecclesiastical architecture the Italian Renaissance has been the leading motif.

The testing of iron and various kindred points were dealt with by the engineering section, in which Professor Winkler delivered an interesting address. The new buildings and harbour alterations necessitated by the admission of Hamburg into the Zollverein formed the subject of Herr Meier's remarks, from which the assembly derived a comprehensive idea of the works in progress; the completion of which is expected to take place in 1889. Dr. Dietrich's paper on "Electrical Transmission of Force" was likewise well received.

Special interest attached to the address of Herr Lange on "Building in the United States," the remarks of the speaker being founded upon personal observations made in his capacity of technical attaché to the German Embassy at Washington. Various details were given as to the Government departments for engineering and building matters which are respectively under the control of the Ministers for War and Finance. The country is divided into districts each of which is under the supervision of a chief engineer. The sum annually voted for engineering works is 3,000,000, to 3,500,000, of which sum about one quarter is being devoted to the regulation of the Mississippi. The building department undertakes the erection of excise offices, post-offices, judicial buildings, naval hospitals, &c., and spends about 1,000,000 annually. These buildings are very solidly constructed, and are fireproof, but their cost is relatively high. In some of the larger cities the post-offices are said to cost from 1,000,000, to 1,250,000, each, and the New York Post-office even as much as 2,000,000. As to dwelling-houses, the speaker alluded to wooden structures as still predominating in the country and in small towns, while in larger cities the external walls at least are obliged to be of brick. Amongst the special features of the internal arrangements is the frequency of passenger-lifts. Americans are fond of painting the outsides of their houses more often than is customary in Europe, the general aspect of the cities being thereby rendered cheerful. Ecclesiastical architecture is not in a satisfactory condition, according to Herr Lange's opinion; it being usual to build small churches, and the habit of placing them on an ordinary street building site was not conducive to their effect, on account of the proximity of other structures. The manner in which many architectural details are carried out is explained by the fact that wood, iron, zinc, and other materials are used in portions of buildings which bear the character of stone as to form and treatment. Some interesting facts were given as to the Tabernacle of the Mormons at Salt Lake city, and their temple, which has been in progress since 1853, and which (contrary to reports which have circulated) has nothing extraordinary in its architecture, measurements, or cost. It has now attained a height of about 90 ft. Special commendation was given to the park-like manner in which cemeteries are laid out. Finally, Herr Lange

attributed the simplicity and boldness of American buildings to the indulgent nature of public criticism, on which architects can usually depend. Americans know that by increasing the responsibility of architects, their courage and inventive faculties must be affected, and that when such is the case the public really suffer a loss.

Dr. Wolpert treated a subject of general sanitary interest in his address upon "The Testing and Improvement of the Air in Dwelling-rooms and Assembly-rooms, as to Temperature, Moisture, and Purity." He explained that for living-rooms and school-rooms a normal temperature of 64° to 68° Fahr. was desirable, while a slightly lower temperature was permissible in bedrooms. At the same time he disputed the advantages sometimes attributed to sleeping in cold rooms. The normal temperature alluded to should be uniform throughout a room, there being no important difference allowable between the lower and higher portions. Various methods of arriving at this uniformity were referred to in detail.

With a view to preparing for the intended visit to the cathedral at Ulm, Herr Von Egle gave the assembly some details, both historical and technical, as to this noted work and the projects for the restoration of the tower and other portions. Works of this nature have been progressing to some extent since 1840. The success of the efforts made to raise money for the completion of the restoration has been so encouraging that it is hoped to terminate it within six years. It is contemplated to utilise as far as possible at Ulm the services of some skilled assistants who are now free on account of the completion of work at Cologne. Herr Lange gave an account of the efforts now being made for the preservation of the Bathans at Augsburg, and a resolution was agreed to in which the Congress expressed its approval of the scheme.

The excursions made were well attended, and proved enjoyable adjuncts to the programme. The cloisters of Bebenhausen were specially interesting from an architectural point of view, and, under the guidance of Herr Beyer and Herr Schlierholz, their various points were seen by the party under circumstances favourable to their appreciation. An exhibition of architectural drawings was held at which the ten prize designs for the Berlin Museum were shown in conjunction with other works of interest and artistic value.

In connexion with the assembly various other special exhibitions were organised, amongst which that of the Society of Industrial Art calls for particular mention. The objects shown included a vase in *rouge antique* marble, a mirror with table and a sideboard in ebony. A Japanese fire-screen and various other decorative objects are spoken of with commendation by the local press. The social festivities were on the usual scale of completeness, and arrangements were made for the visitors inspecting the various new buildings in Stuttgart under the guidance of local architects and officials. The banquet of August 26th was attended by 300 guests, and was thoroughly successful in every respect. The attendance at the Congress numbered 349.

### DOINGS IN DUBLIN: BUILDING AND SANITARY.

THERE are a number of small building operations, but no public buildings of importance, at present proceeding in Dublin proper, but it is anticipated that the new Science and Art Museum will be commenced without any further delay, as Messrs. Deane & Son's plans have been finally decided upon by the Government. The history and circumstances of this project, which has been hanging fire for the last sixteen years, form a very chequered chapter in official correspondence and architectural competition, and if the whole story of ways, means, and motives were told concerning it, some singular and startling revelations would be made. The architectural features of the new building have been already described in these pages. The site is a good one, in proximity to Leinster House; the materials will be chiefly native, and—a not unimportant consideration,—the work will afford employment to a considerable number of building artisans, who need a long spell of constant employment to make up for bad times.

On the borders of the city, the building of the

new Catholic Asylum has been commenced. The structure, which is intended for the male blind, is situated on an elevation beside a mansion known as the Castle of Drumcondra, lately the residence of Lord James Butler. Very few of the old stones of the original castle of Drumcondra,—a building the scene of some important historical transactions in the reign of Queen Elizabeth,—remain. An inscription exists which tells of the building of the old castle in 1560, and it was here the famous Irish chief, Hugh O'Neil, was married to Mahel Bagnell, the castle being then the residence of Sir William Warren. The new asylum at Drumcondra will be about 218 ft. long, and three stories in height. The style will be Gothic, and the materials of red brick, relieved by hands of dark blue brick, with stone dressings. The ground-floor comprises a refectory, 70 ft. by 26 ft.; school-room, 50 ft. by 26 ft.; class-room, 26 ft. by 26 ft.; along with printing-room, music-rooms, kitchen, stores, &c. Four dormitories will be provided on the two upper floors, each 70 ft. by 26 ft., including lavatories, bath-rooms, &c., with four cells for the Brothers in charge. The heights respectively of the floors from the ground upwards are 16 ft., 15 ft., and 14 ft. A top there will be an attic, to be utilised for storage and work rooms. The architect is Mr. W. H. Byrne, of Dublin.

A few miles south of the city, at Stillorgan, a new Convalescent Home and Hospital is approaching completion for a religious brotherhood known as the "St. John of God." The new building will cost between 6,000l. and 7,000l., the whole of the funds being subscribed by the mother house of the order at Lyons. The new structure is severely plain, and destitute of ornamental details, with a frontage of 135 ft. The ground-floor comprises a large hall, extending the length of the building. On the right-hand side of the hall are lavatories, two refectories, prior's room, and reception-room; and on the left are bath-rooms, apothecary's hall, and kitchen. Hereafter it is intended to prolong the hall, with portico to meet the monastic house. The second and third floors have halls similar to that of the ground floor, with bedrooms on each side. It is contemplated also to provide a chapel when funds are forthcoming.

On the site of a large abbey, which was founded at Tallaght, near Dublin, in the twelfth century, and subsequently converted into the summer residence of the Archbishops of Dublin, a new Dominican church and convent are being built. The new buildings include the church and cloisters, the west wing, with the completion and alteration of the east wing. Some years back the west wing was commenced, from the designs of the late Mr. J. J. McCarthy, R.H.A. As the locality is very thinly populated, the new church will be mostly used for conventual purposes. The facing stone is black local limestone, known as "calp," with white limestone dressings. The walls of the nave will be lined with brick, while those of the chancel and choir will have Bath stone. In accordance with the usage in Dominican churches, the choir will be situated at the back of the high altar, and will comprise fifty stalls. Over the sacristy a night choir is provided, 42 ft. by 22 ft., with arched opening into the day choir. The chancel and choir will show groined ceilings in oak, resting on trefoil corbelled shafts. The nave will have a wagon-headed ceiling, with arched principals. The architect is Mr. George C. Ashlin, and the contractors Messrs. Meade & Son, both of the city.

The long-proposed and urgently-needed public baths and washhouses are in course of erection in Tara-street, the site being a portion of the land taken a considerable time ago by the Corporation for the purpose of making a new approach from Great Brunswick-street to the swivel bridge over the Liffey. A loan was obtained from the Treasury, amounting to 4,700l. The plan omits a swimming-bath,—a rather serious omission, considering the wants of the city; but we find by a resolution passed within the last few days in the Corporation,—“That it be an instruction to the Public Health Committee to provide one or more swimming-baths as a department of the public baths and washhouses in course of erection.” This, it seems, will need another application to the Treasury. Why proceed with a plan omitting an important requirement in a poor neighbourhood, and after the buildings have been commenced, begin preparing plans for the always necessary

swimming-baths? The new buildings will comprise a washhouse, 55 ft. long by 40 ft. wide, accommodating about twenty persons; a drying closet, a private washhouse for the use of the establishment; eight reclining baths for men and four for women. There will also be offices, manager's residence, store and other rooms. The walls are of red King's Court brick, the front exhibiting some moulded and ornamental treatment in the same material. The plans are by the City Architect, Mr. J. Freeman.

Somewhat large and imposing business premises are in course of erection in Great Brunswick-street, for Messrs. T. McKenzie & Sons, intended for their new seed and agricultural implement warehouse. The frontage extends about 180 ft., and there will be a conspicuous entrance-porch in centre, with a series of six windows on each side on the ground floor, with dropped arch-heads. The walls will be composed mostly of King's Court bricks with Portland stone dressings and a granite string-course between ground and second story. The height of floors from bottom upwards will range respectively 15 ft., 14 ft., and 12 ft., and they will rest on iron girders supported by columns. On the left-hand side of large ground-floor will be the machinery and workshops, and on the right the seed stores. The architect is Mr. J. O'Callaghan, the builder Mr. Donovan, and the clerk of works Mr. Robert Parker. The iron work is being supplied by Messrs. Courtney & Stephens.

Among the provincial ecclesiastical churches worthy of note is that of the new church of the Trappist Brothers, at Mount St. Joseph, near Roscrea. The building is in the Early English style, with a mixture of Norman in the interior. Ornamentation was avoided as far as possible, in accordance with the instructions given, as the Order is one of those in connection with which austerity of life and surroundings is strictly enjoined. The entire length of building is 225 ft., transept 90 ft., nave 30 ft., and side aisle 15 ft. wide; the height to apex of roof is 75 ft. Tower and spire are yet unbuilt, but provision is made for them on the south side of the transept. When finished the spire will be 220 ft. For about twelve bays in length the west end of the church is separated by a rood screen from the monastic portion, and it is to be used as a secular church. The high altar is composed of marble and Caen stone. The architect is Mr. W. H. Beardwood, of Duhlin, and the works were principally carried out under the supervision of the lay brothers. The contract of the carpentry work was carried out by Mr. Mahler, of Roscrea. The altars were executed by Messrs. Early & Powell and Mr. W. P. O'Neil respectively, of Duhlin. The church and monastery stand in a park of 375 acres, which was presented to the Brothers by Connt Moore, M.P. The new church has cost 8,000l.

The sanitary condition of Dublin, both north and south, still calls for increased vigilance. Although the Corporation has done some commendable work within the last two or three years, much, indeed still remains to be accomplished. The state of the river Liffey, running through the centre of the city, is still abominable, and the stench from it during the last three months has been at times intolerable. Plans have been proposed for mitigating the almost unbearable nuisance, and the Corporation again and again return to a driftless debate upon the subject, but still little or nothing is done. In fact, the only practical remedy is the one we pointed out several years ago,—a parallel system of main drainage on each side of the river, with intercepting sewers. This system was adopted in the scheme of main drainage promoted by the Corporation some years ago, but the project at that time met with fierce opposition on the part of the citizens, on account of the great cost of the scheme, and it being out of proportion with the financial circumstances of the city at that time. The materials of sewer construction, bricks, iron, cement, &c., were, too, very high in price at the period; and these, with other reasons which need not be alluded to here, contributed to give the first main drainage project its quietus. The scheme is being revived again, and, subject to necessary modifications, it no doubt could be successfully carried through. The points of outfall for the sewage of the city, if it is resolved to run it to sea, are questions of some difficulty, on account of marine townships and watering places stretch-

ing for some miles north and south of the harbour and bay. Sewage utilisation processes have not, as a rule, proved profitable, and they have been in some instances ruinously expensive. Public health, however, is a paramount consideration, and money expended in maintaining it is money well laid out, and the cost must not be too closely scrutinised from a mere commercial point of view. In every system of main drainage dealing with the sewage matter of cities and towns the solid portion should be intercepted, and nothing but the effluent water passed into the mouth of our harbours. The present condition of the Liffey, with its many foul tributaries pouring hourly their volumes of filth into the main stream is terrible to contemplate. It is no argument to point to residents who have lived on the banks of the river for years, and to say they have not felt one whit the worse through such residence. Who can tell? It is the sheerest folly to think that any human being can live constantly for years over an elongated cesspool and continue in good health. Clergymen of every denomination, doctors, and lawyers, visitors, and disinterested folk, who can have no object in throwing blame, directly or indirectly, on the Corporation of Dublin, all are loud in proclaiming the Liffey nuisance and appealing for its abatement.

Another great evil that at present obtains in Dublin, and which has obtained for long years, is the dreadful state of many of the old tenement dwellings, wherein are housed thousands of the working classes, and the great majority of the very poorest of their kind. Many of these houses were once private mansions occupied by single families, but from six to a dozen families now find refuge in them, with sanitary accommodation only adequate for one or two families. The Public Health Committee of the Corporation have of late carried out some judicious and urgently-needed arrangements in respect to a large number of these tenement houses; but the number of these dwellings is almost legion, and the state of hundreds of them still as bad as can be. We have entered the dirty yards of several of them, ascended the filthy and dilapidated staircases, and examined scores of the rooms. We will not draw fancy pictures, or exaggerate, but will simply say that many, very many, of these houses in streets north and south of the Liffey are unfit for human creatures to live in. Some poor tenants are, to be sure, very dirty, and miserably poor into the bargain; but apart from this there are a number of unprincipled landlords who own this class of property, and fatten on the rents it yields, who should receive little mercy at the hands of the sanitary authorities. These landlords ought to be made to keep their tenement property in a habitable condition, and failing them, the Corporation should take action, and, if necessary, demolish these rookeries of disease. One of the great wants of Dublin is the provision of houses at low rents suited to the needs of the very poor. Blocks of artisans' dwellings have been provided by companies, and to some extent they have supplied a want; but several of the rooms of the dwellings are occupied by a class of persons one would expect to find elsewhere. These dwellings do not meet the wants of the very poor, nor are the companies who built them particularly concerned in providing rooms for any but the better class of artisans or others who can afford to pay certain rents. Acting on the commercial principle, perhaps they are not to blame for their resolves, only that no credit should be taken on the score of benevolence and philanthropy where they exist not.

We have something more to say on sanitary questions in relation to sundry other matters in Dublin, which we must defer for another article.

**Brighton.**—About a year ago the building committee of the Congregational Church in Queen's-square, Brighton, received a report from their architect, Mr. Arthur Loader, that the Caen stone with which it was encased was in such a state of rapid decay that it requires immediate attention. It was decided to reconstruct with Corsham Down stone, and the work is now in rapid progress, the contractor being Mr. J. T. Chappell, of Lupus-street, London, under schedule, and under the immediate superintendence of Mr. Loader, architect, of Brighton; the stone being selected from the quarries of Messrs. Pictor, of Bath.

**ILLUSTRATIONS OF RECENT PATENTS.**  
 5,845, Improvements in Chimney-Pots. Edwin Samuel Romilly, London.

This invention is designed to improve the chimney-pots of earthenware or metal, such as are ordinarily used for the terminal of chimneys. The upward draught of smoke and heated air is promoted, and by a peculiar arrangement down-draughts are entirely prevented. The terminal is fixed in the ordinary way. The upper end of the pipe or pot is made conical, the smallest end uppermost, and round it a second tubular pipe, slightly conical, is fixed, the lower end of which either forms a part of the inner pipe or rests and is fixed on a ledge or flange formed round the inner pot at or below the point where the conical part of the latter commences. An annular space is thus formed round the conical part of the inner part of gradually increasing area as it rises, and into the lower part of this space openings are made through the outer pot,—these being preferred of a triangular shape, as shown on the drawings. Fig. 1 shows a vertical section,

Fig. 2 a horizontal section, and Fig. 3 is an elevation of the improved chimney pot: a is the inner pot conical at its upper part; b is the outer pot or tube, the two pots being shown made in one piece; and c is the annular space between them increasing in area at its upper end; d the openings through the outer pot, b, into the lower part of the space c.

The air or wind blowing from any direction against the chimney-pot enters the apertures upon the same side into the lower part of the annular space, and is there directed upwards, as shown by the arrows round the inner conical pot a, inducing an upward current through the latter and up the outer pot b, thus accelerating the upward draught in the chimney. Should the escape of the smoke be temporarily obstructed by currents of wind, or a downward draught caused, the smoke will escape through the apertures rather than down the conical pot a. Particular attention has been given by the patentee to the points in the ordinary chimney-pot. The improved form may be made in suitable material,—terracotta, earthenware, or metal,—and may be ornamented. Fig. 4 shows a form wherein the openings

are so arranged as to be unnoticeable at a little distance. Several alternate forms are suggested, and in fig. 6 the pipes are shown of metal, the inner one being riveted or bolted to the outer one, b. These chimney terminals are also adapted to the chimneys of marine or other boilers, furnaces, &c.

**711. Improvements in Fasteners for Window-sashes.** George Bisley, Rotherhithe.  
 The object of this invention is to secure a close and secure joint, such a one as will close the windows fast, and prevent rattle, and furnish additional security by being difficult to interfere with

from the outside. In the drawings, fig. 1 is the plan, fig. 2 front, and fig. 3 a side elevation, and by

a comparison of these drawings, the action of the window lock will be easily understood.

A and B are the two meeting-rails of the sash-frame G. The improvements consist of a pin, stud, or hook (C), fixed on rail A, provided with a recess or shoulder, as shown, into or over which slides or falls the eye or equivalent of a lever E, resting on the other sash-rail, one end of such lever E abutting against the sash-frame, as shown; the other formed with a screwed eye or nut, and operated by a screw bolt, or pin, F, passing through the said eye, and working in a slot, D, of the frame or stand, D, secured on the sash-rail, B. The screwed bolt being operated from one rail, brings the long end of the lever, E, against the sash-frame bead, its eye being over the notch of the hooked pin, C, on the opposite rail, so that the sashes, being previously in place, with their meeting-rails in position, they are firmly secured, and held steadily together. When it is desired to open the sash-frames, the lever, E, is loosened by the screw, F, and its eye removed from the hooked pin, C, when the lever assumes the position shown in the plan by the dotted lines in fig. 1. The lever may be supported on a pin or knob, K, which is provided on both sides, so as to render the fastening suitable for use at either side of the sash.

**8,245, Manufacture of Wall Paper.** J. A. Turner, West Gorton.

This invention has for its object the manufacture of wall-papers that shall have a waterproof back surface, so as to withstand the action of moisture in the walls, and that shall also be of sufficient strength and substance to enable them to be hung up without being cemented to the wall surface. For this purpose the wall-paper, after it has been printed upon, is coated at the back with a suitable waterproof cementitious substance, such as vegetable pitches. To such prepared surface is applied a sheet or backing of other paper or woven fabric, such as cotton, cloth, or canvas,—the paper or cloth being applied to the surface in any suitable manner, but by preference by passing the same while hot between pressing rollers, both the wall-paper and the backing being drawn in continuous lengths from rolls on which they are wound. In some cases the cementitious matter is applied to the paper or cloth backing, or to the backing only. In employing embossed wall-papers for the purpose of this invention the back surfaces of the embossed parts may be filled in flush with the cementitious substance, whereby the front surfaces of such parts will be protected against injury.

**INDUSTRIAL REMUNERATION CONFERENCE.**

THE following is the more detailed statement of the views of the Committee in regard to this proposed Conference, referred to in our "Notes" (p. 348, ante):—

"The Committee are desirous of carrying out the objects of the trust by obtaining the fullest information possible as to the actual working of our present industrial system.

They are anxious to procure from all available sources accurate information, so far as possible in a statistical form, as to the money wages, command of the comforts of life, health, savings, and general condition of those engaged in different industrial employments within the country, and they would invite all persons disposed to assist them to communicate any information and any suggestions bearing on these

points, to the Rev. W. Cunningham, Trinity College, Hon. Sec., before the end of October, 1884.

They also intend to organise a Conference, in which it is hoped that artisans and co-operators will be largely represented, as well as employers of labour and persons interested in the study of social problems; at this Conference such points as the following will be brought forward for discussion:—

1. The existing system by which the products of industry are distributed.
2. Do any artificial and remediable causes influence prejudicially?
  - (a) The stability of industrial employment?
  - (b) The steadiness of rates of wages?
  - (c) The well-being of the working classes?
3. How far, in what manner, and by what means would the more general distribution of capital or the State-direction of capital, contribute, or not contribute, to
  - (a) An increase in the products of industry?
  - (b) The well-being of the classes dependent upon the use of capital? (Co-operative production, profit-sharing, &c.)
4. How far, in what manner, and by what means would (1) a more general ownership of land (peasant proprietorship), or of an interest in land (tenant right); or (2) the State ownership of land conduce, or not conduce, to
  - (a) The increased production of wealth?
  - (b) The welfare of the classes affected by the change?
5. Does existing legislation, or the incidence of existing legislation, affect prejudicially
  - (a) The production of industrial wealth?
  - (b) The well-being of the classes engaged in the production?
  - (c) The natural or the most beneficial distribution of the accumulating products of national industry (including Succession Duties, Friendly Societies, Insurance, &c.)?
 Can any of these be promoted by changes in existing legislation or taxation?

They intend to arrange for one or more papers on each subject, and addresses from one or more selected speakers, and hope to have also short speeches from those members of the Conference who have special knowledge on any particular point raised in the papers.

Trade societies, or other bodies desiring to be represented by delegates at the proposed Conference in January, 1885, and authors who may desire to contribute papers, or to furnish statistical information bearing on these subjects, are requested to communicate with the Rev. W. Cunningham, Trinity College, Cambridge, before November 1st, 1884.

**IMPROVEMENTS IN STOCKHOLM.**

FROM the office of the Grand Governor at Stockholm a report has been issued on recent improvements effected in that city. In the first place, as to the Northern Ethnological Museum, it is pointed out that this valuable and interesting collection has hitherto been located in the principal street of Stockholm, where, for want of a suitable building for its reception, it has been divided amongst several small low houses adjoining each other. A grant of land for the erection of a permanent museum has been made by the Crown in the Royal Park, called Djurgarden, just outside the town, and five prizes have been offered for competition amongst native and foreign architects, who have thus been encouraged to send in plans. The first prize (1,530 kronor) has been taken by a Karlsruhe architect, an extra prize of 1,000 kronor being awarded to one at Dusseldorf. The museum already possesses a building fund of 100,000 kronor, but much more is required for the handsome edifice which it is intended to erect, and public appeals are being made for contributions.

In regard to general improvements in Stockholm, it may be noted that in 1876 the total length of the streets of that city was 38,420 Swedish feet; in 1881 it had increased to 380,878 ft., or over sixty-five English miles, and considerable sums have been expended yearly in repairing old streets. The result has been that unsightly and disagreeable cobble paving stones have nearly disappeared, and have been replaced either by cut stones or by Macadam and asphalt. The cleaning of the streets is, moreover, greatly facilitated by these changes, and a general improvement in their appearance is already discernible. The water supply has also increased considerably since 1876; the pipes have been lengthened from about forty miles to sixty miles, and two new reservoirs have been erected in the north of the town, and hold very large quantities of

water. The drainage of Stockholm has likewise undergone great improvement. Not long ago all the liquid sewerage of the town was carried away by open gutters; the streets became consequently impregnated with impurities, and the air filled with poisonous evaporations during winter months; the gutters, moreover, froze, and great expense had to be incurred in keeping them free of ice. After the improvements introduced in the Stockholm water-works, plans have been made for adopting the self-cleansing system of underground drainage, through glazed earthenware pipes.

The progress of these works has been very slow, as nearly the whole of Stockholm is built upon solid rock, but most of the principal, and all the new streets of the town are drained on the new system. Formerly the landlords were responsible for the scavenging of those parts of the streets which were opposite their houses, but this old custom has been entirely done away with in the chief quarters of the town since the formation of a scavenging company, and the cleanliness of the streets has yearly improved. The town has also been considerably embellished during recent years by improvements in the public squares and gardens. Those especially worthy of notice are the gardens of Humlegården, which now form one of the prettiest and most agreeable quarters of the town. They were formerly used as royal pleasure gardens, and were not open to the public until 1820. The grounds then fell into disorder, and became the haunt of low and disreputable people. In 1870 the municipality, after repeated appeals, succeeding in renting the ground from the Crown, and in 1877 they were presented to the city by the King. Since then Humlegården has undergone extraordinary changes, and is now a great ornament to the town, and is situated in the centre of the new quarter which has sprung up within the last ten or twelve years.

#### THE DOME OF ST. PAUL'S.

Sir,—No one, I think, can contemplate the dome of St. Paul's at the present moment without concurring in your opinion that Thornhill's work is, in the main, the proper thing: \* it is simple and grand in its arrangement, and hits the *via media* between the project of an open empyrean flecked with clouds and angels, setting no limits to a dome as an architectural feature, and the other extreme of cutting it up into panels and plaques. There can be no doubt that architectonic decoration,—the application of art to public buildings,—is a *métier* in itself over and above that knowledge and technical skill essential to the success of a painter of easel pictures. Thornhill had had considerable experience in that kind of work, although his art was by no means of transcendent quality. Moreover, as Wren's intimate and colleague, his designs for the dome must have had Wren's approval and sanction. This is an important consideration. There is another point, too, that ought not to be overlooked, *viz.*, that both the architect and the painter would, if time had permitted it, have introduced colour into the decoration of the dome. It appears to me, therefore, that the right mode of bringing the decoration of this portion of the cathedral to completion would be to translate Thornhill's figure-subjects into colour, and to introduce gold grounds for the open sky spaces in those designs. This treatment would, in its results, produce a magnificent effect,—an effect that, I would venture to affirm, would be unrivalled by the decorations of any other church in Christendom. In graciously and modestly consenting to be yoked to Wren's car, in the present experiments, the two eminent painters have manifestly done themselves an injustice. They would have succeeded perfectly, in all probability, if they had been untrammelled and left free scope.

There is another matter with respect to the embellishment of the interior of St. Paul's that requires reconsidering. It is questionable whether that extensive picking-in of mouldings and other ornaments is compatible with the grand style of ecclesiastical decoration, more especially when pictorial art is to be

\* We did not quite say that; we said that of the three designs now visible it appeared to us the best in general character for that kind of treatment,—*i.e.*, dividing the dome by vertical divisions. This, of course, only in regard to general design; we neither want Thornhill's detail nor his dingy monochrome tone.—Ed.

extensively adopted. In this case gold should only be used in large spaces, as grounds. The picking-in method is more appropriate to palatial decoration. Neither should the native stonework of the edifice be too much overlaid with colour and ornamentation, as its calm grey would form an admirable setting to the pictorial decorations. In the best works of Italian mural art the great painters had a keen sense of the value of plain spaces,—of intervals of repose.

W. CAVE THOMAS.

#### PARTY WALL.

Sir,—May I trouble you with the following question? A row of houses was built some thirty years ago on lease, having at the back a boundary-wall delineated on plan in the lease. A year or two afterwards the vacant land at the back was also built on, the above wall forming the boundary of the second owner's property. Leaseholder No. 1 desires to protect what he considers his wall from trespass, by adding a ridge to the flat top of the wall, but No. 2 objects that he has a right in the wall, and will remove anything that No. 1 may put upon it, although what was intended would prevent decay of the wall as well as the trespass complained of. To whom does the wall belong? Or can No. 2 interfere with the supposed right of No. 1 to do as he pleases?

#### A LEASEHOLDER.

\* \* No. 1 can make any alterations in the wall that are in conformity with the Building Act, subject only to obligation to make good any damage done to the adjoining owner's premises during the alterations.

#### RESPONSIBILITY FOR ACCIDENTS TO WORKMEN.

Sir,—Can any of your correspondents say who is responsible for accidents to workmen? An employer (not a builder or contractor) providing scaffolding and material, or a contractor for labour to brickwork at per rod? SURVEYOR.

#### PROVINCIAL NEWS.

*Berkhamstead.*—The new building lately erected from the designs of Messrs. Batterby & Huxley, architects, of Berkhamstead and John-street, Bedford-row, London, for the London and County Banking Company (Limited), has been opened for business. The work was carried out by Messrs. Taylor & Grist, builders, Aylesbury.

*King's Lynn.*—The King's Lynn Board of Guardians have resolved to take immediate steps to carry out entirely new drainage and sanitary arrangements for their workhouse, as designed by Mr. E. G. Mawbey, the borough engineer, the plans having received the approval of the Local Government Board. The system of drainage is, as far as possible, provided with means of inspection, ventilation, and automatic flushing.

*Nottingham.*—A new reservoir at Mapperley Plains, in connexion with the water supply of Nottingham and surrounding district, has recently been opened. Its interior measurement is 150 ft. by 150 ft., and it will hold about 1,500,000 gallons of water. From the floor to the overflow is 13 ft. There are 212 supporting arches which divide the whole of the interior into fourteen bays and fourteen principal arches. The walls, which are 4 ft. 3 in. thick at the bottom and 2 ft. 3 in. thick at the top, are backed by a battering of clay, varying from 2 ft. 6 in. to 7 ft. 6 in. thick, so as to render the surroundings perfectly water-tight. The first 7 ft. from the foundation upwards is built in Portland cement mortar, and the whole of the remainder of the work, with the exception of the principal arches, is built in ground hydraulic mortar. The floor is composed of concrete, 9 in. thick, and underneath this is 15 in. of clay on the top of the virgin foundation. The surface of the concrete is finished off with a coating of pure cement, which really forms the floor of the reservoir. The arches of the reservoir are covered over with panned clay, 18 in. thick, and above this there is 12 in. of soil. There is a system of ventilation by means of fourteen specially manufactured ventilators, and by this means the air finds continued access to the surface of the water. To give an approximate estimate of the magnitude of the undertaking it may be mentioned that 1½ million of bricks have been used; from 250 to 300 men have been employed, and about 120 horses and carts have been in requisition. The work has been carried out under the direction of Mr. Tarbotton, chief engineer to the Corpora-

tion, and his assistant, Mr. Wharton, Mr. Phillips acting as clerk of the works. The contractor was Mr. T. Smart, of Trent Bridge, who completed his contract a month under the specified time. The bricks used are hand made, and are from the works of the Nottingham Patent Brick Company, and all the "springers" and "stops" are specially made bricks. The clay "puddle" has all been supplied from the best beds of Halwell clay. The reservoir, which has cost something less than 6,000*l.*, is intended to supply Carlton and Netherfield, and from its elevated position will improve the high level supply of the borough of Nottingham.

#### CHURCH BUILDING NEWS.

*Liverpool.*—St. Dunstan's Church, Edge Hill, is about to be commenced, from designs prepared by Mr. H. Roumieu Gough, F.R.I.B.A. The building will be a large and important one, affording accommodation for upwards of 800 worshippers, the estimated cost of the fabric being 8,000*l.*, while the furnishing, including altar and reredos, font, lectern, choir-seats, litany-desk, stained glass, organ, clock and bells, &c., most of which are already promised, will probably bring up the total cost to nearly 12,000*l.*

*London.*—The new church of St. Michael and All Angels, Stoke Newington Common, is being built on a fine site at the fork of the Fountayne and Northwold roads, facing Stoke Newington Common. The church as designed consists of nave, chancel, north and south aisles, morning chapel, organ-chamber, vestries, and lower and spire (the latter to be built at a future time). It is being built with red brick facings outside, and plastered inside, with red brick quoins, jambs, and arches. For the work usually executed in stone the Albion Concrete Company's cast concrete is being used, except for the columns, which are of Suismon's Bath stone. The church is to seat 750. The contract for the church, exclusive of tower and spire, is 5,242*l.* It is being built from the designs and under the superintendence of Mr. J. E. K. Cutts. The builders are Messrs. Holliday & Greenwood.

*Peel (Isle of Man).*—The new church at Peel, Isle of Man, was opened on the 25th ult. by the Archbishop of York, who spoke of the new building as being "possibly the future cathedral of the diocese." The church, which is cruciform in plan, consists of a nave, 96 ft. by 21 ft.; north and south aisles, 70 ft. by 12 ft.; north and south transepts, 32 ft. by 24 ft.; chancel aisle, 23 ft. by 17 ft.; chancel, 38 ft. by 21 ft.; organ-chamber, 18 ft. by 18 ft.; vestry, lavatory, meter-room, north and south porches, and tower. It is of the Early Decorated style of Gothic architecture, boldly and freely treated. The walls are composed of the Peel red stone, in courses of varied thicknesses, and the whole of the dressings to windows and doors, also the quoins, tracery, spire, and other dressed work are of red sandstone from the quarries of Mr. Guest, of Buncorn. The interior stonework is also of red Buncorn sandstone. The lower portion of the tower serves as a porch, which forms the principal entrance to the building. Immediately above this, and approachable by a winding staircase, is the ringing-floor; and above, at an elevation of about 50 ft. from the ground, is the belfry, which contains a peal of eight bells from the works of Messrs. Warner, bell-founders, London. The tower rises to a height of 70 ft., and is 18 ft. square. The tower is surmounted by a spire, which, when finished, will rise to a height of 86 ft. above the square of the tower, and a wrought-iron vane will add 8 ft. more to this height, making a total of 164 ft. above the ground level. The roofs externally are surmounted by red ridge tiles. The whole of the interior fittings are of pitch-pine, stained, and polished. The roofs are open-timbered, and also of pitch-pine. The chancel roof is wagon-headed, with the interior panels of pitch-pine. The whole of the glazing was executed by Mr. T. Holt, of Liverpool. The church is warmed by the hot-water system of Mr. George Knowle, of Liverpool. The whole of the carving was executed by Messrs. Norbury & Co., of Liverpool. The encaustic and tile-work has been executed by Messrs. Chantrell & Son, of Liverpool. The font is of Caen stone, supported on marble columns, and stands at the west of nave in the centre. The pulpit is of Caen stone, with bands of red sandstone,

with marble shafts and carved panels and spandrels. The pannels are of Caen stone also, with richly diapered panels, gilded on the main lines. The reading-desk is of oak. The gas-fittings were executed by Mr. A. Bucknall, of Liverpool, and are a very good sample of ornamental work. The fixing of these, as well as the gas and water mains, was entrusted to Mr. Kermode, of Peel. The fittings of these church have already been mentioned in these columns. The contract was taken by Messrs. D. Anderson & T. Radcliffe, of Peel, Mr. Clague being the foreman mason. The architects are Messrs. Thomas D. Barry & Son, of Liverpool.

**Darwen.**—The new Mission Church of St. Barnabas, in the Culvert District of St. John's Parish, Darwen, has been opened. The church is simple in outline and construction, being under one continuous roof; breaks in the outline being obtained by the reduced widths of the eastern and western bays forming the sanctuary and baptistery respectively,—by continuing the roof over the projecting porch and vestry,—and by a large gabled orner on each side. The total width inside is 31 ft., and the total length from west to east wall 101 ft. The height to the wall-plate of the nave being 14 ft. The roof, which is covered with green slates, is framed with collar-beam principals with moulded curves, the one over the entrance to the chancel and the remainder of the chancel principals being marked by posts carried down to the floor, betwixt which are framed the balustraded screens which partition off the chancel from the organ-chamber on the north side and the vestry on the south side. The walls are built of local stone, faced outside with broken-coursed rubble, and on the inside with Bolton pressed red brick, pointed. The passages are laid with flags, and the chancel with simple patterns of plain and stamped tiles. The windows are of wood with wood casements glazed with lead-lights, except the east window, which is of stone. The nave seats are of pitch-pine, varnished, and the chancel stalls are of yellow pine, painted, as also are the pulpit, altar-rail, and lectern. The font is of Halifax sandstone. There is an open-framed bell-turret on the ridge of the roof close to the west wall. The lighting is effected by hot-water pipes and coils on the low-pressure system, the engineer being Mr. C. Seward, of Preston. The architectural style is Gothic in character, and the aim has been to adapt the principles of ecclesiastical architecture to the simplest forms of construction, and at a very low cost, the cost per sitting being under 3l. The total accommodation is 350. The contractors for the various works, who are all of Darwen, were as follow:—Messrs. J. Orrell & Sons, masons' work; Mr. L. R. Marsden, joiner's work; Mr. Holden Baron, slater's work; Mr. R. Jackson, plasterer's work; Mr. H. C. Jepson, plumber and glazier's work. The architects are Messrs. Paley & Austin, of Lancaster.

**Old Shoreham, Sussex.**—Certain alterations to the ancient Parish Church of Old Shoreham, Sussex, are in contemplation. Plans and estimates have been submitted by Mr. Arthur Loader, architect, of Brighton.

**DISSENTING CHURCH-BUILDING NEWS.**

**York.**—The new Wesleyan chapel in Clarence-street was opened on the 13th ult., by the Rev. F. Greeves, D.D., president of the Wesleyan Conference. The chapel is in the Italian style, and is built of pressed bricks, from Messrs. Williamson's, near Hull, with stone dressings from Bradford. The columns of the portico are of polished grey granite. The interior is fitted up throughout in varnished pitch pine. The ceiling is divided into panels, and enriched with ornament. The organ recess has Corinthian pilasters and enriched entablature. A portion of the windows are of stained glass, by Messrs. Winfield (late Camm Bros.), Birmingham. Accommodation is provided for 830 persons, including free seats. There are also four large vestries or classrooms. The total cost of the building, exclusive of boundary walls, has been about 3,000l. The contractors are Mr. Swallow for stone and brick work; Messrs. Bellerby for painting; Messrs. Walker for heating, all of York. The joiners' work has been executed by Mr. Deacon, of Shipley; the plasterers' work by Mr. Dixon, of Bradford; the plumbers' work by Mr. G. Thompson; and the slaters' work by Messrs. Pycok, both of Leeds.

The gas-fittings and railings have been supplied by Messrs. Freeman & Collier, of Manchester; the ventilation by Messrs. Hill & Hey, of Halifax; and the carving by Mr. R. Boys, of Leeds. The architect is Mr. W. J. Morley (now Morley & Woodhouse), of Bradford and Bolton.

**Freckleton (near Preston).**—Memorial-stones of a new Wesleyan chapel were laid on the 30th ult. The chapel will accommodate 275 worshippers, and the style adopted is English Renaissance, the materials employed being patent bricks and Longridge stone. A new Sunday school, in connexion with the above chapel, was opened on the 31st ult. The entire cost will be about 1,500l. The architect is Mr. David Grant, of Preston.

**Douglas (Isle of Man).**—The foundation-stones of a new Wesleyan chapel here were laid on the 27th ult. The building will occupy a position at the angle formed by Rosemount and Beck's-road. The tower is placed at the corner of the site. Galleries are carried round three sides of the chapel, and the total accommodation is for about 900 worshippers. The building has been designed in the style of English Gothic which prevailed about the end of the thirteenth century, by Messrs. William Waddington & Son, architects, of Manchester and Burnley, under whose supervision the various works will be carried out by Messrs. Kelly & Preston, contractors, of Douglas. The cost of the chapel, omitting the higher stages of the tower and the spire, will amount to 6,000l.

**The Student's Column.**

HINTS FOR THE STUDY OF THE HISTORY OF ARCHITECTURE.—XI. THE RENAISSANCE.

**EXCEPTING** in Oriental nations, it would appear that human nature cannot exist without change of fashion, or, rather, it cannot resist the temptation of following such a change when it has been set in headquarters. Now, Italy was, at the time that we reached in the last article, the spiritual as it had once been the imperial capital of Europe, and in Italy there was, about the middle of the fifteenth century, a revival of classical literature.

Fergusson has written, as a companion to his Handbook, a "History of Modern Architecture," 1862, 1 vol. 8vo., in the introduction to which he remarks that, although the great bulk of the clergy throughout the whole of the Middle Ages could read Latin with facility, it was not till the age immediately preceding the fall of Constantinople that the existence of the great literature of Greece became known in Western Europe; but when Petrarch and Boccaccio first became acquainted with its beauties, they naturally landed their discovery to the skies, and incited those who could not read Homer and Demosthenes in the original Greek to study their echoes in Virgil and Cicero.

Then this revival of letters opened the eyes of the Italians, and especially the Romans, to the beauties of the equally ancient architecture in their midst. And it was but natural that they should crave for a return to this their natural style; and so the fashion was set.

As opposed to stagnation, change is healthy; and up to this time the continuous changes that we have been watching were the results of gradual progress,—attained by general as opposed to individual efforts,—in working out the problems of building, as they successively arose. Fergusson calls these results the true styles of architecture; all those subsequent to the Renaissance, or new birth, of Classic art he calls the copying or imitative styles.

Even in these, however, a distinction is to be noticed. Up to the beginning of the present century Classic art was adapted, or diluted; since then both Classic and Gothic have been adopted, or swallowed whole. Fergusson distinguishes these two systems as the Renaissance and the Revival respectively of former styles, and it must be admitted that he takes a pessimist view of both, so that there is not much consolation to be derived from his pages. More hopefulness may, however, be permitted to practising architects than to even such an eminent critic as he is.

To begin, then, with the Renaissance in Italy, it will be easily understood that the seed fell on very receptive soil, as the Italians had not shown very much sympathy with Gothic art;

but, even during the eleventh century, produced such churches as St. Miniato at Florence, which, says Fergusson, are more Classical in plan, and,—as their ornaments are generally borrowed from ancient buildings,—far more so in detail than many of the buildings of the Renaissance period. That, however, which distinguishes Renaissance buildings is their being wilful adaptations of past styles and being the production of one individual mind, and of that mind only. The consequence is that we shall now come across a multitude of names of men as well as of buildings, or portions of buildings, So-and-So having designed one part and So-and-So another part.

The first of these architects that we read of is Brunelleschi, born at Florence in 1377, died 1444. He found a job ready to hand in the completion of the great octagon of the cathedral. No drawings had been prepared for this, though probably it would have been completed by a series of retreating stages like that at Chiaravalle (Fergusson's Handbook, page 775), a form which, in fact, survived in many Renaissance churches (see Strack's and Lapeyre's works on Italian churches), but our architect was fired with the desire to do something quite different; so off he went to Rome to study "the antique," and on his return in 1420 erected the huge dome that is illustrated on page 121 of Smith's "Gothic and Renaissance." Another famous example of his work in Florence is the Church of St. Spirito, illustrated in plan and section by Fergusson ("Modern Architecture," pp. 41, 42), in which we find a fragment of the entablature placed on each column under the springing of the pier arches, a custom which became common, and which Fergusson deplores, as it was a return to a meaningless feature which had been carefully avoided in the buildings of the fifth and sixth centuries.

Besides churches, Brunelleschi appears to have designed,—or to have been consulted about the Riccardi Palace (1490) and the Pitti Palace, both at Florence. These are illustrated by Fergusson (page 84) and Rosengarten (page 379). The somewhat similar Strozzi Palace, designed by Cronaca, 1489, is illustrated by Smith on page 169, as well as by Rosengarten, and all these palaces have a strong family likeness. There is a good deal of "rusticated" walling about them, their windows are "two-light," comprised under a partly pointed arch, and are, so far, Gothic; but these palaces finish up with a huge classical cornice, that is well proportioned to the height of the wall. The next palace illustrated by Fergusson, namely, the Rucellai, designed by Alberti in 1490,—therefore rather earlier than the Strozzi,—exhibits the introduction of so many Renaissance architects. They could not tear themselves away from their tormenting rules, and their chief ingenuity is displayed in making the best of them. For instance, Sansovino may be said to have "scored" when he surmounted two stories of orders with an entablature proportioned to the two together, in the Library of St. Mark at Venice, from which our Carlton Club is copied; and Palladio, who is looked upon as such an authority as to have "Palladian architecture" named after him, obtained another brilliant victory over two orders which had to be respectively adapted to the lofty nave and lower aisles of St. Giorgio Maggiore at Venice. This *coup de grâce* consisted in raising the latter order on pedestals (see Fergusson's "Modern Architecture," page 75). This same master, however, is responsible for what Fergusson selects on page 28, as an example of all that is abominable, namely, the Valmarina Palace, Vicenza, where a five-storied building is intended to look like one great hall, by means of one huge order, which is "treated" in various artful ways, but without success.

The same use of a gigantic order is found at St. Peter's at Rome, a building which passed through the hands of several designing architects. First of all, Pope Nicholas V. began, from the designs of Rossellino, an enormous building, which, however, was only raised a few feet out of the ground when the Pope died in 1454; and the matter rested till Pope Julius II. instructed Bramante to proceed with the building, and a foundation stone was laid in 1506. On the death of this pope in 1513, and of his architect the next year, Raffaello, better known as a painter, was called in; it was then found that Bramante's piers were not strong enough for their work; Raffaello died in 1520, apparently without having forwarded the building,

and was succeeded by Baldassarre Peruzzi, who altered the design for the building from a Latin to a Greek cross, but died in 1536, before much was done, and was succeeded by the celebrated Antonio San Gallo (not to be confused with Giulio di Sangallo), who made an excellent design, illustrated by Fergusson on page 56, but who had to devote all his time to remedying the defects in construction introduced by his predecessors; and, on his death in 1546, the control of the works fell into the hands of the great Michelangelo, to whom we certainly owe the form of the dome, and probably the ordinance of the whole interior. However, he left the building unfinished, and on his death in 1564, Fontana proposed certain alterations, and it was suggested that the Latin cross plan should be reverted to. This was finally carried into effect by Maderno, and thus the main building was completed. About the year 1661 Bernini added the piazza, with its circular porticos and fountains.

This history of St. Peter's well exemplifies the recognition of the several designers of Renaissance buildings or portions of buildings, and the importation of a personal element into the work, and must serve as a sample of the numerous architects employed in and about Rome. The best special work to study on this subject is Letaronny's "Édifices de Rome Moderne," 1840, 3 vols. fol.

For the buildings in Florence, some of which have been mentioned, the student should consult a work by Gauthier, and mark the distinction between the styles in the two cities.

This same author, Gauthier, has produced a fine book on the very distinct work to be found in the hill-side city of Genoa, "Les plus beaux Édifices de la Ville de Gènes et de ses Environs," 1818, 1 vol. folio. In this book the skilful adaptation of Classic work to the peculiarities of the site will excite admiration. The staircases rising from the street-front level of some of the palaces, and thence to internal landings, and thence again to hanging terraces and gardens, and all contrived apparently without effort or hitch in their dignified architecture, have been called by Professor Roger Smith the "very poetry of planning."

Venice, again, has its special author, Giognara, who published a fine work on the buildings of that city in 1838, 2 vols., folio. Here, again, the peculiarities of the site have wrought their influence on the building. There have been many beautiful predecessors in the Medieval palaces, with their traceried fronts, so enthusiastically dwelt upon in Ruskin's "Stones of Venice." This lightness of treatment survives in the Vendramini Palace, illustrated on p. 93 of Fergusson's "Modern Architecture," and there is a playfulness of outline in most of the Renaissance buildings here, contrasting pleasantly with the more formal buildings of Rome.

For the building of Lombardy, Paravicini's book should be studied. In Milan, Bramante's so-called dome of Sta. Maria delle Grazie is a very refined piece of architecture, untroubled by colossal orders; and there is the Great Hospital, begun in 1456 by Filarete, and continued by Bramante, whose design was finally completed by Richini in 1621. The chief beauty is in the internal courtyards, consisting of two stories of arcades, supported entirely by columns, without any alternating piers.

Mantua has its Palazzo del Té, of which not only the architecture but the painted decorations were carried out by Giulio Romano and his pupils. The subjects selected for these fresco paintings mark the complete change that had come over popular taste since the days when Giotto painted the chapel of the Arena at Padua. If a knowledge of classical mythology be urged as an excuse for them, they are hardly worth the excuse. However, these articles are on architecture, and not on morality.

At Turin, one of the earliest architects we read of is Guarini (born 1624, died 1683), by whose time architecture had become theatrical in its style.

At Naples, the Caserta Palace, by Vanvitelli, is the largest and most nobly decorated palace executed in Italy since the Renaissance, but it will be seen from Fergusson's illustration, p. 128, to be extremely monotonous.

In the next article, the more interesting combinations produced out of Italy by the new style will be considered.

## BUILDING PATENT RECORD.\*

### APPLICATIONS FOR LETTERS PATENT.

Aug. 29.—11,764, H. E. Clark, London, Manufacture of Fire-guards, Window-blinds, &c.

Aug. 30.—11,782, J. Hall, Sheffield, Automatic Whitewasher for Cellings.—11,810, E. R. Busson, London, Laying Apparatus for Schools, Barracks, Prisons, &c.—11,825, G. D. Peters, London, Window-sashes.

Sept. 1.—11,849, S. Lloyd, London, Folding Fire-lighters.

Sept. 2.—11,867, R. H. Holme and U. F. Arveschong, Newcastle-on-Tyne, Tipping Ash-pan.—11,889, A. Mackie & J. Mackie, London, Ventilation of Buildings.—11,890, W. H. Page, London, Construction of Buildings.

Sept. 3.—11,919, W. H. Blackwell, Manchester, Sashes for Windows.—11,926, G. Cresswell, Brighton, Water-closets and Urinals.—11,931, W. Morrison, New Swindon, Chimney-top.—11,937, S. D. Pochin, London, Iron and Concrete Structures.—11,960, H. T. Crewe, London, Glazing Roofs, &c.

Sept. 4.—11,983, C. J. Henderson, Edinburgh, Warming and Ventilating Buildings.—11,990, R. C. Jones and J. W. Cunningham, London, Sash-fasteners.—11,996, J. Hitch, London, Water Supply to Closets, &c.—12,007, W. Saunders, London, Fastener for Stair Carpets.—12,008, E. Edwards, London, Artificial Stone. Com. by T. Grundmann, Hirschberg.

### SPECIFICATIONS ACCEPTED.†

Sept. 5.—2,045, J. Lowley and J. Harold, London, Opening and Closing all the Bolts of a Door simultaneously.—7,903, D. H. Brandon, London, Fire- and Water-proof Material for Roofing, &c. Com. by D. A. Brown, Boston, and C. F. Drigbam, Worcester, U.S.A.

## Miscellanea.

**The New Dock and Railway Works at Preston.**—The contract for the new dock works at Preston, and the improvement and deepening of the channel of the river Ribble, from Preston to the point where it falls into the Irish sea, which has just been entered into with the Corporation by Mr. T. A. Walker, of Great George-street, Westminster, will in a few weeks give employment to a large number of labourers and artisans, as it is intended at once to enter upon the varied works included in the contract both at the Preston end, and also along the channel to the mouth of the river, a distance of fourteen miles. Mr. Walker's contract amounts to 439,359*l.*, which includes the diversion of the river at Preston for about a mile in length; the construction of a river-entrance from the docks, with entrance-gates; a tidal basin four acres and three quarters in extent; locks and lock gates; a main dock of forty acres area; together with the construction of retaining walls along each side of the channel of the river from Preston to the river mouth. The contract is to be completed within a period of five years, or by the 1st of July, 1889. This contract, large as it is, does not include the whole of the intended works under the Act of Parliament which the Corporation have obtained. The dredging of the river will be carried out by the workmen of the Corporation, whilst in addition to Mr. Walker's contract a timber-pond of 25 acres is to be constructed, also graving-docks, coal tips, four large warehouses, hydraulic machinery, and railways round the docks and quays, the aggregate cost of the undertaking when finally completed being estimated at little short of 1,000,000*l.* The width of the proposed new channel at its narrowest point when entering the dock basin and dock at Preston is intended to be 60 yards at the bottom of the slope, with 30 ft. of water at high water spring tides, and 36 ft. of water over the bar at the mouth of the river. Simultaneously with the carrying out of the works, the construction of a new railway from Wigan and Longton to Preston, to be connected with the docks, and also the authorised railway from Preston to Lytham and Blackpool, with a station at the docks, are also to be proceeded with, and it is estimated that the united cost of carrying out these several works during the next three or four years will be upwards of 1,500,000*l.*

**The Edinburgh Improvement Trust.**—At a meeting of the Edinburgh Improvement Trustees on Tuesday last, the Works Committee recommended that Mr. James Lessels be appointed architect to the Trust, in room of his late father, at the salary of 75*l.*

\* Compiled by Hart & Co., Patent Agents, 186, Fleet-street.

† Open to public inspection for two months from the date named.

**Protecting Timber from the Ravages of Marine Animals.**—At the International Forestry Exhibition, Edinburgh, on Tuesday last, Professor McIntosh, of St. Andrews, delivered a lecture on "The Boring of Marine Animals in Timber, &c." Alluding to the methods of protecting submarine timber from the ravages of such animals, the professor said different kinds of wood were mentioned as being impervious by such boring action, but so far none had been successful. There were many preparations for the treatment of the wood before immersion. Soluble bitumen, silicated lime, and various compositions, had each in turn been tried externally, while silicate of lime, crocoite, and other fluids had been forced, under great pressure, into the tissues of the woods. The experiments of the Dutch Commissioners, who investigated the matter, had led them to the conclusion that no external protection other than metallic sheathing or the studding of the wood with broad-headed nails would be successful in resisting the attacks of these borers, while the only impregnation they found reliable was creosoting. In conclusion, Professor McIntosh pointed out that while the Dutch, French, and other Commissions had done material service in regard to the best means of protecting timber from the attacks of borers, the subject was by no means exhausted. On the contrary, it would form a fitting object for research at the marine laboratories, which at last, he was glad to say, were being established on our coasts.

**Liverpool Labourers' Dwellings Company, Limited.**—Mr. Charles T. Bowring presided on Wednesday at the thirteenth annual meeting of the Liverpool Labourers' Dwellings Company, Limited, held in the company's offices, Union Bank-buildings, 5, Fenwick-street. The report of the Directors, which was unanimously adopted, stated that the demand for cottages had fallen off, and many cottages having remained empty, the rents were considerably reduced; but, although this was done, the directors were glad to state that the gross rents received only showed a diminution of about 10*l.* as compared with last year, and the cottages had been better tenanted. The expenditure showed a decrease of about 80*l.* as compared with last year. The net profit on the year's working was 515*l.* 4*s.* 6*d.*, and adding to this sum the amount carried forward from last year, 11*l.* 4*s.* 4*d.*, there was a sum of 526*l.* 8*s.* 10*d.* available for dividend. The directors recommended that a sum of 496*l.* 4*s.* be applied to the payment of a dividend at the rate of three per cent. per annum, and that the balance of 30*l.* 4*s.* 4*d.* be carried forward to next year.

**New Bank Buildings and Shops at Camberwell.**—The London and South-Western Banking Company are erecting a new bank, together with a block of shops, on a portion of the vacant land resulting from the widening of Church-street, Camberwell. The bank buildings are situated in a prominent position immediately opposite Camberwell-green, having a main circular frontage to the green, with an extensive return frontage in Wren-road, 80 ft. in length. The building is faced with Portland stone, rusticated, with an arched entrance in Shap polished granite, at the corner of Church-street and Wren-road. Each floor contains ranges of lofty arched windows with moulded and carved keystones. The four shops, in continuation of the bank buildings eastward, are carried up to the first floor with rusticated Portland stone piers, uniform with the bank, the upper portions of the frontage being in red brick with Portland stone dressings. Messrs. J. & J. S. Edmonstone are the architects, and Mr. G. Kynock, of High-street, Clapham, is the contractor, his contract amounting to 11,748*l.*

**Geneva.**—A Manich window has lately been erected at the east end of the Church of the Holy Trinity, by Messrs. Mayer & Co. It represents in the centre the Crucifixion, on the left the Holy Women at the Sepulchre, and on the right Christ consoling the Women on the way to Calvary. This work is placed in memory of Mr. Henry Christopher Schaeff, of Moirax, Haute Savoie.

**An Electric Brake.**—A trial of the Walker electric brake, which is in use in America, was recently made on the tramway between Turin and Piossasco. It is stated that by its means two cars running at a speed of 35 km. per hour were stopped in six seconds, and within a distance of 18 m. The brake is being shown at the Turin Exhibition.—*The Electrician.*

**Franciscan College and Monastery at Peckham.**—Adjoining the large Franciscan Church in Peckham Park-road, which was erected a few years ago from designs by Pugin, a new college and monastery, now in course of erection, is fast approaching completion. The building is situated at the north-east side of the clergy-house, connected with the church, and has three main frontages. The principal frontage in Peckham Park-road is 70 ft. in length and 80 ft. in height, containing four floors above the ground line. The materials of the elevation are malm brick, with Corsban stone for cornices, strings, window-dressings, weatherings, and chimney-caps. The whole of the basement is arranged for the *cuisine* department of the college. The ground-floor contains, on one side of the corridor, the refectory, an apartment 20 ft. square, whilst, on the opposite side of the corridor, is the library; and, in continuation, on each side of the corridor, are the students' rooms. The first floor also contains students' rooms on each side of a corridor as in the ground-floor below. The upper floors contain the dormitories. Mr. Burns, of Liverpool, is the architect, and Mr. F. Doberty, of Leyton-square, Peckham, is the contractor. The cost of the college will be about 4,000l.

**The London Tramway Company's New Depot at Peckham.**—On the south side of High-street, Peckham, bounded on the east by

Ryo-lane, the London Tramways Company are constructing an extensive new depot, which, with the exception of their terminal establishment at Greenwich, will be the largest of the kind belonging to the company. The site upon which the new buildings are being erected forms a portion of the ancient Basing Manor estate. The property purchased by the Tramway Company for the depot includes the old Manor House, adjacent to the High-street, which, subsequently to the estate being sold by the Gardner family, as lords of the manor, was occupied as a public school. Amongst other property acquired by the company are a number of rickety hovels on the east side of Basing-road, the demolition of which, on sanitary grounds, is very desirable. The depot will cover an area of between two and three acres, with an approach from High-street about 150 ft. in length. The erection of the stables, which are intended to have stalls for about 200 horses, is now in progress, as well as sheds for the cars.

**Open Spaces.**—We hear that the National Footpath Preservation Society will advocate the purchase of land near towns and villages for public recreation-grounds; and we understand that the Town Council of Lancaster have just paid 5,650l. for the purchase of the Giant Axe Field for the benefit of the town. We should like to know the acreage.

For erecting the London Almshouses, Shepherd's-lane, Brixton, for the Corporation of London. Messrs. Davis & Emanuel, architects, 2, Finbury-circle, F.C. Quantities supplied by Mr. H. P. Foster, 5, John-street, Adelphi, W.C.

J. Rowberry ..... 648 0 0  
R. Taylor ..... 642 0 0  
E. Powell ..... 598 0 0  
W. Bower & Co. .... 478 0 0  
H. Gardner & Co. .... 421 0 0  
H. W. Daniels ..... 374 0 0  
\* Accepted, subject to variations and omissions.

For offices and soup-kitchens in Bath-street, Hereford. Messrs. Willett & Waking, architects.—  
H. Welsh ..... £242 0 0  
Colley ..... 915 0 0  
Daniels ..... 813 0 0  
Powell ..... 816 0 0  
W. Bower & Co. .... 750 0 0  
H. Gardner & Co. .... 750 0 0  
J. Ford ..... 750 0 0  
W. Richard (accepted) ..... 639 15 0

For the erection of a new pair soap-houses and offices at Hemel Hempstead, Herts, for the Rev. G. J. Lavelle. Mr. W. A. Fisher, architect, Marlowes, Hemel Hempstead. Quantities supplied.—  
W. L. Sear ..... £1,609 12 0  
Michin ..... 1,537 0 0  
Waterman ..... 1,448 0 0  
W. Sear ..... 1,443 0 0  
Horn ..... 1,382 0 0

For additions to house, Broad-street, Hemel Hempstead, for Mr. G. Rolph. Mr. W. A. Fisher, architect and surveyor.—  
W. L. Sear ..... £161 0 0  
Horn ..... 135 0 0  
W. Sear (accepted) ..... 146 0 0

Special Notice.—Lists of tenders frequently reach us too late for insertion. They should be delivered at our office, 46, Catherine-street, Strand, W.C., not later than four p.m. on Thursdays.

TO CORRESPONDENTS.

G. P. R.—H. P.—F. J. G.—V. R.—T. N.—J. R. D.—W. S. C. D.—(next week).—I. S. P.—R. P. (next week).—J. R. (Shanks).—National Footpath Preservation Society.—C. D. (shall be attended to).—M. H. J.

All statements of facts, lists of tenders, &c., must be accompanied by the name and address of the sender, not necessarily for publication.

We are compelled to decline pointing out books and giving addresses.

None.—The responsibility of signed articles, and papers read at public meetings, rests, of course, with the authors.

We cannot undertake to return rejected communications.

Letters or communications (beyond mere news-items) which have been quoted for other journals, are NOT RECORDED.

PUBLISHER'S NOTICES.

CHARGES FOR ADVERTISEMENTS. SITUATIONS VACANT, PARTNERSHIPS, APPRENTICESHIPS, TRADE, AND GENERAL ADVERTISEMENTS. Six lines (about fifty words) or under ..... 6s. 6d. Each additional line (about ten words) ..... 0s. 6d. Terms for Series of Trade Advertisements, also for Special Advertisements on trade fairs, Compositions, Contracts, Sales by Auction, &c. may be obtained on application to the Publisher.

FOUR Lines (about THIRTY words) or under ..... 2s. 6d. Each additional line (about ten words) ..... 0s. 6d. PREPAYMENT IS ABSOLUTELY NECESSARY. \*Stamps must not be sent, but all small sums should be remitted by Cash in Registered Letter or by Money Order, payable at the Post-office, Covent Garden, W.C. to DOUGLAS FOURDRINER, Publisher, Addressed to No. 46, Catherine-street, W.C.

Advertisements for the current week's issue must reach the Office before THREE o'clock p.m. on THURSDAY.

The Publisher cannot be responsible for DRAWINGS, TESTIMONIALS, &c. sent at the Office in reply to Advertisements, and strongly recommends that of the latter COPIES ONLY should be sent.

TERMS OF SUBSCRIPTION. "THE BUILDER" is supplied gratis from the Office to residents in any part of the United Kingdom at the rate of 10s. per annum, payable in advance. To countries within the Postal Union, 12s. per annum. Remittances payable to DOUGLAS FOURDRINER, Publisher, No. 46, Catherine-street, W.C.

SPECIAL.—ALTERATIONS IN STANDING ADVERTISEMENTS.—ORDERS TO DISCONTINUE same, must reach the Office before TEN o'clock on WEDNESDAY morning.

PERSONS advertising in "The Builder," may have Replies addressed to the Office, 46, Catherine-street, Covent-garden, W.C. free of charge. Letters will be forwarded if addressed envelopes are sent, together with sufficient stamps to cover the postage. All communications regarding literary and artistic matters should be addressed to THE EDITOR; all communications relating to advertisements and other exclusively business matters should be addressed to THE PUBLISHER, and sent to the Editor.

Best Bath Stone. WESTWOOD GROUND. Box Ground, Combe Down, Corsham Down, And Farleigh Down. RANDELL, SAUNDERS, & CO., Limited, Corsham, Wilts. [ADVT.]

Box Ground Stone. Is the Best for Use in all Exposed Positions, being a well-known and tried Weather Stone. 50,000 feet cube in stock. PICTOR & SONS, BOX, WILTS. [ADVT.]

Doubling Freestone and Ham Hill Stone of best quality, in blocks, or prepared ready for fixing. An inspection of the Doubling Quarries is respectfully solicited; and Architects and others are CAUTIONED against inferior stone. Prices, delivered to any part of the United Kingdom, given on application to CHARLES TRASK, Norton-sub-Hamdon, Ilminster, Somerset.—Agent, Mr. E. WILLIAMS, 16, Craven-street, Strand, W.C. [ADVT.]

Doubling Free Stone For prices, &c., address S. & J. STAPLE, Quarry Owners, Stone and Lime Merchants, Stoke-under-Ham, Ilminster. [ADVT.]

Asphalts.—The Seyssel and Metallic Lava Asphaltic Company (Mr. H. Glenn), Office, 38, Poultry, E.C.—The heat and cheapest materials for damp courses, railway arches, warehouse floors, flat roofs, stables, cow-sheds and milk-room, granaries, tin-rooms, and terraces. [ADVT.]

Asphalts. Seyssel, Patent Metallic Lava, and White Asphalts. M. STODART & CO. Office: No. 90 Cannon-street, E.C. [ADVT.]

J. L. BACON & CO., MANUFACTURERS OF IMPROVED STEAM AND HOT-WATER APPARATUS, FOR WARMING AND VENTILATING Private Houses, Churches, Schools, Hospitals, Manufactories, Greenhouses, &c. OFFICES AND SHOW-ROOMS:—No. 34, UPPER GLOUCESTER PLACE, DORSET SQUARE, LONDON, N.W. And at DUBLIN, BELFAST, GLASGOW, and NEWCASTLE. Illustrated Pamphlet on "Heating" post free.

CHAPPUIS' PATENTS FOR REFLECTING LIGHT.

DAYLIGHT REFLECTORS OF EVERY DESCRIPTION, ARTIFICIAL LIGHT REFLECTORS.

WHY BURN GAS?—CHAPPUIS' REFLECTORS DIFFUSE DAYLIGHT.—They are exclusively adopted by and fitted at Buckingham Palace, all H.M. Government Offices, Houses of Parliament, H.M. First Commissioner of Works, the Metropolitan Board of Works, British Museum, South Kensington Museum, Royal Institution, Guildhall Museum, on board H.M. Ships, also Railway Companies' Offices, Hospitals, Institutions, Banks, Insurance Offices, Manufactories, Private Houses and generally from Noblemen's Mansions to Artisan's Work-shops. 30,000 in use in London alone. Patronised by leading Architects, Engineers, Contractors, &c., &c.

N.B.—For Prospectuses and Diagrams, address Stamped Envelope to P. E. CHAPPUIS, Patentee and Manufacturer, 69, FLEET-STREET, LONDON.

NOTICE.—The POLYGONAL REFLECTOR (Latest Patent) FOR ARTISTIC and PICTURE GALLERIES. Its construction allows of the angle of light being readily altered so as to reflect in any desirable direction.

N.B.—On View at HEALTH EXHIBITION (Eastern Gallery).

### The Common Sense of Restoration.

**D**URING the last few days we have heard much talk and seen many letters about "Restoration," one of the subjects which all people think themselves competent to discuss, and about which there is at present a degree of acerbity between restorers and non-restorers which renders it a capital opening for the interchange of newspaper compliments in the off-season. In the consularship of Plancus, as many of us can remember, restoration was a venerable word, representing ideas which were supposed to sum up the whole duty of ecclesiastical man; and what was man in those days if not ecclesiastical? It is touching to read in the *Times* the letter of the secretary to "The Incorporated Society for Promoting the Enlargement, Building, and Repairing of Churches and Chapels," and his half admission that in the early days of the Society the money was not rightly expended; or, rather, as he puts it, not "expended as it would be now,"—a naive admission of the doctrine that whatever *is* (at the present moment) is right. But, he adds, "I do not think that the Society was to blame. It was in advance of the age. Its object was to provide additional church accommodation, and it was its misfortune, not its fault, if ecclesiastical architectural taste was at such a low level that many and many magnificent and interesting architectural features could be ruthlessly swept away to make room for the erection of a large painted deal gallery; or a very beautiful, though small, parish church could be destroyed to be supplanted by a church of the 'Gothic sort,' with cast-iron pillars painted white." That the Society accepted this sort of thing would seem to prove that it was *not* in advance of the age; but the passage recalls our attention to the main object of church restoration, as practised a generation ago. That object was to supplement the revival of the Medieval church spirit by providing buildings for increased church accommodation, and providing them in a style which was supposed to represent the proper surrounding for a revived church and ritual. Restoration of existing churches began in the same spirit. The churches had been suffered to go into decay during the period when the church was

practically dead in the country, and to repair and re-beautify them was, in the first instance, simply a common-sense proceeding of a semi-practical nature. As the Medievalising spirit gathered strength, of course the thing became more and more a matter of sentiment, and everything that savoured of the hated period before the revival, all that was antagonistic to Medievalism, was to go. The Medievalising of churches became a shibboleth, and there was no salvation for any one who remained lukewarm on such a matter.

The anti-restorationists are now having their innings; and bigotry and prejudice on the one side are being answered by stronger prejudice and blinder bigotry on the other side. The ecclesiastical revivers and restorers used to indulge in painful and probably overdrawn descriptions of the state of things in unrestored churches; but the anti-restorers for the most part seem possessed by such a spirit of opposition that people who in regard to other matters would probably be strictly truthful, in regard to the doings or even the intentions of supposed restorers will make sweeping statements upon no authority at all; will distort and exaggerate facts till their statements reach absolute misrepresentation, to use no stronger expression; and will invent wonderful and unheard-of canons of architectural criticism, evolved from their inner consciousness, in order to hold up to ridicule the doings of the hated restorer. Just as a generation ago "restoration" was the orthodox catchword for would-be aesthetic people, by the use of which, without any knowledge of the subject, they could pass as "superior people," so now the abuse of restoration and of restorers is a kind of passport to the ranks of the aesthetes, and mere declamation on the subject, without the accurate knowledge of a single fact, is enough.

We regret to say that ladies are very prominent in this exhibition of zeal without knowledge. They are amongst the most bigoted members of the "Anti-Scrape" Society. As an example, we heard a lady member of that Society with the long name which has been thus indecorously abbreviated, inveighing against any one who pulled down an old building on any pretext whatsoever. We ventured to hint that all the Medieval builders pulled down the works of their fathers ruthlessly, and built up new ones on their very foundations; that almost every cathedral in England consisted largely of work built on the foundations of older work which had been pulled down because the later builders thought they could do something better. "Oh, indeed," was the reply in a tone of severe superiority, "I should like a proof of

that!" The speaker might, of course, as well have asked for a proof that Medieval churches had pointed windows and buttresses; but the abuse of architectural restorers may be indulged in nowadays without the slightest knowledge of even the outlines of the subject. Another example of the kind of architectural criticism which satisfies your anti-restorer is exhibited in a letter by Mr. W. J. Loftie in the *Times* of Wednesday, concerning what he calls the "frightful idea" of restoring St. Stephen's, Walbrook, of which he has heard rumours. To prevent misunderstanding, we may say at once that we have ascertained from inquiry that what has been suggested is merely letting down the pew-woodwork by one panel (removing a small bottom panel), so as to reduce the excessive height of the pews without altering the upper portion or finish of the woodwork at all. We should be very averse to making any alteration whatever in St. Stephen's unless on very strong practical grounds. The alteration proposed can hardly be called necessary, though it must be admitted that the high "sheep-pen" pew, however good the woodwork may be, is a construction very much at variance with modern feelings and habits among worshippers; and certainly the alteration talked of is not such as to materially affect the architectural aspect of the interior. But the very rumour fills Mr. Loftie's mind with indignation and contempt against all architects, who only propose these things out of spite against Wren, and because they cannot produce anything as good as he did. Mr. Loftie, it must be observed, speaks entirely from a standpoint above architects, as one instructing them in matters in which he is better informed. Mr. Loftie's claims to this position appear to rest on some rambling attempts at architectural criticism in his otherwise interesting "History of London," in the course of which it appeared that he had never heard the name of Elmes, and attributed the greatest English building of the Classic revival to Wilkins; and on the authorship of the first volume of the "Art at Home" books, a plea for "Art in the House," written in a style worthy of Laura Matilda herself, and forming probably the very silliest of all that most silly series of booklets. Mr. Loftie's claims to rank as architectural instructor are characteristically exemplified in the letter on St. Stephen's, Walbrook. He says:—

"There is probably nothing, except, perhaps, to remove the dome, calculated so terribly to injure Wren's design as cutting down the pews. They are the chief element in the extraordinary effect produced upon the spectator as he enters the church.

It will be understood at once when I say that the columns which support the dome and divide the aisles rest on bases so high that each column seems to rise from a floor level exactly with the top of the pewing. While, therefore, the visitor sees the whole design as if in a picture, the apparent size of the little building is immensely enhanced. Strange to say, I hear the proposed vandalism has the approval of several architects.

If Mr. Loftie can explain to us how the apparent spaciousness of a building is enhanced by making the floor of it appear 5 ft. 6 in. nearer the roof than it really is, we should be very much obliged to him. Most people in their ordinary senses would think that was the way to diminish the effect of size and spaciousness in a church or any other building. The common-sense of the matter is this:—The cutting down (or rather letting down) of the pews in the way described, by about eighteen inches, would be far more in accordance with the present (and the best) taste as to the furnishing of a place of worship; it would take away nothing very material from the wood-work itself, and it would unquestionably give greater appearance of height and spaciousness to the church than at present. The one real architectural drawback to the alteration is that Wren arranged the bases of the columns to range with the height of the pews, and, if the alteration were made, there would then be eighteen inches of plinth left standing above the pew level. The effect would not be so complete, though it would be possible to treat the bases so as to connect them with the new line of woodwork. Of course this would involve introducing a new detail into a very complete work of Wren's, and we should oppose it on that ground, unless there were a very large congregation (which we believe there is not) who were seriously incommoded and annoyed by the present make of the pews. In that case practical considerations come first, an argument to which Wren himself would probably have readily agreed.

This question of practical expediency is one of the main points to be taken into consideration in regard to altering, restoring, or rebuilding old buildings; and one which is apparently put totally on one side by the anti-restoration champions. There are three lights in which a building may be regarded; we name them in the order of their importance. First, the practical fitness of the structure for the uses for which it is intended; the first and most important in the case of all buildings, except purely monumental or memorial designs, and the one upon which, save in those cases, everything else ought to turn. Secondly, the building regarded as an artistic design. Thirdly, the building, with all the alterations through which it has gone, regarded as a part of history. By the anti-restorationists this latter consideration is put forward not only before the two others, but to the absolute exclusion of the two others. The completeness of the building as an architectural design, and its convenience for the uses for which it is intended, are to them, if one may judge by their own words, matters of no account whatever. History embodied in architectural changes and alterations is undoubtedly of very high value and interest, and to people engaged in special antiquarian studies it is naturally the chief interest. But that is not what buildings were erected for. They are erected firstly for use; secondly, when something higher than mere utilitarian value is aimed at, for architectural beauty, as harmonious and consistent designs. When there is any question of restoring an ancient building, of renewing it where dilapidated, of removing any incongruous additions that have been made to it, perhaps in a period of debased taste, and which are out of keeping with its architecture,—the rational course, instead of uttering hysterical denunciations against touching anything that a former generation has done, is to consider and weigh the balance of advantages and disadvantages of alteration, and decide accordingly. Take a church, as being the most common battlefield of restoration at present. If it is actually a ruin, and a ruin of noble architectural style, to touch it in any way, except for the purpose of mere maintenance against further decay, is

rank sacrilege, and any patching up or reworking would at once destroy all its value and dignity as an architectural memorial. Few people, however, would ever propose such a course as this. But in the case of a church in use for worship, the first claim is that it should be kept in a seemly and decorous condition, that its fittings and interior arrangements generally should be in accordance with the convenience and the habits of the people of the present day who use it, and that it should be in thorough repair and in a state of structural safety. The latter condition we should presume no one would be silly enough to contest, though some of the protests of the "Anti-Scrape" Society would lead one to think that they ignore even this necessity, and that they would rather have the chance of a roof coming down on their heads than see it repaired or a new one substituted. In regard to fittings, if a former generation has filled a church with a style of fittings which are quite at variance with modern ideas of what is either convenient or suitable in a church, are modern congregations for ever to go on using them because they were once put there? As well say that a man who lives in an ancient mansion or castle is not to alter and furnish it with regard to modern ways of living. Then there comes the question, not so easily to be settled, of purely architectural fitness and propriety. Now it is really necessary to remind people at present that there is such a thing as architectural design, and that one object of architectural design is fitness and coherence of all the parts one with another, without which quality the architecture ceases to be a harmonious whole, and becomes only a collection of scraps with no logical relation to one another. At a certain period of our history, our finest Mediaeval churches were filled with objects,—monuments, reredoses, pews, and galleries, &c.,—in some cases absolute monstrosities, in the best cases entirely at variance with the architectural régime of the building. In some cases these are of such good quality of design and execution that it becomes a question whether the gain to completeness of effect by removing them to some other situation is at all equal to the loss of the total architectural interest of the building which would be involved in removing them.\* In the case, however, of things which are not good in themselves, which are in bad and debased taste, and poor in execution, to scruple to remove them (unless they are monuments of those whose memory is worth preserving) is a mere superstition. A bad thing is none the better because it has been where it ought not to be for a hundred years, nor is it worth while to leave it in its place merely to show that some of our forefathers were fools. We have ample evidence of that historic fact, as our descendants will have some similar evidence about their forefathers, but it may be questionable whether it is a kind of fact which it is worth while making much architectural sacrifice to keep on record. But this worship of everything that has ever been done in architecture, because it has been done, is unworthy of thinking people. It is a standard such as has never been set up or acted upon in any previous age. It is carried to the extent of absolute falsifying of architectural criticism. As a prominent example, we may refer to the admiration which one now constantly hears expressed for the west towers of Westminster Abbey. Whoever designed these (for it is by no means certain that Wren was really guilty of them), there can be no question, with any unprejudiced critic who is competent to form a judgment, that they are just about as bad as they can be; poor and weak in outline, and in detail a wretched travesty of Mediaeval detail by an architect who did not understand it, and had not the slightest feeling for it. Had the Society before referred to been in existence when those towers were built the very same men (had they lived then) who now profess to admire them, would have fought tooth and nail to prevent their erection,—must

\* N.B., not destroying them; nothing good in itself should be destroyed in any case. But it may be in its wrong place.

have done so, on their own principles. But because the towers have stood there a couple of centuries they are to be regarded with admiration. Could critical inconsistency and imbecility go further?

The question of removing monuments, however bad, is, of course, one of some complication. The notion at present seems to be that any monument, however execrable in taste, is, by the fact of being a monument, sacred. The general feeling is no doubt a right one, but we would venture to suggest whether there is not a limit to forbearance even in this case. The desire to have our names commemorated on a monument is, after all, rather a weak side of human nature; and when we consider how insignificant were some of the people who got hideous monuments erected to them, and how little worth is the fact of having your name preserved on a slab of marble when nothing worth knowing about the bearer of it has survived, we are inclined to apostrophise these dead names as Frederic did his soldiers who feared to go under fire,—“Dogs! would ye live for ever?” Monuments of nobodies, which are tasteless and poor, we cannot think have necessarily a claim to disfigure a building for ever; especially as they might usually be preserved elsewhere. A case has been prominently mentioned in the course of the recent correspondence on the subject, of the removal of the “Pedlar window” at St. Mary's, Lambeth; a portrait of a pedlar and his dog, who (the pedlar, not the dog) is reported to have left a piece of land to the parish on condition of being thus memorialised in the church. The window should be preserved, and it is reported that it is to be put in the vestry: the proper place for it; but a fuss has been got up about it as if an act of sacrilege had been committed. We should be disposed to say that the pedlar was guilty of a vulgar and unseemly ambition in wishing to be portrayed in the church, of all places, on such grounds, and that the then authorities of the church did an unseemly thing in entering into the bargain. The complainants make a point of the fact that it is displaced to make room for a memorial window to recent inhabitants of the parish, but we may take it for granted that this is not intended to consist of portraits of them (or of their dogs), but of some subject more suitable to a church. There is much more reason in the complaint of a Worcestershire Rector, that he found the old Norman font banished to the outside of the church by the restoring architect, “in favour of a new one of a kind that one may buy any day in London or Birmingham.” If the old font was really in a condition in which it could be used, to banish it was contrary to all church tradition and association, for in most church rebuildings in the Middle Ages the font was preserved, even when the architecture of the church was entirely altered; which is the reason so many Norman fonts are to be found in churches of later date.

To sum up,—the question of restoring and altering an old building is one to be considered dispassionately and in due reference to all the circumstances bearing on the practical utility and the architectural design of the building, and the true value of the objects it is proposed to displace. Each case, so considered, would be found to have its own special features and require its own special treatment, to be decided on grounds of reason and common sense, not on those of exaggerated and over-acted sentiment.

#### AN ANCIENT FOUNDATION RECORD.

THE new volume of cuneiform inscriptions which the Trustees of the British Museum have just issued under the editorship of Sir Henry Rawlinson will be welcome alike to the archaeologist and the philologist. The very extensive and surprisingly productive series of explorations carried out by Mr. Rassam in Babylonia have resulted in very large and valuable additions to our national collection, and it is from these that the selection of inscriptions now published has been made. In the early

days of Assyrian decipherment it became apparent to students that Assyria was, in art, science, and literature, the child of Babylonia, and if they would study that literature in its early editions they must do so in the libraries of Babylonia. The ancient cities of Chaldea were most jealous guardians of the treasures hidden beneath their ruins, and for years the brick hunters and explorers had dug unrewarded. The discovery, some ten years ago, of the Egibi tablets opened up a new era in Babylonian explorations, and from that time there has been a continual flow of inscriptions and monuments into the national collection. The result of the opening up of these hurried libraries of Chaldea has been a very extensive enlargement of the area of encephalic literature, and proofs of a most indisputable kind have been furnished of the great antiquity of Chaldean civilisation. The inscriptions now extant show that long prior to B.C. 3750 the work of civilisation and development in Chaldea must have been going on, and changes in national life had taken place which could not have been accomplished in a few centuries, but must have occupied some thousands of years.

The fortunate accident that led Mr. Rassam to excavate at Aboo Hubba has restored to us the site of one of the oldest cities in Chaldea, in whose temples were preserved antiquities reaching back to a very remote period. The publication of the two cylinders of King Nabonidus, which were found in the coffin or foundation chest of the temple, as we have already described in the *Builder*, furnishes us with an insight into the history of this remarkable building and the changes it underwent during many centuries. Judging by the text of the inscription, which consists of about 170 lines, the cylinder was written in about the tenth year of Nabonidus, B.C. 543, a few years after the capture of Echatana by Cyrus and the overthrow of the Median empire. The cylinder records the restoration and adornment of three temples. 1. The Temple of the Moon-God, in the city of Harran, in North Mesopotamia. 2. The Exploration and Restoration of E-Parra, the Temple of the Sun-God. 3. The Exploration and Restoration of the Temple of the Goddess Anunitiv. Both of the latter were in the city of Sippara, the site of which is marked by the mounds of Aboo Huhba. The archaeological value of this inscription consists in the insight it affords into the way in which the kings carried out their pious works of restoration. The first duty of a king when engaged in the work of restoring some ancient temple was to search for the memorial records of the founder or previous restorers of the temple. All the memorial tablets and cylinders which have been found in the temples and palaces of Assyria and Babylonia conclude with a solemn request to future descendants of the writer to respect his records, to clean and replace them, as for example, in the tablets of Assurnazirpal (B.C. 885) found at Ballawat, which are published in this volume (pl. 69-70), where we read:—"O future prince among the kings my sons whom Assur shall proclaim him! When the temple shall decay and this tablet thou seest, and thou reuovest, its ruins restore thou. The characters of my inscribed name to its place restore thou. Bel, the great god; Assur, the lordly prince; and the god Makhir, dwelling in this temple, in the raising of their eyes, firmly may they establish. His writing, his name, his seed in their land, may they establish. Whosoever this tablet shall see, and sins [curses] many shall repeat. O goddess Istar, lady of war and battle! His weapons then thou breakest, his throne then thou takest from him. Whosoever this tablet shall see and raise it up, the altars shall cleanse, a victim shall sacrifice, and to its place restore. Assur the great lord his praise shall hear, and in the battle of the kings, in the place of the onset, the courage of his heart shall find for him."

In the works of restoration which he undertook, the Babylonian king most religiously fulfilled the prayers of his ancestors, and it is from the record which he gives of the various foundation-stones he found, that we gain

much valuable chronological information. The Temple of Harran, which he restored, was a very ancient edifice, and, though strictly speaking, not a Babylonian temple, was affiliated with the great centre of Chaldean moon-worship, the temple at Ur. In an ancient astronomical tablet, mention is made of the planet Mercury "as the star and prince of the men of Harran"; and there is a seal in the British Museum on which is represented a priest standing before an altar, surmounted by a cone, and above the cone a star, with the inscription, "The God of Harran." This temple was probably in existence when Abraham migrated from Chaldea, and as a colony from Ur would be the city he would most naturally remove to. During the disturbed state of West Asia, from B.C. 625 to the establishment of order by Nebuchadnezzar and his successors, the temple had been sacked by the Sarmatians, or barbarian hordes of Scythians and Medes, and Nabonidus was commanded in a dream to restore it. In his search for the records of his ancestors he found the cylinders of Shalmaneser II. (B.C. 859), the son of Assurnazirpal, who had visited the city when marching against the Syrians. He also found there the cylinder of Assurbanipal, which had no doubt been placed there soon after the king's coronation in this temple, which took place in B.C. 668. The work of restoration seems to have been very important and to have extended to the city as well as the temple, as the king speaks of his restoration of "the city and the temple"; and again he says, "the city of Harran in all its extent" was restored by him. The work of restoration is described as consisting of a thorough rebuilding of the temple, "the walls were rebuilt, and in parts plated with gold and silver, and decorated with white marble." The doors were of cedar-wood, with bands of gold and silver inlaid with precious stones. At the gate of the rising sun (east gate) the king placed right and left two colossal figures of the god Lakhma, the god of Light. The work completed, the king says that amid great rejoicing and shouting he made "the city of Harran and this temple as bright as the rising moon." The city of Harran was a town of considerable importance in North Mesopotamia, and derived its name from the word *kharranu*, a road, it being then as now the centre where all the chief roadways met. The city has recently been visited by Professor Edward Sachau, of Berlin, and is described by him in his work, "Reise in Syrien und Mesopotamien." The town was crescent-shaped, and the Arah chronicles say that Harran was shaped like the moon, no doubt an echo of its ancient celebrity as a moon city. In the centre of the south portion is the castle mound, rising to a considerable height, and beneath which in all probability are the ruins of the temple. There are six gateways; and here centre the oldest commercial roads in the East. The Harran-Serudj-Berejik road, the ancient North Hittite road which passed through North Syria, Asia Minor, to the shores of the Egean; the Harran-Jerabis route, the ancient road to Carchemish and Aleppo, traversed no doubt many times by the armies of the kings of Assyria. The roadway passing south through Kalat Nedjim, the ancient Tul Barsip, to Damascus via Tadmor (Palmyra). Eastward were two roads, the one leading to Diarbeker, the ancient Armenian route to Van, and the Mosul road, the ancient route to Nineveh. Here, then, is one of the most important centres of civilisation in Western Asia, a city old in the days of Abraham, awaiting the touch of the explorer's spade to yield up a rich store of buried records. The cylinders of Shalmaneser and Assurbanipal were cleaned by the pious restorer and placed along with his own, and are no doubt lying *perdu* until unearthed by the explorer. The work of restoration of the two great temples at Sippara was more elaborate than that at Harran, and the search for the records of previous benefactors to the shrine even more careful. During the wars and rebellions subsequently to the establishment of the Sargonide dynasty in B.C. 721, this chief city of North Babylonia had suffered very considerably at the hand of the spoiler, and in B.C. 663 the Elamites had

spoiled the temple and carried off the images of the gods. In the fine terra-cotta cylinder of Assurbanipal (Cylinder B) the king records his works of restoration; also in a barrel cylinder, printed in this volume,—but they appear to have been only partial, and it remained for Nebuchadnezzar, "the Great Builder King," to undertake the thorough work of restoration. The work must have been a very heavy one, for the King (Nabonidus) records in this inscription that his predecessor was engaged for more than forty years on the work, and then had not completed it. Nebuchadnezzar appears to have searched vainly for the records of the foundation of the temple, and the search being continued by Nabonidus he found at last, at the depth of 18 cubits, that is 30 ft., a memorial record of Narum-Sin, son of Sargon I., king of Agadhe or Akkad, one of the quarters of Sippara, which had been placed there 3,200 years previously to his reign, that is in B.C. 3750. This very astonishing date does not rest upon the authority of one inscription, but is repeated in a duplicate copy recently discovered,—and the subsequent discovery by Mr. Pinches of a chronological canon of Babylonian kings, indicates that the scribe who wrote this text no doubt consulted the lists of kings in his temple library.

The depth to which the excavations had to be carried to find this record seems strongly in favour of the authenticity of the date, and the fact that the temple had at various times during that period been demolished and repaired by nearly one hundred kings may account for the accumulation of matter over the record.

Having cleaned and repaired this record, and sacrificed the victims, and poured out libations, the king restored it to its place. During the search for this record, the statue of the Sun-god had been removed from the shrine to another, and it rested there until the works were completed. As in the case of the temple at Harran, gold, silver, and precious stones were lavishly used. One fact recorded is the use of *five thousand* beams of cedar wood for the ceiling of the shrine.\* The work of this temple completed, the king commenced the restoration of the sister temple dedicated to the goddess Anunitiv. This goddess,—the Babylonian form of Istar or Venus,—was the goddess of the morning and evening star, "who," as the inscription says, "at the rising and setting of the sun made glad the heart of Nabonidus." A curious detail of symbolic decorations is recorded in her temple, some chambers of which were explored by Mr. Rassam, was decorated with black and white, as emblematic of the morning and evening. In the exploration of this temple, and the search for records for previous restorers of the shrine, the king found the memorial-stone of King Sagaraktiyas, son of Kurdur-Bel, which, he states, has remained unseen for 500 years, thus fixing the date of this king as B.C. 1050. The work of restoration of this temple was much the same as that of the other temples,—gold, silver, precious stones, marble, and crystal being lavishly used. From this valuable archaeological text we gain many new technical terms, such as the words for foundation, *ussu*, literally "base," the foundation stone being called *imim*, literally "line is made"; roof, *lakhyqi*, that is "covering"; and the bands of brass on the gates, such as the scrolls from Ballawat, were called *sikuruti*, or "ties." This text is one of the fullest and, fortunately, best-preserved records yet recovered from the ruins of Babylonian temples, and its publication reflects great credit upon the Trustees of the British Museum.

In like manner to his ancestors, this royal archaeologist concludes his inscription by commending his foundation record to those who come after,—to read it, clean its inscription, and to restore it to its place un injured. Could he but see the place of honour it now occupies in the New Room of the Assyrian Department, surrounded by the like records of many who before and after him ruled the land of Chaldea, we doubt not that he would be satisfied.

\* The word *imim*, literally means "overshadowing," and is from *imim*, "shade," and must therefore be the ceiling.

### WATER PURITY AND SEWAGE PURIFICATION.

HE recently published volume of Transactions of the Sanitary Institute of Great Britain contains the address of the late eminent analyst, Dr. Angus Smith, at the Congress held last year at Glasgow. It deals so largely with the much-discussed subject of water purity and purification of sewage, that it seems singular no one in the recent Conferences should have thought of quoting the views held and propounded by such a distinguished authority. It may be useful, therefore, at the present time to draw attention to some of the remarks contained in that address. Commencing with an allusion to the labours generally of M. Pasteur in France as "of a kind which cannot be too highly admired," he refers more especially to his latest discovery, viz., "the attenuation of the virus of chicken cholera by the action of the air and oxygen." Quoting Pasteur's own words regarding the cultivation of virus in contact with air, and the experimental test by which he was enabled to pronounce as a principle that "it is the oxygen of the air which attenuates and extinguishes virulence," and which led him to the supposition that "it was oxygen, as an ever-present agent, that set the limits to great epidemics," Dr. Angus Smith explained how he himself, while pondering over the effect of oxygen on organic matter, was led to the conclusion that "it destroyed those minute forms which have been shown to be concomitant with putrefaction and decay." A similar mode of thought had previously led him to consider that it was the want of an excess of oxygen that caused confined sewer gas to be dangerous, whilst the enormous amount of gas coming from decomposing matter, such as on the Clyde, seemed to pass away, leaving comparatively little effect. This purification of the polluted waters of the Clyde, Professor Smith explains thus,—"The air may act in two ways. It may act by rapid oxidation of the substances in the water, or by dilution of the gases when formed, and the destruction of putrid matter in water is really very rapid when plenty of air is allowed. Air is brought to the Clyde by the water, and also by the waves, both artificial and natural, exposing a great deal of surface. The air may act also merely by rapid dispersion of the gases"; but as in the case of the Clyde no marked type of disease, such as is produced by confined sewer gas, has been generated, the conclusion is drawn that "it is not to mere dispersion, but to a more thorough putrefaction and oxidation, and to a more complete destruction of the organic substances by the abundance of air than can take place in sewer water," that the Clyde owes its immunity.

The observations which follow, while unfolding a provision of hygienic action in nature known but to comparatively a small section of the community, explain the process so clearly as not to require any special scientific knowledge for its comprehension; but they have such an important bearing on what may be almost termed the absorbing topic of the day for the dwellers in London and its suburbs, that little apology is needed for transcribing them at length. "If nature," Professor Smith observes, "had contrived no method of destroying such seeds of death, populations such as that of Glasgow would never have grown up. And what is the method? That method is first, putrefaction; at least, I know of none other, except the concluding portion of that work, viz., thorough oxidation. When, therefore, you see the Clyde seething with gases of putrefaction, and when you smell it to such an extent that a feeling of loathing is produced, you may remember this, that the work of destruction is going on with a wonderful rapidity, and that the enemies of life are being slaughtered there millions upon millions, never to appear again in a similar form, though other generations of them may rise up. As putrefaction seems not to take place without the action of organisms, I had the idea that it might be arrested by an abundant use of air, and I had some belief that the oxidation took place very rapidly after putrefaction. It was

when examining this subject that I found it necessary to touch also upon the question of vitiation in water. When nitrogenous bodies decompose with an abundance of oxygen, the nitrogen becomes oxidised, and nitric acid is formed. I had long suspected that the reverse also took place, and that when there was an excess of putrefactive matter, oxygen was absorbed and even removed from the nitrate, whilst free nitrogen was given off. This process I was able to verify by carrying it on in the laboratory. It was clear, then, and beyond all cavil, that rivers could purify themselves in time, and organic matter be thoroughly removed. It was my belief that organic substances, that germs of disease, that microbes, or the smallest organisms themselves, were all subjected to this universal and unsparring attack of putrefaction and oxidation." In his Report on the Rivers Pollution Prevention Act, Professor Smith, referring to the above-mentioned results, pertinently asks, "How far, then, can oxidation, or a great supply of air, be employed to destroy putrefaction, or to purify? The bearing that it has on the analysis of water will be clearly seen by chemists." We took occasion to remark, in a recent notice on the late General Scott's pamphlet, that too little importance had been ascribed to the aëration of water, and the above quotations from Professor Smith's address greatly emphasise our observations on the desirability of the water companies devising some means to give the requisite aëration to water pumped from the Thames and other rivers with a view to still further depriving it of such organic impurities as it may still contain. With such an authority as that of Professor Angus Smith on the self-purifying power of rivers, supported by the opinions and scientific investigations of Professors Sorby and Odling, it seems little short of folly to advocate the disuse of river-water for our domestic supplies (at least in cases where the river is adequate to the demand), and to incur great and needless expenditure in leading water from distant sources, or in raising it from enormous depths, when by a comparatively small outlay on the process of aëration, the obvious sources of surface supply so humbly provided by nature can be rendered innocuous from the pollutions resulting either from an excessive growth of our population or from the ever-increasing demands of our civilisation.

But not only is oxidation a chief agent in the purification of water, but its effects are equally remarkable when applied to sewage. "Substances and living things, the Professor observes, "may be carried by the rapid sewage system into the range of a new activity before undergoing that putrefaction which breaks them up in proximity to us or in the sewers themselves. It seems to point to a plan of causing the destruction of organisms by putrefaction and subsequent oxidation or by chemical action. At least it seems to me that we require to learn if it be true that any of the germs of disease will live in an abundance of good air. We know that abundant dilution will render them all ineffective. It is probable there will be a difference amongst them in this respect, whilst all will yield to the double action of—first, putrefaction, and then oxidation."

After explaining the character of the changes involved in the word "decomposition" the doctrine sought to be emphasised is that putrefaction in a certain stage is one of the greatest of purifiers, and the most complete that nature has devised. By the germ theory, it is supposed by many who use it without knowing its meaning, that some little germ of disease passing from a sewer into a river may carry with it power to infect other organisms, and thus endanger the lives of all within its reach. But it is abundantly evident from actual results that no such power of infection exists in any of the germs yet known when putrefaction and oxidation are abundantly given. Probably the River Clyde is subjected to as great, if not greater, pollution than any river in the United Kingdom, and yet, as Professor Smith observes, the number of persons who go down from Glasgow to the Firth of Clyde, and who receive health and strength there, are living

testimonies to the absurdity of current ideas as to the power of germs in such situations.

The treatment of sewage is certainly the burning question for the day to Londoners, and, therefore, a contribution towards its solution by so eminent a chemist is deserving of the most attentive consideration. Experiments for ascertaining the complete disruption of organic matter in water first led Professor Smith to the thought of driving air through sewage in order to produce oxidation, in the belief that excess of air would be offensive to the microzymes, although a small amount seemed necessary for their activity. But the late Dr. James Young was of opinion that that process would be found too expensive, and he conceived a plan of passing steam through sewage at a very low tension, and, consequently, with an enormous bulk. Dr. Young died before he could perfect his design, but it is believed that he had thoroughly mastered the subject, and that it may yet be possible, from the information contained in the papers which he has left, to bring his process to a practical issue. Unhappily the great mind which would, doubtless, have best contributed to this end has likewise passed away. It is to the marvellous powers of oxygen, however, that Professor Smith was desirous of directing special attention.

"It would seem," he observes, "as if this wonderful agent had the remarkable power of blowing hot and cold, of producing strength and weakness, being our greatest friend and an enemy from which we cannot escape. No wonder, then, if we give it many contradictory duties to perform. It was always known that pure air had a cleansing power, and it has long been known that oxygen was the main agent there; but it has somehow happened that its rapidity of purification has never been brought so clearly to my mind as by these experiments on the purification of sewage. The act of purification is to be seen here rapidly. It is not the work of days or weeks, but the work of minutes; and the belief is taken out of the region of reasoning into that of the simplest observation." If this statement be correct,—and who can call it in question?—the solution of the problem of the disposal of sewage cannot be very far off. In comparison with the Clyde, the Thames, even in its worst portions, is a wholesome river, and there can be little doubt that the dwellers on its banks have, like those on the Clyde, to be thankful for the self-purifying process that Nature has provided for the immunity which they have consequently experienced from the worst form of epidemics, which, according to many authorities, ought to have decimated the metropolis long ago. Nature is long-suffering, and left to itself works miracles more wonderful and sure than human science can do; but at the same time there is undoubtedly a limit even to the powers of Nature, and to that limit it would seem we are rapidly approaching.

It behoves, then, those with whom the authority and the purse-strings rest to bestir themselves ere it be too late, and to relieve the river from, at all events, any further addition to its sewage burden. Prevention is better than cure; and, therefore, the sooner a diversion of the sewage of the metropolis to the sea can be made, the safer will it be for the health of our great city; but at the same time it is to be hoped that the lessons which the late distinguished Professor sought to teach may bear practical fruit in the purification of both our water supplies and sewage.

### NOTES.

HE President's address at the opening of the Social Science Congress dealt mainly with the subject of the increase of State intervention in the form of legislation, of which subject a very comprehensive summary was given, mainly tending to the acceptance of State intervention as a fact of the age, and as in the main beneficial in its results and even a necessity for the proper working of society in the present day. In one class of interests, however, he admitted that Parliament had resisted every attempt to make Government responsible,

viz, in regard to the working and management of railways. We do not know whether Mr. Shaw Lefevre means to hint that Government intervention might be extended in this direction also. We can imagine nothing that could well be more disastrous to the interests of the travelling public. Some of the companies require some pressure to induce them to adopt improvements which they ought to have adopted long since; but in the main, competition, scientific enterprise, and a certain pride which first-class companies take in the working of their lines, are better securities for good service than any that Government could offer.

It not infrequently happens that a myth little known or unknown to literature is specially emphasised by Greek vase-painting. A good instance appears this month in the Monument of the German Institute at Rome. On an amphora recently discovered at Orvieto the following design appears:—Herakles, unmistakable from his lion's skin, is at work digging the earth with a pick, near him an uprooted vine. To his right a bald, old man threatens him with a hammer; the bald, old man is of the type peculiar to Silenus. To the left of Herakles stands his patron goddess Athene. Evidently the story embodied here is the myth of some labour of Herakles, in which he was compelled to work at agriculture, in the service of the old wine-god Silenus. A similar design appears on two other vases, one in the Louvre, the other at Capua. Their style forbids the supposition that they take the inspiration from the Satyric drama of Euripides. The execution of the vase now published in the Monument clearly belongs to the middle of the fifth century. It has all the marks of the manner of the Attic Cylix, masters whose best known representation is Hieron. It has therefore to look for its inspiration to some early form of the legend of which we have no literary record.

NOW that the juncture of the Metropolitan and Metropolitan District Railway is approaching completion, it is a proper time to call attention to the want of a connexion between the Great Western and Metropolitan Railways at Paddington,—a connexion, we mean, by which passengers may be able to pass from one station to another without climbing steps, and having to cross a crowded thoroughfare. Such a connexion has now for some years been in existence between the Great Eastern and the Metropolitan Railways, and it is perfectly scandalous that the same kind of passage has not been made at Præd-street. It is a cause of much inconvenience and very often of considerable delay when passengers from one station to the other are obliged to enter the street. One would have thought that the Metropolitan Railway, from motives of self-interest, would have endeavoured to secure as many passengers as possible from the Great Western system, instead of leaving them to be caught by cabs and omnibuses. It is to be hoped that if these companies do not make the necessary connexion Parliamentary attention will be drawn to the subject whenever a Great Western or a Metropolitan Railway Bill comes before the House. For if the companies will not of their own motion consult public convenience on this point, pressure should be put on them to compel them to do so.

WE hear with great regret of the death of Mr. Walter R. Browne, the engineer, who crossed the Atlantic to attend the meeting of the British Association, and died of typhoid fever at Montreal on the 4th of this month. Mr. Browne, who was only forty-two years of age, combined with great ability and knowledge of professional matters the talent also,—not always found in combination with engineering proficiency,—of clear and forcible literary expression and exposition of his knowledge on special subjects. A brilliant paper read by him at the Annual Meeting of the Iron and Steel Institute in May last led us to invite his co-operation in this journal, an invitation to which he responded with the energy and readiness which seemed part of his nature; he had already contributed several papers and Notes

on engineering subjects to our columns, and voluntarily undertook to act as our special correspondent in the Mechanical Section of the British Association meeting, and it was to his expected communications that we referred in a "Note" in reference to the British Association proceedings (page 284, *ante*); communications which were destined never to be written. He had projected an important series of papers on a special subject for this journal, to be commenced immediately on his return. If we may judge from what we came to know of him in the course of business, those who were his most intimate connexions will have had still more occasion to regret his loss as a personal friend.

UNDER the title of "Links in the History of the Locomotive," the *Engineer* is publishing a very interesting series of illustrated articles. Last week appeared No. 17 of the series, which endeavours to clear up some doubtful points as to the celebrated locomotive built by George Stephenson, and known as the "Rocket." There were, it now appears certain, two "Rockets" built by Stephenson. The first one was built in 1829, and of this the *Engineer* publishes an illustration copied from a drawing made by Mr. Phipps, M.I.C.E., who was employed by Messrs. Stephenson to compile a drawing of the "Rocket" from such drawings and documents as could be found. This gentleman had made the original drawings of the "Rocket" in 1829. But "Mr. Phipps is quite silent about the history of the engine during the eleven months between the Rainhill trials and the opening of the [Liverpool and Manchester] railway." Concurrently with the illustration we have mentioned, there is also published an exceedingly interesting *fac simile* of a sketch made by James Nasmyth (subsequently the inventor of the steam hammer, and of whose facility as a draughtsman we had occasion to speak some time ago) of the "Rocket" of 1830. On this drawing is the following memorandum, in Nasmyth's handwriting:—"This sketch of the 'Rocket' I made at Liverpool on the 12th of September, 1830, the day before the opening of the Liverpool and Manchester Railway, while it remained stationary after some experimental trips in which George Stephenson acted as engine-driver and his son Robert as stoker. James Nasmyth." That the engine now shown at the Patent Office Museum, South Kensington, is not the one which was sketched by Nasmyth, is very evident. Our contemporary does not so much question that the "Rocket" at South Kensington is in part, perhaps, the original "Rocket" of Rainhill celebrity, as that it ever ran in regular service on the Liverpool and Manchester Railway. But then, what became of the "Rocket" of 1830? The suggestion is that the first "Rocket" was cast on one side until it was bought by Lord Dundonald. But the "Rocket" of the Manchester and Liverpool Railway is hardly less worthy of attention than its immediate predecessor, and concerning it information is needed. There are probably men still alive who could clear up the question, and it is to be hoped that they will do so.

THE question of keeping Highgate Woods as an open space is one of immense importance to the metropolis. It is obvious, however, that the Ecclesiastical Commissioners cannot do otherwise than make the most they can out of this property. They are bound to administer their property to the best advantage, without regard to the question of whether or not it is pleasant or advantageous for a neighbourhood. At the same time it seems equally clear that in dealing with a property like these Highgate Woods the Commissioners may, without failing in their duty, make the offer of the ground to the public, or to any body representing the public, if such body can pay the same sum as would be received from selling or letting the ground for business purposes. Of course, Parliament is supreme, and can pass any special measure in regard to the Ecclesiastical Commissioners and Highgate Woods which they please. But one thing there can be no doubt about, and that is, that since public attention is directed to this matter, the Commissioners

should hold their hands before dealing with the property, in order to let the public feeling come to some practical determination.

WE have received from Frankfort-on-the-Maine a pamphlet by Herr Herrmann Ritter, architect, giving an account and illustrations of an ingenious but very complicated drawing instrument invented and patented by himself for mechanically translating the lines of geometrical plan and elevation into perspective. It would be impossible to make a description intelligible without drawings; but we mention the fact that those who feel any curiosity about it may apply, if they like, to the inventor, or to Maubach & Co., of Frankfort. Our impression is that it is just one of those things which look beautifully clever and complete in a drawing, but which in practice would be more trouble than the result is worth. A good draughtsman wants no machine.

THE autumn congress of the Sanitary Institute of Great Britain commences at Dublin on the 30th, under the Presidency of Sir R. Rawlinson, C.B. The department of "Sanitary Science and Preventive Medicine" is presided over by Dr. T. W. Grimshaw; that of "Engineering and Architecture," by Mr. C. D. Cotton, C.E., and that of Chemistry, Meteorology, and Geology, by Dr. C. A. Cameron, the gentleman who cannot perceive any sewage nuisance in the Thames at Barking. As Dr. Cameron is Superintendent Medical Officer of Health for Dublin, it is to be hoped he is more sensitive as to the Liffey.

ON Wednesday last were interred at Highgate Cemetery the remains of Mr. John Netten Radcliffe, formerly one of the Medical Inspectors, and more recently Assistant Medical Officer of the Local Government Board. Mr. Radcliffe has done so much good work for the advancement of public health and the promotion of hygiene generally, that his memory deserves a grateful record in this journal, which has ever aimed at the advancement of those important objects. Mr. Netten Radcliffe, who began his career as a volunteer in the medical service of the Turkish Army during the Russo-Turkish War 1854-5, was the inventor of the hospital tent which bears his name, and which has often done good service in epidemic outbreaks of disease. In 1874 was published his celebrated report to the Local Government Board on certain means of preventing excrement nuisances in towns and villages,—a report which is regarded as a standard work on the subject of that branch of nuisance-prevention. Mr. Radcliffe also wrote some valuable reports on hospital hygiene, and among these were three of special importance relating to the structure and arrangements of the Radcliffe Infirmary at Oxford, the Norfolk and Norwich Hospitals, and the Royal Infirmary at Manchester. These were published in the Medical Officers' Supplement to the Sixth Annual Report of the Local Government Board, 1878, and are well worth the careful study of any architect engaged in hospital work. Mr. Netten Radcliffe retired from official life in 1883, in consequence of failing health, and died on the 12th instant at the age of fifty-seven.

THE *Courier de l'Art* is very severe on the work that is being done in the way of the decoration of the Panthéon:—"Ce sévère colosse qu'on est en train d'affubler d'un habit d'arlequin." The latest additions to the decoration are two frescoes by M. Maillot, in one of the lateral chapels, and a mosaic by M. Hebert. The subject of the latter is "Christ teaching the Guardian Angel of France the Destinies of her Country." The guardian angel is Joan of Arc, who, habited "*en cuirasse*," is "presented" by the Virgin. M. Hebert is credited by our contemporary with skill in the arrangement of the composition, but with far too medicrevalising a tendency in his efforts to consider decorative effect. He has placed in the classic Panthéon mosaics of the early Ravenna type. The artist is accused of having given himself to this style of late, and

exhibiting in the *Salon* every year one of these dying creations, figures with green flesh, hollow eyes, which make the spectator feel ill to look at them. In the mosaic, "Le Christ, la Vierge, les anges, tous sont longs, longs, comme des jours sans pain." Nevertheless, the critic somewhat inconsistently admits that this "longueur" gives a character of idealism to the figures which does not displease him. Some painters and critics with us seem to be of the same mind.

#### SUBTERRANEAN RAILWAYS IN PARIS AND IN LONDON.

THE pressure of population on the channels of communication, of which we have so much experience in London, is becoming intolerable in Paris. In 1881 a population of 2,243,000 persons was contained in 77,000 houses, over an area of thirty square miles, in that city. In the same year the "Greater London" of the Registrar-General contained 4,764,312 inhabitants, occupying 615,818 houses, built over an area of 697 square miles. The total passenger traffic of Paris is returned at 310,000,000 persons in the year, or about 932,000 per day; of whom about 34 per cent. were carried by tramways, 31 per cent. by omnibuses, 30 per cent. by cabs and other vehicles, and 5 per cent. by steamboats. In London the total amount of traffic is not accessible; but 384,000 pedestrians and 75,000 vehicles pass daily over the metropolitan bridges; and the traffic on three of the metropolitan railways, —viz., the Metropolitan, the Metropolitan District, and the North London, — amounted in 1881 to 373,000 passengers per diem. This total takes no account of the daily influx of passengers by railway at Victoria, Paddington, Euston, St. Pancras, King's-cross, Ludgate-hill, and the Eastern Counties Terminal, or of those who, arriving at the London Bridge or the Waterloo Stations, do not cross the river; or, again, of the dense traffic on the high-level line from Charing-cross to Cannon-street. The rate of travelling in Paris, according to the previous statement, is rather more than 150 journeys per inhabitant per annum. Going and returning, then, without counting pedestrians, each Parisian will only take an enumerated trip by vehicle three times in a fortnight. At the same rate the London journeys by railway or other vehicle would amount to upwards of 711,000,000 passenger trips per annum, or nearly 2,000,000 per diem, without counting pedestrians.

Whether we regard London, Paris, or any other great centre of population, it becomes apparent that an enormous amount of inconvenience and loss of time is due to the abandonment of the ancient Roman method, borrowed from the camp, of building cities on the plan of straight thoroughfares, crossing each other at right angles; a return to which excellent method has been accomplished by the builders of the rapidly-growing cities of the United States. The actual loss of that time which has a direct money value that is incurred by the want of a direct thoroughfare, either for locomotives or for common road vehicles, from the northern to the southern railway stations in London, must be something very serious indeed. In Paris there exists a similar inconvenience, although, of course, on a smaller scale, which it is now proposed to remedy. Three lines of subterranean railway are projected for this purpose. One will connect the Chemin de Fer de l'Ouest with the Lyons Station, with a branch to the Arc de Triomphe, and another, by the Trocadéro, the Mont Parnasse, and the Orleans Stations to the Sceaux Station. Lastly a line is to run north and south, inside the existing Ceinture Railway, passing the Nord and Est Stations, the Bourse, and the Halles Centrales, to the Sceaux Station.

The total length of the lines which it is thus proposed to construct is 23·25 miles, for which the estimate is 5,720,000*l.*, or about 246,450*l.* per mile. The average gross revenue of the tramways along the *boulevards* and from the Place de l'Étoile to La Villette, together with that of the three-horse omnibus service along the Boulevards La Madeleine and Le Bastide, is 26,833*l.* per mile per annum. If the new line provide for the traffic a *grande vitesse* only, as will probably be the case, and if the traffic secured by the new line yields an equal revenue per mile to that above cited, there can be little doubt that the undertaking would pay 6*½* per cent. on the capital; while, if the amount of the

omnibus traffic cited be taken as a measure of revenue, the return would be between 9 and 10 per cent. on the capital, assuming the estimate not to be exceeded.

It may be instructive to compare this outcome with that of the railways through London. Unfortunately, the accounts of the Charing-cross and Cannon-street line, like those of the Ceinture Railway in Paris, as involving operations on the part of more than one company, are not distinguished in the annual returns. But we can take the average of the statistical features of the North London, the Metropolitan, and the Metropolitan District railways, which form an aggregate length of fifty-two miles. Of these, the cost per mile, at the end of 1883, averaged 416,538*l.* The gross revenue was 30,047*l.* per mile per annum, and the working expenses came to 14,400*l.* per mile per annum. The resulting earning on capital is only at the rate of 3·52 per cent. per annum; but this net return on traffic is reduced by the omnibus character of the North London traffic, which, following the usual law in such cases, costs 51 per cent. income to work, while the two passenger lines are worked at 42 per cent. of gross income. On the North London Line each servant of the company only earns 227*l.* per annum, while on the Metropolitan District the mean earning per servant is 348*l.*, and on the Metropolitan, 305*l.* On the Ceinture Line (*Rive-droite*), the earning of each servant of the companies engaged averages 358*l.* per annum; while the average earning per servant on the Metropolitan and Metropolitan District Lines, taken together, is 375*l.* It thus appears that it is safe to estimate the working costs of the new Parisian lines as not likely to exceed 40 per cent. of the gross income, while the capital cost is only about five-eighths of that of the three London lines.

It may be hoped that a consideration of these figures may tend to stimulate the attention of the metropolitan authorities to the construction of a better line of communication from north to south in London. The enormous cost of a line through London itself is very formidable, and can hardly be encountered by the promoters of any new line, taken *per se*. In 1878 the cost of the Metropolitan Railway stood at 639,000*l.* per mile, and that of the Metropolitan District Railway at 680,000*l.* per mile. The distances then open were 14 miles and 9 miles respectively; and the extension of the lines to cover distances of 22 miles and 18 miles has reduced the enormous mileage cost, while at the same time it has fed the traffic. At present, however, while regarding the possible development of electric traction, it perhaps is hardly the moment for asking the public to find two-thirds of a million per mile in order to link Euston and Charing-cross by railway. As to a well-laid out and practical street, however, a hint may be taken from the returns of the traffic of the Paris omnibuses. Let us give one pair of facts alone. The earning of each passenger carriage on the Metropolitan District Railway in 1879 was 2,028*l.* The earnings of each three-horse omnibus running along the Boulevards La Madeleine and Le Bastide since 1833 amount to 2,272*l.* per annum. It is true that it costs nearly three-and-a-half times as much to move an equal weight for a mile over the road as it does over the railway. But, on the other hand, the interest of money required is eight times as much in the latter case as in the former. Without expressing an opinion as to what is best, there can be no doubt that a wide, straight, well-paved street, served by a thoroughly well-ordered horse service, would, at the same time, be a great benefit to London, and a highly remunerative enterprise to the purveyors of this mode of communication. In fact the figures above cited, which are the result of a long series of observations, explain how it is that the dividend of the London General Omnibus Company is something more than twice the net earning on capital of the Metropolitan railways.

**Penally.**—The ancient church of Penally, well known to holiday visitors at Tenby, has been reopened after restoration of the interior. The floor has been relaid with encaustic tiles, and the whole series of six windows filled with stained glass. The east window, which was in very bad condition, has also been restored, and the church lighted with the Hesperus lamp, the whole of the work having been carried out by Messrs. Jones & Willis, of London and Birmingham.

#### THE CHURCH OF ST. NICHOLAS, DEPTFORD.

"Sey forth thi tale, and tarye nat the tyme;  
Lo here is Deptford, and it is prynced prime;  
Lo Greenwich, there many a scheyre is inne;  
It were all tyme thi tale to beynne."

CHAUCER, *The Reece's Prologue.*

WE recently directed attention to some extensive repairs which have been begun at St. James's Church, Piccadilly. Subscribers are invited to the amount of 2,415*l.* towards a thorough restoration of another important parish church at the opposite end of the town,—that of St. Nicholas, Deptford. Its ancient grey tower with turret, said to date from the twelfth century, must have formed in generations past, like to the windmills on the opposite Isle of Dogs shore, a prominent landmark to shipping in the Thames. Bearing northwards are Cuckold's Point and Limehouse Church, whilst due east stand the chapels of Greenwich Hospital with the wooded slopes of the Park beyond. Dedicated to the patron saint of sailors, the church stands on a plot of ground lying between Deptford-green and the Stowage, having Rose Cottages and the almshouses to the east. The nave, aisles, and chancel, of red brick, were built in 1697, and have been repaired upon two subsequent occasions. The register contains entries relating to the Pett family, the eminent ship-builders, one of whom, Peter, was master shipwright to Queens Mary and Elizabeth, the royal dockyard having been established here in their father's reign. In the burial-column we read, under date 1st of June, 1593, "Christopher Marlowe, slaine by Francis Archer." There are monuments to two of Evelyn's children, to dockyard officials, to Captain Fonton, a companion of Frohisher in two voyages, and to many naval commanders distinguished for their prowess during the last two centuries against our Dutch, Spanish, and French enemies at sea. The parishes of St. Nicholas and St. Paul, covering nearly 1,700 acres, constitute the lower and upper towns respectively; the latter, made separate in 1730, contains more than seven-eighths of the total population, and is served by a fine stone structure,—one of Queen Anne's "Fifty" churches. It stands in the midst of an extensive and well-kept graveyard. St. Nicholas's burial-ground is detached from the church, and has an entrance in Wellington-street. Having been laid out, at a cost of 300*l.*, by the Kyrle Society, this ground was opened on the 9th of July last by the Countess of Selborne for public recreation.

William the Conqueror, according to Dugdale, gave the manor of West Greenwich or Depeford, so called from the deep or passage through the Ravensbourne, to one Gilbert de Maginot.\* On his great-grandson's death in 1191, without issue, the property passed to the sister and co-heir, Alice, wife to Geoffrey de Say, who gave it to the Knights Templars. That body subsequently exchanged it with his son for Saddlecombe, county Sussex. After a short sequestration Henry III. restored the property (1223) to the Saxes, who again enjoyed possession until the close of the fourteenth century. Passing through various hands the estate, on John Earl of Lincoln's death at Stoke (1457), became forfeit to the Crown. Thereupon Henry VII. gave it, in the year following, to Oliver St. John. But having reverted to the Crown, the property was seized by Parliament on King Charles I.'s death, and was sold, as valued at 1,650*l.*, in behalf of certain state creditors. Since the Restoration the manor has vested in the Crown, the stewardship being held in conjunction with that of Greenwich. The Browne family had long occupied the manor-house or Saxes Court. At the Parliamentary sale they received the Saxes Court site, together with about sixty acres, in lieu of their interest in the whole.† This grant included the Red House (latterly the Victualling Office), a wet and dry dock,—since Deadman's,—and a water-mill. But Saxes Court's chiefest fame rests upon its associations with the Russian Czar and the author of "Sylvia." In 1647, at the Ambassador's Chapel, St. Germain's, Evelyn married Mary, only daughter and co-heir to Sir Richard Browne, our minister in France. Sir Richard died in 1683, in what Evelyn calls "my honse at Saxes Court." Evelyn, it appears, first made Saxes Court his permanent residence in March, 1652, on his return from a tour in France; and laid out the celebrated gardens

\* Compare the Sunderland suburb of this name,—on the river Wear,—where also are shipbuilding yards.

† Two hundred acres in all.

after the succeeding winter. In the Wotton MSS. is a detailed account of his operations, both building and horticultural, from which we gather that he planted the holly hedge, "even with the mount hedge below," in 1670. In the spring of 1683, he says, he planted all the garden out-limits and long walks with holly.\* Peter the Great lodged here, at the sovereign's charges, in 1698. His domestic habits were the reverse of fastidious, yet for his reputed pastime of being dragged through quickset hedges in a barrow, the Czar does not seem to have chosen Evelyn's favourite rampart of holly. For in the "Sylva," lib. ii., cap. vi., occurs this passage,—*"Is there under heaven a more glorious and refreshing object of the kind than an impregnable hedge of about 400 ft. in length, 9 ft. high, and 5 ft. in diameter, which I can show in my now ruined garden at Sayes Court (thanks to the Czar of Muscovy) at any time of the year glittering with its armed and varnished leaves, the tall standards at orderly distances blushing with their natural coral? It mocks the endless assaults of the weather, beasts, or hedge-breakers. Et illum nemo invane laessit."* It is diverting to contrast Evelyn's solicitude for his garden with Pepys's references thereto. The latter, under date May 1st, 1665, mentions his visit "to Mr. Evelyn's, which is a most beautiful place, but it being dark and late I stayed not; but Dean Wilkins and Mr. Hooke and I walked to Redriffe [Rotherhithe]; and noble discourse all day long did please me."† On the 5th idem he writes,—*"After dinner to Mr. Evelyn's; he being abroad [Evelyn was then busy with the care of some sick and wounded sailors, Dutch and English], we walked in his garden. A lovely noble ground he hath indeed, and, among other rarities, a bive of bees, so as, being hived in glass, you may see the bees making their honey and combs mighty pleasantly."* Sayes Court was pulled down in 1728 and a workhouse erected in its stead. The garden site has been lately laid out by the owner as a parish recreation-ground. Other changes followed. The dockyard, established for ship-building in the year 1513, ceased to be used for that purpose in 1865 upon the introduction of armour-plated vessels, and was converted into a victualling-yard for the Royal Navy. One relic, however, had long been jealously kept,—the good ship *Golden Hind*, whereon Queen Elizabeth visited and knighted her great captain, Francis Drake. The state cabin was fitted up as a banqueting-house. A chair was ultimately made out of the woodwork and deposited in the Bodleian at Oxford. In March, 1869, Mr. J. P. Austiu bought part of the old dockyard for 70,000*l.*, and sold it, with considerable profit, to the London Corporation for their foreign cattle market. This, however, was soon relinquished for the existing depot of cattle landed from abroad. The hall of the Trinity House came down in 1787. That Company was founded by Sir Thomas Spert, Comptroller of the Navy to King Henry VIII., and Commander of the *Harry Grace de Dieu*, of which ship one or two faithful models may be seen in Greenwich Hospital.

Lovers of the picturesque in what we must now reckon as part and parcel with Greater London would do well to devote an hour or so to the by-ways and leading thoroughfare of Rotherhithe and Deptford. Few better views can be obtained than those presented by Wellington-street (formerly Flagon-row), conspicuous for its irregular wooden houses and quaint little bulk shops whose floors lie below the road level. Similar points of interest are to be found in Church-street,—notably the Three Compasses,—in Creeke-road (*antique* New-road), together with Grove and New King streets, Deptford. Moreover, the streets which run southwards and eastwards have for distant background varied views of the Surrey and Kentish hills. Church-street, Rotherhithe, can boast of another curious bulk shop opposite to the Pavement, whilst of the many garden houses those in the neighbouring Paradise-row should not be overlooked.‡ Mr. Besant and his coadjutor, the late Mr. James Rice, laid most of the scene of

their "Captain's Room" at the Seven Hoses by Trinity Church, Rotherhithe. But it is to be observed that this name also belonged to a set of tenements which stood where the East London Railway passes underneath the Deptford Lower-road, near to the site of the old China Hall. Southwark Park absorbs the Mill Ponds and Halfpenny Hatch; Jacob's Island scarcely survives even in name.\* Southwark Park-road represents the old Blue Anchor-road. The wide sluice at the northern end of Jamaica-level may possibly be the remains of the canal which was made to relieve the river's current on the rebuilding of London Bridge by Peter of St. Mary Colechurch, at the end of the twelfth century. That cutting is further supposed to have been laid in the course of the water-trench that Crut opened for his abortive attack upon the citizens. Extending from the lower St. Saviour's Dock, Rotherhithe, to Lambeth, it passed through the multitudinous islets and the morass over which these low-lying parts of London have since arisen. The Jamaica Tavern, so renowned for its orchard, lay westwards of the new park, at the end of the now Cherry Garden-street. Hitler Pepsy would repair with his companions enlivening their passage by singing on the water. Cowley and the Earl of Nottingham, Queen Elizabeth's Lord High Admiral, lived in Deptford. Similar honours were conferred on Rotherhithe by Admiral Benbow and Swift, in the person of his Lemuel Gulliver; whilst such names as Hyde, Boscawen, and Hood streets perpetrate the memory of other naval heroes.

#### RESISTANCE OF VESSELS.

ONE of the subjects referred to by Lord Rayleigh in his inaugural address at the meeting of the British Association at Montreal last month was the resistance to be overcome in the propulsion of vessels. Till within a recent period in modelling vessels attention was confined to the resistance offered by the midship section, and experiments were carried out with a view to discovering the best form which could be given to the entrance and run of ships, so as to reduce that resistance to a minimum. Before the application of steam to the propulsion of vessels there were elements affecting the modulus of stability which need not enter into the calculations of the present day, such as the height of the masts, the spread and weight of canvas, the angle at which the sails might be set, and the amount of freeboard necessary for ships liable to be heeled over at a considerable angle by the pressure of the wind in a hurricane on the heavy top-hammer which sailing-vessels are unavoidably obliged to carry. The relative dimensions of length and beam were then much less, and the lines of entrance and run, together with the best form of bilge suitable for cargo stowage or the disposal of a man-of-war's complement and stores, presented a very complicated problem for calculation. The proportion of mid-ship section to the wetted perimeter of a fully-laden ship was much greater than it is in the models of ships in the present day; and, consequently, the resistance offered by the vessel's surface appears not to have been considered, while even that of the angle to be given to the entrance and run-lines, both horizontal and vertical, appear to have been but imperfectly understood. The late Mr. John Scott Russell's interesting series of experiments which demonstrated the wave-line theory, and reversed the old lines by giving a double curve to the entrance and a single curve to the run led to great modifications in designing vessels, and to the increase of speed in that class of ships known as "clippers" which were used, prior to the introduction of steam, in the China trade, and which always commanded the highest freights,—carrying as they did the most valuable products so as to secure the earliest sales in the London market. With steam-propelled vessels, however, it became necessary to alter the models. The proportion of length to breadth became much greater, and that of the wetted perimeter became largely increased over the midship section. The substitution of iron for wood introduced also another element into the calculation,—for while the sectional resistance was much reduced by

the adoption of finer lines, the total resistance was on the other hand greatly increased by the rougher surface exposed to the water. This new element, however, was not understood, though, as Lord Rayleigh pointed out, Professor Rankine, at a meeting of the British Association in Bath in 1864, surprised his listeners by asserting that he regarded skin-friction as the only legitimate resistance to the progress of a well-designed ship. The great importance of providing the smoothest surface possible for a vessel of the modern type of ocean-going steamers will be at once apparent from the fact that the resistance of painted iron has been found to be 1-15th lb. per square foot, while that of copper is only half as much, or 1-30th lb., at a speed of two miles and a half per hour. Taking one of the simplest models of steamers traversing the Suez Canal, say 400 ft. long and 40 ft. beam with a draught of 24 ft., the midship section would probably be about 850 square feet, but the wetted surface would be fully 30,000 square feet. If modelled on fairly fine lines the sectional resistance would probably not exceed 450 lb., while the surface friction (painted iron) would amount to 2,000 lb. at a speed of two miles and a half, as long as the surface remained smooth, but liable to be greatly increased when that surface became coated either with barnacles or any other substance. Lord Rayleigh observed that the nature of skin-friction is itself not well understood. This is quite true. Mr. Froude's experiments in this respect were by no means exhaustive, and there is much yet to be investigated. For instance, Lord Rayleigh is reported as saying that the resistance varies as the velocity. This point, however, has been by no means established; for at the higher speeds the ratio does not appear to continue constant. Moreover, it has been ascertained from other experiments that the surface-friction varies at different parts of the vessel, being greater at the bow than at the sides, and less still in the run; but the reason for these differences has not been yet explained. No doubt, in the words of the president, "it is connected with fluid viscosity, but the *modus operandi* is still obscure; but in spite of the difficulties which beset both the theoretical and experimental treatment, we may hope to attain before long to a better understanding of a subject which is certainly second to none in scientific as well as practical interest." There are symptoms of an increasing interest arising in the restoration of internal navigation. The projected ship canals, the improvements on some of the more important lines in England, the enlargement of the Ribble navigation, the improvements to the Aire and Calder, the discussion of an enlarged connexion between the Thames and Severn, and Bristol and London, are indications of a reviving appreciation of water-carriage, emphasised by the necessities engendered by foreign competition and home railway combination. An important factor in such navigations is, of course, the heats which have to ply thereon, and the more that their resistance can be reduced, the cheaper will be the cost at which they can be worked, and the greater the diminution in the charges for conveyance.

#### BICESTER.

WHATEVER may be the functions of a Rural Dean, we cannot be far wrong in supposing that their due exercise implies familiarity with the parishes of which the deanery is composed, and does not exclude a fair amount of literary leisure. It is pleasant to meet with a man who turns these opportunities to such good account as Mr. Blomfield has done in the book before us,\* and we hope he may find many imitators in the ranks of the country clergy in Oxfordshire.

Bicester is best known in these days as the centre of a good hunting country, and there is not much in its outward appearance to distinguish it from any other Midland market town. There is the usual long street, through which in former days the mail-coaches between London and Birmingham were wont to rattle; and the parish church, around which the town-hall was carried away piecemeal by the mob in 1836, and the parish church, around which the history of the place for some 700 or 800 years centres. Bernecester (*vnde* Burecester, Bisiter, and

\* The lease to him from the Crown was passed on the 30th of May, 1683. It was renewed for ninety-nine years, on the 12th of January, 1672, though a fee-farm had been promised under the king's engagement. See Wotton MSS. † The party had spent the day with Colonel Blunt at his seat, Wickhampton, near to Charlton. Sir Gregory Page Turner rebuilt the house; this was sold in 1784; a set of chairs therefrom is preserved in the Soane Museum. ‡ Most of Paradise-row, where Prince Lee Boo lodged, at Captain Wilson's, is merged in Union-road.

\* This wretched locality, familiar to readers of "Oliver Twist," lay, surrounded by ditches, in the area bounded by the present Mill-street (west), George's-row (east), Hickman's Folly (south), and the Thames (north).

\* The History of Bicester: its Town and Priory. Compiled by Rev. J. C. Blomfield, M.A., Rector of Lamton and Rural Dean, Bicester: Smith & Pankhurst, 1874.

Bicester) is mentioned in the Domesday Survey among the possessions of Robert de Oily, and had then an adult male population of 47, and two mills,—a fact which shows that then, as now, it was in the midst of a corn-growing district. The manor passed by marriage into the family of Bassett, and descended, through several female heirs, to William Stanley, 16th Earl of Derby. In 1536 he sold it to his own tenants,—thirty-one in number,—and thus the individual lordship of the manor has become virtually extinct.

The parish church,—replacing a Saxon structure which occupied the same site,—was built by Gilbert Bassett about the middle of the twelfth century; but the original cruciform plan was not carried out in its entirety. Chancel, transepts, and nave were finished, but the central tower was left incomplete. Its walls were raised high enough to carry the adjoining roofs, but the western arch was only indicated, and the work in the three existing arches was left very plain and void of ornament. The nave was extended to its present length, as three pieces of tooth-moulding, still *in situ*, forming the outer string-course of the north wall, show; and flat wooden roofs were employed throughout the fabric. Gilbert Bassett, the founder of the church, died in 1162, having spent most of his long life in the moated manor-house which he had built for himself at Bernestre. His grandson of the same name was yet more religiously inclined. Coming into possession of the manor in 1179, he immediately took in hand the establishment of a Priory of Augustinian Canons, and assigned the church to their care. The result of this was that the parochial fabric was neglected, and a century and a half elapsed before any addition was made to it. Then the southern wall of the nave was broken into, and an aisle of good Early English work added. Later on a north aisle was built in the Decorated style. The arches are recessed and chamfered and the pillars octagonal, with cap mouldings, and windows in the same style, were substituted for the small Norman lights at the east end and south side of the chancel. A century later the tower was erected, and the western door and window of Perpendicular work inserted. The tower, 75 ft. high, resembles so closely that of the neighbouring church of Islip that both must have been designed by the same architect, whose name has unfortunately perished. About the same period the roofs of the nave and transepts were raised, and the clerestory formed, and a little later the north porch, with a parvise above it, was added. Such is the architectural history of the fabric for three centuries and a half,—a history of growth both in beauty and use. Then follows the usual record of debasement and disfigurement. Pewee and pulpit reigned supreme, and no less than six galleries were intruded between the arches of the nave and chancel. "Nothing," says Mr. Blomfield, "could have been seen in any church more unsightly and unbecoming than this chaos of uplifted boxes." It may be worth while to chronicle an eighteenth-century Archdeacon's notion of what was required for the due preservation of a noble parish church like that of Bicester. The entry is as follows:—

"28 Sept., 1757.—A little under Pinning to be mended at the S.E. corner of the Chancel. The Church Porch to be whitewashed and the steps into the Church at N.W. door to be repaired. The pavement of the whole North Isle and at the S.E. corner of Miss Bosce's burying-place to be new laid, plain and even: Bottoms of some of the seats to be repaired. A new cover to Font, new Chest, 3 locks and key; Church and Chancel to be whitewashed, 10 Commans and chosen new Texts wrote." A little more than 100 years afterwards, viz., in 1862, the thorough restoration of the church after the plans of Mr. C. Beazley was effected, and St. Edburg's now presents a comely appearance, though the modern stained glass must be a poor substitute for that which filled the windows as late as 1660. No distinguished name occurs in the list of vicars of Bicester, but it must be borne in mind that after the prior and canons had taken their share of the ecclesiastical revenues the parochial minister had only a poor pittance left him, and that no augmentation was made when the priory was suppressed. That event took place in 1536, for Bicester was one of the lesser monasteries which were first despoiled. The king held the property only two years, and in 1542 it was sold by the Duke of Suffolk to Roger Moore, one of the serjeants

of the royal household, who seems to have resided in the Hospice or Guests' House,—the only portion of the priory which now remains.

Mr. Blomfield gives the annals of the priory at considerable length, and has reprinted many of the deeds and account-rolls. From these one is able to gather not only a tolerably clear idea of conventual life, but also much valuable information about the cost of living in the fourteenth and following centuries. In the bursars' accounts, which begin with the year 1297, there are, of course, a good many items which seem to substantiate the charge brought against the monks of fondness for good fare. But the expenses were chiefly incurred for the entertainment of wealthy and powerful guests. If 9d. was spent upon "pork and larks," it must be remembered that they were "bought for the coming of the Lord Richard Dainari (Damory) and John Hubert," and against the item must be set "two sextaries of parchment of velum for the Prior's missal, 2s. 4d.; and ink and vermilion pouz and 'staungegrege' and other small things, 4d." Mr. Blomfield does not suggest any meaning for the last of these articles, and in many instances he is at fault in finding an equivalent for a monkish term. But the book, which, we understand, is only an instalment of a work which will include the parochial history of the entire deanery, is very creditable to the author, and deserves to meet with more than local support. The illustrations are scarcely up to the mark. The best, that of Burestret Hall (formerly Nute's Place), is taken from Dr. White Kennet's "Parochial Antiquities." Unfortunately the quaint house which it represents was pulled down at the end of the last century, sharing the fate of most of the older buildings in Bicester.

#### THE INTERNATIONAL FORESTRY EXHIBITION, EDINBURGH.

SEVENTH NOTICE.

ALONG the central avenue there are several stands devoted to the exhibition of wood pulps, and there are models of wood-grinding mills showing different modes of converting the wood into pulp. From early times the leaves and inner bark of trees have been used as writing materials, but it is only within the present century that the idea has been entertained of converting wood itself into a manufactured paper. In 1801 a patent was taken out in this country for such a purpose, but, like many inventions of this kind, it was some time before paper manufactured from wood became an article of commerce. The great and increasing demand for paper of all kinds, especially for the printing of newspapers, combined with the insufficient supply and consequently high price of rags and other fibrous stuffs from which the paper had hitherto been made, called greater attention to wood as a substitute. From experiments made it was found that the pine woods were the most suitable for the purpose; and about ten or fifteen years ago a fair start was made in this direction by German manufacturers, and the industry has since spread into Norway and Sweden, and Denmark, and now hundreds of thousands of tons are produced annually. There are three modes of converting wood into pulp, one of them by a mechanical process, the other two by means of soda and by the use of acids. By the mechanical process the wood is ground in water into small fibres, and is then partially dried. Mr. Carl Christensen exhibits an excellent model of a wood pulp well driven by water. The logs are brought up to the saws by a lade, where they are cut into sections of from 1 ft. to 2 ft. in length; they are then barked and split by machinery, and by another process the knots are got rid of and the pith removed. By means of a hydraulic piston the material is held against upright grinding-stones revolving in water, which can be adjusted to produce either long or short fibre. The fibre is then carried by water to sieves which check the passage of unground chips, while the strained material is passed on to a machine with an endless web, whence it issues in the form of large sheets. These sheets contain about 50 per cent. of water, which is squeezed out of them by hydraulic pressure, and the pulp is then ready for sale. In this state the price in London is about 3l. 10s. per ton. The wood used must not exceed twenty years of age, as thereafter it becomes hard and the fibre too brittle. The Germans prefer the Scotch fir, but in Scandinavia

and Denmark the native pines are used. The preliminary process in the other two modes is similar to that adopted in the mechanical process. The wood, after being cut into small pieces, is boiled in water under high pressure, and is then treated under great heat with caustic soda or sulphuric acid, which extracts from it the resins and gums till it forms a pure cellulose mass, which is then washed and passed through breakers and rolled out upon a cylinder. To withstand the corrosive influence of the acid the iron boilers are lined with lead,—a section of such a boiler is exhibited. In the soda process a large percentage of the soda is recovered for after use by means of evaporation. Difference of opinion exists as to the superiority of these two processes, but the result appears to be equally satisfactory, the respective pulps being regarded as of the same value in the market. Large quantities of wood pulp are wrought up with other materials into papers of different qualities, but that produced by the mechanical mode having less tenacity than that made by the soda-and-acid process is only used for the commonest kinds. The different kinds of wood pulp are sometimes used in combination, and they are largely employed in the manufacture of cardboards, papier maché, &c. This material may, in course of time, be in great demand for building purposes; it possesses great tenacity, may be moulded into various forms, and give a fine uniform surface. It is already used for ceiling and other decorations, but light and serviceable doors, well suited for the cabins of vessels, &c., may be made of it, and we have heard it recommended for roofing, either in large or small portions.

Another product of the forest which has now become an important article of commerce is indiarubber. This material was only known to the mass of the last generation as an article used for rubbing out pencil-marks and surface stains from paper, &c.; it is now extensively used for various purposes, and new uses for it are continually cropping up. The raw material varies in quality, there being no less than fourteen different varieties of indiarubber tree. Of these the most common is *Ficus elastica*, and one of the rarest is *Hevia Braziliensis*, from which latter the finest Para rubber is obtained, the tree itself being remarkable for the beauty of its foliage. The material is used both in its elastic and vulcanised form, and is, in a great measure, superseding leather for various purposes. Every bicyclist knows its value in mitigating the vibration of the wheels of his machine, and the engineer finds it invaluable for a similar purpose. The principal exhibitors of rubber products are Messrs. Thornton & Co., of Edinburgh, who have a stand at the extreme east end of the central avenue of the exhibition buildings, and a large glass pavilion in the adjoining grounds. Specimens of rubber in its crude state, as it issues from the tree, and in various stages of preparation for ultimate use, are shown. The adaptations of the material for waterproofing are illustrated, from the light material used for ladies' mantles, to the strongest as applied to shooting, fishing, and campaigning requisites. There are also examples of portable garden hose for conducting water to plants, foot-mats of various patterns, belts, and other surgical appliances, dolls, toys of various kinds, &c. The North British Rubber Company (Limited), who were the first to introduce the manufacture of vulcanised rubber into Scotland, exhibit an assortment of articles in this material as applied to machinery. As illustrating the adaptation of rubber to the production of heavy material, the company exhibit a traction-engine wheel tyre, measuring fully 4 in. thick, and 15 ft. 6 in. in diameter, which is stated to be one of the largest masses of the material yet produced.

A varied and miscellaneous collection of articles more or less associated with forestry has been contributed by a number of gentlemen interested in the subject. The first of these—and not the least interesting,—which meets the eye is a case containing upwards of two hundred specimens of woodpeckers, contributed by Mr. R. G. Wardlaw Ramsay, of Whitehill. This useful bird is widely distributed, and ranges in size from that of a hummingbird to a crow, and its plumage is as varied as its dimensions. There are only four species of woodpecker found in Britain, the most common of which, *Picus vireidis*, is distinguished by its dark-green body and scarlet head and tuft. The plumage of the whole family is generally

brilliant and strongly contrasted. Mr. C. V. Riley, of the Department of Agriculture, Washington, contributes a case containing a collection of butterflies, moths, and beetles, with their larvæ which attack trees, and whose greatest enemy is the woodpecker. From examples taken from trees attacked by these grubs, it appears that the wood is riddled through and through, and it is stated that very few of the more common forest trees entirely escape their ravages. From Australia we have a singular natural curiosity in the shape of an example of *Spharia Robertsi*, which is produced thus:—One of the great Australian moths, while passing through its last stage of development, buries itself in the earth, where it is often attacked by a vegetable fungus which roots itself in the creature, sending up a long stony shoot of about 9 in. in height. The roots fill up the skin of the larval moth, which remains intact, none of the fibres passing outside, so that when dug up the plant presents a very curious appearance. Other cases contain specimens of various birds, including specimens of white-tailed and golden eagles, sent by Mr. James Sargeant, of New Cumnock; and Mr. D. Johnston exhibits three specimens of the ant-eating armadillo.

Amongst the practical exhibits is a railway wagon frame, fitted up by Messrs. James Kennedy & Co., of Glasgow, to show white oak scantling in the kind of work for which it is employed. And with the object of demonstrating the suitability of the oak for such purposes, where strength is so necessary, there is also on view a number of pieces which were subjected to a series of bending and crushing strains by the well-known testing authority, Mr. Kirkaldy, of London. The oak scantling is sawn in the American forests to sizes required, which, besides giving better quality, effects a saving by having the wood sawn at the point where it is grown,—a saving which is immense as compared with the old system of importing logs, and having them sawn in this country. As showing the durability of oak, the same firm exhibit a table formed from the foundations of the old Stockwell Bridge, Glasgow, built in 1345, and taken down in 1850; and specimens are shown of *Liquidambar* wood, which till lately has not been used to any extent in this country, and which is beautiful in its colour and marking.

Another practical exhibit is contributed by Mr. James Dairsie Morrison, of Swanston, near Edinburgh,—a gentleman who has devoted much attention to the study of ventilation,—consisting of an ingeniously-constructed model of a forester's hut, which aims at providing within the space which can be afforded in such dwellings the most perfect conditions of healthy life. It may be recalled that at a meeting of the Highland and Agricultural Society, Mr. Morrison's system of ventilation came up for discussion, when his model of a "perfect stable" gained for him the Society's medal. The members of the British Association had also their attention twice called to the same subject by Mr. Morrison, whose papers were considered of sufficient importance to merit a place in the Transactions. Since then the matter has been further prosecuted; and the hygienic hut is part of the outcome of experiments which have been made. The principle embodied is that of maintaining in an apartment without creating an objectionable draught a continuous current or circuit of pure air. This air is made to enter at one end of the room treated, and to leave it at the other in a sort of drain underneath the flooring, which terminates in the flame chamber of a newly-invented oil-lamp used for heating purposes, where all impurities are consumed. The due admission of light is also made a feature of the scheme; and in the construction of the hut powerful and ingenious bracings have been introduced so as to prevent it from being injured by falling trees. A drying-shed, shown by the same exhibitor, claims to be an entirely new departure, inasmuch as it seeks to scientifically secure in one process the perfect drying of wood at a low temperature, with the no less perfect poisoning of all the conditions of low plant and animal life. Having regard to the fact that water evaporates at all temperatures, it is proposed to make heat do two distinct things simultaneously,—viz., to evaporate from the cells of the wood every trace of water, and, while doing so, to act as the carrier into the vacuum thus produced any amount of gaseous poison, such as carbonic acid, carbonic oxide, carbolic acid

fumes, or other evaporable poison, which, though entirely harmless to the woody fibre, nevertheless fills every cell with a lining of poison against all low forms of life, and makes dry-rot a chemical impossibility.

The Queen has shown her interest in the exhibition by contributing a neatly-designed rustic chalet constructed entirely of the wood of the grand indigenous trees of the Balmoral forests, with beautiful specimens of the ancient Scots pine, both in a rough and polished state. The *Pinus sylvestris* at one time covered a large portion of the Highlands, and there are still some noble remains, notably on Speyside, Deeside, and the head waters of the Perthshire rivers. But nowhere has this picturesque tree, with its richly-coloured bark and deep green masses of foliage, been seen to more advantage than in her Majesty's forests, which cover about 20,000 acres of the romantic wilds of Upper Deeside. Some years ago the Ballochbuie Forest, where are some of the finest Scots pines in the country, passed into the hands of a firm of Aberdeen wood-merchants, who were proceeding to denude it of the choicest and most stately trees it contained. These proceedings were viewed by her Majesty with dismay, and by stepping in and purchasing the old forest, she put an end to the work of destruction. The old trees in Ballochbuie are now strictly preserved, and part of the ground is fenced in against the incursions of the deer so as to allow seedlings to come up and supply the blanks. By the gale which blew down the Tay Bridge, on the 6th of March, 1883, great havoc was committed in the forest, and the chalet now exhibited is formed from the wood of some of the trees then blown down. The interior is panelled with the polished heart-wood, which is beautifully grained, and the exterior of branches, bark, and moss collected in the forest. The chalet, with most of its furnishing, was made by the joiners at Balmoral, and the specimens show the adaptability of the wood for interior ornamentation and cabinet-making purposes, a table-top by Messrs. Allan, of Aberdeen, showing some very beautiful swirled graining. Over the entrance is the head of a royal stag, showing antlers with twelve points, and two other antlered heads are disposed at the ends of the ridge of the roof. On each side are placed specimens of the wood in a rough state. One of these, from Ballochbuie, is 270 years old, and another shows a girth of 212. This last specimen exhibits a peculiar and most interesting aspect. It had lain on the ground for upwards of forty years, until the sawwood had decayed and formed a thin stratum of soil where heather, cranberry and blackberry plants, and mosses have taken root; but the heart-wood, measuring 3 ft. 6 in. in diameter, remains perfectly sound.

An excellent exhibit of forestry subjects well worthy of notice, both from a botanical and practical point of view, is that of Messrs. Vilmorin, Andrieux, & Co., Paris, in the north-western transept. They have brought together quite a museum of dried specimens of plants, cones, and seeds, comprising upwards of 150 varieties of pines, fifty different kinds of abies, and numerous specimens of araucaria, cupressus, juniper, and cedar. The collection of seeds includes samples of trees and shrubs from every region,—among others being the teak, mahogany, the eucalyptus, the indiarubber, and the cinchona, with seventy varieties of palms and over fifty varieties of oaks. Specimens of the most useful kind of eucalyptus, leaves, flowers, and seeds, are being shown; and as illustrating their rapid growth, there are displayed some stems of the *Eucalyptus globulus* (blue gum), and of the *Acacia dealbata*, grown on Mr. H. Vilmorin's estate in the south of France, which, although only two years old, measures 15 in. in circumference. There are also on the tables a few specimens of various acacia barks, which are now being largely used in place of oak bark for tanning purposes. The same firm also show some beautifully illustrated works on forestry, in English, French, and German. Mr. James Barrie, forester to the Honourable Mark Rollo, Stevenston estate, Devonshire, also sends a well-arranged and representative collection of tree and shrub seeds, and cones, and sections of timber grown on this extensive property.

**Cost of Maintaining Three London Bridges.**—The cost of lighting, cleansing, and repairing London Bridge, for the past year, was 1,267l.; Blackfriars Bridge, 1,292l.; Southwark Bridge, 2,467l., including 624l. for relaying new channelling to approaches.—*City Press*.

#### THE LATE WILLIAM PETTIT GRIFFITH.

We much regret to announce the death of this gentleman, which took place on Sunday afternoon last, the 14th instant. William Pettit Griffith was the son of Mr. John William Griffith, architect, who was a resident in St. John's-square, Clerkenwell, for half a century. The subject of our notice was born July 7th, 1815, and was brought up in the profession of an architect. Although upwards of seventy years of age, Mr. Griffith had only just retired from the profession, after incessantly labouring in it for fifty-three years. He retired from his professional residence in Guilford-street, Russell-square, in June last, and died at his new home, at 3, Isledon-road, Hornsey-road, Highbury, on Sunday last, as above stated. Mr. Griffith was elected a Fellow of the Society of Antiquaries in 1841, a Fellow of the Royal Institute of British Architects in 1847, honorary member of the Bedfordshire Architectural Society in 1847, honorary member of the Liverpool Architectural Society in 1849, and honorary member of the Surrey Archaeological Society in 1856. In 1854 he obtained, in a competition, the silver medal of the Institute of Architects. Mr. Griffith was the author of the following works:—"Grecian Architecture: Suggestions for Developing," "Natural System of Architecture," "Medieval Architectural Botany," "Gothic Churches," and "Architectural Botany." The following were among the papers communicated by Mr. Griffith to various Societies:—In 1852, to the Royal Academy of Belgium, "On the Proportions of the Temple of Vesta at Tivoli"; 1852, the Bedfordshire Architectural Society, "Suggestions for a more Perfect and Beautiful Period of Gothic Architecture"; 1855, Royal Institute of British Architects, "On the Principles to be observed in Designing Medieval Decorations and Ornaments with reference to the Sources of Ornament offered by the Natural Kingdom"; 1857, the Liverpool Architectural Society, "Proportion, its Practical Application to Architecture and the Fine Arts"; 1863, the same Society, "Of the Influence of Fashion in Architecture"; 1854, the Surrey Archaeological Society, "On the Ancient Baptismal Fonts of England"; 1858, the same Society, "An Architectural Notice of the Nave of St. Saviour's Church, Southwark."

Among the works which he has designed and superintended are Ogle-mews Ragged School, for Sir R. W. Carden, 1862; Lamb and Flag Ragged School, 1861; the Goldsmiths' and Jewellers' Annuity Institution Asylum, South Hackney, 1853; new schools, Highgate, for Clerkenwell Guardians, 1858; restoration of St. John's Gate, Clerkenwell, 1845-6; rebuilding spire of St. James's Church, Clerkenwell; Vestry-hall, Clerkenwell, 1857; Royal Hospital for incurables, West Hill, Putney Heath (the foundation-stone of which was laid May 11th, 1804); an illustration and description of this building appeared in the *Builder*, vol. xliii., p. 118, Feb. 18th, 1855. Restoration of tower and porch of St. Sepulchre's Church, Holborn, and various other works.

**The Theatre Royal, Edinburgh.**—Plans and specifications have now been prepared, and estimates received, for the reconstruction of the Theatre Royal, which was destroyed by fire on 30th June last. Mr. C. J. Phipps, of London, who designed the ill-fated building, is the architect for the new building, and his plans show that the new theatre will be built very much on the same lines as its predecessor. Several new features are to be introduced, however, which are calculated to add to the safety and comfort of playgoers. First of all, increased facility is to be afforded on the higher levels of the building for entrance and egress by providing an additional staircase. The wall dividing the stage from the auditorium is to be of solid brickwork, and is to be carried up through the roof of the theatre; while all apartments of the nature of workshops and other necessary rooms are to be erected outside the main building. Last, but not least, the ventilating arrangements are to receive careful attention. As already indicated, tenders have been given in for the reconstruction of the theatre, which Mr. Phipps has undertaken to have completed by the beginning of the pantomime season. As to cost, it is expected that this will be covered by the insurances on the old building, which amounted to 12,500l.

## Illustrations.

## DESIGN FOR WAR OFFICES.

BY MESSRS. GLOVER AND SALTER.

**W**E give this week the design by Messrs. Glover and Salter as submitted in the second competition. The illustrations show the proposed front to Whitehall (from a much more distant point of view, however, than would have been possible in reality), and, as in the other cases, the plans of the two principal floors. The open areas, it may be noted, are in this plan increased in size at the upper levels, and are ventilated by an open subway below the basement; and the corridors are lighted not only from these open areas, but receive direct light at the staircases and the messengers' rooms. The design is a powerful one in some respects, and takes a very good place, architecturally, among the nine; but, bearing in mind the fact that architecture is now a succession of fashions, there can be little doubt that at the present moment it is what in fashions would be called "out of date." No blame to the authors for employing the style they prefer; but there could have been little chance of a purely Gothic design finding acceptance, so quickly in these days does the whirligig of time bring in his revenges.

The following extracts from the Report of the architects will assist in explaining their views in the design:—

"The buildings show two distinct façades in Whitehall for the Admiralty and War Office, connected in front by open covered corridors and arcading, so that, although they are thus united and form one continuous building in the rear, the two offices can be separately identified on the main front. The proposed new street between the Admiralty and Biddulph's Bank is for convenience, and to isolate the buildings.

There are three courtyards behind the Whitehall front, and one grand quadrangle behind the Park fronts. Three great carriage entrances are provided towards Whitehall, and one, generally kept closed, in the west (Park) front; and there are carriage porches in the quadrangle. It will be noted that the centre quadrangle gateway is opposite the middle of the Admiralty Whitehall façade, and the two side gateways are,—the one opposite the centre of the War Office courtyard, and the corresponding one opposite the new street. Carriages can enter at the centre gate in Whitehall, and go out by the side gates, either to Whitehall or to St. James's Park, or vice versa. It is thought that the gateway in the park front would serve as a central feature of that long elevation, and also that it would be of value in giving a glimpse of the trees in the park to passers-by in Whitehall and in the quadrangle.

It has not been thought necessary to adhere to the style of the Horse Guards, which building is probably inadequate to its future requirements, and which is so much lower than the new offices that an attempt to match the two would be a failure. For that and the following reasons a Mediaeval style of the best period has been adopted:—(1) For contrast with the Foreign Offices; (2) for picturesqueness of outline; (3) for the greater number of window-openings available; (4) because it combines the characteristics of a castellated style with the conveniences and enrichments of palatial and domestic architecture, and so appears suitable for the War Offices of a nation. Thus in the accompanying design the turrets and machicolated cornices, and the great central tower or 'keep' present an appearance and character consonant with the purpose of the building, while each serves its own purpose of use or ornament, the 'keep' being utilised in floors of repositories, and the other towers similarly applied for the departments near them.

In further justification of the choice of a Mediaeval style, it may be pointed out that in this design the rooms are well lighted and without slanting sides or awkward corners; the corridors are wide, straight, level, and well lighted, and the staircases are easy and absolutely without winding steps; although Gothic architecture is erroneously supposed to be incompatible with convenience of plan.

Again, if it be asked what modern English public buildings has given most content and satisfaction to the nation, it can scarcely be doubted that the Houses of Parliament would be named. It is true that the Law Courts are considered to fail in internal arrangements and in external unity; but this is not the fault of

Gothic architecture: as stated above, this style is no bar to convenience of plan; and the elevations and perspectives of the accompanying design show that by proper use of horizontal as well as vertical lines, unity, grandeur, and stability can be well expressed in this most pure and beautiful style.

The walls should be faced with Portland, Ancaster, or similar stone, externally, and with white glazed bricks in the areas, and the roofs slated. The floors would be iron joists and Portland cement concrete, covered with tiles in the corridors and with wood in the rooms for comfort.

All the important rooms on the first floor open on to the balconies. It will be noticed that the waiting and 'Interview, or Clerks,' rooms are very numerous, one to every head of department or high official. Besides the public corridors, 10 ft. 6 in. wide, private corridors, 4 ft. 6 in. wide, are provided to all the most important rooms on the first floor, so that communication between the chiefs and their heads of departments can be made in absolute privacy. Both sets of corridors will be well lighted and ventilated by the numerous open areas between them.

The retiring-rooms are arranged in accordance with modern ideas of comfort and convenience too often neglected. Each contains one water-closet or more, with a window to the open air; also a lavatory and lobby, which have other opening windows besides those in the water-closets above the water-closet framing. The retiring-rooms are entered, not from either corridor, but from the short lobbies or staircase landings connecting the two corridors on the first floor, or leading to room on the other floors.

No special or particular system is advocated either for heating or ventilation; any approved scheme could be adopted, as the 2 ft. thick floors and the great amount of spare room in the towers and basement supply more than adequate space for any required apparatus."

As before, we print the key list of references to departments, which will apply also to the other design mentioned below.

## DESIGN FOR WAR OFFICES (FIRST COMPETITION).

BY MR. T. G. JACKSON.

This very elegant and tasteful design, the merits of which would no doubt have come out far better in detail, had the architect been commissioned to present it on the larger scale and with the more complete drawings admitted by the second competition, partakes a good deal of the feeling of the modern manner of London building, which has been supposed to have more or less relation to "Queen Anne," or to have arisen from a preference for Late English Renaissance. The author's note in regard to style in his Report is as follows:—

"A Gothic style would not be suitable either to the site or the purposes of the building, and pure Palladian Classic would be still less fitted for a structure consisting necessarily of several low stories and an infinity of small windows. I have adopted the freer style of the English and German Renaissance, and thus avoided the necessity of running the Classic order through two stories of the building, an absurdity seldom committed by the best masters of the Renaissance in any country, though common enough in our own."

Though we regret the adoption, by several able architects of the day, of some of the less admirable features of the old London brick style, such as the curved pendent ornaments (?) beneath the window-sills, which are ugly in themselves and architecturally unmeaning, we have no doubt that, if carried out, this would have been a building presenting much very pleasing detail, and a general aspect of architectural refinement. But we should very much doubt if it would generally have been taken by visitors for the War Office. It is a great deal too quiet and domestic-looking to convey any such idea. The plan is very symmetrically arranged for intercommunication, but some of the corridors could hardly, we should imagine, have been sufficiently lighted. We append the following remarks from the author's Report:—

"In order to secure ready circulation throughout both offices, I have avoided very large quadrangles, and the plan has fallen naturally into a form very like that suggested by her Majesty's First Commissioner in the article published by him in the *Nineteenth Century* for November, 1882. The public entrances to both offices would be from Whitehall by large archways leading into the smaller quadrangles of the War Office and Admiralty respectively. Each office has a large waiting-hall opening from this quadrangle, and I have placed these, not on the side next the street, but in the interior of the building, tolerably central with reference to all the departments. The public will consequently have no occasion to traverse an unnecessary number of corridors, but can be taken straight from a common centre to the department they are in search of. They need never use more than two of the staircases provided for each office, and the other staircases can be reserved exclusively for the use of officials and persons on special business. The rooms of the chief officials are farthest from the general entrance, and need never be approached at all by the public. The corridors into which the rooms of the Admiralty Board and those of the chief officials of the War Office open are continuous, and those rooms form one suite facing St. James's Park.

There is a similar communication on each floor between the two offices at each of the three points where they touch, except on the upper floor of the Whitehall front, where it did not seem to me necessary.

*Height of Stories.*—In a building consisting of so many rooms of moderate size, seldom larger than those of a private dwelling-house, it has seemed to me that to exceed the height usually given to rooms of that size would make them ill-proportioned and uncomfortable. The average size of the single rooms is about 20 ft. by 17 ft., and the best proportionate height for such a room would be from 13 ft. to 14 ft. on the principal floors to 12 ft. on the top floors, to which dimensions I have accordingly confined myself, except in the case of the Board-rooms and those of the First Lord, the Secretary of State, and the Commander-in-Chief, which are higher, and the entrance-halls, which occupy two stories in height. I may add that I do not think a very lofty building would have a good effect in this situation. Inigo Jones's Banqueting House measures only 67 ft. to the eaves, and the Horse

INCISED SLAB  
BRADING CHURCH ISLE OF WIGHT

*Plö Paul 41 1884.*

Guards is comparatively a small building. I have shown the latter to scale on my elevation that the relative size of my design may be appreciated.

**Construction.**—The walls would be of brickwork with dressings of best selected Portland stone. In the interior of the quadrangles I should propose to face part of the walls between the dressings with rubbed brickwork, which has an admirable effect mixed with Portland stone. The exterior fronts will probably be best faced chiefly with stone, though even there some brick facing might be employed with advantage. It is, however, impossible to study this to so small a scale as that of the present drawings."

#### INCISED SLAB, BRADING CHURCH, I.W.

The slab here illustrated is one of the finest of its kind in England. It is situated in the chancel of Brading Church, immediately south of the altar, and measures 8 ft. in length, and about 3 ft. 6 in. in breadth. The centre is occupied by the figure of John Cherowin, constable of Porchester Castle, who died in 1441. He is represented in plate armour, with a long sword hanging from the left side, and a dagger visible on the right. The feet rest on dogs, and have remarkably long spurs with rowels. The head, hands, and some of the ornamental parts of the sword hilt and scabbard were formerly inlaid with stone or metal, probably the latter. There is a tradition that the inlay consisted of silver. The figure stands underneath a vaulted canopy, with tracery in the upper part, and brickwork below. Against the tracery, one on each side of the head, are two shields, which are charged apparently with the following arms—Quarterly, 1st and 4th fretty, a chief; 2nd and 3rd Barry of twelve, three martlets. Over all, on an inescutcheon, four martlets.

On each side of the figure rises a tier of canopied niches with pinnacled buttresses. There were formerly eight figures, but only six remain at all perfect. Of these SS. Andrew, Lambert, Peter, and James can be made out, but the other two are somewhat obscure. The lowest on the right holds a book. At the top over the centre of the canopy was the Virgin and Child. Some slight traces of drapery alone remain, and the figures which flanked this niche have entirely disappeared. At the angles are the evangelistic symbols, of which two remain. The inscription is marginal, and runs round three sides of the stone. It is as follows:—"Hic jacet nobilis vir Johannes Cherowin armiger dum vivebat Cornetabularius Castri de Porcestre qui obiit anno Domini millesimo quadringentesimo quadrag<sup>o</sup> primo die ultima mense Octobris anima ejus requiescat in pace. Amen." The elaborate details, especially the masonry background, seem to point to the fact that this fine monument is of foreign workmanship.

The drawing has been reduced from a rubbing, and carefully drawn to scale.

R. W. PAUL.

#### THE TRADES' UNION CONGRESS.\*

We now bring to a close our notes of the proceedings of the Aberdeen congress of trade unionists.

##### The Employers' Liability Act.

At the afternoon sitting on Tuesday, the 9th inst., Mr. Woods (cotton-spinner) moved,—

"That this Congress regrets that Parliament has not yet consented to pass the Bill, introduced by Mr. Burt, M.P., Mr. Broadhurst, M.P., and others, to amend the Employers' Liability Act of 1880. The Congress also hopes that these gentlemen will re-introduce the measure next session, and assures them of the continued support of the trades of the United Kingdom until the same be passed in law."

This was seconded by Mr. Jack (Glasgow), and supported by several other speakers, including Mr. Thomas Burt, M.P. It was carried unanimously.

##### The Enginemen's Certificates Bill.

Mr. Swift (Manchester) moved,—

"That in the opinion of this Congress much of the loss of life and injury to workpeople from boiler explosions and accidents to steam engines arises from preventable causes; that many of these causes may be removed or obviated by judicious legislation having for its object the institution of a system of certificated engineers for land engines and boilers as for engines at sea, so that only competent persons may be employed in positions of such responsibility; therefore the Parliamentary Committee is

instructed to take immediate action for securing this much-needed industrial reform."

This was seconded by Mr. W. H. Lambton, of Hetton Colliery, who argued that if it was necessary that men who had charge of marine engines should have certificates of competency, it was no less necessary that parties who had charge of steam-engines and boilers on land should have like certificates, seeing that they had so large a travelling public whose lives were dependent on the good or bad management of locomotives, and that so many engines and boilers had been erected in the towns and cities, in the midst of densely-populated places, and in works where large crowds of "hands" were employed. The resolution was supported by three other speakers, and unanimously agreed to.

##### Factory and Workshops Inspection.

Mr. David Holmes (Burnley) moved, in the absence of Mr. Birtwistle through indisposition,—

"That it be an instruction to the Parliamentary Committee to continue to urge upon the Government the necessity for the appointment of an additional number of practical men, and, where expedient, women, as Factory and Workshop Inspectors, pointing out the utter impossibility for the present staff to maintain a due observance of the Act."

He said he did not want to detract from the efficiency of the present staff of inspectors, but at the same time he was of opinion that if practical workmen were appointed, the administration of the Act would be more efficient than at present. With regard to the number of inspectors, he might say that since the consolidation of the Factory and Workshops Acts they could not get the number of workshops,—that it was impossible to get a report, the inspectors having no report to give. That was because there was such a vast number of non-registered workshops. Those of them who were acquainted with the internal working of the factories of Lancashire and Yorkshire knew the necessity of pressing upon Government for an increased staff, while at the same time they should be induced to pay more attention to the fencing of machinery in order to avoid the chapter of accidents inserted in the annual reports of her Majesty's inspectors.

Mr. McLean (Edinburgh), in seconding the motion, said that when the Factory and Workshops Acts were consolidated in 1878, they were looked upon by a vast majority of those who had taken an interest in them to be a wise and beneficent settlement for many years,—setting at rest the question of factory and workshop inspection. So it would have been if the Government had taken any steps to enforce these Acts.

The resolution was unanimously carried, after a long discussion, at the close of which Mr. Neil McLean, Edinburgh, in answer to Miss Wilkinson, said he had it on the authority of the Chief Inspector that there was no power under the Factory Act to interfere with underground workshops or premises entirely lighted by gas. Then the amount of breathing space was not stated in the Act. The Chief Inspector himself, upon his own authority, had made it 250 cubic feet, being 100 feet per individual less than they were compelled by law to find for the worst criminals in their country.

##### Inspection of Mines.

On the third day of the Congress (Wednesday, September 10), after the presentation of the testimonial to Mr. Broadhurst (mentioned in our last), Mr. Reid (Durham), moved the following resolution, viz:—

"That this Congress has heard with much satisfaction the promise of the Home Secretary to increase the number of Inspectors of Mines, and therefore instructs the Parliamentary Committee to urge upon the Government the necessity of having these appointments made as speedily as possible, believing that the increased number of mines, in addition to their greater depth and extent of workings, imperatively calls for such increase."

This was seconded by Mr. Fenwick (Northumberland), who advocated an immediate increase in the number of inspectors of mines. At present, he pointed out, there were about twenty-four inspectors of mines, who had under their supervision something like 4,000 mines, or an average of 166 mines to each inspector. It was utterly impossible for an inspector to make a thorough inspection of a mine of any dimensions in less time than a week. The resolution was unanimously agreed to.

##### Co-operation.

On the motion of Mr. John Burnett (London), seconded by Mr. Knight (Newcastle), it was resolved,

"That the Congress, in giving a hearty welcome to the Delegates from the United Board of the Co-operative Union, desires to express its earnest good wishes for the success of all well-conducted attempts to promote and maintain establishments for co-operative production, in which the workpeople shall have a share in the product of their labours, and also for the general progress of the co-operative movement."

##### Trade Federation.

On the fourth day (Thursday, September 11), Mr. A. W. Bailey (Preston), moved,

"That this Congress cordially reaffirms the declaration repeatedly made by former Congresses, namely, that the establishment of a Federation of the Trades Organisations of the United Kingdom would be a source of strength to trade unionists, would promote good fellowship, and would prevent the occurrence of many avoidable trade disputes. But, seeing the want of success which has attended previous efforts on the part of the Parliamentary Committee to introduce a code of rules for a National Federation, this Congress is of opinion that it would be unwise to attempt to promulgate another scheme which would possibly prove abortive. It is, therefore, hereby resolved that it be an instruction to the Parliamentary Committee to assist and put into communication with each other trade societies and trade councils desirous of forming a federation, and to convene a meeting of representatives of such societies and councils whenever and wherever a sufficient number may desire to meet to prepare for themselves an acceptable basis for the formation of a permanent National Federation of Trades Organisations."

This was seconded by Mr. F. Willis (London), and carried by an overwhelming majority.

##### Goods Qualities.

On Friday, the 12th inst. (being the fifth day of the Congress), Mr. Utley (Sheffield) moved, Mr. Church (Birmingham) seconded, and it was resolved,—

"That the attention of the Congress be called to the ever-increasing necessity of maintaining the excellence of our manufactures in the face of constantly increasing competition abroad; and seeing that the tendency on the part of many manufacturers is to sacrifice quality to cheapness,—which, while it may tend for the time being to enrich unscrupulous manufacturers and speculators, in the end will entirely destroy confidence in our British manufactures, and eventually bring ruin upon the workmen,—would earnestly commend the attention of the Parliamentary Committee to the question of obviating some direct and easy method of protection against the present system of falsely marking spurious goods, thus imposing upon the inexperienced purchaser."

##### Employment of Young Girls as Ironworkers.

Mr. Juggins (Darlington) moved,—

"That it be an instruction to the Parliamentary Committee to use their best exertions to re-introduce the Factory and Workshops Amendment Bill of 1883 that applies to the employment of female children under fourteen years of age at forging nails, chains, bolts, or any such articles that are made from iron or steel."

He asserted that it had not been an uncommon thing for years past in South Staffordshire and East Worcestershire for girls of seven, eight, and nine years of age to be engaged in the manufacturing of nails, chains, rivets, bolts, and so on, a calling which was a disgrace to their sex. This had been allowed to go on, and without extraordinary exertion on the part of the Parliamentary Committee or the bringing to hear on it the influence of the Congress, it must continue to go on unless it was stopped by legislation. In submitting the resolution, he did not wish to interfere in the slightest degree directly with female labour, although he had not the slightest doubt he should be charged with the intention of, as far as possible, preventing the introduction or carrying on of female labour. He considered that the trades best adapted to female labour were those that should be encouraged for females, and not those that were adapted only to males, such as those of blacksmiths and of working in shops. He had travelled through the district of which he spoke, and could tell of a state of matters that would shock the modesty of every man and woman in that Congress; for great immorality, depravity, and pauperism prevailed, and everything that was calculated to lower and disgrace the sex in whose interests he was speaking, and the raising of whom in the social scale he advocated.

The resolution was seconded by Mr. Joseph Arch, and carried by a large majority against an amendment which proposed to instruct the Parliamentary Committee to obtain a Commission to inquire into the cause of complaints made in reference to the employment of females and young persons in the trades named in the proposition. Miss Wilkinson, in seconding this amendment, said she thought that in taking up this question they should remember that the boys wanted protection quite as much as the girls, and if there was a Commission of Inquiry that would be brought out. Mr. Juggins had said he had no intention of directly levelling this motion against female labour, but indirectly he had, because he would keep them from work under 14, knowing that would be as good as keeping them from work after 14. In the

\* See p. 352, ante.

course of the discussion, Mr. Corbet (Nottingham) said he had seen girls carry away 3,000 bricks in a day, and the distance they had to go was about twenty-five miles, and the weight carried about twenty-five tons in all. Moreover, they would be wet through with sludge from the chin to the toes, and without a bit of shoe on their feet. He thought it was thus that female labour was done away with where the workers were under 14 years of age.

*Sanitary Inspectorships.*

Mr. Petrie (Aberdeen) moved,—  
“That in the opinion of this Congress it is desirable that only thoroughly practical men should hold the position of sanitary inspectors.”

He observed that though the subject might not appear in the eyes of the delegates or of the public to be of much importance, viewed in its wider aspect it would be found to be of first-rate importance with regard to public health. The subject was touched upon the other day by several of the delegates in connexion with the Factory and Workshops Act, and it was pointed out by one of them that the evils to be found could be remedied by applying to the sanitary authorities in the district; but what he wished to bring before the Congress was, that the authorities responsible for the appointment of sanitary inspectors in the large towns should be held responsible for having such appointments made from the ranks of practical men who had wrought at and understood the subject. They never heard of such a person as a practical plumber receiving such an appointment, and this was not as it ought to be, for who knew better than a man who had engaged in, and was thoroughly conversant with the work, and could tell when it was done in a safe and satisfactory manner, or the reverse? From his own experience, he felt the present system to be a great injustice, and the grade which he had the honour to represent there felt it very strongly. That men who never learned, or who, perhaps, had never given any thought to the subject prior to their appointment, should be in a position to dictate to practical workmen who have such work to execute, was a highly unsatisfactory state of things.

The motion was seconded by Mr. Forbes (Aberdeen), and unanimously agreed to.

*Recovery of Wages.*

Mr. Smyth (London) moved:—

“That, in the opinion of this Congress, it is desirable that for the recovery of wages a workman should have a first lien on the work accomplished by him, and that the Parliamentary Committee take action to so amend the law that a workman may recover his wages by some summary procedure.”

Mr. Smyth is reported (in the *Aberdeen Free Press*) to have observed that in the building trade in England men were continually defrauded out of their week's earnings by “sloping” employers, who set up to do piece-work and at the end of the week vanished, and the men got no money. This was a system which prevailed largely in London and other large towns, and the only way that a man could find redress was by spending about six times the amount of his wages. He considered that every man should have a claim upon the produce of his labour.

Mr. Abrey seconded, and the resolution was unanimously carried.

*Free Libraries.*

On Saturday last the Congress was brought to a close.

Mr. Foster (Hull) moved:—

“That this Congress, being of opinion that a general adoption of the Public Libraries Act would tend to greatly improve the social condition of the people, strongly recommend that the adoption of these Acts should be made compulsory in all towns, parishes, or districts where the Compulsory Education Acts are in force.”

This was carried by twenty-seven to twenty-two, against an amendment which sought to make the adoption of the Act optional.

*Sunday Opening of Museums and Art Galleries.*

Mr. Freak (London) moved:—

“That it be an instruction to the Parliamentary Committee to use their best endeavours to secure the opening of the national museums and art galleries on Sundays.”

Considerable difference of opinion was manifested on this question, and “the previous question” was moved, and carried by forty votes to twenty-one.

**International Inventions Exhibition.**—The latest date for sending in applications for space has been extended from the 1st October to the 1st November.

A MANUAL FOR MECHANICAL ENGINEERS.\*

THIS work, which now appears in a third edition, can scarcely be considered as otherwise than a compilation of the investigations of eminent authorities upon mechanical science. The author is frank enough to give a detailed list of those he has “consulted or quoted,” and consequently we may be forgiven if we say that there is nothing really new in this volume but the evidence of a vast amount of patient and careful research. Unfortunately, the author seems to have fallen into the same error which is characteristic of most modern scientific writers, viz., that of crowding into a book a multitude of tables and other data which have already been exhaustively treated as specialities. Surely, in a work such as Mr. Clark claims this to be, it is hardly necessary to introduce the well-worn “geometrical problems,” especially as he aspires to produce a high-class text-book for mechanical engineers; nor is it satisfactory to find plane trigonometry finished off in a page and a half. Thus, the first thirty pages are devoted to an attempted elucidation of the elementary principles of mathematics, which, we are of opinion, might well have been omitted. Again, his subsequent chapter on “Mathematical Tables,” he gives logarithms up to 1,000, but only in six places of decimals, so that in abstruse calculations, where an accurate result is essential, these tables will be almost valueless. The book illustrates, too, a bad habit on the part of scientific writers of swelling their volumes with reproduced matter, which can be obtained in a more convenient form elsewhere: thus we have in this book over 120 pages of such matter, all of which is contained in “Molesworth” or other equally well-known hand-books.

Under the head of “Weights and Measures,” the author produces some valuable information, which is arranged in a very useful form. Commencing with water and air as standards, which are very clearly dealt with, he proceeds to treat the question of “Imperial Weights and Measures of Great Britain” in a most exhaustive manner, dealing with the various “wire-gauges,” and our national standards of measurements and weights, with their decimal equivalents. That this chapter will be found extremely useful there can be no doubt, its value being enhanced by the comprehensive arrangement of the weights and measures of various nations. Not only mechanical engineers, but members of other branches of the profession require to use very frequently the standards of weights, measures, &c., of foreign countries; and we can, so far, confidently recommend this work, which clearly places before one the relative value of the standards of all parts of the world, as compared with our own country; indeed, we know of no other work which contains such concise and useful information upon the subject. Again, the following chapter on “Money” will be found to be extremely useful to those professional men who have business transactions abroad, enabling them, as it does, to reduce the value of work into the currency of the particular country in which they may be engaged. Of course, this chapter can only be considered as typical, as the rate of exchange, especially on the Continent, is constantly changed; but, notwithstanding, the information herein contained will be found to be invaluable. The following chapters and tables, on the weight and specific gravity of various materials, present nothing new really, but the tables are arranged usefully. In his treatment of “the weight of iron and other metals,” the author has adopted the system of giving the equivalents of length to weigh 1 cwt. This will be found extremely useful for Continental and foreign work, in which the question of shipment and freights enter largely into one's calculations. With some elaboration, the author deals with the “fundamental mechanical principles,” and especially that of the “inclined plane,” which is very clearly demonstrated.

Under the heads of “Heat” and “Steam” are collected some very useful and interesting information, accompanied by copious tables; equally with a short chapter on the “Mixture of Gases and Vapours,” with a clear description of the hygrometer. A brief consideration of combustion in its various phases introduces a very elaborate treatment of the question of “Fuel,” dealing with British, American, French,

Indian, and other coal in a most comprehensive manner; as also wood, wood-charcoal, peat, peat-charcoal, liquid fuels, and coal-gas. It is by the arrangement of such information that a work of this character will be found chiefly valuable, and we are pleased to be able to bear testimony to the satisfactory accomplishment of the evident object of the author. Again, under the head of “Application of Heat” will be found information of the highest value and assistance to those who are interested in warming and ventilation, treated, as the subject is, with an evident desire to be as complete and authoritative as possible.

The question of “the strength of materials” has evidently taxed the author's faculties to the uttermost, as, with few exceptions, he is obliged to traverse familiar ground. At the same time, we must commend the very clear way in which he elucidates some well-known theories, aiming at clearing up rather than creating difficulties, and we are especially impressed with those pages devoted to “the shearing stress of beams” and the “deflection of beams.” The “strength of timber,” illustrated by the results of experiments of M. Morin, MM. Chevaudier and Wertheim, Lassel, and others, will prove very valuable, backed up as they are by a carefully-arranged table of results. Cast iron, under varying circumstances, is dealt with by an elaborate analysis of the investigations of some of the most eminent authorities; whilst wrought iron is considered in a most exhaustive manner, giving the results of German, American, and other experience. Upon the subject of steel, the author has much to say, dealing almost historically with its manufacture, but there is nothing novel in his treatment of the question. We must confess that we are disappointed that so important a question has not received the attention it deserves, taking, as it does, so prominent a position in construction. “The strength of elementary constructions” is treated in a series of short chapters, of which the first on “Rivet Joints” will be found to be both interesting and useful; as, not only does the author deal with the question in a practical way, but he has arranged a series of experiments based upon the highest authorities. The succeeding chapter on “Pillars and Columns” is equally valuable, by the comparative results placed before the student. There is, of course, nothing new on cast-iron beams, though the volume would be incomplete without reference to what is now an almost obsolete form of construction.

In the chapter on “Wrought-iron Flanged Beams or Joists” an excellent opportunity of dealing with this new universal system of construction is marred. A short chapter on “Railway Rails” forms a compilation of reliable information, which in this case cannot be found in a collective form elsewhere. The strength of ropes, chains, helings, &c., is treated in some detail, and renders the work all the more complete; whilst upon the question of “bolts and nuts” the author appears to have consulted the highest authorities with a very satisfactory result. Some useful data is given in reference to hollow cylinders, but really nothing new; and this section of “Strength of Elementary Constructions” is concluded by a very well-considered and useful chapter upon “Framed Work.” Although devoid of novelty, there is much in this chapter of a commendable character; for a somewhat difficult subject is clearly set forth, in a way likely to prove of great assistance to the student.

Under the head of “Mill Gearing” the author deals in a very comprehensive manner with the various mechanical appliances, especially toothed gear. This section has been most ably considered, more particularly with regard to the horse-power transmitted by toothed wheels. A very brief notice of “Frictional Wheel-gearing” is considered sufficient, but a half-page can hardly be deemed adequate for so important a question, whilst the following twenty-four pages deal with belt-pulleys and belts, and shafting, in a clear and complete manner. The “Evaporative Performance of Steam Boilers” in this and other countries is dealt with in great detail, and forms one of the most interesting features of the book, indicating a vast amount of very careful research. This is followed by an elaborate chapter on the steam-engine, with copious tables of results of experiments and actual practice, notably Table No 297, of the “Net Cylinder Capacity, with relation to Steam admitted, and total actual

\* “A Manual of Rules, Tables, and Data for Mechanical Engineers.” By Daniel Kenner Clark, M. Inst. Civil Engineers. Third edition. Blackie & Son, Old Bailey.

Work done." Under the head of "The Practice of expansive Working of Steam" the author is enabled to give some very interesting results of the experience with some of the principal condensing engines extant, in America and France as well as in this country. Two able chapters, one on the "Flow of Air and other Gases," and the other on the "Work of Dry Air and other Gas, compressed and expanded," deal with this important question in a very comprehensive manner, illustrated as they are by records of the experiments of the highest authorities at home and abroad. We regret that the author did not see his way clear to treat the important subject of "compressed air machinery" in more detail, an opportunity being thus lost to enhance the value of the work; indeed, he treats the whole question of "air machinery" in a very cursory manner. The chapter on "Flow of Water" would have been better omitted, and the same may be said of that on "Water-wheels"; the author elects to pass over so important a question as the effective power of turbines, contenting himself with simply reproducing well-known data. It is upon subjects like these the value of such a work is tested; and when, under the head of "Machines for raising Water," no notice is taken of the "Pulsometer" and other modern appliances, we feel it to be our duty to protest that the volume under notice can hardly claim to rank amongst the standard works upon mechanical science. A useful chapter on "Frictional Resistances" brings this work of nearly a thousand pages to a conclusion, and the impression left upon our mind, after a very careful perusal, is that for some things it will be found of unquestionable use, but the information might easily have been contained in a book of much less size, and we are all the more convinced that the tendency of authors to crowd a well-intentioned work with useless and inadequate elementary tables is to be strongly reprehended.

#### CONCRETE-BUILDING IN NEW ZEALAND. BAKER'S CONCRETE MACHINE.

JUDGING from a recent number of the *New Zealand Industrial Gazette*, concrete-building is growing in favour in the colony, and among Auckland industries one of the most important appears to be the production of hydraulic lime by Messrs. Wilson & Co., who, according to the periodical in question, have been forced, by the prejudices of the local builders, to enter into the business of building, "in order to provide an outlet for their own produce, and to practically demonstrate that concrete made of their lime is a reliable and cheap substitute for bricks or stone, the relative costs of brick and concrete per cubic yard being:—brick, 33s. to 40s.; concrete, 22s. to 25s. In fact, the difference between a concrete and a really good wooden house is estimated at 10 per cent. only." An interesting account of the manufacture is given by the *Gazette*, from which we gather that Messrs. Wilson & Co. are determined to pit their hydraulic lime against Portland cement, which has to be imported.

An indication of the extent to which concrete is coming into use in the colony is afforded by the production of "Baker's Combined Ganging, Mixing, and Compressing Concrete Machine," which is the invention of the patentee, Mr. Robert Baker, manager of the Union Sash and Door Factory, Auckland. Mr. Baker, we are told, has had much experience in connexion with concrete work in America and other countries, and the invention is the result of numerous experiments suggested by this experience. Mr. Baker's machine is thus described:—

"About 10 ft. from the machine's foundation is a platform which slopes to the gauger," so that the materials fall into the gauge boxes by their own weight. The gauger consists of a series of compartments, the number and sizes of which may be regulated to requirements by means at once simple and effective. These compartments have movable bottoms, that is to say, they are bottomed by a peculiarly constructed iron wheel, working horizontally, of course, the movements of which are regulated by an ingenious clutch on a vertical shaft. The compartments being supplied, the revolution of the horizontal wheel admits the required quantities of each of the ingredients into the receiver. To the vertical shaft just mentioned are fixed arms, which most effectually mix the contents of the receiver, while the water is added in an even and easily regulated shower by means of a perforated iron tank, fixed to the underside of the horizontal wheel already spoken of. The mixture is constantly passing from this receiver or mixing pan into two chambers immediately below, one on the right and the other on the left side of the machine. These chambers are very cleverly fitted with the object of submitting the material to a very different process of

mixing to that of the horizontal revolutionary motion which it undergoes in the pan above. The chambers in their turn deliver the perfectly mixed concrete into a mould beneath. . . . The mould is fixed on a set of trolley wheels, running on rails spiked on to the top of the travelling bed, which is steadily moving backwards and forwards beneath the chambers and compressors. When the mould is nearly full, two compressing rollers speedily bring the concrete to a perfectly even and level surface. The trolley containing the block is then run off the travelling bed to a convenient place to set and harden, another trolley with empty mould taking its place. From the tipping of the materials from the trolley into the mould as concrete blocks, no hand labour whatever is employed: it is a self-feeder and a self-deliverer. The quantity that can be put through in a day is estimated at from 1,500 to 2,000 cubic feet, in blocks up to 80 cubic feet, or from five to six tons weight. It will also turn out landings and pavings up to 42 ft. superficial, and from 3 in. to 12 in. thick. The machine is capable of being set to forty different combinations or arrangements of proportions. The weight of the machine is between four and five tons, and the power necessary to drive it is from eight to ten horses."

#### NEW TOWN HALL, LEAMINGTON.

THE new town-hall at Leamington was opened on Thursday last, the 18th inst. Hitherto the corporate and magisterial business has been transacted at the accommodations and inconveniently-situated edifice in High-street, erected in 1831 at a cost of 2,000l. With the incorporation of the borough in 1875, the need of better accommodations made itself urgently felt, and the corporation invited architects to send in designs for a new town-hall, a local practitioner, Mr. John Candall, A.R.I.B.A., being the successful competitor. Tenders having been invited for the erection of the building, that of Mr. John Fell, of Leamington, amounting to 14,000l., was accepted.

The exterior is designed in the Renaissance style, and the materials used are finely-pressed red bricks with stone dressings from the Camden quarries. The Parade façade is 150 ft. in length, and is approached by a terrace formed of Stuart's granolithic pavement. The principal entrance is by a portico supported by twelve massive square stone columns, and six pilasters, with elaborately-carved capitals, surmounted by a stone entablature and halustrade. The lintels from the different pillars are of Portland stone. The portico has a vaulted covering of Camden stone, on which is formed a balcony of granolithic. For the erection of the portico a separate contract was made with Mr. Fell, the cost being 2,000l. The central block is entirely of stone, with carvings, mouldings, fluted columns, cornices, and other embellishments. The central pediment,—which is surmounted by the heron, an indigenous bird,—is especially noticeable (according to the *Leamington News*), the sculpture being relieved by a mosaic representing Hygeia, who is holding in her right hand a goblet and in the other a serpent, while a couple of cherubs are supposed to be offering libations of Leamington water at the foot of her throne. The pediment in the northern wing, which contains the Court-house, has a sculptured tympanum, illustrating Music, Science, and Art. Similar subjects are portrayed in the spandrels over the west window of the Court-house. The pediment in the south wing, over the oriel window of the Council-chamber, contains sculptured subjects illustrative of Wisdom, Justice, and Authority. The elevations are lofty and imposing, those of the wings being 60 ft., while that of the central feature is 70 ft. The main entrance in the Parade is provided with iron gates, manufactured by Hart & Son, of Birmingham and London. Leaving the stone vestibule, with its granolithic floor, enriched with panels of ceramic tesserae, and its groined roof, the visitor passes through a pair of large folding mahogany and pitch-pine swing doors, with English oak framing, the lead lights above having been filled up with coloured glass by Mr. Holland, St. John's, Warwick.

The corridor on the ground floor,—which is several feet above the street level, and extends the whole length of the building,—is 10 ft. wide, 14 ft. in height, and floored with Stuart's granolithic paving. From this corridor access is obtained to the various offices of the Corporation officials. On the right side of the corridor, immediately opposite to the Town Clerk's quarters, is the Surveyor's office, which is lighted from the Holly-walk, and fitted with one of Barnard & Barnard's slow-combustion stoves, with Minton tile sides.

The approach to the first floor is by the grand central staircase, facing the main entrance, and consisting of a flight of twenty-eight steps, those in the first flight being

12 ft. in width, and, like the floors of the lower and upper corridors, composed of Stuart's granolithic. The staircase has a stone halustrade and handrail all the way on each side. At its base rise two massive square stone columns, supporting the landing above the cothel, consisting of sculptured figures.

The Council-chamber on the first floor is situated at the south end of the upper corridor, which extends to the Court-house at the north end. Opposite to the main entrance to the chamber the first object which arrests attention is the richly-carved and moulded chimney-piece of Portland stone. This is the work of Mr. Boulton, of Cheltenham, who also executed all the stone-carving throughout the buildings. The walls are panelled with mahogany and pitch-pine, to a height of 12 ft. At the east end is a gallery for the accommodation of the public. The apartment is lighted by five windows on the south side, and an oriel window, flanked by two side-lights in the Parade front. Stained glass is largely inserted in the windows, the best specimen being the six-light window presented by the Mayor, Mr. S. Flavel, jun. Five of these lights contain designs taken from Shakspeare's "As You Like It," and depict scenes in the Forest of Arden. The design of the remaining light is "Shakspeare reading his Plays to Queen Elizabeth." This window was executed by Mr. Holt, of Warwick. The wood-carving is the work of Mr. James Flower, Dale-street.

The Court-house, 80 ft. by 40 ft., has an elliptic ceiling, which is relieved with panels and enrichments, with centre flowers, two of which, with Boyle's ventilators fixed through the roofs, answer a useful purpose. From the sixteen pairs of double pilasters on either side of the room rise enriched curved ribs, which extend across the ceiling 30 ft. high, from which at intersections of the main ribs depend gables on each side.

The Tower, at the east angle of the southern frontage, is 130 ft. in height, and contains a granolithic staircase, which was intended by the architect to lead to the School of Art, had that portion of the original design been carried out. It now forms an approach for the public to the Council-chamber, and also to the upper portion of the building. The clock has four illuminated dials, and strikes the hours upon a bell weighing about 15 cwt., cast by Messrs. Taylor & Co., Longhborough.

The contractor, as before stated, was Mr. John Fell; Mr. C. Franklin was foreman of plasterers; Mr. William Robbins was foreman of bricklayers; Messrs. Robert Lines and H. Smith were foremen of carpenters; and Mr. Henry Smith was foreman of masons.

The furniture was made from Mr. Candall's designs by Messrs. Pucknett & Stevens. All the stained and coloured glass windows were supplied by Mr. Holt, of Warwick. The heating apparatus was manufactured by Mr. Jenkins, Leamington. The brass gas-fittings are by Messrs. Barwell, of Hampton-street, Birmingham. Mr. E. W. Atkins was the clerk of works.

#### THE DOME OF ST. PAUL'S.

Sir,—I agree with your correspondent, Mr. W. Cave Thomas, that the experiments in decoration now on view in St. Paul's prove that Thornhill's idea is the best yet put forward; and that to translate it into colour would be desirable.

It is capable of improvement, however, and that with little difficulty, its principal defect being in the vertical divisions are right, the rapid diminution of the architectural features of which these are composed (sham pilasters or columns), is most unpleasant, and the arches they seem to sustain are ridiculous in proportion to their supports, and appear necessarily distorted, from being on a curved surface, as real arches could not be. Here the painter's skill could mend the evil by obscuring the arches and pilasters. The figures of angels with spread wings would do this service for the former, and hold decoration on the latter would suffice for them. Then the grand simple spaces left are just what would give scope for the painter's art on a proper and sufficient scale, and such as Wren contemplated. This would be far better than the *petite* and confused treatments of circular panels suggested to be substituted for them.

JOHN P. SEDDON.

## NEW ADMIRALTY AND WAR OFFICES.

Sir,—While thanking you for the accurate and excellent plans and view of the design for the above building given in the *Builder* of this date, allow me to point out that you have inadvertently reversed the order of the authors' names, that of Mr. Aston Webb having hitherto invariably, and properly, held the first place. E. INGRESS BELL.  
Sept. 13th, 1884.

## SKETCHING AT THE HEALTH EXHIBITION.

Sir,—Whilst examining the plans, placed on the walls for public inspection and instruction, of the "sanitary" and "insanitary" houses, their sewerage and drainage, it struck me an improvement would be effected by a slight alteration in the ventilating pipe or shaft; and I began to copy on a small piece of paper this portion of the work, with the view of showing therein the proposed alteration, but had scarcely commenced when a police constable on duty immediately stopped me, as acting under orders to that effect. I dare not venture to question the policy of such proceeding; but permit me, through you, to ask the Commissioners and other authorities having the management of this Exhibition of Health instruction, whether they have, in fact, issued any such prohibiting order; and if so, whether, to prevent any unnecessary irritation on the public by coming in contact with the police, they have caused printed notices to be affixed at the several entrances of the building and other suitable places for the guidance of the public?  
A Visitor.

## PARTY WALLS.

Sir,—I should be greatly obliged if any of your numerous readers could inform me where I could obtain a good book relating to the laws and rights of party-walls?

I am about to build a house attached to another I sold a short time since, reserving to myself the use of the end wall as a party-wall to rest beams in, &c., or other supports as are generally required. But in building this new house adjoining, I want to build on the party-wall, as I have to build an additional back bedroom.

The question is, Can I raise on this party-wall, without the consent of my co-partner? Of course, there would be no lights or obstruction in the said wall intended to be raised, and I should have to protect my co-partner from any injury to his house, and hold him free of any cost in the matter.

An early answer will oblige,  
SUBSCRIBER.

## A COST CLERK'S DIFFICULTY.

Sir,—Will you kindly allow one of your correspondents to instruct me upon the following:—

I am engaged as a cost clerk. Having looked up the time on the various jobs, I next proceed to book up the stores and miscellaneous charges: such charges are not booked direct on each job, but are spread proportionately over each; the miscellaneous charges consist of foreman's, labourers', &c., wages.

Now, the doing so seems to me to be incorrect. Say, for instance, that the wages are for one week, 20*l.* or 30*l.*, and the stores and miscellaneous charges amount to 6*l.* or 8*l.* Posting up such charges proportionately on the bulk of jobs seems to be utterly wrong. Jobs of the value of 3*l.* will have, perhaps, 1*l.* or 2*l.* for such charges, whilst others of 10*l.* will have, say, 5*l.*, such items depending upon the weekly charges distributed over the various amounts for labour.

Will you kindly say if my method is correct, and if not, point a more suitable way of keeping such costs? The nature of the material does not enable me to book the exact quantities used on each job.  
A CLERK.

\*.\* Our correspondent seems to have failed to express his precise meaning. If the charges are, as he says, distributed "proportionately," how can the disproportion suggested arise?

## RESPONSIBILITY FOR ACCIDENTS TO WORKMEN.

Sir,—In answer to the inquiry of "A Surveyor" (p. 374, *ante*), if a sub-contractor undertakes the labour of constructing the scaffolding, he alone is responsible for the manner in which it is constructed.  
X.

## "A PERIODICAL QUESTION."\*

Sir,—Cockroaches may easily be got rid of by mixing one teaspoonful of dry red lead with three teaspoonfuls of good dry flour. When well mixed, place some on the bottoms of inverted plates, throw some loosely into corners and holes where they are seen to come from. Mix again fresh in, say, forty-eight hours, and soon you will be quite free. The flour must not be in the least sour.

WM. HOSKEN.

See p. 349, *ante*.

## PROVINCIAL NEWS.

**Wigan.**—It will be remembered that a new infirmary was erected in Wigan about ten years ago, and opened by H.R.H. the Prince of Wales. This building (known as the Royal Albert Edward Infirmary) provided accommodation for about 100 beds, and the success of the undertaking has been very complete and satisfactory to those who supported and inaugurated it. So much is this the case, that it has been found necessary to enlarge the building, and a detached wing is now in course of erection, containing accommodation for twelve special wards for severe cases, children's wards, and a separate nurses' home of twelve rooms, with the necessary kitchens, lavatories, bath-rooms, &c. These will be connected to the main block by a glazed corridor, which it is proposed to make into a winter garden and exercising-place for the convalescent patients. Mr. Thos. Worthington, of Manchester, was the architect of the original building, and Messrs. Worthington & Elgood are now carrying out the additions in a similar manner. Mr. J. Preston, of Wigan, is the builder employed, and his contract for the portion of the works already decided upon amounts to about 3,600*l.*, exclusive of the internal fittings and other works.

**Derby.**—A Fine Art Exhibition is to be opened at Derby, by the Mayor, on November 3rd. The exhibition is inaugurated for the encouragement of amateur art work, such as painting on china, terra-cotta, silk, tapestry, Lincrusta-work, designs for Christmas cards, wood-carving, etching, &c. The awards to successful competitors will comprise thirty-six silver and bronze medals, a silver badge, twenty guineas in money prizes, statuettes, vases, &c., and one hundred diplomas of merit. The exhibition is being organised by Mr. W. W. Winter, of the Alexandra Fine Art Galleries, Derby.

**Weymouth.**—The new banking premises for Stuckey's Banking Company, on the Parade, at its junction with Bond-street, have now been completed. The style adopted by the architects is French Renaissance of the Burgundian type, the elevations being of red brick and Portland stone, while the roof is covered with green slates. Internally, the only apartment admitting of special treatment to harmonise with the exterior is the banking-room. The entrance to it (from Bond-street) is through a handsome semicircular-headed doorway, the principal feature in the whole of the stonework. Pitch pine is the material used for all the woodwork in the banking-room, except the counter and desk tops, which are of mahogany. Connected with the public room is the bank parlour, which also communicates with the manager's residence. Upstairs the oriel windows, facing Bond-street and carried upon stone corbels, give large additions to the drawing-room and three bedrooms, besides a sea view to each. The architects are Messrs. Paull & Bonella, of Chancery-lane, London; the builder being Mr. Albert Clarke, of Weymouth.

## CHURCH BUILDING NEWS.

**Drayton Beauchamp.**—The east end of Drayton Beauchamp Church has just been enriched by the addition of a new oak reredos, designed by Messrs. Carpenter & Ingelow, as a memorial to the late rector. The design is of the Perpendicular period, to assimilate with the architecture of the church. In addition to much richly-carved detail, it contains a sculptured representation of the "Sermon on the Mount," also in oak. Mr. Forsyth, of Finchley-road, Hampstead, was the sculptor.

**Newark.**—A costly reredos has lately been erected in North Clifton Church, Newark, to the memory of the late Mr. George Freeth, of North Clifton Hall. The designs were made by Mr. John T. Lee, architect, of 26, Great James-street, Bedford-row, London; and are intended to illustrate the doctrine of the Incarnation. The reredos contains panels, in which are figure-subjects, painted in gold and colours. The centre panel, over the altar, represents the Epiphany, with the shepherds and wise men adoring the infant Saviour. The centre group is flanked by two panels, representing the Annunciation, one containing the figure of the angel Gabriel, the other the blessed Virgin Mary receiving the message. The side panels are surrounded by foliage of the vine, wheat, olive &c., and represent the busts of the four

evangelists who wrote the history of our Lord. Above them are standing figures of the four great prophets, viz. Isaiah, Jeremiah, Ezekiel, and Daniel. Above the east window the vine ornament is again introduced on a larger scale, to form the ground-work for three medallions with angels. The framework of the reredos is executed in oak, by Mr. Earp, of Lambeth, from the designs of the architect, and is decorated in the style of the best examples of the old Norfolk screens. The decoration of the walls and the reredos are by Messrs. Heaton, Butler, & Bayne, of Garrick-street, London.

**Bristol.**—On Monday last the Bishop of Gloucester and Bristol laid the foundation-stone of St. Lawrence Church, Lawrence-hill, Bristol. The parish has, in accordance with the scheme of the Bristol Church Extension Commission, been formed, principally from the large and overgrown parish of Holy Trinity, and partly from St. Matthew's, Moorfields. The district contains a population of 4,500, almost entirely of the labouring classes. The style of architecture adopted for the building is Early English. The site, which is hemmed in by neighbouring properties, presented many difficulties to the architect, especially in the matter of lighting. The church will consist of narthex, nave, north and south aisles, tower and spire, western gallery, chancel, chapel on south side, organ chamber, and vestry. The total internal length will be 115 ft., width across the nave and aisles, 55 ft., and height from the floor level to the apex of the nave roof (which will be open-timbered), 58 ft. For the general walling, Pennant stone will be employed, with dressings of Bath stone. The walls on the inside will be stuccoed. Arches of Bath stone and brick will divide the aisles from the nave; the columns which are to support them will be of rubbed and sanded Pennant stone. The windows are to be filled with rolled cathedral glass in geometrical patterns, supplied by Mr. Ben Gay. Sitting accommodation will be provided for about 700 worshippers, the seats and gallery being of red deal, varnished. The gangways and narthex are to be paved with Staffordshire tiles, and the chancel with encaustic tiles. Artificial heat is to be imparted to the interior by one of Grundy's heating apparatus. The west elevation, with its tower and spire rising to a height of 115 ft., will present an important frontage to the main road. The accepted estimate for the first portion of the church is 3,200*l.*, and a provisional contract has been entered into for the completed work, inclusive of upper portion of tower and spire, for 590*l.*, making a total of 3,790*l.* The work has been entrusted to Messrs. Wilkins & Sons, of Surrey-street; Mr. Honey acting as clerk of the works. The architect is Mr. John Bevan, of Unity-street, Bristol.

## SCHOOL-BUILDING NEWS.

**Peel (Isle of Man).**—On his recent visit to the Isle of Man, His Grace the Archbishop of York laid the foundation stone of the Isle of Man Navigation, Grammar, and Mathematical School, which is being erected on a site close to the new church at Peel, of which we gave some particulars on p. 374, *ante*. Messrs. T. D. Barry & Sons, of Liverpool, are the architects of the building.

**Goudhurst.**—A large and substantial block of buildings has just been completed here for the Rev. J. J. Kendor, for a ladies' college. The buildings are in the form of the letter H, the centre being the residence, on the right the school, and on the left the dining-room, bedrooms, lavatories, and other necessary conveniences. The walls throughout are built hollow, on account of the elevated and exposed position of the building. The sanitary arrangements and water-supply have, we are told, been well cared for. Accommodation is provided for about fifty boarders, besides teachers, family, and domestic offices. This is the second large establishment erected in the locality, besides additions to a third (the two latter being boarding-schools for boys), the builder in each case being Mr. A. Martin, of Horsmonden, Kent, and the architect Mr. William Theobalds, of Watling-street, City.

**Architectural Association.**—As will be seen by an advertisement on our front page, Session 1884-85 of this Association will commence early in October.

## The Student's Column.

## HINTS FOR THE STUDY OF THE HISTORY OF ARCHITECTURE.—XII. RENAISSANCE (CONTINUED), AND THE REVIVALS.

ON page 162 of Professor Roger Smith's "Gothic and Renaissance," the author remarks that "design in Renaissance buildings may be said to be directed towards producing a telling result by the effect of the buildings taken as a whole, rather than by the intricacy or the beauty of individual parts; and herein lies one of the great contrasts between Renaissance and Gothic architecture."

In Italy, which was treated of in the last article, this distinction was aimed at from the very beginning by Brunelleschi, and still more by his contemporary, Alberti, whose Church of St. Andrea, at Mantua, and Rucellai Palace at Florence, fulfil the above-named definition as completely as possible.

In other countries this submission to rigid rules of composition was delayed, and, in the meantime we find a coy flirtation going on between the styles of the soil and the elegant stranger, which it is most interesting to watch. In the end they all gave way to the Classic influence, as the universally fashionable thing to do.

After Italy, Fergusson, in his "History of Modern Architecture," goes on to Spain, where the good points of Gothic work asserted themselves bravely before giving in. See the illustration on page 148 of the Court of the Archbishopal Palace at Alcala, built early in the sixteenth century, in which the entablature over the upper column is carried by very pleasing (though "incorrect") brackets. In other examples, such columns support flat cusped arches inherited from the native architecture. These flat arches survive in the Paraniño, a State apartment, though here they are placed between more correctly Classical pilasters and entablatures. At the same time the ceiling of the apartment is panelled into a pattern of hexagon and six-pointed stars that is quite Moorish in style. The palace of Charles V., at Granada, 1527, though quite an "orderly" design, has more circular windows and medallions about it than one would find in Italy. When it came to building the Escorial, a huge palace, including a cruciform domed church, in 1563, the design, prepared by Gianbatista de Toledo, and executed by the celebrated architect Herrera, is quite Classic. So, of course, is the palace at Madrid, rebuilt after the fire of 1734, from the designs of Irara, an Italian architect. The palace at Mafra, in Portugal, of about the same date, is as Classic, but with a skyline pleasingly broken by spires and lofty roofs over certain portions.

In the provinces, Fergusson hints at the existence of a more national style, but regrets that Renaissance art in Spain has not been illustrated. Street has since drawn and described her Gothic work; there is an opening for an equally good professional work on her Renaissance buildings.

Turning now to France, we find that Francis I., 1515-1546, was, to use Fergusson's expression, fairly bitten by the Italian mania of the day; and that, after visiting Italy, he brought back Leonardo da Vinci to France, and that he invited thither Benvenuto Cellini, Primaticcio, and Serlio, and occupied them all on his works at Fontainebleau and elsewhere. Soon there followed a group of palaces and châteaux, that have all the play of plan and outline belonging to Gothic buildings, combined with refined Renaissance details,—a very beautiful phase of architecture. The Louvre and Tileries were treated in a comparatively formal manner, but the châteaux of Blois, Chambord, Amboise, Fontainebleau, Chenonceaux, Madrid, Gailion, Vallery, Verneuil, Charleville, and Ecouen, are enumerated by Fergusson, page 164, as examples of the graceful architecture of the day. Churches were the exception among those buildings. That of St. Eustache at Paris is an example, dating from 1532, which is completely Gothic in all its arrangements, with Classic details, attenuated to do duty in novel positions, and thereby losing all their proper proportions. It is thus an adaptation of the two styles one to another, but not an amalgamation of them, and soon there came the inevitable "orders," very much as we find them in Italy, but mixed with all the vagaries affected by the Jesuits.

From this there was a reaction which, under the eminent architect, Jules Hardouin Mansard (nephew of François Mansard), produced the dome of the "invalides," in Paris (see page 172 of Fergusson), a building that may fairly be compared with our contemporary St. Paul's.

This Mansard also designed the extensive Palace of Versailles, of which Fergusson says, on page 211, that its dimensions are probably unsurpassed by those of any in ancient or modern times, the entire length being 1,320 ft.; but the design is very monotonous.

The completion of the Louvre at Paris seems to have passed through the hands of several architects. François Mansard was consulted, Bernini was sent for from Rome, Marot and Lemercier presented designs, and ultimately the design of Perrault was preferred before those of all the other competitors. Although Fergusson admits that no design of that day (1670) can at all compete with the eastern façade of the Louvre, he proceeds to heap critical abuse on it for a couple of pages. If, however, an external "telling result" is what we look for in Classical buildings, surely this façade fulfils the requirement most satisfactorily. Let any student run over to Paris and rush to this end of the Louvre early in the morning, before the sun goes off it, and he will not regret the trouble.

The French have gone through their fair share of slavery to Classic art, but, after all, they have now assimilated it very satisfactorily, and evolved a modern style of which they may be justly proud.

Besides their ecclesiastical and domestic architecture, the French have produced public trophies, triumphal arches, fountains, &c., that show their taste in these matters to be far ahead of that of other nations.

Altogether, a stroll in the streets of Paris on a fine day is a thing to be enjoyed, and renders the contrast with the streets of London a painful one; in fact, it always takes many days before we can reconcile ourselves to our dingy disorganised capital on returning to it, especially if we are intent upon getting at the beginning of the Renaissance in England.

For this purpose we must go to the Rolls Chapel, near Chancery-lane, and after getting due permission, and probably a lantern, see what we can of the monument of Dr. Young. This is said to be the earliest example of the imported style, and to have been executed by Torrigiano, the sculptor who broke Michelangelo's nose, which fact will assist one in remembering the date of the monument, 1516. It was followed by a more important one, namely, that which Henry VIII. erected to the memory of Henry VII. and his Queen, in his chapel at Westminster.

In time the style spread to structures of greater size; perhaps the earliest example of a building is at Layer Marney, 1525, and we have records of gateways at Whitehall, designed by Holbein, who was chiefly known as a painter,—another of those foreign artists whom our many-winded king encouraged. St. James's Palace is another instance of the dawning Renaissance, as may be seen in the carving of the spandrels over the four-centred arches of the main gateway. Another foreigner, this time from Cleves, namely, Theodore Have,—or Havenius, as the Classic fashion required him to be called,—designed the Gate of Honour at Caius College, Cambridge, in 1574 (see page 247 of Fergusson). Here, four-centred arches and "orders" are cleverly put together, but hardly united. This University and Oxford, being of course the headquarters of learning, contain many examples of the "learned" style. At the Schools, Oxford, we have the five orders piled one over another, according to the Vitruvian precept.

Yet another foreigner, John de Padua, is said to have designed, in 1567, Longleat, in Wiltshire, the present seat of the Marquis of Bath. There is certainly much Italian feeling in the treatment of the wall surfaces, though the plan of the house is essentially English; that is to say, the chief windows command the views of the surrounding country, and do not look into a courtyard, according to the Italian fashion.

This continued importation of foreign talent had led to a rising on May Day, in 1517, with the intention of cutting to pieces all the strangers in London, amounting, it was said, to 6,000 or 7,000, and so it is satisfactory to find that in the time of Queen Elizabeth the fashionable architect was John Thorpe, who

designed many of the houses which have gained the name of "Elizabethan" for the style of her period. Many of these are to be found illustrated in Shaw's "Elizabethan Architecture," 1 vol., quarto; Richardson's "Old English Mansions," 4 parts, folio; Richardson's "Specimens and Observations on Elizabethan Architecture"; J. Nash's "Mansions of the Olden Time," 3 series, folio; Hakewill's "Elizabethan Architecture," 1 vol., octavo, in which the style is compared with Italian work, but the mullions and transomes are omitted from the English work. Last, but not least, John Thorpe's original drawings are to be seen at the Soane Museum in Lincoln's-Inn-fields, and are, in a sense, the most interesting of all.

The style goes on through the reign of James I., but by the time of Charles I. an English architect, Inigo Jones, had been to Italy to study the fashionable architecture at the fountain-head, and after erecting a few buildings in which he retained mullions and transomes, he threw off even these vestiges of Northern custom, and went boldly and entirely for Italian, treating it, however, with great originality and ingenuity. The banqueting-hall (now the Chapel Royal) at Whitehall, is a very small portion of an intended enormous palace that he designed. This elevation may not look anything out of the way on paper, but any one who passes slowly under it must become aware of the great amount of variety introduced into its seven bays. Except in the very centre, there are not two consecutive columns or pilasters alike, and the great projection of the pediments over the windows, gives great play to the perspective of the whole front, as seen from below.

After Jones,—to whose numerous works Fergusson specially devotes eight pages,—he goes on to pay a still larger tribute to Sir Christopher Wren, whose grand opportunity was afforded by the Fire of London in 1666, and who graced the City with a forest of steeples so varied and beautiful that we jealously begrudge the present removal of some of them because the resident population of the City has, for the moment, migrated into the suburbs. When the secret of smoke-consumption has been found, men of business may be glad to "live over their shops" again as in days of old, and then they will regret the want of church accommodation.

Wren's buildings are so numerous that we can only name one or two besides St. Paul's Cathedral. Every student should enter St. Stephen's, Walbrook, near the Mansion House, to see the elegant arrangement of a dome carried on eight Corinthian columns. The interior of St. James's, Piccadilly, is a good example of a church with galleries, which were the fashion in those days, and for which most of the churches were so specially designed that one stands aghast at the removal of them and the consequent utter destruction of proportion that has, since the Gothic Revival, been placidly effected here and there.

Of Wren's steeples (for which A. Taylor's Prize Essay at the Institute, since published by Batsford, is a handy companion), that of Bow Church is considered the best. Greenwich Hospital,—where he followed Inigo Jones,—Chelsea Hospital, and Hampton Court Palace, are examples of his secular work.

After Wren there were several architects who have formed a fine school of Anglo-Italian work, among them Hawksmoor, Vanbrugh, Kent, Gibbs, Sir William Chambers, the brothers Adam, Taylor, and Dance. The latter designed Newgate Prison, which is as expressive a piece of architecture as the world has ever seen.

The domestic architecture of this period, the eighteenth century, became painfully symmetrical, as may be seen from the illustrations of Kedleston Hall and Holkham, on pp. 294-295 of Fergusson's "Modern Architecture," the plan of the former resembling one of those insects that rest on the water poised on four long legs, representing the corridors leading to four outlying symmetrical departments.

As has been said above, the beginning of the present century introduces us to yet another phase of imitative architecture. Hitherto the Classic styles have been adapted. Now they became adopted. Fergusson attributes this to the publication of illustrated works upon Roman, and more especially Grecian architecture. He says, "once the fashion was introduced it became a mania." He instances

the new Church of St. Pancras, in the Euston-road, designed by Inwood, as giving us a very exact reproduction of Grecian Ionic, and also of the corinthish portico of the Erechtheum at Athens, and, so far, we may be thankful for it. There are several other dead bones in our midst.

While men's minds were still in this state of resignation to anything so long as it was correctly ancient, the revival of Gothic architecture came as a welcome change. While equally inexorable in its demand for correctness, it had the advantage of re-introducing the style of our climate, and, whatever may be preached to the contrary by votaries of the mouldy picturesque, its attendant mania for "restoration" has done (on the whole) more good than harm.

"Correct" Gothic has lately been found either too expensive or else inappropriate for ordinary domestic buildings, and we are now gradually developing something quieter and more in harmony with our tastes and habits, and in which there shall be no sense of frantic effort,—either to copy a past style, or to suddenly invent a new one. "*Ans est celare artem.*"

#### THE SACRAMENTS-HAUSLEIN AT NUREMBERG.

SIR,—May I venture, with all due respect to the able writer in the Student's Column [p. 341, ante], to suggest that he is possibly mistaken in thinking the summit of the spire of the Sacraments-Hauslein at Nuremberg was bent beneath the vaulting because it was too high to stand upright? It is my humble opinion that it was originally designed so, to represent a crozier; and I am confirmed in that opinion by the fact that a somewhat similar sacred receptacle was erected by one Veit Stoss in St. Mary's, at Hersbruck, a small town of the ancient territory of Nuremberg, that has an unmistakable crozier as a finial.

The minor pinnacles seem to be curled over from mere caprice.

I send the above that I and others of my acquaintance may be put right,—if we are wrong.

REUBEN G. NORMAN.

London, Sept. 11, 1884.

\* Mr. Norman and others of his acquaintance may mean a bishop's *pastoral staff*, which terminates in an ornamental crook, while an archbishop's *crozier* always terminates in a cross (Hook's "Church Dictionary," p. 307); but if this spire-head be nubby, it will be found to continue the *sloping* lines of the rest, whereas a *pastoral staff* is straight until the crook begins.

In Lonsdale and Tarver's "Costume" will be found, on plate 9, an archbishop of the thirteenth century with his crozier, and on plate 36 a bishop of the fifteenth century, with his pastoral cross. The latter is taken from Boutell's "Brasses," in which also will be found the brass of Archbishop Cranley, A.D. 1417, with his crozier.

If the example illustrated in Ferguson's "Handbook," p. 759, be earlier than that at St. Mary's, Hersbruck, which the writer has not seen, the suggestion of a *pastoral staff* may have been carried out in the latter.

Probably the real fact is that the designer of the Sacraments-Hauslein turned the finial because he liked doing it.

#### Miscellaneous.

**New Vicarage House for St. Bride's Fleet-street.**—The parish of St. Bride, Fleet-street, has not hitherto had the advantage of a clergy-house within the parish, but this is about to be remedied by the erection of a new vicarage, which has already been commenced. The site fixed upon for the new building is a portion of the vacant land in Bridewell-place, situated between the police station and the London City Mission Buildings. The principal frontage of the new vicarage faces Bridewell-place. It is 44 ft. in length, and 48 ft. in height from the pavement line to the ridge of the roof. The style of architecture may be described as a mixture of the Elizabethan and Queen Anne. The building will be faced with red Fareham brick, the dressings, architraves, and cornices being in gauged brick, with a free introduction of carving and ornamentation. The building will contain a basement, together with ground-floor, first and second stories, and attics, having alternate arched and pediment windows. The basement contains the kitchens and other offices. The ground-floor, which will be approached at the entrance by a flight of steps, contains a spacious entrance-hall, dining-room, library, and offices. The first floor contains the drawing-room, a bed-room, and bath-room, while the second and attic floors contain together six bedrooms, with dressing-rooms in addition. Mr. Basil Champneys, of Buckingham-street, Strand, is the architect, and Mr. B. E. Nightingale, of the Albert Works, Lambeth, is the contractor. Mr. Goodchild is clerk of the works, and Mr. J. Snook the foreman.

**The State of the Thames.**—Mr. Edmund Kimber, of Walbrook, has addressed a letter to the Secretary of State for War, calling attention to the fact that the Royal Commission appointed to inquire into the condition of the Thames, and to report upon what remedies ought to be adopted to meet the grievance, has now been sitting for about a year and a half, and has not yet reported upon the remedies. "In the meantime," says Mr. Kimber, "cholera has been, and is now, raging in Franco and Italy, from whose ports ships daily enter the Thames, and the people on the banks of the Thames have been afflicted with diarrhoea and dysentery. Were it not for the otherwise cleanly habits of Englishmen there is no doubt these maladies would have turned long since to cholera, and would have decimated the working men and officials in the Royal Arsenal, Dockyard, and Barracks at Woolwich, with the greatest certainty. Even as it is, many of the working men have complained to me of the horrible and loathsome stench coming from the river as they are working in the Arsenal, bringing on, as it does, a certain weariness and sickness, which prevent them from doing their work properly. Now, this is manifestly a great loss to the nation, especially at this time, when the greatest care, skill, perseverance, and nicety are required on the part of the men in preparing for the Nile expedition." Mr. Kimber urges the Secretary for War "to cause the Royal Commissioners immediately to send in their report, or else to advise her Majesty to discharge them. They might," Mr. Kimber thinks, "very easily have reported long ago."

**Metallic Cement for Repairs.**—Messrs. Dreyfus & Co. call attention to the use made by them of Tabary's patent metallic cement in repairing the stonework of the pediments and columns of St. Peter's, Eaton-square, and also in one of the bays of the Houses of Parliament. They state that "the process of restoration consists of hacking off the decayed portions of stone and facing it with the cement, instead of removing the block of stone and replacing with new. It consists of a pure stone reduced to powder and reconstituted to its primitive state, producing a stone impervious to all atmospheric effect; it is carved in the same manner as ordinary stone."

\* Open to public inspection for two months from the dates named.

**Hot Blast, and Economy in the Blast-Furnace.**—At a meeting of the South Staffordshire Institute of Iron and Steelworks Managers, held at Dudley on the 8th inst., Mr. A. E. Cooper, of Middlesbrough, read a paper on this subject. The wide adoption of the system in the North of England had led the Staffordshire furnace proprietors to inquire more closely into its suitability for South Staffordshire, where at present only a few establishments have adopted it, amongst others the Spring Vale Furnaces of Mr. Alfred Hickman, where the pigs are obtained for the New Staffordshire Steel and Ingot Company's Works. In the discussion which followed the reading of the paper, the general opinion was in favour of the stoves. The Chairman, Mr. Hudson (president of the Institute) said they had two furnaces,—one with the temperature at 900° and the other at 1,500°—and they found the difference in favour of the hot-blast stove to be from 3½ cwt. to 4 cwt. of coke to 1 ton of iron. Moreover, the coal and slack, which amounted to 6d. or 9d. per ton of iron produced by the iron pipe stove, was entirely saved, since no coal or slack was needed in the hot-blast stove. The only repairs necessary during eight years of use had been one change of the gas valves and an occasional change of the hot-blast valves.—*Mining Journal.*

**Harrogate.**—The three windows of the south transept of St. Peter's Church, Harrogate, have just been filled with stained glass, presented by the Mayor, Mr. Nicholas Carter, and his brother Richard Carter. The transept has two tall three-light windows, surmounted by a rose in the gable. In the upper part of the north-eastern window, and in the central light, there is the figure of St. Gabriel, the angel of the Annunciation, while in the corresponding central position, in the other window, is that of the Blessed Virgin, thus portraying the subject of the Annunciation. In the light below there are figures of several Biblical characters and early Christian martyrs, with legends and scrolls, all having a bearing either on the Incarnation of our Lord, or suitable to the figure over which they are placed. The windows are given in memory of four sisters by their brothers. They have been successfully carried out by Messrs. Burlison & Grylls, under the direction of Messrs. G. F. Bodley, A.R.A., and T. Garner. By the same donors and designed by the same architects, a carved and painted reredos has also been added. In the centre of it is a painted panel, the subject being "The charge of St. Peter."

**Cadzow (near Hamilton, Glasgow).**—On the 7th inst. the new Roman Catholic Church at Cadzow, dedicated to Our Lady and St. Anne, was consecrated and formally opened for divine service. The church is situated on the Eddlewood Estate, about midway between Quarter-road and Cadzow. The buildings stand on an elevated site, one acre in extent, facing the Quarter-road. They are in the Early English Gothic style, with a frontage of 90 ft. and a depth of 80 ft. The church and a commodious presbytery form one group of buildings. The chapel is entered by a side porch with arched doorway, and internally measures 70 ft. by 26 ft., with side transept 20 ft. by 18 ft., and small sanctuary. It is fitted with stained and varnished convertible seats and desks, suitable for school and chapel purposes. The architect of the buildings was Mr. William Ingram, Bath-street, Glasgow, and the contractors for the principal works were Messrs. Brown & Henderson, Hamilton; Mr. Thom, Uddingston, and Messrs. McEwan & Savage, Glasgow.

**Difficulties of the Historical Painter in a New Country.**—At Washington the grand historic fresco designed to belt the rotunda of the Capitol has been brought to a standstill in an unfinished state by an unforeseen obstacle. The artist who has the work in charge declares that "there isn't history enough to go round." The fresco begins with the landing of Christopher Columbus, and at present it finishes with scenes of the Mexican War. To take designs from the scenes in the recent Civil War would hardly be in good taste under the circumstances; the time has not yet come for the artistic commemoration of that great chapter in the annals of the United States, at least in the building where Congress meets. So a serious blank remains to be filled. An Emancipation panel has been suggested, but objections have been raised to this also. The indications at present are that the work will linger on till more history has been made.—*Furniture Gazette.*

**Typhoid Fever and Rainfall.**—In the last number of the *Archives Italiennes de Biologie* (tome iv., p. 26) is an interesting paper by Professor Louisa Pagliani on the "Oscillations of Typhoid Fever in Paris," in relation to the quantity of rainfall and the conditions of sewage. He finds, from an examination of the weekly bulletins, that for the last three years a heavy rainfall is followed about two weeks later by an increase in the number of cases of typhoid reported as admitted to the hospital, and in about four or five weeks by an increase in the number of deaths from this cause. As the disease has a period of incubation of from one to two weeks, and, if fatal, is usually so in from the third to the fifth weeks, this coincidence, which he finds repeated several times, would seem to be something more than a mere chance occurrence. Professor Pagliani does not find that the same thing happens in other localities having a soil as impure as that of Paris, and therefore concludes that rainfall and filth are insufficient by themselves to develop the disease, and that the reason for the effects observed in Paris is connected with its system of sewerage, and more especially with the effects produced by heavy and rapid rainfall in gorging the main sewers and obstructing the flow of sewage proper from the houses, or even causing a reflux of foul water into the cellar. Many of the smaller sewers have very little fall, and are readily obstructed. The explanation is somewhat doubtful, but the fact seems established.—*Health.*

**Notes on Coal.**—The beds or seams of coal form but a small portion of the thickness of the great geological group of strata to which they for the most part appertain. This group is called the *carboniferous*, and not uncommonly "The Coal"; but even where coal is most abundant, it forms only a minute part of the whole mass. Thus it has been estimated, Sir Charles Lyell tells us, that in South Wales the thickness of the carboniferous strata amounts in all to between 11,000 ft. and 12,000 ft. (or more than two miles); "but the various coal-seams do not," according to Professor Phillips, "exceed in the aggregate 120 ft.," or little more than one-hundredth part of the whole. In North Lancashire the carboniferous strata occupy a depth of more than three and a half miles, with the same relative disproportion between the thickness of the coal-seams and that of the complete series of strata. Again, in Nova Scotia, the coal-bearing strata attain a thickness of more than three miles. Here no fewer than eighty seams of coal have been counted (seventy-one having been exposed by the action of the sea); but these seams are nowhere more than 5 ft. in thickness, and many are but a few inches thick. Thus it is evident that the formation of coal can have been in progress but for a short portion of the time during which the great carboniferous series of strata was in process of deposition. Throughout by far the greater portion of that time other minerals were being deposited.—*Mr. Richard A. Proctor, in "Knowledge."*

**Large Sale of Building Land and Ground Rents on the Clapham Park Estate.**—Last week, at the Auction Mart, Mr. G. Brinsley, of New Bridge-street, disposed of an extensive quantity of freehold building land and freehold ground-rents, forming a portion of the Clapham Park Estate, near Clapham Common, which is between 35 and 40 acres in extent. The property submitted at the sale covers an area of about nine acres, comprises thirteen plots of freehold building land with frontages to several new roads which have been made upon the estate. The sale also included several other plots of land which had been let to various builders upon building agreements for the erection of private dwelling-houses on the estate at ground rentals amounting in the whole to 424l. per annum; and likewise freehold ground-rents amounting to 395l. per annum, arising out of houses already built upon the estate. The sale took place under an order of the Court of Chancery in the case *Nicholson v. Haynes*. The whole of the several properties were submitted in one lot, and were sold for the sum of 25,000l.

**National Art Training School, South Kensington.**—The winter session of the National Art Training School at South Kensington will commence on Wednesday, the 1st of October. The first examination for the forthcoming session will be held on Tuesday, the 30th inst.

**Public Library and Art Gallery for Auckland, New Zealand.**—Some time ago the city authorities of Auckland invited designs from architects for a new public library and art-gallery for that city, adjoining the Albert Park, and the first premium of 2000l. has been awarded to the design bearing the motto, "Litera, Scientia, et Artes," from the twenty-seven designs sent in, which was prepared by Messrs. Grainger & D'Ebro, architects, of Melbourne. The style of architecture adopted is Early French Renaissance. The principal entrance is situated at the intersecting corner of the two streets, where there is a tower which, judging from a view given in the *Australasian Sketcher*, is the least satisfactory feature of the design. The whole of the building will be carried out in cast stone, with fireproof construction.

**A New R.C. Ecclesiastical Seminary at Boston, U.S.**, is to be opened on the 22nd of this month. The architect of the new building (says the *Boston Pilot*) is Mr. J. H. Bassarick, and the estimated cost is 150,000 dollars (about 30,000l.) When finished it will be a quadrangular pile.

**Builders' Ironmongery.**—Mr. James Hill, of Queen Victoria-street, has just issued a useful price list of builders' ironmongery of a serviceable description. The price list and previous catalogues devoted to architects' specialities form a complete compendium of locks, door furniture, and general ironmongery.

**Surrey Bells and London Bell-founders.** A hook with this title, by J. C. L. Stahlachmidt, is announced by Mr. Elliot Stock. The work is very fully illustrated by wood-cuts and *fac-similes*; it will furnish information concerning some of the early bell-founders which has not been hitherto published.

**Hamilton (Glasgow).**—The new Free Church in Hope-street, Hamilton, was formally opened on the 10th inst. The building is Gothic in character. The church internally is 50 ft. long by 42 ft. wide, divided by means of light iron columns into nave and aisles of four bays, each bay being lighted by a two-light window with tracery on the head. There is a gallery at the sides, two seats deep, and a larger gallery at the end extending over the entrance vestibule. At the further extremity, within an arched recess, is placed a pulpit with canopy, and over all a large marigold window, filled in with stained glass by Messrs. Ballantyne, Edinburgh. The carpentry of the roof is all exposed to view, framed of pitch pine, varnished, and of its natural colour. The seats, with solid bench-ends, the doors, and other joiner work, are also of pitch pine, varnished. Instead of the usual wood lining round the church, which is so liable to rot, the walls are lined to a height of 4 ft. with a dado of red pressed bricks. The front elevation to Hope-street has, at the left-hand angle, a tower 17 ft. square, rising up to a height of 50 ft., provided with a deeply-recessed belfry window of two lights on each of the four sides, and crowned with a spire, rising to a total height of 133 ft. Adjoining the tower is the main gable. The walls are faced with square ragstone from the Lanark quarries, and with hewn freestone from Wishaw. Messrs. Martin & Symington, Carlisle, were the masons; Archibald Millar, Motherwell, the joiner; Thomas Lithgow, slater and plasterer; James Wood, plumber; Robert Symington, painter—all of Lanark; Meikle & Sons, Glasgow, glaziers; Messrs. W. & J. Hay, Liverpool, architects; and Mr. William Cassels, Lanark, clerk of the works.

Yeo.....	865 0 0
Ridout.....	837 0 0

For alterations, &c., to the Pegasus public-house, Green-lane, N. Mr. W. West, architect:—

Godden.....	£2,065 0 0
Spencer & Co.....	1,820 0 0
Reach.....	1,750 0 0
Mills.....	1,628 0 0
W. Shurmer.....	1,590 0 0
Jackson & Todd.....	1,325 0 0

For residence and stabling, Monkton Combe, near Bath, for Mr. W. Vaughan Jenkins. Mr. George Rhodes, architect. Quantities supplied by Mr. F. Warburton Stent:—

J. R. Hunt, Bow.....	£4,690 0 0
Pack Bros, Brixton.....	4,578 0 0
Birdwell & Parsons, Bath.....	4,150 0 0
Macey & Sons, London.....	4,155 0 0

[Surveyor's estimate, £3,913 0 0]

Accepted for additions to stables, &c., at Fern Lodge, Orpington, with extra works to the house. Mr. St. Pierre Harris, architect:—

W. & F. Craker.....	£339 0 0
---------------------	----------

[No competition.]

For repairs and alterations to Inchcape, Chislehurst, for Mr. L. Fry. Mr. St. Pierre Harris, architect:—

Horrocks, Croydon.....	£134 0 0
Wood, Chislehurst.....	119 0 0

\* Accepted, not including easements.

For rebuilding premises, No. 357, Wandsworth-road, S.W., for Mr. F. S. Schuller. Mr. H. S. Woodcock, surveyor:—

Lathey Bros.....	£165 0 0
Mallet.....	155 0 0
Holloway Bros. (accepted).....	531 0 0

Accepted for sundry alterations to twelve houses in the Lansdowne-road, E., for Mr. T. W. Rhodes. Mr. J. H. Jones, architect:—

J. Jarvis & Sons.....	£1,680 0 0
-----------------------	------------

For sundry works at No. 8, Cowcross-street, E.C., for W. Robinson & Son. Mr. C. Aubrey, architect:—

Thomson & Son.....	£104 10 0
J. Jarvis & Son (accepted).....	75 0 0
Thompson.....	69 0 0

For sundry alterations to the Baxendale Arms, Columbus-road, E., for Mr. C. Lees:—

Gilson.....	£297 0 0
J. Jarvis & Sons (accepted).....	235 0 0

Accepted for fitting coffee-house, No. 364, Bethnal Green-road, E., for Mrs. E. Young:—

J. Jarvis & Sons.....	£220 0 0
-----------------------	----------

Accepted for enlarging carpet department, for Messrs. C. & R. Light, Curtain-road. Mr. R. Creech Harrison, architect:—

J. Jarvis & Sons.....	£130 0 0
-----------------------	----------

For additions to house, Daphne crescent, Woodbridge-road, Guildford. Messrs. Peak, Luna, and Peak, architects, Guildford:—

Strudwick, Guildford.....	£238 0 0
Nye, Guildford (accepted).....	215 0 0

Accepted for the erection of a house and small stable on the Artillery Field Estate, Guildford, for Mr. A. Lucas. Messrs. Peak, Luna, and Peak, architects:—

R. Downey, Guildford (Excavator, Bricklayer, &c.).....	£321 15 0
Hill & Son, Guildford (Carpenter, Smith, &c.).....	230 0 0

Special Notice.—Lists of tenders frequently reach us too late for insertion. They should be delivered at our office, 48, Catherine-street, Strand, W.C., not later than four p.m. on Thursdays.

TO CORRESPONDENTS.

R. R.—A. W. C. send drawings.—A. B.—E. B.—R. A. B.—Old Subscriber.—W. C. T.—Baudouine (will reply).—W. T. (below our mark).  
All statements of facts, lists of tenders, &c., must be accompanied by the name and address of the sender, not necessarily for publication.  
We are compelled to decline pointing out books and giving addresses.  
NOTE.—The responsibility of signed articles, and papers read at public meetings, rests, of course, with the authors.  
We cannot undertake to refer to rejected communications. Letters or communications beyond mere news-items which have been duplicated for other journals, are NOT DESIRED.

### The Strength and the Weakness of Art.

THESE words were the text selected by Mr. Beresford Hope for his address as President of the Art Section of the Social Science Congress,—an address which, both in diction and in thought, sounds a higher note than is usually heard now in discourses on the subject of Art. For it is a characteristic of the decided emphasis which has of late years been laid upon the importance of a sound and complete technique in art, that many who discuss the subject have come to speak of technical excellence as if it were the one thing needful, and too many artists have put this thought into act in works destitute of any very apparent aim beyond that of exhibiting technical mastery. It is somewhat remarkable that this material way of regarding art should be, as it certainly is in great measure, the outcome of the movement in favour of a greater earnestness in art which in the younger days of this generation was called pre-Raphaelitism. The men who initiated that movement meant an earnest protest against slackness of execution and cold conventionalism in the choice and treatment of subjects. They would have been heart and soul in sympathy with the spirit of Mr. Hope's remarks at Birmingham. But the doctrine of close and precise study of technical correctness was more easily adopted and carried on than its correlative doctrine of earnestness and loftiness of aim and feeling, and we have the result in a prevalence of works of art of which the subjects interest us little, and in which technical achievement seems the principal object. This tendency to exalt technique disproportionately may be said to be the besetting "weakness" of the artist, considered as a craftsman; while the tendency to think more of the spirit and meaning of the work than of its technical power or shortcoming is the special weakness (for it is a weakness when carried too far) of the amateur. Mr. Hope's address was essentially that of an amateur, though not an ordinary one. For there are amateurs and amateurs; and it is worth while for artists to pay regard to the remarks of an amateur who thinks and feels strongly on the subject of common interest to both.

There has always been a little difficulty, since the Art Section of the Social Science Association was inaugurated, in drawing the line between that which is pure and unadulterated art-criticism and that which is within the proper scope of the association,

the consideration of the relation of art to our theory of life and of social organisation; or rather, the line has sometimes not been drawn at all, and the audience have listened to addresses the proper locality for which would have been the lecture-platform of an academy of art. Mr. Hope, as he observed at the close of his address, set himself to find a connecting link between art and "social science." And he finds it, in the first place, in calling our attention for a moment away from the mere question of artistic execution and artistic success, to consider the origin and the meaning of art itself in the widest sense of the word. Objects of art are manifold; art herself is "the one informing, harmonising, life-giving spirit which runs through all the visible creation"; and Mr. Hope boldly but happily presents it as synonymous with what is truly styled "wisdom," "the breath of the power of God, and a pure influence flowing from the power of the Almighty," of which wisdom art is the visible sign. And the deduction from this is that art cannot be regarded as existing for itself alone; it is strong in proportion as it is the helpmate and the herald of morality, and weak in proportion as the artist worships himself, and deals with his art as if it were the end as well as the means.

"This is a position on which I very emphatically insist. It is important at all times, and it never was more so than in the present day, when æsthetic perceptions,—for the old word 'artistic' is quite out of fashion,—would, if we would believe the depth or precision of thought of excited and gushing votaries, seem ready to pose as the substitute of old-fashioned morality and generally accepted common sense. As you love art, and if you love art, resist this. True art never can be immoral, for it remembers of what it is the influence. False art,—that is, art which thinks of itself and not its mission,—has only self to rely on, and self's perceptions;—and in its weakness it must become sensual."

How many pictures on the walls of contemporary exhibitions in England and France illustrate this position it is hardly necessary to remark. Mr. Hope, though declining any claim to be a critic, in the strict sense, of pictorial art, goes to the painters of the past for an example, in a parallel or contrast between Rubens and Fra Angelico; the one confessedly great in all attributes of art except the very highest; the other, with no vestige about him of the heroic, yet so absolutely self-forgetful in his enthusiastic devotion to the higher aim of art as to have a claim to be cited as showing forth the strength of art.

The comparison is, perhaps, not entirely just to Rubens. He is an exceptional figure among artists. Of a large proportion of eminent painters, sculptors, and musicians it might be said that what was highest and best in them came out in their art. With Rubens it appears

to have been the reverse; he was an instance of the less numerous class of whom it may be said that the man was higher than the artist. All that we know of Rubens shows him to have been a man of high stamp, a man eminently healthy and noble in character; and it might perhaps be more truly said that it was in artistic rather than in moral elevation that he was, as a painter, defective. Rubens's real sin in his paintings is against "good taste" rather than against any more serious or important canons of life and conduct, and against that sin a higher and keener artistic sense would have safeguarded him. That he was not possessed by any very serious aim in his painting, however, must be conceded. He was a man who took life joyously and easily, but he seems to have had the great merit of living a life of prosperity and affluence in a thoroughly healthy and generous spirit. In speaking of Angelico Mr. Hope admits the weak side,—the want of human nature in his work,—involving partial failure, because "the painter was forgotten in the friar." In the case of Rubens we might say that the painter was a little forgotten in the man. The daily life of the man was wholesome and honest, what may be called in a sense princely (the word seems somehow to fit Rubens well), but he did not cherish any ideal beyond it.

For that is what, as Mr. Hope says, the matter comes to; the strength or weakness of art consists in the conformity or divergence of the artistic product from an ideal, "the closest representative of which, allowing for the poverty of language in lending itself to abstract thoughts, would be morality." When we attempt to apply the same principle of reasoning to architecture, another element is introduced. Architecture is not only occupied with beauty of composition, but with soundness of construction; it has the morality of construction as well as the morbidity of composition. So Mr. Hope puts it. It is surprising that he should entirely pass over the immense difference between the nature and degree of the possible moral element in painting and sculpture, which represent actual ideas and characters, and reflect life, as compared with that possible in architecture, which is only an abstract or metaphysical form of art. Some one has said of music that it has the privilege, as an art, of being incapable in itself of expressing a wrong or pernicious idea. The same holds true of the art which is in the realm of form what music is in the realm of sound. Architecture, pure and simple, cannot express an idea of *morale*, right or wrong. The distinction is really, when we come to speak of the morality of art, a tremendous one; to pass it over was to let slip one of the points of the subject. In a lesser

and more special sense, however, there is no doubt a kind of moral right and moral wrong in architecture. There is truth or falsity of architectural style, regarded as the expression of constructional fact; and there is, what is more important and touches more nearly upon serious moral ground, soundness or falsity of construction, in all its branches, statical and sanitary. It is only in regard to this latter part of the subject that the morality of architecture can be spoken of as a matter involving serious moral praise or reprobation. The question of truthfulness of style, as an expression of construction, involves the question of good or bad reasoning, and of more or less true artistic perception, but these are hardly matters of morality, unless we come to the extreme case, that in which an architect deliberately puts up some architectural features which are not wanted and have no relation to the construction, in order to give a more attractive and important appearance to his building. The capability of doing even this, however, though it is no doubt in one sense a sham and a falsehood, hardly involves moral culpability. It would not surprise any one to find that a man who put up useless columns or buttresses for mere garniture in his buildings, was nevertheless generally truthful in his speech, and paid his bills honestly. But a man who would habitually, to save trouble, time, and money, build houses which were unsafe in construction and insanitary in arrangement, we should not be surprised to find would take advantage of his fellows in other immoral ways; we should regard him as a man not to be trusted in any relation of life. This latter kind of defect implies real immorality of principle; the former only implies vulgarity of mind.\*

It is only this question of refinement and truthfulness of expression which is really concerned in the battle of the styles, to which Mr. Hope referred at some length, and in regard to which he might have said "*quorum pars magna fuit*." According to his view, the whole battle of the styles was a conflict for the two architectural moralities, the morality of construction and the morality of composition. But we do not see what the morality of construction has to do with that question. Mr. Hope retraced some former ground and fought some old battles over again in defence of Gothic architecture, saying with fresh point and emphasis what has been said before, and what in the main few of us would question; only that there are other sides to the matter which were not represented. But Mr. Hope concluded by speaking strongly in regard to the importance of the constructive morality of building, in whatever style. The engineers on the one hand, he said, if they invade the province of the architect, "must condescend to those principles of composition, of dignity in masses, of grace in details, which are the features which make a building delightful to an unscientific eye." Would the Thames Embankment, he asks, have been worse if the artist's hand had been visible in the details, and particularly in the parapet? But the very fact that the engineers have to some extent, and not with happy results, invaded the field of architecture, should make the architects the more careful not to fall in the practical problems in which the engineers are their real rivals. It was a blow to Gothic architecture when the most eminent Gothic architect of his day was forced by official orders into Classical harness. But, says Mr. Hope:—

"Talking in this connexion, I must say that, in my opinion, a more severe blow was dealt to the credit of Gothic architecture by the discovery that, with all the pains which the chief of Gothic artists had taken to prove how gracefully he could dance in the fetters of that alien style which official prejudice had forced upon him, he has yet shown himself so strangely unappreciative of the responsibility which rests on every architect to master, and so bestow his personal care upon the sanitation of his building, than by the apparent readiness with which he ever assumed those fetters; for an ill-drained building produced by an able man must be weak, lamentably weak, in the trappings of whatever style it may be garnished."

\* Here we may be reminded, perhaps, of the moral dictum of the motto, in *Punch*,—"It is worse than wicked, child; it is vulgar."

That unfortunate defalcation from architectural principle in the matter of the Foreign Office has evidently never been forgiven by the Gothicists. The perpetrator of the deed is to the last "A lost leader,"—

"Just for a handful of silver he left us!"

and may, like the hero of the poem, be "pardoned in Heaven," but not here. But Mr. Hope should be impartial. Is there no other Government building, of pure Gothic type, the practical deficiencies of which have caused it to be regarded by many as a blow to Gothic architecture?

However, we are grateful for an address which holds up so high a principle throughout, in such dignified and manly language, and which was more directly practical even than at first appeared, seeing that, as Mr. Hope observed, his subject had led him from Fra Angelico to the drainage of public offices; not fitly reminding us, by this long transition, how large a field is covered by the subject, how many things in life are more or less connected with and acted upon by the strength or weakness of art.

#### TECHNICAL EDUCATION IN ITS APPLICATION TO BUILDING UNDER THE CHRISTIAN BROTHERS.

IN the rooms devoted to the display of the educational exhibits of the Christian Brothers of France and other foreign countries, in the new building of the City and Guilds of London Institute, South Kensington, the builder, the building workman, and the young architect and engineer too, will learn not a little to their advantage. As a preliminary we would, however, recommend the intelligent and practical-minded visitor to rid himself of his bias and local prejudices, if he has any, and judge whatever objects meet his view on their intrinsic merits alone. We are not concerned in this journal about the peculiar political or religious views of any party, and certainly, in the important matter of technical education in its application to our building industries, we are desirous of assisting, as far as it lies in our power, any and every movement judiciously directed towards that end, whether without or within this country. It therefore affords us pleasure to direct special attention to the practical character of the teaching in connexion with building construction imparted by the Christian Brothers, and so well and elaborately illustrated by the diversified exhibits shown in the French Department of the Health Exhibition in the room already mentioned. The system pursued by the Brothers is the suiting of their instruction to the places in which their schools are established, and they make a special study of building materials in connexion with practical geometry, of which they have thousands of specimens. A noteworthy feature in the system is that no pupil is allowed to do anything mechanical till he has, as a matter of sketching and designing, shown that he fully understands what he is about to undertake. The many designs that may be seen, hung up or in the portfolios free to inspection, will prove that this is practically acted upon. In France the Brothers have a large number of public elementary private day and boarding schools, as well as technical and agricultural schools. Besides ordinary schools and colleges in Belgium they direct art schools and training colleges. Again, in the United States and Canada the community have numerous schools, academies, and colleges, and everywhere the same general methods are followed of teaching, modifying, however, the details to the custom of the country, and varying the programme to meet local requirements and growing wants. It may not be amiss *en passant* to say here that the Institute or the Society of the Brothers was founded in France, so far back as 1680, by J. B. de Salle, Doctor of Divinity and canon of the metropolitan church of Rheims. Educational reforms, as well as social and sanitary ones, as is proved by the course of history, take a long time to carry into effect. La Salle

appears, though fully bent on the moral improvement and training of the young, to not only have realised the wants of his age in France, but, to some extent, to have anticipated, paved the way, or provided for some of the educational wants of unborn generations. The Brothers were essentially from the beginning an order or society of teachers, and as such, under La Salle, in France, public primary education was established. Of course, as a first, special attention is still given to religious instruction in the schools of the order, but it is remarkable that La Salle required the Brothers to make the vernacular tongue the basis of their teaching, instead of Latin, which up to his day, if not later, had been the language of the schools. Modern languages, mathematics, drawing, and architecture entered into the programme of La Salle upwards of two centuries ago, and formed the course of instruction.

Coming to the fine art exhibits, the Brothers show in the rooms of the City and Guilds of London Institute their educational manuals or books on the various kinds of drawing, with corresponding charts, diagrams, and models in the flat, supplemented by a large number of working models in wood and plaster of masonry, stone-cutting, carpentry, and joinery, including several well-executed models in staircase construction. The method of drawing exhibited by the Brothers, though applicable to individuals, is chiefly for class instruction, and as such it is used in their primary schools, and so graded as to lead the student by easy steps to the applications of art to industrial design. The course includes (1) frechand, ornament, and figure drawing; (2) drawing from nature; (3) tinting and the theory of shadows (sciography); (4) building construction and design; (5) machine construction and drawing. Comprising in the foregoing there is also, firstly, a manual for the master's use to render the teaching methodical, and for facilitating oral explanation; secondly, model copy-books, with numerous exercises for reproduction under the direction of the master. Thirdly, a number of models and objects to be drawn to a given scale. Models which bear more directly upon technical instruction are provided with the principal sections required for professional demonstration, but there are others specially constructed to illustrate planes in space,—their intersections and projections. Fourthly, a collection of charts, comprising some of the more important subjects of the model-copy-books reproduced in bold but clear outline for class teaching. Fifthly, there is a model illustrating the principles of Perspective. In the albums and portfolios (numbering 390), which are certainly arranged with the view of facilitating inspection, will be found the work of the students. These comprise architectural drawings from actual measurements, sketches of machinery made by the students when visiting large factories and engineering workshops, field books of compass and theodolite surveying, together with a number of the corresponding designs and plates fully developed. The following schools contributed the largest number of ornamental drawings:—The schools of Paris, Rheims, Marseilles, Aurillac, Lille, Rome, Caen, and Toulouse. The more important geometrical collections came from Béziers, Commeny, Rheims, Le Gua, Dreux, La Motte, Dijon, Avignon, Douai, and Bordeaux. An unpublished folio work on drawing is exhibited by the Brothers in charge of the class at Rheims.

We would specially direct the attention of our young building workmen who are seeking to qualify themselves for the position of foreman or clerk of works, to the collection of plaster and wooden models on view, illustrating sundry of the most difficult pieces of work or masonry, carpentry, and joinery, that occur in building construction. There is no guesswork, groping, or "rule-of-thumb," evidenced in the models of the students on view. Each vousoir, or stone, or whole course, whether it appertains to an oblique arch or bridge, a niche, a groat, the soffit of a circular-headed door or window, in a circular wall, a spiral stair, a cylinder, a wreath, or any other form in stone or wood of double curvature, each and all are the outcome

of practical geometry applied to the development of surfaces in building construction. Difficult though some of these problems may be on the drawing-board in the building workshop, the construction is here made easy to the intelligent youth who has mastered but little more than the rudiments of practical geometry. Several of the models in plaster of Paris are exceedingly well executed to scale. The joints are all shown on every external face, and though the model in itself is solid, as it were, certain sections or stones are made to lift off to show the development of the faces of the through joints or inside surfaces that abut against each other. Thus at the intersection of a groin, the central stone atop is made to lift off; and in the model of a circular stair one of the treads can be lifted off, and so in other models designed to illustrate various forms of masonic construction. The plaster modelling by the students (some of them not half-way yet in their teens) is not only good in point of execution, but affords a good technical lesson to the young building workman visitor who may not have had in this country an opportunity of seeing how work of a similar kind is "set-out" and performed. In some of the drawings we examined in connexion with stone-cutting and joinery we were much struck with the powers of delineation displayed by students in the schools of the Christian Brothers. A mere outline plan, say, of a cylinder of a staircase, to a youth or an apprentice in one of our workshops, may appear to his eye merely a curve, but when developed and projected with its winding surfaces, even on paper, it speaks to his mind more palpably, and shows something approaching an embodiment in fulness and form, though not actually so, until the science in the drawing is applied to the construction in wood or other material. A youth must learn to draw before he can learn to model, but, at the same time, modelling and drawing can proceed by easy stages together. There are many young building hands in our workshops still who scarcely understand anything about plans, although they may be passably good workmen at certain branches of their trade. A model of a house or other building would be easily understood by the majority of such operatives. With the plan of the house in their hands, together with the model of it before them, a more practical lesson, of course, would be conveyed to them, but this sort of lesson under present circumstances in this country seldom occurs. We, however, in this journal many years ago advised the construction of models when both private and public buildings of importance were about being erected.

Returning to the art-teaching of the Christian Brothers, the school of St. Luke, at Ghent, comprises a comprehensive programme of Christian art. The courses include, in addition to drawing and painting, modelling, sculpture, and architecture, and extends over seven years. There is an essential difference in the method followed to that pursued in the State schools of Belgium and other countries. Specimens of the work done will be found in the Belgian Courts. The technical schools conducted by the Brothers are represented by a large number of various exhibits from the New York Catholic Protectory, the school of La Salle at Lyons, the Orphanage at Versailles, and from the schools of St. Nicholas, Paris. The Protectory dates back twenty-one years, and was founded for the purpose of caring for the destitute children of New York, and teaching them useful trades. Part of the day is spent by the boys in the class-room, and part in the workshops. The handicrafts include chairmaking, silk-weaving, tailoring, printing, and electrotyping. Examples of the work done are on view. The school of La Salle admits a number of the most successful students of the school at Lyons free of expense, who desire to acquire a theoretical and practical knowledge of local industries. In addition to modern languages, political and social economy, the courses include descriptive geometry, plane trigonometry, with its applications to surveying, experimental physics, organic chemistry, along with the various kinds of drawing and industrial design. Laboratories and workshops are pro-

vided in which the students are afterwards instructed in analytic chemistry, cabinetmaking, and particularly in silk-weaving, which is an important local industry. A certificate of proficiency is given to the students who satisfactorily complete the course. The exhibits at South Kensington in connexion with this comprise,—(1) fifty specimens of different coloured silk, (2) albums of patterns and designs; (3) specimen-frame, containing the arms of the City of London (specially prepared for the Exhibition); (4) senior albums of drawing, some of which contain the rough draft; and (5) school work generally. There are several very notable features in connexion with the Agricultural Schools, the schools of St. Nicholas, and the school museums under the management of the Brothers, of which a large number of exhibits are shown. The courses in the first extend over three years, students of seventeen who pass a satisfactory preliminary examination being admitted. The instruction is not confined to the lecture-rooms, physical and chemical laboratories, and natural history museums, but includes systematic work on the model farm, comprising 370 acres. The students are also required to visit the best farms in the vicinity, and to attend certain markets and sales of live-stock, with special professors. They also have to accompany the Brothers on appointed field-days for the practical study of botany, geology, and entomology. Among the exhibits of the schools, besides seeds and grains, plants peculiar to certain soils, fodder plants, injurious plants, gramine, and cereals, are geological specimens and samples of various woods indigenous to the district. In the schools of St. Nicholas, which are conducted on a large scale, the boys are put through a regular course of instruction, special attention being paid in the higher classes to subjects connected with technology. There are several workshops in which are taught various kinds of carving in wood and stone, engraving on wood and metal, cabinet-making and printing, and the construction of scientific instruments, levels, telescopes, microscopes, &c. Some of the workshops and other rooms are illuminated by electric light, a steam engine and a Gramme dynamo-electric machine being provided. Edison's incandescent lamps are utilised in the physical and chemical laboratories. Including the branch establishments at Issy and Igny, the St. Nicholas schools have an aggregate of upwards of 2,500 boys. The exhibits at the Health Exhibition of these schools are as a whole very commendable, though many of them are the work of mere youths. Among these exhibits are walnut bookcases, cabinets, lathes, microscopes, and telescopes, bronze statuettes, sundry specimens of modelling, and numerous specimens of carving, printing, engraving, and bookbinding. The Brothers are alive to the importance of providing museums as a portion of the machinery of practical education. Indeed, the founder of their order, two centuries ago, was of the same mind, and anticipated some of the educationists who came after him. The list of the museums sent from the schools of the Brothers in France, Italy, the United States, and Canada, though incomplete, is a remarkable one, and as it will serve an educational purpose, it will not be out of place to include it in our notice:—(1) Annecy.—Specimens of the geology, mineralogy, and flora of Savoy, and of the local industries, with analysis of the principal mineral waters. (2) Marseilles.—Specimens of local trades and industries (oils). (3) Beauvais.—About 1,500 specimens of various handicrafts. (4) Rome.—The marbles and principal earths of Italy. (5) Rheims.—Specimens of the local woollen industry. (6) Dreux.—A number of separate classified collections, showing among other matters the successive stages in the manufacture of needles, combs, clocks, flutes, mirror-making, wood gilding, printing, &c. (7) Memphis, U.S.A.—Numerous specimens of cotton. (8) Quebec.—Specimens of Canadian woods presented to the Brothers' Commercial Academy by Sir Theodore Robitaille, Lieutenant-Governor of the Province of Quebec. (9) Havre.—Objects imported from various parts

of the world. (10) Chambéry.—Specimens of the industries of Savoy. (11) Le Gua.—Varieties of coal and iron ore (local). (12) Arles.—Insects, molluscs, verberia. (13) Trévoux.—School herbarium and objects of local industry.

The collections are well worth examination and study, and they are suggestive of similar work that ought to be done over the three kingdoms. True, we have a number of field naturalists' clubs, entomological, microscopical, and composite clubs and societies, in whose mixed "Transactions" archaeology, geology, natural history, botany, and other studies are reported, but these, for the most part, are for grown men or otherwise for those blest with means, and who have ceased to be boys or youths long since. Systematic study and instruction of the kind we have noticed is not as yet to be found in connexion with our school system.

## NOTES.

THE past summer has yielded to American enterprise an abundant archaeological harvest. America has its archaeological school at Athens (when is England to have the like?), and it is the discoveries of a member of this school,—Dr. Sterrett,—during the past summer that are shortly chronicled in the *Nation* of August 21st. When the full report appears in the papers of the Athenian school, we shall hope to notice the discoveries in detail. Meanwhile, we may mention that Dr. Sterrett has directed much of his attention to the identification of ancient sites in the interior of Asia Minor. He has also investigated the ruins of Antioch, where considerable sculptural remains are still extant. He has collected above sixty unpublished inscriptions at Antioch, and upwards of a hundred in other parts. Dr. Sterrett has a special claim to English sympathy, because his work has been carried on to a great extent in conjunction with a member of our own Hellenic Society, Mr. Ramsay, whose discoveries in Asia Minor have been a notable feature in that Society's work. By an arrangement between the two, Dr. Sterrett is to publish the inscriptions, Mr. Ramsay the topographical discoveries made while the work was undertaken in common.

THE ever-recurring question of house-drainage has for the past week been under discussion in the columns of "the leading journal," but we cannot say that any new facts have been brought forward. It is natural enough that any one who has suffered from the consequences of bad drainage should feel sorely aggrieved, and that he should be strong in his denunciations of architects and builders,—without always stopping to inquire whether an architect had anything whatever to do with the construction and sanitary arrangements of the house that may be in question. As we have frequently pointed out, architects are not engaged by speculating builders to supervise the execution of the suburban "villas" and "terraces" which spring up with such mushroom-like rapidity on what were but yesterday meadows and market-gardens. We have always been, and ever shall be, strenuous advocates for efficient sanitary arrangements in dwellings; indeed, we insisted upon their vital necessity many years ago, but it is only now that the importance of what we urged so long ago is beginning to be generally recognised. By all means let the builder who "scamps" his work, and particularly the drainage arrangements, be brought to book and adequately punished. But we are afraid that the public is not altogether blameless even for the builder's sins of omission and commission. We some time ago heard a builder of good repute deploring the fact that his houses, which were soundly-built and properly "sanitized," would not sell, because they were either less "showy" or slightly higher in price than those of a less scrupulous rival. The moral of all this is that house-purchasers or intending lessees should take competent professional advice, and that the law which requires the local authorities to see

to the proper drainage of every house should be enforced. As one of the correspondents of the *Times* points out, in nine cases out of ten "it is not the law in England that is wanting, but the strict administration of it." But in justice to the speculating builders, we are bound to say that some of them show a laudable desire to arrange the sanitary fittings of their buildings on the most approved principles, even as to details regarding which they are under no legal compulsion. For instance, in many new houses which we have seen lately in the metropolis, the sink-wastes have been carried through the wall to the external air, so as to discharge over an open gully, thus avoiding direct communication of the sink-pipe with the drain,—a communication which is a constant source of illness in households.

AS usual the annual autumnal building operations have been undertaken in Cadogan-place during the month. When the inhabitants of this part of London return to their homes they will find three or four more houses raised a story, and presenting an appearance of even a more dreary monotony than the plain old red brick fronts, which are sometimes pleasantly varied with verandahs and creeping plants. Cadogan-place is one of the best sites in London, with the great length of fairly broad garden stretching from one end to the other, and with an important thoroughfare beyond. Moreover, it is the property in its entirety of Lord Cadogan, and the leases are only renewed on certain conditions as to rebuilding and enlarging the houses: consequently there existed an opportunity of improving the appearance of London by re-facing and enlarging the houses with good architectural supervision and according to picturesque and attractive plans. Lord Cadogan might thus have not only directly added to the beauty of the capital, but have given an example to smaller and less important landlords. But, so far from having done this, the style of the enlargement is of the most common-place, characterless, and ugly kind, and the whole of Cadogan-place will, in a few years, present a line of gray and dreary monotony, to serve not as an example, but as a warning. It will serve also to show that a great deal which is urged in favour of large properties in our times, on the ground that their rich owners are able to improve the general appearance of a town more than single individuals, is quite false. Had Cadogan-place been owned absolutely by individuals it would certainly by this time have been a far more attractive spot than it is at present, when what small amount of picturesqueness which yet exists has been destroyed under the supervision of Lord Cadogan's surveyor.

AT the Social Science Congress Mr. John Blamer, the author of the paper on "The best means, legislative or otherwise, of securing those improvements in the dwellings of the poor which are essential to the welfare of the community," entered very fully and vigorously into the question. Most thoughtful persons will agree with him in the prominence which he has given to the necessity of efforts being made so to instruct the people as to enable them to learn for themselves their real state. "The condition of thousands of our fellow subjects is what it is because they do not know what it is." The Council have wisely adopted the principle long ago laid down by the Charity Organisation Society. No distribution of charity is made, but help is afforded to those willing to help themselves. One of the remedies in course of prosecution, that of buying up bad properties and erecting proper dwellings on their sites, called forth some discussion, not so much as to the desirability of removing the objectionable dwellings, as to the agency by which the operation should be carried out. The view that the provision of the requisite improved accommodation should be left to private enterprise under effective State supervision seemed to commend itself most to the judgment of the meeting, and was supported by Professor Gairdner, of Glasgow, who considered that it would prove

"the best preventive against the monstrous evils which had occurred in many towns."

IN his paper before the Social Science Congress Mr. Walter Besant struck the keynote of a very important question in his remarks regarding the failure of the Bethnal Green Museum to meet the ends for which it was founded. "It was," he said, "an institution intended to be a great educational centre"; and, "had done none of the things for which it was intended. It was simply a dumb and silent gallery. There was no teaching." The charge thus plainly put forward is one by no means confined to the Bethnal Green establishment; it may be made, with equal truth, against most if not all our Museums. The thousands of visitors who frequent them wander about in a listless manner, and a certain amount of wonder and astonishment is kindled in their minds; but do the visitors, taken in the mass, derive any real, artistic, or educational benefit from what they see? We seem to have failed to fully grasp the educational use of a Museum. Once let there be commenced a series of open public lectures in the galleries of our large Museums, and we shall see how the people will appreciate them. A gentleman who for several years has had experience in lecturing, especially to working men, furnishes the following illustration of the value of a tour through the galleries of the British Museum when a few simple explanations of the meaning and value of the treasures there exhibited were given. "Three or four working men," he says, "were one day staring in blank wonder at the Assyrian marbles when I was taking a party of friends through the collection and explaining some of the inscriptions. I noticed the men listening to the remarks, and presently one of them came to me and asked if they might follow us round. Permission was readily given, and the men commenced to take notes of what was said. Some months after I met one of these men taking some of his fellow-workmen round and using the notes he made on the former occasion to explain to them the objects exhibited." Here, then, is a practical proof of the value of even casual instruction, and of the willingness of working men to listen to and benefit by it. It may be said that the officials are too much occupied with departmental duties to find time to prepare and deliver lectures. But this is a difficulty which is perhaps over-estimated. The general public are not likely to require elaborately-prepared discourses such as might be submitted to a learned society; it would be sufficient if the lecturers were fairly well up in their subjects, and acquainted with the most typical and important examples in the collections to be used as illustrations. Short conversational lectures by men possessing these qualifications would entail no hard work or great loss of time, and good results would soon make themselves manifest, especially among the younger students. Very strong testimony as to the educational value of a museum as an adjunct to a public school was recently given by the head-master of Rugby at one of the educational conferences at South Kensington.

WE may call the attention of our readers to the full description given in another column, accompanied by illustrations, of the details of plan and construction of the Temporary Infectious Diseases Hospital recently formed at Liverpool, under the direction of the City Engineer, Mr. Dunscombe. The enthusiastic young draughtsman, to whom architectural study means the opportunity of making effective sketches of piquant points of ancient building, may regard two such pages as of slight interest to his aesthetic mind; but they represent what forms the very basis of practical architecture, the provision for the most healthful conditions for life. We have noticed elsewhere some recent remarks touching on the "morality" of art and architecture; and part, and a much neglected part, of architectural morality consists in securing sanitary completeness in a building. The care which seems to have been taken in securing the best sanitary conditions in this hospital, where sanitary

completeness is exceptionally important, renders it a useful and typical example of its kind, and hence we have thought it worth while to give some space to the full statement of what some may regard as rather dry details.

CONSIDERABLE difference of opinion has been expressed, and continues to find expression, as to the best means of sewer ventilation. The question is one of much importance, involving as it does to a great extent the principles to be observed in the construction of the sewers themselves, for properly-designed and well-constructed self-cleansing sewers will obviously, under normal conditions, always be sweeter than badly-constructed sewers,—such sewers of deposit, for instance, as some of the older London *cloacs* are, if they still exist. Notwithstanding the outcries occasionally made against the London system of ventilating the sewers by means of openings in the crown of the street, a large number of engineers of repute and experience adhere to the opinion (in which we are disposed to agree with them) that, all things considered, the London method is the best, provided that the openings be sufficiently numerous and therefore sufficiently near each other. It would seem, however, that this system of street openings is likely to be supplemented, in that limited part of London which is under the control (for sanitary purposes) of the City Commission of Sewers, by the use of shafts. We notice that at the last meeting of the Commission, on Tuesday, Mr. Altman brought up a report from the Streets Committee, relative to the suggestion of Mr. J. S. Scott, "That in all instances where new houses are being erected the Commissioners of Sewers place themselves in communication with the building or other owner, and treat with him or them for the construction of a proper ventilating shaft in the chimney breasts or party or other walls, for the purpose of ventilating the sewers, carrying the ventilating shafts well above all adjoining roofs," and recommended that the same be acted upon. The Engineer to the Commission (Colonel Haywood) said this was their custom at the present time. The Commissioners were quite prepared to erect ventilating shafts at their own expense. We are glad to see that Mr. Alderman Lawrence urged the importance of carrying the shafts sufficiently high so as not to be detrimental to other buildings, to which we would add: "nor to the occupants of the buildings to which the shafts are attached," for it is matter of actual experience that drain-ventilating shafts and soil-pipe heads are sometimes so placed that the foul gases emitted from them will, under certain conditions of atmosphere and temperature, pass down chimney-flues and through dormer windows into bedrooms and other apartments.

THE common tradition that the timber of old churches was frequently of chestnut seems to have been exploded by the researches of the French chemist, M. Payen, who procured a large number of pieces for examination, and pronounced that they were not chestnut, added to which, chestnut trees, whatever their abundance in old times, are now extremely rare. We are told that if letters are drawn upon oak and chestnut planks, by means of pure sulphate of iron dissolved in distilled water, the characters appear at once in black upon the oak and in deep violet upon the chestnut, while ammonia produces a short-lived red upon the chestnut, which is much paler and less distinct upon the oak. Another mode of examination is by making sections of the wood, which cannot well be mistaken, as chestnut timber possesses only concentric layers, while all French and American varieties of oak show the medullary rays crossing the woody fibre from the centre across the circumference.

A NEW paint, consisting of a mixture of zinc white with zinc chloride, has been for some time in successful use at Brest for painting wood and metals; it becomes very hard, and can be washed or brushed without injury. It should not be applied, however, in

rainy or frosty weather, as it then becomes mealy and scales off easily. Chloride of zinc is not the only salt which possesses the power of forming a mastic by its mixture with zinc white, for Sorel long ago showed that the proto-chlorides of iron, manganese, nickel, and cobalt were good bases for mastic. The Dockyard authorities at Brest have extended their experiments, and have shown that the sulphate and nitrate of zinc, the nitrate and chloride of iron, and the sulphate and nitrate of manganese, all form good mastics with zinc white.

#### THE PUBLIC WORKS OF EGYPT.

AN account of the Barrage of the Nile, the greatest work executed in Egypt since the fall of the Thirty-third Dynasty, is by no means easily accessible in this country. We have sought in vain in the best scientific libraries for information on the subject; and not only so, but we have also been unable to discover a section, or to obtain any other exact information, of the now dismantled railway from Cairo to Suez. We have pleasure, therefore, in calling attention to a work just published in Paris by M. Felix Paponot, a French engineer, under the title "L'Égypte, son Avenir Agricole et Financier," which, while chiefly intended to advocate the project of a sweet-water canal from Ismaïlia to Port Saïd, gives a fuller account of the régime of the public hydraulic works of Egypt than can easily be met with elsewhere.

M. Paponot commences his work with a reiteration of a well-known fact. "It is without dispute admitted and recognised that Egypt has been from all time a fertile country, of great productive wealth, but on condition of a good rise of its nignic river, and of an intelligent distribution of its water." The cultivable soil of Egypt is the creation and gift of the Nile; but the construction of an enormous reservoir designed to regulate the inundations of the river is ascribed to King Amenamhat III., the sixth monarch of the Twelfth Dynasty, who reigned at Thebes, according to Brugsch, 2,300 years before Christ. At this date, as appears from rock-cut inscriptions, collected by Lepsius during his stay in Nubia, the inundation reached at Semne and Koomme a point 8·17 metres above the greatest height ever attained at present. M. Linant, to whom we owe the best map yet made of Egypt, has proved that the ancient lake Moëris was situated in the south-east part of the province of the Fayoum, where the depression of the ground and the ancient dykes exactly define its site. At the epoch of the inundation the waters of the river entered by means of a canal into the lake, where locks retained them. At the time of low water the gates were opened to irrigate the great plains of the districts in the neighbourhood of the lake.

Stipendous as the work of this lake was, the amount of water which it could store depended on the height to which the Nile rose, in any particular year. In this height there is a great variation. The flow of the river varies from a minimum of 480 metric tons per second in June to a maximum of 7,457 metric tons per second in October, according to the measurements of Mr. Fowler. The mean flow, of 2,874 metric tons per second, is about one-third of the mean flow of the Danube, at Pesth, or almost exactly sixty times the mean flow of the Thames. The area of Lower Egypt, according to a report to the Viceroy from the International Commission on the Suez Canal, dated 7th December, 1855, forms a triangle covering 1,375 square leagues (or 8,071 square statute miles). The cultivable lands of Lower Egypt are estimated in the same report at about 3,800,000 feddans, or Egyptian acres, each of which is equal to nearly 1·46 English acres. The water required for irrigation, according to the same report, is equal to 20 cubic metres per feddan in twenty-four hours; requiring, for the service of the 950,000 feddans which the barrage of Saïdich was intended to supply, 19,000,000 cubic metres per twenty-four hours, or not much less than half the minimum flow of the Nile as ascertained by Mr. Fowler.

The recent efforts of the engineers in the way of regulating the flow of the Nile have been directed either to the damming up the river at selected points, so as to divert a flow of water into artificial canals made at a sufficient height to irrigate the surrounding districts, or to pumping the water by steam

power into similar canals. As to this, it is stated, in the report to the Viceroy of Egypt before cited, that there is only one point in the course of the Nile through Upper and Middle Egypt, where the spurs of the mountains descend to the bed of the river; and where, in consequence, it is possible to construct a solid and substantial barrage, founded on the rock. This is at Sillsis, which, on Brugsch's map, is marked at about 24° 40' N. latitude, and this is too far above Cairo to have been regarded as suitable for the erection of a great controlling work of this nature. The spot selected for the barrage actually constructed was Saïdich, at the origin of the Delta, where a massive brick viaduct was constructed, and finished in 1853. This work, which crosses the two branches of Rosetta and of Damietta at their origin, is founded on a wide, but not very deep, mass of concrete. The length of the barrage across the Rosetta branch, comprising sixty-one arches of about five mètres span each, and two locks of twelve and fifteen mètres in width, is 465 mètres. The total length of the barrage across the Damietta branch, which contains ten arches more than the former, is 545 mètres. In the original plan it was projected to close the arches of the viaduct partially during the low water by means of iron sluices, so as to raise the level of the water above the viaduct to a height  $\frac{1}{2}$  mètres above that below it. By this means it would have been possible to supply the canals of Lower Egypt with water at such a level as to render unnecessary the laborious methods now in use of the "sakihs" and "chadoufs," or rude machines worked by men and by bullocks. Lower Egypt, it was thought, would be thus rendered independent of the rise of the Nile; as, by regulating the floodgates, the quantity of water applied to cultivation might be increased or diminished at will.

The water-way afforded at low water, with all the sluices and flood-gates open, by the barrage, is about 990 square mètres, a larger area than that of the cross-section of the river about 2 kilometres lower down. At the height of the inundation in 1874, the current occupied an area with a cross-section of 7,000 square mètres at the barrage, while the water-way at the bridge of Kasr-el-Nil, was 6,500 square mètres, and that at Querremat, about 114 kilometres above the barrage, was 6,850 square mètres.

Just, however, as were the calculations as to water-way afforded by the barrage, which it will be seen is such as to allow a full Nile flood to pass at a speed very little exceeding a metre per second, the execution of the work was not such as to admit of the intended benefit resulting from its use. The soil at the spot, which has been tested by boring to a depth of 40 mètres, consists (as is the case in the greater part of the Delta) of a fine Nile silt, readily pervious to water. In consequence, it is said, of the haste, and of the positive orders, of the Viceroy, the foundations of this costly work were laid at an altogether inadequate depth. "My conviction is," reported Mr. Fowler in 1876, "that the foundations of the apron have been laid at an inadequate depth, and if the barrage is to be repaired and finished in such a manner that it may be exposed without fear and for many years to the action of the waters of the Nile, costly and important works must be added in order to put it in such a state as it would have been in if the foundations had been carried, in the first instance, to the proper depth." The apron, or submerged platform, as shown on the plates of M. Paponot, has only a depth of from 4 to 5 mètres below the bed of the Nile, and a width of 34 mètres. The zero of the Nilometer given is 28·21 mètres; the level of the lowest water 27·75 mètres; and the top of the apron is from 26·96 to 26·46 mètres above the datum. The piers, each 2 mètres wide, are continued up the stream as dolphins or breakwaters, and the apparatus of their iron sluices is fixed at the end of the dolphins. The apron is laid on a mass of uncombed stones, the depth of which is shown on the drawing as 16 mètres; but as to the careful construction of which evidence is wanting. "Great part of the concrete on the Rosetta side," says Mr. Fowler, "was simply laid on an uncombed mass of detached stones, 12 mètres in height, through which the current must necessarily and continually have filtered, carrying away the cement before the mass was solidified." At all events, this mass of stone, with the interstices filled with silt, is pervious to water. Thus the whole structure of the

barrage is liable to be undermined, and, in the event of a head of water being raised to such a height as to counterbalance the weight of the structure, is liable to be thrown up by hydrostatic pressure. How far it is due to calculation and how far to experience, we are not told; but, instead of  $\frac{1}{2}$  mètres, or 14·76 ft.,  $\frac{1}{2}$  metre, or 4·92 ft., is the greatest difference of height which it is considered safe to produce by the sluices. It will be obvious that under these circumstances it is not so much the simple hydraulic pressure due to height that has to be regarded, as the effect of the movement of water, or the velocity due to the head, or difference of level. As to this, a head of 13 ft. was found at Birkenhead to produce a current which the solid masonry of the culverts was unable to resist. A head of 14·76 ft. of water gives a pressure of 920 lb. per square foot, and a tabulated velocity of 30·33 ft. per second.

The unique character of the elevation of the Nile barrage, architecturally regarded, is due to the erection of a small tower on the northern or down-stream end of each pier. In the plates of M. Paponot the towers or turrets on the Damietta branch are shown as square, and those on the Rosetta branch as round. The height of these turrets, which are battlemented above the heavy line of the parapet of the viaduct, or main structures of the barrage, is about 3 mètres. The object of the arrangement does not appear from anything adduced by M. Paponot.

Such being, in the opinion of Mr. Fowler, the state of the foundations of the barrage that it would be unsafe to expose them to any greater pressure than they actually experience, as "they would be entirely destroyed and carried away by the water passing beneath at the pressure and with the speed originally projected," the question arises how the loss of 3 mètres in the height of the water taken for irrigation is to be met. To this end Mr. Fowler proposes the construction of a second series of sluices, built on foundations carried to a great depth, immediately below the present apron, while he would protect the bed of the river from erosion by additional works. By this means there would be two steps, or differences of elevation, in the water confined by the barrage; the one of  $1\frac{1}{2}$  metres, caused by the present work, and the other, of 3 mètres, based on the cross wall to be run athwart the bed of the Nile, reaching to a depth of 18 mètres below the surface of the present apron, which, moreover, is to be covered with a layer of ashlar masonry  $\frac{1}{2}$  metre thick.

M. Paponot, on the other hand, proposes the construction of a cross-wall, or diaphragm, descending to a depth of 20 mètres, on the south or up-stream side of the present apron. Above this diaphragm he would place a mass of loose stones, protected by a line of iron piling, of ingenious design, which he distinguishes by the name of "pieux-palpinoches." The additional head required for the water he would give by the construction of entirely new barrages, of which he considers that no less than six should be erected on different parts of the river. He does not propose to emulate the magnitude of the existing work, but to construct movable barriers, resembling the needle weirs erected on the Seine, at Bois le Roi, of which he gives engravings taken from photographs.

The cost of the rectification of the barrage is estimated by Mr. Fowler at a million sterling, involving, for interest and maintenance, an annual cost of 100,000. The interest and maintenance on a pumping establishment with the adjuncts necessary to provide an equivalent amount of water for irrigation is estimated at 280,450l. per annum, or nearly three times as much. The advantages to be derived from a proper system of irrigation are twofold. In the first place the cultivators of the soil will be relieved from a vast amount of costly and laborious work, and will be enabled to devote their time to remunerative labours. In the second place, not only will the soil actually under cultivation be more adequately watered than at present, but its area may be doled or trebled; and thus not only will a given area be rendered more productive, but land now desert will become fertile. The Commission of 1837 calculated that in the six specified provinces 263,772 men, or nearly one half of the men existing in the districts, were employed in agricultural labour. The mere saving of the annual work of deepening the irrigation canals, which would be rendered unnecessary by raising

the head of water, would save forty days' labour in the year for each of these men; amounting, at the pay of 1½ Turkish piastre per day, to 15,768,320 piastres, or upwards of 140,000*l.* per annum; a sum which the saving effected in the same manner on the Kataké and Cherkik canals would raise to about 196,000*l.* per annum.

In addition to this saving of human labour, 50,000 "sakiels and tapontes," or contrivances for raising water worked by hullocks, would be rendered unnecessary. (This is without counting the chadons, which are worked by hand). The allowance for these machines is three oxen apiece, with one man at least to each machine. The time for which the irrigation is carried on by these means is six months. The food of the oxen costs two piastres a day each. Thus the cost amounts to 54 million piastres for the cattle, and to 13½ million piastres for the men. To that has to be added the maintenance and repairs of the sakiels, at 120 piastres each, giving a total of 73,500,000 piastres. One hundred piastres go to the Turkish or Egyptian pound, which is worth 18*s.* of English money. Thus a saving to the country, over about one-fourth of the area which will be cultivated under a well-planned system of irrigation, amounts to 657,000*l.* per annum from the simple suppression of the "sakiels and tapontes."

In addition to the sum of 853,000*l.* per annum thus saved, and to the product of the labour so economised when applied to directly remunerative work, the Commission reported that the water power due to the construction of the barrages would be equal to 12,000 horse-power, which, at 20 piastres per day per horse-power would amount to 51,120,000 piastres a year. How far this water-power,—the existence of which is, of course, matter of very simple calculation, would actually be utilised in Egypt "for founding factories and new workshops, and for replacing the motor powers now used," is of course liable to question. But in a country where fuel is so rare and costly that one cause of the decreasing fertility of the soil is the consumption of the animal manure as a combustible, the utilisation of so cheap a power as that of water is not to be disregarded. It was the outcome of the labours of the Commission, the detailed exactitude of which can be studied to great advantage in the pages of M. Paponot, that the whole of the estimated cost of the works projected would be replaced, in three years, by the increased value of the productions of the country. This is equal to a net return on capital of 33 per cent. per annum. Enormous as it seems, there is, at all events, a *prima-facie* case in its favour made out, and that not by speculators or schemers, but by Ministers of State, and Military, Civil, and Mining Engineers, native, English, and French. The view which these gentlemen submitted to the Viceroys is consistent with the long established character for fertility of the Egyptian soil, and it should be observed that the experience of 1861 is such as strongly to confirm the statements. The Suez Canal Company purchased, in that year, what is called the Wady domain, which at that time contained 4,500 inhabitants, who cultivated about 6,000 feddans of ground, with a resulting profit of about 4,000*l.* In 1866 the inhabitants had increased (under the irrigation system introduced by the Company) to 14,000; the soil under culture was over 12,000 feddans; and the revenue derived by the Company amounted to an average of 270 piastres, or 70 francs, per feddan, or 33,400*l.* per annum.

The work of M. Paponot, which is published at the Librairie Polytechnique, 15, Rue des Saints Pères, Paris, is extremely opportune, and will be read with interest by a large class of readers, whether their tastes incline to the architectural, the engineering, or the agricultural details of the book.

**Monumental.**—A large number of the Hertfordshire Freemasons, with their Provincial Grand Master, Mr. Thomas F. Halsey, M.P., assembled in Watford Cemetery on Friday last, to unveil a marble memorial they have erected to their late deceased Deputy-Provincial Grand Master, Doctor Wilson Iles. On the removal of the covering by the sculptor, Mr. James Forsyth, the Grand Master addressed those assembled. The monument consists of a tall Latin cross, with kerbing to enclose the ground, executed in Sicilian marble.

#### CHANGES IN ALDGATE.

A FEW months ago Mr. Birch addressed a meeting of the St. Paul's Ecclesiastical Society, collected within the church, upon the early history of St. Katharine Cree, in Leadenhall-street. Could he have foreseen the occurrences of the past three or four weeks Mr. Birch might have been tempted to say a little about a neighbouring thoroughfare,—Bevis Marks,—whereof the outer aspect was then as curious and picturesque as of any in Aldgate Ward. But, together with the demolition of part of Castle-street, fully one half of Bevis Marks, on the northern and southern sides, has disappeared likewise, with all its quaint old tenements, including one which was once popularly known by the sign of the Blue Pig; perhaps from reminiscences of Richard III., at Crosby Hall. A continuation of Wormwood and Camomile streets,—their titles commemorating those herbs which grew plentifully there,—Bevis Marks forms with them a link in the chain of thoroughfares along which lay the course of old London Wall.\* Its very name has a peculiarly genuine and characteristic sound of its own. Stow, who lived in St. Mary Axe, in the adjoining Lime-street Ward, derives it from a house which, having passed from the Basset family to the abbots of Bury, was "therefore called Bevis's Marks, corruptly Bevis Marks." The property then came into possession by the Henegge family; hence the present Bury-street (where Dr. Watts used to preach), Bury-court, and Henegge-lane; also Mitre-square and Mitre-street. In course of time Bevis Marks, with many other thoroughfares in its immediate vicinity, was appropriated by the Jews, who thronging into London under Cromwell's favour extended to Rabbi Manasseh Ben Israel in 1655, found but insufficient room at their former haunts of Jewin-street and Old Jewry. On its southern side may be seen the principal gateway of the Spanish and Portuguese synagogue, which, with the Jews' school adjoining, lies between King-street and Henegge-place. This synagogue was established here in the year 1656, and was rebuilt in 1701, when the learned Rev. D. Nieto was Chief Rabbi of the Portuguese community. Eastwards of St. James's, more generally called by its recent name of Duke's-place, is the German and Polish Jews' synagogue, dating from 1692. Upon the passing of the United Synagogue Act in 1870, this has ranked and is known as the Great Synagogue. With a far less imposing interior it is larger than the other we mention. Close by in St. James's-place stands the Bath, or as a German Jew pronounces it, the *Bise Hamedrash*, House of Learning, an autocratic court, yet one whose decisions are always observed, for the summary adjustment of minor differences, mainly of a monetary nature, arising amongst the inhabitants.

A warehouse along the south-eastern side of Mitre-square occupies the site of St. James's Church, built in 1622, and gable-ended. The latter were demolished about six or seven years ago. The parish was united with that of St. Katharine Cree, when some monuments and tablets were removed to St. Katharine's Church, and the remains of interments taken to the cemetery at Ilford. We should regard St. James's Church as a representative of the ancient Holy Trinity Priory. The establishment of the Priory is attributed to the deservedly-popular consort of King Henry I. The history of its endowment is somewhat involved, but may be briefly given as follows:—Between the fens where Fenchurch-street now runs and the open space of Moorfields, Maud, or Matilda, owned a little property, or soken, by Aldgate, near the end of the highway for which she built the bridge at Stratford, in lieu of the Old Ford where she is said to have once narrowly escaped from a flood higher up the many-channelled and slowly flowing Lea. Just beyond her soken extended outside of the wall that of the Knights-Guild, whose head was portreeve in St. Edward the Confessor's days and for some while later. Influenced by the pious exhortations of one Norman, an Augustinian monk, her confessor, and who himself owned land and advowsons, &c., in the City, the Queen gave her soken, together with, as some would say, her property in Ald Gate for a

house of canons regular to be dedicated to the Holy Trinity or Christchurch. This house supplanted a church which Steydy, a canon of St. Paul's, had erected in honour of the Trinity and St. Mary Magdalen, and of which the dean and chapter of Waltham were wont to receive yearly 30*s.* Matilda acquired her priory of this incumbency, giving the dean and chapter a mill in exchange. At his wife's death Henry confirmed her gifts to the priory, and shortly afterwards a similar gift by the Knights-Guildmen\* of their property to this same house, Holy Trinity, burial-place of the great Henry Fitz-Aylwin, ultimately grew into one of the most important and wealthy monasteries in England, inasmuch so that up to the Dissolution its prior sat as alderman for Portsoken Ward, which had arisen upon the Knights-Guild liberties. King Henry VIII. bestowed the priory upon his Lord Chancellor, Sir Thomas Audley; but the residents were granted their existing privilege of choosing their alderman. By his marriage, for his second wife, with Margaret, Baroness of Walden, daughter and heir of Audley, Thomas (Howard) fourth Duke of Norfolk, succeeded to the estate; and in his house heric died Hans Holbein, who was buried at St. Katharine's Cree. Duke Thomas shared his father's untoward fate in 1572; his son Thomas, by the Lady Margaret of Walden, was created Earl of Suffolk. He sold his inheritance at Aldgate to the Corporation, and built Audley End, Lord Braybrooke's seat in Essex, with the proceeds. Stow tells us that St. Katharine's Cree Church, standing over the burial-ground of the dissolved priory, derives hence its appellation,—a corruption of Christ Church. Many views of the conventual buildings, or, rather, the ruins, are preserved in our national collections. The gateway, for example, of R. B. Schnobell's drawing is in all probability what was subsequently known as the Thrum, or Mop, Gate, being a place for the hiring of servants. All remains are commonly stated to have been finally demolished early in this century, and these have been followed by the destruction of Norman's little crypt of St. Michael's beneath the roadway of Leadenhall-street. But in a wire-blind maker's shop in Mitre-street (No. 39) the curious will find an archway, well preserved, its base some feet below the shop floor, which, doubtless, is a relic of the monastery. The alteration of the ground level is plainly apparent in the fact that the capital of a pillar within St. Katharine's Cree is only a few feet above the modern church pavement.

The name of Trinity found its way into the adjoining Minorities. Here the works for the completion of the Inner Circle Railway have involved the destruction of a portion of the eastern side of the street, together with Fountain-court (originally London Prentice-yard), Harrow-alley, and some of the unique old houses, their ground-floors converted into to carcass-hutcher's shambles, which faced the Three Nuns Tavern, now rebuilt, by St. Botolph's, Aldgate.† But Trinity Church, a relic from the Fire, and rebuilt in 1706, at the end of Church-street, Minorities, is a totally distinct foundation, says Mr. Peter Cunningham and others who blindly follow him, from the priory in Aldgate. For it carries us back to the munery of St. Clare, or the Nuns Minorities. They owed a safe settlement in this quarter to the good offices of Blanche of Navarre, and of her husband, the Edmond, Earl of Lancaster, a brother of Henry III., who lies beneath the beautifully canopied tomb at West Minster. The Minorite Convent was granted by Edward VI. to the Duke of Suffolk, father to Lady Jane Grey; his decapitated head is still preserved in a box beneath the pulpit. The convent farm passed to one Goodman, who gave his name to Goodman's Fields and Goodman's Yard, whilst Vine-street marks the former convent garden. Within this obscure little church lay in state the body of Sir Philip Sidney on the way to old St. Paul's; Edward I.

\* The brothers' names are worth recording:—Ralf, son of Algeud, Willard le Doylerle, Orger le Trade, Edward Hupocorhill, Blakstan and Albyn his kinsman, Albyn and Robert, sons of Leostan, Hugh, son of Wigar, Leostan, the goldsmith, and his son Wizo, Algar Secensu, Orger Dermans's son, Othert Drinchepey, and Adalard Homptesson. The Rev. W. J. Loftie, in his "History of London," directs attention to so early a mention of Cornhill, and opines that the Deerman, father to Orger, is the James Deerman (the "Deerman of London"), to whom by a charter preserved at Guildhall, the Conqueror gives a hide of land in Gaddesden, co. Essex.

† The Fountain Inn, dating from 1493, which, with the gate of the Holy Trinity Priory, is reproduced in "Old London" at the Health Exhibition, was pulled down in 1795.

\* We lately adverted to the discovery of relics of the wall which has just been made at this spot. See the *Builder*, p. 311, ante.

deposited within its walls the heart of his mother, Eleanor of Provence, wife to Henry III.; and here was buried he whom King Charles I. bade his son to remember as "the faithfullest servant ever prince had."—William Legge, ancestor of the Earls of Dartmouth, who attended his sovereign on the scaffold before Whitehall.

#### ART QUESTIONS AT THE SOCIAL SCIENCE CONGRESS.

The proceedings in the two departments of the Social Science Congress in which we are specially interested, the Health and the Art departments, were this year of more than usually interesting and practical character. To Mr. Beresford Hope's address as president of the Art Section we have referred elsewhere. The first question for discussion in this department was "Ought elementary instruction in drawing to be made an essential part of national education?" The subject was opened by Mr. J. P. Seddon, a portion of whose remarks we give as under:

"This question contains three distinct points of importance requiring consideration:

1. Is it possible to make even elementary drawing part of a national education?
2. If it be possible, is it desirable; and should it be done at public cost?
3. If both possible and desirable, what should be the character of the elementary drawing to be taught?

Firstly, then, as to the possibility of such an undertaking. This, which is necessarily the preliminary question, may, I think, be answered decidedly in the affirmative; that is to say, that every person of fair, ordinary intelligence can be taught to draw, not at any rate to a sufficient extent to subserve many valuable practical purposes. Drawing is, I believe, very much easier to learn than writing, because it is a far more interesting occupation in itself, and the result of it is the more immediately visible and encouraging. Most children of their own accord seek to be permitted to make attempts to draw, and, when allowed to do so, generally follow them up with tolerable persistence, and, if they abide by the well-known motto, '*Nulla dies sine linea*,' they soon make appreciable progress in the art; whereas, on the other hand, as a rule, young people have to be constrained to learn to write, and they look upon the task as one to be avoided if possible; and the proficiency they attain in it is seldom either rapid or remarkable.

The second point for consideration is whether, granting it be possible, it is a desirable thing to do, and so desirable that it ought to be carried out at the public cost. Now it is obvious that this question has to be viewed both in regard to the advantage of the individuals themselves, and in the light of the public policy. In the former case there can be but little doubt but that it would be highly to their own advantage to have opportunity afforded to them of availing themselves of their inherent power of learning to draw, and that this power should be reasonably developed; for whatever be their rank or position in life they would thereby be made more efficient, and therefore more valuable instruments for their special work in the world. They would, in fact, become in consequence more capable and happier beings.

Then, again, from the public point of view, the desirability seems to be equally evident, since the profit and pleasure of the community is very dependent upon the capacity of all its members to be able to perform properly what the rest may require of them. Now in truth a man can hardly be considered human with this capacity for drawing being left so completely undeveloped and in neglect as it is, as a rule, in England in this nineteenth century. He is not really a being capable of properly ministering to others as he should be. Nine people out of ten, for instance, nowadays, when asked to describe an object or a place, bewilder their questioner with futile gyrations of their fingers; but, if requested to explain their meaning more definitely by means of drawing, not once sadly deplore their inability to do so.

Even, then, for the simple purpose of making people intelligible, it is certainly desirable that they should all receive some elementary instruction in drawing; and in case of those that are not able to afford it for themselves, this should, in my opinion, be provided at the cost of the State, as being more practically useful to everybody than many of the by-roads of literature which are now taught in our national schools.

But drawing in reality does for more than stand for or illustrate words. It teaches, and indeed compels, observation, and thereby becomes in itself a most valuable system of education. Therefore, from this point of view also, its importance is so great that it ought certainly to be made an essential part of the national education. The majority of people are, it is true, in the possession of good eyesight, but unless they have been specially taught, or of themselves learned to draw, paradoxical though it may appear to say so, they cannot, or at any rate do not, for want of this training, see properly; that is to say, they do not really observe with any degree of accuracy. It must have been the want of trained observation that was the cause of the very able painters Claude and the two brothers Poussin remaining all through their lives content to draw, out of their own imagination, trunks of trees tapering like the roots of carrots, and foliage-like bunches of leaves tied on to the ends of sticks. The world has, it seems, condoned the glaring inaccuracy of these artists in these particulars, because of the exceeding excellence of their colouring and the artistic feeling which pervades their work; but really, in all probability, this has been because the fact has escaped its own notice. By the very process of being taught to draw, young persons have the shapes and other details of what they are set to imitate engraved as it were upon their minds. They thus learn what are the points they should notice and how to observe them, and so a valuable habit of attention to details and accuracy in recording them becomes engendered.

There are, besides, several other, perhaps subsidiary, yet obviously moral advantages, as well as a considerable amount of pleasure to be derived from the art of drawing, as an occupation for leisure hours; and it further enables people to enjoy and understand more thoroughly, because more critically, the manifold beauties of nature and art with which they are surrounded. But, after all, in view of the cost of tuition being borne by the public, in case that elementary instruction in drawing should be made a part of the national education, the strongest reason why it should be given is that it would form a most material aid to that technical instruction which has now become to be universally recognised as having a quite vital importance to the English nation. The very stringent competition which it already has to meet in all branches of its manufactures from other countries is likely rather to increase than diminish hereafter. Foreign artisans are fully conscious of the value to themselves of gaining a facility in drawing, and are not likely to neglect this valuable source of self-improvement. Whatever be the trade or the occupation in life, to be able to draw correctly is sure to further its interests, and to improve the character of the work done in it.

I think, then, that I have adduced quite sufficient reasons to prove that it is both possible and desirable to make elementary drawing an essential part of the national education, even if it be at the cost of the public, for those classes who are not able to afford it for themselves. It now, therefore, behoves me, in the third and last place, to consider what should be the character of the elementary instruction in this art which should be given.

With regard to this, it is of the utmost importance to keep prominently in mind throughout the practical technical purpose for which mostly this drawing is needed by the nation in general.

It is not now only the designers, but the whole body of the executors of our multifold manufactures for whose instruction in the elements of art I am pleading, and the character of the drawing that they require is such that, while it would tend to their practical improvement, it would leave those who are workmen workmen still; but workmen endowed with increased power and intelligence in their own crafts, and not such as would unsettle them by turning them into, or giving them the ambitions of indifferent oil-painters or water-colourists, of pseudo-architects or decorative designers, for so many of whom there would be neither room nor need in the country.

Now there is a right method and a wrong method as regards elementary instruction in drawing, as is the case with most other things in this world; and unfortunately, as so often happens, it is the wrong one which is generally followed. This wrong method has unhappily obtained the curious misnomer of 'freehand,'

whereas there is little that can be called free about it. Freedom permits a man to use his own eyes for observation, and his own intellect in its translation by the hand, but this system compels him to follow those of another, and is veritable slavery, leading to mannerism. It consists in teaching drawing by copying drawings instead of objects; and its error lies in its directing the mind to the observation of what is unimportant to the neglect of the important, and what are mere matters of detail to the prejudice of the grasp of the whole.

The damage that this single error in elementary instruction in drawing has done is simply incalculable. It has given a wrong bias to the art of the country. Persisted in, as it commonly is by amateurs, who learn sketching and water-colouring by copying the drawings of their masters, it stifles originality and perpetuates the worst mannerisms, till even the foliage of the various trees are rendered by them with specific dodges of the pencil or brush.

Now, in the instruction that should be made part of national education, it is obvious that there should be no escape from the elementary stage, which is all that the majority need. Therefore the elementary instruction should be both right in character and thorough. What is wanted is simply line drawing; that is, correct draughtsmanship with the pencil or point, without the stump or the brush, without shading or colour, and this gained by drawing from objects and not by copying the drawings of others.

The fact is, that if you give a student a single object to draw, such as a leaf, the construction of which is obvious, or a cast of one or more convenient, his mind grasps at once the problem that has been put to him; he naturally looks at it first as a whole, and with time and some help to begin with, he will soon be able to solve it. Whereas, if a drawing of a leaf be given him instead, he looks merely to the lines, as if they were the problem, and he loses himself in the detail which they represent.

Not only English, but all modern Occidental art, seems to have lost precision, in consequence, as I think, of the wrong bias 'freehand' copies have given, and of the consequent impingement of the drudgery of learning line-drawing properly. The civilised world seems full of amateurs, and even artists, who can produce pretty or pretentious but inexact effects with the stump or the brush; but it is sadly empty of such as can draw clearly and accurately objects with the pencil or the point. Whereas, in comparison, Oriental drawing is altogether better and different. The Japanese, for instance, seem a nation of draughtsmen. They seem able to draw in the fewest necessary lines all manner of natural and other objects, with perfect precision, and to give the essence of their character, as it were, in a species of shorthand. This is totally different from, and superior to, the sort of 'Impressionist' smudges which have to do duty for the like generally in Europe. If England, then, is to undertake to make elementary instruction in drawing an essential part of its national education, depend upon it that to make it serve any really useful technical purpose it must be somewhat after the character of that of the Japanese.

The drawing of the human figure would, perhaps, hardly enter into my general scheme for elementary instruction, but as it is so highly important a branch of the subject, it is impossible to pass it by wholly without consideration. It is, in fact, the ultimate aim of all good draughtsmanship.

The character of figure-drawing wanted by architects, and the workmen connected with architecture or its furniture, is such as will enable them to get the general proportions and poses correctly. This is to be obtained by rapid, though careful, sketching of the human figure in numerous and various attitudes, and not by laborious imitation of the light and shade on its surface, such as, doubtless, painters and sculptors require; and yet the students in the schools of art seem all likely to be put to this latter class of work alone, spending too much time, in my opinion, in furnishing up drawings, as if for exhibition rather than practice, with the stump.\* Would it not be better, as a rule, for such to have had the opportunity of drawing the outlines and proportions of a dozen figures, than to have elaborated the surface of one? At any rate, I venture to suggest that such should be the limitations of

\* We have repeatedly protested against this practice of the schools.—E.P.

any development of the artistic instruction that may be established with the aim of furthering the technical education of the country."

Mr. Chas. G. Leland and Mr. Rowland Hamilton followed with papers on the same subject; the former urging the necessity of teaching drawing in schools, on the ground that all children whatever of both sexes should be trained while from eight to fourteen years of age, to develop the constructive faculty by the exercise of certain arts, all of which depend on a knowledge of decorative outline design; while Mr. Hamilton read a paper chiefly enforcing some of the previous arguments in regard to the educational effect of drawing. The feeling of the meeting, so far as it was expressed, appears to have been, we are glad to say, unanimously in favour of the views urged by the speakers.

In the consideration of the second main question, at this Friday's meeting, "What is the value to the ear, the mind, the health, and the disposition of the young produced by class instruction in music?" Mr. Manby Serjeant took a line very similar to that taken by Mr. Seddon in regard to drawing; music being the training of observation and of expression through sound, as drawing is the training of observation by the eye and of expression through form; and Lady MacLaren's paper was a more concentrated, more scholarly, and generally better expressed testimony in the same direction. Mr. P. H. Rathbone, on the same day, read a suggestive paper on "The Place of Art in Political Economy," which we must be content to mention now, but which we may give in another number.

In the consideration of the third special question in the Art Section on Monday, "How can a love and appreciation of art be best developed among the masses?" to which we have before referred as a vague and unpractical form of question, Mr. Walter Besant said that his remarks were only based on East London, and must not be taken as applying to any other city whatever. "Even as regards East London, this place is so vast that it is impossible to lay down any proposition which is not open to contradiction. As regards art there are certain limits imposed by poverty; it is impossible to look to house decoration, or any striving after things beautiful where people live from day to day. The most that can be expected is to extend the influences of art into those classes where work, living, and wages are fairly good."

Teaching, therefore, the East End of London, let us inquire into the agencies which are at work there for art. First there is the Bethnal Green Museum. This institution, intended to be a great educational centre, has done nothing of the things for which it was founded. It is simply a dumb and silent gallery. There is no teaching at all; people are expected to teach themselves. It is worth while to study the contents and management of the museum, if only to find out what is not wanted for the people. It is, however, a place which attracts a great many visitors on free days.

The other agencies at work in the East End are one or two institutes, the parish organisations, and the chapels with their systems of meetings, lectures, &c. As yet, however, the people do not show the least enthusiasm for art, and are contented to be amused. We must endeavour to make them desire art of all kinds and follow it, in some one of its numerous branches, of their own accord. This means the establishment of a society for the encouragement of art in all its branches, especially the minor arts, because these can be quickly perceived to have a practical value of their own. There will be local committees, local museums, schools, exhibitions, &c., in which all the teaching work shall be done for nothing, and there shall be,—at all events at first,—no fees. But when the society has been started by voluntary effort it must, if it is to succeed, be carried on by the people themselves, and they will have to be paid,—but at workmen's wage-rate,—for teaching in the schools. So that sooner or later fees will be introduced."

The Rev. W. Tuckwell read a second paper on the same subject, in which he said that the craving for ornament and decoration among the masses is universal, and that the supply is execrable. The most popular, the cheapest, and the loveliest of possible ornaments were flowers. Attempts to introduce these into the poorer parts of Birmingham were mentioned;

hints were given for enlarging the enterprise; penny flower-shows, peripatetic lectures, Sunday field-classes, were proposed. Artificial decorations were treated under the heads of wall-paper, ornaments, pictures; cheap and graceful specimens of these were shown.

We may return to some of the discussions which ensued.

#### HEALTH IN ENGLAND.

This was the title of the address of Dr. Norman Chevers, the president of the Health Section at the Social Science Congress. We extract the following passages, embodying the impressions of a sanitary reformer who has been long working in a foreign climate, and regards England to some extent from the position of an outsider:—

"No power of concentrating language would enable us to detail, within a space of twenty minutes, even a bare list of the gross sanitary shortcomings which every stranger must perceive within a week after he sets foot on British chalk. I must only attempt to make little more than bare allusion to a very few of the most salient of these defects. Precedence may be given to a question which is sufficiently designated by the title "Our Slum Death-Rates." One of our leading subjects for inquiry is, How far may the average death-rate of a population be considered an efficient test of its sanitary conditions? To this it would be difficult to reply without entering into a little detail. That fashionable and delightful resort, Bilge-Water-on-the-Silver-Sands, is reported to 'enjoy,' to borrow a phrase from its only undertaker, let us imagine, the very exceptional death-rate of ten in the thousand. This singular phenomenon in vital statistics is revealed by an elaborate calculation, and is attributed to a variety of causes, which include the fact that forty-nine fifths of its salubrious area are occupied by the Riviera roads, N., S. E., and W., Engadine square, crescent, and parade, and that vast and sublime district the Mount Olympus Estate. Here the mortality-rate of each family is about the same as it would be if they spent one half of the year in a yacht and the other in a Highland palace; but what death-rates prevail in the few remaining lanes of the old smuggling village, Fish-alley, Wash-tub-court, and Blockade Man's-corner? With only an alteration of names, I will give the data as I find them recorded in the unpublished reports of unquestionably high sanitary authority, which I now hold in my hand. The mortality-rate in the Fish-alley group (some call it 'Stinking Fish-alley') is not ten, the general town rate, but has been reported by the eminent health officer as 45 per 1,000 for the last twenty-nine years. Dr. — writes,—I cite his report to the borough authorities *verbatim*, the names only being changed:—"Calculated on population enumerated at the inspection, the death-rate of the group from all causes, during 1873, was 46·6 per 1,000, ranging from 21·0 in Section C (Smuggler's Point) to 84·4 in Section D (Fish-alley), Blockade Man's-corner being 44·5, and Wash-tub-court 48·7."

'Yes,' it may be said, 'this is unavoidable; the men and women of the court and alley are a low lot,—always drinking.' 'True,' is the reply; 'let us take, then, the most demonstrative of all slum mortality-rates, the death-rate of the poor little children under five, who never "drink" and seldom eat.' The health officer reports that, at Blockade Man's-corner, which is a comparatively airy locality, the deaths of young children to total are 31 per cent.; in Wash-tub-court they are found to be 64 per cent. It appears to me that, in all future returns, the statements of Slum Death-rates cannot be too strongly accentuated. 'It will never be happy in England' until we have these rates painted in red letters, with the plague motto, 'Lord, have mercy upon us!' over the door-way of every condemned house, as long as the besom of improvement fails to sweep it away for ever.

One of the peculiarities of English house-construction, which is most irreconcilable to the ideas of a stranger who has long resided in the tropics, is that arrangement by which all wall-to-do people have secured death as a perpetual dweller in their homes, thus providing that they and their children shall be subject to a high mortality rate. I speak of the skeleton that works in all our cupboards,—the latrine on the lobby. 'What, a mere skeleton, a poor, quiet, harmless anatomy, whose worst vice is a

tendency to clank and clobber a little when autumn draughts are abroad?' No; but, only separated from you by a slender bar, a giant with a drawn sword, who may at any moment leap forth and slaughter your little ones. In the construction of new houses the remedy is clear: the isolation of your skeleton cupboards,—diphtheria traps, and plumbers' happy hunting grounds as they are,—in detached towers. It is in the highest degree needful that this measure should be made obligatory by the Royal Commission on the Housing of the Working Classes.

I wish that I had time to emphasise the absolute contempt, the utter abhorrence, in which all honest workers in the field of public health must hold that most loathsome and futile of all vain conceits, Sanitary Brag. As if one engaged in mortal contest with the King of Terrors should pause every now and then, and exclaim, smirkingly, 'That was a good stroke!' 'I had him there!' 'Aha, I have stamped him out!' Let us do our good work patiently and humbly, expecting fair success hardly and slowly earned; but, assuredly, pretentious quackery, dishonest assumption of power which we do not possess, will never effect the real triumphs of sanitary reform.

It may, perhaps, be said, 'You have spoken to us as a pessimist; you can see no good in our sanitary endeavours,—the God-strengthened war of mortal man against inevitable death!' No, had I not believed with never-failing ardour in this Providence-granted sanitation, I should not have studied and practised it, lovingly and hopefully, for forty years. I should long ago have directed my attention to something more practical. No one esteems and glories in more appreciatively than I do the admirable work done in the past half-century, by such sanitarians as Chadwick, Miss Nightingale, Simon, Sidney Herbert, Sutherland, Parke, Gavin Milroy, Benjamin Richardson, Netten Radcliffe, and George Buchanan; but I recognise with painful clearness the disheartening fact that without powers, full almost to benevolent absolutism, the benefit conferred upon their suffering fellow-countrymen, even by such enlightened administrators of the public health as these, must always be very tardy in its advance and very narrow in its scope.

Why, forty years ago this great sanitary question which we are now assembled to discuss, especially the drainage and scavenging of towns, the combustion of smoke, and the diminution of our infant death-rate, were very nearly as advanced in men's minds as they are at this moment! I declare that I regard these old and most vitally important, but still absolutely undetermined, questions in that spirit of sickening, wearied disappointment with which we may picture Sisyphus, doomed to interminable fruitless labour, as gazing upon the stone which, throughout eternity, he will never cease to roll up the hill obstruction. To use plain language, the discussion which we are carrying on here is not very unlike the talk which an old officer used to cite, as being held when provisions fell short during a winter's cruise in the North Sea, of good things only to be enjoyed in a painfully indefinite future. I do not, of course, in any way undervalue the admirable work which has been done by many good men in many places, and especially at the meetings of this association, now and in the last twenty-seven years, and which has still to be perfected, in treating great sanitary questions as matters of science and statistics. I merely insist, as all my predecessors in this chair have done, too often in vain, upon the necessity of persuading,—would that I could say of compelling,—the world's blockheads to act upon our scientific teaching. In a treatise on public health and vital statistics, which I published two-and-thirty years ago, I expressed a wish to strike those stolid faces, and I am not ashamed to say that the wish still exists in its original vividness.

I cannot hope to live to see the day, but I confidently anticipate that all who do will find that, in a very short time after the appointment of a Minister of Public Health, invested with great powers, against which all narrow self-interested opposition will be futile, and commanding large means, nothing more will be heard of sewage-poisoned rivers, smoke and fog blocked cities, or of public buildings and attractive suburban retreats constructed upon burial-grounds, quagmires, or abandoned lay-stalls. They will also find that all the great questions which we have been considering here are undergoing practical solution,

and that valid progress will have been made in carrying into effect these urgently needful public measures,—the approximation of the death-rate of our mercantile marine to that of the Royal Navy, a most important question, upon which many, including myself, worked steadily ten years ago, but which, at the present moment, appears to have fallen into undeserved abeyance; the publication of medico-topographical and sanitary reports for all towns and districts in the United Kingdom, a measure which I have lately advocated in the Epidemiological Society; the sanitary administration of our cities upon a uniform plan; and the reform and strict regulation of our systems of medical education and practice.

On one essential point we may feel confident. During the last ten months, I have heard from two competent authorities, speaking of two very important and quite distinct questions, the solution of which is needful for the public good, the expression, "We shall never be able to get those statistics!" Assuredly neither those nor any other statistics which he may think fit to demand will long be held beyond the grasp of a Minister of Health.

Duly empowered, Britain's Minister of Public Health will work, not as you are working now, struggling, decade after decade, for certain good ends which you can only hope, probably in vain, to achieve by another and yet another of those already innumerable Acts of Parliament, despite which every crime against sanitation is still paramount throughout the realm; he will be able to declare with confidence,—The public health of England is, at length, protected and administered by measures which worthily claim to be distinguished as a sanitary system.

#### FURTHER NOTES AT THE HEALTH EXHIBITION.

##### SOME MISCELLANEOUS EXHIBITS.

AMONG the exhibits which we have not yet had an opportunity of noticing, but which are fully deserving the attention of visitors, are many to which we cannot now refer at any length. Of some of these, however, we append a few brief notes.

Stand 376 (South Central Gallery) is occupied by Messrs. Clark, Bennett, & Co. (Limited), who exhibit some good safe luggage and dimer lifts, as well as iron staircases, ventilating apparatus, and a patent crab, well suited for builders' use.

Mr. John Stone (Stand 382), of Ulverston, exhibits his patent revolving shutters and sound-proof movable partitions. The swivel partitions exhibited are constructed of several leaves or divisions moving entirely independent of each other, and in no way connected except when brought out side by side into position. Their usefulness for schools, as a ready means of dividing up a large room into class-rooms, is obvious. They are also applicable for use in private houses,—and in how many homes would these divisions be appreciated in lieu of the wretchedly-constructed and awkward "folding doors" of which a certain class of speculating builders are so enamoured, but which are continually being anathematised by the unfortunate tenants? The admirable partitions exhibited by Mr. Stone are susceptible of any kind of decorative treatment, and can be made sound-proof by means of felt or other non-conducting substance.

Stand 384 is occupied by Chubb & Sons' Lock and Safe Company, of whose exhibits it is unnecessary to speak in detail, inasmuch as the name of Chubb is a synonym for excellence in locks and safes.

Messrs. Joseph Kaye & Sons (Stand 385), of High Holborn, exhibit their specialities in locks and latches, the merits of which are becoming widely recognised. They are exceedingly simple and strong (and therefore durable), and very easy and quiet in action.

Mr. J. D. Tucker, of Bromley (Stand 397) exhibits some very well constructed sashes and frames, which claim (apparently with good reason) to be water-tight and to exclude draughts and dust. They are very easily opened and closed, and are a safeguard against thieves, as the sashes can be left open for ventilation and locked.

Stand 468 (South Annexe) is occupied by the exhibits sent by Mr. Henry Masters, architect, Bristol, illustrative of his "double-check" system of house drainage, which is well worthy of examination. Mr. Masters has issued a very

useful card, on which are set forth "Twenty-five Golden Sanitary Rules." If this card could be hung up somewhere in every house, it would no doubt be the means of getting people to take an intelligent interest in the sanitary or insanitary arrangements of their buildings.

At Stand 734 (West Corridor), Mr. Thomas W. Webber, of Kellyville, Athy, Ireland, shows his patent method of roofing with single slate or glass, which is simple and economical. We have not space to describe it in detail, but it is claimed for it that slating done on this principle costs only 7d. per foot complete with timber, whereas ordinary slating costs 11d., and open slating, 8d. The stand occupied by the Dawson Economico Gas Company is roofed by this method, which is certainly worth the consideration of all who are interested in finding a cheap roof-covering,—an article constantly in demand for farm buildings and other purposes.

Messrs. Wigors Bros. (Stand 811, East Central Gallery B), of Pavilion-road, Chelsea, exhibit some specimens and sections of solid floors laid with their flooring-blocks as imported from Sweden. Floors constructed on this principle have many advantages, and they have been largely used in Board Schools in London and elsewhere.

Stand 818 is occupied by Mr. Thomas Jennings, of York-road, Lambeth, who shows some admirable flooring specimens, specially prepared and polished on the surface with paraffin, and particularly well adapted for use in hospitals, sanatoriums, &c.

Mr. William White, of Abergavenny (Stand 830) exhibits his "Hygeian Rock" building composition, to the great merits of which, as a damp-resisting and strength-imparting material we have on previous occasions called attention. It may be useful to note that the composition is now materially reduced in price.

Stand 831 is occupied by Messrs. Francis & Co., of Nino Elms, who show a variety of specimens of their material and of the constructive and decorative uses to which it can be applied. An instructive series of specimens of the materials used in the manufacture of the machine exhibiting the manner in which the cement is also shown, together with a testing material is tested for strength. The machine exhibited is Michele's patent. A large tablet illustrates the manner in which Parian cement is used for stuccoing internal walls and for mouldings and other decorative features. The centre panel is, of course, Parian, and, we are told, was painted within twenty-four hours of the time when it was laid on. Altogether this stand affords a very good "object-lesson" to all who wish to understand and appreciate the value of Portland cement. The name and standing of the firm are vouchers for the excellence of the material supplied by them.

Stand 814 (East Gallery) is occupied by Messrs. Craven, Dummell, & Co., of the Jackfield Works, Ironbridge, who make a very good display of tiles of every variety at present manufactured. Some ceramic mosaics of good design and colour are also shown by these exhibitors, besides some excellent reproductions of ancient tiles, such as were made by the firm for Chester Cathedral and Christ Church Cathedral, Dublin, under the direction of Sir Gilbert Scott and Mr. Street respectively.

Stand 851 is occupied by the Embossed Tapestry Company, who show a new patent wall decoration described as "sanitary" (washable?) and "indestructible."

At Stand 852 Mr. Henry Carr, of Clapham Common, exhibits an interesting series of specimens of arsenical and non-arsenical wall-papers, also an interesting display of apparatus for detecting the presence of arsenic in wall-papers, clothing, &c. The specimens of paper shown make it clear that the non-arsenical papers can be made quite as bright as those which contain the poison, and they also serve to emphasise the fact that other than green papers are arsenical. It is a common belief that only green wall-papers are arsenical. Mr. Carr delivered an interesting lecture on this subject some time ago, and he has done a public service in giving so interesting and instructive an object-lesson as his exhibits afford to the visitors to the Exhibition,—a lesson which should not be missed.

At Stand 856 Messrs. Heywood, Higginbottom, Smith, & Co., of Manchester, exhibit their sanitary washable paperhangings, stated to be printed in non-arsenical colours; they are very effective and suitable in design.

The old-established firm of Woollams & Co., of High-street, Manchester-square, exhibit at Stand 860 an excellent collection of wall-papers. Amongst the specimens we may mention a very effective "tapestry paper," and some good "leather papers." The "Morton" and "Yardley" dado decorations,—which, like all the other exhibits of this firm are free from arsenic,—deserve the attention of visitors. A very rich black-and-gold paper, and the "Peony" and "Lyre Bird" wall decorations shown by this firm, are examples of sumptuousness, while, on the other hand, a simple wall-paper of quiet design is exhibited as having been selected by the Exortive Council for the "bed-rooms" of the "Sanitary House." Messrs. Woollams' exhibit affords another illustration of the fact that bright green papers can be had free from arsenic. Messrs. Woollams deserve credit for being pioneers in showing that bright wall-papers could be produced without resorting to the use of arsenic and other poisons. They exhibit an analyst's certificate showing that twenty years ago they were producing non-poisonous wall-papers.

At Stand 866 Mr. J. F. Ebner, of Clerkenwell-road, has an admirable display of accurately-made and highly-finished parquetry. This, which is of Hungarian manufacture, we believe, is well worthy of examination by visitors. The designs are suitable, so that the different combinations of varying-coloured woods have a very good effect, rich though void of vulgarity. Parquetry is a material for floors which has a great value from a sanitary point of view, owing to its close joints and non-absorbent surface, and it is likely to be in considerable demand for a long time to come. The merits of Mr. Ebner's work are sure to secure for it an extended use. Mr. Ebner also shows some good specimens of marble-mosaic and marble concrete work for floors and staircases; also some glass mosaic work for mural decoration. We understand that a great deal of marble mosaic pavement is being laid by Mr. Ebner in the new buildings for the Middlesex Hospital. Mr. Ebner is also an exhibitor in the Belgian Section, being the London agent for the society known as La Construction Industrielle, who, through him, exhibit some very richly-carved and moulded dados and doorways, as well as some school desks and seats capable of adjustment to the exact physical requirements of the particular scholar using them.

At Stand 803 Mr. Chappuis, of Fleet-street, shows to good advantage the merits of his patent day-light reflectors, which in many situations are of great sanitary value, inasmuch as they render it unnecessary to burn gas which would have to be burnt but for the daylight reflected by Mr. Chappuis's valuable contrivances.

Next week we shall proceed to deal with the stores and grates shown in the Exhibition.

**Sanitation at Brighton.**—There is no doubt that families run great risk of illness from the insanitary condition of the apartments occupied during the usual summer holiday, and were it not for the out-door life they lead under the circumstances, and the ever-open windows and doors to dilute the inner atmosphere of the house, we should hear of more cases of serious illness than is now brought to notice. It is no exaggeration to say that in many of the smaller seaside towns none of the houses comply with the ordinary sanitary requirements of common sense, and it is only in special cases in the larger towns that anything like a satisfactory state as regards individual houses can be pointed to. An example on a very large scale of "sanitary houses" is exemplified at West Brighton, where a number of high-class flats have just been completed by the building owner, Mr. John T. Chappell, of Lupus-street, Pimlico. The various points of sanitation are attended to on the principles laid down for the "Sanitary House" at the Health Exhibition, and it speaks well for the sanitary movement that property of this kind should be carried on in this style without regard to expense, the one idea being consistently kept in mind that whatever is necessary to make it complete is to be included. When we see building owners coming to the front like this, we realise the great advances that are being steadily made in the direction of housing people in a healthy manner.—*Sanitary Record.*

## DESIGN FOR WAR OFFICES.

BY MESSRS. VEIBY AND HUNT.

**T**HIS design, which, as our readers will remember, was one of the three selected from among the nine of the second competition, for special consideration, shows far more knowledge and capacity in what may be called the technique of Classic design than the selected design evinces, though it would probably not be considered so generally attractive. It has, however, the merit of coherence and consistency in grouping, and has an expression of stability which is in keeping with its purpose. The authors have adopted the system of one large central quadrangle, which is not only better on sanitary grounds than a larger number of small courts, but gives opportunity for a spacious architectural effect in the quadrangle, a view of which we give, as well as that of the Park front. In the latter it will be observed that the design shows what might be termed a *decrecendo* towards the Horse Guards, though there is not a definite attempt to connect the two architecturally. The following is the architects' statement in regard to their own views in the plan and design:—

"In preparing our design, the following appeared to us to be the leading features necessary and of the first importance in a plan which should satisfactorily meet the requirements of these buildings, viz. :—

1. All parts should be thoroughly well lighted and ventilated.
2. The various departments should be arranged and grouped in the simplest way, but upon some definite method.
3. There should be great facility of communication between the various parts of the building; and
4. That, if possible, the building should be so arranged that persons having business with one department need not traverse corridors belonging to other departments. Guided by these requirements, it at once becomes apparent that the usual system of rooms on either side of a corridor, or rooms lighted from internal areas, would be both inconvenient and unsuitable, as either there must be a great loss of space or a serious deficiency of light and natural ventilation; and, further, it would be almost impossible to group and concentrate the various departments upon a simple and intelligible system.

The scheme, however, which meets all these requirements in the easiest and most practicable way, and upon which this plan is worked out, is that of grouping the rooms of each department round a central vestibule or hall, and disposing these halls symmetrically with a series of open courts between them around the extreme limits of the site, so as to obtain one great internal court, which should be large enough to secure efficient light and ventilation. By this arrangement no frontage is lost; all offices look either into the Park, Whitehall, or the quadrangle; only messengers', waiting, and other unimportant rooms being lighted from the internal courts. The departments are grouped in three proper relative positions as nearly as possible in the order suggested in the 'Instructions' with the more public rooms on the ground-floor, the principal offices on the first floor, and the working staff on the upper floors. For private communication between the heads of departments, the whole of the outer or Park side corridor on the first floor is entirely private from the Controller's room in the Admiralty division to the rooms of the Commander-in-Chief and his staff in the War Office block, it being intended that the staircases in the angles next the court-yard should be for the use of the public, and those on the outer or Park front for officials, so that the inner becomes the working corridor, and the outer, as before mentioned, the private corridor, all the rooms of the chief officials opening therefrom, and each point of access being commanded by messenger lobbies. Great care has been taken to group the civil and military departments in separate blocks. The Secretary of State and the Commander-in-Chief are placed on the Parade front, in the most central position, the secretarial departments extending westward and round the south-west hall, and the military departments occupying and being grouped around the south-east and south halls. In the Admiralty their lordships' rooms are placed on the west and north Park fronts; with their departments grouped around the north-west

and central halls; the controller and his departments being grouped round the north-east hall.

The messengers' rooms are everywhere arranged one over another.

Carriage-entrances to the courtyard are provided from Whitehall and Spring-gardens in positions where they do not interfere with the general arrangements of the buildings or cut through any departments.

The principal public entrances to the building are placed in the most central position for each division,—the War Office in Whitehall and the Admiralty in Spring-gardens. Private entrances from the Park are also provided to the rooms of the Secretary of State, the Commander-in-Chief, and the Lords of the Admiralty.

The natural gradient of the ground, together with raising the ground-floor 2 ft. 6 in. above the highest part of the site at the north-west corner, gives the opportunity of providing a mezzanine (or what is really a floor above ground) on the Park and Parade fronts, giving thereby all the accommodation required for the various departments which it is desirable to place on the lower floors.

As it is evidently important that those having business in these offices should not have to ascend to a greater height than necessary, no space has been lost merely for the sake of external architectural effect, but in all cases the rooms being of moderate size the heights of the various stories are only sufficient to insure properly-proportioned rooms."

Next week we propose to give a parallel illustration of the detailed elevations of the three first designs side by side, so that the architectural treatment of each may be better appreciated and compared.

## ANCIENT FRENCH SHIELD.

The original of this curious and interesting example of relief work in metal is said to have been the property of Henry II. of France; it is now, we understand, in the possession of M. G. Pilon, of Paris.

## TEMPORARY INFECTIOUS DISEASES HOSPITAL, PARK HILL, LIVERPOOL.

The temporary Infections Diseases Hospital illustrated in this number has just been erected by the Corporation of Liverpool, from the designs of Mr. Clement Dunscombe, M.A., M. Inst. C.E., City Engineer, and under his immediate supervision.

The primary cause of its erection was a threatened epidemic of small-pox, which, happily, is now subsiding. The proper isolation of infectious cases in a city with a population such as Liverpool, viz., 573,300, has been a most difficult task for many years past, owing to the fact that but a very small area of unbuilt-upon land exists within the city limits upon which hospital accommodation can be provided to meet the most recent requirements of sanitary science.

To meet the present emergency, the Park Hill Estate, 20 acres in extent, was kindly placed at the disposal of the Corporation, at a moderate monthly rental, by the Mersey Docks and Harbour Board, who have recently acquired it, to command the foreshore of the river Mersey and for future dock extension.

The site, which has a south-west aspect, is at a moderate elevation, sloping quickly to the river Mersey, the encampment being between the 70 ft. and 50 ft. contours, the levels being reduced to old dock sill, which is 42 below Ordnance datum.

Park Hill House has been utilised as the administrative block in connexion with the encampment, as shown upon the block plan. The out-offices attached thereto have been converted into a steam laundry, disinfecting-chamber, stores, ambulance-shed, &c.; while the mansion-house proper has been fitted up for the use of the administrative staff.

The hospital occupies a site 460 ft. by 220 ft. This area has been carefully under-drained, and two terraces formed 410 ft. by 40 ft. The tents and buildings stand upon a Portland cement concrete foundation, 6 in. deep, laid over the entire area of these terraces, upon which the joists carrying the floors of the tents and buildings rest, adequate ventilation under the same being secured.

The encampment consists of four pairs of double hospital tents of the most recent pattern, and two pairs of iron buildings. Each pair of tents and buildings is connected by a building consisting of nurses' day-rooms, bath-rooms, closets, &c.; a covered footway 9 ft. wide traverses the centre of the encampment, with similar covered ways, right and left, to each of the blocks of buildings placed between each pair of tents or iron buildings.

The footway is formed of 6 in. of Portland cement concrete laid on a suitable foundation. The covering of this footway is constructed of wood and roofed with four-ply Willemsden paper painted "light green," the rafters, posts, and battens on roof being finished in chocolate.

The roof at entrance over roadway is similarly treated. On the south side of the entrance there is provided a kitchen, scullery, larder, and airing-room, and a dry-earth store.

The airing-room and dry-earth store are heated by steam pipes from a boiler fixed in the kitchen.

The kitchen, scullery, airing-room, and dry-earth store are built in red brick, tuck-pointed, with blue brick dressings. The kitchens are fitted with complete steam and other cooking appliances sufficient for 200 patients. The larder and store-room are framed buildings covered in Willemsden paper, match-boarded on the inside, and finished similarly to the buildings described further on.

The connecting-block situated between each pair of tents or huts in the encampment is built in the Bungalow style, with a verandah in front, and consists of wooden framing covered with four-ply Willemsden paper, lined inside with grooved-and-tongued match boarding, the space between the outside covering and inside lining being filled in with silicated cotton, and the woodwork finished internally with asbestos fire-proof paint.

Each connecting-block contains two nurses' rooms and two bath-rooms, each 12 ft. 6 in. by 11 ft. 3 in. and 11 ft. 3 in. by 9 ft. 3 in. respectively, and 12 ft. 6 in. high. A lobby 5 ft. wide, provided with thorough ventilation, divides each hospital ward. Doors, with top panels glazed, are provided in each nurse's

Scale for Furniture: 1" = 1'  
Scale for Main Hall: 1" = 10'

Drawings by Mr. Clement Dunscombe, M.A., M.I.C.E.

room to act as inspection windows for the wards.

At the rear of each bath-room there is a slop-sink discharging external to the building, and provided with hot and cold water supplies, placed in a lobby with through ventilation, and beyond are earth closets 5 ft. by 3 ft. provided with constant through ventilation and pivot-hung windows.

The corrugated iron hospital huts are 52 ft. by 25 ft., and 14 ft. average height. The iron

Adequate cross ventilation is secured. The whole area of the windows is made to open, the top sashes being pivot-hung. In every case there is a free current of air under the floors, and fresh air is admitted into the wards through a sufficient number of conical air-bricks. Exit ventilators are provided near the ceiling-line and by means of louvres fixed in the roof.

At the end of the encampment a hut for convalescents is provided, 40 ft. by 12 ft., and

grooved-and-tongued boarding, the roof being ceiled with Willesden paper. The walls and ceilings are finished in green, with a chocolate dado, and the rafters are dressed and similarly painted. The mortuary is provided with rubbed slate shelves, supported on blue brick tuck-pointed piers; the floor is finished in best black and white tiles on 4 in. Portland cement concrete. The post-mortem room has ample top light, and is similarly finished, except that the dado consists of 6 in. glazed and enamelled white tiles. There is provided a slate post-mortem table, slate sink, with hot and cold water supplies, &c.

A constant-service water-supply is provided throughout the encampment, slate storage cisterns being provided for supplying the hot-water cylinders which supply the baths throughout. In each hut and building, and also in the nurses' rooms, there is provided a drinking supply direct from the main, and a fire supply, with hose ready attached, ready for use. Hydrants, with hose ready attached, are also provided in suitable positions along the covered ways. The hot-water supply for each block is obtained by means of coil grates fixed in each of the bath-rooms, and these, while acting as an ordinary open fire-grate, the fire-bars of which form portion of the coil, supply through the hot-water cylinder fixed over each pair of bath-rooms an adequate and continuous supply of hot water.

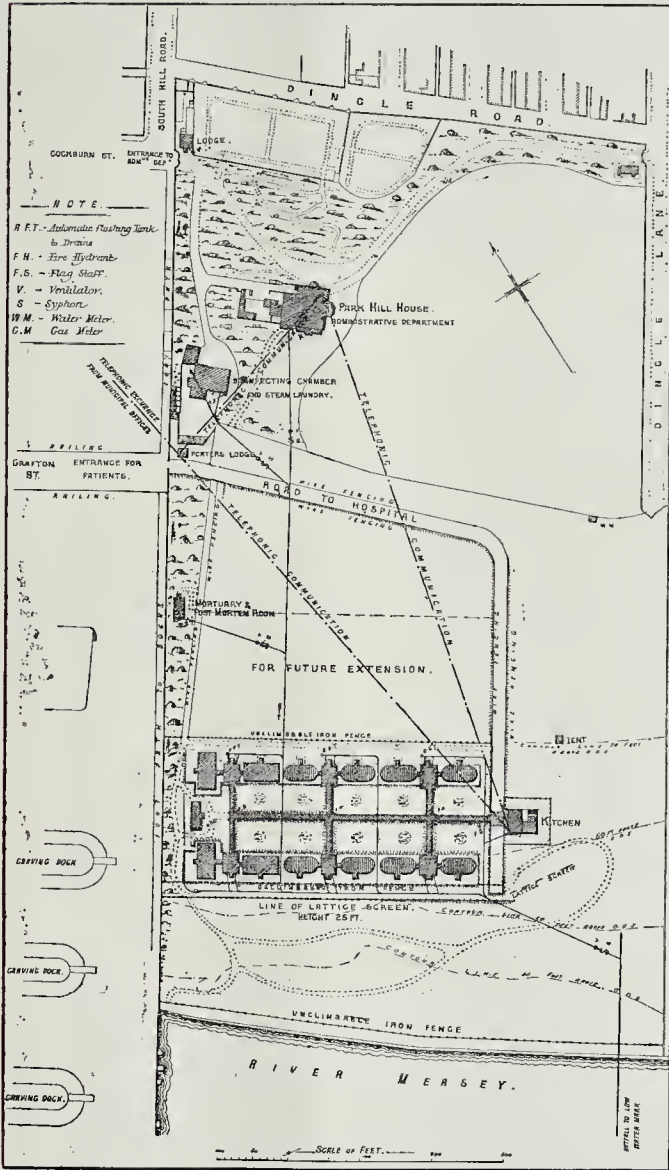

The drainage has been most carefully attended to, and forms as complete a system as could be devised. A reference to the block plan shows the arrangement. The whole of the drainage is external to the buildings; the sink wastes, &c., emptying over external traps. The drains are adequately ventilated, suitable inlets and outlets being provided. Disconnecting chambers are constructed to sever any connexion with the drainage from the hospital, mortuary, &c., and the administrative block. The drains, which consist of glazed earthenware pipes, caulked and jointed in Portland cement, finally discharge through a 9-in. pipe into the River Mersey at low-water mark. There is, therefore, no connexion with the drains from the hospital, so to speak, having an independent outfall. At the head of the drains from each block an automatic flush-tank of simple construction is provided, which is filled by a tap in a given time. Six hours has been fixed in this case.

A small tank containing carbolic acid is fixed near each flush-tank, and communicating therewith. This tank discharges a given quantity of carbolic acid automatically into the flush-tank, and when this is full the siphon comes into operation, and the contents of the flush-tank, about 40 gallons, consisting of a powerful disinfecting solution, is discharged from the head of each drain. The same arrangements are provided at the mortuary, post-mortem room, kitchen, &c. In the case of the kitchens and mortuary, grease-interceptors are provided in the flush-tanks. It will be seen, therefore, that the whole of the drains are automatically flushed with a disinfecting solution four times in every twenty-four hours. The value of so complete and perfect a system of drainage, acting automatically, cannot be over-estimated in a hospital designed for infectious diseases.

**Heating Arrangements.**—It is intended to heat the tents and iron buildings by means of a specially-designed circular open fire-grate in the centre of each ward or tent, the firebars forming portion of a coil placed centrally at the back of the fireplace, with a steam-pipe from same running round the ward or tent, special provision being made for this to act as a ventilator. By this means it is believed that an equable ward temperature will be secured.

Gas is laid on throughout the buildings, tents, and covered ways. The brackets are in every case fixed and supplied with enamelled steel covers, acting as reflectors.

Telephonic communication is established from the Telephone Exchange in the City Engineer's office, municipal offices, the medical officer of health's office, and Park Hill House (administrative department), the porter's lodge, and the encampment. Triangular communication as shown on the plan is established, which provides telephonic communication between the medical officer of health's office, or the City Engineer's office, and Park Hill House, the porter's lodge, or the encampment proper. There is a telephone office on the west side of the verandah attached to the kitchen, by which,

Block Plan.

roofing is laid on boarding, and internally the walls are boarded with grooved-and-tongued boarding, the space between them being filled, as in the other blocks, with silicated cotton. The roof is ceiled up the rafters with four-ply Willesden paper, the intervening space being also filled with wired silicated cotton, about 1 1/2 in. thick. The walls are finished in two coats of asbestos fireproof paint. There are sixteen windows in each ward,—twelve side windows, 5 ft. by 3 ft. 9 in., and four end windows, 3 ft. 9 in. by 3 ft. 6 in.

12 ft. in height, constructed of wood framing, covered with Willesden paper, and lined with grooved-and-tongued boarding, and finished in the same manner as before described. The space in front is laid out as a garden. In fine weather this hut can be used as a reading and recreation room.

The mortuary and post-mortem room,—the former, 14 ft. by 14 ft., and the latter, 14 ft. by 9 ft., each 11 ft. to the ridge,—are similarly constructed, viz., wooden framing covered with Willesden paper externally and internally, and

in case of emergency, communication can be made to the resident medical officer at Park Hill House, or with the municipal offices. The porter from his lodge can likewise communicate with the medical staff at the Park Hill House, or with the encampment, on the arrival of a patient. By this means no time is lost in either dealing with a patient on arrival, or answering any questions from the municipal offices relative to patients.

**Wind Screen.**—Owing to this site being exposed to the prevailing winds, which vary from south to north-west, and it being also exposed to the river Mersey on the south-west side, it was considered advisable to protect the encampment from these winds. The construction designed for the purpose is both a novel and most effective arrangement. It is 600 ft. in length and 30 ft. in height, and consists of Norway poles, placed 6 ft. apart, to which are fixed battens at intervals of 1 ft. 3 in., battens being interlaced between the same, forming a screen which most effectually breaks the force of the heaviest gale. The screen is carefully braced and stayed with steel wire ropes, and it and the tents and buildings are well secured by steel wire ropes to ground anchors. Behind the screen there is formed a footpath, 5 ft. wide, for the use of convalescents.

The encampment is inclosed with wrought-iron unclimbable fencing, and wire fencing on each side of the road leading thereto, and also along the river frontage.

The lower grounds have walks laid out through them for the use of convalescents; the quadrangles formed by the covered ways are laid down in grass relieved by flower-beds and shrubs.

The hospital is generally supplied with all the furniture, fittings, and appliances of the most perfect and complete description, necessary for the requirements of the best appointed hospital.

The furniture, which is in polished pine throughout, has been specially designed, and also the fittings,—all plain, easily cleaned, and specially adapted for the purposes for which they are applied.

No unnecessary outlay has been incurred. The aim, however, has been to provide a temporary hospital second to none as regards its completeness in every detail, and one which will be readily available for those unable to provide proper isolation or medical care for patients in their own houses.

The endeavour has been to make the encampment and its surroundings as attractive-looking as possible, in contrast to what is too frequently designated as a "Temporary Infectious Hospital," and which in many cases consists of a repulsive-looking aggregation of wooden sheds.

As an evidence of the care taken in the designing of the buildings, and also in providing an adequate constant-service water-supply and all requisite fire appliances, it may be mentioned that the fire risk over the encampment is covered by a responsible fire office at the low rate of 3s. 6d. per cent.

The total cost of the hospital complete in every respect will be under 12,000l. This is exclusive of the value of the site or Park Hill House, which has been utilised for the administrative staff, but is inclusive of all furniture, fittings, and other appliances of every description.

It has been erected ready for use within two months, although the preparation of the grounds, water-supply, drainage, concreting the site, has entailed considerable labour, 300 men having been constantly employed for that period upon the works.

**The New Hall and Library of Sion College.**—The works in connexion with the erection of the new hall and library of Sion College, on the Thames Embankment, has just been commenced. The site fixed upon for the new building is at the angle of the Embankment and the new street on the west side of the City of London School. The building will cover an area of about 10,150 superficial feet, having a frontage to the Embankment of 75 ft., with a return frontage of 135 ft. The work of getting in the foundations is now in progress. The contractors for this preliminary portion of the work are Messrs. Foster & Dicksee, of Engby. In consequence of the Metropolitan District Railway passing underground in front of the site, the main elevation of the building will be set back a few feet. The architect of the building is Mr. A. W. Blomfield, M.A.

#### THE DISPOSAL OF TOWN SEWAGE AND OTHER REFUSE.

In the Health department of the Social Science Congress at Birmingham, the first question was:—“(a) What is the best method of dealing with (a) Town sewage? (b) The products of home and street scavenging? and (c) The products of combustion?” papers being read on these three subjects respectively by Mr. E. Pritchard, Mr. Lawson Tait, and Captain Douglas Galton. The latter we may be able to print separately on another occasion. As the discussion appears to have turned chiefly on the sewage question we give extracts from two papers which dealt with the sections a and b.

Mr. Pritchard, in regard to the first part of the question, said:—

Had this question been asked me some fifteen or twenty years ago I, like many others, would have suggested irrigation; but experience of the last few years has caused a modification of my views, and the answer now would be to the effect that local circumstances must necessarily govern the particular method of treatment; and what might possibly be considered the best system for one place would prove to be an undesirable one for adoption in another.

The methods generally adopted in this country for the disposal of town sewage, and to which I propose to briefly refer, I have classified as follows:—

1. Land purification.
2. Chemical precipitation.
3. Discharge of sewage into the sea.

Under the first head may be considered two methods for the purification of sewage:—(a) Sewage irrigation; (b) Intermittent filtration.

(a) *Sewage Irrigation.*—Broad irrigation is the application of the minimum quantity of sewage to the maximum area of land, whereby the sewage is allowed to flow over the land, the greatest return being obtained from this process of sewage utilisation. With suitable land and proper management good results are obtainable without the creation of nuisances; but as the true value appears now to be more generally known, sewage treated by broad irrigation, unless under exceptional circumstances, does not at the present time find much favour. It is estimated that one acre of land will purify the sewage from 50 to 100 persons; this is on the assumption that such land is not continuously treated. Heavy crops are obtainable from land so treated; large quantities of rye grass, mangold wurtzel, and various green crops being readily grown. On the Earl of Warwick's farm at Leamington, a few years since, over 80 tons of mangolds per acre were grown. It will, however, be perceived that in broad irrigation the first consideration would generally appear to be “how to make it pay,” leaving the purification of the sewage as the lesser factor.

(b) *Intermittent Filtration.*—In 1868 Dr. Frankland, one of the Rivers Pollution Commissioners, determined, by experiments, that by deep drainage of land of a suitable description, sewage could be purified in large quantities upon a small area. This system was termed “intermittent downward filtration,” and requires that the land shall be laid out in level beds, and properly drained at a sufficient depth, the surface of the land being prepared in a ridge and furrow, and upon the ridges green crops can be successfully grown. As the name implies, the sewage is applied in an intermittent manner. This process of sewage treatment is a costly one in the first instance for the preparation of the ground, the outlay in some instances reaching a sum in excess of 200l. per acre, whilst the cost of preparation of ground for broad irrigation might not exceed, under favourable circumstances, 10l. to 15l. per acre. The cost of works, however, whether by irrigation or filtration, must be governed by local conditions, my own experience proving that sums from 7l. 10s. to nearly 700l. per acre have been expended in the preparation of land for sewage treatment.

The treatment of town sewage by chemicals has now occupied the attention of engineers and others for many years. I do not propose in this paper to refer to the numerous processes that have been brought before the public during the past twenty years; and although not prepared to support a scheme of chemical precipitation *per se* for the purification of sewage, assuming the effluent has to be discharged into a stream of ordinary purity, still I am strongly of opinion that great improvements have been made, and

it is somewhat satisfactory to find that lime, the first precipitant used, still holds its own as being able to produce fair results in sewage purification. The great difficulty for many years was how to dispose of the considerable volume of sludge, which is the natural result of precipitation. This difficulty has, however, been successfully overcome by means of the improved system of sludge presses in operation at various works. The sewage effluent from any scheme of chemical precipitation should pass through a properly-constructed artificial filter, or through land deeply drained on the principle of intermittent filtration.

The sewage from towns situate upon the sea coast is generally cast into the sea, at a point below low-water mark. In some instances this is done without in any way separating the heavier matters held in suspension; in other instances,—notably Brighton, Torquay, and other places,—intercepting sewers have been constructed at considerable cost, by which means the sewage has been diverted to a point some distance from the town, where the influence of the tides has not exerted any disagreeable effect upon the towns so sewered, by causing any return to the beach of the sewage discharged. In other instances sewage from large cities and towns, such as London, Liverpool, Glasgow, Newcastle, and Bristol, is discharged into tidal rivers. This emptying of sewage into rivers is, however, in some instances, productive of great nuisance to the public and injury to the river. At the present time a Royal Commission is sitting to consider remedial measures for the metropolitan sewage. I had the honour of appearing before such Commission as a witness, and advised what, in my opinion, was the most desirable course to adopt, *viz.*, the extension of the existing outfall sewers of the metropolis, so that the sewage may be discharged into the sea beyond the range of tidal influence, even assuming that such works would entail great outlay.

Mr. Lawson Tait, in treating of “The Utilization of Town Refuse,” gave some account of his practical experience in dealing with the sewage of Birmingham. He said that Birmingham, from its situation on the highest part of the Midland district, was obliged to adopt in its early history the system of surface household wells, and until recently these had an almost universal prevalence throughout the town; indeed, they exist now in very large numbers. Closely associated, the midden privy was constructed, and in 1871 there were nearly 20,000 of these centres of disease existing in the borough, their aggregate area exceeding thirteen acres. As by far the greater part of the town is built upon hills of loose sand and gravel, it is perfectly needless for me to say that soakage from the privies into the wells was of constant occurrence, and is still far too frequent. Of these privies about 14,000 drained at that time into the sewers. There were about 7,000 water-closets, the contents of which, together with all the road-sweepings, manufacturers' refuse, and countless other impurities, were turned, and had been ever since the town existed, into the small river traversing its area. Up to 1871 the government of the town was conducted upon lines which it is no part of my business here to discuss or condemn, but no one who knows the town at all but will be able to substantiate my statement that, the new *régime* inaugurated by the distinguished statesman who at the present moment presides over the Board of Trade has, as it were, reconstructed every aspect of our municipal life. The town has improved in every possible way; its death-rate has fallen nearly five in the thousand, and the average age at death has been raised six years, and the whole of these beneficial changes are due to the inauguration of Mr. Chamberlain's sanitary policy.

The problems we had to solve were two,—How we could treat the fluid impurities which ran into the river, and how we could dispose of the solid household refuse; but they were extremely complicated, from the enormous bulk of the material to which they had to be applied, and it is from this chiefly that our progress in their solution was so slow. We found, in fact, that theoretical chemistry was of but little help, and that laboratory experiments were absolutely futile. We sent out inquiries, and we visited by deputation all the large towns in Great Britain which were in any way comparable to our own, and these inquiries and investigations, concurrently with our experiments,

occupied a period of nearly seven years. As they advanced, and as the results of our experiments became more accurate and more extended, the more certain did we become that the original conclusions established by the report of the Birmingham Sewage Inquiry Committee were those alone which were applicable to our town. The recommendations were as follow:—"The exclusion of animal excreta from the sewers is, in the opinion of the Committee, essential both to the effectual treatment of sewage and to the health and comfort of the population, and they have arrived at the conclusion that this object may be attained by a reform of the system of exposed privies and open middens now prevailing in the town, and which defile the air, poison the water, and, by means of connecting drains, pollute the sewage."

The first principle we established, and we arrived at it chiefly from the disastrous experience of other towns, where it had not been adopted, was that it was absolutely essential to keep the two elements with which we had to deal,—the household refuse and the excreta,—entirely separate, and for this purpose we established a system of dual and joint collection which has proved perfectly satisfactory. In the reconstruction of closet accommodation, we filled up the old middens and replaced them by simple closets, under the seats of which we placed large galvanised pans. These pans are coated inside from time to time with holling tar, an operation which very much diminishes the smell and enables them to be easily cleaned. Somewhere near the closets ash-tubs, either of wood or iron, are placed, into which the tenants are requested to place their household refuse, and they are strictly forbidden to empty slops into the pans. It took a long time to educate the population to the fulfilment of even these simple directions, and much trouble was encountered for several years in establishing the fresh arrangement. We found that many people objected to it, and clung with a mistaken but most affectionate pertinacity to the foul middens to which they had been accustomed. The arrangements for the collection of the pans and ashes were at first defective, and a good deal of outcry was raised from time to time against the objectionable smells which they emitted as they passed through the streets; but as the details became perfected one after another these objections ceased, and we were not troubled with any complaints. Indeed, the complaints now are all against the old system, for when the remaining middens are to be emptied the overwhelming stench which prevails all over the neighbourhood for some hours after the process is a never-failing theme of complaint for exactly the same people who, when they were accustomed to its nightly recurrence, thought it hardly worth mention.

The collecting-vans are arranged to carry eighteen pans and about one ton of ashes, and the collection is made from each house on the average once a week. When the pan is removed it is covered by a lid, made to fit perfectly tight by means of a strong spring and a band of indiarubber, so that any smelling is avoided. The ash-tubs are emptied into a special receptacle at the hinder part of the van. These vans are taken to our central depot, and there are subjected to processes of which I shall shortly speak.

The continually increasing cost of collection and the continuously-diminishing value of the material gave indications that the continuation of that policy would have been ruinous. At this point it may probably be convenient to anticipate a criticism which is sure to be raised upon the general system of our policy for the disposal of refuse which has been adopted in Birmingham. Towns will be pointed to, of great importance and large size, in which no such costs as these are incurred, and instances of towns where the water-carriage system is in use will doubtless be especially indicated. We may, and probably will, be asked the question, Why has not the water-carriage system been adopted in Birmingham? And there are some amongst us still, I am sorry to say, who are disposed to take such a retrograde step. I need not answer the objection in detail, because the answer to it will be found in the volume I have already quoted, the report of the Birmingham Sewage Inquiry Committee. Suffice it to say generally that as Birmingham has a very elevated position we cannot obtain a water supply by gravitation. Every ounce of water used in the town, unless obtained from a soft-water

cistern placed on the roof of a house, has to be pumped, and the public supply has to be raised from 200 ft. to 600 ft., and I need not say that not only is this an extremely costly process, but that the quantity we can obtain, and from reservoirs, is such as is calculated only for the maximum requirements of a constantly growing population for all purposes exclusive of a water-carriage system of sewage. It is extremely doubtful if we could obtain in any way the additional quantity of water required for this purpose, and even if we could obtain it our difficulties would be increased instead of diminished by every gallon of water-closet liquid which was added to our already enormous bulk of sewage. The conclusion is, therefore, that the true economy is to preserve from waste these materials which having been taken from the land should be restored to it, and that it is a mistake to waste them by such dilution as renders them practically valueless.

Acting upon these principles, the plan we adopted was to act upon the one kind of refuse by means of the other. Immensely to our surprise, and to our no small satisfaction, we found that the solid ash-tub refuse, which amounts to 72,000 tons per annum, would burn in properly-constructed furnaces without the addition of any other kind of fuel, and in this burning it is reduced to one-fourth of its original bulk, and the result is a peculiarly useful silicious clinker, which we turn to all kinds of useful purposes. It has been used to erect buildings with, to make roads and paving blocks, staircases, horse-troughs, tables, and ornamental fire-places, examples of all of which may be seen at our works. Of this kind of household rubbish there has been about eleven boats per week sent out into the country, the mere cost of transit being 500*l.* If we burned the same amount, the cost would be 270*l.*; and if we used all the clinkers, as we hope to do, we should save 230*l.* The burning of this amount would occupy three furnaces of the kind we have erected for the purpose, and of the total bulk of the rubbish thus burned, 75 per cent. would be dissipated in the form of heat.

In order to utilise this waste heat, the plan adopted by the Health Committee was to apply it for the removal of moisture from the contents of the pans. The means by which this is done is extremely simple. Boilers are placed in the furnaces, and the heat is transferred by means of steam to large machines, of which a working model is here exhibited, into which about sixteen tons of pail stuff are put as a charge with sufficient sulphuric acid to fix the ammonia. A hot-air blast from the furnace flue is drawn through the machines by means of a blower. The steam is applied by means of a steam-jacket and hollow rotating spindles, and in from sixteen to twenty hours the sixteen tons are reduced to one ton of solid podrette containing from 7 to 9 per cent. of ammonia, according to the time of the year, and from 2 to 3 per cent. of phosphates. Without any further treatment or addition this forms an admirable manure for top dressings, and for all kinds of rapidly-growing roots, particularly the beet-root, and in the growth of those vegetables for the purpose of sugar manufacture this kind of manure has been found extremely valuable, and doubtless it will also have a ready sale for sugar-cane and cotton.

Concerning its commercial value no absolutely certain statements can be made. So long as we were making ten or fifteen tons per week, and until we were satisfied we could make a much larger amount, we did not very energetically enter into the question of the price we could obtain for it. We were quite satisfied to hand it over to a large firm of artificial manure manufacturers, who took all we made at 5*l.* per ton without any reduction for carriage. When our output rose to twenty and twenty-five tons per week, this firm found the quantity larger than they could deal with, and we accepted a temporary reduction of price to 4*l.* a ton. During the last two months, however, we have been making efforts to obtain other markets and a better price, and we found no difficulty in getting 5*l.* a ton; in fact, we have been able to get as much as 7*l.* 10*s.* We also find that the Corporation of Warrington can command a steady price of 6*l.* 10*s.* per ton for exactly the same material.

In the course of the discussion which followed,

Mr. Baldwin Latham, C.E., said he had always been a great advocate of the application of sewage to land, although he did not deny

that there were conditions and occasions when it was necessary to use other agents. He did not approve of the use of lime, as the French people had shown that it did not destroy the small microbes which caused the unpleasantness of the sewage, while filtration through land did so. With respect to the pan system, he might say that at Saltley the amount of solid in the sewage was about 4 lb. per head, and by that system they asked the people of Birmingham to live over pans which altogether gave the same area as the land used at Saltley. He certainly would not live in a town where such a system was in vogue. Besides, they were told that ashes by themselves were a valuable commodity; but if they were mixed with sewage, the cost of separating them would not be covered by the sum realised by the sale of the ashes afterwards. Speaking of London, he said he believed the only way of dealing with its sewage was to carry it all near the sea, where they would get large quantities of land for filtration. The land on the north of the Thames was of such a character that the sewage could be applied to it without detriment to the water supply, but on the south side the system of irrigation would be inimical.

Mr. Vivian Sillar said there were now really only two systems of treatment,—that in use at Aylesbury, and the precipitation by lime process. He found that the lime displaced ammonia, so from an agricultural point of view that treatment was mischievous. At Aylesbury, instead of lime they used charcoal, clay, and alumina; when treated with that the water was purified to such a degree that it could be allowed to go into any river. The manure was sold for 3*l.* 10*s.* per ton, and that paid.

Dr. A. H. Drysdale (London) was also of opinion that land was the only purifier for sewage, and 6 ft. depth would purify the water so that they could drink it. In France that system was used, and the consequence was that the land produced from three to five times the amount of crops. He would vehemently oppose if the suggestion to throw away the sewage of London were carried out; it would be frightful waste, whereas if they could only get a piece of land sixteen miles long and one mile broad they could treat the sewage in a way to add to the wealth of the country.

Major Fosbery (Warwick) said one of the great difficulties was the treatment of the storm-water: it rushed into the sewers, and carried everything to the outfall without its going into the tank at all. No doubt later that matter would be dealt with. The A B C scheme had to be put a stop to at Leamington, because it did not fulfil the necessary conditions. That and other schemes might have their value, but it seemed to him that precipitation alone was not sufficient to purify the water, and that land filtration was necessary to accomplish it.

Mr. Edwin Cheshire (Birmingham) was of opinion that they were all wrong, and that the only way to properly treat sewage was to intercept it at the very first point, and not at the outfall, as they could never thoroughly stop it all there. In ordinary weather there was a large amount of solid, and when a storm came this floated at the top, and was carried to the outfall, making the river worse than before. He felt inclined to say, "Sewage, sewage, everywhere. Oh, what a nasty stink!"

Mr. Ald. Avory (Birmingham) detailed at length what was being done at Saltley, and said that the effect was all that could be desired. There they used lime, and found it a very powerful auxiliary; the results of their working were constantly increasing crops, and diminution of the nuisance. They had intercepted 550 tons per day, and could treat that satisfactorily; but if they got the sewage from 70,000 more houses, he was afraid that there would be considerable inconvenience caused before it could be dug into the ground, so that if the pan system were abolished, they would be worse off than now.

Lord Norton said he must disagree with the last speaker as to the purity of the water turned into the river, and would send a sample of it for members to see, from Forge Mills.

Mr. Avory said the proper place to take a sample was at the outlet and not at Forge Mills.

Mr. Geo. Hurst (Bedford) said earth was the most effectual disinfectant they had, and sewage matter thrown upon it lost its smell. The question of storm-water was one that would have to be dealt with, and he believed that would only be by duplicate sewers. At

Bedford the sewage system was self-supporting, except the pumping, and had given every satisfaction.

Mr. Pritchard, in reply, said he was of opinion that at first the pan system presented great legal difficulties in Birmingham, but now the circumstances were altered. He did not say that lime was a complete agent; but thought it was a re-agent to be used in the process. With respect to storm-water, he maintained that it was impossible to prevent the storm-water carrying the sewage to the outfall unless they had duplicate sewers. In conclusion, he would say that no system would do for every town; each place must be governed by its own peculiar circumstances.

#### ILLUSTRATIONS OF RECENT PATENTS.

1,164, Improved means for Fastening Door-handles in their Spindles, &c. W. A. Gill, London.

Here the object is to avoid the frequent failure of the fastening as at present used, and to secure an efficient, simple, and cheap fastening for door-handles to their spindles. Fig. 1 shows a part

longitudinal section of the improved appliance. Fig. 2 is a back view of the rose, showing the slotted disc. This same slotted disc is also shown at fig. 3. Figs. 4, 5, and 6 give perspective views of handle

and rose with the square-slotted disc, which is one of the main features of the patent. One end of the spindle, *b*, is threaded and the other end left plain. To secure the knob *e* to this spindle *b* the spindle is passed through the door which is marked by *c* on the drawings (see fig. 1). At the other end of the spindle *b* it is made with a thread to correspond with the thread at its first end, and the face of the knob *e* is provided with a lump of metal, shown on fig. 4; when this is in position it abuts against the door when the knob is screwed on the spindle. Before the knob is screwed on, a rose, *g*, is slipped over the neck of the knob handle, *e*, and when the lump, *d*, is screwed up against the door a square-slotted disc or key, *f*, is slipped down between the face of the knob and the door; the slotted portion covering the spindle, *b*, which is square, and also the lump, *d*. The rose, *g*, is then screwed on to the door, and the fastening is complete. One knob may be attached permanently to the spindle, and the key, *f*, for cheapness may be stamped out of sheet iron.

3,878, Improved Water Waste-preventing Apparatus for Closets, &c. John Smeaton, London.

This invention is to control and prevent the waste of water as under the present system. To a water-closet a double valve is fixed on a supply-pipe with spindle and cup leathers to the said valves. When one of the valves is lifted, it allows the flush to the closet, and when released, the other valve regulates the after-flush, so that only a given quantity of water can pass at each operation. Between twin valves is a lever fixed on a centre between the two valves, free to move, and on the lever being actuated, it pushes up one valve by coming in contact with the spindle of it, and releases the other valve, which gradually shuts off. When the lever drops again, it pushes up the other valve, and the first-mentioned valve gradually drops. In our woodcut, *A* is the body of the valve; *B*, the valve; *C*, cup leather; *D*, *D*, guide for the spindles; *E* and *F* are the

spindles on the lever, *G*, to actuate the valve; *H* is the inlet; *J* is the pull acting on the lever in the manner described. In adapting his invention, the inventor particularises the closet he prefers, but with an "Eclipse" trap, as shown above the floor-line, the trap and valve box may be formed in one.

9,308, Improvement in Stove Grates. G. W. Chambers, York.

In an ordinary stove grate or range the fire passes up through the bottom grate into the fire, and supports the free combustion of the coal, while that which is called a slow combustion has a solid bottom of brick, stone, or iron. The ordinary stove grate or range may be converted into a slow-combustion by taking out the bottom grate and substituting a brick, which involves the removal of the whole of the fire; or by covering the bottom grate over with a loose iron plate, which is inconvenient, troublesome, and even dangerous; or by means of a tightly-fitting ash-pan, which is expensive and seldom satisfactory. This invention has for its object the immediate stoppage of the draught of air through the ordinary bottom grate, thus converting the stove grate or range into a slow-combustion, which may at any moment be turned again at will into a free-combustion without any difficulty or inconvenience. This is effected by raising an iron plate from below the ordinary bottom grate, so that it shall come into contact with it, and thus at once check or stop the draught of air through it. It is not necessary that it should be in immediate contact with the whole of the bottom grate; but only the rim or raised margin of the plate should be in contact with the outer portion of the bottom grate. The novelty claimed for this invention is the method of converting an ordinary stove grate or kitchen range into a slow-combustion one by raising an iron plate from below the ordinary bottom grate so that it shall so cover the under-surface of the bottom grate as to stop or check the draught of air through it, while retaining the power of restoring the fire to free combustion at will by again lowering the said plate.

#### THE DOME OF ST. PAUL'S.

Sir,—It is to me a new experience, in questions of art, to find myself at variance with my old and valued friend Mr. W. Cave Thomas. Nevertheless, I must demur to his plea, urged in your issue of the 13th inst. [p. 374], viz., that Thornhill's rococo monochromes on the cupola of St. Paul's should be accepted as the best art now available for its decoration. This, as a proposition, is startling enough; but it fairly takes one's breath to be told, further, that Thornhill's compositions should, for decorative effect, be translated into colour on fields of gold. It is just possible to imagine a person, more or less colour-blind, and imperfectly acquainted with art, pleading for the conservation, in their integrity, of Thornhill's floundering groups and distorted architecture in drab,—this in the interests of history. It is easier to comprehend an urgent desire for their total effacement in the interests of art.

To advocate the retention of such works, and, at the same time, the application to them of after-thought effects in colour and gold, for which they are intrinsically and hopelessly unfit, is only to offer a serious suggestion for their destruction under a humorous plea for their preservation.

JOHN R. CLAYTON.

#### PARTY WALLS.

Sir,—In reply to "Subscriber" [p. 408, ante], I think the Metropolitan Building Act contains what information is sought. If "Subscriber" owns the half of the party-wall, he has the right, so far as appears, to build on the party-wall, but subject to every liability in the Building Act detailed, if in London. HENRY AMBROSE.

Sir,—The law allows a party-wall to be raised; the addition to it does not prevent the lower part from retaining its original character. A. B.

\* \* \* Our correspondent of last week will find two articles on "Party-walls" in the *Builder* of May 8th and 15th, 1880, which contain a general summary of the law.

#### UTILISATION OF TIDAL POWER.

Sir,—In your issue of September 6th [p. 317] you were good enough to refer to the model which is now being exhibited by Messrs. Henry Greene & Son, of 155, Cannon-street, City, at the Health Exhibition, illustrating my proposed method of utilising the rise and fall of the tide to the particular purpose of the discharge of town sewage,—in which reference a doubt is implied as to the economical practical application of the invention. As the subject is admittedly one of great national importance, a word or two from the inventor explanatory of this part of the question may not be unwelcome to your readers. Your proposition is that the necessary works cannot be erected except at so large a capital outlay as to make the interest amount to a very heavy item in comparison with that chargeable on the first cost of steam pumping machinery, but I venture to think that your conclusion,—that the working expenses of steam power would probably fall short of that interest,—is somewhat premature. I frankly admit that I am unable to give an exact estimate of the cost of the works for places of such importance as London, Glasgow, or Liverpool, as we have not entered into such calculations, but there is no reason why the system should not be economically applied even to the largest of our cities. The cost of large installations is generally less in proportion than smaller works, but assuming a town with a population of 10,000, let us see what will be required. We will suppose the town in question to be situated on the coast, where a 20 ft. neap tide obtains, and that the sewage will run by gravitation to low-water mark, being thus tide-locked; the sewage must therefore be lifted so as to run out to sea. By my plan the cost for the necessary works would be under 5,000*l.*, which, at four per cent. interest, would be an annual charge of 200*l.* This estimate, being from a *bona fide* quotation from a firm ready to undertake the work, is indisputable. Moreover, as far as the mechanism is concerned, there would practically be no cost whatever. Now, as to steam-power. To erect and maintain in efficiency a steam-engine to raise the daily outfall of sewage (250,000 gallons) would incur an annual charge of not less than 300*l.* These facts speak for themselves.

C. MAYNARD WALKER.  
155, Cannon-street, E.C.

Metropolitan Drawing - Classes.—Lord Carlingford, K.P., has acceded to the invitation of Mr. W. Busbridge to deliver the Queen's prizes to the students of these classes. The meeting will take place in the Guildhall, on Monday, November 3rd, under the presidency of the Lord Mayor.

The Student's Column.

A SIMPLE LESSON IN PERSPECTIVE.

**M**OST students have been taught the ordinary rules of perspective, and many have drawn on a sheet of glass the perspective appearance of an object seen through it. The following process may perhaps assist them in connecting the rules with the appearance.

Place a sheet of paper on a level table. Fix up a ring, at the level of the eye, at the near edge of the paper, to look through. Hold up a sheet of glass vertically and facing the ring, half way across the paper. Place a match-box on the far end of the paper, opposite the ring, and nearly square with the glass, so that the right side of the box is just seen.

Draw a pencil line on the paper round the

and less of the surface of the glass, than it did when the ring was in its original position.

From those experiments it will be evident that a perspective view is regulated by the relative positions of the box (the object), the glass (the picture plane), and the ring (the station point).

Next draw a line right across the glass, still held in position, at the level of the ring. This is called the horizontal line.

Next continue the lines on the glass representing the right side of the box, and observe that they meet together; observe further that they meet on the horizontal line.

Make a dot at the point where they meet, this is called their vanishing point.

Now look through the ring and shift the box gently to the right, keeping it at the same angle to the picture plane, until its right side comes immediately under this vanishing point,

appearance on the glass, and observe that the right side still tends to the same vanishing point as before.

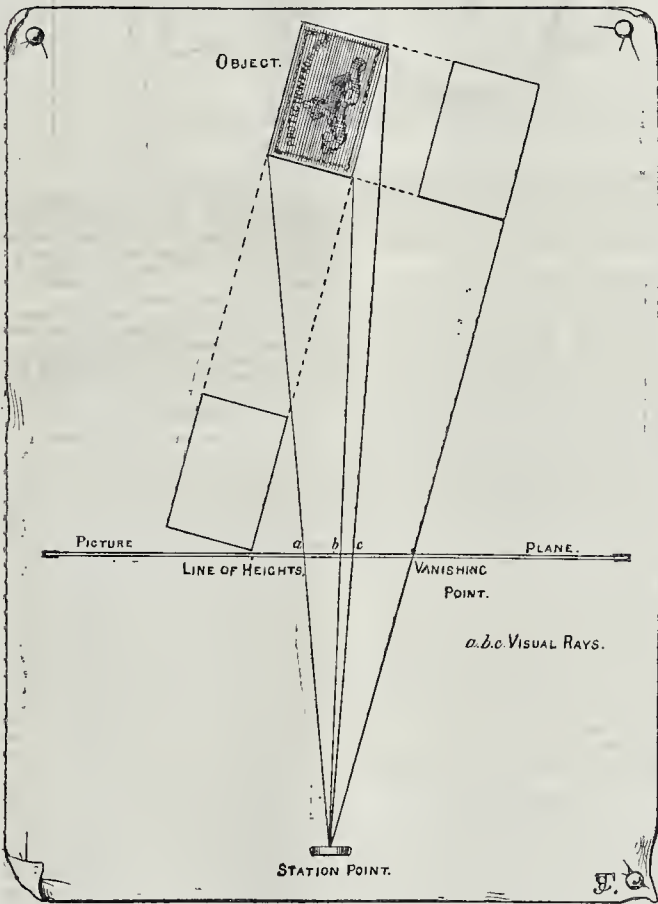

Therefore to find in perspective the height of any part of an object, bring the plan of it back to the picture plane, there set up a line called its line of heights, mark the height thereon, and then carry it back towards its vanishing point until it intersects its visual ray; which is the rule.

Books.

*Quantities: a Text-book for Surveyors, in Tabulated Form.* By BANISTER FLETCHER, F.R.I.C.E. Fourth edition, revised, with supplementary chapters. London: Batsford. 1884.

**A**BOUT four years have passed by since the publication of the third edition of Mr. Fletcher's book on "Quantities." In the interval he has sought for suggestions as to improvements, and having been requested to show a complete specimen of "taking off" has added Chapter V. This gives examples,—founded on five plates of a neat detached villa being erected under the author's superintendence. The brickwork of the front is taken off completely, and then the whole of the interior work of the drawing-room. The book contains now over 250 pages between cover and cover, and will be found to answer the author's modest wishes. It has proved, and will prove, useful in teaching the young practitioner, and the more mature may refer to it with satisfaction. It is perhaps not strictly necessary to repeat the statement we have frequently made, but it makes things safer to be precise, and to observe once more in this connection that there is no royal road to the possession of the knowledge, required for the satisfactory practice of the responsible and arduous profession of a quantity surveyor. He must be trained by long and persistent practice. Still, many people, who have no intention of regularly practising, want to know generally how things are done; and for them text-books, in some form or other, are indispensable.

As suggestions are invited, a few points of detail may be touched upon, mainly, of course, for the sake of the principles involved, in which we find ourselves generally at one with Mr. Fletcher. Instead of the saying, "If you want to be cured of the conceit of infallibility, make an index," standing as aforesaid, for the last three words should be substituted, "make a text-book." This author has evidently stood in no need of curing for a good length of time;—the form of the book, with five supplementary chapters, bears witness to this. One method in taking dimensions should uniformly be followed,—length, breadth, and then depth or height. On pages 15 and 31, for instance, there are slips, and the heights are misplaced. Under "Bricklayer," on page 18, and in Table II., Damp-courses generally are dealt with; but "Slate Damp-course" appears in Table IV., where Slate of all sorts is being treated of. The best rule would seem to be to follow Table II., and keep all damp-courses with the brickwork. On page 99 a figure is referred to as showing how to measure the girths of mouldings; the figure (No. 21, p. 55) in question shows, in fact, the shaping of the feet of rafters,—a diagram of the kind suggested might be useful. There is a slip on page 143 in telling "the student how to ascertain the number of slates required to cover a given area of roof"; the method happens, however, to be stated rightly on page 26, so that an active-minded person would be on his guard. In mentioning skirtings on page 65, the paragraph reads, "also state if the backings, or grounds, are intended to be included in the one item." This, as it stands, might easily be misread. The backings are usually included with the skirtings, and the grounds as usually taken separately, as indeed Mr. Fletcher recommends in Table VIII. All manufacturers do not fall in with the measurement of revolving-shutters (page 78) by the foot, super merely. They call for an allowance in the height, sometimes measuring from the oil to the top of the roller, and sometimes asking for a height of 1 ft. more than the opening. If in measuring paperhanging, as recommended on page 121, the number of superficial feet of wall space is divided by 60, there will not be sufficient allowance for waste in matching patterns in a good-sized room. Some surveyors divide by fifty-four instead of by sixty, that is, they make an allowance of one

bottom edge of the box, draw another line along the bottom edge of the glass, and mark a dot on the paper under the centre of the ring.

Look through the ring, and holding the glass quite vertically, draw upon it with a pen and Indian ink the appearance of the box (in other words, the intersection of the visual rays by the picture plane); this is best done by first marking dots at the corners, and then connecting them by lines in Indian ink.

Now shift the box nearer to, and farther from the glass, and observe that it appears respectively larger, and smaller than when it was in its original position.

Replace the box and shift the glass backwards and forwards, and observe that again the box appears, respectively larger and smaller than when the glass was in its original position.

Replace the glass and shift the ring backwards and forwards, and observe that again the box appears respectively larger and smaller (to speak correctly, that the box occupies more

and observe that the right side, as well as the continuation of it up to the vanishing point, now appear to be vertical.

While the box is in this position, mark its plan on the paper, and observe that if its right side be continued backwards through the picture plane it will touch the station point.

Conversely, a line parallel to the right side drawn from the station point to the picture plane gives the vanishing point for it; which is the rule.

What is true of the right side of the box is equally true of the front and back of the box, though their angle to the picture plane renders this more difficult to be proved by shifting the box about.

Now replace the box in its original position, and then draw it backwards, in a line parallel to its right side, until it touches the glass.

Mark its height on the glass, and observe that this is the actual height of the box.

While the box is in this position draw its

piece in ten; others are more liberal, and add one piece to the amount for every seven. Fixing smith's work in connexion with carpenter's work is best included in the Carpenter's Bill as suggested in Table VII.; but the ironwork must be in the Smith's Bill with a special note to the effect that the fixing has been put in the carpenter's bill. In Table IX. (Smith's Bill) we have "wrought iron in straps and ties; bolts and ties; bolts, &c. (including fixing),"—which would result in the fixing coming twice into the estimate. With reference to patterns for casting there is some doubt whether the recommendation on p. 93 should be followed. It is stated there that, when the patterns are taken separately, they should be billed with the carpenter. Good custom can be quoted against this, and practical convenience may be alleged also as a reason for making each pattern follow directly after the castings for which it is made. Estimates from founders are frequently arranged also as to the patterns. "French polishing, where described in the specification, must also be included in the description in the bill of the joiner's work" (p. 85). There is no objection to this; indeed, the course is that frequently,—perhaps that most frequently,—pursued. But at pp. 116, 117, and again in the specimen of a fair bill, at p. 176, the polishing is grouped under "Painter." In Chapter V., in the example of taking off, "Pay a b," and appear out of a clear sky; the abbreviations in "Painter," p. 133, would, indeed, supply a clue to the latter sign, if "the student" had the good luck to look in the right place; but he might be guided there, or the abbreviations might have been scattered about more plentifully in the specimen.

Too much importance may, however, be easily attached to minutiae; they may, at any rate, serve to show that a diligent examination of the book has been made. One or two *obiter dicta*, not especially connected with "quantities," may be referred to. The clause in the preamble of Smith and Fonder (page 173),—"All girders to be tested to half their breaking-weight at the contractor's expense,"—would not meet with universal approval, a test of more than one-third of the breaking-weight for cast iron meets with strong objection. "Number the D-traps" on page 110, and their innocent intrusion into Table XIII., might be resented by earnest sanitarians,—who do not willingly see those objectionable articles mentioned as among the possibilities of ordinary life. The instruction on page 111 to state the number of the gauge of the zinc would also meet with objections, as would the provision (on page 112), of No. 13 for flats, and No. 12 for gutters. The weights of zinc have been put in such confusion, owing to the changes in the gauges, that no one ought now to specify the gauge, but the weight per foot only. Mr. Fletcher gives, at p. 151, a list of weights according to the old Belgian gauge; the present No. 13 gauge of the Vieille Montagne Company is 17 oz. to the foot against 19.56 oz. as aforesaid and in that table. In the summary of the fair bills (page 178) the surveyor's charges are given as 24 per cent.,—which may be correct for that case. The general understanding, however, is that 2½ per cent. is to be charged for very small or very difficult works, and 1½ per cent. for ordinary works. If we pursued this, however, we might possibly be led a good way from our original purpose,—which was merely to call attention to the publication of a new edition of Mr. Fletcher's very useful Text-book.

Miscellanea.

**An Alleged New Motive-Power.**—A discovery of particular value in the engineering world is just announced in the form of a new motive power. The discovery is due to Mr. Edwin Sturge, who has patented its mode of application. It is claimed that for all purposes of light locomotion, or for driving light machinery, it will eventually displace steam. Private experiments of the new motive power are stated to have proved very satisfactory, and arrangements are being made to give it a public trial.

**A New Font** has been placed in the Earl of Zetland's private chapel at Ask Hall, from designs by Messrs. Clark & Moscrop, architects, of Darlington. The work was executed by Mr. Ralph Hedley, of Newcastle-upon-Tyne.

**Birkbeck Literary and Scientific Institute, Bream's-Buildings, Chancery-lane.**—The prospects for the sixty-second session of this, the parent and largest, institution has just been issued. The inaugural address will be delivered by Professor Tyndall. The new building, the foundation-stone of which was laid by the late Duke of Albany, is now completed, and provides superior accommodation for 6,000 students. The new institution has been erected for the special purpose of enabling the extensive educational work to be carried on with comfort and efficiency, and we are glad to hear that great attention has been paid to lighting and ventilation. The long list of classes includes languages, mathematics, natural, applied, and mental science, technology, art, music, law, literature, &c. Special attention has been paid to the establishment of practical classes in many of the subjects, and the chemical and biological laboratories have been thoroughly fitted up. The spacious art room will afford unusual facilities to the students of the School of Art, which will open at the commencement of the session. The classes will not, as heretofore, be restricted to the evening. In many of the subjects morning and afternoon classes will be held. The large lecture-hall seats 1,200 persons. We regret to observe that the sum of 6,500*l.* is still required to complete the payment for the building. This amount should be at once cleared off by the contributions of those who support the great cause of education, to which this institution has rendered unique service. Amongst the recent donors is her Majesty the Queen, who has sent 50*l.* to the fund. The bankers are Messrs. Smith, Payne, & Smith, Lombard-street.

**Conference of Plumbers.**—The conference of plumbers held at the Health Exhibition on Friday divided its labours into the following sections:—1. The technical instruction of plumbers. 2. Apprenticeship, the duration and condition of indentures suited to the present state of the plumbing trade and to the modern system of technical instruction. 3. The establishment of metropolitan and provincial boards of examiners of plumbing work. 4. The registration of journeymen plumbers. 5. The suitability of materials used in plumbing, and particularly of those materials recently introduced as substitutes for lead. 6. The desirability of fixing upon a system by which uniformity in the quality of material used in plumbing may be insured. 7. The formation of district associations of plumbers to investigate and secure, as far as practicable, correction of evils and abuses arising in connexion with the trade. 8. A general and executive committee to be formed for the purpose of receiving reports from district associations of plumbers and others, with a view to the preparation of a general report by the Plumbers' Company, to form the basis for an appeal to Parliament for necessary amendments and extensions of the law relating to plumbers' work under the Building and Health Acts, and otherwise.

**Evening Classes in Metallurgy and Fuel at King's College, London.**—We understand that, in addition to the usual course of evening lectures in connexion with Prof. Huntington's Department, which will be given this session on Mondays from eight to nine, upon the "Properties of Metals and Alloys, and their Uses in the Arts," Mr. W. G. McMillan, the Demonstrator in Metallurgy, will give a new course treating of "Fuel and its Applications," from seven to eight on the same evening. These lectures are designed to be of assistance to intending candidates for the examination of the City and Guilds of London Institute in Metalplate Work, Plumbing, and Iron and Steel, and in Fuel respectively. The first meeting of the classes will be on the 6th of October. The laboratory for practical work is open to evening students on Friday from seven to nine, and will remain open as usual every day during College hours, alike for occasional students and for members of the Engineering Department, &c., of the College.

**International Health Exhibition.**—We have received the third edition of the Official Catalogue, which is much bulkier than the previous editions. It contains an elaborate Subject-Index to the exhibits of the United Kingdom, and considerable additions to the Foreign Section of the Catalogue; the most important of these being the extensive contributions made at a somewhat late period by the Japanese Government.

**The New Offices for the "Daily News."** The extensive premises which for some months past have been in course of erection in Bouverie-street for the proprietors of the *Daily News* are making good progress towards completion. The new buildings cover a ground area of about 10,000 superficial feet, some buildings adjoining the old premises having been acquired to enlarge the site. The Bouverie-street elevation is about 100 ft. in length, and upwards of 70 ft. in height, presenting a bold and massive façade. The ground-floor portion of the frontage, which is very lofty, is faced with Portland stone, having a commanding central entrance about 20 ft. in height, surmounted by an elliptical arch and pediment resting on massive corbels. On each side of the entrance, and architecturally uniform with it, there are three arched windows, each window being divided by circular columns and capitals. The upper portion of the frontage, containing two lofty floors, is faced with red brick and Mansfield stone, relieved by carvings. The building extends back for upwards of 100 ft., that portion of the structure in the rear of the frontage showing three and four floors above the ground line. In the centre there is an area or well admitting of an abundance of light to the numerous rooms and apartments on the several floors of the building. This is inclosed by a lantern light, in which are placed a number of ventilating shafts. The principal entrance leads into a spacious hall or vestibule, on each side of which are the advertisement and general business offices. A wide stone staircase leads to the upper floors, containing the editors', reporters', and other offices. The composing-rooms are amongst the largest apartments in the building. The works have been carried out without disturbing the greater part of the machinery in the basement of the old building. Mr. T. Chatfield Clarke is the architect, and Messrs. Brown, Son, & Blomfield are the contractors, Mr. Crossley acting as clerk of the works.

**New Post-Office Buildings at Tooting.**—The Government are erecting new district post-office buildings on a vacant plot of ground in Lower Tooting, a short distance from the High-street. The building has a frontage to the main high road 33 ft. in length, with a return frontage 60 ft. in depth, thus covering a ground area of about 2,000 superficial feet. The building is faced with red Bracknell brick, with Portland stone cornice, &c. The façade is upwards of 30 ft. in height, terminating with a gable, and is covered in with a high-pitched roof. The principal room in the building is a spacious sorting-room, 40 ft. long and 30 ft. broad, which is lighted by three lofty windows in the principal frontage, and four similar windows in the return elevation, in addition to a lantern-light in the ceiling. Adjoining is a receiving-office and other offices for the transaction of general post-office business. At the rear of the building is a kitchen and other domestic offices, together with sheds for post-office vehicles. The building is being erected from the designs of Mr. Williams, of her Majesty's Office of Works. Mr. Joseph Dowry, of High-street, Brentford, is the contractor, and Mr. S. Novel is foreman of the works.

**Architecture at University College.**—The opening lecture of the courses at University College, London, on Architecture, Construction, and Professional Practice, will be given by Professor T. Roger Smith on Friday, the 3rd of October, at six p.m. Admission free. The subject of the lecture is "The Wall as an Architectural Feature, including the Gable and the Tower."

**Architectural Association.**—The opening *conversazione* of Session 1884-85 will be held in the galleries of the Royal Institute of Painters in Water Colours, Piccadilly, on Friday, Oct. 10.

TENDERS.

For Willenden main drainage, Mr. Claud Robson, engineer.		
Beadle Bros.	£25,614	0 0
Rogers & Dickens	25,600	0 0
Movlem & Co.	25,200	0 0
A. Oliver	25,000	0 0
Bottoms Bros.	24,200	0 0
Jas. Dickson	24,168	0 0
J. Mears	23,920	0 0
J. W. & T. Newb	23,540	0 0
Novell & Robson	23,470	0 0

B. Cook & Co.	22,830	0 0
Killinghall	22,800	0 0
Neave & Son	22,600	0 0
Sanders	22,300	0 0

Accepted, the schedule of the lowest tender being too high.

COMPETITIONS, CONTRACTS, & PUBLIC APPOINTMENTS.

Epitome of Advertisements in this Number.

COMPETITIONS.

Table with 5 columns: Nature of Work, By whom required, Premium, Designs to be delivered, Page. Includes College at Norwich.

CONTRACTS.

Table with 5 columns: Nature of Work, By whom required, Architect, Surveyor, or Engineer, Tenders to be delivered, Page. Includes New Offices, Bewick-street, Newcastle.

PUBLIC APPOINTMENTS.

Table with 5 columns: Nature of Appointment, By whom advertised, Applications to be in, Salary, Page. Includes Surveyor.

For the erection of three houses and shops at Upton Park, Essex, for Messrs. Hopwood & Son. Mr. John Hudson, architect, 80, Leman-street, E. Quantities by Mr. C. Stanger.

For repairs and decorations to Pontypool Wesleyan Chapel, Mr. E. A. Lansdowne, architect:— Dando & Son, Newport, £284 15 0

For the construction of pipe sewers, receiving tank and engine houses, engines and pumps, formation of irrigation area, &c., at Glaines (Worcester):— Thomas Adams, London, £7,982 0 0

For additional stabling, High-street, Bromley, for the London General Omnibus Company, under the superintendence of Mr. G. T. Lanham. Quantities by Mr. A. J. Bolton.

New residence at Glifans, near Crickehowel, Brecknockshire, for the Rev. Wm. Henry West. Messrs. Broome & Gill, architects, Bath. Quantities by Mr. B. W. Pope, Bristol.

For alterations, &c., to premises at rear of No. 157, King-street West, Hammer-smith, for Mr. W. Foss. Mr. T. Woodbridge, Biggs, surveyor, £285 0 0

For building offices and warehouses, Mill-street, Kidderminster, for Messrs. R. Smith & Sons:— C. Claridge, London, £3,849 0 0

For alterations, repairs, &c., to the Seven Sisters Public House, Tottenham, Mr. E. Clark, architect:— W. Ovan & Son, £273 0 0

For building a billiard-room, and for alterations, at the Conservative Club, Llanelli. Mr. J. Buckley Wilson, 15, Castle-street, Swansea, architect:— G. Davies, London, £339 0 0

For rebuilding premises after fire at 64, Mare-street, Hackney, for Mr. Chopping. Mr. H. R. Allen, architect, 50, Finsbury-square:— Warr, London, £1,112 0 0

For establishing, &c., at the Railway Tavern, Herea Hill, Mr. S. C. McMeekin, architect:— W. D. Palmer, £349 12 0

For alterations, repairs, &c., to the Seven Sisters Public House, Tottenham, Mr. E. Clark, architect:— W. Ovan & Son, £273 0 0

For works at Llansaintffraid Church, Breconshire, Mr. S. W. Williams, architect, Rhayader:— Williams & Son, Brecon, £3,063 0 0

For the erection of school buildings at Charlotteville, Guildford. Mr. W. G. Lower, architect:— Colls & Sons, Dorking, £5,876 0 0

For additions to the Scottish Club, Dover-street, Piccadilly, W., for Lieut.-Col. Gordon Alexander. Mr. B. F. Loftus Brock, F.S.A., architect:— Hall, Boddall, & Co., £2,620 0 0

For alterations to buildings, No. 1 to 5, Cedars-terrace, Lavender Hill, for converting same into shops. Mr. Zeph. King, architect:— Gerrard & Son, £915 0 0

Accepted for the making up of private roads within the district of the Horesey Local Board, Mr. T. de Courcy Meade, engineer and surveyor:— Oakfield-Road, £260 14 3

Accepted for the erection of new infants' schools at Norbiton, Kingston-on-Thames, Mr. C. L. Luck, architect:— Jarvis, £1,315 0 0

Accepted for new farm buildings at Over Dinades, Darlington, for the executors of the late Mr. Charles Henry, Messrs. Clark & Moscrop, architects, Darlington. Quantities supplied:— T. Boyd, Cleasby (bricklayer and tiler) £372 7 7

For new counter and piewtering at the White Hart, King's-road, Chelsea, for Mr. J. J. Pope. Mr. J. Miller, architect:— J. Warr, £119 17 0

For photographic studio, High-street, Dorking, for Mr. W. G. Fenn. Mr. Frederic W. Ledger, architect, London:— F. G. Hammond, Dorking, £471 4 2

For additions to two cottages, East Malden, near Er-mouth, for Admiral Sir G. P. Hornby, K.C.B. Mr. J. Newman, architect:— George Blackmore (accepted), £185 0 0

For re-building and re-internalisation in Jerusalem-court, St. John's-square, Clerkenwell, for Mr. Thomas Capps. Mr. Henry John Hanson, architect:— Tertle & Appleton, £295 0 0

\* Subsequently stated had made an error of 100l. in estimate.

For taking down and re-erecting portions of the parapet walls, &c., at the St. Marylebone Workhouse, for the Guardians of the Poor of the Parish of St. Marylebone. Messrs. H. & A. Snell & Son, architects, 22, Southampton Buildings, W.C.—

Table with 2 columns: Name and Amount. Includes J. Webb (£185 0 0), W. Bamford (170 0 0), and others.

For the erection of a Bible Christian Chapel, Whitwell, Isle of Wight. Mr. James Newman, architect. Quantities supplied:—

Table with 2 columns: Name and Amount. Includes A. Newham (£213 0 0), Creeth & Jacobs (57 0 0), and others.

For sanitary works and alterations at the Poplar and Stepney Sick Asylum, Devon-road, Bromley, Middlesex. Messrs. A. & C. Harston, architects:—

Table with 2 columns: Name and Amount. Includes Gardner (£1,450 0 0), Holland (1,395 0 0), and others.

For repairs and alterations to Nos. 315 and 317, Oxford-street, W., for Mr. Patrick Ness. Messrs. Harris, Vaughan, & Jenkinson. Mr. R. T. H. Stoneham, architect, 6, Moorgate-street, E.C. Quantities by Mr. O. Jackson, West Brighton:—

Table with 2 columns: Name and Amount. Includes E. Conder (£3,995 0 0), Ashby Bros. (3,861 0 0), and others.

Ironwork. Messrs Brothers & Co., London ... 466 0 0. Granite. A. Macdonald & Co., Aberdeen ..... 895 10 0 [Four tenders.]

Residence and Stables, Monkton Combe.—Messrs. Pack Bros. write to say that the amount of their tender was £4,476, not £4,678 as stated last week.

Lists not vouched for by Senders.—We have received, in an envelope bearing the Reading post-mark, a list of tenders which is not accompanied by the name and address of the sender, and which is therefore excluded. The attention of correspondents is respectfully requested to our standing notice that all lists of tenders and other communications must be accompanied by the name and address of the senders, not for publication, but as an extract of good faith. Non-observance of this rule on the part of correspondents frequently compels us to omit communications of importance.

Special Notice.—Lists of tenders frequently reach us too late for insertion. They should be delivered at our office, 48, Catherine-street, Strand, W.C., not later than four p.m. on Thursdays.

TO CORRESPONDENTS.

O. B. D.—W. O. S.—W. G.—H. & C. D. & Co.—H. B.—A. B.—J. J. R.—S. J. N.—E. C.—V. B. (had better say his complaint before the Vestry).—W. H. H.—E. G.

All statements of facts, lists of tenders, &c., must be accompanied by the name and address of the sender, not necessarily for publication.

We are compelled to decline pointing out books and giving addresses.

Note.—The responsibility of signed articles, and papers read at public meetings, rests, of course, with the authors.

We cannot undertake to return rejected communications.

Letters or communications (beyond mere news-items) which have been duplicated for other journals, are NOT DESIRED.

All communications regarding literary and artistic matters should be addressed to THE EDITOR; all communications relating to advertisements and other exclusively business matters should be addressed to THE PUBLISHER, and not to the Editor.

PUBLISHER'S NOTICES.

CHARGES FOR ADVERTISEMENTS. SITUATIONS VACANT, PARTNERSHIPS, APPOINTMENTS, TRADE, AND GENERAL ADVERTISEMENTS. Six lines (about thirty words) or under ..... 4s. 6d. Each additional line (about ten words) ..... 6s. 6d.

FOUR LINES (about THIRTY words) or under ..... 2s. 6d. Each additional line (about ten words) ..... 6s. 6d. PREPAYMENT IS ABSOLUTELY NECESSARY.

Advertisements for the current week's issue must reach the Office before THREE o'clock p.m. on THURSDAY. The Publisher cannot be responsible for DRAWINGS, TESTIMONIALS, &c. left at the Office in reply to advertisements, and strongly recommends that of the latter COPIES only should be sent.

SPECIAL.—ALTERATIONS IN STANDING ADVERTISEMENTS OR ORDERS TO DISCONTINUE same, must reach the Office before TEN o'clock on WEDNESDAY morning.

PERSONS Advertising in "The Builder," may have Replies addressed to the Office, 48, Catherine-street, Covent-garden, W.C. Free of charge. Letters will be forwarded if addressed envelopes are sent, together with sufficient stamps to cover the postage.

TERMS OF SUBSCRIPTION.

"THE BUILDER" is supplied direct from the Office to residents in any part of the United Kingdom at the rate of 12s. per annum, PREPAID. To countries within the Postal Union, 20s. per annum. Remittances payable to DOUGLAS FOURDRINER, Publisher, No. 48, Catherine-street, W.C.

Best Bath Stone. WESTWOOD GROUND, Box Ground, Combe Down, Corsham Down, And Farleigh Down. RANDELL, SAUNDERS, & CO., Limited, Corsham, Wilts. [Adv.]

Box Ground Stone. Is the Best for Use in all Exposed Positions, being a well-known and tried Weather Stone. 50,000 feet cube in stock. PICTOR & SONS, BOX, WILTS. [Adv.]

Doubling Freestone and Ham Hill Stone of best quality, in blocks, or prepared ready for fixing. An inspection of the Doubling Quarries is respectfully solicited; and Architects and others are CAUTIONED against inferior stone. Prices, delivered to any part of the United Kingdom, given on application to CHARLES TRASK, Norton-sub-Hamdon, Ilminster, Somerset.—Agent, Mr. E. WILLIAMS, 16, Craven-street, Strand, W.C. [Adv.]

Doubling Free Stone For prices, &c., address S. & J. STAPLE, HAM HILL STONE, Quarry Owners, Stone and Lime Merchants, Stoke-under-Ham, Ilminster. [Adv.]

Asphalte.—The Seyssel and Metallo Lava Asphalte Company (Mr. H. Clou), Office, 88, Poultry, E.C.—The best and cheapest materials for damp courses, railway arches, warehouse floors, flat roofs, stables, cow-sheds and milk-rooms, granaries, tan-rooms, and terraces. [Adv.]

Asphalte. Seyssel, Patent Metallo Lava, and White Asphaltes. M. S T O D A R T & C O. Office: No. 90 Cannon-street, E.C. [Adv.]

J. L. BACON & CO.,

MANUFACTURERS OF IMPROVED STEAM AND HOT-WATER APPARATUS, FOR WARMING AND VENTILATING Private Houses, Churches, Schools, Hospitals, Manufactories, Greenhouses, &c.

OFFICES AND SHOW-ROOMS: No. 34, UPPER GLOUCESTER PLACE, DORSET SQUARE, LONDON, N.W. And at DUBLIN, BELFAST, GLASGOW, and NEWCASTLE. Illustrated Pamphlet on "Heating" post free.

EMPLOYERS' LIABILITY ACCIDENTS. RAILWAY AND MARINE ACCIDENTS. GENERAL ACCIDENTS. ALL ACCIDENTS DURING EMPLOYMENT. FIDELITY GUARANTEES.

THE EMPLOYERS' LIABILITY ASSURANCE CORPORATION (Limited). Nos. 84 and 85, King William-street, London, E.O. Capital, 1,000,000. Fully subscribed, 600,000. Paid up, 100,000. Names of Workmen not required; premium charged on total wages at 2s. per cent. and 5s. per ann. Protection granted during issue of Policy. Reduced rates for GENERAL ACCIDENTS with bonus on all renewals. Collective Fidelity Guarantee Policies for any number of persons. Applications for Agencies invited. S. STANLEY BROWN, General Manager.

GUARDIAN FIRE AND LIFE OFFICE. Head Office—11, Lombard-street, London, E.C.; Law Courts Branch—51, Fleet-street, E.C. Established 1821. Subscribed Capital, Two Millions. DIRECTORS: CHAIRMAN—ALEXANDER G. H. OSMER, Esq. DEPUTY-CHAIRMAN—BRAUNTON W. LUDGEC, Esq. Rowland Nevill Bennett, esq. George Lake, esq. Henry Boulton-Carter, esq. H. Hon. G. J. Shaw Lefevre, M.P. Charles F. Devas, esq. John B. Martin, esq. Sir Walter R. Farquhar, bart. S. Hugo Morley, esq. James Goodwin, esq. Henry John Norton, esq. John J. Harcourt, esq. David Powell, esq. Thomson Mackay, esq. Augustus Frowde, esq. Richard M. Harvey, esq. John O. Tolbot, esq. M.P. R. Hon. J. O. Hubbard, M.P. Henry Vigne, esq. JOHN HUNTER, Esq. MANAGER OF FIRE DEPARTMENT—F. J. MARSDEN. ACTUARY AND SECRETARY—T. O. C. BROWN. Share Capital at present paid up and invested ... £1,000,000 Total Funds upwards of ... £3,803,000 Total Annual Income ... £725,000 N.B.—Fire Policies which expire at MICHAELMAS should be renewed at the Head Office, or with the Agents, on or before the 14th day of OCTOBER.

THE BUILDERS' ACCIDENT INSURANCE, LIMITED.

Particular attention is called to the STRICTLY MUTUAL character of this Office, which is established for the benefit of the Trade. At the Annual Meeting, on the 30th July, a further Bonus of 12 1/2 per cent. was declared on all premiums paid during the year ending the 31st May, 1884, payable to all Insurers on renewal of Policies. Intending Insurers are requested to apply for prospectus to the secretaries as under:— Mr. E. S. HENSHAW, 27, King-street, Covent Garden, W.C. Mr. WM. KNOX, 6, Lord-street, Liverpool. Mr. W. H. PHILLIPS, 1, Small-street, Bristol. [Insurance Companies see also p. xviii.]

CHAPPUIS' PATENTS FOR REFLECTING LIGHT.

DAYLIGHT REFLECTORS OF EVERY DESCRIPTION, ARTIFICIAL LIGHT REFLECTORS.

WHY BURN GAS?—CHAPPUIS' REFLECTORS DIFFUSE DAYLIGHT.—They are exclusively adopted by and fitted at Buckingham Palace, all H.M. Government Offices, Houses of Parliament, H.M. First Commissioner of Works, the Metropolitan Board of Works, British Museum, South Kensington Museum, Royal Institution, Guildhall Museum, on board H.M. Ships, also Railway Companies' Offices, Hospitals, Institutions, Banks, Insurance Offices, Manufactories, Private Houses and generally from Noblemen's Mansions to Artisans' Workshops. 30,000 in use in London alone. Patronised by leading Architects, Engineers, Contractors, &c., &c.

N.B.—For Prospectuses and Diagrams, address Stamped Envelope to P. E. CHAPPUIS, Patentee and Manufacturer, 69, FLEET-STREET, LONDON.

NOTICE.—THE POLYGONAL REFLECTOR (Latest Patent) FOR ARTISTIC and PICTURE GALLERIES. Its construction allows of the angle of light being readily altered so as to reflect in any desirable direction. N.B.—On View at HEALTH EXHIBITION (Eastern Gallery).

### Sanitary and Realistic Dublin.\*

WITH the exception of a few leading thoroughfares and squares, decay and dilapidation are making marked progress, not only in the very heart of Dublin, but in once fashionable districts north and south of the Liffey, on the borders of the old municipal boundary. Trade has completely deserted many of the streets where it flourished a quarter of a century ago; wealthy merchants and prosperous traders have disappeared in scores from their old haunts, and their extensive premises have undergone strange transformations, to suit the exigencies of a smaller class of traders, who, in many instances, are engaged in a life-and-death struggle throughout the year to keep their heads above the water. The seat of the Vice-Regal Government even is getting hemmed in by decayed streets of houses which threaten at no distant date to form a complete cordon round Dublin Castle, if no industrial revival takes place in the meantime to check the downward ruin that appears to be steadily making headway. The only redeeming feature to the dismal picture is in the growth of the townships and suburbs north and south of the city,—but particularly on the south side,—to which places many hundreds of the well-to-do families, who formerly resided in private streets in the city, have removed. Many of the city traders and shopkeepers who have lost their best customers still struggle on, while many more have followed in the wake of those who patronised them, and commenced business in the fashionable suburbs. The taxation in the city is very high, and the Corporation, partly conscious at least of the tide of decay that is setting in, or has already set in, have been contemplating for some time past the obtaining of powers to absorb some of the more immediate townships in a new city boundary, and of rendering the well-to-do inhabitants of these localities amenable to city taxation. It is argued that a large number of the township residents derive their income through business and appointments in the city, and that they should be made to contribute to the cost of the administration and improvements necessary to its well-being. The spectacle of a rapidly decaying capital is anything but a cheering sight, particularly when the decay is real and manifest. Several plagues from the thirteenth to the nineteenth century made their appearance in Dublin, including the two serious

cholera visitations of 1832 and 1849. We are told of one which occurred in the sixteenth century which was so severe that the majority of the inhabitants and their rulers took flight into the suburban districts, some of the people even removing to small islands in the bay. Grass, says the historian, grew in the streets of the city, they became so desolated; but we fear there is a likelihood of grass again growing in the streets of Dublin without the intervention of any epidemic, but through causes we have indicated. It is a thousand pities that a city still reflecting in the architecture and art of her old public buildings the grandeur and prosperity of a happier era, should be so stricken with the paralysis of decay. Dublin, unlike what she was of old, has now little trade, her greatest industries being the manufacture of whisky and porter, and unfortunately her own sons are among the greatest consumers.

In some former notes we alluded to the wretched condition of the tenement houses of Dublin, and to the need of a class of dwellings suited to the wants of the very poor, comprising a large and very miscellaneous class of workers of both sexes, many of whom eke out life by uncertain employment. It is but justice to the Superintendent Medical and Executive Officer of Health, who is also City Analyst, to say that he has more than once urged upon the Corporation the necessity of providing dwellings for the poorer classes, mainly because the Public Health Committee, by its action, led to the clearing of many hundreds of houses within the last few years which had been totally unfit for human habitation.

The leases of some Corporation property in a locality in the north-west part of the City having recently fallen in, a clearance of an area of houses of a very bad kind was determined upon, in view of carrying out a street improvement. On a portion of this cleared area in Barrack-street the Corporation have agreed to erect a block of dwellings for workmen of the poorer kind. A loan of 50,000*l.*, for the purpose of providing dwellings has been sanctioned by the Civic Council, and it was proposed to expend a sum of 25,000*l.* this year. Municipal intentions are sometimes very good, but Corporate projects take a long time before they are realised in Dublin. New street openings and improvements promoted several years ago are not practically begun yet; still, we shall be pleased to hear of the commencement and completion of the proposed block of workmen's dwellings in the Oxmantown district, with a repetition of the same work for other poor quarters of the city north and south.

Forbidding-looking and barrack-like blocks of houses have been erected for workmen by

artisans' dwellings companies some time back in Buckingham, Ebleen, and other streets in the northern and southern parts of the city, but from an examination of them we can say little in their favour, either on the score of room-space, comfort, or amount of rent. The houses, however, erected on the area cleared in the Coombe district, and leased to an artisans' dwellings company, form an exception to the usual class of industrial dwellings. On this area are built four classes of houses,—one-story cottages, containing one living-room and one bedroom; cottages containing one living-room and two bedrooms; two-story cottages, containing two living-rooms and two bedrooms; and again some containing one large sitting-room and two bedrooms. The first two classes are built of Portland cement concrete, the front walls being 8 in. thick. The third kind have front walls of red brick, and partitions and yard walls of concrete; and the fourth class have front and end walls of brick, and the remainder in concrete. Sanitary accommodation and other requirements have been fairly provided for in the houses erected on the Coombe area. For the two classes of one-story cottages, the rents charged are respectively 3*s.* 6*d.* and 4*s.* per week; 6*s.* 6*d.* and 7*s.* for the four-roomed two-story houses; and 5*s.* 6*d.* for the three-roomed houses. Six out of the 210 houses in this area are used as shops, and the remainder by tenants of various trades and callings. The rental received for these 202, excluding those used by caretakers, is 2,680*l.* per annum, and we were informed that bad debts are practically non-existent.

The Coombe district before the commencement of the present century was a prosperous locality, occupied to a great extent by silk and cloth merchants, and a thriving weaving trade flourished there for many years, founded by a Huguenot settlement. This south part of old Dublin has gradually decayed, and ruin and squalor are now widespread over a district once ripe with opulence and trade. The clearance made for the erection of the cottages we have described has led to the improvement of that particular portion of the district. Some years ago the Government valuation of the Coombe area was only 424*l.*, and average total rates paid yearly, taking the three years ending in 1878, amounted to only 63*l.* At present the valuation is 1,429*l.* 15*s.*, and the total rates paid in 1883 amounted to 611*l.*

The clearances of areas for improvements are costly not only in London, but, allowing for the altered condition of matters, in Dublin they are also costly. Preposterous claims are put forward by landlords and tenants in respect to a class of house property which, if the Sanitary Acts were rigidly enforced, would have been

\* See p. 371, ante.

declared unfit for habitation. A nominal sum would be amply sufficient compensation for a large number of landlords who own wretched tenement property, and who systematically neglect for years to expend a shilling in repairs or in the abatement of the nuisance their neglect occasions. Another unhealthy area, known as the Plunket-street area has recently been cleared by the Corporation, and is ready for building operations. A portion of this area could also be utilised for the erection of workmen's dwellings or houses for the very poor. Over-crowding exists still to a considerable extent in tenement houses, and particularly in the houses in back streets, lanes, courts, and alleys north and south of the Liffey. The large back offices, coach-houses, lofts, and stable buildings attached to houses that were once and not many years ago occupied by wealthy private families have in various quarters been converted into dwellings, and are tenanted by the poor. The passers-by in the front streets are, for the most part, unconscious of colonies of such a class of poor dwellers in their midst, yet in whom stable buildings many hundreds of these vegetate and die, starving on one meal a day, and hiding their rags on Sunday. Indeed, the old proverb is still true to the letter, that "One-half of the world does not know how the other half lives"; and in many cases we fear we might add, does not care to know.

The Artisans' Dwellings Company, we may observe, are erecting a large number of cottages, having procured sites at Portobello, Harold's Cross, and Rutland-street. We examined a number of these short streets of cottages situated on the banks of the Grand Canal at Portobello. Some of these two-storied cottages have only three rooms, one on the ground-floor, and two above. The four-roomed cottages are 8s. per week, and the three-roomed 6s. The walls are chiefly of concrete, the fronts alone being of red brick. Though an improvement on the ordinary class of tenement dwellings, we consider these cottages are deficient in necessary domestic accommodation in respect to wash-houses, scullery, &c., provided in industrial dwellings in London and suburbs. The rents are also two high for the accommodation provided, and this is particularly the case in respect to the three-roomed cottages. We do not admire the planning of these cottages. When the door is opened (we will not say hall-door, for there is no hall), the fireplace, and nearly the whole room, is exposed to the sight of each passer-by without. It is somewhat remarkable that Irish cottage dwellers, whether living in the streets of a town or in a straggling country village, are fond of keeping their front-doors open even after nightfall.

Considering the very large number of tenement houses that exist all over the city, once in the occupation of private families, the question may be asked, is it not possible to make structural alterations in hundreds of these houses, and fit them for the needs of the industrial and working classes? Without any expensive structural alteration, save by the provision of necessary sanitary accommodation, a large number of these tenement houses could be made suitable for the healthy and comfortable habitation of the industrial poor. Of course there are hundreds of these tenement houses so dilapidated, and so fouled and impregnated with the seeds of disease, that no system of reparation could effect their cure. As they are a standing menace to the public health, their demolition is called for. The number of houses unfit for decent habitation in Dublin probably falls little short of 10,000; and in respect to these a very moderate estimate of the number of persons contained in them would run the figures up to 100,000. If even this number of persons have to be housed in a healthy manner, what machinery exists for doing it? Is the Corporation of Dublin willing to do its share in the work of properly rehousing the poor? When, we would ask, will the Artisans' Dwellings Company meet the urgent want? This company tells the public that when they have completed their present arrangements they shall have covered with buildings nineteen acres of ground, and accommodated nearly 6,000 persons. It would take

a dozen of artisans' dwellings companies working for several years to provide for the admitted want; but, at the same time, it is not desirable that Dublin should be converted into a city of artisans' dwellings, and that the Corporation and citizens should close their eyes to the fact that miles upon miles of streets of well-built private houses and mansions have drifted and are still drifting into use as tenement dwellings. It behoves the Corporation of Dublin, as a body, to grapple with the difficulty in respect to this decaying class of house property, and to see that it is utilised in a sanitary way by the new and jobbing class of landlords who have and are obtaining possession of it. There are a number of respectable citizens and traders who say it is madness to encourage the operations of artisans' dwellings companies while such a mass of house property as we have indicated is not utilised to some extent for the healthy habitation of the people. For ourselves, we would not discourage, but rather favour, the erection of well-planned artisans' and labourers' dwellings here and there in the city and on its borders, but we are decidedly of opinion that persistent efforts should be made on the part of the municipal authorities to keep the city respectable. If streets of houses must drift into tenement dwellings, surely, under their new conditions, the Corporation can make their landlords keep them in a habitable state and provide the necessary sanitary requirements of civilisation for their occupants? It was more than once, during our visits to the homes of the poor, pointed out to us that certain members of the Corporation or the Public Health Committee were also shareholders in the Artisans' Dwellings Company, while others were large owners of low tenement house property, and that it was incompatible with the proper exercise of the public duties of those members that their private interests should enter into the question of housing the poor.

According to a sanitary survey of the city made in 1882, at the instance of the Executive Officer of Health, it is stated there are in Dublin 7,284 houses occupied by two or more families coming under the denomination of tenement dwellings. In addition there are 6,000 small houses, houses in the yards of larger houses, and cottages occupied by the poorer classes, said to be subject to periodical sanitary inspection. There are 88,116 rooms in the tenement houses, and they are occupied by 32,202 families, or more than three-fifths of the total number of families in the city. According to this enumeration, the greater number of families in Dublin occupy each one room and a half on the average. These figures are suggestive indeed, and their bearings and results are obvious. There is, however, good reason for believing that the above figures are a good deal under the mark, and that the evils they point to are more widespread. It may be well to add here that the municipal districts, or city of Dublin proper, comprise an area of 3,754 acres, and at the date of the census in 1881 contained a population of 249,602, or estimated up to the middle of last year, about 250,557, being at the rate of 65·8 persons per acre. In 1881 the city was returned with 21,211 inhabited houses, 3,060 uninhabited houses, and only 316 in course of erection, making a total of 27,587 houses.

Within the last few years a considerable improvement has taken place in the general drainage of the city, long lengths of new sewers being constructed to replace the old and most defective ones that existed, but the house drainage in sundry places north and south of the Liffey is very bad, and in spots non-existent. In the northern and southern suburbs a low-class speculative house property has been run up, and operations are still proceeding. We fear that the erection of these buildings obtains very little inspection on the part of the local authority. We found bad materials and workmanship, and also scamped drainage in abundance. The Building Act appears to be violated in several instances, even within the municipal boundary. These houses are made to assume a "neat and genteel" appearance in their fronts to catch the eye, but a skeleton lurks beneath. An improvement has taken

place in the matter of the domestic scavenging of Dublin, and a large number of the yards or courts of the tenement houses of the city are cleansed daily, but there is much to be done still in this direction and in the general cleansing and scavenging of the town. During the late year scarlet fever and whooping-cough assumed serious proportions; indeed, the former disease has often ravaged Dublin, where it periodically presents an epidemic form. It has proved a formidable malady in London and other great cities, we must admit, as well as Dublin, but the causes of "filth diseases" are not occult, and they were heretofore, to a great extent, traceable, to sanitary neglect in the Irish capital. Besides the carrying out of a well-divided system of main drainage, including the purification of the Liffey, much sanitary and improving work remains to be accomplished by the Corporation, if decay is to be arrested, disease stamped out, and the capital once more made worthy of the country.

#### ANTIQUITIES FROM SAN.

MR. FLINDERS PETRIE has brought safely home the first and more portable section of his remarkable find at San, — the site of which is some twenty miles south-west of the modern Port Said, — and the Egyptian Exploration Committee may congratulate themselves on the result of his labours. Some hundreds of small articles are on view at the rooms of the Archaeological Institute, in the Oxford Mansions (near Regent-circus, on the site of what was Oxford Market), and are open to inspection on the presentation of an address-card. The visitor may be so fortunate as to find Mr. Petrie at the Institute, and will have the benefit of his stores of knowledge on this most interesting subject. The articles are not arranged in chronological order, but in groups as they were discovered. They consist of charms, domestic utensils, and personal adornments, — many of them very minute in scale, most of them of rare beauty, and all of the greatest interest. They were found at depths varying from 20 ft. to 30 ft. from the surface, and their separation from the debris in which they have lain for centuries must have been a work of great care and nicety. By far the most beautiful amongst the objects displayed are the glass mosaics, exquisite alike in design and colouring, and so microscopic in their dimensions as to be only properly seen by the aid of a magnifying-glass. Next to these in attractiveness are the small silver figures, worn as charms, modelled with extreme delicacy. After these the terra-cotta fragments, adorned with ornament in relief, of which the vine-leaf is the most prominent feature, must be classed. Some terra-cotta paterae of several colours, arranged in geometrical designs, are extremely interesting as art, and interest deepens into wonder when we learn that they date from about the year 1200 B.C. The treasures found in one house comprise a statuette of its owner, Bak-akhu-in, who was evidently an art patron and aesthete of the period. In particular, a bronze lamp, with a long curved neck, for suspension from the ceiling of his house, may be noted as an evidence of his taste.

Of greater interest to the architect than trinkets, however rare or beautiful, is a bronze window lattice, which is believed to date from the fifteenth century B.C., and to be the only one of the kind hitherto met with of so early a date. The fragments are arranged to show the general design, and measure, as so disposed about 18 in. by 9 in.; but there are portions of the same lattice laid loosely about, which, if pieced together, would form a much larger panel. The sides and one end only have been discovered, and it is evident that this identical panel was a very long one. Hence the suggestion that it was placed along the upper portion of the enclosing wall of a hall or other apartment as an internal screen to the "clearstory" by which such apartments in Egyptian structures were lighted. The pattern is a mere reticulation of thin flat bars placed at an angle of 45 deg. with the enclosing frame. The bronze

nails by which it was attached to a wooden frame are laid beside it. Indeed, nails of all sorts and sizes, and bearing a strange resemblance to their modern counterparts, form a considerable portion of the exhibition, and divide the attention with keys, haps, and staples,—one of the latter specimens having a knob to receive the blows of the hammer, and protect the eye from being bent out of shape.

Amongst the exhibits are some small bronze capitals, probably connected with a shrine or similar structure. They are quite destitute of ornament, and resemble the iron capitals at the Oxford Museum to which the wrought-iron ornament is affixed. The mouldings are not in the least suggestive of Egyptian work, and are, in fact, without any character at all. Other fragments of architecture are adorned with incised ornament of delicate design and workmanship, or with applied decoration in the form of glass mosaic.

A glass lense, some 2 in. or more in diameter, is held to be a great rarity, and the glass and porcelain objects generally, both in respect of the shape and colour, are of exquisite beauty.

A quantity of cloth ornamented in simple colours (in which red predominates), and which clearly shows the aptitude of this remarkable people for art in all its forms, is disposed about the rooms, and the gentlemen who are distressed at the failure of the Chinese hair-crop (*vide the Times*) may be curious to see a specimen of human hair 2,000 years old, which belonged to the lady whose cements were furnished by the cloth in question. The hair is long and wavy, of a rich auburn colour, and apparently as perfect as when its owner proudly wore it. There is no end to the themes for wonder which this collection provides. Mr. Petrie is about to return to Egypt for the terra-cotta, granite, and other specimens which form the bulkier part of his collection, and which will probably find its way before long to the Egyptian section of the British Museum.

If we might venture upon a suggestion in the re-arrangement of these curiosities, it would be that the dates of the several objects should be stated in figures, and not by references to dynasties. Outside the charmed circle there are not many wondering spectators who can attach any meaning to dates concealed under such dynastic hints; and it is the extreme antiquity of many of these objects which constitutes their claim upon general attention. By all means let the learned keep to their own occult system; but let their weaker brethren have the benefit of a translation of the otherwise insoluble chronological enigmas.

#### NOTES.

**N** exhibition of Women's Industries is to be held at Bristol early in January. The idea of the promoters, we are told, is to bring together specimens of work requiring skilled training, so as to illustrate the part taken by women in various arts and manufactures demanding special technical and artistic training, professional and not amateur work being desired. Among the class of exhibits which it is desired to exemplify are painting, sculpture, wood-engraving, wood-carving, modelling, designs for articles of household furniture, designs for decorative work generally, and for textile fabrics, lace, needlework, &c. The loan of ancient needlework and of other articles "representing the occupation of women in past times" is also invited; and it is hoped to form a loan collection of portraits of eminent women, and relics of interest connected with them.\* The special motive for all this appears in the footnote to the prospectus of the exhibition, stating that the proceeds derived from the exhibition will be handed to "The National Society for Women's Suffrage,"—for the promotion of women's suffrage, we presume, is what was intended to be said. That the exhibition will excite a great deal of interest, and contain much that is worth looking at, we have no doubt. As far as the more distinctly artistic side of the programme

\* Communications in regard to the Exhibition are to be addressed to the Hon. Secretaries of the Exhibition of Women's Industries, 20, Fark-street, Bristol.

is concerned, however, the subjects of painting, sculpture, engraving, &c., we can only repeat what we have said before in reference to the female art-exhibitions in London, that no good is done either to women or to art by any endeavour to set up art-exhibitions for women alone. The few women who have really achieved a high place in the higher arts have contended with, and prefer to be ranked with, other artists, without distinction of sex; and all the women's art-exhibitions we have hitherto seen have resulted in a display of artistic mediocrity. If women have attained sufficient power in art to take a high stand in it, let them do so as artists, not as women. If they have not attained such power, they have no right to expect compliments for their efforts merely because they are women.

**A**T a meeting of plumbers in reference to the proposed plumbers' conference, reported in another column, it was remarked that an ordinance of Edward III. had provided that no one should meddle with such a trade unless he had the testimony of the best and most skilled men in the city that "he could well and completely do his work." The feeling of the meeting was that such an ordinance, now practically obsolete, was exactly what was wanted in the present day. Many persons will no doubt entirely approve, as we do, of the attitude taken by the plumbers' meeting in that respect. But it is, as Peypys would have said, "mighty curious" to see how plumbers may take such a line with the support of outsiders, while architects, if they attempt, through their representative corporate body, to protest against incompetent persons being employed on architectural work, are only regarded with indifference or twitted with self-interested motives. The inference is that the public care about plumbing, but do not care about architecture.

**A** PAPER has been recently read before the French Engineering Society on "Ancient Metallic Architecture," by M. Normand, the architect who restored the Vendome Column, the subject of which was the employment of metallic architecture before the Christian era. He shows that there are evidences of its use, not only in the details of public and private edifices, but also in the erection of buildings in which almost the whole structure was of metal. Columns of iron and bronze were used in many of the Assyrian and Jewish monuments, and some metallic beams of the Roman Pantheon were remaining in the sixteenth century. Metallic joists and terra-cotta panels were also used in ceilings, much as they are in modern buildings.

**W**E have received a revised edition of the "Practical Suggestions" made by Sir Robert Rawlinson, C.B., and issued by the Commissioners in Lunacy, in reference to the sewerage, drainage, water-supply, &c., of lunatic asylums. These suggestions have been carefully rewritten by the author, and, as may be inferred, they contain a great many useful and necessary rules applicable to town-houses and public buildings other than asylums. It may be noted that an outlet-sewer for the largest asylum need not exceed 12 in. if of earthenware, and 9 in. if of cast-iron. The Commissioners, from their experience, stipulated "No brick sewers. No sewer larger than 12 in. diameter." Sewers larger than necessary are not only more costly, but they are in a degree mischievous, as liable to accumulate silt. There are large houses in the country,—and in towns also,—built, say fifty or a hundred years since, under which there are brick sewers 5 ft. high by 3 ft. 6 in. wide, flat-bottomed, and branch harrel drains of brick, rude in construction and porous as to material, from 3 ft. to 12 in. Rats swarm in all such sewers and drains. In small well-formed sewers of earthenware or cast-iron pipes, rats cannot exist. The presence of rats about dwelling-houses, either in town or country, is generally a sign of defective sewerage and drainage, and means had health to the occupants.

**T**HE old moss which is found in beds of more than 1 ft. thick in various places in Norway and Sweden has been found to be an excellent material for the manufacture of paper, even in its half-decomposed state, and cardboard has been made from it, some leaves of which are 7/87 in. in thickness. It is as hard as wood, and can be very easily dyed and polished. There is no reason indeed why this product should not in some cases be substituted for wood with advantage, for it possesses all its good qualities and none of its defects, and can be used in the manufacture of doors and windows, cornices, and many ornamental portions of a house, while under the hydraulic press it receives a consistency and power of resistance far superior to those of straw-board.

**M.** CHAMBERLAND, the director of M. Pasteur's laboratories, has been endeavouring to find, for the very delicate experiments carried out by M. Pasteur, a filter which will absolutely purify water of all, even the most infinitesimal, germs or "microbes." He claims to have found it,—and we may place every reliance on testimony coming from such a source,—in the shape of a biscuit porcelain tube through which the water is slowly forced under pressure. The following further details are extracted from M. Chamberland's account of the filter:—"All previous forms of apparatus called filters, invented up to the present time, have been confined to clarifying the water; that is to say, they retain matters in suspension, but do not in any way arrest the morbid germs contained in all liquids. Water, filtered by M. Chamberland's process, is the same as when taken fresh from the spring; spring water being, as is well known, absolutely free from microbes. This filter may thus be said to constitute a spring at home. The apparatus consists of a tube of biscuit-porcelain, closed at one end, and having at the other an enamelled porcelain ring in it, with an aperture for the discharge of the water. The tube is placed in another metallic tube, which screws on to the top, soldered to the water-pipe. A nut placed at the bottom of the apparatus, and screwed up by hand, allows of the space between the metallic and porcelain tube being hermetically closed by the aid of an indiarubber washer attached to the enamelled ring. When the tap is turned on the water fills the vacant space between the metallic and the porous tube, or filtering-rod. It filters slowly under pressure from the outside to the inside, by these means being relieved of all solid matter, including any microbes or germs it might contain. With a pressure of about two atmospheres one obtains, through one single porous tube or filtering-rod (8 in. long by 1 in. diameter), about five gallons of water per day, which seems to be sufficient for the ordinary purposes of a household. The greater the pressure the more filtered water can be obtained. By multiplying the number of rods and coupling them together in batteries it will be easy to obtain the water-supply necessary for schools, hospitals, barracks, hotels, &c."

**L**AST week we witnessed a trial, at the Health Exhibition, of Pyfe's patent "columnar valve" hydraulic ram, which claims, by the arrangement of the valves and their adjuncts, to obtain the greatest possible result with a minimum of head. Upon the occasion of our visit, two of these rams,—one a double-action and the other single,—were arranged with falls of 5 ft. and 1 ft. respectively, and the delivery-pipes were carried to the top of one of the highest buildings in the grounds. With the greater fall a lift of 92 times the head was attained, whilst 157 times the fall was recorded with the minimum head. Again, with a fall of 5 ft., and an expenditure of twelve gallons of water, 1,592 gallons per minute were raised to a height of 42 ft. We are not prepared to endorse the confident statement of the inventor that these machines "are able to raise water to almost any height, and from any place where a few inches of water can be obtained," because there are many conflicting circumstances in

connexion with placing these motors that would not prove so favourable as those under which we saw them. Nevertheless, we fully believe that an average lift of 60 to 70 times the head may safely be depended upon, and in some cases even greater. The action of the ram is exceedingly regular, and the valves are guaranteed to last four years, with which exception the machines will work automatically for a considerable length of time.

A GERMAN mechanic has discovered that damp parchment paper, when strongly compressed, forms a homogeneous and ductile material, which has great rigidity and toughness. Observing that when exposed by its cut-edges to the friction of a smooth metallic surface it undergoes but an insignificant amount of wear, he took out a patent for the manufacture of journal boxes from compressed parchment paper, one great advantage of this being that lubrication can be produced by water alone. A slight greasing with oil is sufficient to prevent rust.

THE report of the Medical Officer of Health for Clerkenwell for the past year, which has been forwarded to us, contains very bitter words against the Home Secretary and Sir Charles Dilke, the latter of whom has called Clerkenwell a retrograde parish, while the former has expressed a general want of faith in vestry government and (apparently) in that of Clerkenwell more particularly. The report includes a handbill which the vestry drew up when cholera was considered imminent, earnestly advising the inhabitants to take certain precautions specified, all of which appear to be proper and needful cautions; 10,000 of these were distributed, arrangements were made with the Local Government and the Hospital Boards for hospital accommodation and ambulances, and a map was prepared showing where cases would be received in the event of an outbreak. "Fortunately, we have so far been spared; yet the arrangements are still in order, flow, in spite of what was then done, and what has always been done, under similar circumstances, Sir William Harcourt could assert, in the House of Commons, that in the event of an epidemic occurring in the metropolis, there was no uniformity of action and no central guiding power over the vestries and local Boards, seems to me only intelligible on the plea that he is a special pleader in a cause." The vestry have, perhaps, some right to feel ill-used; but their statement does not prove that there was a central guiding power, but only that, in their opinion, they did not require one.

IN regard to the taunt about the "retrograde" parish, the medical officer of Clerkenwell makes some statements as to the real foundation for the charge, which may be worth the attention of those who legislate for the poorest class of house property and tenants. He says,—"For some years past many of the well-to-do residents of the parish have been gradually leaving their houses, which become occupied by a poorer class of people, many of the houses which were formerly held by one family being now let to several. When these poorer and rough people, especially the labourers, enter a house, at once begins a course of dirt and destruction. The locks and handles of the doors become toys for the children, and are soon demolished. The drain-traps are sold at the bone and hottle shops, those left are never kept on, the closets are stopped up and the pans are broken. The chimneys are never swept, so that the rooms become black and disfigured. The paper is torn off the walls, the floors and passages are never washed, and there are no door-mats, so that the whole place becomes a mass of dirt and destruction. The water-buttl lids and the dust-bin lids are used for firewood, the ball-cocks are broken off, so that there is great water waste, which floods the yards and washes away the cement from the paving. The very handrails of the staircases are broken away, and even the walls are picked out with nails, or something of the kind, so as to leave large holes. The windows are constantly broken and

stopped up with brown paper; in fact, there exists in every parish a juvenile window-breaking club, the members of which demolish every pane of glass they can, especially in empty houses." With such a class of tenants (and we suspect the account is not exaggerated) the prospect of being otherwise than a retrograde parish is certainly, as the Report observes, "not favourable."

A RECENT number of the "Transactions of the American Society of Engineers" contains some notes by Mr. E. B. Dorsey on "the comparative liability to, and danger from, conflagrations, in London and in American cities." The fire average of London, it appears, is very low as compared with that of New York (taken as a representative American city), and Mr. Dorsey is at first under the impression that the difference must be due to the superior efficiency of the London Fire Brigade. Further investigation, he says, led him to the conclusion that the American Fire Preventive Service was not inferior to the English, but that the circumstances were very different. The damp climate and consequent saturation of wood in London is an element in reducing the liability to fire; and, in addition, the author gives the following list of favourable circumstances in London:—

- 1st. The small size of most of the houses, which confines the fire to a very limited space between brick walls.
- 2nd. The low, strong and well-braced walls, which enable the firemen to approach them without danger.
- 3rd. The high and effectual fire-walls between adjoining houses.
- 4th. The great benefit derived from the houses being low and small, enabling the firemen to throw water easily all over them, and with a very short ladder to reach the roof. And also avoiding the great draught drawing the fire up the stairways and wells of high buildings.
- 5th. The use of more brick and less wood in buildings.
- 6th. Absence of all frame buildings.
- 7th. Absence of all wooden additions, outbuildings or tenocs.
- 8th. Fire-proof roofing.
- 9th. Absence of ash barrels or hexes.
- 10th. The moist or wet climate, which prevents sparks or weak flame from igniting wood.
- 11th. The parks and Thames river, which divide the city into distinct fire divisions.
- 12th. The numerous parks, squares, private grounds, wide streets, railroads, &c., all of which are effectual barriers to the extension of fire.
- 13th. The mildness of the winter climate.
- 14th. The great care of the authorities in prohibiting the manufacture or storage of combustible materials, &c., in the populous portion of the city.
- 15th. The very few telegraph wires in the streets above ground to interfere with the work of the firemen.

Contrast the preceding with New York, with its numerous wooden buildings, wooden or asphalt roofs, buildings from four to ten stories high, with long unbraced walls, weakened by many large windows, containing more than ten times the lumber the average London house does, and that very inflammable, owing to our dry and hot climate; the five and six-story tenement houses, with two or three families on each floor, each with their private ash barrel or box, kept handy in their rooms, all striving to keep warm during our severe winters; the narrow streets and high buildings, with nothing to obstruct the spreading of a fire except a few small parks; the perfect freedom with which the city authorities allow in the most populous portions of the city large stables, lumber yards, carpenters shops, and the manufacture and storage of inflammable materials; the absence of high or effectual fire-walls between buildings."

#### NOTES AT THE IRON AND STEEL INSTITUTE MEETING.

At the autumn meeting of the Iron and Steel Institute held this year in Chester, the "visits and excursions" were really the principal features of interest. Of these probably the most interesting excursions were the visits to the salt-mines at Northwich and the Weaver navigation. They were taken on the Thursday, and the Festing Railway and slate quarries, on the following day. A few years ago the Flint Alkali Works would also have afforded a point of great interest as a part of the programme, but the great changes that have been for some time taking place in this industry have shifted the centre of attraction to another spot. The proprietors of those chemical works that would

afford information of the greatest interest and value to the chemist and engineer are keeping their doors resolutely shut, and indeed most carefully guarded, being fearful no doubt that prying eyes might discover a means of sharing in the enormous profits that are now being made in this branch of industry.

Amongst the establishments open to the inspection of members during the week were the well-known lead works of Messrs. Walker, Parker, & Co., and also the Hydraulic Engineering Company's shops.

At Saltney were to be seen Messrs. Wood's anchor works. At this establishment some of the largest anchors in the world have been produced in times past, those of the *Great Eastern*, the largest of which weighed 7 tons, each, having been forged here. Messrs. Wood have now in hand the anchors and chain cable of the last new Cunard liner, so they can claim to have made the holding tackle for the two largest ships that have ever been built.

The Dee Oil Works, which are also at Saltney, are well worth a visit. Here may be seen the process by which petroleum refuse is made into lubricating oil, by means of distillation and filtration. This company makes a special feature of manufacturing that particularly fine description of oil required for certain classes of textile machinery. In order to make a lubricant fit for cotton spindles every particle of paraffin wax must be extracted, and this can only be done effectually by subjecting the mixture whilst in the filter press to a very low temperature in order to solidify the softer wax. At the Dee Oil Company's Works there is an important installation of refrigerating machinery on the ammonia system, which is used for this process. The wax expressed is made into candles, the part of the works set apart for this purpose forming an important branch.

The Sandycroft Foundry and the Mostyn Ironworks were also open to inspection. The former is about five miles from Chester, and well worth going to, especially for those interested in mining affairs, as the Sandycroft firm devote their attention principally to mining machinery. The Mostyn Ironworks are twenty-one miles away, and are small and unimportant compared to the vast establishments of South Wales that were recently visited by the Mechanical Engineers during their summer meeting. The Mostyn works are, we believe, engaged solely in the production of Spiegel Eisen.

From our own special point of view the lead works and hydraulic engineering works were of the most interest.

The firm of Joseph Walker, Parker, & Co., have works at Chester, Newcastle, Liverpool, Glasgow, Bagillt, and London, most of which are establishments sufficient in themselves to constitute a fairly important business. The Bagillt works are situated in North Wales, on the estuary of the Dee, and about seventeen miles from Chester, on the Chester and Holyhead Railway. Here the first processes of procuring lead from the ore are carried on by means of smelting in ordinary reverberatory furnaces after the manner usually followed in North Wales. There is at these works a flue of rather larger size than is usually met with. It is somewhat under two miles in length, and is arranged in a continuous spiral on a conveniently elevated plateau at the back of the works. It is built of brick in the ordinary way, and is of oval section, 7 ft. high, and 6 ft. across in a horizontal direction. Into this flue are led all waste furnace gases which have been brought in contact with metal in process of reduction. The flue-dust which is carried over with the smoke and products of combustion is deposited during its passage through the long winding flue. The latter, at stated intervals, is flushed by water when the flue dust is carried through and is collected by allowing it to settle in large ponds made for the purpose. The sediment so obtained contains 55 to 60 per cent. of lead. This, under the old system, would have been impartially distributed over the adjoining land to the complete destruction of any crops that might have been attempted to have been grown in the immediate neighbourhood. At the present time such vegetation as is to be seen is as green and pleasant as it can be expected to be within a short distance of a manufacturing centre. The large flue naturally occupies a great deal of land which is, perhaps, not an object of great importance at Bagillt. The principal difficulty in an arrangement of this nature is to get the dust to settle without at the same time sacri-

of the draught required for the furnaces. At these works there is a chimney over 250 ft. high and 12 ft. in diameter, and the additional height required to compensate so long a flue must be considerable. We do not know whether there is any special reason why the necessary space required for the settlement of the flue-dust should not take the form of large chambers. These would occupy far less ground, whilst the rapidity with which the fumes would travel would be far less. Naturally in a flue which has the same sectional area throughout the gases will travel at approximately the same speed, and it is this speed which delays the deposition of the suspended particles of dust. Possibly, too, if chambers were used a better means of abstracting the flue-dust than the somewhat primitive one of flushing by water might be devised.

The furnaces used for smelting lead are generally about 20 ft. long and about 10 ft. wide. There are doors on each side, and the hearth is made up of slag. About a ton of ore with 2 cwt. of flue-dust is the usual charge at Bagillt. The reduction is by air, the furnaces in which ordinary coal slack is burned being placed at the sides and delivering the flames above the charge on the hearth. As the metal forms during the process, at which time the charge is well worked by hand, it flows towards the tap-hole and ultimately runs out and is cast into pigs. About ten per cent. of the metal remains in the slags left after the first working. In order to recover as much of this as possible the slag is worked up again, and in this way a hard inferior description of lead is obtained. There is an exceedingly well-arranged desilvering plant for the zinc process at Bagillt, which has recently been erected under the superintendence of Mr. W. M. Hutchings, the manager. The melting-pots are 5 ft. 5 in. in diameter. This plant is capable of producing over 600 tons of lead per week, whilst the annual output of silver at these works is about 13 tons a year. Litharge and red lead are also made in large quantities at these works. Red lead is, as is well known, an oxide of lead. The first process of manufacture is carried on in "drossing-ovens," of which there is a large number at Bagillt. These are of the ordinary beehive form, with a rather high dome in which the smoke and gases from the furnace collect until they pass out at the working door and are carried off by an uptake conveniently placed. The pigs of lead are melted on the floor of these ovens, the molten metal being kept from running out by a dam composed of the refuse from the last working. Antimony is introduced into the bath, and the whole is kept agitated by hand-rakes. In the process of time, - about six hours, - the greater part of the lead has become oxidised, and the remainder is allowed to run away to be recast and used again. The "dross" is left in the oven and kept at a high temperature, and is then ground and levigated, after which it is subjected to further oxidation in other ovens in order to improve the colour. After a further process of levigation and grinding the material only requires drying in stoves in order to become the red lead of commerce.

Sheet lead is rolled at these works, there being a rolling-mill capable of producing sheets up to 100 in. wide. A pair of cast-iron rollers, 33 in. in diameter, are mounted in cast-iron tanders, and have a long bench with loose rollers on each side for working the sheets upon. There are also a couple of live rollers worked by spur gearing, close to the mill on each side, for the purpose of feeding-up the sheets. The rolls are driven by a separate engine, and the reversing is effected by a clutch gearing on to the bottom roller, which is the driven one, the top roller running loose in its bearings. When a sheet has to be rolled a slab of metal is cast, and a piece of the necessary weight, according to the gauge and area of the sheet required, is cut off. This is passed through the rolls whilst quite hot, and is gradually reduced in thickness and extended in area as the operation proceeds, until finally it becomes the familiar sheet-lead which is used for such a large variety of purposes. At each pass the top roll is brought closer to the other, its journals and their bearings being lowered in the framing by suitable hand gearing.

At the Chester Works of this firm white-lead making, pipe-drawing, and shot-making are the principal occupations. The shot are dropped from a tower in the ordinary way. The globule of molten lead assumes its spherical form as

soon as it leaves the perforated tray, known technically as a card, through which it is allowed to percolate, and hardens during its descent, when it is finally caught in vats containing water, in order to prevent injury through falling from so great a height on to any hard substance. Larger shot are cast in moulds. At the Chester Works there is a large plant for drawing lead pipe, consisting of several hydraulic presses and the necessary gear for working them.

A press for making solid drawn lead pipe consists firstly of a hydraulic ram and cylinder, the former pressing upwards in a vertical line. On the upper part of the press there is a cylindrical vessel with which molten lead is poured and a die of the same diameter as the pipe to be drawn is then firmly wedged into the upper part of this cylinder. An iron core of smaller diameter than the hole in the die is placed concentrically to the latter, and an annular space is thus obtained, through which the lead is forced by means of the head of a ram which fits the bottom of the cylinder containing the lead. It will be manifest that the outer diameter of the pipe is regulated by the diameter of the die, whilst the thickness of metal is dependent on the size of the core. In order that the lead which comes in contact with the walls of the cylinder may not be chilled when it is first poured in, small fires are made up in receptacles provided for the purpose, or, in the case of larger presses, the cylinder is hotly heated by being placed in a gas-heated chamber. Considerable judgment is required on the part of the operator in determining when the lead is at the right temperature for the purpose. Should it be too soft it will run out in a shapeless mass, whilst if allowed to set too hard it will not work at all. A pressure of about 2,200 lb. is obtained in the hydraulic cylinder for the smaller presses, whilst those used for producing heavier pipe work up to 6,000 lb. to the square inch. Pure tin pipes are made in the same way, whilst tinned pipe of lead is produced by pouring a small quantity of molten tin into a hollow formed on the upper part of the die, and also by pouring a small quantity into the first few inches of pipe made as it emerges upwards from the die. This tin remains molten for a considerable time, and deposits a thin layer on both the outside and inside of the leaden pipe as it is formed.

Solid round lead is formed in the same way as the leaden pipe, the only alteration in the process being the omission of the core.

Lengths of lead of any required section, such as caln lead for glazing, can be drawn in these presses, dies of various descriptions being provided for the purpose.

Water-pipes of all standard sizes are here made as stock articles, ranging between  $\frac{1}{2}$  in. pipe, from 34 lb. to 53 lb. per yard up to 6 in. barrelling up to 84 lb. per yard. Lead and composition gas-pipe is drawn from  $\frac{1}{4}$  in. diameter up to  $1\frac{1}{2}$  in. diameter. A special gas-pipe of  $\frac{3}{8}$  in. diameter, is drawn for using in glass chandeliers.

White-lead is made at Chester by the ordinary stack process, in which thin castings or "crates" are subject for several weeks to the corroding influence of the fumes of acetic acid, damp bark being used to generate the required heat. The product is carbonate of lead, which, having been washed and dried in a stove, becomes the dry white-lead of commerce. Messrs. Walker, Parker, & Co. also grind large quantities of white-lead in oil, having several mills of the ordinary description, and a roller-mill of ingenious construction for the purpose. The acetic acid used for the production of lead is made on the premises, and there are also appliances for boiling and refining the oil used in grinding the lead into paint.

The Hydraulic Engineering Company, of Chester and Palace-chambers, Westminster, are well known as manufacturers of hydraulic machinery in general; Ellington's patent hydraulic balance-lifts for hotels, warehouses, and private dwellings, being amongst their special productions. These lifts are direct-acting, the ram, which is of the same length as the height of the lift, working in a cylinder placed in a well immediately under the cage, which in every position rests on the column of water beneath it. Lifts of this description have been up till recently mostly worked at low pressure, obtained from the mains of the ordinary water supply, or from a head of water in a tank on the roof. In such cases a large ram is a necessity, and the cage and ram have

to be counterbalanced by weights and chains. The dangers that may arise through the failure of such appliances are well known and have received too many lamentable proofs in practical working. It is in order to obviate these risks that Mr. Ellington has introduced his hydraulic balance, and works only at higher pressures. There are several modifications of this hydraulic balance, but they are all arranged on the same fundamental principle. At the side of the lifting cylinder a second cylinder is placed, the ram of which works in an opposite direction to the lifting-ram, so that the balance-ram ascends when the lift is coming down, or descends when the lift is rising. The stroke of the balance-ram is necessarily less than that of the lifting-ram, but the area of the former is greater. In this way the balance governs the action of the lifting-cylinder, and prevents it rising too high or descending too rapidly. It would be impossible, without illustrations, to give a clear idea of the various means by which the principle is fitted to the different conditions of working that may be required, but we hope to be able to refer to the subject again at a future date.

At the present time several lifts on this principle are in course of construction at the works. One order for thirty is being executed for dwelling-houses on the Kensington Court Estate. The power to work these will be supplied by the London Hydraulic Power Company, which is erecting a hydraulic pumping-station in the district. Two more lifts are also being made for the Hôtel Métropole, whilst two others have lately been fitted to the First Avenue Hotel. Possibly, however, the best known of Ellington's lifts is that at the Bedford-street Branch of the Civil Service Stores, which has for several years been carrying on an average 2,000 persons a day without accident or delay.

One of the principal features in the erecting shop at these works is a set of vertical hydraulic pumping-engines that have been made for the General Hydraulic Power Company, and which are about to be erected at this company's principal station at Blackfriars. The engines are of the three-cylinder compound type, having one high-pressure cylinder, 19 in. in diameter, which exhausts into two low-pressure cylinders, each 25 in. in diameter. The stroke is 24 in. Cowey's automatic expansion gear is fitted. This is worked by a governor and a chain attached to the accumulators actuating cans, which in turn operate on a trigger-gear. There are three pumps 5 in. diameter, and of the same stroke as the steam pistons, being, in fact, placed below the steam cylinders, and driven directly from the pistons-rods. These pumps will work to the standard hydraulic pressure of 700. Another object of interest in these shops is a hydraulic intensifier, by means of which a water-pressure of 2,500 lb. can be obtained from the ordinary hydraulic main pressure of 700 lb. This is got by the differential action of two rams, one of larger area and lower pressure forcing a second of smaller area to a considerably higher pressure. The apparatus would be of great service for testing purposes in cases where it would not be desirable to work the pumps at the full test pressure.

THE PLACE OF ART IN THE POLITICAL ECONOMY OF A NATION.

This was the title of a paper read by Mr. P. H. Rathbone at the Social Science Congress, Birmingham, last week, and which we now give in full:—

Some years ago I ventured upon a few remarks upon the political value of art to a great nation, but art is many-sided, and has its ethical and even scientific value if properly understood. At the present moment, however, it is perhaps even more important to insist upon its economical value. It is one of the most serious functions of a statesman to strive that the great body of the nation be well clothed, fed, and housed. It is not unnatural that he should ask himself whether it is wise to divert energies which ought to be mainly directed to these important ends, to what has been too much considered as a mere ornament of life. I propose to ask your attention for a few minutes while we try to solve this problem. Art is the logic of beauty and of efficiency. Art, in form and in colour, is the knowledge of how to select and arrange lines, colour, and shades, so as to rest

the eye, stimulate the intellect, awaken the imagination, and last, not least, satisfy the reason. In short, the main object of art is to do whatever we have to do so as to be of most use and give most pleasure. We have been too much in the habit of unconsciously confining the term art to the imitative arts of painting and sculpture, &c., with perhaps a partial exception in favour of architecture, so far as it is considered as an object of beauty rather than of use. Hence many of our errors of taste in regard to architecture. We have taken buildings, eminently adapted for the purposes to which they were applied, and copied them for purposes to which they were not adapted. Then we wonder that these copies do not produce in us the same sense of beauty as their prototypes. In the last century attempts were made to adapt Greek temples as mansions, and the owners felt much surprised that a style of architecture suited for large halls lighted from the roof should look heavy and unsuitable when applied to two-story dwelling-houses with a multiplicity of rooms. We forgot the original use of sculpture as the enrichment and complement of architecture, and send hapless statues shivering about our squares, without buildings to which they have any relation whatever, and without apparent reason why they should be there, or we stick them up on the top of poles, like orna in a zoological garden, waiting to be fed with buns by the angels. Look, on the other hand, at the Column of Trajan at Rome; there it stands in the middle of a square, completing the square and marking its centre. The record of a series of campaigns is sculptured round the column, which was originally crowned by a portrait figure of the chief actor in these campaigns. Every portion of the column has its *raison d'être*,—its definite relations to its surroundings, but what sense is there in Charles James Fox presiding over a cabstand in Hanover-square, or Victory dispensing her wreaths among the bus-drivers at the bottom of Waterloo-place?

But, it may fairly be asked, what has this to do with the economical value of Art? Much, I venture to think, if we look closely into the matter. For many years we have devoted ourselves, with considerable success, to being the cheap-jacks of the world. We have been able to effect this by the aid of our coal mines, and by the practical possession of the cheapest labour in the world; I do not, of course, mean the lowest priced,—for low wages beyond a certain limit do not mean cheap labour. We must look forward, and that in no remote period, to losing this supremacy. Coal and steam are rapidly supplanting bone and sinew; and the invention of a furnace adapted to anthracite coal might entirely and most rapidly enable America to supplant us in the matter of coal. Let her repeal her insane protection laws, and our manufacturing supremacy, so far as cheapness is concerned, would probably become a thing of the past. If, therefore, we are to maintain our manufacturing position in the world, we must in future learn to manufacture the best and most tasteful fabrics rather than the cheapest. Low-priced articles will, in future, be more and more manufactured on the spot where the raw material is produced,—witness the growth of cotton-mills at Bombay. We shall have to turn our attention to manufactures which increase the value of raw material so much that the freight and carriage become unimportant items; and it goes without saying, that such manufactures must have a large artistic element in them. A few years ago, Mr. Morris devoted himself to introducing sound art into wall-papers, and the general world gently smiled at the æsthetic craze. But what is the practical result? Why, that as a direct effect of his action a large export trade (so I am told) in wall-papers is growing up which did not before exist. It is good wall-papers, not cheap wall-papers, that we are exporting. Look at Nottingham,—its lace manufacture and consequent prosperity,—and then inquire into the enlightened amount of thought and energy expended in impregnating the population with artistic feeling.

The history of the potteries is an equally instructive one. Go where you will,—Russia, Italy, &c.,—you will find the remains of old Josiah Wedgwood's pottery in old pawnshops,—pieces of a character which show it must have been exported in large quantities. The common articles in daily use were produced in their most artistic form, because a true study of the

principles had taught him, and, through him, other potters, one of the most important lessons of Art,—the adaptation of means to the proposed end, and economy in raw material. Unfortunately, Wedgwood died just at the dawn of that dreary period when the country was dominated by that crass stupidity which was dignified by the name of *plain common sense*; the time when Pitt refused 100,000*l.* to buy the Pitti Gallery, because England did not require pictures. The pottery trade of England declined and languished till the Exhibition of 1851 stimulated the potters to the study of art; and the effect upon the export trade of Great Britain is too well known to be insisted upon. I am told that the firm which has most conspicuously devoted itself to the best forms of art in its manufacture, is also the firm which has suffered least in the present period of extensive depression. I need not insist upon the example of Birmingham, and the work Messrs. Elkington and many others have done here. I ask those who doubt to inquire for themselves, and to ask those manufacturers who have devoted themselves to producing good artistic work what have been the pecuniary results of their endeavours. The artistic education which would have prevented our defacing our towns with absurd and incongruous statues and buildings at outrageous expense would have enabled us to supply Europe with those tasteful manufactures which, until lately, we have chiefly derived from France, where the necessity of artistic education for her workmen has been so long realised.

What more striking instance of the material value of art education could you have than Paris? Here is a city without coal, with an insignificant river, with no natural manufacturing advantages whatever, which supports an enormous population by the taste of her artisans. Her position as capital,—geographically an unfortunate one,—is not sufficient to explain this.

For want of it much highly-paid artisan's work falls into the hands of foreigners, and till the establishment of art schools this was still more the case. Sculptors reside in Italy because they can get marble-cutters there, and it was but the other day that a young artist confided to me his great joy over finding a skilful Italian marble-cutter in London at 5*l.* per week. It is but a few years ago that the best decoration of pottery was chiefly in the hands of foreigners, and we owe much to Messrs. Doulton for their efforts to create an artistic school of British pottery, and put the higher wages paid for artistic work in the hands of our artisans. It was not pleasant some time ago in Liverpool, where we have some of the best bricklayers in England, to find that, when it came to the ornamental and more highly-paid brickwork, artisans from a distance had to be imported. I cannot altogether absolve trade societies from blame in this matter. The objection to having wages regulated in proportion to the skill and industry displayed, which they have occasionally evinced, is most immoral and demoralising. No language can be too strong to denounce, no laws can be too strong to pitilessly crush any attempt at interference with a free workman's full use of all the skill and industry of which he is capable, or to deprive him of his right to the increase of wages which those qualities deserve. Any action which cramps the growth or energies of the nation is high treason to the country, and should be relentlessly suppressed as such by public opinion and by public laws.

It is not, however, only necessary that our workmen should be artistically trained; they must live in an artistic atmosphere, among a public ready and able to appreciate and criticise their works. I have heard told that one of the largest firms of calico-printers finds it desirable that their designers (Englishmen) should live in Paris, because they find by experience that life in artistic and unsympathetic surroundings chills and blunts their designing powers. A poet may slant himself up in his interior consciousness, and develop out of it the sweetest powers of song. An artist, for the most part, requires stimulation from the surrounding sympathy; for he has to express to those around him his sense of beauty and fitness, or else it ceases to be beauty and fitness to him. Nor is it necessary that it should be in the same forms of art as he himself practises.

Nothing is more remarkable than the many-sidedness of the very greatest artists. Michelangelo was painter, sculptor, and architect; Leonardo da Vinci added music to his other artistic acquirements, and his master,

Verrocchio, turned from painting to sculpture late in life, and succeeded. Many others tell the same story, and we have among ourselves artists of whom it would be difficult to predicate whether they were more at home with the chisel or the brush, and who would, no doubt, shine as architects were they required to turn their energies in that direction. In the Ober-Amergan we find a population of peasants, supporting themselves by wood-carving, who have attracted crowds from all parts of Europe and America to witness their skill in dramatic representation. Through a more thorough artistic education, we should enable our handicraftsmen to turn from an overstocked occupation to one understocked, and render their intelligence and labour more mobile and fluid. Art thoroughly acquired in theory and practice trains the powers of observation, of discrimination, and of selection; trains the eye to accuracy, the hand to prompt efficiency, and gives command over materials. A man thoroughly trained in drawing finds little difficulty in modelling in clay. Only those who have given attention to the subject would guess what varied powers of united knowledge and observation are required to produce any work of art which has any real claim to be so called. This question is deserving of very serious consideration.

At the present moment we are face to face with a very perplexing paradox. The average price of wheat this year has been the *lowest* on record, as we are informed by the *Spectator*. Meat supplies are opening all over the world, and good Scotch American mutton cannot secure more than 6*d.* per lb. in London, wholesale. Wool and cotton have been, and remain, extremely low. Many, if not most, of our duties are over-billed. And yet, with the main necessities of life,—food, clothing, and shelter,—over-plentiful and cheap, the best informed employers are looking forward to a period of more than ordinary distress among industrious workmen during the coming winter. There must be something wrong about this state of affairs. It seems mockery to talk of over-production of food, shelter, and clothing, when so large a proportion of our population are half-fed and clothed, and worse lodged than cattle. It is not so much that more necessities are produced than are wanted, as that more are produced than can be paid for. Now, what is the reason of this? Doubtless, there are temporary causes which will pass, but I venture to think that there is a permanent cause. Facilities of transport, the development of machinery, have enabled the population of the world to feed, clothe, and house themselves by working much fewer hours a day than formerly. Now, this would be all very well if they did work fewer hours a day, but they do not, and what is more they will not, at least not to sufficient extent. Let us suppose that the civilised population could formerly furnish themselves with necessities by working ten hours a day and we can do it now by working seven hours a day. Of course the number of hours is a mere hypothesis, but, I believe, a moderate one. If they all did work seven hours, well and good,—they would have three extra hours to spend for rest, amusement, and enjoyments; but what is the real cause? Why, that seven-tenths work ten hours a day, and three-tenths look on with idle hands. What is the remedy? Not working shorter hours: competition will prevent that; and you may as well attempt to sweep back the ocean with Mrs. Partington's broom as to arrest the action of competition. If we were a single nation, thoroughly organised, something might be done, though even then I doubt it; as it is, we are a family of nations, speaking different languages, and with very imperfect means of organisation. What is the consequence? Why, that at the end of the year the seven-tenths have produced sufficient necessities for the whole community, and that the three-tenths have earned nothing to pay for their share, a large proportion of which, therefore, is thrown back upon the hands of the producers, and we have the curse of over-production amid a semi-starving population. What is the remedy? Surely that the three-tenths should be employed in producing means of making the lives of the seven-tenths brighter, happier, more varied than at present. It is producing superfluities if you will, but superfluities that will do much to raise our workmen from the rank of machines and animals, into that of thinking, reasoning, life-enjoying men. They have as much right to the enjoyment of life as we. Much, no doubt, has

been done, but much remains to be done. At present the means of enjoyment most freely offered them is drink. Can you blame them altogether if they avail themselves of it too freely? But it is said that you cannot force these things upon our working population; certainly not, but let them be offered the option. If it be refused,—and I believe it would not,—then, and not till then, you may accuse our fellow-countrymen of innate sensual instincts. Of course, it will take time. A taste for art requires time to cultivate; but that it can be done we have had satisfactory proofs in Liverpool, and, I have no doubt, you will have even greater in Birmingham, for many forms of manufacture require a nicety of eye and delicacy of hand, which are in themselves the first and by no means least important steps towards the cultivation of a love of art.

In a small town near Liverpool, devoted to chemical manufactures, a theatre has been recently erected, and the publicans complain that when it is open their takings are reduced by a third. Thus a large proportion of the population are kept out of mischief, and remunerative employment is provided for a deserving and hard-working class of men and women; for an actor's life is not the mere play-work outsiders are apt to imagine. Cultivate the taste of our population by art galleries and museums, by concerts and theatres, and they will not only patronise the latter, but they will crave to possess as their own such forms of art to decorate their houses as may be within their means. They will frame the coloured prints provided by the *Graphic* and *Illustrated News*, after our best artists, and photographs of the pictures in our galleries; they will cover their chimney-pieces with pretty and inexpensive specimens in the potter's art; they will fill their rooms with elegant, if plain and simple, furniture; and the very tea-cups and plates in daily use will be, not dearer, but in better and purer taste than has hitherto been the case. Lastly, they will dress their wives and daughters and themselves so as to do justice to one of the most beautiful populations that has ever existed, if we may trust the records of art. Day by day will elevate and purify their taste, till it creates a demand for artistic work that will overflow the limits of the country, and create an export trade which may do much to counteract the loss of that supremacy in mere cheapness, hitherto our mainstay, and a discrimination and judgment in our working population will be developed which we are not yet prepared to consider them capable of possessing.

If you think these ideas Utopian, I ask you to look back some five-and-twenty years, and compare the style of music which was provided for the working men's concerts with that to which they listen now with earnest and intelligent attention; I ask you to note the gradual disappearance of the glaring and ill-assorted colours which used to disfigure the dresses of the working women and those of much wealthier classes; to compare the woodcuts of the cheap illustrated papers with those of former days, and then deny, if you can, that there has been an improvement in the taste of the nation, which gives every hope for its future progress, and I maintain is a new source of material wealth. If I am right, here is a prospect of supplying the supposed three-tenths (or whatever the proportion may be) of our nation, and of making the lives of the remaining seven-tenths happier, better, and more beautiful than they now are; and so I believe that, looking at the question in a purely material light, and as a source of wealth, putting aside all other considerations, the cultivation of the artistic taste is well worth the statesman's serious attention. It would be worth while to have a committee to inquire what effect schools of art have already had upon the export trade of the country. I believe much has already been done, is doing, and in a right direction, only do not let us relax our efforts. There is, however, one direction to which I do not think sufficient attention has been paid. I think every large town should have a good typical collection of casts of the best sculptures of all schools; not confining it, as has been too much the case, to the Greek and Græco-Roman schools, but including the early Florentine, French, German, and other Mediæval schools. Casts are the cheapest forms in which the best specimens of the highest art can be produced, and so little altered, except as to material, as to be, for practical purposes, almost as educational as the originals.

I wish the subject had fallen into stronger hands, but trust I may have said enough to prove that art has no unimportant place in the political economy of a nation.

SANITARY CONGRESS AND EXHIBITION IN DUBLIN.

The seventh congress of the Sanitary Institute of Great Britain was opened on Tuesday last with an address by Sir Robert Rawlinson, C.B., the President of the Congress. Having referred to the Royal Commission of which he was president, and which sat in 1879 to inquire into the sewerage, drainage, and general sanitary condition of Dublin, he observed that since 1879 the Corporation had carried out various sanitary improvements, but the purification of the Liffey still remained to be accomplished. Sanitary science, he said, was as old as literature. The Book of Leviticus contained laws and regulations for preserving health, and the reasons for some of the ceremonial regulations might be easily understood, such as avoidance of unclean meats, and isolation of contagious diseases,—leprosy for instance. There were at this day what might be termed leprosy sites, produced throughages of continued pollution. In the great towns, such as London, hospital surgeons recognised types of disease the most malignant and deadly as coming from special streets, and even houses, and when those streets and houses had been removed, cases of those types of disease ceased. One of the greatest objects of sanitarians was to stem the torrent of sanitary ignorance now working so much mischief and causing incalculable human misery. Quarantine, as now practised, was worked at enormous money cost as well as inconvenience, and produced much misery without having the effect intended. He referred to the antiquity of cholera, which was said to have been known in China as well as India, and to the peculiar conditions and characteristics of the disease in the East. He reminded the meeting that the disease was not so destructive as the ever-present fever under its various forms. Typhoid was answerable for far more deaths than cholera. Unsound meat and impure water might be factors in causing cholera, but were not the sole cause, as these were ever present, and many who died of cholera were not water-drinkers. In some outbreaks the most destitute portion of the population had not suffered, while the artisan class had. The very poor in summer lived mostly in the open air, and drank water.

Referring to the question of sewage disposal, Sir Robert Rawlinson said:—"The work of entirely freeing the River Thames of sewage from Teddington to the North Sea is merely a question of time, and there will be no further tampering with the question in London; and out to sea also must go the whole of the crude sewage of Dublin, because the river Liffey must be purified, and intercepting sewers, having a sea outlet, will be the cheapest remedy. Every large town in Great Britain which is situate on the seashore or on the margin of a salt-water estuary, sends the crude sewage direct to the estuaries or to the sea, and I know no valid reason against it. There are, undoubtedly, manurial elements of value in crude sewage; but if it must cost thirty or more shillings to utilise it by deposition with chemicals, or in land-irrigation, to earn 20s., I fail to see that to dispose of it into the sea at a less cost in rates is waste."

The business of the Congress was continued on Wednesday, when the Registrar-General for Ireland delivered an address on "Statistical Measures of the Health of Communities." Dr. Flinn read a paper unfavourably contrasting the administration of the Public Health Act in Ireland with that in Great Britain. Mr. E. Spencer, M.A., read a paper giving a deplorable account of the condition of the houses of the working-classes in Dublin. He recommended the demolition of old houses; but stated that the improvement of the homes of the working classes did not altogether depend on the provision of suitable abodes, but to a great extent on the education of the people themselves.

In connexion with the Congress an exhibition of sanitary appliances was opened in the buildings of the Royal Dublin Society, Ball's Bridge. This exhibition will remain open until the 18th

inst. Many firms well known to our readers are amongst the exhibitors. The judges\* have made the following among other awards, viz.:

Medals and Starred Certificates.

- Bradford & Co., London; for washing machines.
- British Sanitary Company, Glasgow; for self-acting earth-closets.
- J. & M. Craig, Kilmarnock; for white enamelled fire-clay ware for sinks.
- Doulton & Co., London; for art pottery; ditto, for ventilating tile stoves; ditto, for anti-percussion high-pressure valves.
- J. E. Ellison, Leeds, for conical ventilators.
- R. K. Heap, Manchester, for dry earth and ashes closets.
- Maguire & Son, Dublin; for sanitary and domestic appliances.
- R. H. Maiguen, London; for salt rapid.
- Maistrava & Co., Belfast; for slow combustion stoves.
- J. L. Smallman, Dublin; for Stott's mercury gas governor.
- Shanks & Co., Glasgow; for siphon-action water-waste preventors.
- Wilson Engineering Company, London; for their Wilson cooking range.
- J. Wright & Co., Birmingham; for Eureka gas cooking stove, and Silver Medal of the Exeter Gas Company.

Certificates.

- Robert Adams, London; for the Norton door-spring, and for adjustable pivot for fanlights.
- W. Baird, Dublin; for butler's sink, bath, and lavatory.
- David Thompson & Co., Glasgow; for Watt's sphygmator, for testing drains with smoke.
- Bournehill Coal Company, Dregthorn, Ayrshire, for stoneware drain pipes; and for white enamelled fireclay sinks.
- W. Carson & Sons, Dublin; for Willemsen waterproof paper and canvas.
- T. Cardingley & Sons, Bradford; for granite concrete pavement.
- J. M. Craig, Kilmarnock; for Buchan's disconnecting tray.
- Doulton & Co., Lambeth, London; for cheap glazed stoneware sinks; for bath fitting locking apparatus; for Lambeth combination water-closet; for enamelled-ware open channels for manholes; for manholes for drains with connexions complete; for London-made stoneware pipes; for silicon treads for steps; and for glazed-ware mantelpieces with slow combustion grate.
- J. E. Ellison, Leeds; for radiator ventilator.
- W. R. Leggett, Bradford; for opener for fanlights and skylights.
- Maguire & Son, Dublin; for white enamelled fire-clay sinks; for cast-iron drain pipes worked with Angus Smith's preparation; for Maraden tiling for wall decoration; for new laundry stove and copper boiler; for Scott's self-regulating disinfecting chamber.
- Pennycook Company, Glasgow; for their system of glazing without putty.
- T. R. Scott & Co., Dublin; for solid oak parquet flooring.
- Shanks & Co., Glasgow; for cast-iron baths and porcelain lavatories.
- Smith, Elder, & Co., London; for sanitary publications.
- T. Twyford, Hanley; for lavatory basins and soap sinks.
- T. & M. Craig, Kilmarnock; for white enamelled bricks.
- Bournehill Coal Company; for white enamelled bricks.
- J. Wright & Co., Birmingham; for ventilating open gas fire.
- W. Carson & Sons, Dublin; for slow combustion stoves.
- T. Twyford, Dublin; for indiarubber connexion for joining lead and earthenware pipes.
- Arden, Hill, & Co., Birmingham; for gas cooking stove lined with white tiles.

The awards as to a number of other exhibits are deferred.

SURVEYORSHIP ITEMS.

**Belfast.**—At a special meeting of the Belfast Town Council held recently, Mr. J. C. Bretland was appointed successor to the late Mr. J. J. Montgomery as Borough Surveyor of Belfast. Mr. Bretland has been in the service of the Corporation for the past sixteen years, during which period he has become familiar with the duties of the office. The present salary is 500*l.* a year.

**Edmonton.**—Mr. F. J. Bancroft, who has during the past three years held the post of assistant surveyor to the Finchley Local Board, and who has been engaged assisting Mr. Brumell, the Board's engineer, in preparing plans for the main drainage schemes, has accepted a similar appointment under Mr. Eacnns, engineer to the Edmonton Local Board.

**Gas v. Coal for Cooking.**—At a recent meeting of the Guardians of the St. George's (Hanover-square) Union, it was reported from the Infirmary that cooking by gas apparatus had been tried for three months, the result being a saving of 20*l.* as compared with the cost of coal. The Infirmary Committee recommended that a gas roaster and hot-plate be purchased of Messrs. H. & C. Davis & Co., Camberwell, which was carried.

\* Professor W. H. Corfield, M.D., chairman; Professor F. De Chaumont, F.R.S.; Mr. Saxon Snell, F.R.I.B.A.; Mr. Rogers Field, M.I.C.E.; Dr. H. C. Bartlett, Ph.D.; Mr. Ernest Turner, F.R.I.B.A.; Mr. W. Eassie, C.E.; Mr. J. W. Pegg, M.I.C.E.; and Dr. Louis Parkes, sec.  
† These recipients would have received a medal each but for the fact that one had been awarded to them on a previous occasion.

### ECCLESIASTICAL ART EXHIBITION AT CARLISLE.

In connexion with the Church Congress, at Carlisle, an interesting exhibition of ecclesiastical art has been opened. The loan collection includes 300 exhibits, embracing specimens of ancient and modern embroidery, wood carving, metal work, carved ivories, and other *instrumenta ecclesiastica*. Pictorial art is represented by various photographs and chromolithographs of ancient pictures, illuminations, drawings of churches and ecclesiastical furniture, engravings of chalices, and a large collection of rubbings of monumental brasses and incised slabs, from what is believed to be the oldest known specimen, representing Sir John D'Aheron (A.D. 1277), down to that erected to the memory of the late George Edmund Street in Westminster Abbey. Amongst the hooks may be mentioned a York Missal of about 1500; an early edition, dated 1596, of Marot & Beza's French Psalter; together with several service books, prayer-books, books of homilies, &c. A striking feature of the collection was an assemblage of disused plate, obtained from various churches in the diocese. It included about seventy pieces, mostly belonging to the sixteenth and seventeenth centuries, many of which were of great interest. The various guilds of the city of Carlisle have also contributed their plate, amounting to twenty-five pieces, or thereabouts: including tankards, porringers, cups, and salvers.

Messrs. Cox Sons, Buckley, & Co.; Messrs. Jones & Willis; Messrs. G. M. Hammer & Co.; Messrs. Heaton, Butler, & Bayne; Messrs. Keith & Co.; Milner's Safe Company; Messrs. John Smith & Sons; Messrs. Ward & Hughes; Messrs. John Warner & Sons; and other well-known firms, were amongst the exhibitors of church furniture, decorations, plate, &c.

While speaking of the Church Congress, we may make mention of the pastoral staff presented to the Bishop of Carlisle. It is the work of Messrs. Barkentin & Krall, of Regent-street, London, the well-known goldsmiths and art-workers in metal. The design was furnished by Messrs. Bodley & Garner. The work appears to be one of much merit, but we have no space for a detailed description of it.

### Illustrations.

#### DETAIL ELEVATIONS OF WAR AND ADMIRALTY OFFICE DESIGNS.

**W**E give, as we promised last week, the detail elevation studies of the three designs which were placed first in the second competition, those by Messrs. Leeming & Leeming, Webb & Bell, and Verity & Hunt, devoting a page to each. These will enable a better comparison to be made between the treatment of the three than could be made from a general view only. We fear such a comparison cannot possibly be favourable to the selected design, which consists of more or less pretty bits with no coherence whatever, and the columnar order is, as used here, as complete a piece of architectural sham as could be seen; a ponderous base, and a great column and cornice carrying nothing but a single statue. The elevation from Messrs. Webb & Bell's design is by far the most refined in detail of the three, but whether any one who saw it executed would take it for a War Office, may be a question to be asked. Messrs. Verity & Hunt's elevation, like their general view, suggests "War Office" more than either of the other two; there is a massive stability about it which is expressive of its purpose; but it must be admitted that it does not present anything which is of much architectural interest in itself; it is the old material suitably worked up by a practised hand, that is all. Even so, however, the coherence and balance of the design brings out the more by contrast the singularly piecemeal character of Messrs. Leeming's elevation, which also consists entirely of well-worn details, with the difference that they are not combined or worked up into a whole at all. Consideration of this detail elevation certainly leads to the conclusion that the amateur element in the Committee of Selection must have been in the ascendant when this design was chosen. In fact, the other two elevations have style; this has no style. To remodel it to the extent that would be desirable would be nearly equivalent to

making an entirely new study of the design in detail. If this were done, as surely it must be, may we suggest among other improvements the removal of the irrepressible flower-pot from the top of the balustrade? It is really melancholy to think that at this time of day it should be proposed to repeat such a piece of senseless and worn-out *rococo* as this, as part of the design of the most important national building of the day.

#### GLAZED HALL AND STAIRCASE, ADMIRALTY.

BY MESSRS. ASTON WEBB AND E. INGRESS BELL.

IN speaking of the design by Messrs. Webb & Bell generally the other day, we adverted to the fine points in the interior plan which would have been formed by the large glazed and arched courts which were to contain the principal staircases, and also to act as *salles des pas perdus* to the several departments, thus making a point of manifest convenience, in the laying out of an elaborate plan, subservient also to architectural effect, as the central features in the arrangement of a plan ought to be. The view of one of these halls, which formed the most noteworthy feature among the fine set of drawings sent in for the second competition by Messrs. Webb & Bell, is here reproduced by the ink-photo process, which gives a certain amount of surface tone and texture to what in its original form was a plain line-drawing, without losing the original lines. This hall was the one which would have formed the principal entrance to the Admiralty Department from the Spring-garden end of the site. Its connexion with the past and present of the Admiralty Department is sufficiently typified in the drawing, by the statues of former distinguished admirals in chronological succession, and the figures of the departmental clerk or private secretary and the obviously maritime official with whom he is holding converse in the foreground; not to mention the seaboards at the foot of the balustrade, and the anchors worked into the pierced panelling above. These specialised details, however, are very minor considerations in an admirable piece of architectural design, which has the merit of being elegant and graceful without weakness. There is, indeed, a remarkable degree of solidity of effect in the piers of the two lower stories, in comparison with the actual mass of the material employed. It is perhaps rather to be regretted that the old conventionalism of breaking the cornice lines over the pilasters and columns has been so much employed; that may be considered the one weakness of the design, and has the disadvantage of producing too marked a vertical division in the upper stages. Of course, when one objects on strict theoretical principle to these conventionalisms of Classic architecture, one may be met by the question, "What would you do instead?"—a question not always easy to answer. Other forms of language besides that of architecture are full of convenient conventionalisms, and life is too short to allow us to do more sometimes than take them as we find them, as part of the current and accepted mode of expression.

Taken on the whole, however, it may be said that this hall, for the design and drawing of which we believe Mr. Aston Webb is specially responsible, is the best piece of architectural work which the competition has elicited.

#### STATUE OF THE LATE

#### LORD FREDERICK CAVENDISH.

THE bronze statue which is about to be erected at Barrow-in-Furness in memory of the late Lord Frederick Cavendish, was, it will be remembered, exhibited (in plaster) in this year's show at the Royal Academy. Our view of the statue is from a photograph of the work as finished in bronze, without any deviation from the cast as exhibited. It was cast in bronze at the foundry of Mr. James Moore, of Thames Ditton. It is of colossal size, being 10 ft. 6 in. high, and is intended to stand on a pedestal of polished Aberdeen granite 14 ft. high, supplied by Messrs. Alexander Macdonald & Co., of Aberdeen. The site selected is in front of the Town-hall at Barrow, and it is expected that the work will be unveiled in about a month hence. In the opinion of those who were most intimate with the deceased, the sculptor has been very successful in his work. The figure is draped in a long Inverness cape, which Lord Frederick was in the habit of wearing.

#### PARISH CHURCH OF ST. LEONARD, MIDDLETON, LANCASHIRE.

THE church lies about seven miles out of Manchester. It was rebuilt in 1412 by Thomas Langley, Cardinal Bishop of Durham. He obtained permission from John (Bourghill), Bishop of Lichfield and Coventry, to visit and consecrate the church. The date of consecration is August 2nd, 1412. Before this time it had been allowed to fall into decay. Parts of the church are built out of fragments of the old church.

In 1524 the south aisle was reconstructed by the Assheton family. The inscription on this aisle (over the window next to the porch) runs thus:—"Richardus Assheton et Anna Uxor eius Anno D'ne MDXXIII." The Assheton arms are carved in the panels of the chancel screen and other places.

There is a large public-house near the church, built half-timbered, called the Old Boar's Head. A boar's head is conspicuous in the arms. It is conjectured that there was a church here in Saxon times. There is a record of a valuation taken by order of Pope Nicholas IV., 1291.

There are fragments of diaper-work, &c., which seem to date much earlier,—1091. The arch in the baptistery seems to have been the chancel of a Norman church altered at the transition.

The drawing is by Mr. Lecson, of Werneth, near Oldham, who has also made an excellent set of measured drawings of interior details, which we will give in another number.

#### NEW ENGLISH CHURCH, HYÈRES.

THE Church of St. Paul, Hyères, France, was consecrated on Wednesday, February 6th, by the Lord Bishop of Gibraltar, Bishop Courteney taking part, and a large number of clergy being present, both from the Riviera and from England.

The church consists of nave and aisles, with organ-chamber and invalids' chapel, gabled as transepts. It is in the Decorated style of the thirteenth, or early part of the fourteenth, century, and is built of walling-stone obtained from a neighbouring quarry, and freestone of fine and durable quality from near Toulon. The roofs are boarded with moulded ribs, both longitudinally and transversely, having carved bosses at intersections, and all in pitch-pine. The chancel-stalls are wainscot-oak. There is no plastering, the walls being worked inside and outside as random rubble, and pointed in black mortar. The windows are in three-tint quarry cathedral glass, by Brewster, of London, and the east window of richly stained glass, manufactured by Messrs. Jones & Willis, of London, who also supplied the whole of the chairs, stalls, and fittings, and executed the rather elaborate carving. The floor encaustic tiles are by Mr. Collier, of London. There is a bell-cot, and (by special and rather exclusive permission of the authorities) a bell by Messrs. Warner. The church will seat 450 persons, and a special characteristic is that the invalids' chapel is arranged for Bath chairs, an easy sloping way having been formed, and screens are to be fixed in each of the arches dividing the chapel from the chancel and church respectively. There are crypts for library and waiting-room and clergy vestry. The church is heated by Muegrue, of London, with hot air, and especial care has been exercised in ventilation.

The cost has been 4,500l., two-thirds of which, with the site, was given by a munificent French gentleman, named Godilliot, residing at Hyères, to whom the thanks of the Prince of Wales were conveyed upon the opening day by the Rev. D. L. McAnally, the secretary of the Colonial and Continental Church Society, who have liberally supplied the remainder of the needful funds.

The contractors were Messrs. Bousquet & Son, of Marseilles, the very indefatigable clerk of works being Mr. Gilling, an Englishman, but thoroughly acquainted with foreign languages and works; and the architects are Messrs. G. Habershon & Fawcner, of London.

**Dangers of Staircase Wells in Artisans' Dwellings.**—Another child has been killed by falling down an imperfectly-protected staircase well in one of the large blocks of artisans' dwellings in flats in South London. Children abound in these blocks of buildings, and efficient means should be taken to render such "accidents" impossible.

THE SOCIAL SCIENCE CONGRESS.

ART DEPARTMENT.

In the course of the discussion which ensued upon the reading of the papers mentioned in our last (p. 419, ante),

Mr. T. C. Horsfall (Manchester) said he did not believe that the mere formation of the society suggested by Mr. Besant would be sufficient. Mr. Besant, he gathered, only contemplated the influencing of adults, but it would be necessary even more to get hold of the children. They must not rest contented till they had carried their system into every elementary school in the kingdom. It was necessary that they should keep in mind two principles, if any good or healthy knowledge of art was to be engendered,—in the first place they must teach the people to recognise the superiority of beauty, and in the next they must also have some means of calling their attention to it. They could not possibly attain these without introducing art into the schools. He believed the South Kensington authorities would do much more good if they lent to the local authorities specimens which appealed to the people's knowledge rather than the specimens which they now sent, and he moved a resolution to that effect.

Mr. P. H. Rathbone seconded the motion. They must appeal first of all to the scholars in the Board Schools, and they could only do that by receiving different specimens from South Kensington to those which were usually now sent. They must have specimens which appealed to the knowledge of the people to whom they were sent. He had been very much interested in what Mr. Tackwell had said about the large number of new makes of artistic pottery, and he himself had been very much struck by the fact that, in pottery especially, they were witnessing efforts on the part of the manufacturers to excel each other in the artistic character of their work.

Mr. Osler (hon. local secretary) deprecated the passage of Mr. Horsfall's resolution, which, he said, was tantamount to asking the Department to go into competition with the shops, and would lead to a great deal of jobbery.

Mr. F. Wilson insisted on the necessity of an education in colour for the young as a primary necessity for an appreciation of a love for art.

Mr. E. R. Taylor explained the principles on which the selections were made by the Science and Art Department for the loan collections in the provinces.

Mr. W. H. Wills, M.P., said he thought that Mr. Horsfall's proposition had been somewhat misunderstood by Mr. Osler, and was of opinion that South Kensington might be made to supply what he termed the missing link. Unless the artisan, or the child in the Board school, was taught to distinguish between what was radically wrong and what was intrinsically good, he did not see how they could make much progress. They must teach the A B C of any language before they could expect any one to progress with its literature. He was afraid, however, from his experience of South Kensington, that unless they found volunteers to explain the objects sent, they would not be of much use. He thought much more might be done by those who, like himself, were large employers of labour, if they provided in the buildings set apart for the refreshment of their workpeople some artistic decoration.

Dr. Heinemann spoke in terms of eulogy of the papers which had been read, and maintained that we must go to the elementary schools if we wished to change the artistic character of the people.

Mr. Mark H. Judge, hon. secretary of the Sunday Society, after an ineffectual attempt to move a resolution asking the Council to seek information from the towns where the museums and art galleries were opened on Sunday,—the Chairman having ruled it out of order,—urged that it was only by opening the museums on the only day of the week when they were available for the great bulk of the working classes that they could bring home to the masses a true appreciation of art.

Mr. Besant, in reply, pointed to what had been done in a single generation by South Kensington as evidence of what might yet be accomplished among the lower classes. He would have his proposed college as elastic as possible, both in regard to its curriculum and its management.

ECONOMY AND TRADE DEPARTMENT.

At one of the meetings of this section, Viscount Lymington, M.P., presided over the discussion of the special question, "Would it be advantageous to give to leaseholders powers entitling them to the purchase of the fee simple of the lands and premises they occupy, or otherwise to interfere by law with the prevailing system of holding and other long leases?"

Mr. John T. Emmett read a paper on the subject, and gave a description of the method of procedure in the manufacture of leaseholds. He observed that the legal costs are heavy, and are needful only because the system is cumbersome; that as a contrivance for inducing wretched building work and miserable houses for the population no more clever and efficient system could have been invented; that leasehold houses are inconvenient and the holding is bad; and that this bad system is, in the metropolis and other districts, rapidly extending. The system was then shown to be enormously disadvantageous to the leasing freeholder, whose property is taken by the lessee at an abatement, owing to the nuisance of the tenure, of some 25 per cent. below the freehold value of the land. The reversion to the freeholder, at the end of the lease, of the lessee's property in buildings is only worth one-eighth part of the 25 per cent. and compound interest lost by the effect of the lease, which 25 per cent., moreover, had it been continuously employed in trade for ninety-nine years, would have amounted to about twelve hundred times as much as the reversion. Leasehold tenure is not the only cause of evil to house property, but it is a most malignant evil, and near London, and in many leasehold towns, the inferiority of leasehold houses to the corresponding work in freehold districts is remarkable. Enfranchisement would be gradual in its operation, and in due time universal, thus improving the condition and morals of the entire population.

Mr. J. S. Rubenstein submitted a second paper on the same subject, which was read by the hon. secretary. The writer started by asserting that there can be no dispute as to the evils of the present system of leasehold tenure. The opinion of the late Master of the Rolls, Sir George Jessel, was quoted to the effect that if lessors were to enforce their rights to the full extent allowed them by law, leases would not exist in this country for six months. The lessee, it was pointed out, is not a free agent in the matter of taking or refusing a lease, as in our large towns it is almost an impossibility to obtain a house fit for the lessee's purpose otherwise than on lease. The hardship to the lessee of being subject to unreasonable and antiquated covenants, and the injustice of sinking his capital in another man's soil in making any alterations or improvements, were dwelt upon. These troubles were, it was suggested, intensified where the lease is granted for lives and not for years, and the pernicious and immoral effects of this system were enlarged upon. Stress was laid upon the fact that the evils of leasehold tenure were not confined to the individual tenant, but that the community was interested in repressing the jerry building, the scamped work, and the sordid uniformity that disgraced the suburban districts, and attention was directed to the fact that neglect on the part of anyone of sanitary precautions may injuriously affect the health of others, however observant of hygienic requirements. The provisions of the two Bills introduced into Parliament by Mr. Broadhurst and Lord Randolph Churchill were briefly referred to. It was, however, suggested that there was one class of persons, the occupiers, whose interest deserved legislative consideration. The occupier was, for the time being, largely interested in the house, and the writer would confer on a *bona-fide* occupant a person who had been in continuous occupation for, say five years, the right to acquire all superior interests. A special tribunal, after the model of the Court created by the Irish Land Act, was advocated as the best form of tribunal for assessing values.

Professor Leone Levi, in opening the discussion, said he desired that the labouring classes should have a greater interest in property. Let the franchise be extended to them, but give them, at the same time, something to defend. He presumed that the readers of the papers would limit their ideas to municipal areas; therefore they were now speaking of house property within the towns, and not of land in general.

The terms would have to be settled by arbitration or by a competent tribunal. It was not a question of confiscation, but of giving fair value, and there would be considerable difficulty in settling the values of certain properties.

Mr. Hurst was inclined to believe that a man who had a ninety-nine years' lease was likely to build as well or even better than he would on his own land.

Mr. Rowlands (hon. secretary to the Leaseholds Enfranchisement Association) believed that no private Bill would carry out what they desired, but it could be done with the aid of the legal officers of the Crown. There seemed to be a tendency to deal with the matter only in its relation to London, but he believed the leasehold system had a much more detrimental effect in some of the provincial towns.

Mr. King Fordham thought that the evils of the present system were very much exaggerated. Those who wished to live in houses of their own would find little difficulty in doing so. It was desirable that there should be two distinct classes, the capitalists who built and the occupiers who inhabited.

Councillor Granger (Birmingham) remarked that the papers had only dealt with the transference of property from one individual to another, forgetting that it was the community at large who made the increased value, and who should have the advantage of the unearned increment. Land ought to be made a marketable commodity; and the proposals of Mr. Broadhurst and Lord Randolph Churchill were a mere tinkering with the question. It was said that a man who built ought to be able to purchase the ownership of the land, but the most difficult part of the question was the standard of value to be fixed. In order to maintain the sanitary position of large towns the generality of dwelling-houses ought to be rebuilt every third generation. There was a great difference between moderately substantial and "jerry" buildings. He admitted the want of a thorough reform of the land laws, but unless it were thoroughly done the land would get into the hands of capitalists, who were worse, as far as workmen were concerned, than the large landholders. The Scotch system of feuing would, if adopted in England, meet all the wants of the community as far as the individual transfer of land was concerned. The Birmingham Improvement Scheme was running on the right lines. The Corporation bought land at its current value, but anticipating that with the progress of the town its value would increase, and giving the community the whole of the increased value.

The Chairman, in summing up, said they were all convinced of the importance of increasing the ownership of land. He had gone so far in that direction as to second on two occasions a proposal introduced by Mr. Jesse Collins, which would have the effect of enabling the State to lend its credit for the purpose of increasing the number of owners. He had opposed Mr. Broadhurst's Bill, not being convinced of its practical benefit. The gist of the matter depended on the unearned increment on land. The great question was to make the law insist that the tenure of land in the large cities should be used for the advantage of the community and not of the individual. Mr. Broadhurst suggested that this would, to a large extent be effected by conferring on every leaseholder the potential right to become a freeholder. In the course of the debate those who supported his views had not answered the financial difficulties embodied in the proposal. It seemed to him that Parliament had a doubtful right to interfere with and override the conditions of a contract originally entered into. The solution of the question seemed to be in the direction of the municipalisation of land, and he could not see why large corporations should not possess compulsory powers to purchase land from individuals on fair terms.

HEALTH DEPARTMENT.

In this department, Mr. J. Hamer, honorary secretary to the Mansion House Council on the Dwellings of the People, contributed a paper upon "What are the best means, legislative or other, of securing those improvements in the dwellings of the poor which are essential to the welfare of the people." Amongst the "other" means for remedying the particular evils, the writer placed in the foremost rank associations of men and women whose object was by personal visitation of and familiar intercourse with the masses to arouse

quality of architectural design,—dignity,—it is superior to them. The introduction of columns extending through two stories secured this effect, so important in a national building of immense size, while, at the same time, variety in the subdivision of the height of the façade was secured. All things considered, I venture to think that the judges have come to a fair and just decision. At the same time, it must be remembered that there are 119 other designs which the judges alone have seen, but which I venture to assert the public had a right to inspect. What I have ventured to object to above is,—though very important,—a matter of detail. It shows, however, such poverty of resource that I feel convinced it will, in some way or other, be altered. The lower entablature must be got rid of. The fenestration is, of course, fixed. The difficulty would appear to me to be solved by slightly reducing the height of the columns and turning arches from them. By this arrangement we should have elegance and variety in place of the proposed rigidity and monotony.

SIGMA.

### The Student's Column.

#### ON THE CONSTRUCTION OF FLOORS.

**T**HE nature of the materials employed in the construction of the floors of a building, as well as the mode in which they are applied, must depend on the character of the building, and the uses to which it is to be put when completed. The surface of the floor may be of wood, stone, cement, or asphalt, while the structure may be of timber, iron, concrete, or brick.

Wooden floors are those most commonly used in this country, and consist of thin smooth boards, nailed closely together, and laid perfectly level upon a row of timbers placed across from wall to wall, and called *joists*. In carpentry the term "floor" is applied to the timbers only which carry the boarding, to which the term "naked flooring" is sometimes applied, and we shall now consider the modes in which these timbers can be arranged so as to give the greatest amount of firmness to the floor.

*Single-joisted floor* is the simplest kind of naked flooring that can be employed, and is the one most commonly used for private dwellings and other buildings where the span between the walls is not very great. The joists are narrow beams, 2 in. to 3 in. thick, and varying in depth from 4 in. to 12 in., according to the distance apart of the bearings; these are placed horizontally across from wall to wall without any intermediate supports, and from 10 in. to 12 in. apart, their ends should be made to rest upon flat pieces of timber hedged on the walls and called *wall-plates*, which are generally  $\frac{3}{4}$  in. wide by 3 in. thick; the ends of the joists being spiked to the plates, and resting not less than  $\frac{1}{4}$  in. upon them. The ends of the joists should not touch the brickwork or masonry, but a space of about  $\frac{1}{4}$  in. should be left between the wood and the walling to allow the circulation of air, and prevent the ends of the joists from rotting. In houses having back and front rooms with a partition between them, the joists should, if possible, be laid in one length from front to back wall, and rest upon a plate on the cross-wall or partition, as their strength and stiffness are greater when they are in one length than when in two lengths. The joists should never be laid wider apart than 12 in. where ordinary floor-boards and ceiling-laths have to be fixed to them; in fact, 12 in. from centre to centre is the most convenient both for floor-boards and ceiling-laths, since the latter are generally 3 ft. in length.

The *scantling of joists*, or the dimensions of breadth and thickness, will depend upon the length of bearing or clear space between the points of support. Allowance 1 cwt. per foot superficial as the utmost weight that an ordinary house-floor will have to sustain, the minimum depth for joists 2 in. thick and 12 in. apart from middle to middle, should be as follows:—

Length of Bearing.	Depth.
5 feet.	4 inches.
7 "	5 "
10 "	7 "
13 "	9 "
16 "	11 "
18 "	12 "

If the scantling is made less than the above, the vibration produced by persons moving about

on the floor will cause cracks to appear in the ceiling below, and will also tend to weaken the walls of the house. When the bearing exceeds 8 ft., it is advisable to stiffen the joists by means of a row of crossed pieces of wood nailed between each pair, called *herring-bone strutting*; of which there should be two rows when the bearing exceeds 12 ft. Before fixing the strutting, a slight camber is sometimes given to the joists by placing a plank underneath them, and forcing up the centre about 1 in.; this plank being removed after the strutting is fixed causes it to tighten so as to render the floor more rigid.

In order to lessen the liability of the ceiling under a single-joisted floor to become cracked, Tredgold suggests that every third or fourth joist be made a little deeper than the rest, and the ceiling joists fixed to the deeper ones, and crossing them at right angles, being notched and spiked to the underside; by this plan the depth is but slightly increased, sounds will not pass so freely as in an ordinary single-joisted floor, and the ceilings will stand better.

The passage of sound through floors is usually prevented to a considerable extent by nailing fillets of wood half-way down the sides of the joists, and laying short pieces of rough board upon them, so as to form a floor on which a coating of rough plaster, called *pugging*, is laid about 2 in. in thickness.

It is sometimes necessary to leave an opening in the naked floor wider than the space between two joists, in which case one or more joists have to be stopped short of the opening, and their ends are let into a cross piece of timber called a *trimmer*, which itself has the ends let into the two joists which form two sides of the opening. A plan of this arrangement is shown on fig. 1, where *a a* are the trimmers; *b b* the

Fig. 1.

trimmer joists, to which the trimmers are fixed by means of tenons cut on their ends, and let into mortises in the middle of the joists; the joists, *c c*, are cut off to allow for the opening and their ends tenoned into the trimmers. The trimmers and trimmer-joists should be rather thicker than the other joists, to allow for the additional strain upon them, and the reduction of strength by cutting away for mortises. In the case of a chimney opening, the trimmers have one end resting on the wall at the side of the chimney-breast, and a fillet of wood is nailed at the side of the trimmer-joist to support one side of a brick trimmer-arch, which is thrown across to the chimney-breast for the purpose of carrying the stone hearth. According to Tredgold, it will be sufficient to add  $\frac{1}{4}$  in. to the thickness of a trimming-joist for each joist supported by the trimmer.

The mode of constructing the lowest floor of a building where the floor is raised only a foot or two above the ground, differs somewhat from that of the upper floors, advantage being taken of the nearness of the ground to make it act as a direct support to the timbers. Pier bricks or walls are built about 5 ft. apart across the building, and on these are laid horizontal pieces of timber called *sleepers*, generally about 4 in. by 3 in.; the floor-joists are laid across the sleepers and spiked to them; the bearing being short we are enabled to use joists of light scantling, about 4 in. by 2 in. being sufficient for ordinary floors. In this kind of floor no trimming is required round the fireplace, *fender* walls being built to support the hearth, and also to receive the ends of the joists. Air gratings should always be introduced in the outer walls below the level of the ground-floor

to allow a free circulation of air, so as to prevent the timbers from being affected by dry-rot. A coating of concrete and asphalt, or else a layer of smith's ashes should be laid on the surface of the earth to prevent damp and noxious exhalations from rising to the floor above, and all vegetable mould or other organic matter must be removed from the ground before the building is commenced. It is recommended that the sleepers should be charred on the surface before being laid to prevent them from being attacked by dry-rot.

*Double-floors* are those in which the floor-joists and ceiling-joists are quite distinct, being notched and spiked to stronger timbers called *binders*, which are laid from wall to wall, and placed from 5 ft. to 10 ft. apart. Fig. 2 shows

Fig. 2.

section of a double-floor taken across the binders, *b*; *a* being the floor-joist notched upon the top of the binders, *d* the floor-boards, *c* the ceiling joist notched to the underside of the binders. Fig. 3 is a section taken at right

Fig. 3.

angles to the previous one, and across the joists *a* and *c*, *b b* representing the binder taken longitudinally. This kind of floor is most effective for preventing the passage of sound, and also for preserving the ceiling from being injured by cracks. The following are the depths that may be given to the binders when placed 6 ft. apart according to the length of span for ordinary house floors, the breadth being supposed to be 6 in. in all cases; for 12 ft. bearing, 11 in. deep; for 15 ft., 13 in. deep; for 18 ft., 16 in. deep. The floor-joists may be 4 in. by 2 in., and the ceiling-joists 3 in. by 2 in. If the binders are placed further apart than 6 ft., their scantling must be increased accordingly, and that of the floor-joists must be as given above for single-joisted floors.

If the floor has to carry heavy weights, as in warehouses, the scantling of the binders and floor-joists must be increased; for ordinary warehouses, binders having a 10 ft. bearing require to be 12 in. deep by 10 in. wide if placed 6 ft. apart; for 15 ft. bearing they should be 12 in. wide by 15 in. deep; and for 20 ft. bearing they require to be 14 in. wide by 19 in. deep. The floor-joists having 6 ft. bearing should be 9 in. deep by 3 in. thick.

In framing these floors the notching out of the joists where they rest on the binders should be as small as possible, since the more cut away the weaker they become; a notching of 1 in. in depth will generally be ample, and a notching, 1 in. square, may be cut out of each side of the binder, so as to allow the full depth of the joist to rest upon it, as shown at *b* in fig. 2.

Sometimes the floor-joists are omitted altogether, and floor-boards, 3 in. thick, laid directly on the binders, which, in that case, must not be placed more than 3 ft. apart; this method, however, is not an economical one as far as quantity of material is concerned, although there is less labour required in the construction; it is only employed where an extra thickness of floor-board is necessary from the heavy wear and tear to which the floor is subjected.

*Framed-floors*, properly so called, are those in which the binders do not rest directly on the walls of the building, but have their ends framed into larger beams, called *girders*, laid across from wall to wall. This method is generally used where the span between the walls is very considerable. The method of framing the binder into the girder is shown on fig. 4, where *G* represents the cross-section of the girder, *B* the binder placed lengthwise at right angles to the girder; the tenon *a* should be about one-sixth the depth of the binder and should be cut at one-third of its depth from the bottom; it should enter the girder as near as

possible to the middle of the depth of that beam which is the part where the girder is subjected to the least strain. The floor-joists *b* are notched on the top of the binders as before

Fig. 4.

described, unless thick boards are used for the flooring and nailed upon the binders themselves, in which case the top of the binders must be placed on the same level as the top of the girders. If there is to be a ceiling below, then the ceiling-joists *a* must be fixed to the bottom of the binders, and must be of sufficient depth to clear the bottom of the girder as shown in the figure.

The scantling of the girders depends upon the distance they are placed apart, the length of bearing or span between the walls or supports, and the loads they have to carry. When placed 10 ft. apart from middle to middle the scantling of girders for ordinary floors, allowing 1 cwt. as the load on every square foot of flooring, should be as follows:—For 17 ft. bearing, 12 in. wide by 13 in. deep; for 20 ft. bearing, 12 in. wide by 15 in. deep; for 22 ft., 12 in. by 16 in.; for 25 ft., 12 in. by 18 in.; for 30 ft., 15 in. wide by 22 in. deep. If the floor has to carry very heavy loads, as in warehouses, factories, and such like buildings, the additional strength may be obtained by placing a pillar of wood or iron under the centre of the girder, by which means it is enabled to carry four times as much load as before. If the length of the pillar is 12 ft., and made of oak, it should be 6½ in. square for a girder of 20 ft. bearing, and 7½ in. square for a girder of 30 ft. bearing.

When timbers of large scantling are employed for girders it is best to saw them down the middle longitudinally, reverse the ends and bolt them together, with slips of wood between the two halves to keep them about an inch apart, the saw-cut being vertical. By this means the carpenter is enabled to see whether the haul is sound in the middle, as it is in the centre that decay usually commences. By reversing the ends the strength of the beam is more equalised; and by leaving a space between the halves the air is allowed to circulate, and prevents decay. The strength may be somewhat increased by fixing an iron tie-rod between the two halves of the girder, in the manner shown on fig. 5, two pieces of iron being fixed

Fig. 5.

at *a* on the bottom edge of the beam, the rod *b* being passed under them and bent at an angle, and secured at the top ends of the beam by means of nuts and screws, which enable it to be tightened up; by this means a slight camber or rise in the middle can be given to the beam, and its stiffness considerably increased. This method is called *trussing* a beam, and a girder so treated is termed a *trussed girder*.

A method of increasing the stiffness of a girder is shown on fig. 6; the beam being

Fig. 6.

sawn in two, and the saw-cut being placed horizontally; the two halves are kept apart by blocks of wood, *a*, which increase its depth, and thereby the resistance of the beam to flexure, which, as we shall presently see, varies as the cube of the depth. Light iron bolts are used to hold the two halves together, the bolts passing through the intermediate blocks. By this method we can get a beam of greatly increased strength and stiffness, with very little more material than is used in a much

weaker beam, as the middle of a beam has very little strain put upon it when loaded, and the removal of that portion takes very little away from its strength.

TEACHING PERSPECTIVE.

SIR,—The diagrams and explanations giving a simple lesson in perspective in the Student's Column of your last issue show lucidly the system as adopted by architectural draughtsmen, and as taught in architects' offices. The principle can be mastered in half an hour, and is applicable to the most elaborate architectural drawing. Students who have not been taught this practical way must be indebted to you for publishing it.

I wish, however, to call your attention to the fact that the examination papers issued by the Science and Art Department at South Kensington to schools are prepared in such a way as prevents students from applying your system; and further, I am informed, by students who have attempted to work out their papers by this simple rule, that they have not passed, although able to draw correct architectural perspectives. I have also found from experience that students who had learned the complex mathematical system of the text-books used and taught from in schools of art, and had received the certificate of the Department, could make no *practical* use of the rules they had been taught.

I am in hopes you will use the powerful influence of your journal to get such a stumbling-block removed from the path of students.

DAVID BARCLAY, F.R.I.B.A.

Glasgow, Sept. 27, 1884.

\*\* We have always considered, and have frequently said, that the study of perspective is rendered needlessly difficult by those complicated systems and diagrams which make a mystery of what really is a simple principle, capable of universal application when once grasped.

THE SOANE MEDALLION COMPETITION.

SIR,—I should be much obliged if any reader could tell me whether persons other than students or members of the Royal Institute of British Architects can go in for the "Soane Medallion" competition. JACK.

\*\* The competition for the Soane Medallion is open to all members of the profession under the age of thirty years. See "General Conditions" and particulars, which may be had for a few pence by writing to the Secretary of the Institute.

MEETINGS.

MONDAY, OCTOBER 6.

King's College, London.—Mr. W. G. McMillan on Fuel (I). 7 p.m.

TUESDAY, OCTOBER 7.

Royal Victoria Hall (Waterloo-road).—Mr. P. H. Carpenter on "Our Bodies, and How they are Kept Going" (Penny Science Lecture). 8.30 p.m.

WEDNESDAY, OCTOBER 8.

Crystal Palace School of Art.—Mr. G. Richards Julian on "Styles of Architecture and their Relation to the Art of Landscape Gardening" (I). 4 p.m.

FRIDAY, OCTOBER 10.

Architectural Association.—Annual Conversazione, in the galleries of the Royal Institute of Painters in Water Colours, Piccadilly. 8 p.m.

Miscellanea.

Builders' Clerks' Benevolent Institution.

A special general meeting of the subscribers and donors was held at the new offices of the Institution, 21, New Bridge-street, Blackfriars, on Tuesday evening last, September 30th, when Mrs. M. E. Robinson and Mrs. A. P. Friend were duly elected pensioners on the Relief Fund. At the close of the proceedings, a vote of thanks was tendered to Mr. Thos. Sirling (who was supported by Mr. J. Howard Cobb, Mr. H. Weller, of the Weston Quarries, and other gentlemen) for his kindness in presiding in place of the president, Mr. Joseph Randall, who was unable to attend.

Typhoid Fever in Kidderminster.—In consequence of the alarming spread of typhoid fever in Kidderminster a Local Government Board Inquiry is being held by Dr. Parsons, and the Corporation and their sanitary officers are now engaged in investigating the cause of the epidemic. The Corporation have called in to advise them Mr. Edward Fritchard, C.E., of Birmingham.

Glasgow Institute of Architects.—On the 25th ult. the annual excursion of the Glasgow Institute of Architects took place. The party started by the 9.50 train from the Central Station, and arrived at Merchiston, near Edinburgh, about eleven o'clock. From Merchiston they drove to Dalmeny Church, where nearly an hour was spent in examining this interesting building, claimed to be the most perfect remaining example of Norman work in Scotland. Luncheon was served at South Queensferry, and the party then drove on to Hopetoun House, the seat of the Earl of Hopetoun. The central portion of this large building was designed by Sir William Bruce in 1702, and the wings by Robert Adam at a later date. The collection of paintings and other works of art was examined with great interest. About half-past three the party arrived at the Forth Bridge works, where they were met by Mr. Arrol, and the rest of the afternoon was spent in a careful examination of this undertaking. A drive to Edinburgh, and dinner in the Windsor Hotel, under the presidency of Mr. James Thomson, F.R.I.B.A., closed the excursion, and the party returned by an evening train to Glasgow.

Art Copyright.—A telegram from the Brussels correspondent of the *Daily News* states that at the Wednesday morning sitting of the Literary and Artistic Congress, in the discussion of the question of artistic property it was admitted that there are two kinds of property involved,—the one material (that of the picture or statue sold), the other immaterial (that of the conception of the work of art). It was impossible for the congress to settle the relations between the artist and the purchaser. After a debate in which several members took part, the congress voted two resolutions proposed by the committee:—First, the right of reproduction of a work of art belongs to the artist independently of the material property of the work. Consequently, the disposal of a work of art does not imply on the part of the artist, unless in case of express stipulation, the alienation of the right of reproduction. Secondly, All reproduction unauthorised by the artist, even by a different art, is an infringement of the artist's right.

Cumberland and Westmoreland Archaeological Society.—The second two days' meeting of the season of the Cumberland and Westmoreland Antiquarian and Archaeological Society commenced on the 25th ult. Under the guidance of Dr. Parker the company went, in the first place, to Wabertwaite from Eskmeals, visiting the church and cross. After luncheon they went along the new road which Lord Muncaster has made through his park at Muncaster Head, and visited the Roman tile-kiln which was found when excavating the new road. This kiln was explained by Dr. Parker and Mr. Ross, Lord Muncaster's steward. From here the company went to Dalegath Hall, and Mr. C. J. Fergusson, of Carlisle, and Dr. Parker read papers. The visitors then proceeded to Hardknot Camp, and to Seascale, where, after dinner, a meeting for the transaction of business was held, Dr. Parker presiding.

A Man Killed by Electricity at the Health Exhibition.—Mr. A. Braxton Hicks, the deputy-Coroner for Westminster, held an inquiry on Wednesday at St. George's Hospital respecting the death of Henry Pink, working electrician, who was killed at the Health Exhibition by an electric shock on Saturday evening last. The deceased has been engaged at a powerful dynamo machine, which generated a current utilised for illuminating purposes. He had informed his father that he was acquainted with the working of the machinery, but it appeared by some carelessness or inadvertence he placed his hands in such a position that the current was diverted, and, passing through his body, killed him. The jury returned a verdict of "Accidental death," expressing their opinion that, though there was no danger to the public, a notice that the machines should not be touched with both hands at the same time should be posted at the spot.

The National Art Library.—The new rooms devoted to the National Art Library at South Kensington Museum were opened for public use on Tuesday last. There are in the library upwards of 60,000 volumes and over 190,000 drawings, designs, engravings, prints, and photographs, all bearing upon art. The number of readers has reached a normal yearly average of 24,000. The new reading-rooms will accommodate about 160 readers with comfort.

**The Fatal Accident in a Board-School Playground.**—Last week Dr. Diplock, the coroner for Middlesex, concluded the inquiry into the death of the little girl who was killed by the breakage and fall of a pole of the "giant's stride" which formed part of the gymnastic apparatus in the playground of a Board-school at Queen's Park, Paddington. On behalf of the School Board, Mr. Spencer Chadwick, of 17, Parliament-street, Westminster, architect and surveyor, deposed that he had seen the pole, and was of opinion that had it been in frequent use it would have shown signs of weakness before it fractured, and had the pole been mended, as it would have been by use, the water would have found its way down to a lower level than where it had evidently lodged, and that portion where the fracture would then never have become so saturated. The pole was comparatively sound a few inches below the fracture, and was a good piece of wood. On the other hand, William Brace was called, and said that he was a timber foreman, and had been thirty-two years in the business. He had examined the broken pole, and his opinion was that the timber was put into the ground when it was wet. It was also tarred, or "pickled," which caused the sap to flow to the heart of the wood and perish the grain.—By jurymen: A pole planted in that condition would rot in five to seven years. That in question was yellow Dantzig (spruce) (?). In his opinion, it had never been properly inspected.—The jury announced as their verdict, "Accidental death," expressing the opinion that the School Board for London was to blame for not providing efficient inspection.

**Amusements for the People.**—The concert season at the Royal Victoria Hall and Coffee Tavern (long known as the Victoria Theatre), Waterloo Bridge-road, commenced on Thursday last, Oct. 2. This and the second Thursday evening concert, to take place on Thursday next, are under the charge of Mr. Lenthal Swift. Arrangements for several succeeding concerts are being rapidly completed with well-known singers. Much care is being given to the arrangement of the programmes so as to secure all possible brightness and variety. The "ponny science lectures" have also been commenced, the first one having been given by Dr. Andrew Wilson on "Our Bones: what they are, and how they are made." The lecture for Tuesday next will be by Mr. P. H. Carpenter on "Our Bodies, and how they are kept going." The lecture on Tuesday, Oct. 14, will be on "Air and Ventilation," by Mr. J. M. Thomson, F.R.S.E.

**East London Union for Advanced Education.**—This society is commencing a series of evening classes on Monday evening next at Dempsey-street, Jubilee-street, Mile End, and we learn that the Council have secured the services of Mr. Howlett, practical carpenter and builder, certificated by the Science and Art Department and the City and Guilds of London Institute, to teach Building Construction and Carpentry during the course extending from October to May. The Council have also secured the services of Mr. G. C. Dymond, practical engineer, certificated by the Science and Art Department, to teach Machine Construction, Mechanical Engineering, and Steam; and those of Mr. Coombs, architect, to teach Practical, Plane, and Solid Geometry. The Hon. Secretary of the classes is Mr. F. H. Parsons, White Horse-lane, E.

**The Societe d'Encouragement pour l'Industrie Nationale**, founded in 1801, and declared of public utility by a decree of 21st April, 1824, has determined the subjects for the competition of 1886. The large medal, bearing the image of Jean Gonjon, will be devoted to Architecture and the Fine Arts. The following have been the recipients of this prize:—1870 (Commerce), M. F. de Lesseps; 1870 (Chemistry), M. H. Sainte Claire Deville; 1872 (Agriculture), M. Boussingault; 1873 (Physics), Sir Charles Wheatstone; 1875 (Commerce), Mr. Jacques Siegfried; 1876 (Mechanics), M. H. Giffard; 1877 (Chemistry), Mr. Walter Weldon; 1880 (Fine Arts), M. Charles Carnier. Further information may be obtained at, and descriptions should be addressed to, the offices, 6, Place Saint-Germain des Prés, Paris.—*Society of Arts Journal.*

**Crystal Palace School of Art, Science, and Literature.**—The programme for the twenty-fifth session, 1884-85, includes a course of six lectures on "Styles of Architecture and their Relation to the Art of Landscape Gardening," by Mr. G. Richards Julian, A.R.I.B.A.

**Building Estates at Clapham and Stockwell.**—The estate on the east side of High-street, Clapham, formerly belonging to the trustees of the Clapham Grammar School, is about to be built upon, having just been disposed of on lease. The estate covers an area of between two and three acres, and has been laid out for the erection of about sixty houses, letting at rentals ranging from 50l. to 60l. per annum. A new road, 40 ft. in width, called St. Luke's-road, approached from High-street, passes through the centre of the estate, and is at present being drained and paved by the freeholder. The houses are intended to be built with red brick. The architect to the estate is Mr. W. Randal Lacy, and amongst the principal lessees and builders are Mr. H. A. Brown and Mr. Bach, both of Clapham.—The Stockwell Small-pox Hospital in Landor-road, about midway between the Brixton and Clapham roads, seems no longer to have any terrors for the speculative builder. Within the last twelve months upwards of 500 houses have been erected on two large estates, which have been laid out immediately in front of the Hospital, and tenants are found for the houses almost before they are completed. What has for many years been known as Theobald's Farm, immediately adjoining the Hospital, on the east side, has now got into the hands of the builder, and the stables and other buildings on the estate are now in course of demolition preparatory to the laying-out of several new streets, in which between 300 and 400 houses will shortly be erected.

**The Surveyorship of Chelsea.**—At the meeting of the Chelsea Vestry on the 16th inst. consideration was given to the letter from Mr. George H. Stayton, C.E., dated August 6th (to which we have previously referred), resigning the office of Engineer and Surveyor to the Board. Mr. Churchwarden Wheeler moved "That Mr. Stayton's resignation be accepted by the Board, with very sincere regret, accompanied with every expression of their high appreciation of the talents he has displayed during the nine years and a half he has held the appointment, and with their best wishes for his health, prosperity, and success in any sphere of action he may hereafter enter upon." In supporting the resolution, Mr. Wheeler spoke at length upon the importance of the work carried out by Mr. Stayton, of his successful administration, and of the great regret that all felt at his departure. Mr. Davidge seconded the resolution, which was agreed to *nem. con.*, and it was determined to engross it, and present it to Mr. Stayton. Mr. Stayton at the same meeting submitted to the Vestry a report which he had been instructed to make to them as to the electric lighting at Colchester, to which we may return.

**Conservatory at Bradford.**—The Mayor of Bradford has just added a spacious conservatory to his residence at Daisy Hill, Bradford. All the latest improvements in ventilating apparatus and hot-water heating have been introduced. The conservatory may be described as a rectangular building, 40 ft. long by 25 ft. broad. The whole work has been designed and carried out by Messrs. Messenger & Co, horticultural builders, of Loughborough, who have also carried out the heating of the building with their patent elastic jointed pipes.

**University College, Bristol.**—As will be seen by an advertisement in another column, a special course of instruction has been arranged for those intending to become architects, which has received the entire approval of local architects. Amongst other lectures and classes are included lectures on the history of architecture, and also the theoretical and practical treatment of the science of building. The engineering department of the college also includes civil, mechanical, or electrical engineers, or surveyors.

**The New Council Chamber of the City of London** was opened on Thursday last, the 2nd inst. The building has already been pretty fully described in our columns, but there are a few details of interest to which we may return. A large view of the interior was published in the *Builder* nearly a year ago (Dec. 1, 1883). The building reflects much credit on the City Architect, Mr. Horace Jones.

**"Sanitation at Brighton."**—As to the notice of Mr. Chappell's new flats at Brighton under the above heading in last week's *Builder* (p. 421), we are asked to say that they were dried by Messrs. A. Dreyfus & Co. with "Ligny's Patent Process."

**New Bank of Victoria, South Melbourne.** One of the newest buildings in the new city of South Melbourne is that lately erected for the Bank of Victoria. It has a frontage of 40 ft. to Clarendon-street, with an elevation of 41 ft. The lower story is carried out in the Doric order, set on a polished Malmsbury base-course, having an imposing entrance to the banking-chamber, with columns on each side, surmounted with pediment, terminating with a Doric cornice. The upper story is in the Corinthian order, with columns above the main entrance, and circular windows and enriched impacts, above which is the Corinthian cornice and balustrade. The whole building (including fittings) have been erected under the supervision of and from plans drawn by Mr. W. S. Law, architect, South Melbourne. Mr. C. H. Martin is the contractor for the buildings, and the fittings were executed by Mr. Charles Beecham, of Post-office-place. The building will cost about 3,000l.—*Australasian Sketcher.*

**Phosphorized Brass Wire.**—The advantages of phosphorized wire are that it is very tough, takes a high polish, and does not corrode. The operation consists in placing bronze or brass wire in a solution of from 1 to 5 per cent. of phosphorus in either bi-sulphide of carbon or olive oil, together with 5 to 10 per cent. of sulphuric acid and 85 to 95 per cent. of water, until the metal takes up the phosphorus. The wire is then drawn to one number finer, and placed in a closed retort, with a thin layer of phosphorus, so that the vapour may spread over the surface of the wire. It is next packed in charcoal and kindled, and, after proper annealing, the wire can be again drawn to a finer number, the process being repeated until the desired fineness is obtained.

**Commercial Failures.**—According to *Kemp's Mercantile Gazette*, the number of failures in England and Wales gazetted during the week ending Saturday, September 27th, was sixty-one. The number in the corresponding week of last year was 147, showing a decrease of eighty-six, being a net decrease in 1884, to date, of 5,033. The failures in the building trades last week numbered four, as against eighteen and fifteen in the corresponding weeks of 1883 and 1882 respectively.

**Westminster Technical Schools.**—The Technical Classes in connexion with the United Westminster Schools were opened on Wednesday evening by Sir J. C. Lawrence bart., M.P., Mr. W. E. M. Tomlinson, M.P., and other Governors. The classes are held in the evening. The prospectus sets forth the very complete scheme of classes and lectures which has been arranged, the subjects including Drawing, Building Construction, and Machine Construction and Drawing. The fees are low.

**Westminster Abbey.**—The stone which is being used in the restoration works now in progress at Westminster Abbey is, we understand, being supplied by Mr. T. P. Lilly, of the Chilmark and Wardour stone quarries, Wiltshire. Mr. Lilly has supplied stone for a long time for restoration at Westminster Abbey, the Chilmark stone having been used by Messrs. H. Poole & Sons, the Abbey masons, for many years, notably in the Chapter House, the south transept front, and the north porch.

**Alnwick Water Supply.**—For some time past considerable inconvenience has been felt in summer time in consequence of insufficiency of water at Alnwick, and the local authorities have therefore resolved to go thoroughly into the question of increased supply and new waterworks. They have called in Mr. J. P. Spencer, C.E., of Newcastle-on-Tyne, to report upon the whole subject, and advise them as to the best means of providing for the requirements of the district.

**The Statuary for Blackfriars Bridge.**—The groups of equestrian statuary designed for the pedestals at the extremities of Blackfriars Bridge appear to have been decided on, and to include representations by Mr. Brock of Edward III.; by Mr. Hamo Thornycroft of Edward I.; by Mr. Birch of Henry V.; and by Mr. Belt of William the Conqueror.—*Althenam.*

**Exhibition at Eastbourne.**—The Eastbourne Arts, Sciences, and Sanitary Exhibition was opened on the 23rd ult., in the Pavilion, Devonshire Park. Lectures on subjects more or less bearing upon the objects of the Exhibition have been delivered.

**Mr. Thomas W. Cutler.**—We learn with regret, which will be shared by many of our readers, that Mr. T. W. Cutler lies seriously ill at his house in Queen-square, Bloomsbury.

Photographic Society of Great Britain The private view of this year's exhibition takes place to-day (Saturday), October 4th. The exhibition will be opened to the public on Monday next, and will remain open until the 13th of November.

The Inner Circle Railway.—The Inner Circle completion line was opened for experimental traffic on Wednesday morning. In the event of the directors' expectations being realised, the line will be available for public traffic on Monday next.

For girls' and infants' department of Board Schools Edward-street, Deptford, for the School Board for London Mr. E. R. Robson, architect.—

CONTRACTS AND PUBLIC APPOINTMENTS.

Epitome of Advertisements in this Number.

CONTRACTS.

Table with columns: Nature of Work, or Materials; By whom required; Architect, Surveyor, or Engineer; Tenders to be delivered; Page. Includes entries for Broken Granite, Effluent Sewer, Filter Bed, Kenning Tar-Faving, etc.

Table listing names and amounts: J. W. Hobbs £11,400 0 0; Turle & Applton 10,994 0 0; J. Grover 10,897 0 0; C. Cox 10,836 0 0; Stimpson & Co. 10,833 0 0; Scrivener & Co. 10,520 0 0; W. Downs 10,484 0 0; Wall Bros. 10,462 0 0; Atherton & Latta 10,440 0 0; W. Bangs & Co. 10,340 0 0; C. Wall 10,330 0 0; H. Hart 10,300 0 0; Lathey Bros. 10,232 0 0; W. Johnson 10,182 0 0; Kirk & Randall 10,114 0 0; S. J. Jerrard 10,039 0 0; W. Oldrey 10,000 0 0; J. Holway 9,951 0 0.

For rebuilding workshops and organ-room, Kings-road, Camden Town, for Messrs. Goodall. Mr. Silvester C. Capes, architect. No quantities.— Wall Bros. £340 0 0; A. G. Holding 517 0 0; Gladis Bros. 460 0 0.

For alterations to 3, Jewry-street, Aldgate, for the Great Tower-street Tea Company. Mr. Richard Peters, architect, 72, Wool Exchange, Coleman-street, E.C.— Omson & Co. £1,300 0 0; Richardson Bros. 888 0 0; Kemp 812 0 0; Watson (accepted) 731 0 0.

For the erection of church and presbytery, Broxwood, near Pembridge, Herefordshire. Mr. C. F. Hanson, architect, Clifton, Bristol. Quantities supplied.— Bullock & Co., Wellington, Salop £2,738 0 0; J. Sandford, Letton, near Hereford 2,225 1 5; J. Wilkins, Bristol 2,710 0 0; R. Morgan, Kingston, Herefordshire 2,329 0 0; C. Edwards, Leominster 2,477 14 8; J. Perrott, Bristol 2,294 0 0; J. Williams, Knighton, Radnorshire 2,218 7 0; H. Welsh, Hereford (accepted) 2,200 0 0.

For the pulling down and rebuilding of the Raven Inn, situate in Rawson-street, New Baford, Nottingham, for Mr. Wm. Malby. Mr. Herbert Walker, C.B., architect, Nottingham.— Dudson & Parrish £1,389 13 8; E. Hind 1,347 0 0; Woolf Bros. 1,170 0 0; Bell & Son 1,260 0 0; H. Vickers 1,253 0 0; J. R. Morrison 1,243 0 0; J. F. Price 1,230 0 0; Wheatley & Maud 1,220 0 0; G. Brownell 1,220 0 0; S. J. Cargell 1,200 0 0; H. Scott 1,173 0 0; Bains & Turton 1,170 0 0; W. H. Taylor 1,123 10 0; W. Bailey 1,097 0 0; J. Noble (accepted) 1,093 0 0. [All of Nottingham.]

PUBLIC APPOINTMENTS.

DOUGLAS FOUNDRY, Publisher. Addressed to No. 46, Catherine-street, W.C.

Advertisements for the current week's issue must reach the Office before THREE o'clock p.m. on THURSDAY.

SPECIAL.—ALTERATIONS IN STANDING ADVERTISEMENTS OR ORDERS TO DISCONTINUE same, must reach the Office before TEN o'clock on WEDNESDAY morning.

PERSONS Advertising in "The Builder," may have Reprints addressed to the Office, 46, Catherine-street, Covent-garden, W.C., free of charge. Letters will be forwarded if addressed envelopes are sent, together with sufficient stamps to cover the postage.

TERMS OF SUBSCRIPTION. "THE BUILDER" is supplied direct from the Office to residents in any part of the United Kingdom at the rate of 12s. per annum, PREPAID. To countries within the Postal Union, 20s. per annum. Remittance payable to DOUGLAS FOUNDRY, Publisher, No. 46, Catherine-street, W.C.

TO CORRESPONDENTS.

Received.—J. H. T. P. Bros.—F. H. N.—W. W.—C. H. T.—J. P.—W. B. G. B.—D. L. A.—C. M.—M. F. B.—J. H.—Justitia—G. N.—Nemo (and name and address)—J. & J. E. (last week).—Stenton (no title for this week)—W. G. (MS. received)—E. G. (your letter published true, we fear, as to facts, but the deductions therefrom quite untenable, not to say mischievous).

All statements of facts, lists of tenders, &c., must be accompanied by the name and address of the sender, not necessarily for publication. We are compelled to decline printing out books and giving addresses.

Note.—The responsibility of signed articles, and papers read at public meetings, rests, of course, with the authors. We cannot undertake to return rejected communications.

Letters or communications (beyond mere news-items) which have been duplicated for this week, are NOT DESIRED. All communications regarding literary and artistic matters should be addressed to THE EDITOR; all communications relating to advertisements and other exclusively business matters should be addressed to THE PUBLISHER, and not to the Editor.

Best Bath Stone. WESTWOOD GROUND, Box Ground, Combe Down, Corsham Down, And Farleigh Down. RANDELL, SAUNDERS, & CO., Limited, Corsham, Wilts. [Advr.]

Box Ground Stone. Is the Best for Use in all Exposed Positions, being a well-known and tried Weather Stone. 50,000 feet cube in stock. PICTOR & SONS, BOX, WILTS. [Advr.]

Doubling Freestone and Ham Hill Stone of high quality, in blocks, or prepared ready for fixing. An inspection of the Doubling Quarries is respectfully solicited; and Architects and others are CAUTIONED against inferior stone. Prices, delivered on any part of the United Kingdom, given on application to CHARLES TRASK, Norton-sub-Hamdon, Ilminster Somerset.—Agent, Mr. E. WILLIAMS, 16, Craven-street, Strand, W.C. [Advr.]

Doubling Free Stone. For prices, &c., address S. & J. STAPLE, HAM HILL STONE, Quarry Owners, Stone and Lime Merchants, Stoke - under - Ham, (Ground or Lump), Ilminster. [Advr.]

Asphalte.—The Scyssel and Metallo Lava Asphalte Company (Mr. H. Glenn), Office, 38, Poultry, E.C.—The best and cheapest material for damp courses, railway arches, warehouse floors, flat roofs, stables, cow-sheds and milk-rooms, granaries, tun-rooms, and terraces. [Advr.]

Asphalte. Scyssel, Patent Metallo Lava, and White Asphaltes. M. STODART & CO. Office: No. 90 Cannon-street, E.C. [Advr.]

### Bricks, Tiles, and Terra Cotta.

R. DAVIS'S work on the manufacture of bricks, tiles, and terra cotta\* in every respect bears out its title of "A Practical Treatise," and is eminently characteristic of the nationality of its author, for it deals only with the practical side of the art on which it treats, and enters into the minutest details of the various branches into which that art is divided. We have hitherto flattered ourselves that as a nation we had pretty well mastered the art of brick-making, however short we may have come in the manufacture of the finer descriptions of pottery, but a perusal of Mr. Davis's work shows that we have yet a good deal to learn in all the various processes through which a brick has to pass before it arrives at the proper degree of perfection for the particular purpose for which it may be required. While admitting, however, that in this special class of our manufactures there may yet be much to be desired, we hope Mr. Davis's anticipations are not likely to be realised, that it has reached its highest standard, and will henceforth have to give way before the superiority of American art, and that Staffordshire is destined to become the *entrepôt* of American tiles, as Liverpool is of American meat. "Sending tiles to Staffordshire may seem to the majority of Englishmen as a wild improbability, but ere long that fact will be established," writes our author; but the fact which he assigns as aiding to this end is not usually understood as "too entirely dominating the English mind," viz., "a tendency to lower the high standard of wares, and produce something cheap." We are accustomed, on the contrary, to attribute this failing to our cousins, and to wonder how it can ever be worth while to produce even, much less to export, the number of cheap trifles which are exhibited in the special "notions" shops to be found in some of our principal streets. There can be no doubt, however, as to the rapid strides which America has made in ceramic art, and there are many valuable hints and facts to be gathered from Mr. Davis's work, which as a whole, cannot fail to be appreciated in this country, embracing as it does the entire field of manufacture, from the simple plain wall-brick to the artistically-ornamented encaustic tile or terra-cotta ware.

\* "A Practical Treatise on the Manufacture of Bricks, Tiles, Terra Cotta, &c." By Charles Thomas Davis, London: Sampson Low, Marston, & Co., Philadelphia: H. C. Baird & Co.

It would scarcely be supposed that so prosaic a subject as that of brick-making could offer attractive material for history; but the first chapter in the book contains much which is interesting even to the general reader. In it is traced the manufacture from its commencement on the plains of Shinar, when the descendants of Noah in 2247 B.C. said "Go to, let us make bricks and burn them thoroughly," through the period of Israel's bondage to their Egyptian task-masters, down to the age of Grecian and Roman dominion, along Medieval times, and ending with the present day. During the first two centuries of the Christian era, the art under the Romans appears to have reached perfection, only afterwards to decline until the fifteenth century, when it revived, as evidenced in England by such specimens as the Lollards Tower and Hampton Court; and in Italy, in the beautiful brickwork and elaborate ornamentation of its ecclesiastical and palatial architecture. In Holland, however, brick was the chief building material from the earliest times, and it was under the direction of a Dutch Governor seemingly that bricks were first used in the construction of houses in America; but it was not until the eighteenth century that they were brought into common use, and then only such as were imported from England. For some time America appears to have made but little progress in the art; "but," adds Mr. Davis, "at the present time, for both quantity and quality, we have no equal in any nation of the world," being indebted, in his opinion, for this position "to the American patent system, which greatly fosters and encourages development in this line, as in other and kindred arts." That the patent system of Great Britain is faulty is generally acknowledged, and steps have recently been taken for its amendment, but it is questionable whether its defects are answerable for all the results attributed to it by Mr. Davis, and whether the machines for the production of bricks described in the volume, and which are said to be fruits of the superior American patent system, "evidences of a high civilisation" though they may be, yet deserve to be considered "as but tokens which are in time to place the manufacturers of the world under American control." Mr. Davis, however, discusses the conditions of the amended Patent Law, and while admitting that some of its points are worthy to be copied, yet describes it on the whole "as too much a relic of a period which is long since past," and the general conclusion at which he arrives is that a nation which adheres to antiquated ideas and customs must give place to the one whose new-born energy is continually causing it to develop its ingenuity in new and varied directions. The argument would have weight

if the premises were correct, but the fallacy consists in the assumption of our adherence to an obsolete past. That necessity stimulates the faculty of invention is undeniable, but it is this very necessity, engendered by the keen competition of the present day, that is acting on the English inventive faculty, just as it has done in America, and is daily calling forth in this country discoveries in science, and improvements in manufactures such as have never before been witnessed, and which will continue to keep Great Britain in the van amongst the nations of the world.

Before describing the processes or the machines employed in the manufacture of bricks, the author devotes a chapter to a description of the various clays, and of the changes they undergo under the several conditions to which they are subjected, justly observing that a thorough knowledge of the clay to be employed in any particular manufacture is essential to insure a successful result. It sometimes occurs that clays are found satisfying all the conditions necessary for turning out good bricks, but more often the earth requires an admixture of other material, or else has to be specially treated in order to get rid of substances which are hindrances to the production of even a passable quality of building bricks. The proper way of overcoming these and other difficulties is clearly explained, and the various methods to be employed in dealing with the different descriptions of argillaceous earth that are suitable for brick manufacture are minutely detailed. The efflorescence, commonly known as "saltpetering," that is so often to be seen on buildings and walls is a phenomenon better known than understood. It is remarkable that during the autumn of 1882 more of this efflorescence was to be seen upon buildings on both sides of the Atlantic than had appeared for many years; old structures as well as new, and those in process of construction, such as the Technical College at South Kensington, being covered with it. "The question of what this efflorescence was, and its cause was investigated by various scientific societies, the Academy of Natural Sciences in Philadelphia discussing it at length; and the substance of their decision was that it was simply ordinary Epsom salts or sulphate of magnesia, which dissolved in the water passing over the bricks, and in evaporating left the deposit; the sulphurous acid, resulting from burning coal, combining in the presence of moisture with the magnesia in the mortar and forming the salts." Various other theories have been set forth as to its origin, but Mr. Davis adds that "there appear to be certain conditions which facilitate the production of the saltpetre, viz., a degree of humidity about equal to that of

garden earth is very favourable; between 60 deg. and 70 deg. Fahr. vitrification is the most abundant; at 32 deg. it does not take place at all." Whatever the cause of it, however, there is no doubt but that it should, as urged by the author, "render the research into it highly interesting to the architect and the builder, on account of the disagreeable effect it produces upon decorations, internal as well as external, and of its action in greatly lessening the durability of stone," an instance of which occurs in the Houses of Parliament. It is well known to engineers, however, that its appearance is not always due to the bricks, but that it is often owing to the ingredients of which the mortar has been composed; and hence, probably, its effect upon buildings erected or faced with stone.

While on the subject of clays, mention is made of the earth described by Strabo A.D. 24 as found at Pitane in the Troad, from which bricks were made so light as to float upon water. For centuries the art was lost until rediscovered by Giovanni Fabroni, in Tuscany, in A.D. 1791, who succeeded in making such bricks, the strength of which at the same time was but little inferior to that of ordinary building bricks. One remarkable peculiarity possessed by them was that of being very poor conductors of heat, as they could be held by one end with the bare hand while the other was red hot,—the practical use to which that property could be turned being illustrated by the experimental construction of a powder magazine on board a wooden ship, which, being set on fire, sank without explosion of the powder. There are several purposes to which these bricks can be profitably applied, such as the fireproofing of floors, ceilings, and roofs,—and notably in the construction of walls in substitution of the frame partitions now commonly used in the upper stories of lofty buildings for the sake of lightness, wherein economy is studied at the expense of security against fire. Hollow bricks of this description, it is suggested, would be sufficiently light to be easily supported by the iron girders now used wherever large spans of floors are required to be partitioned off, while the advantage of diminishing the danger from fire would lessen the rate of insurance, not only on the building but on the stock it contained, and so, probably, be a sufficient set-off against the increase, if any, in the cost of construction.

A common practice in this country, viz., that of mixing ashes in large quantities with the clay, with the view of gaining time in the burning, is severely condemned by Mr. Davis, not only as rendering the bricks "very porous, greatly weakened, and generally shaky," but as causing an intolerable nuisance to the whole neighbourhood where the kilns are in operation, and a serious source of injury to the health of the inhabitants in the nauseating fumes given out from the various substances which are mixed up in the "soil." That the odours arising from brick-kilns are unpleasant is unquestionable, but they are not generally understood to be injurious to health. No doubt, however, that the practice is rightly condemned, and that brickmakers would consult their interests best by abandoning it. Some interesting particulars are given as to the strength of different descriptions of bricks, and perhaps few people are aware of the enormous pressure that the best quality of hard-burned bricks are capable of bearing. Mr. Davis states that, according to tests made by the direction of an officer of the United States army, the bricks used in the erection of the Pension Office at Washington stood a pressure of from 6,050 lb. to 10,290 lb. per square inch, or from 420 to 700 tons to the square foot, "which is more than good granite, and three times as much as good building stone will stand." In comparing the merits of dry and damp clay, preference is given to the latter, for the reason that "the nearer clay approaches the plastic condition when moulded into bricks, the better will be the stock produced; for when clay is dried before being moulded it is impossible to produce a strong brick, the particles of clay will not agglutinate under pressure, and in the kiln the heat will pass through the brick and not be so effective as in a damper and denser made brick." Not

only so, but "it will require 25 per cent. more fuel and longer time to burn the dried clay brick than the one made with damp clay," a fact which is probably not known to many manufacturers. Much valuable information follows in the two sections of Chapter III, on the process of enamelling and glazing bricks and tiles, earthenware, &c., and on the various substances used for the purpose, accompanied by some illustrations of ornamental bricks produced by the Peerless Brick Company, of Philadelphia.

A couple of chapters are devoted to the manufacture by hand and by machines, in which the details of preparation of the clay, and of the processes of tempering, moulding, drying, conveyance to the kiln, and burning, are minutely described and discussed. Mr. Davis claims for the bricks manufactured in Washington and its neighbourhood a superiority over any and all others in any part of the world for "strength, uniformity in colour, as well as in size, good edges and corners, and for all other reasons that can be named," alleging as the reason for this "that the enormous quantities of bricks consumed by the United States Government and the local Government have in both cases to pass the inspection of Engineers of the United States Army, or of experts employed for the purpose." We doubt if English manufacturers are prepared to admit such a claim, and shall be greatly surprised if equally good samples of every kind of brick that is made are not to be found in this country. At the same time, unquestionably many improvements appear to have been introduced in the American machines and modes of manufacture, which, if not already known in this country, will soon be appreciated and adopted. Amongst other minor articles is a pattern of brickyard barrows so constructed as to be easily folded up for transportation, to be used wherever needed in the construction of tunnels, culverts, on lines of railways, or other purposes.

The hints given on the burning of bricks, with the improved designs for kilns, are invaluable, inasmuch as they are the results obtained from actual working, the arrangement of the flues being especially noticeable as calculated to effect a more regular and equable diffusion of the heat than takes place in the kilns in ordinary use in this country.

Perfect, however, as hand-made bricks are, yet the enormous demand which has arisen consequent on the development of railways and extension of public works generally has rendered the introduction of brick-making machinery a necessity, and has called forth much ingenuity in the construction of machines for saving labour in the moulding of bricks from the crude clay. Of these machines there are two classes,—one employing moulds, into which dry clay is forced and shaped; the other, in which moist or plastic clay is forced through a die in the pug-mill in a continuous string, and cut off by some arrangement to the requisite size. The author is of opinion that bricks produced from dry-clay machines are unsuitable for engineering construction, though they may be used for architectural purposes, but inasmuch as their porosity is considerable, and they consequently absorb moisture very readily, it is necessary to be very careful in their selection, especially for buildings which are to be devoted to public speaking or to music, for dampness in walls affects the acoustic property of rooms by conducing to a great reverberation and confusion of sound. Consequently much importance is attached to the drying of bricks thoroughly. This operation is carried on in America by means of steam-driers, the use of which, besides effecting great economy in the after consumption of fuel in the kilns, saves handling the stock twice,—once in the "packing," and once in conveyance to the kilns. "The cost of coal to dry bricks artificially is therefore much more than saved by the economy of labour, while the amount of fuel to burn the bricks is less because they have been more thoroughly dried than by the open air." Hence, it is asserted, "the expense of artificial drying is less than that of sunshine." There is also the additional advantage of being able to keep the establishment employed in all weather, and throughout the whole instead

of only a portion of the year, "but," adds our author, "these advantages sink into insignificance when the superior quality of the bricks is considered."

The chapter devoted to fire-clays, fire-bricks, and other products affords much valuable information, especially as to the composition and varied constituents of fire-clays, a point, however, on which the practical brickmaker does not usually much trouble himself, being content with that material which yields the best results in actual use. It is here that the dry-clay machines are invaluable, as the quality required in fire-bricks is not strength, but resistance to heat, a property which is secured by severe pressure producing tenacity of texture, the best condition for assisting vitrification. Illustrations are given of several machines for the treatment of fire-clays and for working them into any desired degree of fineness, one of the best being an arrangement of elliptical rollers by which the material is subjected to a rubbing action between their impinging surfaces. Amongst other purposes to which fire and terra-cotta clay has been applied, an instance is quoted of the columns which have been constructed in the United States Peruvian office for supporting the galleries which run entirely around the interior of the building, which is 400 ft. long by 200 ft. wide. The columns are bricks in sections 6 in. thick, laid in Portland cement, in which material the bottom section is carefully bedded, being encircled with a cast-iron rim, and forming the base of the column. When finished, the whole is cemented over with the same cement kept damp for several days to prevent its drying too rapidly. In the same building hollow fire-clay tiles are used for the floor-arches and ceilings, an 8-in. tile arch, with a span of 5 ft. between the beams, sustaining a weight of 2,000 lb. per square foot of floor. General Meigs, of the United States Army, who is superintending the construction of the same building, has carried out a series of tests as to the resistance of terra-cotta sheathing-tiles to a superimposed weight, which was applied to the middle of the tiles, the edges of which were supported so as to leave a clear span of 22 in. "Tiles of pure clay sustained a weight of 2,394 lb. before yielding, while those of mixed clay and saw-dust gave way under a pressure of 1,940 lb."

The seventh chapter in the book is devoted to terra cotta, and opens with the following interesting remarks as to its durability:—"Many early productions, even of less durability than those now made, are found in ruins of stone, in which the latter material has been steadily disintegrating for thousands of years; but leaving the terra cotta as perfect, in many cases, as if recently produced. In faithfully-made and vitrified terra cotta we have the great and only lasting triumph of man over natural productions; for timber will rot; stone, even granite, will disintegrate; iron will oxidise. These and all other metals will succumb to the action of fire and other destroying influences of the elements; but properly-made and thoroughly-burned terra cotta will pass through the centuries and be the last to yield to those influences to which all natural productions must give way, the material being not only absolutely fire-proof, but also, in all architectural employments, practically time-proof and indestructible. Bank-notes, notes of hand, deeds of property, private transactions, public records, and many things of this character, have been and can still be found in a good state of preservation among the ruins of the great city, ancient Babylon, but they are not in the shape of perishable paper or parchment, but in the indestructible terra cotta." The application of terra cotta to many purposes and in many designs is clearly explained, but the character of design and the manner of treating it are well said to be subjects for much thought, and a true piece of criticism is conveyed in the following sentence:—"Truth is an absolute necessity in all terra-cotta designs, and as a desire for real in the face of sham materials is the cause of its revived use, why should the object of its employment be defeated? by using it so as to imitate other materials? One use to which terra cotta has been turned in

America is the manufacture of "lumber," by mixing resinous sawdust with the wet clay, which is left porous after the burning by the sawdust being consumed. After being treated in the mill, compressed, dried, and finally burned, it is planed, tongued, grooved, or sawn into any desirable shape, and is capable of being applied to a variety of uses. It can be united like joiner's work, or nailed into place like so much wood. It has been used for filters on waterworks, and, as a good insulator, being easily made water-proof, it will probably be utilised for underground telegraphy. If all that is stated of it turns out to be correct, the New York Terra-cotta Lumber Company has seemingly a brilliant future before it.

The next chapter is occupied with the manufacture of roofing-tiles and sewer-pipes, and contains minute descriptions of the various labour-saving machines which have been invented and are in use in America, and, with reference thereto, certain remarks are made with regard to the unreasoning objection of labouring men to machinery which deserve to be quoted in full:—

"Machines stimulate business, and increased interest to all pursuits, concentrate the hours of employment, and it is only from this source that the hours of labour which the workmen in all countries are trying to curtail, can be successfully reduced, and all the wants of mankind supplied at the same time. From the start, working-men have directed their influence against labour-saving machinery; but in defiance of their efforts against it good has resulted to them in spite of themselves. Would they like to go back to the old hours of labour, from sunrise to sunset, live as they did then, and do without the advantages of education to themselves and children, now so common in this country? Cheap homes, food and raiment, as well as cheap books and other sources of knowledge are the results of labour-saving machinery."

The manufacture of roofing-tiles and sewer and drain pipes has reached a pitch of such excellence in this country that it is doubtful whether it is surpassed by that of any other country, and whether England has anything to learn in this respect; so also with ornamental tiles, which form the subject of the concluding chapter of Mr. Davis's work. We have already alluded to his expectation that America is to supplant the rest of the world in this as well as other branches of manufacture, and excellent as some of the pottery out-turn of that country may be, we certainly cannot agree in the assertion which claims for it a superiority over English manufactures, or that "English art in the whole line of artistic pottery has reached the highest points of development that it can ever attain under the present constitution of its society, and, what is more, it has been stationary, but is now on a decline." A visit to any of our principal potteries would be sufficient evidence that our author's assertion is incorrect. While quite ready to acknowledge the wonderful inventive faculty exhibited by Americans, and the exceedingly practical results attained by it, we scarcely think the time has yet arrived for the displacement of English for American machinery. It is certainly with great interest that we look forward to the Exhibition of Inventions which has been promised for next year, and hope that we may have an opportunity of seeing for ourselves specimens of all the ingeniously-designed machines which Mr. Davis's volume contains, and we feel sure that whatever merit they may be found to possess will meet with a full appreciation by British manufacturers in every trade; we would meanwhile commend Mr. Davis's volume to all who are interested in the subjects which it so ably treats.

**Caseine for Sizing.**—An albumenoid substance may be used for paper sizing, the albumen extracted from eggs or blood is too expensive for general employment. Caseine from milk has been substituted for egg albumen, by M. Muth, of Karlsruhe, for it has the same chemical composition. It is but slightly soluble in pure water, but may be wholly dissolved in water that is slightly alkaline.

#### "TO SURVEYORS AND OTHERS."

**I**T is, unfortunately, a well-known fact that for some considerable time past there has been so great a depression in public works that a large number of engineers and surveyors have had little to do, or have been out of employment entirely. Never do we remember having known Westminster to be so dull. It is a sad reflection that so many well-educated men, who have devoted considerable time and money to qualify themselves for an honourable and distinguished profession, should now have to realise that the market (if we may so call it) is glutted, and there is little or no scope for their abilities. India and the colonies are overflowing, and only in countries of questionable climate does there seem any chance of work. Public works in England have assumed such formidable proportions that with the present condition of affairs little remains to be accomplished for which there is not more than an ample supply of technical skill, whilst on the Continent a vast field of engineering enterprise seems to be stagnated by the clouded state of the political horizon.

We do not wish to appear to take a lugubrious view of the aspect of affairs; indeed, we earnestly hope that the day is not far distant when public confidence may be restored, and a fresh impetus given to all branches of industry. In the meantime, parishes wanting surveyors appear determined to have a high time of it, and to ride roughshod over unemployed talent. An advertisement will appear in which application is invited from qualified professional men to fill the post of "Surveyor and Inspector of Nuisances," the fortunate aspirant being required "to devote the whole of his time to the duties of his office." He must "be competent to prepare plans, specifications, quantities, and estimates for, and to superintend the construction and carrying-out of, any sewerage, water-supply, or other works, which may be required in the district; also to perform all the duties of an Inspector of Nuisances, as prescribed by the order of the Local Government Board."

It is further stated that the district over which this enviable office will have jurisdiction comprises thirty-three parishes, and he will require to keep a horse. Salary, 200*l.* per annum, to include all travelling and other expenses, excepting postage and stationery. Here, at least, is one chance. In the number of those of whom we have spoken, only thoroughly-qualified men of unquestionable ability will stand the slightest chance of securing such a prize, and to avoid any possible disappointment to many who may apply, we propose to briefly glance at what we suppose is expected. The candidate should be an excellent mathematician (a University man preferred), have regularly served his articles with an eminent civil engineer, should have subsequently been engaged upon some of the principal public works in the kingdom, whilst a Continental experience, with a knowledge of several languages, would augment his chances. He should be able to prove to the satisfaction of the Board that his knowledge of water-supply and sewerage is of so advanced a character that, if needful, he could prepare a scheme for the new water-supply of the metropolis, whilst to meet the outcry against the present state of the Thames he is capable of formulating an entirely new scheme for the disposal of the metropolitan sewage. In fact, his experience and abilities should be of so high an order as would enable him at a moment's notice to assume the joint duties of engineer to the City and Metropolitan Board of Works. This is in no way an exaggerated view of the standard which is frequently set up by local magnates who may be in want of a surveyor, and we venture to think that if a record had been kept of the proceedings of various municipal and other authorities upon such occasions the *videlicet* vocations of the select few applicants by members of the Board would clearly substantiate all we have said.

We have occasionally heard accounts, half humorous and half pathetic, of the interviewing of such a candidate by the authorities. Out

of several hundred applicants, if he has exceptional testimonials (or, what is better, local influence) he may be one of the fortunate number,—selected for further consideration. And here we may say that, in one instance, an enterprising competitor conceived the happy idea of having his testimonials printed in chocolate ink upon toned paper, with his photograph as a frontispiece. Little attentions like these go down very well with some of the local authorities, who, being butchers, horse-dealers, &c., may be considered fair judges of appearances, possibly more so than of the highest testimony of qualification. Upon a certain date, the "select" are invited to attend a meeting of the Board, where, assembled in solemn conclave, are the intelligent representatives of local constituencies, by whose judgment the important office of surveyor has to be filled. In alphabetical order "the select" are called into their august presence, and it generally happens that amongst their number is a well-to-do builder, a retired cheesemonger, an enterprising ironmonger, or a fully-informed stationer, who takes a leading part in the affairs of the place, and who either by assumption or general consent constitutes himself the mouthpiece of this collective authority, by whom the candidates are one by one severely interrogated as to their experience and abilities. Now and then some of the other members are bold enough to interpose a question. On one occasion a local shoemaker requested to be informed how much water a wind-mill could pump in a year; whilst another member of the Board seemed anything but satisfied with the answer to his query as to what size drain-pipe should be laid down a street he had never seen. It was the candidate's first visit to the town, and upon his replying that it was necessary to know the length and fall of the street, and the number of inhabitants at present and in prospective, a very ominous look of incredulity passed round. One intelligent stationer, doubtless availing himself of the facilities of his business, had armed himself with one of Weale's rudimentary books on well-sinking, but the difficulty he experienced in understanding it himself,—and the still greater one the candidate laboured under in understanding what he meant, rendered the case of the latter far from satisfactory. In fact, by not endorsing the theory that water will flow up hill, the said candidate effectually forfeited all claims to have abilities of a character to attain the standard which this gentleman had fixed in his own mind as necessary, and the gentleman with his testimonials upon toned paper and illustrated by his photograph was successful.

It appears that whilst applicants for surveyorships are expected to know and do everything, the real gauge of qualification, in the eyes of many local authorities, is that he should be as "little of the gentleman" as possible. A man of manner and address, bearing evidence of good education and social status, seldom stands much chance with these local magnates, who, even if he be successful, take particular pleasure in snubbing and hurting the feelings of their more intelligent officer; and, in order to maintain anything like a position in his office, he must divest himself of everything that can possibly bear sign of culture. After paying for interest upon capital for the purchase of the horse (which, with thirty-three parishes to supervise, seems indispensable) and its keep, with travelling and other expenses, the surveyor will have the satisfaction of devoting all his time and abilities, at the "beck and call" of over-exacting employers, for less than three pounds a week. Here is a pointed answer to the question of "What to do with our boys?" Possibly the advice of our humorous contemporary upon the important subject of matrimony will be the best we can give to those of our professional brethren who contemplate applying for such an appointment; "Don't."

**New Town-hall, Eastbourne.**—The first stone of this building was laid by Lord Edward Cavendish, M.P., on the afternoon of Thursday last. Mr. W. Tadman Poulkes is the architect.

EXCAVATIONS AT PIEDIMONTE  
D'ALIFE.

**I**N the central valley of the Volturno lies the small mountain village of Allife, built approximately on the site of the ancient Samnite town of Allife, the seat of a pre-Roman civilisation. For years past it has not infrequently happened that peasants at work in the fields have lighted on ancient graves and turned up pottery, coins, and even gold ornaments: hence the place is known locally as "La Concha d'Oro." Fortunately for science, this ancient site has recently fallen into the hands of an intelligent man, Giacomo D'Egg. A woollen manufacturer by trade, he employs his leisure hours in superintending careful and exhaustive excavations. These during the past summer have been rewarded by large finds, to which several points of special interest attach. The graves opened are, doubtless, of widely different ages. Sometimes the dead bodies appear to have been simply thrown into the earth without any tomb whatever; sometimes the graves are tiled; sometimes huge coffins are found hewn out of tufa. One uniform burial custom distinguishes all the graves. In the mouth of the dead man is placed a small silver coin; in the right hand is held, or on it is laid, a shapeless copper piece, the raudus, or aes rude. There would be nothing surprising in finding the raudus in the same grave with the silver coin, as the old-fashioned money lingered on long after the new coinage became current, but the fact that the two appear uniformly together, and arrayed always in the same manner, is noteworthy, and seems to point to some ritual custom hitherto unobserved. The matter deserves the attention and investigation of archaeologists. The silver coins found have in themselves a further interest, but of forty-three found by Sig. D'Egg, seven belong to Allife, twenty-three to Phistaleia, only one to Naples, twelve are yet undetermined. About the *locale* of Allife there is no dispute; but controversy has long raged among numismatists as to where the ancient Phistaleia stood. Opinion has, on the whole, inclined to placing it on the coast in the neighbourhood of Cumæ. Numismatists have been influenced by the fact that a dolphin, the current symbol of a seaboard town, appears in the coinage type. Signor Minervini has, however, constantly maintained that Phistaleia was situated in the heart of the Samnite mountains. It appears from these recent excavations at Allife that his opinion, which coincided with local tradition, was most nearly, though not quite, right. We can no longer doubt that, when so large a find of Phistaleia coins is discovered near the Samnite town of Allife, Phistaleia itself was not far distant. Her coins do not appear except quite occasionally in the necropolis of Capua, where they would assuredly have been found had Phistaleia been situated on the sea-coast. The town then stood not indeed in the heart of the Samnite country, but in the outlying slopes in the middle valley of the Volturnus. The vexed question is thus happily set at rest. But these excavations have a great interest to the general student of ancient art as well as to the numismatist. We are only just beginning to feel our way in the quest of the earliest Italian, i.e., of pre-Roman art. The excavations provide an invaluable store of new material. From the inscriptions in Oscan characters on the coins, and indeed from the style itself of some of the coin types, we can see at once that we have here to do with no Græco-Campanian art, but with an Oscan-Samnite element, at present but little known. This Oscan-Samnite art we may expect to find, and we do find, characterised by a certain harsh and almost fierce directness of expression foreign to Græco-Italic art. A full account of the excavations is to appear in the next issue of the German Archaeological Institute at Rome, whose publications we have recently had occasion to notice. The numismatic and topographical notes that we have here summarised appear in the dedicatory volume presented to Prof. Curtius on his seventieth birthday (Sept. 2).

## NOTES.

**T**HE whole civilised world has just escaped suffering an irreparable loss, for such would have been the destruction of the Thorwaldsen Museum and its contents, which seems to have been at one time imminent during the burning of Christiansborg Castle in the early part of this week. A building between the museum and the burning structure was judiciously blown up with dynamite, and this seems to have placed the relics of the great neo-Greek sculptor (as he may be said to have been) out of danger. The greatest spirit was evidently shown in the attempts to save the larger groups of sculpture within the castle, but one or two fine works by Rauch, who was given to verge on the colossal, proved too heavy to carry off with the immediate means available, and had to be abandoned.

**T**HERE appears to be a clerical demonstration in process against the proposed site for the Liverpool Cathedral, to which we referred some little time back. The main complaint against the site is that it would not allow of the clergy dwelling in cathedral precincts and "under the cathedral shadow." It is quite easy to understand the feeling of a section of the clergy on this point; but the question is whether any site can be commanded which will give sufficient area for "precincts" and residences which will be otherwise so suitable, central, and architecturally effective in locality. As to the latter point, we deny that there are any serious architectural objections to the site. A very fine building may be produced there; but there is no doubt that, owing to the nature of the ground and the close neighbourhood of the surrounding public buildings, some special treatment of the plan and design would be called for to realise the highest effect possible; the building would have to pile up rather than to spread. But special conditions and special difficulties ought surely to be an additional stimulus to architectural originality.

**T**HE list of papers to be read at the meetings of the Architectural Association during the ensuing session, which we print elsewhere, provides plenty of matter for discussion, and includes also one or two good practical subjects, such as "Farm Buildings" and "The Ventilation of Public Buildings." There is, however, we must confess, a larger amount of pure theory and less of the illustrative element, on the artistic side of architecture, than is usual in the programme of the Association. There are two papers on "Proportion," and two (the first two) which seem rather like the same subject essentially, viz., "The Modern Architect and his Art" and "The Prospects of Architecture." Perhaps some practical conclusions may be drawn from these theoretical discussions; that at least should be the object to be kept in view.

**A**GENT the recent Sanitary Congress we observe that no one has yet noticed the important influence which estate and house agents may have on sanitary progress. If such an agent understands the value of proper sanitation, he will always urge on a client who desires to dispose of house property to have it put into good sanitary repair, and he is almost certain, if this be done, to obtain a purchaser or tenant with much greater rapidity and frequently of a much better character. The man who cares to have his drains in good order is almost certain to keep the rest of the house in proper condition, whereas the man who is careless about the general condition of his house will probably be careless about the condition of his drains. If house agents were alive to the importance of this, a gradual but wide-spread influence would be brought to bear on house sanitation. But any agent who does not think his positive duty lies in this direction has at any rate a clear duty cast on him of a negative character, and that is not to recommend houses as being up to the mark in a sanitary point of view when they are quite the reverse.

We have before us, for example, an advertisement of a country house, issued by a very high-class firm, in which it is stated that "the drainage and water supply are excellent." A very superficial inspection of the house in question showed that a cesspool was immediately beneath the front door, that it had no overflow and no ventilation, and also that the soil-pipe was unventilated. If any one had taken the house on the strength of this representation, it is clear that an action would have been maintainable by him for a false representation, if he had suffered any damage in consequence of it. And undoubtedly, on the strength of this assertion by a high-class firm, there are numbers of persons who would have taken the house without more inquiry, or without a thought of altering the sanitary arrangements. If, on the other hand, the firm had at once pointed out the state of things to the owner, it would, no doubt, have been remedied as soon as possible. It would not be easy to find a more striking example of the possibility of improving sanitary arrangements through the influence of estate agents, or, on the other hand, of an unwarrantable assertion likely to throw persons off their guard.

**I**T appears that the Disused Burial Grounds Act, which was passed at the close of last session of Parliament at the instance of Lord Brabazon and the Metropolitan Playground, &c., Association, is found to be practically inoperative, in consequence of the numerous exceptions which it was found desirable to introduce in order to secure the passage of the Bill. The operation of the Act is limited to burial grounds which have been closed by order of Council, and graveyards which are the property of Dissenting bodies and private persons are exempted from its provisions. It is these latter which are most in danger from the action of the speculative builder, and it is a matter for regret that no check has been imposed to prevent the absorption of these valuable open spaces.

**I**N the keen competition which now exists between the various steamship companies crossing the Atlantic, every endeavour is being made to render the vessels as attractive as possible. A complete alteration of the arrangement of accommodation on shipboard, and the introduction of several new features, have been made by Messrs. Allan Brothers in their twin screw steamship *Richmond Hill* (4,225 tons), which has been built for them by Messrs. Henry Murray & Co., of Dumbarton. The most noticeable feature here is the abolition of the fore-castle, the crew and engine-men being accommodated in the after-part of the vessel, while the whole of the midship is occupied by the saloon cabins and officers' quarters. The saloon, measuring 30 ft. by 25 ft., is furnished and decorated in a manner quite different from that formerly in vogue, the ancient crimson velvet and heavy gold mouldings being banished. This saloon has all the appearance of a modern dining-room, furnished in the Queen Anne style. The walls are lined with walnut, with carved panels, and between the port lights a series of large hand-painted tiles, illustrative of Shakspeare's plays, are introduced. In place of a close stove an open tile fireplace, with handsome walnut chimney-piece, is introduced, and the ceiling is finely carved and moulded. The upholstery-work of the saloon and cabins is old gold-embossed plush. The cabins, to carry forty-two saloon passengers, are all fitted on the cot system, thus avoiding the unpleasant upper berth. The ladies' cabin is placed well forward, and has separate bath-rooms, lavatories, &c., connected with it.

**T**HE Metropolitan District Railway Company have just announced that they have diminished the number of the trains to Windsor to five in the day, as the traffic has not been remunerative. It is equally notorious that the branch of the Metropolitan Railway to Harrow, which will soon be extended to Pinner, is a loss to the general undertaking. It is quite certain that when the Metropolitan Railways

get beyond a certain short distance from their central traffic, for the present, and for a long time to come, they cannot successfully compete with companies like the London and North-Western and the Great Western railways. Persons who wish to go to or from Windsor wish to go with as little delay as possible, and no man will voluntarily travel by a line which stops at every station between Earl's Court and Windsor. Persons who travel between termini at any appreciable distance will go in the system of that company whose trains travel with the most expedition. A passenger from Harrow to Euston can by many of the North-Western trains run into Euston with only a single stoppage, at Willesden, whereas between Baker-street and Harrow there are six stations. The trunk lines to which we have alluded, having four lines of rails, can always run fast and slow trains contemporaneously, but the metropolitan companies can scarcely accommodate fast and slow traffic, or serve terminal and intermediate stations to the satisfaction of all travellers. It appears, therefore, that the experiment tried by the District Railway of running to Windsor was in any case destined to certain failure, and that the like fate awaits similar undertakings.

WE have noticed what is probably one of the earliest references to the use of indiarubber for the removal of pencil-marks from paper in a note to the introduction of a treatise on perspective by Dr. Priestley, published in 1770. The author remarks, at the conclusion of the preface, "Since this work was printed off, I have seen a substance excellently adapted to the purpose of wiping from paper the marks of a black-lead pencil. It must, therefore, be of singular use to those who practise drawing. It is sold by Mr. Naime, mathematical instrument-maker, opposite the Royal Exchange. He sells a cubical piece of about half an inch for 3s.; and he says it will last several years."

A PASSING visit to Coventry suggests a note in regard to a place the architectural interest of which is known to many, though not to so many as one could wish. There may be two opinions upon the beauty of St. Michael's Church, which, though a wonderful example of Perpendicular style, and somewhat impressive by its vastness, is so full of windows as to suggest the idea of an ecclesiastical conservatory. There is a monument in it to a "glazier," and we can readily believe that he may have expressed a wish to be buried within a fabric where so much of his time was probably spent, and that not unprofitably. Holy Trinity Church, which stands so close to St. Michael's that by telephonic agency one service and one sermon might do for both congregations, is, to our mind, a more pleasing edifice than its bigger neighbour, and, since its restoration by Sir Gilbert Scott, a more practically convenient church. Its pulpit, which projects from one of the piers which support the central lantern tower, is coeval with the pier itself, and, besides being a very striking feature, has the advantage of being so placed that a preacher with a fairly good voice is audible from it even in the choir and side-chapels. The lectern, too, is a fine piece of pre-Reformation work, and, if the eagle be not particularly aquiline in all respects, the metal is unusually subdued and pleasing in colour. In neither church has the zeal for restoration passed beyond its legitimate bounds, and, though the stained glass is chiefly modern, we cannot yet afford to condemn without measure the taste and execution of even twenty years ago. One unhappy and unique bit of modern barbarism in St. Michael's Church must be noticed. A new and elaborate font was erected there some ten or twenty years ago, and among the figures which stand within niches round its base is one which is supposed to represent "Infidelity." The figure holds in its hand, or clasps to its breast, a volume, on the outside of which are carved the words "Essays and Reviews." We are not aware whether the Bishop of Exeter or Professor Jowett ever

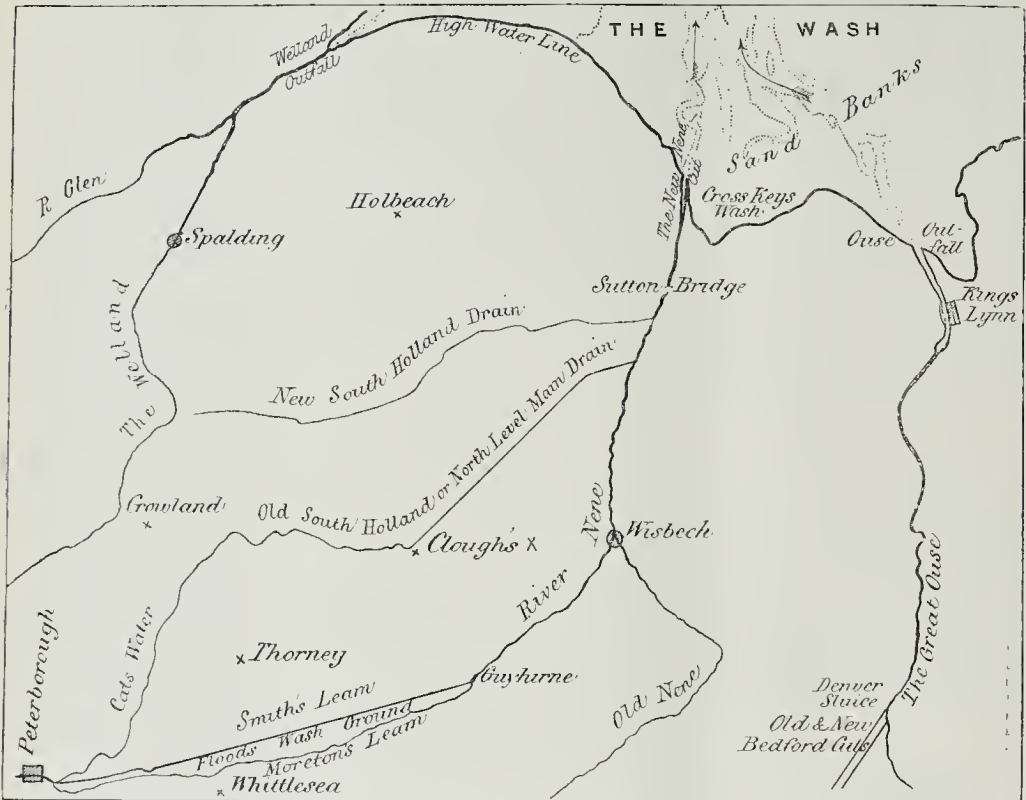

preach within the walls of St. Michael's, but it is clear they have no right there.

THERE is now on exhibition at the Architectural Museum a series of photographs taken on the recent excursion of the Architectural Association by Mr. John L. Robinson, architect, of Dublin. They are the work of an amateur, and are not put forward as specimens of photography; but, as records of buildings little visited, they are of great value. Photographs of show houses are generally to be obtained in the next town, but there are many small subjects which, though entirely neglected by the ordinary photographer as not appealing to his customers, are of considerable interest to the architect. The advantage, therefore, of this series, taken by an architect, and including many buildings not visible to the general public, is obvious. They show at a glance the main characteristics of Suffolk work,—its flint panelling, its brickwork, its considerable lack of wrought stone, as well as its fine church roofs. There are 112 views altogether, and they embrace subjects from every place visited on the excursion. The series is headed by the beautiful Abbey Gate at Bury, which was built to overawe the turbulent townfolk. The Abbot's Bridge follows; and those who are concerned may find in these photographs some help towards determining the exact use to which that structure was really put. Then we have the great gateway where Abbot Sampson was received on his first entry as abbot; the solemn roof over the nave at Mildenhall; the fine porch at Woolpit, handsome in design, but coarse in detail; a great many of Lavenham Church and Long Melford, among which not the least interesting is the purely technical view of the base of the church outside, showing the hold panelling, in which the mallet of the De Vere's plays so important a part. There are also the wonderful Spring pew in the same church, and some excellent views of the south porch and south side. Hengrave Hall, one of the first unfortified houses built in England, and the red brick and picturesque mansions of Rushbrooke, Kentwell, and Coldham are also among the series. Thanks are due to Mr. Robinson for the care and trouble he has bestowed upon this very interesting work.

IT is curious, in fact, to observe, as we may at the Photographic Society's Exhibition now open at the Water-Colour Society's rooms, how completely "your photographer" neglects architecture as a rule. Of the nearly 600 plates exhibited by the Society, not one represents an architectural subject properly so called; there are a few commonplace street views, and that is all. Yet there is no subject for which photography is more eminently suited than the reproduction of architectural detail. In the Photographic Exhibition, taken generally, there is doubtless much good technical achievement; yet how dull is the interest excited by these microscopically perfect reproductions of form and detail in nature, as compared with that aroused by the imperfect works usually exhibited in the same room. In the one case we place between us and nature a chemical machine; in the other case, a sensitive human mind and hands. In a certain way the balance is in favour of the human agency, even in regard to verisimilitude. The instantaneous photographs of breaking waves and sea-spray, for instance, do not, somehow, look like sea. A painter would convey the idea of motion; modern photography, by its very perfection of instantaneous imprint, loses the motion, and gives us a rigid mass thrust permanently up into the air. The effect is curiously seen in a photograph of an express train, taken in the 300th part of a second. The train appears to be standing still. A photograph of lightning, which is shown, still retains the idea of motion: lightning is too quick even for the photographer. The scientific value of photography is finely shown in some photographs of magnified objects, sections of parts of plants and insects; but in regard to the representation of natural scenery the failures of the painter are worth more than the successes of the photographer, even apart from the question of colour.

#### THE VAGARIES OF A WATERWAY.

THE River Nene, though by no means occupying a foremost rank amongst English rivers, whether as regards length, volume, or navigable facilities, yet possesses peculiarities of history, as well as of existing condition, which are in no small degree notable and interesting. The valley of the Nene in old times offered the shortest cut of all from the eastern seaboard into the very heart of England, and colonists and invaders from the earliest Roman era down to the final irruption of the conquering Normans made free and frequent use of it over many turbulent centuries, whether by boating on the bosom of the stream itself, or by following the bridle-paths to be found on either bank. Rising towards the south-west corner of Northamptonshire, in the immediate neighbourhood of the field of Naseby Fight, the Nene after being reinforced by a number of springs affects the eastern water-shed, passing in its north-easterly course the county town of Northampton, Wellingborough, Thrapston, Gundle, Peterborough, and Wisbech, the lower and more notable, though much the shorter part of its track, being through the fen and marsh border lands of Cambridgeshire and Lincolnshire. The Nene above Peterborough is now pretty much, as to course and windings, what it has been always, even back to the most remote notions of history or tradition; at Peterborough it enters the great fen country, and in doing so exchanges a comparatively free and joyous sylvan life for one of infinite makeshift, harassment, and trouble. This is the inevitable fate of all streams which incidentally wander upon such a vast, flat, and dreary domain as that represented by the great Bedford and hounding levels. Formerly the immense flat through which the rivers Welland, Nene, and Great Ouse had to drag their weary maze-like lower courses, ere the final refuge of the sea might be reached, was under no order to speak of; river waters made passage across with the utmost irregularity and difficulty, and as for foot or bridle path there was none. So recently as 1820 the fen country, now scored in all directions by railways and embanked drove roads, offered no feasible passage at all to Norfolk travellers bound north or north-west, these being invariably reduced to the necessity of a great southern detour, if they did not relish embarking on the open sea with a view to a landing in North Lincolnshire or the Humber. These fen expanses were in the old time essentially chaotic in their conditions, demoralising every thing with which they came in contact, and especially acting most detrimentally on the tempers and dispositions of the unhappy rivers which wandered thither. The old abbots and monks of Crowland, Peterborough, and Ely early set themselves to some mitigation of the evils of the chaos reigning within view of their several monastic battlements. What little draining there was in those days came in for execution under their direction; the water-courses were annually "waded," as it was termed, that is, the weeds were cut and removed to some limited extent, and thereby the incessant choking up of the sluggish channels in some measure avoided. Towards the close of the fifteenth century, the monks of the Isle of Ely became so exasperated at the loose and vagrant habits, and occasionally riotous and destructive conduct, of the river Nene in its lower reaches, that they set determinedly to work, and from Peterborough, in a straight line seawards, cut an artificial channel, to which the unruly stream was for a long time thereafter somewhat strictly confined. Monkish attentions of this kind were not always well required. It was up the sprawling course of the Nene, in their Viking boats, that in 870 the Northmen were carried to the pillage of Peterborough monastery, the burning of the Saxon church, and the wholesale murder of unoffending Abbot Hedda and all his monks. Hereward the Wake, the "last of the English," at a later era, by means of his knowledge of fen navigation, and to avenge himself on the new race of French abbots and friars, steered his marauding cousins from across the North Sea right up to Peterborough Ferry, and delivered over the monkish colony on Nene bank a second time to the rude sbrift of these picturesque robbers. Still, notwithstanding the occasional infliction of "unkindest cuts" of this nature, the old monks remained solicitous for the keeping open of the navigation and the

Map of the Main Drainage of the Fen Country (as now existing).

maintenance of as free a course as possible for the outflow of the dangerous flood waters. Whatever may have been their sacerdotal shortcomings, they were persistent and not unenlightened drainers at least; and it was clearly noticed, after the suppression of the monasteries and the dispersement of Peterborough, Isle of Ely, and Crowland, that the Nene and its brethren gradually reverted to former disreputable habits in all their intensity, and ultimately reduced the great level to the condition of a vast watery waste, utterly useless, even if not positively pestilential.

Anciently, the natural outfall of the waters of the Nene was situated a short distance to the east of the present artificial cut. But the Nene had all along a suicidal propensity to choke itself up at its mouth and elsewhere, by means of accumulated weeds and mud brought down in suspension, and now and again for a season its so-called natural outfall would become practically disused. This meant packed-up floods for the unlucky fen expanses inland, until such time as the pressure of necessity worked out some new outfall for the ill-regulated stream. Sometimes this would be effected at a point close to the old mouth thus rendered inoperative for a time; but oftener, so it appears, the river was sadly put to it for relief, and was made to search far and near, not only north and south, but back inland as well, before some kind of tolerable makeshift of an outlet could be hit upon at all. Oftener than once in its history, and sometimes for great consecutive periods, the Nene has been obliged to the great Ouse in the matter of a passage out to sea for its sorely wandered waters. At other times it is found holding to the left, and borrowing outfall from the Welland. Indeed, the former irregularities of these rivers of the great fen region appear to us almost past belief. The River Nene has, perhaps, been the greatest of the three sinners, but if truth be spoken it is

kept fairly well in countenance by the scarcely less eccentric pranks of both the Welland and the Ouse. These rivers, also, were addicted to a periodical choking up of their mouths, and then it would come to pass that they, also, had to turn back on search, and borrow or steal that accommodation failing which the up-country rains must soon transform the great East Midland level into an immense lagoon. The Ouse at times fell out by the mouth of the Nene, thus to some extent sparing the current account so long enmeshing between the two waterways. The Welland also, after having utterly choked up its own proper outfall, was periodically vain to cast about southward, and beg the necessary succour from its neighbour the Nene. It does not appear, however, that the three fen rivers at any epoch ever made exclusive use of any one outfall simultaneously, but the peculiarities named sufficiently account for the discrepancies observable on the old maps, hardly any two of which, it is often remarked, agree in precise manner of outfall. The neglect consequent upon the suppression of the monasteries had in its effects reached a climax by the close of the sixteenth century, and ultimately resulted in the Government of the day according some attention to the degraded condition of the fen country. In the year 1618 Sir Clement Edmond and Commissioner Atkyns made independent surveys, and severally reported to the Privy Council on the subject. Atkyns describes the Nene at Peterborough as "a goodly fair river, 200 ft. broad and 16 ft. or 20 ft. deep." A little below Peterborough, he says, it spread out into many branches, one stretching northward, by way of Crowland, to the Welland, but, on account of that river being partly choked at the time, not receiving any very great encouragement there. "This," he says, "for want of an outfall below Spalding, thrusting in his head at every ditch, and his main body falleth to Noman's Land nigh Croy-

land, and there runneth back by Southee, along by Clows Cross Head, and so to Wisbeach, with but little better success than at Spalding." After describing the wanderings of the various branch streams to the south, chief of which he shows as finding long-deferred deliverance at King's Lynn by the Ouse month after most dreary pilgrimage, the Commissioner continues,—"The waters of this river [that is, the Nene] he thow which at this day most annoy the hody of the fenns; for now that Wisbeach outfall is by mere negligence overthrowen, it is apparent that that water, which is within four miles of the outfall at Wisbeach, ought never to return nor offend the country, though now, through defect of Wisbeach river, it turneth away and takes its course where it may, and much of it passeth about fifty miles before it can recover an outlet, drowning yearly by the way many thousand acres."

The earliest mention concerning the curious habits and conditions of the river Nene and the other waterways, which, by the laws of gravitation, are in their lower courses brought upon the great flat, is to be sought for amongst monastic archives only. The State at first did not regard the subject as coming within its province; and it was not until the reign of Elizabeth that the powers of Parliament were conspicuously invoked for the better governance of the fen rivers. About the middle of the fifteenth century the Nene below Peterborough, as already mentioned, had arrived at such a pitch of bad behaviour as to arouse the monastic authorities to vigorous action. Bishop Moreton of Ely headed and directed the movement, and towards the year 1455 the works resolved upon were completed, and in satisfactory operation. This was, undoubtedly, a courageous effort of civil engineering for that age. The new cut, "Moreton's Leau," as it is called to this day, commenced at Peterborough and extended in a comparatively straight line to Wisbech. Nene waters, which previously by

means of innumerable paltry branches, meandered aimlessly and hopelessly untold distances over the larger area of the great level, were by Bishop Moreton's contrivance, sped swiftly on in one powerful stream in the direction of the desired goal, and thereby both navigation and drainage raised to a degree of order and excellence never dreamed of before. The high bank on the south side of this cut kept the fenland to the south comparatively dry, and even now when Moreton's Leam is almost disused as a watercourse through gradual choking of weeds and silting up of channel, its south bank is still regarded as the barrier which, during the times of flood water, keeps the "washes" within moderate bounds, and holds the sunk lands to the south comparatively scatheless. In the 13th of Elizabeth the condition of the fen rivers was brought under the notice of Parliament, and in that year an Act was passed with a view to scouring the Welland from Stamford to the sea for the restoration of the navigation. Six years subsequently the Commissioners of Sewers sat at Peterborough; but it was not until the year 1600 that the General Drainage Act was passed. James I. encouraged the movement and brought from Holland Cornelius Vermuyden, the great water-drainage engineer of the time. James himself became an "undertaker" for the reclamation of the fenland from the trill of the wandered river water, as did also his son Charles I.; but it was under a national contract with the Earl of Bedford, concluded 13th of January, 1630, and afterwards known as "Lynn Law," that really serious operations were commenced. The earl, as the owner of a vast marshy acreage on the banks of the Nene, was a chief sufferer from the vagaries of that stream. His contract embraced a wider area, however; and, if under the operations of his engineer Vermuyden, he could contrive to confine the rivers Nene and Ouse within bounds, so as permanently to free from intermittent flood-water a certain large expanse of the fen region, his recompense was to be a free grant of 95,000 acres of the land so reclaimed. Huge works were entered upon. The Ouse was furnished with a capacious and quite straight cut from Earith to Denver, christened the Bedford river, while the Nene, as the chief seat of the disease, received attention in the shape of numerous relieving cuts both to north and south of its main stream. A great stone sluice was erected at a place below Wisbech, called the Horseshoe, to hold the tides out of Moreton's Leam (then the main stream of the river), and another sluice at Stanground, a mile and a half below Peterborough, to shut the waters out of the old course of the Nene, and confine them to Bishop Moreton's Cut; the latter at the same time having its banks heightened on each side, and for the time thoroughly made good from Peterborough right down to Wisbech. Yet so formidable a task was the subjugation of this watercourse to prove, that, as recorded by Wells the voluminous historian of the fens, the river subsequently made light of its elaborate straight-jacketings; the curators for a time lost faith in the ultimate result of the warfare, and all these costly works were suffered to fall into decay.

In the year 1637 the Corporation of the Fens received formal charter licence from Charles, but for a time nothing followed. The Great Level Drainage Act passed in 1649, and then the Nene was again taken in hand under the direction of Sir Cornelius Vermuyden. Its banks below Peterborough were raised to a height of 8 ft., and extended at the bottom to a width of 70 ft. Moreton's Leam, a work of great service in its day, had by this time gone the way of most of the Nene channels, having, through the inevitable propensity of the river and negligence combined, become stifled with growth of weeds and gathering of mud deposits out of all efficient usefulness, whether as a navigable course or drain conduit. A new and straighter cut was now made, first called Hill's Cut, but now known as Smith's Leam, and still upheld as the main channel of the waterway. The north bank of this new cut was made of massive construction, and it has generally proved efficacious in keeping the overflow out of the fens on that side, while the considerable space left between the new Leam and the still maintained South Bank of the old or Moreton's Leam, afforded the necessary wash area for the restricted bedding of the flood-water in times of continued rainfall along the upper course of the river. The works thus executed were excellent

in conception, and from this period may be dated the first tangible approach to an appreciable taming-down of water so long destructively unruly. The upper or orderly part of the Nene above Peterborough had received no great share of attention while the lower struggle was going on, but in the time of Queen Anne an effort was made to perfect the navigation from Peterborough to Northampton, though with but small measure of success. This was renewed subsequently, and the canalised upper Nene for about half a century was made lively by a tolerably brisk traffic, though the railways have since almost entirely extinguished that.

Besides the evils of weeds' growth and silting of mud and sand, the moles, if unwatched, are apt to work havoc on such embankment works as those which restrain the Nene within limits in its course over the fens. The spread of these animals has to be kept within bounds, and accordingly the hankmen in the employment of the Fen Corporation are under obligation to wage unceasing warfare on them. The outfall below Wisbech suffered severely from these and concurrent causes, and necessitated from time to time reformatory works more or less thorough-going. Kinderley's Cut, delouching into the Crosskeys Wash, formed one of those executed last century, but it was reserved to a comparatively recent period to construct such a permanent series of outfall works as are now to be found at the mouth of this river. The Act empowering these works is dated October 27, 1829. Operations were confided to Sir Edward Banks and Mr. John Kennie, and within a year or two thereafter were brought to completion, with the result that Nene navigation and drainage were found placed upon a footing of efficiency far in excess of anything previously attained. Wisbech, in subsequent years, became a seaport of importance and promise; and although of late the progress of the place has suffered a check through the operation of various causes, it has not, as the port of Nene-mouth waters, entirely lost faith in its future. Docks on a large scale, for the accommodation of steamers and sailing vessels of size, in addition to those already made at Sutton Bridge, are deemed by many as essential for the future advancement of the place, and even by some as absolutely necessary if the port is not to be permitted to become wholly decayed; but during last session the promoters failed to convince Parliament of the desirability of works of the kind, and an ambitious, and at one time rather promising, Bill was thrown out accordingly. Whatever may be the future of Wisbech, the river which serves it, and which so long troubled sorely the whole of that region, is not likely to be held much to blame. Its works are now permanently consolidated, and while, as a main artery of the fen drainage, its functions are performed fully to satisfaction, its navigable qualities and capacities depend upon nothing more serious than the requisite care in dredging, and in watching and guarding against the formation of shoal-banks in the neighbourhood of the outer mouth.

THE SANITARY CONGRESS AT DUBLIN.

FROM the very practical address delivered last week at the Dublin Congress of the Sanitary Institute of Great Britain by Sir Robert Rawlinson we append some passages for which we had no space last week.\* After dealing with the question of sewage disposal, Sir Robert referred to other things essential to the health of towns. He said,—

"Public baths, washhouses, disinfecting apparatus, mortuaries, abattoirs, and a scavenging department are all necessary. Public baths, washhouses, and disinfecting apparatus should be as near the population for whose uses they are intended as may be practicable. They should be plain in appearance, inexpensive, and fitted up with efficient apparatus. If 20,000l. has to be expended in any town, it will be wiser to construct ten separate establishments placed where they are most wanted, rather than to erect one or two imposing-looking buildings to which the poor will not go,—one reason being that they are too distant. Examples of the utter breakdown of grand and costly baths and washhouses may be given. The people for whom they were intended would not use them, and so the money they cost

was wasted. Disinfecting chambers should be attached to such wash-house establishments, but isolated; that is, infected clothing should be received and washed apart. To stamp out contagious disease, burning or disinfection of infected bedding and clothing should be prompt. It will be the cheapest process to disinfect, wash, cleanse, and restore the articles to the poor owners free of cost rather than retard the process by using compulsion and demanding payment; as, in this case there will be secretiveness and opposition; in the other case, ready compliance and thankfulness. Mortuaries and ambulance conveyances are an absolute necessity in towns, and should be a part of every establishment. Public abattoirs, situated in open spaces, well drained and ventilated, are necessary. Private slaughter-houses ought not to be permitted. A fire establishment is necessary; and in towns having a population exceeding 100,000 there may be several stations having electric communication with the head establishment. The scavengers' department I consider a prime necessity. All forms of scavenging should be under the absolute control of the municipality. There should be no private scavenging. To require householders at any time to scavenge their own premises is a remnant of barbarism, as when it is so left it never has been done, nor ever will be done. Scavenging should be at short intervals, and every spadeful of refuse should be cleared from the streets daily, and taken to some depot. Such of the refuse as will burn should be burned, and other forms of refuse should be harmlessly disposed of outside the town or city. It will be a mistake to retain any refuse which is liable, by keeping, to become offensive, in the hope of selling it to make a supposed profit, as it is not the business of a scavenger to sell refuse, but to produce cleanliness. In seaport towns, if refuse cannot otherwise be disposed of, it may be sent to be sunk at sea in hopper barges. Hospitals have been much discussed in recent years, and there have been great improvements, both in their construction and management; but with improvement there has been much extravagance. The prime purpose of a hospital should be to afford temporary shelter to the poor and injured; and that hospital relief should be of practical use to the greatest numbers the buildings should be cheap in construction, and the administration economical. It must surely be gross extravagance to build grand palace-like hospitals costing from 1,000l. up to 2,500l. per bed on which to treat a sick or injured man who never earned half the amount of his bed's rental when well; to make matters worse these extravagantly costly hospitals are not always found to be wholesome. A hospital to be of the greatest use should be on a dry site, well ventilated, out in the open country. The construction should be cheap, the space large, the means for ventilation abundant. Warming by hot-water or steam may be admissible, but warming by heated air transmitted through flues never, as it is not wholesome. Open fires and open windows will be best, and in summer verandahs for patients will be of great advantage. There are new hospitals near Berlin where the beds, with the patients, are moved into the open air on fine days throughout the summer. Sheds of wood, which could be burned at ten or twelve years' interval, would give the best results, and, if saving life is the prime use of any hospital, would be most economical. In such hospitals, in surgical cases, the greatest bungle could not kill; whilst in some of the grand town hospitals the most expert surgeons cannot save. This has been said by an eminent physician. I do not attempt in this address to enter at any length into the details of the reduction of disease by sanitary works and regulations. Sir James Paget, in his recent address before his Royal Highness the Prince of Wales, at the opening of the Health Exhibition at South Kensington, gave chapter and verse, setting forth great money savings by prevention of cases of sickness and premature deaths. Such saving is undoubtable. In all ranks of life, from the royal family to the poorest household, it has been shown by Mr. Edwin Chadwick, C.B., the father of modern sanitary science, that there has within the last twenty years been on the entire population a reduction of some 20 per 1,000 in cases of sickness, and of 2 per 1,000 in deaths. In the Army and Navy the saving is from 17 in each 1,000 to at present 8½ to each 1,000. In the British army in India from 69 per 1,000 down to 20 per

\* See p. 453, ante.

1,000, and it is hoped further reductions may be accomplished. In looking over the advances made in sanitary science, it must never be forgotten that to undertake and perfect good works is one thing, but that to maintain them good is the main thing. It must also be remembered that sewers, drains, and waterworks are only means to an end,—they are only good so long as they are sound, clean, and cared for. Again, the most complete works of sewerage and water-supply may leave untouched the slums and room tenements; and these places may remain nests of contagious disease, out of which stalk the grim forms of typhoid and cholera. There are towns in England where sewers and drains have been formed and a good water-supply established, but where scavenging and single-room tenement-inspection and cleansing have been shamefully neglected. The first should be done; the latter not left undone. This question of sanitary improvement is an all-round question; it embraces the entire nation, as no rank or station is exempt from disease. Fever strikes down the highest in the land as the most lowly. A nation may be wealthy, and yet be unhealthy. Richly endowed colleges may impart learning to the select few, but in town-slums vicious habits are much more profusely engendered, leading to vice and crime. In the world there is no value but in human life, and human life has the greatest value when healthy and moral. It is the aim of the members of this Congress to induce improvement, to show statesmen and the public generally that the only safety will be in assisting to remove causes which lead to sickness, incapacity, and premature death. The strength and glory of a nation is not in standing armies and ironclad fleets, but in the health, well-being, and contentment of the people."

On the second day of the Congress, Dr. Grimshaw, Registrar-General for Ireland, read a paper entitled "Statistical Measures of the Health of Communities," in the course of which he said,—“I am glad to say that the old sanitary, or unsanitary, maxim, 'that a dense population has a high death-rate,' is becoming less true every day, as it has been proved by the operations of artisans' dwellings companies and others who have undertaken to provide dwellings for the working classes, that with reasonable precautions very dense populations can enjoy very good health and have very low death-rates. The natural inference has been drawn that the principal zymotic, or infectious diseases (as they are popularly called), contribute largely to this high death-rate in dense populations. This inference, however, cannot be very potent, and, indeed, Liverpool is the only instance where it is well marked. It would appear that more can be done by re-arranging and redistributing the dense populations within existing areas than by making futile attempts to diminish density."

Mr. Edgar Flynn, Surgeon to St. Michael's Hospital, Kingstown, read a paper on "The Administration of the Public Health Act in Ireland with regard to the Duties of Officers of Health." He said that, having held the appointment of medical officer of health in a district comprising a wide area in England for nearly six years, and having had considerable experience of the working of the English Public Health Act, he had been particularly impressed since his return to Ireland, two years ago, with the manner in which the sanitary laws appear to be carried out in Ireland. The working of the Public Health Act in Ireland, he continued, has in a great majority of districts well-nigh become a dead letter. One of the main causes of the slow progress of sanitary reform in Ireland is that there are no local boards or combination of districts, the boards of guardians are the sanitary authorities for the Irish rural districts; and, though it cannot possibly be stated that they are, as a general rule, opposed to sanitary reform, yet they are never anxious to move in any measure of sanitary work that will cause any outlay, and are deep in their expressions of gratitude to their medical officers of health for not troubling them with verbose reports, which may involve them in a heavy, and, in their opinion, useless expenditure, for sewage, water, or other works; and so year after year the Public Health Act is systematically evaded.

In the course of the discussion which followed the reading of this paper,

Mr. H. H. Collins, District Surveyor for the Eastern Division of the City of London, spoke, and attributed the small success of the Public

Health Acts to the dense ignorance and apathy of the population in regard to sanitary matters. He advocated the compulsory enforcement of the Public Health Acts.

Dr. Alfred Carpenter, Dr. Cameron, Mr. R. O'B. Furlong, and Surgeon-General de Renzy having spoken,

The Chairman (Sir R. Rawlinson) commented on the fact that in Ireland the engineering officer attached to the Local Government Board had no staff, and that it has no medical staff whatever. In these respects it differed from the English Local Government Board. All applications for sanitary works came before him as Engineering Inspector of the Local Government Board, and he assured them the extravagance of some of them was so appalling that he looked over them with heart-ache. If that kind of work were proposed in Ireland, it would amount to confiscation. In Ireland they must begin with the most economical work. He had seen water-works erected in parts of England, by which the poorest person could have as much pure water as he wished, all the year round, at the cost of 9d. per quarter.

Dr. De Chaumont insisted upon the necessity of the medical officers of health being independent of the local bodies.

At the afternoon sitting, Dr. Grimshaw presiding,

Mr. Edward Spencer, M.A., read a paper on "The Homes of the Working Classes," in which he said,—“The greatest bar to the improvement of the homes of the working classes in Dublin is the present anomalous conduct of the valuation of property. This affects not only the provision of such dwellings, but the improvement of every class of buildings. Passing to the bones of the working classes, and selecting at random seven tenement houses in various parts of the city, and seven improved dwellings, the valuation of each being the same, viz., 9s., or 63l. for all, I find the annual rental of the old houses to be 322l., of the new 118l. That is to say, the proprietors of the tenement dwellings contribute 10 per cent of their income to the rates, while the owners of the new dwellings pay 27 per cent of their income to the rates. This inequality presses on the very class we are supposed to be benefiting, as the following facts will show. I have investigated the present and former rents paid by 427 of the tenants of the Dublin Artisans' Dwellings Company, and find the present rent to average 5s. 8d. per week, the former rent is 3s. Dividing these gross rents into the two items of 'rent' and 'taxes,' and applying the proportion of taxes to rent given above, it will be seen that the 'rent' of the new dwelling is 3s. 10d., and taxes 1s. 6d.; while the 'rent' of the tenement dwelling is 3s. 10d. and taxes 5d.; it will be, therefore, seen that the extra price which the tenant pays for the improved accommodation is made up entirely of increased taxation. If a revaluation were ordered, and the expense provided for (which can only be done by legislation), the effect would be, as far as Dublin is concerned, unequal and unjust. The valuation must be made according to unions or baronies; and the boundaries of these areas are not continuous with those of the municipal district. The result would be that if the city were revalued the new valuation would be made out of proportion with the existing valuations of the portions of the North and South Dublin Unions that are outside the city. The number of tenement houses in Dublin is being constantly increased by the conversion of single dwellings; and diminished by natural decay, demolition, or by being closed for want of sanitary accommodation. Accommodation has been within a comparatively brief period provided, or is being provided, for 1,816 of the artisan and labouring class, and for 800 representing about 16,000 persons.

In the course of the discussion which ensued, Mr. Parke Neville, City Engineer, said that one of the greatest obstacles to improvement was the fabulous prices which were obtained by owners for their premises where new streets were to be made. This had been exemplified in the case of the new street called Tara-street, where the awards had been, he believed, excessive. He believed that some sort of summary law should be introduced to deal with the subject.

Surgeon-Major J. Wycliffe Jones, in medical charge of her Majesty's troops at Nass, then read a paper upon "The Insanitary State of Small Irish Towns." In the course of it he said,—“I will endeavour to describe a small court

of dwellings very recently visited. The entrance is in a narrow lane of cabins, and this opens to the main street of the town. Picture then a horrible little courtyard, some 50 ft. by 28 ft., almost completely enclosed by small dwellings; the ash-pits, pigstyes, and backyards of the front row of hovels forming the only prospect possible for those inside the court. The entire block of building does not occupy, to the best of my judgment, nearly one rood of land; nay, indeed, the one-sixth of an acre. Upon this site are built thirteen simply frightful dens; all have damp or clay floors, pools of green and black water lie all around, black typhoid mud and festering manure in abundance. Some fifty-five to sixty souls live in this court, and many pigs are kept. I measured several of the houses, and append a few results. No. 1 house, 57 by 14'2 by 6'9 = cubic feet less than 588; four souls live here. No. 2, 15'7 by 12 by 9'6 = cubic feet less than 1,800; five souls resident. No. 3, 15'7 by 10'8 by 9'6 = cubic feet less than 1,600, and eight souls resident. In the first about 100 cubic feet of foul damp air could be enjoyed, in the second about 300, if no lodgers came for the night; in the third about 142. For the worst description of dwelling I saw, 1s. 6d. per week is paid, but 2s. 6d., 2s. 8d., and 3s. is very commonly demanded even for cabins, which can, with truth, be described as "unfit for human habitation." A very wide field of observation, both in Europe and in India, has not furnished me with any parallel to all this.

Sir R. Rawlinson said that he had come across in the course of his inspection parallel cases in Great Britain to those which were mentioned in this paper. The condition of affairs in England and Scotland, he was sorry to say, was not very different to that of Ireland.

On the third day, the Congress divided itself into two sections, the proceedings in both being carried on simultaneously. The more popularly interesting was that of "Sanitary Science and Preventive Medicine." The principal paper, and the one which gave rise to the most interesting discussion, was that of Mr. Robert O'Brien Furlong on "The Objects and Work of Ladies' Sanitary Associations." Mr. H. H. Collins, of London, expressed surprise that the health of the people of Dublin was so good, considering the "miserable lairs" in which the people were housed. Dr. Cameron contrasted house accommodation in Dublin with that in London, very much to the disadvantage of Dublin. Mr. J. Byrne Power read a paper on the health of Kingstown.

In the second section, Mr. Cotton, C.E., read a paper on the operation of the Public Health (Ireland) Act. He favoured the shorter term of forty years rather than that of fifty years for the repayment of loans, and said that although many of the works executed by means of the loans granted in the period of distress in 1850 and 1851 presented a minimum of utility, yet on the whole they had effected a vast amount of good.

A banquet was held at the Shelbourne Hotel in the evening. Sir Robert Rawlinson presided, and the Lord Lieutenant, in responding to the toast of his health, delivered an interesting speech, and one thoroughly germane to the occasion.

The work of the Congress was brought to a close on the 3rd inst., when

Dr. Charles A. Cameron read a paper dealing in great detail with the "Water Supplies to Irish Towns."

Professor Hull, F.R.S., followed with a paper on the "Supply of Pure Water to Country Residences," in which he stated outbreaks of typhoid and other zymotic fevers in villages and country houses might be traced to an impure water supply. Where cholera was prevalent, contaminated water was the prime cause of attack. It was to be regretted that Ireland was not so favourably circumstanced for local water supply from deep wells as England.

Mr. G. J. Symons, F.R.S., read a paper on "The Rainfall of Ireland," in the course of which he detailed the history of the observation of rainfall in Ireland. The rainfall in Dublin was probably about 30 in. Most places within about sixty Irish miles of the south or west coast had upwards of 40 in. of rain per annum, and the central, east, and north-east of Ireland have between 30 in. and 40 in. Dublin being almost, if not absolutely, the driest place in Ireland.

The Rev. M. H. Close, A.M., read a paper on

the "Geology of the Neighbourhood of Dublin as affecting its Sanitary Conditions."

Mr. John P. Griffith, M. Inst. C.E., read a paper discussing the most advantageous position for the outfall of a main drainage system for Dublin, so as to accomplish the purification of the river Liffey by discharging the sewage beyond the limits of the harbour. Having examined the different schemes proposed, he submitted that to insure successful results the whole drainage districts surrounding Dublin Bay, including Dalkey, Kingstown, Monkstown, Blackrock, Pembroke, Rathmines, Kilmalsham, Drumcondra, Clontarf, and the city of Dublin, should be dealt with by a joint main drainage Board, and that the whole of the sewage should be pumped, so as to have a constant discharge at the outfall, thereby requiring no storage, and that the outfall should be at Drumloch Point, Howth. He contended that the proposed outfall at the North Bull would necessitate larger storage accommodation and costly appliances for removing all solid matter from the sewage, inasmuch as steep tides would bring large quantities of the sewage on to Clontarf strand, and also injure the harbour bar.

A long discussion followed.

Sir Robert Rawlinson remarked that Mr. Griffith, though most competent to deal with this question, was a representative of the Port and Docks Board, and might accordingly take a view quite different from persons examining the question solely from the public point of view.

Mr. Parke Neville, City Engineer, argued in support of his own scheme for bringing the discharge to the end of the North Bull-wall. Ample experiments had shown that the set of the tides would carry the discharged sewage away from the bar without leaving any deposit either on Clontarf strand or on the bar.

Professor De Chaumont, a member of the Commission for inquiring into the Condition of the Thames, unhesitatingly declared that the discharge of crude sewage into a river should not be permitted under any circumstances.

Replying to Mr. Cotton,

Mr. Griffith said he understood the cost of the Drumloch scheme over the North Bull scheme, if no reservoirs were used in connexion with the latter, would be about 50,000.

The four succeeding papers related to kindred subjects,—(1) "On House-drainage in connexion with Town Sewers," by Mr. J. B. Nicbells, C.E. In all cases the work of connecting should, he urged, be under the control and supervision of a thoroughly-qualified person paid by the local authority. The Local Government Board would do well to insist that the house-drainage and connexions should be made to form part of the whole scheme of sewerage. (2) "On Domestic Drainage in Dublin," by Mr. W. Kaye Parry, Engineer to the Dublin Sanitary Association. (3) "Practical Sanitary Lessons derived from Inspections," by Mr. William Maguire, who said that house-drainage in Dublin generally was extremely defective. Out of more than 1,000 dwellings inspected, from noblemen's mansions to six-roomed cottages, only twenty could be truthfully certified free from danger to the health of the residents. (4) "On Defects in House Sanitation in and around Dublin," by Mr. F. Conner.

A long discussion followed, in the course of which Mr. Parke Neville, City Engineer, said he thought the dangers in Dublin had been much exaggerated. When he became engineer to the Corporation the drains were almost entirely the old-fashioned square pattern, and when he proposed the use of 6-inch pipes the people almost rose in rebellion, and 9-inch were employed as a compromise. It was impossible for him to oversee the laying of all the drains, and to prevent workmen scamping their work.

In the evening Dr. Alfred Carpenter delivered a lecture on "Education by Proverb in Sanitary Work."

On Saturday last excursions were made to the Varty Waterworks and to the Railway Works at Inchicore.

It has been decided to hold next year's Congress of the Institute at Leicester.

**The Nineteenth Century Art Society.**—Monday next, October 13th, has been appointed for the receiving day for the works of art intended for the Autumn Exhibition of the "Nineteenth Century Art Society," at the Conduit-street galleries.

## STOVES AND GRATES AT THE HEALTH EXHIBITION.

THE whole of the East Arcade is given up to the exhibition of grates, stoves, kitcheners, ranges, boilers, &c., for domestic use, as well as other apparatus for heating and warming, and appliances for smoke-abatement. Many of the exhibits are shown in action, and as the warmth imparted by them to the corridor is more agreeable at the present time than it was a few weeks ago, visitors are more likely to spend a little time in their examination. We have been unable to find many novelties in this section of the exhibition, most of the best exhibits having been shown either at the Smoke Abatement Exhibition, or in one or more of the Building Exhibitions.

Commencing at the south end of the Arcade, near the main entrance, we notice that Messrs. Barnard, Bishop, & Barnard, of Norwich, have a very attractive display of their specialities in slow combustion and other stoves and grates, set off with all the advantages that costly and elaborate mantelpieces and over-mantels, with tiled hearths and splays, can give them. The central feature of the stand is a carved mantelpiece in wainscot oak with bevelled mirrors; this, with the fire-basket, and-irons, &c., has been designed by Mr. J. B. Pearce, architect, of Norwich, for Mr. Samuel Hoare, of Cromer.

Stand 577 is occupied by the Coalbrookdale Company, who exhibit cast-iron grates, over-mantels, and other of their specialities, including the "Kyrie" grate for burning anthracite coal; a patent under-fed grate, the "Holland," for burning, smokeless, bituminous coal; a patent grate by Dr. Moore, combining both the foregoing advantages; and the "Escoutille" grate, with hoppers or scuttles for coals on either side of the fire. Another grate well worth notice shown at this stand is Dr. Pridgin Teale's "Economic" grate, of which we have heard good accounts from more than one source. Some additional fireplaces are shown by these exhibitors in Class XX., in Mr. Taylor Smith's suite of apartments in the south enclosure (entrance from Main Gallery, Queen's Gate), and the patent grates referred to are duplicated in action in a building in the grounds contiguous to the Water Companies' Pavilion. The Company also exhibit their patent kitchen ranges and Smith's "Unique" range, and a circular-fronted kitchener. Altogether this Company fully maintains its position.

Stand 578 is occupied by Messrs. Mappin & Webb with their "new patent smoke-consuming slow combustion grates," with the details of which we are not acquainted. They are shown with chimney-pieces and over-mantels, brass fenders and fire-iron, tile hearths, and all the usual accessories.

Messrs. Yates, Haywood, & Co., of Rotherham (Stand 579), are exhibitors of cast-iron chimney-pieces and over-mantels, fire-irons, fenders, and cooking ranges.

Messrs. Steel & Garland (Stand 581), of Holborn-viaduct and Sheffield, exhibit their "Wharfedale" grates and slow-combustion grates, together with a variety of chimney-pieces and over-mantels,—one of satin wood and another of chonised wood inlaid with bronze. These exhibitors also show a stove which, they claim, gives a smokeless fire in an open grate. It is on Dr. Siemens's principle, having a gilled-bottom grate, a directing-plate, and a gas-bar (behind the bottom bar). Air passes through the gilled-bottom grate, and thence is directed by the directing-plate past the gas-bar, so promoting combustion on the regenerative principle.

At Stand 582 Messrs. Herring & Son, of Clertsey, exhibit a very good kitchener, and the "Brookwood" warming and ventilating grates.

Messrs. S. Belham & Co., of Buckingham Palace-road (Stand 584), exhibit a chimney-piece with a very large over-mantel, ornamented with panels in Rust's vitreous mosaic. It would be well-suited for the end of a large room, although the fireplace itself looks too small. Whatever might be the effect on the combustion of the fire, the *tout ensemble* would, we think, be improved by the removal of the marble and mosaic spandrels and the enlargement of the fireplace-opening. Messrs. Belham's grates are on the slow-combustion principle. The same exhibitors show an ornamental terminal for chimneys.

Stand 585 is occupied by Messrs. Starkie,

Gardner, & Co., who exhibit wrought-iron coal-cases, cressets, fire-irons, basket-grates, &c.

Messrs. Alexander Boyd & Sons, of New Bond-street (Stand 587), are exhibitors of fresh warm-air grates, by which cold air is admitted at the back of the grate, warmed, and passed into the room. A tiled pedestal-stove, with linen-airer, shown by the same exhibitors, appears to be a good and useful thing.

At Stand 593 Mr. William Peck Taylor shows his patent terra-cotta wind-guard for preventing down-draught in chimneys; it is far preferable to most of the zinc contrivances intended to effect the same end.

Mr. James Smith, of Liverpool, shows (Stand 594) a grate which claims to be smokeless and capable of being maintained at a cost of less than 2d. per day.

The Carron Company (Stand 595), of Upper Thames-street, make a very good display of serviceable stoves and ranges, including the "Becton" portable kitchener or range, which is self-setting and appears to be well adapted for use in workmen's cottages and artisans' dwellings. It is made in various sizes, and should be looked at by visitors interested.

Stand 596 is occupied by Messrs. Newton, Chambers, & Co., of Sheffield and Great George-street, who exhibit their "Thorncliffe" ranges in various forms and sizes. We have on previous occasions spoken favourably of these ranges.

Messrs. Thomas Waller & Co., Stand 596, exhibit a cooking-range with oven and boiler, constructed to burn either gas or coal. They also show a patent steam-heat and a grilling stove of good arrangement.

The exhibits of Messrs. W. Neilson & Co. (Stand 598), of Glasgow, are characterised by excellence of finish. Amongst them may be mentioned the "*Sine quâ non*" range.

Messrs. Rosser & Russell (Stand 599), of Hammersmith, exhibit hot-water and steam-heating apparatus for warming buildings, together with a large cooking-range, and a number of boilers for gas as well as for other fuel.

Stand 600 is occupied by Mr. J. B. Colbran, of Holborn, who exhibits Dow's patent close and open fire cooking ranges.

Mr. H. Thompson, of Canonbury (Stand 601) shows a stove which appears to possess some merit as a smoke-consumer.

Mr. Richard Crittall (Stand 602) exhibits steam-cooking apparatus for use in large establishments and public institutions.

Messrs. Dean & Son, of Oxford (Stand 603), exhibit the Oxford "heat-utiliser,"—a stove with a hollow back, apparently, from which tubes project into the room on either side.

The Wilson Engineering Company (Stand 604), of High Holborn, exhibit the Wilson cooking-ranges in various forms.

Stand 605 is occupied by Messrs. A. J. West & Co. with gas-stoves; while the next stand (606) is occupied by the General Gas Heating and Lighting Apparatus Company, who exhibit various gas-stoves for cooking and heating purposes, most of them being of Leon's patent construction.

Col. H. Stuart Wortley (Stand 607) has an exhibit which will claim the attention of visitors. He shows a variety of small stoves suited for various purposes, economical in use, and requiring little or no attention. Among the stoves shown are the "Sick-room" stove, the "Nursery" stove, the "Working-man's" stove, and the "Greenhouse" stove.

Messrs. Doulton & Co. (Stand 608), are exhibitors of majolica and other stoves for the warming of halls and other interiors. They are clean and bright in appearance, need little attention, and are economical in use.

Messrs. T. Potter & Sons (Stand 609), of South Molton-street, exhibit, among other things, their Thermidric grate (H. Saxon Snell's patent). This stove has been used in several large public institutions, and with much satisfaction. We have on previous occasions spoken with approval of it, and its merits were acknowledged in the report of the judges of the Smoke Abatement Exhibition.

Messrs. Clements, Jenkes, & Co. (Stand 611), of Great Russell-street, have on view a large roasting-range in the old style, with roasting-jack in action, carrying four vertical "dangles" or revolving hangers for joints, with motions right and left for four horizontal spits upon which a whole sheep or baron of beef could be cooked. The chimney-piece and jack are

similar to those erected by the firm at Pembroke College, Cambridge, under the direction of Mr. G. Gilbert Scott.

Stand 612 is occupied by Messrs. Crabtree Bros., of Leeds, who show their patent kitcheners.

Messrs. H. Chappell & Co. (Stand 615), Fulham-road, exhibit a smokeless close-fire kitchener, burning coke with the assistance of gas, on the principle suggested by the late Sir William Siemens.

At Stand 617 Messrs. E. Siddaway & Sons, of West Bromwich, exhibit gas-heating and cooking stoves.

At Stand 618 Messrs. Whyte & Bradford, of Bo'ness, N.B., exhibit the "Hotspur" smokeless cooking range. It has a revolving fire-basket, and appears to have other points which entitle it to the attention of visitors.

We must reserve notice of the remainder of the exhibits in this Arcade for a future article.

#### ARCHITECTURAL ASSOCIATION.

THE following is the Syllabus of Papers for the Session 1884-5:—

1884.  
Oct. 24.—Address from the President.  
Nov. 7.—"The Modern Architect and his Art," by J. D. Sedding.  
Nov. 21.—"The Prospects of Architecture," by G. Atchison, B.A., A.R.A.  
Dec. 5.—"Some Features of Japanese Architecture and Ornament," by Dr. Dresser, Ph.D., F.R.S.  
Dec. 19.—"The Ante-chamber To-day and Yesterday in French and English Plans," by W. H. White.
1885.  
Jan. 2.—"Proportion and Style," by L. A. Shiffer.  
Jan. 16.—"The Ventilation of Public Buildings," by F. R. Farrow.  
Jan. 30.—A Discussion upon the Paper entitled "English Architecture Thirty Years hence," read by Professor Kerr at the Conference of the R.I.B.A., 1884.  
Feb. 6.—"Farm Buildings," by A. Young.  
Feb. 20.—Paper (subject to be announced), by H. A. Gribble.  
March 6.—Paper (subject to be announced), by J. Slater, B.A.  
March 20.—"Proportion in Architecture, especially as exemplified in the Works of the Greeks," by F. C. Penrose, M.A.  
April 9.—Members' *Soirée*.  
April 24.—"A Prism for Architecture," by Prof. T. Royer Smith.  
May 8.—"The Treatment of Angles and enclosing Lines," by J. H. Ince.

#### COMPETITIONS.

*St. Pancras Mortuary*.—Mr. H. H. Bridgman writes:—"I beg to forward you copy of a letter I have this day received from the Vestry Clerk of St. Pancras on the above matter, my object being to let competitors (some of whom have complained of the delay in deciding the competition) see that the cause of the delay appears to have been unavoidable, as, since the competition took place, a Bill has been introduced into Parliament, and become law, forbidding the interference with the burial-grounds of the metropolis, as was proposed by the Vestry, for building purposes. Another site will therefore have to be found, and I have no doubt if the complaints referred to had reached the Vestry an explanation would have been given to this effect."

[Copy.]  
Vestry Hall, Pancras-road,  
October 3rd, 1884.

Dear Sir,—A Committee of the Vestry have reduced the number of designs sent for erection of Mortuary and Convener's Court to six.

Your design is one of the six, and I am directed to inform you that some delay may probably elapse before the Vestry can decide which of the plans they will adopt, inasmuch as difficulties have arisen as regards a site.

If you have no objection to this your plans will be kept until the final award has been made.—Yours faithfully,  
T. ECCLESTON GIBB,  
Vestry Clerk.

H. H. Bridgman, Esq.

*Baptist Church, Newcastle-on-Tyne*.—The old church in Bewick-street having been bought by the River Tyne Commissioners, a new site for more extensive buildings, to accommodate an aggregate of 1,500 persons, has been secured. Invitations were recently issued to eight architects, who have submitted plans in competition. The first premium, of 50*l.*, has been awarded to Mr. J. Chnht, of London, who will be employed to carry out the works; the second, of 25*l.*, is awarded to Messrs. Clark & Moscrop, of Darlington; and the third, of 15*l.*, to Messrs. Thompson & Dunn, Newcastle-on-Tyne.

#### Illustrations.

#### DESIGN FOR ADMIRALTY AND WAR OFFICES.

BY MESSRS. HALL AND POWELL.

WE give this week the view towards Whitehall of this design, and the two principal plans as usual. As to the general wants of the design we expressed ourselves sufficiently in our general critique on the competition at the time the drawings were exhibited. The Whitehall front is the richer and more effective of the two, and has, therefore, been selected for illustration. We append the following extracts from the architects' "report":—

"The buildings are so disposed, and the staircases so arranged, that they can conveniently be erected in blocks at intervals.

Our aim throughout has been to preserve extreme simplicity of arrangement in the plan, and an avoidance of any irregular lines of corridors beyond what is rendered absolutely unavoidable from the nature of the site.

A leading feature in our design is thought to be the system of double corridors that is adopted almost throughout the entire building, and we believe it to be the only one in so vast a building that will enable the main arteries of communication to be properly lighted and ventilated.

It may be thought to involve a certain profligality in space occupied by building, but it is submitted that is of small moment when compared with the result obtained, and the arrangement lends itself to a very convenient situation for such neutral purposes as waiting-rooms, interview-rooms, lavatories, and latrines, which occupy the space between the corridors that is not required for areas for light, and which are in common use by the occupants of the rooms on either side.

The upper part of all the corridors not being required to be of the height of the rooms, is made use of as a channel for heating and ventilating pipes, electric and telephonic wires, and speaking-tubes, all of which will be more fully alluded to further on.

Glazed screens and doors divide the several lengths of corridors, into sections, as necessary respectively for the subdivision of departments.

All the principal staircases have spacious well-holes, and are lighted by lantern lights from the top, thereby facilitating the ventilation of the building. The most important stairs are those on either side of the central halls in each department, affording light to them through arched openings on the several floors.

It should be observed the internal angles of the buildings are utilised for staircases, which being lighted from the top render these points, usually dark and useless, as light as other parts of the buildings.

The efficient window lighting of the several rooms or corridors is a point to which we have given much attention, and our aim has been to distribute the light equally over all areas to obtain for all rooms direct external lighting. As has been before pointed out, the corridors, waiting-rooms, interview-rooms, lavatories, and latrines are chiefly lighted by windows looking into the open courts or areas between the corridors.

The buildings would have been constructed of brick, faced with brown hard Portland stone, as being the best known material to withstand the effect of the London atmosphere, and the basement of the several fronts, and the large quadrangle carried up in grey Aberdeen granite in rusticated courses drafted at the arrises. At the bases of the principal external piers of the angle towers, &c., bronze castings are introduced, intended to contain the effigies in high relief of those distinguished in the services of the respective Departments. The areas for light and the internal corridors in the basement would be faced with white glazed bricks, in order to reflect as much light as possible. The internal corridors are proposed to be lined with coloured tiles or bricks, having a dado with border, and the space above to have a lighter colour.

Our chief aim in the preparation of this design, and in the matured reproduction that it has undergone, has been simplicity of parts and similarity and breadth of treatment in the several façades. Ornament has been kept subservient to utility, and proportion has been relied on rather than embellishments for the effect that it has been sought to produce.

A simple type of Italian architecture has been adopted as most appropriate for the situation and surroundings of the building."

#### LYCH GATE.

The lych-gate in our illustration is designed by Mr. W. Rickwood, and was intended for presentation by Mr. George Mence Smith to the old church of Bexley, Kent, the contract of Mr. H. Avard, of Maidstone, at 170*l.*, having been accepted, and the greater portion of the work has been performed. The material employed is oak and wainscot, standing on a foundation of Kentish rag filled in with split flints. Encaustic tile paving has been employed, and brinded tile roofing. It appears that circumstances led to an abandonment of the original destination of the gateway, and it is now, we understand, to be erected at Erith.

#### PULPIT IN WROUGHT IRON.

This pulpit, which has been executed for St. Saviour's Church, Warwick-street, Paddington, was designed by Mr. F. B. Wade, and executed by Messrs. A. Newman & Co. It is an interesting example of a somewhat novel application of wrought-iron work. The only portion which in style does not seem quite to harmonise with the idea of wrought-iron work is the succession of brackets under the top rail of the pulpit. These are rather formal and stiff in outline. The panels seem very suitable and effective. Of the generally excellent artistic character of the work done under Mr. Newman's direction we have before spoken.

#### ST. LEONARD'S CHURCH, MIDDLETON.

WE gave last week Mr. Leeson's perspective view of this interesting little church, and now give his plan and measured drawings of details. These include, as will be seen, some very interesting and pretty bits of detail in woodwork.

## THE WALL AS AN ARCHITECTURAL FEATURE.

PROFESSOR ROGER SMITH gave an interesting introductory lecture on this subject to the architectural students at University College, on Friday, the 3rd inst., of which the following remarks formed a portion:—

The preparation for building a wall is, as every one knows, to find or make a foundation. A had foundation is literally, as well as in a figure of speech, at the bottom of most of the failures that occur in walls. When a good foundation is secured, the success of the wall is rendered possible. What is a good foundation? The best is one that is perfectly immovable and incompressible, such as rock. The house built upon a rock is the one safe to stand. Next to this, and only one degree less good, is the foundation which may yield or compress slightly under a load, but will do so with perfect uniformity. Soft, irregular, shifting foundations and those exposed to the action of water, frost, and air, are among the most notoriously bad ones. The ordinary London foundation is clay, in some cases mixed with loam or sand. In building on it great care is necessary; the foundation must be carried so far below the surface that frost will not penetrate to it. To secure this in the London climate you should go 4 ft. deep, and even more. The surface round the building should also be protected so as to prevent the percolation of water. The weights of the different parts of the wall should be as nearly uniform as possible, and they should not be extreme. Four tons per foot superficial is quite enough. It has become a practice of late years to form a kind of artificial rock of concrete upon the foundations of earth or clay, composed of small stones and lime or cement. This concrete, which hardens into an incompressible slab, admirably spreads and distributes the weight, and is of great use in preventing disaster. In the case of very bad foundations enormous quantities of concrete are often employed, and with success. The base of the wall, like the concrete, is below the level of the ground. It is, to some extent, a modern improvement, or, at least, it hangs on to the modern notion of building thin walls. In the Middle Ages, when walls were immensely thick, it was not very often customary to build them with spreading footings; now it is usual, and a most useful custom it is. Walls in London are required by law to be twice as wide at the bottom of the footings as they are themselves. Of all the properties a wall can possess I think stability is the most noteworthy. Of old this was sought in great thickness. The Romans first showed that constructive skill would enable men to build walls thinner than had been customary, and yet stable. Our modern walls are vastly thinner than those of the Romans; but then there are few modern buildings for which we expect, or could desire, a durability like that of ancient Roman work. Good materials, good putting together, and strong cement, with some amount of protection from weather, are what we must rely upon for the preservation of our walls. Homogeneous-ness, or the use of materials all of one sort, would seem at first sight to be essential to the construction of a good wall; and yet, though many ancient walls like those of Munich, and, I believe, those of Athens, were practically homogeneous, the walls cleverly put together by the Romans of three or four different sorts of materials have proved, some of them, to be all but indestructible. Uprightness is essential to stability, and to look safe a wall must be obviously upright, though a tapering form, like the pylon of an Egyptian temple, also looks strong, and really is so. Length was the ancient way of giving importance and dignity to walls; height is the comparatively modern way. In the early ages of the world, and in the ruder stages of the development of modern nations, it is extent that is relied upon where an effect is to be produced. The greatest of the temples of Egypt, for example, the temple of Ramses, with its dependencies, extended over about 2,000 ft., or more than the third of a mile. The rude stone avenues of prehistoric origin to be met with at the spot of the same name in Brittany, extend over about a mile and a third of country; and, as another example of a different kind, I may recall to you the Roman wall which stretched right across the north of England. As the power of building, and skill in the production of architectural effect increased in any nation, height was more sought

after than extent; but it was, with a few exceptions, reserved for Christian and modern architecture to attempt with success buildings in which height is the main feature. Straight lines and right angles seem to have been almost the only rule in very ancient work, such as the Egyptian and the Assyrian. The Greeks first introduced curved walls in their theatres. The Romans continued and extended their use, and introduced polygonal shapes, all of which have obtained ever since. Coloured materials are to be met with at all periods of the world's history; but as their use always has reference to the architectural effect of the wall, we will postpone them to the second part of the lecture. Having now looked a little at our wall, let us try to look into it as far as we can, and perhaps an architect can look further into a stone wall than some other people, notwithstanding the old proverb. What, then, are walls made of? You may lay it down as a general rule that a wall must be made of something that lies ready to hand. In many cases the fact that the material of which some small or ornate object is to be made comes from far is a point in its favour. We prefer Italian marbles to Devonshire, or to the serpentine of Cornwall, not because they are always more beautiful (for they are not), but because they are Italian. But for wall building so much and such heavy stuff is wanted that it never does to bring it far. Accordingly, in localities where nothing else is to be had, walls are built of earth. In Devonshire, for example, cottages, barns, and the walls of gardens and orchards are commonly of earth, and they are warm, solid, and, if well taken care of, durable; but moisture must not be allowed to get into the heart of them, or they will soon crumble. Next to earth is a material not, so far as I am aware, known in England, but once in use in the East, sun-dried bricks. Vitruvius says that the walls of Babylon were built with sun-dried bricks laid in hitmen; and it is supposed that they were largely used in Assyria and Bablylonia, and that some of the shapeless mounds which now mark the site of ancient structures consist of a mass of what was once sun-dried bricks. Next, of course, we should come to brick, the material only too familiar to the London eye, and the refuge of builders throughout the world and of every age who, like the London builder, were not so fortunate as to have stone within reach. In Egypt and many parts of Italy there are remains of brickwork of great antiquity, and in Lombardy, North Germany, France, Belgium, and our own country brick has been extensively used, and is in use at the present day. Bricks were not always of the sizes and shapes we are familiar with. The Romans made them flat, more like our tiles, and in many European countries they have been used considerably smaller. The size is a good deal influenced by the weight. An English brick can be held and managed by an artisan with one hand. If it were much larger or much heavier it would take two hands, or even two men, as were probably employed on the Roman bricks. The most refined kind of brick is called terra cotta. It is of the nature of brick, but bears the same kind of relation to it that marble does to stone or silver to pewter. Terra cotta is, in theory at any rate, the most appropriate ornamental substance to employ with brickwork, and though there are some practical difficulties in the way of using it, when these are overcome it is an admirable material. The best and most desirable material for wall building is, however, stone. Every sort of stone that is in the least degree deserving the name of stone has been made use of for the purpose of wall building,—from flints, which are some of them as inconvenient in shape for the mason's use as potatoes would be, up to the hardest granite, the finest and truest freestone from our many excellent limestone and sandstone quarries, or the beautiful and precious marbles of Greece and Italy. There are stone walls in Greece and in the Etruscan plain, which have come down to us from remote antiquity, made of large polygonal stones unwrought,—or but slightly wrought,—and coarsely fitted together without mortar. There are others in Egypt of the finest polished granite with joints so close and true that the edge of a sheet of paper cannot be got between the blocks; but as remarkable in its way as these specimens of consummate handicraft is the construction of the Roman walls which were often made of small stones, such as we make macadamised roads of, set in a tenacious mortar which has hardened till it is as strong as the stone itself, and studded at intervals by the introduction of a

bond-course of flat bricks or large stones. With this mode of construction, which could be carried out anywhere, the Romans built vast works, the ruins of which remain all over Europe. There is quite as much to learn about stone as about brick; in fact, a great deal more, as, for example, how to select stone, for, owing to the ease with which many sorts of stone are acted upon by the weather, there are many precautions to be taken in the selection or use of material. I will just name the three cardinal ones, which are these:—First, select for use stone from a quarry, and from a bed in that quarry which experience has shown to be durable. Secondly, let that stone lie in the building in the same way as it lay in the quarry, or, as masons would say, bedwise. Thirdly and lastly, take such precautions as will insure that no moisture gets into the inside of your wall, or into the heart of the stones that compose it. The materials I have named all of them require to be held together by some sort of cement if the wall is to be durable and weather-tight. Lime is at the bottom of all the cements in general use, and its faculty of hardening after being calcined and slaked, and, as it hardens, of adhering to the surface of the stones or bricks with which it is in contact, is invaluable. Mortar is made of quicklime and sand. Cements and hydraulic limes are compounds (natural or artificial) of lime and other substances, chiefly alumina, which enables it to set harder, and under water, and more rapidly than in its unmixed state. I need hardly point out that where the heart of a wall is of many rough stones laid with much mortar (a substance more or less incompressible), while the face is formed of few well-dressed and squared stones laid with little mortar, there must be the great risk of the two parts of the wall behaving differently the one from the other when weight comes upon it. This happened in much of the work of the builders during the eleventh and twelfth centuries in England,—the period of the Norman style. Professor Willis has gone so far as to say that if a Norman tower has not fallen, that circumstance throws great doubts upon its being Norman. Certainly an immense number of them have fallen, and as an example of failure, happily anticipated before there was a fall, I may remind you of Peterborough, where the core of the Norman piers carrying the great central tower has crumbled, and the piers have arched, and have been taken down within the past year. Different from the practice of building composite walls is another which I will only just mention, that of building hollow walls as a protection against damp. We have by no means exhausted the list of materials for walls if only your patience will hold out. A modern material which I will just name, but not dwell on, is concrete, excellent if well looked after, dangerous otherwise; cheap if used in large quantities, and where there are few features or irregularities, but far from cheap in small or intricate buildings; very strong, very durable, and sometimes valuable where nature yields few materials for walls of another sort. Timber has been used time out of mind for the walls of houses, and even churches and dignified buildings, in the spots where it is plentiful. There is evidence that timber buildings were in use in Assyria, Egypt, and Lycia, from the curious fact that ancient remains of stone or marble are actually cut into shapes that imitate timber; indeed, the whole system of architectural treatment in use in Greece is a kind of petrification of timber construction. The countries of Europe where timber buildings are now mostly to be met with are Sweden, Norway, Russia, and Switzerland. They are in many ways excellent. A timber wall is by no means a bad protection against weather; but it is liable to catch fire, and so is quite unfit for use in cities. Many railway stations in England, however, are built of timber, and any one of these will serve to illustrate a cheap way of building timber walls. In Sweden whole logs, halved at the angles, are used, and a wall far more solid, durable, and weather-tight can be obtained. The same method is followed in Russia,—and you may see a good specimen at the Health Exhibition in the Russian house at the back of the dairies. Timber framing filled in with plastering or with brickwork in the spaces, called usually half-timbered work, is an excellent material for walls if done with the solidity and liberal use of strong timbers that was common in England in the sixteenth and seventeenth centuries. In Lancashire and Cheshire, in Worcestershire and Gloucester, in Kent and Surrey, and in other

parts of England you may find many fair half-timbered walls, and even here and there one still lingers in London or the outskirts. We have in these later days taken to build our walls of glass, as at Sydenham, and of corrugated iron, as in many temporary rooms and churches, and each has its uses. The newest material for wall construction in England (though not, I believe, new in China and Japan) is paper. At the Health Exhibition a very serviceable little cottage walled and roofed with paper may be found. It is known as the Willesden Cottage, and I think I may say from some little experience of it that its walls are by no means the worst within which I have been sheltered in my lifetime. We will now leave the construction of walls and turn to their treatment as an important factor in architecture. A wall, as we look at it, ought to have three parts: its base, which, though below ground, ought to be represented by some description of plinth or base-moulding; its body; and its top, which may be a coping to throw off water, or may be the overhanging eaves of the roof which it carries. These, then, are, infinitely varied, but they are generally all to be seen in any wall that is architecturally satisfactory to the eye. The different ways of dealing with a wall as an architectural feature may perhaps be grouped as follows:—

- I. Emphasising construction.
- II. Masking construction.
- III. Varying the outline or plan of the wall.
- IV. Enriching the surface of the wall.
- V. Colour.

Of the method of emphasising construction, which is our first division, a very ancient and obvious one is to use large stones. This was a favourite plan with the Egyptians, and the Greeks, especially in archaic times. Great stones were used in the Pelagic walls, large remains of which still exist in Greece and in the Etruscan plain in Italy. These stones were usually polygonal, very carefully fitted together, built up without mortar, and they impress the spectator very much by the appearance of savage strength which they present. Stones of very large size occur in Greece and in Egypt, and in Syria stones remarkable for their dimensions and for the way in which their outline is marked round with a broad, round mark.

Another mode of emphasising construction, which the Jews seem to have taken a pride in, is the employment of large corner stones. When a wall is built of small or loose materials, it is not easy to make the corner strong; in fact, in parts of England the towers, which would otherwise be square, are round, because there is little else but flint to build with, and with flints you cannot make a square corner. It is usual, on account of this tendency, to weakness, to fortify the corner by building it of larger stones or better than others; and the Jews seem to have attached some semi-superstitious importance to the top stone at the corner of a building,—perhaps a more really appropriate place for a famous stone than our foundation-stone, which rarely, if ever, is part of the foundation. These stones at the corners come up again in Roman work, and still more frequently in the styles derived from Roman. The famous long and short stones at the corners of Gothic ones of all ages, and the carefully-wrought, rusticated, and raised quoins of Renaissance buildings, all go upon the principle of marking construction. In simple and homely structures, built of materials with a fine surface on good colour, any method of marking the structure of a wall is successful. In Cumberland and Westmoreland, where many varieties of stone, rich in colour, are met with, the walls of humble churches, or even cottages, are sometimes quite a sight to see and admire from their beautiful and varied tints, especially if a method of walling be adopted which allows the natural cleavage of the stone to be seen without any tooling. Another and an opposite mode of emphasising treatment, if not construction, consists in exaggerating the squaring and dressing given to stone, and bringing it to a surface of the utmost smoothness. In the later part of the Gothic period, and in much of the Renaissance architecture which followed it, the whole surface is rubbed, and no trace of the tool is left. The same completeness of workmanship was also to be met with in Greece and in Egypt, and wherever we encounter it the spectator seems to be made sensible of the immense pains and care that have been lavished by the builders upon their wall; and

to a less extent the same effect is produced by the selection of materials with a fine texture of surface and a good colour, like choice bricks. A wall consists of stones and joints, and one way of marking the construction is to make the joints more conspicuous than they naturally would be. We have seen that in ancient Jewish masonry a drift or breadth of finely-tooled work surrounds the margin of the stone. In some Greek work we meet with a severe square sinking at the joint, and in Roman work with a more strongly-marked channel. In the revived Roman, which we know as Renaissance, this accentuation of the joints of stone is practised often with great frequency; and the refined mason's work, to which we have given the absurdly inappropriate name of rustication, is one of the sources of great beauty of many Italian palaces and houses. There are many other ways of emphasising construction to which I have not time specifically to allude, but may say generally that any treatment of a wall which makes its materials or its construction evident almost invariably adds a natural and, so to speak, a spontaneous grace to buildings.

#### THE INTERNATIONAL FORESTRY EXHIBITION, EDINBURGH.

##### CONCLUDING NOTICE.

It has been arranged that the Exhibition is to be closed this Saturday, October 11th, and a committee has been formed to consider what can be done with regard to the formation of a museum and school of forestry. It is gratifying to know that the undertaking has proved a success, and that the committee will have a surplus in hand; but in regard to this exhibition, as in so many similar affairs, it is found that dissatisfaction exists as to the awards of the jurors. A meeting of exhibitors has been held, when it was moved by Mr. Taylor, of Taylor Brothers, Sheffield:—

"That, seeing the glaring inconsistencies of the awards as published, we, as practical men, consider that such adjudications cannot have emanated from competent jurors, who should have been appointed under rule 11 of the regulations; or otherwise their original decision must have been altered, after being submitted to the executive Committee. We therefore demand that the committee appointed from this meeting have access to the original reports of the jurors."

The successful operation of an art such as forestry depends upon the application of principles borrowed from a wide range of sciences, and the classification of the theoretical branch of the study must of necessity be a matter of difficulty. To exhibit the scientific basis of such an art is hardly possible except in the form of diagrams, maps, and unattractive tables of statistics. The field of study is a wide one, embracing geology, meteorology, botany, vegetable pathology, vegetable physiology (especially in regard to the cultivation of healthy trees), fungology, entomology, and zoology, so far as they bear upon tree-life and disease. It also involves the application of mechanics and chemistry to the obtaining, preservation, and manufacture of timber and other forest produce. It will be seen that there is ample scope and range for those who desire seriously to study the subject, and it will be readily understood that in the few notices we have been enabled to give of the Exhibition we could only glance shortly over the wide field of view, and may inadvertently have laid ourselves equally open to animadversion with the jurors to whom was entrusted the awarding of prizes. Although strongly tempted to do so, we have not been allured by the artistic exhibits into following a congenial subject. The furniture shown was especially attractive, ranging from the simple work of the cabinet-maker to the most elaborate productions of the carver; and we are given to understand that the number of such articles sent for exhibition would have been much greater but for the delay in issuing the prospectus caused by the difficulty of procuring a site for the Exhibition building. The application of timber to building requirements has not been shown to the extent it might have been.

The various modes of roof-construction and laying flooring, the fitting up of window-sashes, doors, &c. with mouldings applied or cut on the solid, might all have been shown in an interesting and instructive manner. Mr. G. C. Douglas, of Edinburgh, has indeed done good service in this direction by exhibiting specimens of lath imported from Russia, consisting of quartered tree or billetwood, split in lath three-sixteenths

of an inch thick, and ready for placing on walls and ceilings to receive plaster. The lath shown is of excellent quality and of unusual length, being 8 ft. long, and yet split so clean as to appear as if it had been planed. It is displayed in the form of a neat barbour, having a circular-headed doorway and domed roof made ready to receive a coating of plaster or cement. But the coach-builder has been in advance of the house-carpenter, and Messrs. John Hislop & Son, of Haddington and Edinburgh, show the art of vehicular construction in various stages in an admirable manner, with several appliances for ventilating the interior of carriages, keeping them water-tight, and easy as regards motion. The vehicles are constructed both of home and foreign timber, and are remarkably light and elegant, and yet strong and serviceable. We must not overlook "The Manitoba Farm," where is shown a complete farm-steading on a small scale, such as many an emigrant to this rapidly-growing colony would be delighted to have at his disposal. The department of machinery in motion deserves more attention than we have been able to bestow upon it. The largest exhibitors are Messrs. John McDougal & Sons, Johnstone, near Glasgow; and Thos. Robertson & Son, of London. Robey & Co., of Lincoln; Sagor & Co., of Halifax; and others, show admirable machines for cutting up and working wood into the forms required. This exhibition is the forerunner of one to be opened in the metropolis, which will doubtless be upon a larger scale, but which may benefit from hints derived from it.

#### LECTURES ON ARCHITECTURE AT THE CRYSTAL PALACE.

ON Wednesday last, Mr. G. Richards Julian, A.R.I.B.A., delivered the first of his course of six lectures on "Styles of Architecture, and their Relation to the Art of Landscape Gardening," in the Lecture-room at the Crystal Palace. The lecturer, after acknowledging the courtesy of the Council of the Royal Institute of British Architects in lending him a selection from the collection of lecture diagrams in the library at Conduit-street, said that to design the simplest architectural decoration, it is necessary to be acquainted with the characteristic forms and proportions, and the details of moulding and of ornament proper to the style with which such decoration is to harmonise, and the only satisfactory mode of preparation for such a work is a study of those forms and details. The works of the great artists of the past are our inheritance, and an attempt to ignore them must arise either from presumption or from idleness. To gain the power to design well a balustrade or a summer-house, there is no more a royal road than there is to the planning of a cathedral or of a palace. On the subject of architectural styles, the lecturer pointed out that one style did not cease suddenly and a new one spring up complete and, as it were, ready-made, but that between each there was a period of transition, when the marks of one were slowly fading and the characteristics of the next becoming more prominent,—a process most probably unnoticed by those who were creating the new style, and only evident to their posterity, who are able to look back over the ages, and trace the rise and fall of different modes and forms in design and building. Having given a rapid sketch of the history of European architecture, from its rise in Greece until the present time, the lecturer proceeded to point out in detail the distinctive features of the Doric, Ionic, and Corinthian orders, the peculiarities of Greek mouldings, and the forms of Greek ornament. After describing the celebrated hanging gardens of Babylon, and quoting the account given by Pausanias of the public garden at Athens, he referred the students to the several casts and reproductions of Greek architecture and ornament to be found in the Crystal Palace.

**Hull General Infirmary.**—This building is about to be enlarged by the addition of two wings and the erection of an out-patients' department, and the first stones of these new buildings were laid by the Duke and Duchess of Edinburgh on the 1st inst. The architects are Messrs. H. Saxon Snell & Son, of London, and the builders of the portion now being executed are Messrs. Jackson & Son, of Hull. The cost of the whole work will, when completed, amount to 25,000*l.*

RECENT PATENTS.

2,045, Improved Apparatus for Opening and Closing all the Latches or Bolts of a Door simultaneously. John Lowley and James Harold, Battersea. 6d.

The object of this invention is to provide a secure fastening for doors, while at the same time they can be opened with ease in cases of fire or other such emergency. The latches or bolts are fixed in series, and are operated upon in opening and closing by one and the same operation, a weighted rod, e, carrying latches and bolts, which extends from end to end of the door. Fig. 1 is a perspective view of

part of a door fitted with the improved latches; and fig. 2 a vertical section of the same part. Fig. 1a is a view in front elevation. The device as fitted to two doors is shown in elevations and section, figs. 3, 4, and 5. The latches shown in parallel perspective, fig. 6, are similar to those shown also in figs. 1 and 2. Figs. 7, 8, and 9 show modified forms of latches

with special devices in catches and loops, which may be adapted to this invention. The inventors, in describing their drawings, refer to the lettering as follows: *aa* are the latches and bolts, *ccc* are the metal plates to which the latches or bolts *a* are pivoted at *b*. These plates are attached, by screws for example, to the door *d*, and metal plates may be sunk flush with the surface of the door, or otherwise arranged. The rods marked *e* are for operating the latches or bolts *a*, and are weighted at top and bottom as indicated by the letter *f* in most of the figures. The object of weighting the rods is to give them a downward tendency, and thus to keep the latches and bolts *a* in the loops or catches *gg*, which may be made of any convenient form or shape according to the position in which they are to be placed, or as fancy or taste may dictate. The several arrangements shown in the different figures are applicable to different portions, and for single or double doors respectively. Thus, when a latch is applied to the top of a door, the kind used is such

as is marked *e* in the diagrams, figs. 1 and 3. This latch, which is fixed to the rod *e* on the descent of the rod, falls into the loops, and securely fastens the door. They may be used either alone or in conjunction with other dropping latches. The arrangement, when used together as shown in fig. 1, is most suitable for single doors. For double or margin doors the arrangement shown in fig. 3 is regarded as the best. When the bolts are in position, and the door secured, to unfasten the door it is only necessary to lift the rod *e* by the knob *h* into position shown by the dotted lines *m*; this rod being connected with each of the latches, they are all raised to one time, and the door can be opened. To close the door again, and fasten it, it is only necessary to raise the weighted rod, and bringing the door to its closed position release the same, when all the latches fall into the loops. The arrangement for double doors is equally convenient, and is worked in the same way. These fastenings are particularly applicable to those doors which are required to be opened quickly in cases of emergency, while at the same time the fastenings are very secure. They are meant mainly for churches, chapels, and other public places and warehouses, and for doors to dwelling-houses. It is also suggested that they are applicable to railway-carriage doors.

7,305, Improved Fire and Water Proof Material for Roofing, Sheathing, &c. Com. by Messrs. D. A. Brown & Brigham, Boston and Worcester, U.S.A. To David Hunter Brandon, London and Paris.

This invention is for a suitable material for roofing sheathing and such like purposes, when a fire and water proof material is desired, and it consists essentially in a material composed of asbestos, moulded or formed into boards or sheets treated in succession with silicate of soda and chloride of calcium. The figures represent the material fixed to a building on sides and roof. Fig. 1 shows the building; fig. 2 is a section taken through part of the roof at *x*; fig. 3 shows another section through

the side at *y*. In adapting the ordinary asbestos board or paper made in the usual manner to the purposes of fireproof roofing, it is treated by applying the silicate of soda with a brush, and afterwards chloride of calcium, these two liquids saturating the surface of the board or paper, and forming a surface upon which is practically fire and water proof, the silicate of soda and the chloride of calcium preferably entering the joints in the roof or sides between contiguous pieces of asbestos board or paper. The fire and water proof material may be composed of narrow boards as at *a*, having their edges suitably overlapped, as shown at fig. 2, or the edges of the material may be abutted more closely, and be covered by a batten *b*, as shown in fig. 3, and the parts may be nailed or screwed to the frame of the building in the usual manner, or the edges may be overlapped as usual in clap-boarding and shingling. The improved material may be shaped to resemble shingles or boards. The strength of the silicate of soda is usually reduced to about half its commercial strength, as it then better penetrates the paper and incorporates itself with the asbestos, but the chloride of calcium is used preferably of standard strength, and should be applied when the silicate of soda is partially dried.

9,246, Improvements in the Process of Etching or Engraving Marble and Granite. Frederick Walter Coons, St. Louis, U.S.A.

The stone is first faced off. It is then coated with a mixture composed of white dammar varnish two parts, and spirits of turpentine one part. When the mixture becomes so dry as not to adhere to the fingers, the whole surface to be engraved is covered with lead foil that is pressed down upon the varnish. Then draw the design on the lead, and cut out with a needle previously placed in a holder the parts of the lead-foil over the parts of the stone to be recessed. After having removed the foil where the face is to be etched, the edges of the foil are rubbed down. Then the whole face is cleaned with spirits of turpentine to remove all the varnish from the places from which the lead-foil has been removed. The turpentine is then cleaned off with fine saw-

dust; and next, all oil or other grease is removed with a brush and whiting. The face to be etched or engraved being horizontal, a sufficient quantity of chemically pure nitric acid is poured on to cover the whole surface and allowed to remain on a shorter or longer time according to the depth it is desired to eat into the stone. Then drain off the acid, wash with clean water, remove the foil, and clean off all the varnish with spirits of turpentine, and then dry with sawdust.

Gregg, Philadelphia, U.S.A., Brick Machines.

The Society of Architects.—This society held its opening meeting in a room at Exeter Hall on Tuesday last, when the President, "Colonel" Ellison, delivered an address. Judging from the list of members which we have seen, the title of the society would seem to be rather a misnomer.

## THE SCHOOL BOARD FOR LONDON.

This Board reassembled on Thursday afternoon, when the usual annual statement by the Chairman, Mr. Edward North Buxton, was read. It appears that the Board have now under their charge 367 Board Schools, accommodating 328,683 children. Of these, 289 schools, accommodating 302,674 children, are new permanent schools built by the Board. One of the passages in Mr. Buxton's address was as follows,—

"In the Works Department the planning of the schools has been to some extent affected by the general adoption of large, in preference to small, schools. This change, which was recommended for the sake of greater economy of administration, enables us, in many cases, to provide a central hall for each department. Special rooms for drawing; accommodation for the centres for cooking instruction, and for the central classes of pupil teachers, though they are only needed in a few of the schools, are supplied with the least disturbance of arrangements in schools of the largest size. The tendency towards the employment of adults in substitution for pupil teachers also requires some modification in the planning. A certain number of square class-rooms, accommodating a larger number than are entrusted to a pupil teacher, are thus a feature of our newer schools. A better concentration of the class is thus secured, and left-hand lighting for the whole room is rendered more generally possible. In other respects, minor improvements suggested by experience are adopted from time to time. At the instance of the Chairman of the Works Committee, whose connexion with measures for arresting disease in London is well known, special attention has been paid to the sanitary condition of our schools, and it may be safely said that this is now as well considered and as complete as in a first-rate hospital. At a time when dangerous epidemics threaten the metropolis, I feel that this will be satisfactory to the public mind. In some of our schools considerations of expense and contracted sites have compelled us to provide playgrounds on the roof. It is worthy of note that the winning school in the drill competition this year was confined for its practice to an airy but limited space of this kind."

## THE SOUTHWARK AND VAUXHALL WATER COMPANY'S NEW WORKS AT STREATHAM.

In addition to their existing works in connexion with the supply of water from the Thames, the Southwark and Vauxhall Company are constructing new works at Streatham for obtaining a further supply from the numerous springs in that locality. They have purchased, for the purposes of the undertaking, about four acres of land on what is known as the Manor Park estate, situated between Streatham and Tooting, which is at present being laid out for building upon. On a portion of the land so acquired a deep well has for some time past been in progress of sinking. The well is 10 ft. in diameter. The first contract was taken by Mr. W. Webster, who completed it about six months ago. Since that time the company have taken the further sinking of the well into their own hands, and the works have been carried forward by the company's workmen, under the superintendence of Mr. J. W. Restler, C.E., the company's engineer. Some two or three weeks since a depth of about 220 ft. was attained, and it was intended to go down through the chalk to a further depth of 30 ft., but in consequence of the abundant and apparently inexhaustible supply of water met with it has for the present been deemed unnecessary to proceed further down through the chalk. During the last three weeks incessant pumping has been necessary in order to keep down the water. The engines have raised about 1,500,000 gallons of water every twelve hours, notwithstanding which the well registers a depth of 180 ft. of water. The engines and pumps have been constructed at the company's works, the pump being the invention of their engineer. The works include the erection of a lofty water-tower and the construction of a capacious storage reservoir.

Meanwhile, the inhabitants of Tooting and the neighbourhood are up in arms against the action of the company. There are several springs, and upwards of 120 artesian wells, in the locality, from which Tooting and Mitcham are principally supplied with water, without any necessity for having recourse to the water companies. It is alleged that within a few days after the pumping at the company's new well commenced the supply from these springs and artesian wells ceased, causing the inhabitants serious inconvenience. On Monday night a crowded meeting of the owners and occupiers of property in Tooting was held in the Vestry-hall, when it was stated that upwards of 500 houses had been deprived of water since the pumping commenced, and that several breweries and other works, which had for several years past been supplied from their wells, were now

deprived of water. A committee was formed with a view of ascertaining the rights of the inhabitants on the question, and whether the Southwark and Vauxhall Company could legally deprive them of water and afterwards charge them for its supply. The matter is causing much agitation, and is not unlikely to occupy the attention of the law courts.

## DECORATION OF ST. PAUL'S.

SIR,—In his rejoinder to my remarks on his first letter to your columns on the dome of St. Paul's, Mr. W. Cave Thomas concludes by asserting that "it is the duty of Englishmen, of the citizens of London, and of artists, to respect the name and works of Sir James Thornhill." How Mr. Thomas can reconcile this ultra-conservative claim on behalf of Thornhill's monochromes with his own special programme for their destruction, viz., by translating them into colour, by over-painting, and the use of gold fields, of which Thornhill never dreamed, is wholly beyond my comprehension. Thornhill, if he could speak at this juncture, would surely cry, "Save me from my friends!"

As against the proposal to efface Thornhill's work, in favour of one or other of the designs now before the dean and chapter, Mr. Thomas asks, "Did the great Italian masters lend themselves to the effacement of the perle works of the early painters and sculptors?" The reply to this challenge, obviously, that while it is difficult to cite an instance where a painter destroyed a predecessor's work by speciously altering its colour-effect by over-painting, it is easy enough to give instances where painters and architects destroyed outright works of former epochs, to make clear way for their own. Not needlessly to take up your space, Mr. Thomas will perhaps be content with my brevity in instancing, as a pertinent case in point, the effacement of Perugin's "Assumption of the Virgin," to make way for Michelangelo's "Last Judgment."

JOHN R. CLAYTON.

## SEWER VENTILATION.

SIR,—Referring to your "Notes" in the *Builder* of the 27th ult. on the ventilation of sewers, I cannot understand how eminent authorities can advocate for the proper ventilation of sewers, "gratings in the road, and as many as possible,"\* as the best means of effecting it. Why not open the sewers at the top with gratings all along the street? The danger would be no greater, and ventilation would be complete.

The proposed shafts, in my opinion, cannot be made to work effectually (even if they are prevented from subsidence of brickwork, or faulty workmanship, from being absolutely dangerous) without an efficient supply of fresh air; and it will be found sooner or later to be necessary to pump such into the sewers by artificial means.

The sewers will have to be more effectually flushed, especially when the fall is slight, and this applies to the majority of sewers; and the best means of effecting this is by tubes at the top laid on to a bountiful supply of water turned on when necessary, and the deposits thereby effectually disposed of.

K. C. J.

## SURVEYORSHIP OF THE PARISH OF CHELSEA.

SIR,—This important and responsible post has recently been advertised as vacant in the *Builder* and other papers. The words usually added to advertisements of this class, "Canvassing either directly or indirectly will disqualify a candidate," have, no doubt accidentally, been omitted. May I suggest that any who may attempt to obtain an advantage over their fellow candidates by canvassing may have their testimonials returned?

FAIR PLAY.

## ZINC ROOFS.

SIR,—In your review of Mr. Fletcher's "Text-book" [p. 443, ante], you state correctly that it is better to specify the weight per foot super, as well as the gauge. We believe that the gauge since 1875 has been alike for all qualities.

What is meant by "No. 13 for flats and No. 12 for gutters"?

Nothing less than No. 15 (equal to the old No. 14) should be used for roofs; and gutters should be thicker, of course, say No. 16.

The Vieille Montagne Company do not stamp anything below No. 14 as suitable for roofs.

Every sheet rolled by them is stamped with their mark and the gauge.

J. & J. S. EDMISTON.

\* Those words were not used in our note.

## "ARCHITECTS' AND CONTRACTORS' HANDBOOK."

SIR,—You were good enough some few months ago to notice the "Architects' and Contractors' Handbook," and to offer some suggestions as to classification, of which I propose to avail myself in the forthcoming issue.

May I be allowed, through your columns, to ask architects, manufacturers, and others, for particulars of any materials, inventions, and appliances not included in the last edition, as it is my desire that the book may contain as much information as possible, and be of real value for reference by architects and contractors?

J. DOUGLASS MATHEWS,  
Editor of the "Architects' and Contractors' Handbook."  
11, Dorgate-hill, London, E.C.

## CHURCH BUILDING NEWS.

*Asthall (Oxon).*—The parish church of St. Nicholas was re-opened on the 6th inst., after complete restoration, the cost of the works to nave and aisle having been borne by Mrs. Collier in remembrance of her husband, the late Mr. John Collier (who was architect and surveyor to the Salters' Company), and that for the chancel by Eton College. New open-timbered roofs have been substituted for the flat ones, the original pitch being indicated on the gables and tower, the chancel being ceiled under the collar in octagonal form, with moulded intersecting ribs and carved bosses. The walls have been rebuilt where absolutely necessary, and the windows and stone dressings most carefully renewed where decayed, and the floors have been laid with Gregory's wood-block flooring. A memorial of stained glass has been inserted in the east window of Bateman's Chapel, and a restoration of the old north window has been well executed by Hardiman. An oak screen has been fitted to the tower arch, forming an enclosure which will be used as a vestry. A new pulpit has been well carved in oak by Frith, of Gloucester, on a mass of Milton and Forest of Dean stone, as also a reading-desk to correspond with the latter, being the gift of Mrs. Bateman. The Vicar has given an oak lectern and altar, with altar space. The works have been carried out by Mr. Alfred Groves, of Milton-under-Wychwood, Chipping-Norton, from the designs of the architect, Mr. Charles W. Merrin (of the firm of Messrs. Collier & Merrin), 23, Rood-lane, London, at a cost of about 1,100*l.*

*Knighton-on-Teins (Worcestershire).*—It has been thought desirable to restore the old Norman church, which is in a rapid state of decay. The seats and pulpit are to be in English oak, the latter richly carved. Messrs. Weaver & Ayle, of Deveses and Bradford-on-Avon, Wilts, are the architects, and Mr. George Moore, builder, of Trowbridge, has been entrusted with the work.

*London.*—During the past few weeks that are described by the *City Press* as "considerable improvements" have been made in the interior of the parish church of St. Sepulchre, Holborn Viaduct. These were completed on the 12th ult. Two lobbies have been added, one upon the north and another on the south entrance doorway from the porch. They have been designed so as to accord with the ancient architecture of the tower and vestibule, as rebuilt in 1450 by Sir John Popham. They are constructed entirely of oak panelling, the upper portions being formed of richly-carved open tracery, filled with plate glass, and large and elaborately-carved cornices. The doors are made to swing both ways, so desirable in the event of a panic arising at any time, giving at once direct exit from the church. The lobbies have been erected by Mr. John Emery, of the Gray's Inn Joinery Works, Theobalds-road, W.C. The architect is Mr. Arthur Billing, of Tooley-street.

*Whitwood Mere, Castleford.*—The Potteries Mission Church here will consist of nave, chancel, vestry (with heating-chamber under), and porch, and is to be constructed of brick, with pressed facings, and stone dressings externally and internally, with open-timbered roof of pitch-pine, having hammer-beam principals, moulded purlins, and battlemented cornice. The roof is to be covered with boards, roof-felting, and Welsh slating. A flèche will serve the double purpose of bell-turret and foul-air extractor. The chancel arch is to be formed in three orders of brick, with moulded stopped angles, and the windows glazed with cathedral glass in leaded lights. The heating is to be performed by means of hot water. The church

will seat 250 persons. The architects are Messrs. Perkin & Bulmer, of Leeds.

**Bromsgrove (Worcestershire).**—The Bishop of Worcester has consecrated the new church for the ecclesiastical district of Finstall, which is part of the parish of Stoke Prior. The new church has been built to supersede the old church, which has become inadequate for the accommodation of the congregation, and, like the old building, is dedicated to St. Godwald. It has been erected upon an elevated site at Rigby, near Bromsgrove Railway Station, from the design of Mr. John Cotton, architect, of Bromsgrove and Birmingham, and at present consists of nave, south transept, and chancel, but is capable of extension by the addition of north transept, organ-chamber, and vestry, and a tower and steeple can also be added at some future time. The building is faced with axedressed local sandstone, and lined inside with buff pressed bricks tuck-pointed in red mortar. Box-ground Bath stone is used for external dressings. In style it is of the Early Decorated type. The church has an open-timbered roof covered with purple tiles. Encaustic tiles are used in sanctuary and transept. There are sittings for 214 adults and twenty-six children, and for twenty-two choristers. The cost of the building has been nearly 2,000l., Messrs. Brazier & Weaver, Bromsgrove, being the builders.

**Camberwell.**—A new church dedicated to St. Michael and All Angels has just been erected in Camberwell, and it is to be consecrated by the Bishop of Rochester in the course of a few days. Although the church is situated in the parish of Camberwell, it is in connexion with the neighbouring church of St. John the Divine, Vassal-road, Kennington. The church and schools in connexion are situate in Toulon-street, off Wyndham-road, extending eastward to Sultan-street, in which is the principal entrance to the church, although the main elevation, and also the entrance to the schools, is in Toulon-street. The frontage of the block in this street is upwards of 100 ft. in length, and Gothic in character. It is faced with red Suffolk brick and concrete stone windows and dressings. The church, the interior dimensions of which are 66 ft. in length and 28 ft. in width, forms one unbroken oblong area, without being divided into nave and aisles as in most churches. At the west end there is an organ and choir gallery, under which is the vestry, the chancel being at the east end. The church will seat a congregation of about 400 persons. The two schools forming portions of the block, one for boys and the other for girls, are each 66 ft. in length and 22 ft. in width, containing almost as large an area as the church. The boys' school is on the ground-floor, and the girls' school above. Mr. F. W. Hunt, of Upper Baker-street, is the architect, and Mr. F. Buchan, of Camberwell, is the contractor. Mr. Hockey is clerk of the works, and Mr. Double the foreman. The cost of the buildings will be about 5,000l.

**Leith.**—St. John's Parish Church, Leith, has been re-opened, after being re-decorated and painted, the rather dismal appearance of the interior having been changed into one of lightness and cheerfulness. The end wall required to be treated as a suitable background for the pulpit, and this has been done by combining the two large windows with a band running round the outside of each, and on the inner side as far down as the spring of the arch, and there joining horizontally, leaving a square space below, the upper part of which shows a rich arrangement of borders and bands, enclosing a ribbon, with the text, "We praise Thee, O Lord our God." Below this is stencilled a tapestry pattern in the later Gothic style, in gold colour on brown, against which the new pulpit stands out in good relief. The new pulpit is by Mr. Jno. C. Hay, architect; while the decorations have been designed and executed by Messrs. Geo. Dobie & Son, 23, George-street, Edinburgh.

**Whiston.**—At the harvest thanksgiving at Whiston church, near Rotherham, on the 25th ult., the new font-cover which the Earl of Eppingham has just presented to the church was unveiled. It has been especially designed by Mr. John Oldrid Scott, by whom the general restoration of the fabric was carried out. The new cover is spiral, and of a slight ogee outline, taking at the base the octagonal form of the bowl. The lower parts are richly moulded and unshaded, whilst every cant above exhibits much tracing and carved work. The cover has been made by Mr. Harry Hems, of Exeter.

**Finchley.**—The committee for building the new Church of St. Paul at Finchley selected nine architects in June last to send in competitive designs by the 20th of August, Prof. Roger Smith being appointed professional assessor. He selected three designs, from among which that by Mr. John Ladds, under the motto "Faith," was finally selected, and the architect has been commissioned to proceed with the work. The church is to be faced with Kentish rag stone, with Bath stone dressings, and will seat 632 persons. The architect's estimate of the cost was 5,850l., and Professor Smith reported that he considered it could be carried out for 5,500l. If so, it is a rather rare and all the more creditable example of an architect's competition estimate being above the actual amount required.

#### DISSENTING CHURCH-BUILDING NEWS.

**Loughton.**—A new Baptist chapel and school were opened on the 15th ult. at Loughton, Bucks. The building is in the Italian style, and is built of red brick with white brick mouldings and dressings from the Hathers Station Brick Company. It has an open-timbered roof. All the woodwork is of red deal, stained and varnished. The architect was Mr. H. H. Dyer, of Northampton, and the builder Mr. R. Hickman, of the same town.

**Richmond (Yorks.).**—A new Congregational church at Richmond was opened on the 18th ult. The cost of the new building has been about 1,522l. The architects are Messrs. Clark & Moscrop, of Darlington. The mason and general building work was let to Mr. W. Shaw, Richmond; joiner's work, Mr. Harwood, Mansfield; plumbing, Mr. C. Fryer, Richmond; painting, Mr. Johnson Stephenson, Richmond. The buildings comprise church and chancel, recess for organ, with present accommodation for 250 persons, deacons' and ministers' vestries, school for 150 children, lobby, and the usual out-buildings. Provision is made for an end gallery, which will give further accommodation for 80 sittings. Externally the building is of local stone in regular courses, freestone dressings being largely introduced. The roofs are covered with Westmoreland green slates. At the south-west angle there is an octagonal tower with slated spire. The buildings are Gothic in style.

### The Student's Column.

#### ON THE CONSTRUCTION OF FLOORS.

II.

**W**E have hitherto considered floors from the carpenter's point of view, which includes only the substructure of the floor; it is the business of the joiner to lay upon the timbers the boards which render the floor complete for persons to walk upon; and the methods he employs we now proceed to describe. Boarded floors are made of long narrow slabs of wood, to which the terms *planks*, *deals*, or *battens*, are given according to the widths need. Thus, *planks* are hoards 11 in. wide, *deals* are 9 in., and *battens* vary from 3 in. to 7 in. in width. The thickness varies from 1 in. to 3 in., those used for ordinary floors being from 1 in. to 1½ in. thick; 7 in. is the usual width of floor boards, as the wider they are the more liable they are to shrink and leave a space between the boards, and also to warp and become hollow in the middle.

The cheapest kind of floor is that which is termed a *folding-floor*; this is laid by placing together on the joists four hoards of equal length, and forcing them down so as to squeeze them tightly into a certain space; four others are then laid by their side, but so as to *break joint* with the other four, and so on. A better kind of floor is that termed the *straight-joint* floor, in which the boards are of unequal length, and all *break joint* with each other, so that no two *heading-joints* come side by side. The boards are laid closely together and tightened up with a floor-cramp. The *heading-joints*, where two ends of boards meet, are splayed so as to lap one over the other, or a groove is cut in each, and a *tongue* of wood or iron inserted. Floor boards are fastened down to the joists by means of nails called *floor-brads*, which are usually driven through from the top of the boards; where, however, the thickness of the boards admits of it, it is better to drive the brads

obliquely at the edge of the boards, so that no nails are seen on the surface; this is termed *edge-nailing*.

*Tongued-floors*, form the best kind of flooring, the hoards having a groove cut in each edge, into which a *tongue* of iron or hard wood is driven, which holds the boards firmly together, and also prevents dust from passing between the edges of the boards. A cheap kind of tongued floor is made by cutting a *tenon* on one edge of each board and a *groove* on the other edge, so that one fits into the other as they are laid, and the trouble of inserting the tongues is saved.

*Dowelled-floors* have the boards made with holes cut in the edges into which pegs of hard wood or iron, called *dowels*, are tightly driven. The hoards are held down to the joists by floor-brads as above described. This makes a very excellent floor, but the method is now but little used.

*Wood-block* flooring consists of short pieces or blocks of wood 1 ft. 6 in. long, 3 in. by 3 in., which are laid crosswise, or herring-bone fashion, on the joists; this is employed for school-room floors, and others where there is heavy wear and tear.

*Parquetry* floors and others of a superior description of wood are not laid immediately on the top of the joists, but a deal floor is first nailed to the joists, and the finishing floor laid upon it, the edges being tongued.

When there are openings in a floor, such as is required to be made round the hearth of a fireplace, it is usual to finish it with a margin or narrow frame of wood which is *mitred* at the angles; against this the ends of the floor-board are made to abut, and an even joint can be made.

In order to prevent sounds from passing from one floor to another, it is a good plan to lay felt or list upon the top of the joists before nailing down the floor boards.

*Stone or tiled* floors are sometimes required to be laid on timber in the upper stories of a building; these are formed with 2½ in. or 3 in. *stone flags* cut in lengths of 3 ft., and laid across from binder to binder without the intervention of joists; the width of the binders being not less than 6 in., so as to allow sufficient bed for the flags. Since the flags weigh about one-third of a cwt. to each square foot, the load on the beams is considerably more than that of a wood floor, and they must be made somewhat stronger. By floating a thin layer of cement on the top of the flags, ornamented tiles or marble flooring can be laid. If *asphalte* or *tile paving* be used for the upper stories of a building, stone flags must first be laid on the joists or binders as above described, then a thin coating of fine concrete, and the asphalte poured thereon. The thickness of asphalte for flooring is about ½ in. It is usual to sprinkle fine sand over the surface before it hardens. If tiles are to be used, a thin coat of cement is laid over the stone paving or concrete, and the tiles bedded and jointed in cement.

Having described the methods employed in practical building of arranging the timbers for carrying floors, we now proceed to consider the strains to which those timbers are subjected, their power of resistance as ascertained by experiment, and the scantlings that it is necessary to give them in order to combine the maximum strength with the minimum load upon the supports. In order to do this we must first lay before our readers the theoretical principles upon which the strength of materials is determined.

When a horizontal beam is supported at the two ends and loaded in the middle or any other point with a heavy concentrated weight, or by a weight distributed uniformly over its entire length, the effect upon it is to produce a certain amount of *deflection*, or bending from the horizontal position; the underside being curved downwards or convex, and the upper one hollowed out or concave. The amount of deflection is found at first to increase nearly in proportion to the load put upon the beam, but, after a time, the deflection increases in a greater ratio than the load, until the resistance of the material is at length overcome and fracture ensues. In a beam of uniform strength and of homogeneous material, the place of fracture will be at the middle point between the points of support; but, if one part is weaker than another, as is often the case at a knot in a piece of timber, fracture will generally take place at the weakest point, the actual strength of a beam being only the strength of the

weakest part, however strong it may be elsewhere.

There are two kinds of resistance which a loaded beam offers to the strain put upon it; one is the resistance to bending or flexure, which is termed *stiffness*; the other is the resistance to fracture, which is called the *strength* of the beam. The laws which regulate these two qualities are very different, and a beam may have great *stiffness* and very little *strength*; that is to say, a beam may bend very little under a heavy load, but fracture may take place very suddenly; this is the case with most crystalline substances and what are commonly termed *brittle* materials. On the other hand, we may have a beam that bends sensibly under a very moderate load, and yet its resistance to fracture is so great that it is almost impossible to break it; this is often the case with non-crystalline or fibrous materials, which possess a great degree of what is commonly termed *toughness*.

The laws of the resistance of beams to flexure and fracture have been investigated theoretically by writers on the strength of materials, and as they agree very closely with the results of numerous experiments, we may consider that the truth of them is sufficiently proved for all practical purposes. The law of the *strength* of a beam supported at its two ends and loaded in the middle is that the resistance to fracture is directly proportional to the square of the depth, and inversely as the length of the beam. If the load is uniformly distributed over the whole length of the beam the resistance to fracture is doubled, or the beam will bear twice as great a load when distributed as it will when all collected at the centre before fracture takes place.

The law of the *stiffness* of a beam is that the resistance to flexure is proportional to the cube of the depth, and inversely as the cube of the length. If the load is uniformly distributed, the deflection is to that when the same load is all at the middle, in the proportion of 5 to 8, or the resistance in the former case is eight-fifths of what it is in the latter. Both *stiffness* and *strength* are directly proportional to the breadth of the beam. Now as in practical building it is never required to load a floor-beam with a weight at all approaching that which would produce fracture, while it is absolutely necessary that the amount of flexure should be all but imperceptible, it is evident that we may generally leave out of consideration the question of the *strength* of a beam, and confine our attention to the property of *stiffness*, especially as it has been laid down by Tredgold that a floor-beam ought never to be loaded by any weight that will produce a greater deflection in the middle than one-fortieth of an inch to every foot of its length. It is by this rule that we shall be guided in calculating the scantlings of various beams required in the construction of floors.

We have seen that when a horizontal beam is strained by a load at the centre, the underside becomes convex and the upper one concave, or the fibres at the bottom are stretched or extended, while those at the top are compressed or shortened, and a little consideration will make it clear that the fibres nearest the bottom are more extended, while those at the top are more compressed than those near the middle of the beam's depth. Hence it appears that the fibres near the middle of the beam have very little strain upon them, and add very little to the strength or stiffness of the beam; in fact, they only serve to connect together the upper and lower fibres which really do the effective work. It is by taking advantage of this principle that we are enabled to construct a stronger beam with the same amount of material in the manner described in our former article, and there shown by fig. 6 (page 475, ante).

By comparing the theoretical deductions with the results obtained by direct experiment, and adopting the principle stated above, that the deflection of an inch for every foot of length, we obtain the following rule for calculating the depth of a fir joist of given breadth and length. Take three times the cube of the length of bearing (in feet), and divide it by four times the breadth (in inches), and we obtain the cube of the depth in inches, for ordinary floors. For warehouse-floors the cube of the depth should be at least three times as much as that which the above rule gives.

For example, let the bearing be 15 ft. and the breadth 2 in., then the cube of 15 is 3,375,

three times which is 10,125, and this, divided by four times 2, or 8, gives 1,266 as the cube of the depth, the cube root of which is nearly 11 in. for the depth of the joists of an ordinary floor. For a warehouse floor we have three times 1,266, or 3,793, as the cube of the depth, the cube root of which is about 15½; or the depth of joist for a warehouse-floor should be about half as much again as that for an ordinary floor, where the breadth and length are the same.

In a similar way we can obtain a rule for finding the depth of the fir *binders* of a double floor, supposing them to be placed 6 ft. apart: Take four and half times the cube of the length (in feet), and divide it by the breadth (in inches), and we obtain the cube of the depth for ordinary floors; and for warehouse floors take three times the above for the cube of the depth, or else 1½ time the depth with the same breadth. For example, let the length be 10 ft., and the breadth 6 in., then 4½ times the cube of 10 is 4,500, which, divided by 6, gives 750 for the cube of the depth in ordinary floors, or the depth should be 9½ in. For a warehouse the cube of the depth will be 3 times 750 or 2,250, or the depth of 13¼ in.; it might, however, be better to increase the breadth to 9 in., when the cube of the depth will be 1,500, which gives 11½ in. for the depth: this will require rather more timber, but saves nearly 2 in. in the depth.

### Miscellaneous.

**Putney's Patent "Nail-less" Solid Wood Flooring.**—Visitors to the International Health Exhibition, especially those who are connected with building operations, should make a point of calling at the office of Mr. Samuel Putney, a little to the west of the dairies on the south side of the great corridor devoted to food exhibits. Here (as well as at Baltic Wharf, Paddington, and at his other establishments) Mr. Putney is exhibiting his so-called "nail-less" solid wood flooring. (It is not nail-less, but the heads of the nails do not come near the surface of the floor). The grooved joints are made of different sections to suit the character of various woods. For instance, it has been practically ascertained that one section is the best for flooring prepared from yellow deal, having no acute angles touching the surface, which, in the softer woods, could be easily damaged, while another section is preferable for oak, teak, walnut, pitch-pine, or other hard woods. One good feature about this method of flooring is that it is absolutely essential that the wood from which it is prepared should be thoroughly well seasoned, of the very best quality, and in narrow widths (not exceeding 5 in.). Among the advantages claimed for this method of flooring are the following, viz.—(1) Cheapness and saving of labour combined with good appearance and durability. (Only one-fourth of the usual quantity of nails required in laying). (2) Airtight and dust-proof joints (no loose tongues), thus effectually preventing draughts and the penetration of foul gases and unhealthy odours. (3) Nail-less surface (the nails being driven through the patent joints). The floor, presenting a surface of excellent appearance, is suitable for polishing, having no indentations for secreting dirt.

**Metallisation of Wood.**—By Rubennick's process the wood is steeped in a bath of caustic alkali for two or three days, according to its degree of permeability, at a temperature between 164° and 197° F. It is then placed in a second bath of hydro-sulphate of calcium, to which a concentrated solution of sulphur is added after twenty-four or thirty-six hours. The third bath is one of acetate of lead, at a temperature of from 95° to 122° F., and in this the wood remains from thirty to fifty hours. After a complete drying, it becomes susceptible of a very fine polish, especially if the surface be rubbed with a piece of lead, tin, or zinc, finishing up with a burnisher of glass or porcelain. After all this treatment the wood looks like a metallic mirror, and is entirely unaffected by moisture.

**Congregational School for the Education of the Sons of Ministers, Caterham.**—This building has now been completed, and the building was to be opened this Friday, the 10th inst. A view of the building, and a plan of it, appeared in the *Builder* for Dec. 8, 1883. Mr. E. C. Robins is the architect.

**Bronze Alloys for Engineering Purposes.**—At a meeting of the Society of Engineers, held on Monday evening last, at the Westminster Town-hall, Mr. Jabez Church, past-president, in the chair, a paper was read by Mr. Perry F. Nursey, vice-president, on "Modern Bronze Alloys for Engineering Purposes." The author commenced by a reference to the age of bronze, and pointed out that, considering the variety of new bronzes there now were, and the extent to which they were used, snperstition in some cases even iron and steel, the present might be considered as a revival of that age. As the stone age was sub-divided into the old and the newer, so he would designate the present as the newer bronze age. He then briefly referred to the bronzes of the ancients, observing that modern analyses of many of the bronze coins made in different countries and at periods extending over several centuries B.C., brought to light a remarkably close analogy in the proportions of the ingredients. The author then touched on the composition of French bronzes, after which he described the varieties of phosphor bronze (which was invented by Dr. Künzel, of Blazewitz, Dresden, in 1873) and their applications. He then described silicium bronze, which was invented by M. Weiller, of Angoulême, in 1882, and which is especially applicable and is largely used in the manufacture of telegraph wire, on account of its high conductivity. The author then described the manganese bronze, which was invented by Mr. P. M. Parsons, in 1876, and Delta metal, in which iron and copper were successfully and chemically combined by Mr. A. Dick, in 1883. These, the author explained, were the modern bronzes of what he called the primary series, and which were largely used for all kinds of engineering purposes, from a spanner to a screw propeller, and from a boiler tube to a piece of artillery. He then entered upon the consideration of those modern bronzes, which he observed formed a secondary series, in the sense that several of them were more or less but modifications, combinations, or adaptations of those of the primary series. This secondary series includes Otto's phosphor copper; Cocksott's phosphor manganese bronze; Kiehnle's phosphor lead bronze; Billington's phosphor-tin for bronze-making; Webster's aluminium bronze; and Wiggins' silveroid and cobalt bronze, which were all described, and their special attributes pointed out by Mr. Nursey.

**Modern Mummies.**—A subject which has important bearings on the vexed question of cremation was broached at the recent meeting of the Social Science Congress, in a paper by Mr. Thomas Bayley, of Birmingham. In spite of much that has been said and written to the contrary, the practice of burning the dead must, in our opinion, and as we have stated elsewhere, lack the sanction of law so long as it does not afford a further guarantee than that required in cases of burial that death has not resulted from foul play. The paper alluded to recognises this difficulty, and proposes a plan by which it may be met. It is the following. The bodies, loosely but completely enveloped in cotton-wool, and placed within air-tight cases, are exposed, in a subterranean gallery lined with cement, to the action of cold air, which is chemically dried, and purified from putrefactive bacteria. After a time dry air at a higher temperature is used in the same way. The result is mummification, the integument remaining white. Bodies which have undergone this process may, it seems, be kept for an indefinite period without evidence of change, if protected from damp; may, if required, be submitted to examination by analysis or otherwise in an adjoining cool and dry mortuary-chamber; may be cremated or otherwise disposed of. Mr. Bayley's plan has considerable merit on the ground of its philosophical ingenuity.—*Lancet*.

**Inner Circle Railway.**—The Metropolitan and District Companies having completed the working arrangements, the Inner Circle Railway and its extensions to Whitechapel, with the five new stations, viz., Cannon-street, East-cheap, Mark-lane, Aldgate East, and St. Mary, Whitechapel, were opened for public traffic on Monday last. By means of the completion of these railways, the two companies are also enabled to run through trains over the East London Line (of which they are part lessees) to New Cross, there interchanging traffic with the entire systems of the Brighton and South-Eastern Railways.

**Deleterious Dyes.**—The crusade against aniline dyes has, after a long interval, been energetically revived. It is a notorious fact that in green wall-papers, in articles of clothing (gloves, stockings, and fabrics used for feminine dress and ornament), and in confectionery, aniline is used. Several years ago many obscure cases of arsenical poisoning were traced to arsenite of copper. At that time this compound was largely used as a pigment, particularly for the fancy patterns of paper in the ordinary cheap bed-room papers. In the process of manufacture the colour was laid on so thickly that it represented nothing less than a mass of solid arsenic, which, under the influence of warmth, was diffused in particles through the room, and breathed by the occupants. Many children, as was afterwards discovered, died from inhaling the poisonous odours. It would seem that lately the objectionable poison,—no longer in the colour of green, against which nearly everybody is on his guard, but in various other tints,—has been re-employed. We are told on high authority that in these cases the poisonous effects arise from the imperfect removal of arsenic, which is used, not as in itself a pigment, but as a reagent in the course of manufacture. Many sensible people, in view of this, are suggesting a return to the pre-aniline stage of manufacture. But the remedy is not to be found in the prohibition of aniline dyes; it lies in the hands of the purchaser of fabrics deleteriously charged with them. The detection of arsenic, as most persons are aware, is one of the simplest processes in elementary analytical chemistry, and at a trifling outlay any chemist will conduct an analysis.—*British Trade Journal.*

**The Acton Sewage Scheme.**—The Acton Local Board have decided to adopt the A B C system of treating the sewage in connexion with their drainage scheme, which has been planned by Sir Joseph Bazalgette (Engineer to the Metropolitan Board of Works), with the assistance of Mr. Lailey, the Surveyor to the Acton Local Board. A part of the scheme is the laying of a 5-ft. effluent sewer through the parish of Chiswick to the side of the Thames, into which will flow the effluent water. The Chiswick Board, however, have decided to oppose the laying of this sewer on the ground that it is unnecessarily wide, and that its construction will cause needless damage to some of the streets; but the reply of the neighbouring Board is that this width is required to hold the effluent sewage during the back flow of the tides, which it was expected will be considerable at the proposed outflow. It is probable that the dispute will necessitate a Local Government Board inquiry. The general intention in Chiswick evidently is that the Acton Board are proposing to construct this large effluent sewer in view of the prospect of an arrangement being come to with the Metropolitan Board of Works to pay a portion of the cost of its construction, on condition that the Board be allowed to divert the storm-water of Stamford Brook into it, and so relieve the sewage works in the East of London of a considerable volume of water, which increases considerably the pumping expenses of the Metropolitan Board of Works.

**A New Screw-driver.**—What is claimed to be an improved screw-driver has been patented by the head of an American firm. The screw-driver consists of three parts,—the handle, the hit, and the points. The handle is made of polished rosewood, and is 7 in. in length, and finely finished. It has in it a receptacle for the points not in use, which is furnished with a brass cover operated from the other side of the handle, a little pressure on a projecting button slightly raising the cover and permitting it to be easily turned in opening. A spring in the interior of the handle draws the cover down and holds it snugly in place. The handle has also a socket or stock for the reception of the bit, which is secured by a screw. The hit is represented ready to be attached to the handle with one of the screw-driver points fastened to it, being firmly held in place by a screw. This screw can be readily operated by one of the points held in the fingers. These points, of which each screw-driver has six, are intended to be shown in this implement; the points can be turned obliquely to or at right angles with the hit, and the screw thus he successfully driven home; and, third, that the hit can be taken out of the handle and used in a brace.—*Science Monthly.*

**Portland Cement,** on emerging from the factory, is composed of an almost impalpable powder, mixed with coarser grains, which have but little adhesive quality. The necessity for fine grinding is shown by the fact that the portions that pass through a No. 175 sieve (which has 31,000 meshes to the square inch) have five times the adhesive strength of those that pass through a No. 103 sieve, which has only 10,500 meshes to the square inch. No. 175 is the finest that is made, and will prevent 45 1/2 of ordinary cement from passing through. Cohesion, it must be remembered, is not adhesion, its force being much greater by from three to ten times. The best test of Portland cement is its adhesive power, although this varies, according to whether the substance is stone, brick, slate, marble, or glass. The No. 175

sieve should prevent 45 per cent. of the cement from passing the sifted portion, which should have an adhesive power of 95 lb.; the musifed, of 75 lb. per square inch.

**New Railway Station at Brimsdown.**—The Great Eastern Railway Company have just opened the new Brimsdown Station on the Cambridge line, midway between Ponder's End and Ordnance Factory. The station harmonises in style with the buildings on the adjoining Brimsdown estate.

**Science and Art Department.**—Mr. Stannus, the lecturer on "Applied Art" in the National Art-training Schools at South Kensington, will commence his course on "Elementary Art" on Monday, the 13th instant, at eleven a.m., and on "Advanced Art" on Tuesday, the 14th instant, at two p.m.

**COMPETITIONS, CONTRACTS, & PUBLIC APPOINTMENTS.**

*Epitome of Advertisements in this Number.*

Dixon, Appleby, and Thorn * ..	82,177 0 0

\* Accepted.

For the erection of a School to provide accommodation for 120 children, on the site in Montagu-street (Finchley Division), for the School Board for London. Mr. E. H. Robson, architect:—

W. Goodman .....	£17,983 0 0
Patman & Fotheringham .....	17,278 0 0
Kirk & Randall .....	17,774 0 0
W. Downs .....	17,797 0 0
J. Grover .....	17,338 0 0
W. Shurmer .....	16,569 0 0
Stimpson & Co. ....	16,524 0 0
C. Wall .....	16,429 0 0
Priestley & Gurney .....	16,399 0 0
W. Bangs & Co. ....	16,357 0 0
W. P. Shillet .....	16,299 0 0
S. J. Jerrard .....	16,107 0 0
Wall Bros. ....	15,994 0 0
Atterton & Latta .....	15,939 0 0

For alterations and repairs to Higher Mount, Galpin, Dartmouth, for Mr. W. H. Hawke. Mr. E. H. Back, architect, Dartmouth. Quantities by architect:—

E. J. D. Henley, Dartmouth .....	£137 10 0
Oleando Veale, Dartmouth .....	137 10 0
Vaisey & Co., Dartmouth .....	135 0 0
B. Williams, Dartmouth (accepted) ..	127 0 0

For new departments to accommodate 910 girls and infants, in lieu of the present Girls' and Infants' Departments, on the site in Edward-street, Deptford, for the School Board for London. Mr. E. R. Robson, architect:—

J. W. Hobbs .....	£11,400 0 0
Turdle & Appleton .....	11,094 0 0
J. Grover .....	10,557 0 0
C. Cox .....	10,556 0 0
Stimpson & Co. ....	10,535 0 0
Scrivenor & Co. ....	10,520 0 0
W. Downs .....	10,454 0 0
Wall Bros. ....	10,432 0 0
Atherton & Latta .....	10,430 0 0
W. Bangs & Co. ....	10,340 0 0
C. Wall .....	10,330 0 0
H. Hart .....	10,300 0 0
Lathey Bros. ....	10,233 0 0
W. Johnson .....	10,152 0 0
Kirk & Randall .....	10,114 0 0
S. J. Jerrard .....	10,059 0 0
W. Oldrey .....	10,000 0 0
J. Holloway * .....	9,801 0 0

\* Recommended by Works Committee for acceptance.

For Postypridd Hall, shops, &c. Messrs. James Savard & Thomas, architects, Cardiff:—

D. W. Meredith, Postypridd .....	£6,891 8 10
D. C. Jones & Co., Gloucester .....	6,820 0 0
John James & Co., Swansea .....	6,165 0 0
William Symonds, Cardiff .....	5,199 0 0
E. and T. Hatherly, Bristol .....	5,524 0 0
David Davies, Cardiff .....	5,595 0 0
William Seaton, Postypridd * .....	5,718 18 11

\* Accepted.

For alterations at Chase Side, Southgate, for Dr. Vivian. Mr. Arthur W. Saville, architect. Quantities supplied:—

Stevenson .....	£125 0 0
Kerry .....	125 0 0
Royal .....	123 0 0
Newby .....	99 0 0

For demolition of existing stables and re-erection on the site thereof of new stables, Gascyne-street, Liverpool, for the Corporation of Liverpool. Mr. Clement Dunscombe, M.A., M. Inst. C.E., City Engineer:—

Table with 2 columns: Item (A-I) and Amount (£, s, d). Total: £5,881 0 11.

For roads and sewers on Ferme Park Estate, Horsely. Messrs. E. E. Croucher & Co., Chancery-lane, surveyors:—

Table with 2 columns: Name (Novell & Robson, T. G. Dunmore, George Bell, James Pizzev, C. Killingsworth, Thomas Adams) and Amount (£, s, d).

For new Sunday Schools adjoining the Wesleyan Chapel, East Mecksey. Mr. Charles Bell, architect, New Broad-street. Quantities supplied by Mr. H. Lovegrove, Budge-row, Cannon-street, E.C.:—

Table with 2 columns: Name (J. Holloway, J. H. Jones, Wheatley & Sons, Oldridge & Sons, Smith & Robinson, J. Piller, Allen & Sons, F. Higgs, Hiclesbottom, Poterton & Co.) and Amount (£, s, d).

For rebuilding the Royal Standard Public-house, York-road, Battersea, for Messrs. Sanson and Ewington. Mr. H. I. Newton, architect, Queen Anne's-gate, Westminster. Quantities supplied:—

Table with 2 columns: Name (Hammond, Battersea, Richens & Moutt, Battersea, Royal, Ken oxville, Canning & Mullins, Newington, Steel Bros., Dalston, Spencer & Co., Knightbridge-street, Lambie, Kentish Town, Godden, Braystone-square, H. Burman & Sons, Kennington) and Amount (£, s, d).

For three houses on the Artillery Field Estate, Guildford, for Mr. J. Ross. Mr. A. B. Harding, architect:—

Table with 2 columns: Name (Trie & Robinson, T. Downes, Hill & Downes, G. & R. Smith, Barham, Carrington & Peto) and Amount (£, s, d).

For the erection of shop and dwelling-house, 74, Marylebone-lane, for Mr. J. Ch. Spink. Mr. Alfred J. Hopkins, architect, 10, Berners-street, London, W. Quantities supplied by Messrs. New & Son, 62, George-street, Portman-square:—

Table with 2 columns: Name (W. H. Burcher, Adams, Tozer, Scott, Clark, Ashwell) and Amount (£, s, d).

For rebuilding No. 11, Fore-street, City. Mr. John Slater, B.A., architect. Quantities by Mr. L. C. Riddett:—

Table with 2 columns: Name (W. King & Son, Brown, Son, & Blomfield, E. Cook, G. S. S. Williams & Son, L. H. & R. Roberts, J. & J. Greenwood, E. Conder, W. Downes, Patman & Fothergill) and Amount (£, s, d).

For erecting cottage at Coed Bell, Chislehurst, for Miss Anon. Messrs. Haldersham & Fawcner, architects, Bloomsbury-square:—

Table with 2 columns: Name (Hooper, Sperring, William Groom, Dulwich) and Amount (£, s, d).

Accepted for new church, Alverston, near Bristol including tower, Mr. Henry Lloyd, architect, Bristol. Quantities supplied:—

Table with 2 columns: Name (Stephens & Bartow, East Ham, Mr. Bethell, architect, Brickwall, Baxter, Wyles, Parsons) and Amount (£, s, d).

Accepted for the carriage of detached house, St. John's-road, Eastbourne. Messrs. William Reddall & Son, architects and surveyors, 10, South-street, Finsbury, and 86, Terminus-road, Eastbourne:—

Table with 2 columns: Name (Dore & Son) and Amount (£, s, d).

For the erection of skilled linen room at the Lambeth Infirmary:—

Table with 2 columns: Name (Chapman, Haxter, Parker, Robinson & Miller, Lathorn, Dickinson, Hayes, Smith, Altridge & Jenvey, Coe & Lye) and Amount (£, s, d).

For making-up Palace-road, Crouch End, for the Horsely Local Board. Mr. T. de Courcy Meads, engineer and surveyor:—

Table with 2 columns: Name (Dunmore, Crouch End, Brown, Upper Holloway, Pizzev, Horsely, Jackson & Sons, Finsbury-park, McKenzie & Co., City, Walker, Holloway) and Amount (£, s, d).

For new sculpture studios in Vincent-square, Westminster, for Messrs. J. Whitehead & Sons. Mr. John Adams, architect:—

Table with 2 columns: Name (H. Bealey, Westminster, T. Brunsden & Co., Brentford, A. Carman, Richmond, T. Richards, Westminster, A. Garraut, Brixton, Gordon, Kell, & Smith, Chelsea) and Amount (£, s, d).

Special Notice.—Lists of tenders frequently reach us too late for insertion. They should be delivered at our office, 46, Catherine-street, Strand, W.C., not later than four p.m. on Thursdays.

PUBLISHER'S NOTES.

CHARGES FOR ADVERTISEMENTS. SITUATIONS VACANT, PARTNERSHIPS, APPOINTMENTS, TRADES AND GENERAL ADVERTISEMENTS. Six lines (about fifty words) or under:— 4s. 6d. Each additional line (about ten words) 6s. 6d.

PREPAYMENT IS ABSOLUTELY NECESSARY. Stamps must not be sent, but all small sums should be remitted by Cash in Registered Letter or by Money Order, payable at the Post-office, Covent-garden, W.C. to DOUGLAS FOULDRINE, Publisher, Addressed to No. 46, Catherine-street, W.C.

Advertisements for the current week's issue must reach the Office before THREE o'clock p.m. on THURSDAY. The Publisher cannot be responsible for DRAWINGS, TESTIMONIALS, &c. left at the Office in reply to Advertisements, and strongly recommends that of the latter COPIES ONLY should be sent.

SPECIAL.—ALTERATIONS IN STANDING ADVERTISEMENTS must reach the Office before TEN o'clock on WEDNESDAY mornings.

PERSONS Advertising in 'The Builder,' may have Replies addressed to the Office, 46, Catherine-street, Covent-garden, W.C. free of charge. Letters will be forwarded if addressed envelopes are sent, together with sufficient stamps to cover the postage.

TERMS OF SUBSCRIPTION. 'The Builder' is supplied gratis from the Office to residents in any part of the United Kingdom at the rate of 12s. per annum, PREPAID. To countries within the Postal Union, 20s. per annum. Remittances payable to DOUGLAS FOULDRINE, Publisher, No. 46, Catherine-street, W.C.

TO CORRESPONDENTS.

A. H. B.—C. D. A.—"Bentor" (your suggestion is not likely to find favour at present, and it is too important a move even to suggest without careful consideration)—F. C. (tribal appeal)—J. M. (ditto)—J. R.—E. F. R.—L. H.—W. B. G. B.—M. B. M. N. (photography received)—T. M.—D. & Co.—J. K. C. (tracings received)—J. H.—G. S.—E. L. G. C. and H. (received)—T. & Co. (received)—K. J. W. (cannot reply to your letter, as you give no address)—A. V.

All statements of facts, lists of tenders, &c. must be accompanied by the name and address of the sender, not necessarily for publication. We are compelled to decline putting out books and giving addresses.

Non.—The responsibility of signed articles, and papers read at public meetings, rests, of course, with the authors. We cannot undertake to return rejected communications.

Letters or communications (beyond mere news-items) which have been duplicated for other journals, are NOT DESIRED. All communications regarding literary and artistic matters should be addressed to THE EDITOR; all communications relating to advertisements and other exclusively business matters should be addressed to THE PUBLISHER, and not to the Editor.

Best Bath Stone. WESTWOOD GROUND, Box Ground, Combe Down, Corsham Down, And Farleigh Down. BANDELL, SAUNDERS & CO., Limited, Corsham, Wilts. [Adv.]

Box Ground Stone Is the Best for Use in all Exposed Positions, being a well-known and tried Weather Stone. 50,000 feet cube in stock. PICTOR & SONS, BOX, WILTS. [Adv.]

Donning Freestone and Ham Hill Stone of best quality, in blocks, or prepared ready for fixing. An inspection of the Donning Quarries is respectfully solicited; and Architects and others are CAUTIONED against inferior stone. Prices, delivered to any part of the United Kingdom, given on application to CHARLES TRASK, Norton-sub-Hamdon, Ilminster, Somerset.—Agent, Mr. E. WILLIAMS, 16, Craven-street, Strand, W.C. [Adv.]

Doubling Free Stone For prices, &c., address S. & J. STAPLE, Quarry Owners, Stone and Lime Merchants, Stoke-under-Ham, (Ground or Lamp), Ilminster. [Adv.]

Asphalte.—The Seyssel and Metallo Lava Asphalte Company (Mr. H. Glenn), Office, 38, Foultry, E.C.—The best and cheapest materials for damp courses, railway gables, warehouse floors, flat roofs, stables, cow-sheds and milk-rooms, granaries, tan-rooms, and terraces. [Adv.]

Asphalte. Seyssel, Patent Metallo Lava, and White Asphaltes. M. STODART & CO. Office: No. 90 Cannon-street, E.C. [Adv.]

J. L. BACON & CO., MANUFACTURERS OF IMPROVED STEAM AND HOT-WATER APPARATUS, FOR WARMING AND VENTILATING Private Houses, Churches, Schools, Hospitals, Manufactories, Greenhouses, &c. OFFICES AND SHOW-ROOMS:—No. 34, UPPER GLOUCESTER PLACE, DORSET SQUARE, LONDON, N.W. And at DUBLIN, BELFAST, GLASGOW, and NEWCASTLE. Illustrated Pamphlet on "Heating" post free.

CHAPPAUS' PATENTS FOR REFLECTING LIGHT. DAYLIGHT REFLECTORS OF EVERY DESCRIPTION, ARTIFICIAL LIGHT REFLECTORS. WHY BURN GAS?—CHAPPAUS' REFLECTORS DIFFUSE DAYLIGHT.—They are exclusively adopted by and fitted at Buckingham Palace, all H.M. Government Offices, Houses of Parliament, H.M. First Commissioner of Works, the Metropolitan Board of Works, British Museum, South Kensington Museum, Royal Institution, Guildhall Museum, on board H.M. Ships, also Railway Companies' Offices, Hospitals, Institutions, Banks, Insurance Offices, Manufactories, Private Houses and generally from Nobleman's Mansions to Artisans' Workshops. 30,000 in use in London alone. Patronised by leading Architects, Engineers, Contractors, &c., &c.

N.B.—For Prospectuses and Diagrams, address Stamped Envelope to P. E. CHAPPAUS, Patentee and Manufacturer, 69, FLEET-STREET, LONDON. NOTICE.—The POLYGONAL REFLECTOR (Latest Patent) FOR ARTISTIC and PICTURE GALLERIES. Its construction allows of the angle of light being readily altered so as to reflect in any desirable direction. N.B.—On View at HEALTH EXHIBITION (Eastern Gallery).

### Further Evidence on Thames Pollution.

#### PARLIAMENTARY

Return of great interest has just been published, containing copies of or extracts from correspondence which has passed between the Secretary of State for the Home Department on the one hand, the Metropolitan Board of Works, the authorities of the City of London, and others, on the other, as to the pollution of the River Thames by sewage. The correspondence commences, in January, 1882, by a representation made by the Town Clerk of London to the Secretary of State, to the effect that the Port of London Sanitary Committee of the Corporation, "guided by personal inspection, and the results of careful chemical analysis of the water of the Thames, urge upon the Government, under the provisions of the Metropolitan Local Management Act of 1858, cap. 104, section 31," the extreme importance of taking steps towards "remedying that which must be admitted to be a great and growing evil."

The Home Office applying for further particulars, the Town Clerk encloses the Report of the Port Sanitary Committee, together with a letter to that body from the Medical Officer of the Port of London, containing the analysis of the water. "The worst specimen examined was the one taken at Barking on the 23rd of November, when the tide was running down, and which is reported to contain one-fifth of its volume of sewage."

Upon this the Home Office call for reply from the Metropolitan Board of Works, whose clerk answers on April 4, "that the water of the Thames is not so pure as may be wished may be admitted without hesitation, but there are other sources of pollution than the Metropolitan Sewage outfalls, which would go far to account for the conditions which give rise to complaint." The Board go on to say that the statements with respect to the polluted condition of the river "are, if not totally unfounded, greatly exaggerated," and "wish to continue the investigations it is now making during the time when hot weather prevails." We need not follow the system of fencing of which the key-note is struck in the above letter. An old report, signed by Sir J. W. Bazalgette, and Messrs. Law and Chatterton, of April 15, 1878, in reply to Captain Calver's report of the preceding October to the Conservators of the Thames, is reproduced, together with a report of about the same date signed by Mr. T. W. Keates,

Consulting Chemist to the Board; and one by Dr. Dupré, Chemist to the Medical Department of the Local Government Board.

It should be noticed, as a marked characteristic of the line of defence adopted by the Metropolitan Board of Works, that the last-named reporters say that their attention has been called to the quantity and character of the solid matter suspended in the river water. This limitation of the analysis to suspended matter, instead of total solids, was rendered possible by the error of the Thames Conservators, who attempted to prove a material silting up of the river, instead of taking the broad ground of the nuisance caused by the outfalls. The effect has been to give, as the outcome of chemical analysis, an average of 23.06 grains of suspended matter per gallon, while the analysis made for the Woolwich Board of Health by Mr. G. W. Wigner, F.C.S., on September, 1878, showed that the surface-water in Limehouse Reach contained 516 grains, or considerably more than one ounce in the gallon, of organic matter dissolved in the water. Mr. Wigner further points out that the samples analysed by Messrs. Keates & Dupré were taken when the river was in flood, and when a large discharge of upland water substituted pure for impure water throughout the whole course of the river. Whatever excuse there may have been for adducing Mr. Keates's report in reply to the charge of producing material obstructions to the river, there can be none for sending, in 1884, to the Home Secretary a statement so eminently calculated to mislead in the broader inquiry instituted by the Sanitary Port Authority.

On 22nd May, 1882, the Secretary to the Local Government Board writes to the Home Department to the effect that the condition of the Thames has been so often the subject of complaint that it is impossible to avoid an investigation, adding "the officers of the Metropolitan Board of Works have been persistent in the denial of the existence of any serious nuisance at the outfall," and for this reason the Board think it essential that the inquiry should not be postponed until a date when the Commission will not be able to satisfy themselves by personal observation of the effect produced by the outfall works during the hot weather. This part of the return concludes by a copy of the Royal Commission, headed by the distinguished name of Baron Bramwell, issued to inquire into and report upon the system under which sewage is discharged into the Thames by the Metropolitan Board of Works, dated 22nd June, 1882.

Of the first report of this Commission we spoke at the time of its appearance (vol. xlv. p. 221). On the 14th of July last, the Secretary of State for the Home Department wrote

to the chairman of the Metropolitan Board of Works, stating that in consequence of reports that he had received he had personally consulted Lord Bramwell, the chairman of the Commission, as to the state of the Thames, and had received from him a letter which he transcribes. "On Wednesday last," it runs, "five of the Sewage Commissioners, of whom I was one, went to examine the condition of the river. I do not like to use strong language, but, unless I do, I cannot adequately express my opinion. The river was in such a state as to be a disgrace and a scandal to the metropolis and civilisation. We went on it at Woolwich Dockyard. It was for its whole breadth black sewage, with a stench intolerable. We proceeded up the river, and traced the sewage nearly to Limehouse. Up to Greenwich it appeared unmixed sewage, then patches of natural water appeared, which increased till the sewage ended. The tide had then two hours to flow, and I cannot see why some sewage should not reach London Bridge, or nearly. We then went down the river, and again encountered the sewage till we got to Barking outfall, where the water was tolerably pure. The distance was ten miles of sewage, more or less."

The Home Secretary next calls attention to the fact that at the time when the Metropolitan Board obtained their powers to construct the main drainage, by the Act of 1855, it was understood that the sewage, if discharged at the present outfall, should be purified and deodorised. And he concludes that unless he is satisfied that ample and adequate means have been taken to abate the nuisance described in the police reports, and the letter of Lord Bramwell, it will be his duty to take action under the statute 20 & 21 Victoria, c. 104, s. 34.

On the 21st of July, the Chairman of the Metropolitan Board of Works replies that the experience of twenty years has shown that any injurious or offensive results of the discharge of the metropolitan sewage "only occur under the combined conditions of a reduced flow of water in the river, and a high temperature, such as existed during the latter part of June and the early part of the present month of July. These combined conditions occur, generally speaking, only at distant intervals, and prevail only for a short time." At the beginning of July, he continues, the estimated flow of the river at Teddington was only 400,000,000 gallons per day, or 50,000,000 more than the minimum flow. At the same time, the temperature in the shade has been as high as 86 degrees. Since the 10th of July, he adds (the day after Lord Bramwell's visit), "the whole of the sewage at both outfalls has been thoroughly deodorised, and care has, from then

first, been taken to flush the main sewers under the Board's control." Further, "furnaces and pans are now being erected, at which the Board itself will manufacture the deodorising material required."

A partial report of the visit of the Commissioners to the Thames is given by the Secretary of the Commission on July 23. On the 26th of July the Secretary to the Local Government Board points out that the letter of the Metropolitan Board of Works gives no definite information as to the means adopted by them for the deodorisation of the sewage at the outfalls, and offers to send one of their Engineering Inspectors to visit the spot. A communication is next printed from the East and West India Dock Company, complaining that no less than 400 tons of sewage enter their docks from the river at every tide, and that 37,300 tons of sewage mud have been removed from the docks within three months.

On the 2nd of August the Clerk to the Metropolitan Board of Works writes to the Home Department "to observe that the allegation which the Board contested, and the correctness of which it still denies, is that the river was generally in such a condition, owing to the sewage discharged into it, as to be offensive and injurious to health;" and concludes, "the complaint, so far as relates to the offensive smell arising from the latter, has been remedied." This cheering view, however, is not shared by the Secretary of State, who replies on the 5th of August that "the reports received from the police show that the state of the river, due to the sewage, has been by no means remedied by the measures recently adopted by the Metropolitan Board of Works, and that the enclosed report indicates that the state of things appears to have become worse in the last few days, showing that the scheme of deodorisation now in practice is not effectual for its purpose."

On the 7th of August the Secretary to the Commission writes to the Secretary of State, who has called for another report, to say that on the 30th of July the river was inspected by one of the Commissioners, and by several of them on the following day, and that "there did not seem to be any evidence of material improvement by the treatment of the sewage adopted by the Metropolitan Board . . . . A scum arising from chloride of lime was floating about in many places," resulting from a process "likely to be injurious to the river in other ways, and which can be only regarded as a temporary expedient to palliate a state of things that ought to have a more suitable permanent remedy." The Metropolitan Board, on the 9th of August, "much regrets to receive the expression of opinion," by the Secretary of State, "and the more so, because it conflicts with the results of the observations both of the Board's professional advisers and of Members of the Board themselves, a number of whom visited the neighbourhood of Woolwich last Saturday (a very warm day) and could detect no offensive smell from the water." The dispute is kept up in numerous short letters, and on the 15th of August the Secretary to the Commission writes that on the 14th of August the river was decidedly worse than before, but that on the 15th it had improved.

Daily reports from the superintendent of the Thames division of the Metropolitan Police are added, generally to the effect that there is no improvement. These reports would be of more value if they had stated the temperature. This we have taken the pains to ascertain, at a point higher in the Thames system than Woolwich, but which may serve as a comparative guide. On the 9th of August "the river water appears to be in as bad a condition as ever." The temperature on that day was 79° 5". On the following days the temperature was as follows:—Aug. 11, 79°; Aug. 12, 69° 5"; Aug. 13, 63° 8"; Aug. 14, 66°; Aug. 15, "no improvement," 69°; Aug. 16, 69°, "clearer and much better on the flood"; Aug. 18, 72°, "still further improvement"; Aug. 19, 68°, "slight improvement sustained"; Aug. 20, 67°, "still a steady improvement in the state of the river water, both in colour and smell." The series of thermometric readings is enough to show to what cause that improvement is due.

It only remains to speak of what is probably the most important of the sixty documents contained in the Parliamentary paper now under review. This is the report of Mr. John Thornhill Harrison, M. Inst. C.E., an inspector of the Local Government Board, to the president of that Board, under date of August 13th, 1884. Mr. Harrison states that he has examined the state of the river on seven occasions. To make his remarks the clearer he has prepared a sketch of the course of the Thames, on the scale of four miles to the inch, divided into five-mile lengths, above and below Crossness, from Teddington Lock to Southend, a total distance of 62·15 miles. He has added a table showing the volumes of water in each of these portions of the river, at both high and low water, of both springs and neaps, as well as the volumes of salt water in the same at springs. We must refer to the patient and lucid document itself for the details. The conclusion from this part of the investigation is "that at the present time there is a month's sewage from the metropolis oscillating backwards and forwards between Greenhithe and Teddington."

Thus far Mr. Harrison only confirms the statements put forward in 1877 by the Conservators of the Thames, on the report of Captain Calver, R.N., F.R.S.—statements which, as we have seen, are fully supported by the judicial testimony of Lord Bramwell. But the special value of Mr. Harrison's reports lies here. He has not confined his observations to the floating island of sewage which has been steadily increasing in extent from the opening of the main outfalls to the present time. He has examined also the river above Bridge. He reports that "the water during high spring tides is polluted even up to Richmond; and it leaves a foul deposit on the banks of the river and on the towing-path. . . . The Thames in its present condition can only be compared to a huge sewage-tank, which now for many months has not been cleaned out: it is notorious that under such circumstances the sludge, wherever it settles, becomes putrescent, and most offensive."

"The Metropolitan Board of Works," Mr. Harrison continues, "deny altogether that there is any deposit of sludge in the Thames from their sewage. I feel confident that this contention is no longer tenable." Here is the kernel of the whole matter. Relying on an Act of Parliament which Sir W. Harcourt, in his letter of the 14th of July, intimates to have been obtained under conditions hitherto unfulfilled, the Board of Works have, up to the present time, defied alike the Conservators of the Thames, the Port Sanitary Authority, the Local Government Board, the Home Office, and we may say the public sense of truth and of sanitary principle. It is tolerably clear that they are likely to resist any proceedings which the Home Secretary may institute under Section 34 of the Metropolitan Management Amendment Act of 1848. And such is the effect of the neglect to institute proper control by the Acts of Parliament constituting the Metropolitan Board, that it is at least conceivable that the latter might continue to defy any interference short of that of Parliament, based on complaints as to the state of the Thames below London.

But the very object of calling the Board into existence was "to prevent the sewage of the Metropolis from passing into the Thames within the Metropolis." This object, according to the report of Mr. Harrison, has been entirely missed. If, therefore, the Home Office take the action that they indicate, in which they will be thoroughly supported by public opinion, it is on the facts now adduced by Mr. Harrison that their success will, we apprehend, depend.

Mr. Harrison states that between 17 tons and 18 tons of chloride of lime was used by the Metropolitan Board daily from the 10th to the 21st of July, at a cost of about 2,000l. per week. The imperfect action of this disinfectant has been pointed out. Mr. Dibdin, who has charge of the work, is now making manganate of soda at Crossness, and will shortly manufacture 20 tons a day. The cost of this is not stated; but on the 5th of August

last Sir Charles Dilke stated in the House of Commons that the cost of permanganate of potash was about 130l. per ton. We thus obtain intimation of a cost ranging from 100,000l. to 675,000l. a year as likely to follow from the concentration of the refuse of 5,000,000 persons in one locality, for the purpose of turning it bodily into the river. It is only the more costly disinfectant that succeeds. And this is because the large dose of oxygen which it contains actually burns up that effluvia organic matter which is the source of the sewage poison. It deserves not only serious consideration, but the test of experiment, whether precipitation, followed by the actual combustion of this organic matter, which itself would supply the fuel, will not prove at once more certain and more cheap than the application of this costly chemical product. We recommend the study of this report to our readers.

#### TURNING AND MECHANICAL MANIPULATION.\*

FROM a literary point of view, the votaries of the art of turning have little cause to complain that justice has not been done to the lathe both as regards its history, construction, and manipulation; in fact, with the exception, perhaps, of the steam-engine, more has been written about it and the wonders it can accomplish, than upon any other branch of mechanical engineering.

The old books by Bergeron, Teubers, and others, are well known, and do infinite credit to the writers; but the subject has never been so exhaustively treated,—whether taken from a scientific or practical standpoint,—as by the Holtzapffels, father and son. The present volume, No. V. of a series of six, is by the son, John Jacob Holtzapffel, and is a continuation of the important work designed and begun by the father.

In the introduction the author deals briefly with the early history of turning, and says that probably the earliest record of what may be called ornamental turning is that described by Virgil, *Bucol. III.*, v. 36, translated by Dryden as,—

"Two bowls I have well turned, of beechen wood," &c.

He also quotes Pliny and other old writers, but we think that the antiquity of the lathe, not only in Europe, but in Asia and Africa, has already been proved to demonstration, and drawings of lathes used by the Kabyles and other African tribes many hundreds of years ago are still in existence.

In Section I. the Division Plate and Index are dealt with at length. In speaking of the cutting action of tools the author justly urges that to secure perfection in work every cut in every series of operations should be perfectly regular and equal in disposition and depth, and,—given a perfectly-constructed lathe,—this, with skilful attention and with ordinary materials to work on, can be obtained. With difficult materials, however, which vary in density,—such as stones or marbles containing in places shelly fossil deposit, which is often hard and crystalline,—it has been found a matter of extreme difficulty to obtain equal cuts, an ordinary straight tool often springing from or digging into the material. For this kind of work saucer-shaped revolving cutters of chilled cast-iron or steel can be used with advantage, as these roll over the material they are cutting. The dead contact is small, and the friction is, therefore, much reduced, and the cuts are much more regular than with a fixed tool.

The author now refers to the grinding of angular, straight, and curvilinear-edged tools, and gives much useful information thereon. We agree with the recommendation that tools with flat-cutting edges should be ground mechanically instead of by hand, as by fixing them in an indexed quadrant frame any desired cutting-angle may readily be obtained, and the

\* "Turning and Mechanical Manipulation," Vol. V. "The Principles and Practice of Ornamental or Complex Turning." By John Jacob Holtzapffel, A.M.I.C.E. London: Holtzapffel & Co.

result is absolutely accurate. This is especially applicable to broad-faced tools.

In Section II. the author deals with form and ornament and materials, in a concise and able manner. Section III. treats on the different methods of chucking work,—we need hardly say a matter of very great importance to the ornamental turner, and one not always carefully done. Much useful information on this subject is to be found in vol. iv. of the author's work.

Chapter III. deals with slide-rests for ornamental turning and the application of fluting stops. Illustrations of a cradle, quadrant, and counting ratchet, designed by the author, are also given; for high-class complex turning these should be found extremely useful. To obviate the unevenness and uncertainty of the advance of the slide-rest and cutting-tool, when traversed by hand, Mr. Holtzapffel gives descriptions and illustrations of several kinds of automatic driving-gear, including a tangent-screw gear, in which the micrometer and worm-wheel are in one solid. Ashton's automatic driving-gear is also described; this gear carries its own fluting stops, which, as they determine the extent of the traverse, throw the tangent screw out of action. Further on, Ronald's curvilinear apparatus (contrived about 1830), which translates a rectilinear into a curved traverse, is noticed, and, as we read it, the author considers that this application of a guide principle contains the germ of all turning and carving machinery for the production of fac-similes.

We have no wish to deny Mr. Ronalds any honour to which he is justly entitled, but we think the author will find he is quite in error in ascribing to Mr. Ronalds the honour of being the introducer of the guide principle for the production of fac-similes, as previously to the present century Condamine describes in his work how a lathe may be made to turn irregular figures by means of tracers moved over the surface of models, and we have before us illustrations of two machines constructed by the great engineer Watt, in the year 1809, for the production of fac-similes of carving, or sculpture in marble, alabaster, or wood. These machines are still in existence, together with samples of busts and bas-reliefs produced by them, and are to be seen in the "Watt Room" at the residence of Mr. George Langye, Heathfield Hall, near Birmingham. As the matter is of some interest, we give a short description of these machines. Of the two machines constructed, one was designed for reproducing of the same size as the original, and the other for making a copy of a reduced size.

The first machine Watt called an "Eidograph," and it consisted, firstly, of an ordinary lathe with treadle and fly-wheel, to supply the motive power; and, secondly, of two tall uprights, about 7 ft. high, carrying at the top a slide on a strong horizontal bar, the slide being capable of motion horizontally either at a slow or quick speed.

Then, hinged to this slide is a light square frame of metal, and, at the outer edge of this another light square frame of metal is hinged, so that the lower end of such frame is capable of motion up and down, or in and out, like an elbow joint, and horizontally when the top slide is moved. The weight of these frames is balanced by levers and balance-weights and chains above, and the lower edge of the second frame is furnished with a "feeler" or "guide" to traverse over the original model. There is a noticeable feature in the frames above mentioned, and that is, that in order to prevent their springing or going "winding" they are practically formed into solids by the erection of the outlines of a pyramid on each; this plan gives extreme stiffness at the expense of very little weight. With this machine undercutting as well as straight cutting can be performed. Watt called his second machine for making reduced copies a "Diminishing Machine."

In this he employed a stout hollow tube, forming a long lever, fulcrumed at one end on a universal joint, so that the other end can be moved in any direction about the centre. This lever carries a "feeler" or blunt point near its outer end, and a drill near the fulcrum. The slides above named slide on the bed of the

lathe, and are moved by a pentagon or arrangement of levers. A further motion is provided for turning round the original and the copy, as is sometimes necessary when undercutting a bas-relief, and, of course, when copying the round figure.

Again, Thomas Blanchard, of Philadelphia, invented his well-known copying-lathe in 1819: in this, too, a "dummy" or model and tracer guide are employed.

Chapter IV. contains lucid descriptions of the construction and working of the various cutting-frames and the revolving tools used in complex shaping and ornamenting, with illustrations in autotype taken from executed work. This is followed by a chapter on one of the most important classes of tools used in the production of elaborate work, viz., the different forms of drills for ornamental recessing and piercing purposes, and of these the author gives a large number of illustrations, rightly urging the necessity of keeping their profiles absolutely true, or high-class work is an impossibility. A number of illustrations of patterns,—chiefly used for surface ornamentation,—produced by the eccentric cutting frame are now given: many of these are extremely complex, but some of them exhibit remarkable beauty of design. Plate 14 illustrates in autotype a very elaborate specimen of inlaid eccentric and concentric turning executed by an amateur, Mr. T. Brocklebank. It is in the shape of a plaque of African blackwood, with medallions ornamented with camwood, and edged by tulip-wood and ivory. Great ingenuity has often been exhibited in such work as this, and it has a beauty of its own in a geometric sense; but its artistic value is very low, compared with the means which go to produce it.

In Chapter VI., elliptical, epicycloidal, and rose-cutting frames are dealt with; interesting though they are, the limit of our space prevents more than a passing notice. We would, however, draw the author's attention to an extremely novel motion in this connexion recently invented by an amateur, Mr. Tighe Hamilton, of Dublin. For want of a better term it may be called a "drunken eccentric" motion, combining both revolving and horizontal traverse motions at the same time. At present it is utilised in cutting fine gear wheels from the solid, to the teeth of which it can give any desired degree of curvature, all sizes, pitches, angles, and tapers being variable at will. With some alterations it could be added to the turning-lathe, and used for dovetailing, and dovetail tonguing and grooving, as well as for various kinds of ornamental work.

The author, in Chapter VII., treats at length on eccentric and oval chucks, and Plate 35 shows two fine specimens of oval surface decoration. Chapter VIII. deals with the spherical and other chucks, and some very useful instructions as to working them will be found. Plate 41 illustrates a good example of a model clock-tower turned in ivory. This is intended by the author to show chiefly the capabilities of the rectilinear chuck, and no portion of the model was touched after leaving the lathe. A full description of the method of working pursued is given, which should be extremely useful to amateurs desirous of carrying out similar work; and this feature, showing what tools are to be employed, is one that could be extended with advantage. The great range of the work that can be performed by the lathe and its various adjuncts is well shown by a large number of illustrations of vases, tazzas, Gothic windows, recessed panels, &c. These two latter, by the way, can be much more rapidly produced on a vertical spindle, irregular moulding, and recessing machine than by a lathe.

In taking our leave of this really admirable book, we cannot help thinking that if some of the language and descriptions given were a little simpler it would be of still greater service to those for whom the book has been designed, viz., amateur turners; in point of fact, to understand it thoroughly, the amateur must really be a somewhat advanced technologist, which we are afraid, in the great majority of cases, he is not.

During a long series of years the lathe has gradually developed, until it has become the most advanced of all mechanical tools; but the author can congratulate himself on having done it ample justice, and on the completion of his next volume will have practically exhausted the subject, and completed a work on the lathe and its manipulation unequalled in any language.

#### RAILWAY GOODS RATES.

"OWNER'S RISK."

 HIS subject, on which we have before offered some observations (see p. 183, ante), is one which may be approached from many points of view, but in whatever aspect it is looked upon there are considerable difficulties to be overcome. So uncertain and inconsistent are the regulations that a large amount of patient attention is necessary to comprehend them, and many of them will be found open to various interpretations.

A fruitful source of contention and litigation is furnished by the "Owner's Risk" system, and some information on this point may not be uninteresting, especially to those of our readers who are in the hauling trade, and to whom the subject must often become one of very practical importance. The rates charged for carriage of different articles vary in proportion to their bulk and value, goods of a damageable nature being highly rated accordingly. In an early stage of railway history it was found to be advantageous both to the Railway Companies and the public to adopt a system whereby the rates for certain easily breakable goods should be reduced on condition that the consignors agreed to relieve the companies from liability in case of damage. The amount allowed off the ordinary rates in such cases varies from 10 per cent. to 20 per cent. Articles rated second class are generally subject to a reduction of 10 per cent. or 15 per cent.; third and fourth class rates are reduced 15 per cent.; and fifth class 20 per cent. Thus, to take a few articles used by the trade as examples:—Carved stone for building purposes (not being for interior decoration) is chargeable at the second class rate, and, when at Owner's Risk, 10 per cent. less. Iron mantel shams, palisades, spoutings and connexions, kitchen and furnace boilers, ranges, grates, and stoves, are second class less 15 per cent. Window glass, joiners' work, marble and enamelled slate slabs (in cases) are rated third class less 15 per cent., and tomb-stones and carved decoration stone fourth class less 15 per cent. The 20 per cent. reduction only applies to such goods as organ work, looking-glasses, and a few other articles included in class five. It may be mentioned that the class rates run in something like the following proportion per ton:—For a distance of about 200 miles,—first, 33s. 4d.; second, 40s.; third, 50s.; fourth, 61s. 8d.; fifth, 75s. There does not, however, appear to be any rule on this point, as the proportion varies considerably between different places. The system of charging just described only came into operation on the 1st of January, 1883, and is therefore comparatively new; and though it was a step in the direction of uniformity, it was found, as a rule, to involve an increase in the owners' risk rates. Previously, the rule (with a few exceptions) was to charge one class lower when at owner's risk than when not so conveyed. It will be seen that the per centage now allowed does not amount to a reduction equal to that caused by adopting the next lowest class rate, and in many cases the proportionate difference between the class rates is much more than in the example given. Thus, though it is satisfactory to find a uniform system adopted, the change amounts to as great a revolution in the charges as did the scale for "small" introduced in 1877, which has been treated of in a previous paper. There are special owners' risk rates in force between certain points for exceptional traffic, and heavy traffic not included in the five classes is also subject to special arrangements. In addition to reducing the rates, the companies undertake to return certain goods to the senders to be repaired or replaced free of charge when

conveyed at the owner's risk, and damaged in transit. This arrangement does not apply to all goods which are so conveyed, it being obvious that some of the articles just mentioned are of no value whatever when broken, and that it would be useless to return them. But when the present system of charging was introduced, the railway companies raised a storm about their ears by announcing that they should discontinue the "free returns" altogether. This, as it was well put by one of the trade associations protesting against the alteration, would be putting a premium upon carelessness, as, when it was necessary for an article to be returned for repairs, the carriage upon it would have to be paid three times over; and the companies, recognising the manifest unfairness of their proposal, reverted to the original arrangement in this respect. This regulation also includes free conveyance of the repaired articles, or those sent to replace the broken ones.

The declaration signed by the sender of the goods, though familiar enough to many, may here be quoted:—"The Railway Company are requested to receive and forward, as per address and particulars on this note, the undermentioned goods, to be carried at the reduced rate below the Company's ordinary rate, in consideration whereof I undertake to relieve the Railway Company and all other companies over whose lines the goods may pass, from all liability in case of damage or delay." Some of the companies add the following:—"Except upon proof that such loss, detention, or injury arose from wilful misconduct on the part of the companies' servants." The omission of this last clause would not affect the right of a trader to sue for compensation in the event of the loss being caused under the circumstances therein mentioned, as the oft-quoted "Cardwell's Act" (Railway and Canal Traffic Act, 1854) affords protection in such cases. That Act provides that every company shall be liable for loss of or injury done to any goods in transit, occasioned by the neglect or default of such company or its servants, notwithstanding any notice limiting such liability. At the same time it is provided that nothing contained in the Act shall be construed to prevent the company from making such conditions as shall be adjudged to be just and reasonable. Now, a contract without the latter clause would scarcely be looked upon as just and reasonable by any court or judge, as the company's servants would thus be protected, even in malicious and wilful damage, and the agreement would therefore be manifestly unjust. The only conclusion that can be arrived at with regard to the omission of the clause by some of the companies is that they rely on getting rid of some demands through the claimants being ignorant of the law, and being thus deterred from prosecuting their claims. Of course there is always a difficulty in bringing home a charge of wilful misconduct, but still it is quite possible for any one unaware of the provisions of the Act of 1854 to abandon a very clear case on being referred to the terms of the contract. Lord Justice Brett says, with his usual clearness, that although there is the alternative rate of carriage, if the exception as to the wilful misconduct does not appear in the document he would hesitate to allow the reasonableness of the contract, his opinion being that the consent of the parties does not make that reasonable and just, which, in the opinion of the court, is unjust and unreasonable. Other authorities have, however, expressed a different opinion, and this clause is an anvil upon which many a case has been hammered, there being numerous precedents to be referred to on both sides in cases of this nature. "Wilful misconduct" has been variously defined, but the exposition given by Lord Justice Cotton is, perhaps, one of the clearest. He says that wilful misconduct is a doing of something which the person doing it knows will cause risk or injury, or the doing of an unusual thing with reference to the matter in hand either in spite of warning or without care, regardless whether it will or will not cause injury. Perhaps this would have been more complete if he had added that it would include

the omitting to do something which the party would know it was wrong to omit, being aware that the omission would be likely to result in damage. But this is a nice question, and one to be determined rather by the merits of the case than by legal or general definitions. Certain it is that the same words have been claimed as protecting opposing parties, and different circumstances give the verdict first to one side and then to the other.

## NOTES.

**I**n reference, we presume, to our "Note" of last week in regard to the Liverpool Cathedral site controversy, a printed protest with no names to it has been sent to us, accompanied by a plan of the site with the cathedral and cloisters of Wells laid down upon it, to show the inadequacy of the site. The cloisters stretch beyond the site considerably, though the cathedral plan is purposely drawn away to the west side of the site to emphasise the insufficiency of the ground. Of course if a residential cathedral with a cloister-garth is regarded as a *sine qua non*, the site is too small; it is too small also, without the cloister and residences, for a professional Medieval cathedral of the largest type. It seems to be quite forgotten, however, that the cloister had its *raison d'être* as part of a monastic institution, of which the church itself was only a part; and as it may be presumed that the intention is to build a cathedral and not a monastery, the necessity of the cloister is not apparent. As to the cathedral, we have already expressed a hope that some effort would be made to build an essentially modern cathedral for congregational worship, such as Wren would have made St. Paul's had he been allowed. Such a building would naturally be square in general plan, not long; and there is room for a fine building of such a type on the selected site. The clerical party (for we presume the circular emanates from them) have put a Medieval plan on the site, which is certainly not suitable to it, as if that were the only alternative. We very much hope to see a people's cathedral built, and not a mere Medieval imitation, which, in such a town as Liverpool, we should regard as little better than a costly anachronism.

**T**HE works of Blake in which his genius appears at his best, the poems written and decorated by himself in his own extraordinary and unique style, have hitherto been known only to the few who possessed copies or who had studied those in the Print Room of the British Museum. *Fac-similes* in colour of some of the pages were given in the appendix to Gilchrist's life and in Mr. Swinburne's book, "William Blake, a Study," but these did not convey the feeling of the hand-painted originals. Mr. Pearson, of Pall Mall, has commenced the publication of a limited number of hand-painted copies of Blake's works, including the "Book of Thel," the "Visions of the Daughters of Albion," "The Songs of Innocence," and "Songs of Experience," the "Europe," the "Los," and the "Milton." Of these, the first two named are complete, and in the hands of subscribers, the issue of each book being confined to fifty copies. These are very remarkable examples of reproduction; and without seeing the originals alongside of the copies, it would be difficult to judge whether they were not original Blake copies, Blake's peculiar colouring and touch being so well imitated. The names of the artists who have worked upon them are not as yet published, but it is stated that there are several hands at work, and that each artist works on some portion of every plate, with a view to the obliteration of mannerism. The "Vision of the Daughters of Albion" exhibits more of the eccentricity and less of the real power of Blake as a designer than many others of his works, and some of the designs display that childish crudity in the drawing of the figure which is one of the most extraordinary characteristics of an artist who unquestionably could draw when he was minded to. Not so with that ethereal little work, the "Book of Thel," in which the sketched figures (for they are only

sketches) are exquisite in their grace and fancy, and the poem, in Blake's quaint printed writing, reads like some "emanation," as he would have said, from an ideal world quite different from ours. It is something at least that fifty more people can now possess this little gem almost in its original beauty; and one only laments that the conditions of production are necessarily such as to limit the number of copies, and render the price prohibitive except to the few. Perhaps, however, it would not do to make Blake too common. One shudders at the idea of the thumb of the Pbūstiushe brushing the bloom off his pages.

**P**ART II. of the Transactions of the Royal Institute of British Architects for 1883-4, which is just out, exemplifies the great and desirable advance made in the employment of illustrations, as well in quantity as in quality. A large proportion of the illustrations are representations of buildings recently erected in India, to accompany Mr. Emerson's paper; some of the Pagin Travelling Studentship drawings are also reproduced; and among more practical illustrations are two pages of constructive details, showing the "precautions to be adopted in introducing the electric light into houses." The Institute volume is now one which may become not only valuable to architects for reference, but of considerable interest to the educated public outside the profession.

**T**HE *Daily News* calls attention to the neglected condition of the oddly-shaped open spaces at Hyde Park Corner which were formed in connexion with the so-called improvement recently effected in that locality, and suggests that they should be put in order pending arrangements being made for adorning these spaces with statuary, which, it appears, is in contemplation. It seems to be the fate of all new metropolitan improvements that the site should remain a blot and disfigurement for a considerable period. The Courts of Justice are no exception to this rule, a large plot of ground on the west side of the new buildings remaining to this day in a disgracefully neglected condition, being covered with all manner of *débris* and old building materials. If the Government cannot make up their mind as to the appropriation of this site, they might at least level it and make its appearance endurable; at present it is a scandal and an eyesore.

**C**ONSIDERABLE weight should attach to the opinion expressed at the Congress of Railway Servants on the subject of automatic brakes. No class of persons are so competent to form an opinion on the value of this appliance as are the engine-drivers; and they appear to be tolerably unanimous in favour of the automatic method. As to the outcome of the discussion on the subject of overtime, the enforcement of a return to "set forth the number of men that are required to resume duty without an interval of rest of less than nine hours," if coupled with a return of any who are engaged for more than nine hours continuously, or with brief intervals for food, might not only tend greatly to the reduction of accidents to railway servants, but would also give satisfaction to the public. It is not easy to over-estimate the importance of any regulations affecting the safety of our great railway army, which contains some 365,000 men. Out of these, about 17 per cent. are directly concerned in working the traffic. It is on that small number, therefore, that the heavy per-centage of injuries to the servants of the companies has principally to be reckoned,—a fact which imparts irresistible force to the demand for a system of couplings which would avoid the necessity of the workmen going between the vehicles.

**W**E have received from Mr. Chas. Barry a copy of his Report on the designs sent in for the proposed new building for the Lincoln School of Science and Art, in reference to which he has been acting as professional adviser. As we stated a fortnight ago (p. 473), he has recommended, as the best three, the designs marked respectively "Forever," "Study," and "Academia." The

Report touches on some matters of general principle in regard to competitions. The treatment of the site has been of every variety, some competitors building over the whole of it, while others utilise only a part, while all equally declare their confidence in being able to carry out their building for the limited sum named in the instructions. Calculations convinced Mr. Barry that some of them would cost double the stipulated amount, and many would be considerably in excess of it. He therefore rightly decided to deal only with the best of those which could be executed for something like the maximum amount allowed in the instructions (7,150*l.*), and concludes his Report with these very pertinent remarks, which deserve to be duly weighed by Competition Committees generally:—

"I hope I may urge on the committee, on behalf of the profession to which I and the competitors have the honour to belong, that the object architects have in view in entering into a competition such as this is not the obtaining a premium (however well deserved that generally is for the labour in making a design), but the honour and professional credit of being allowed to carry out their design into execution. I do not doubt the committee are fully aware of this, and unless some serious reason should be found to exist to the contrary, that the authors of the three designs I have named will, in the order named (subject to the verification of estimate), be deemed to have the first claim on their regard.

I trust the committee will not think it presumptuous on my part to make the above remarks, which I am sensible are beyond the strict duty laid upon me, viz., to select the three best designs, and those which were also found to be most in accordance with the conditions issued to competitors.

The committee will understand from what I have said that there are designs among those sent in of superior merit to those I have named, some as regards larger accommodation, convenience, and good arrangement, and some as regards design, and I regret that I do not feel at liberty to make my selection on the ground of merit only, irrespective of cost.

THE Architectural Association *conversations*, at the Prince's Hall, on Friday last, was a considerable improvement upon that of last year. The number of invitations was restricted to the capability of the rooms, and the cloak-room arrangements were upon a more liberal scale than formerly, but in this last particular the accommodation still left much to be desired. The exhibits were of the usual miscellaneous character, wall-papers and carpets predominating; Messrs. Morris & Co.'s contribution was the most important, and included a small tapestry hanging of "The Goose Girl," from a design by Walter Crane; a very gorgeous wall-paper designed for the Waterloo Chamber at Apsley House; and some very handsome specimens of window curtains. Mr. R. Phené Spiers contributed some water-colour sketches in his usual effective style, and there were a large number of drawings by students of the Association classes. The sketches by Mr. Oakshott, which obtained the Architectural Association travelling studentship, were deservedly admired. Some of these we published some little time since.

THE letter of an American landlord (or rather house-proprietor) which has appeared in a daily contemporary would seem to show that the woes of the tenant are absolutely unknown "in an important city" across the Atlantic. The name of this clysmus is suppressed,—perhaps for fear of overcrowding,—but in it, we are assured, the tenant has discharged every obligation when he has paid his rent, while the landlord's responsibilities are almost incalculable. "I am obliged," he says, "to make all repairs, to keep the drains, hot and cold water pipes, furnaces, range,—in fact, everything in the house, in perfect order, and to do this at any time I may be called upon by the tenant. In fact, I am compelled to maintain everything connected with the house in first-rate condition." We presume the rents are high enough to cover this indefinite expenditure, and are punctually paid; otherwise the position of landlord must be one which only a philanthropist with a full purse would care to occupy. But, be this as it may, we certainly have here what, from a tenant's point of view, is a very enviable condition of things. The writer goes on to hint that legislation could and should bring it to pass in England

also. We have frequently said that a tenant who desires to improve the sanitary state of a house should have a legal right to call on the landlord to contribute to permanent improvements of this kind. But *quid leges sine moribus?* The best sanitary system may be, and often is, rendered useless by the culpable carelessness of the very people in whose interest it has been devised. Without general education on the one part and special knowledge on the other, the mere addition of new laws to the Statute Book will be quite unavailing.

THE Junior Carlton Club, Pall-mall, is about to be enlarged by the addition of the site of Adair House, at the corner of George-street, which adjoins the club on the west side. A new reading-room, with a handsome library on the first floor, and a billiard-room over, will be formed on the site of Adair House; the principal staircase will be reconstructed, the present smoking-room enlarged, a new strangers' smoking-room provided, and considerable improvements made on the ground-floor of the building. An open portico will be formed in the centre of the front next Pall Mall, and new bay windows thrown out in the east and west wings. The architect is Mr. J. Macvicar Anderson.

THE Metropolitan Board of Works are about to reconstruct Hammersmith Bridge, at a cost of 82,000*l.*, including the provision of a temporary bridge. The design of the present bridge is simple and appropriate, but the Board appear to be dissatisfied with it, and propose to convert the plain massive stone towers carrying the chains into Chinese pagodas modelled apparently upon those at Albert Bridge, Battersea.

THE completion of the Inner Circle Railway has proved for the present to be a curse rather than a blessing. The state of things on the lines converging from Hammersmith, Putney, and other out-districts, to Earl's-court Junction, is simply intolerable, the greater part of the journey being occupied in blocks, not only at the station, but at intermediate points. Business men who travel by the Underground Railway will not stand this for long, the companies may be assured; and they had better recognise at once the fact that in trying to crowd too much on their lines they have simply choked the traffic, and must reduce it at once to such a number of trains as can really be worked, unless they want people to take to cabs and omnibuses again, as the faster method of locomotion.

A PUBLIC meeting is announced to be held at Woolwich on Wednesday the 22nd, under the presidency of Lord Forbes, when resolutions will be proposed "condemning the disgraceful state of the Thames, and pointing out proper remedies." The railway companies and the Lower Thames watering places (Margate, Ramsgate, &c.) appear to be among the interests specially represented at the meeting.

WE have received from Mr. Stayton, the surveyor to the parish of Chelsea, a copy of his special report to the Chelsea Vestry on the system of electric lighting as in use at Colchester. He says,—"The area supplied is in the centre of the borough, and comprises Head-street, High-street, and Culver-street. The generating station is in a yard in the latter street, the engine for driving the two 40-hp brush dynamo-machines being of 25-h.p. nominal. I saw the machinery in full operation, and feel bound to add that there was no apparent cause of annoyance, and that similar stations might be established in any part of a town without creating inconvenience. The current is conveyed to six storage stations, five of which are ordinary cellars underneath street shops, and in which the necessary number of accumulators or secondary batteries are placed. The cables are carried underneath the footways in a brick trench, 9 in. by 7½ in., suitably arranged for drainage. The cables and service wires are all suitably insulated by lead coatings, and the service connexions to the houses are laid in wooden troughs under the

footways." Only about thirty premises are at present supplied with the light, and at present it is not and cannot be a commercial success, but "the practicability of house lighting has been successfully demonstrated."

THE Fulham District Board of Works have printed a copy of a letter addressed to the Home Office, in reference to a case in which they had been accused of unnecessarily prosecuting costermongers and others for creating obstruction in King-street, West Hammersmith, by the establishment of fifty to sixty barrows or trucks remaining stationary in the roads for many hours, the barrows forming a continuous line, and the sales carried on causing crowds in the streets and greatly impeding the vehicular traffic. We are only in possession of the Board's statement, but on that we should be disposed to support them in their crusade. In connexion with the subject we may advert to the nuisance which has been occasioned during the whole time of the Health Exhibition by the crowd of low hawkers standing in a row on the curb, from the corner of Cromwell-road onwards, and making the locality hideous with their discordant cries. We do not believe there is any large city in England, except London, where such a nuisance would be tolerated, or where visitors to an important exhibition would be obliged, as it were, to run the gauntlet of a set of howling vagabonds each trying to shout louder than the other the recommendation of his particular gimcracks.

#### THE KIND OF ARCHITECT WHO CANNOT GET ON.

His father was the vicar of a small country parish, and the church requiring restoring, he thought it a good opportunity to make terms with the eminent architect who conducted that nowadays thankless operation for the professional education of the subject of our sketch. The anxious father was moved thereto by several considerations. First of all, young hopeful had missed the scholarship which was to have smoothed the way to a University career and had disconcerted all the family plans thereby; and, secondly, the good Vicar was taken aback at the, to his thinking, ample remuneration which the fashionable architect received for a few slight drawings and a casual visit or two,—an amount which contrasted sharply with the very moderate stipend which rewarded his own ministrations. He was, moreover, dazzled by the long list of similar commissions which the professional gentleman had on hand, and upon which he expatiated with off-hand volubility. And so the preliminaries were discussed and settled, the premium paid (not without a pang), and the young man, duly articulated for three years, left his country home for the office of the great London architect, carrying with him the hopes and fears of his impoverished parents. He was not badly equipped for the profession selected for him. He had received a fair education at the local Grammar School. His breeding and his home life in an English parsonage had given him the manners and hearing of a gentleman, and his father's position might reasonably be counted upon for an introduction to the superior clergy and the county families.

His reception in the office of the master of the building arts was not quite what he expected. In the first place, his Principal was rarely seen. The important commissions he had on hand, and the still more important ones he had in view, kept that accomplished artist running about the country a good deal. His office business was conducted by one scantily remunerated, but trusty, clerk, of tried fidelity, skill and experience, and of untiring industry, assisted by a number of pupils, who did as little and absented themselves as much as possible. The new pupil was taught nothing. He picked up the simple but showy art of tracing, and he copied specifications. In response to the importunate clamours of sundry clerks of works, he adapted to new circumstances some stock details which had done similar duty on several occasions, and he compiled some wonderful specifications by a process of selection from a store of originals. In neither of these occupations did he take any real interest, nor did either of them afford any suitable opportunities for his advancement. The rationale of the art

he was supposed to be acquiring was never explained to him, and he knew but little at the end of his three years' apprenticeship that he did not know at its commencement. The excellent aids to study which the ingenious youth of the present day has at command did not then exist, and if they had existed our friend had not the energy to avail himself of them. When the day of his emancipation arrived, which his friends certainly thought would have brought with it a secure and honourable position in his employer's office, or a crop of cathedrals to restore, or churches and parsonages to build, they were surprised to learn that there was no longer room for him in the office. He was "pushed from his stool" by a newer crop of pupils, who were about to pass through the same course of "study." In this predicament he tried various devices. He failed to find an entrance to the offices of other architects. His friends with one accord recommended him to "set up for himself" to "start upon his own account." To their innocent minds this seemed like securing fortune by a sort of *coup-de-main*.

He took a dingy office in the Adelphi, very high and airy, and he added his name to the long list on the doorposts, garnished with his professional titles. And he soon discovered that "setting up" and "starting" were not quite the same thing. He did not "start," but "stagnate." It was very dull, sitting alone in that dingy apartment waiting for the clients who never came; and soon those little leaflets which grow on many an office-door began to show themselves, bearing dates which could not be reconciled with the confident statements as to the imminent return of the tenant. The young gentleman was meanwhile consorting with other young gentlemen similarly conditioned who railed on Lady Fortune in set terms, and could not for the life of them make out how it was that the Scotts, and Streets, and Waterhouses of the period got all the work. This state of things was brought to a sudden close. The youth returned to his ancestral home, whence he was driven by the death of his father, and the consequent disruption of his home. A compassionate friend found him office room and a pound a week,—as a temporary measure. This asylum failed him after a short time, and then his path in life led undeviatingly downwards. He had no qualifications for the battle of life. He was not even a draughtsman in any sense of the word, and could not subsist on that "charing" which has found for so many young men the bridge from clerkship to independent practice.

That "able assistance" which is so very easy to obtain,—vide advertisements,—was not his to give. Pen-and-ink perspectives of the effective sort he could in no wise prepare. The designs which he once undertook to furnish a deluded employer were returned to him with a scornful letter rougher than the sketches. Of all practical knowledge he was quite innocent. "Quantities" had always been so repugnant to him that he never fully understood the meaning of the word, and was certainly unacquainted with the operations involved in their preparation. He could not have written an intelligible specification to save his life, and to price or criticise a builder's account was not to be thought of. He could trace what was drawn for him and copy what was written, and these he could do but "indifferent well." There is but a limited demand for such arts as these, and the remuneration they command is but trifling. And thus it came to pass that he fell into disgrace and poverty, and kept out of the way of those friends whose patience and purses he had long since exhausted.

There are but few architects in town who have not recently suffered a call from one or another of the numerous specimens of this class. The type varies but little, and one portrait will serve for the whole. He has no card, but sends in a name; a very good one, of course. The office-boy delivers it with mysterious reserve, but cannot enter upon explanations in the hearing of the caller, who is close upon his heels. The embarrassment he manifests is variously interpreted by his master. It may mean another vicarious application for that is perturbed at the thought and at the impossibility of retreat. Offices are generally so badly planned. Or it may be a new client. Hope springs eternal in the human breast, and this delusive suggestion gains a decisive victory. The stranger is

admitted, and his whole story is read at a glance. It is an oft-told tale. His costume is mainly noticeable for new and ingenious adjustments. His bearing is either offensively servile or swagger of a familiar friend. Has Mr. Blank a vacancy in his office? Unfortunately, no. Things are flat. It is found by the visitor to be so in other quarters. Even the great Mr. Friba cannot offer him employment. Will Mr. Blank kindly look at a few drawings? At this juncture Mr. Blank suddenly recollects a very important engagement. But his retreat is out off, and before he can escape the dirty package is untied, and some dirtier drawings displayed. Poor things enough! Designs for a country school, or something of the kind, culminating in a pen-and-ink perspective ludicrously out of drawing, with inhuman figures more preposterously ill-drawn still. A short lecture is delivered thereon with the volubility of frequent repetition. It appears that they were submitted in competition; but "of course a local man got the job," &c.

The conversation, or rather monologue, takes a sudden turn in the direction of certain irregularities in the matter of daily meals: of the absence of breakfast on that particular morning,—on many previous mornings, and finally settles down upon the immense relief which would follow the temporary,—merely temporary,—advance of half a crown. Sometimes the appearance of the applicant is a sure indication of the real cause of his misfortunes. In the saddest cases ability is not wanting,—only the ability to keep away from the establishment at the corner. And there are cases where the failure to keep a footing in the crush and crowd of modern life is not culpable. As the American *Esop* wisely says in his modern version of the fable of the Tortoise and the Hare, "The race is not always to the slow." We have exact information as to at least one instance in which merit is but inadequately rewarded. Nevertheless a specialist can always get a living of some sort,—an artist will always find a market for art, a practical man can at least find employment as a clerk of works. If luxury cannot be attained, no one able and willing to work need despair of modest comfort. But woe to those who fail to qualify for some branch of the great profession which they adopt. As the world is more and more the individual certainly becomes less and less. He drops out of the crowd and is lost sight of. As the years go by the descent into Avernus becomes increasingly easy, and it is now more than ever necessary for those to hestir themselves who are ambitious even to keep their foot-hold; doubly so for those who would "get on."

#### WHO IS A WORKMAN?

It is noticeable that, though well nigh ten years have elapsed since the passing of the Employers and Workmen Act, 1875, there has been very little litigation on the meaning of the term "workman." This shows, at any rate, that the explanation of that word in this Act has been comprehensive and clear enough to prevent disputes from arising. It is perhaps more important therefore to take careful note of judicial views which help to explain or to affect this statute, and some recent decisions enable those interested in the subject to obtain further light on the meaning of the word in question. Section 10 of the Act of 1875 defines a workman as not a domestic or menial servant, but, with this exception, to include any person who, being a labourer, servant in husbandry, journeyman, artificer, handicraftsman, miner, or otherwise engaged in manual labour, whether under the age of twenty-one years or above that age, has entered into or works under a contract with an employer, whether the contract be made before or after the passing of this Act, be express or implied, oral or in writing, and be a contract of service or a contract to execute any work or labour." It will be remembered that this section has, in recent years, become of greater importance, because the Employers' Liability Act of 1880 defines a workman to mean "a railway servant and any other person to whom the Employers and Workmen Act, 1875, applies." Until quite recently, as we have said, there has been little judicial discussion of the clause in the Act of 1875, but quite at the end of last year the Queen's Bench Division decided that an omnibus conductor was not within the meaning of the section. In so

deciding they differed from the Court of Session in Scotland, who held in an earlier case exactly by the opposite. Where judges disagree it would not be for us to stop in. Nor is the question whether an omnibus conductor is within the statute of direct importance to readers of this journal. It is interesting and important, however, from the fact that it shows a judicial tendency to lessen the meaning of the words "engaged in manual labour," for, said Mr. Justice Smith, "the mere fact that a workman works with his hands is not enough to constitute him a workman within the section." A case, however, has just been reported (Jackson v. Hill & Co., Law Reports 12, Q. B. D., p. 618) which directly affects all enterprising manufacturers, and many others besides. A mechanic had been engaged by a firm "to assist as a practical working mechanic in developing ideas the firm wished to carry out, and in himself originating and carrying out ideas and inventions sui able to the business of the firm." This person worked by himself in a separate room, but disputes having arisen between him and his employers he was put to work in "the shop" as an ordinary practical mechanic. Very naturally this was resented, and the mechanic absented himself from the place, and was therefore summoned for unduly absenting himself from his work without lawful cause. The stipendiary magistrate held that he was a workman within the Act of 1875, and he thereupon appealed to the High Court. This tribunal considered that a person engaged as was this mechanic, not as an ordinary practical working mechanic, did not fall within the meaning of the words in the Act, and they reversed the decision of the magistrate. Yet, though the person was superior to the ordinary mechanic, it is clear that the gist of his employment was that he should, as a working mechanic, develop the ideas of those who were not skilled in manual labour, and certainly one would have called him a handicraftsman or a person engaged in manual labour. It may, perhaps, be said that this man was somewhat like a sculptor, who works with brains and hands; but it appears to us that whereas the sculptor is primarily a brain-worker, this man was primarily a hand-worker. We have said enough, however, to show the effect and the importance of this decision without further criticising a judicial opinion.

#### THE DUTIES AND QUALIFICATIONS OF TOWN SURVEYORS.

##### THE EXAMINATION QUESTION.

IN the course of the discussion which took place at the meeting of the Association of Municipal and Sanitary Engineers and Surveyors at the Health Exhibition, mentioned in another column,

Captain Douglas Galton said it was absolutely necessary that those who undertook the duties of surveyors of towns, or those of sanitary inspectors, should be qualified for their work. The Sanitary Institute, recognising this, had led the way in the matter by initiating examinations. A medical officer was not appointed unless he had obtained some diploma which certified that he was thoroughly competent; and, similarly, a diploma should be required from surveyors and sanitary inspectors before they undertook work which so eminently concerned the health of the community. He did not say that the Sanitary Institute was the best body for the purpose, but he did contend that some examination should be required, and a diploma obtained from one of the many colleges and universities which were now spread all over the country. But, on the other hand, having obtained an appointment under such conditions, it was equally necessary that some protection should be afforded the surveyor or inspector in his office, so that he should not be liable to be turned away after four or five years by the Board whom he was serving, without some power of appeal to a central authority, such as the Local Government Board. He hoped the hon. chairman (Sir Charles Dilke), as President of the Local Government Board, would consider these points.

Mr. E. Chadwick, C.B., advocated larger and more extended areas of local government, as calculated to secure the employment of better-qualified and more experienced officers, especially where towns had large and populous suburbs outside the borough boundaries. Qualified service was cheap service, and sanitary

officers should have their qualifications tested by the central authority. The economy to be sought by sanitation was a burden three times greater than the burden of the poor-rates, and the eradication of that burden by skill and responsibility was the greatest of all economies. There was no economy equal to the prevention of preventable sickness and mortality. They had proved that mortality was preventable by sanitation in towns where the death-rate had been reduced by one half or a third. He hoped his would be extended by legislation, in which to trusted the chairman would take an active part in the housing of the poor, and the removal of the slums.

Mr. Ellice-Clark expressed his opinion that a Minister of Health should be appointed, whose sole attention should be devoted to sanitary questions. Alluding to the observations of Captain Galton on the subject of examinations, although he would rather that the discussion should not take the form of a dispute between the Sanitary Institute of Great Britain and the Association of Municipal Engineers, he certainly thought its dignity had been somewhat compromised by the attitude taken up by the Institute in regard to the examination of surveyors. The Sanitary Institute had a field before it to enforce sanitary ideas, and he thought it might have left the examination of local surveyors to the Municipal Association. True, the Sanitary Institute was the first to think of the examination of local civil engineers, but it was within the experience of borough surveyors that assistants who had passed high examinations upon paper had proved altogether incompetent when put practically to the test. Then as to all local surveyors having a diploma. What kind of a diploma could they expect that man to have who was offered a salary of 120*l.* a year? Why, the idea sank into ridicule. The important borough of Northampton was actually advertising for a borough surveyor at a salary of 200*l.* a year! Two hundred pounds a year! Why, he was himself now carrying out a small work where the clerk of the works was in receipt of four and a half guineas per week. Again, reference had been made to some local authorities grudgingly allowing the wages of a boy to aid the surveyor; and he could hear this out, for when he was acting as the Borough Engineer at Derby, it was actually the subject of division whether an assistant should receive 12*s.* a week or 80*l.* a year! No doubt the existing staffs were in many cases inefficient. In all towns fees should be chargeable upon the owners for superintending the erection of new buildings, as was the case at West Ham. It was quite impossible, under present arrangements, for the local surveyor to see the foundations of a building were properly carried out; and although there was a great objection to the demanding of fees, yet he believed that was the only solution of the difficulty. Next he came to the question of protection, which was necessarily a delicate one. The spirit of the age was to extend local government, and if they were now to deprive the local authorities of the power to dismiss their officers, they would be curtailing, rather than extending, the functions of such authorities. At the present time, however, he said emphatically that it was perfectly impossible for the majority of local surveyors to do their duty in such a manner as the Local Government Board would approve were they acquainted with all the circumstances of the case. It often happened that those sitting on committees were interested in the subject under consideration. Although he had an exceptionally good Board, he could bring forward one little case which would prove this up to the hilt. Within a few years he had had to summon six builders for using bad mortar, when there absolutely went into the witness-box two members of the Board to say that the mortar was good! And one of these very gentlemen was sitting on the Works Committee when the prosecution was ordered; while both, six months later, had to sit in committee on the question of the increase of his salary. In the mortar case, several analyses had to be obtained before the magistrates could arrive at the conclusion that the "muck" of which he complained was not mortar! He suggested that such cases should be tried by some special tribunal instead of by the local magistrates, and in conclusion said he hoped Sir Charles Dilke, by giving his attention to the several points that had been raised, might be able to devise some means for practically aiding the local surveyors in more effectually carrying

out the duties which devolved upon them under the provisions of the Public Health Act.

Mr. Jones (Baling) spoke in favour of fees for proper inspection of new buildings being made universal and compulsory. This would enable a Local Board to employ an adequate staff of competent men to supervise the erection of buildings. He felt they were right in pressing this point upon the President of the Local Government Board. He also urged that there should be power given to compel the drains to be laid at the commencement of a building, and to prevent them being covered up until they had been properly inspected. He held, too, that when a surveyor had been articulated to a person of repute, had served his time, and had had practical experience, he held a position beyond what could be given by a certificate by the Sanitary Institute, without any disrespect to the latter body. As to protection to surveyors, he thought there was a great deal of truth in the remark of Mr. Robinson, that when a surveyor and his Board quarrelled, the sooner they parted the better. If an officer retained his position under the protection of the Local Government Board, he would not find his life a very bappy one.

Sir Charles Dilke said he thought this would be a convenient time for him to offer the few remarks which he proposed to address to them. In the first place, he was glad to have the opportunity of meeting a representative assembly of the surveyors throughout England, and of saying that in the discharge of the duties which had been thrown upon him, not only in his capacity of President of the Local Government Board, but also as the Chairman of the Royal Commission on the Housing of the Working Classes, he found that the greater sanitary evils still existing throughout the country, were not mainly in those departments which came under the control of the surveyors. He thought the exceptions which still existed to the enormous general improvement which has taken place in sanitary science and public health were attributable to sources which did not come very directly within the province of the surveyors. Generally speaking, he was disposed to think that an enormous advance had been made in regard to those matters with which the surveyors would have been most concerned. There could be no doubt that there had been a great diminution of mortality in the country; and although this diminution had been general, there was no doubt that England compared to advantage with other countries; and for this result there was no man to whom more credit was due than to Mr. Edwin Chadwick. The exceptions to the general advance which he had come across were to be found in rural districts, which were not within the control of any urban sanitary district,—localities lying within the jurisdiction of boards of guardians not possessing urban sanitary powers. In the metropolis, too, there were numerous sanitary evils still in existence. Not only was there a good deal of conflict of local authority, but there was constantly going on an enormous creation of population. Hence the state of things in London was no fair test of what exists in the country generally. The surveyor's work in the metropolis was different from the work of the local surveyors in the country; for in London the work which in boroughs was done by the local surveyors fell partly on the Metropolitan Board of Works and partly on the vestries. There were, in fact, no fewer than thirty-nine different authorities concerned in the metropolis; and he was bound to say, while he wished to avoid controversial topics, that he felt it would be impossible to get rid of the evils which still existed without some further concentration or unification of authority. As regarded rural districts, he thought they would still find, in some places, that people were drinking water drawn from small ponds into which the drainage of rows of cottages passed. He had found this to be the case at Marston-green, Birmingham, in Essex, in Surrey, and in the West of England. He had not, however, found this state of things to exist in urban sanitary districts, and he believed the instances were now exceedingly rare. There had been some great exceptions to the general improvement in the health of the country. There had been painful epidemics at Kidderminster and at Beverley, and an outbreak of typhoid and small-pox at Liverpool. He did not, however, think that any of these cases were traceable to causes within the control of the local surveyors. He thought they arose out

of other people's business than more directly theirs. The condition of the River Thames, of the River Lee, and of the Cam at Cambridge, were all questions which might occupy the attention of the surveyors of the country. He was inclined to greatly congratulate that body upon the work of the past, and he repeated that he had very little fault to find with those matters which came within their care. Passing from general considerations to details, he found there had been complaints that, upon Local Boards, there were persons interested against sanitary reforms; and that this element constituted an immense difficulty in the way of the surveyors, as also, of course, of the medical officers. This was no new charge. He had himself made it matter for comment in Parliament, and the charge was one which could be substantiated by an immense amount of information every day. Now, how could this be got over? It had been suggested that the Local Government Board should take steps to remedy the evil complained of. At present, when matters came under the notice of the Board, suggestions were at once forwarded by letter in small cases; and in other cases, where the public health was likely to be seriously affected, an inspector was sent down to hold a local inquiry. But, as regards doing the work or becoming responsible to the public for its performance, there were enormous difficulties in the way. He did not think any Government department could be made sufficiently large,—he did not think they could have a sufficiently enormous staff,—to perform the duties which would, in such case, be thrown upon it. At present, there existed power for the Local Government Board to declare an authority in default, and to step in and do the work; but this power had never yet been acted upon, and he did not think, unless in a case of very great emergency, where the public health might be jeopardised to a very great degree, it was ever likely to be acted upon. Next, he came to the question of the examination of local surveyors. This was a matter which had been brought very prominently before the Royal Commission of which he spoke just now. They had had examinations suggested, and they had on the Commission Mr. George Godwin, who had very strong opinions upon that point. He (Sir Charles) must not anticipate what the nature of the report of the Commission would be, but he might go so far as to say that he thought it probable some allusion would be made to the question of examinations, and that possibly some observations might also be made on the subject. Mr. Ellice-Clark, in the admirable remarks he made, had summed up very concisely the arguments upon what the Association called the question of protection. Nothing could have been better than the way in which he had stated the case. The reader of the first paper had referred to the case of Poor Law officers, and had shown that they already possessed that protection, which meant, supporting a man in his appointment against the wishes of the local authority who appointed him. If such were very generally the case, he (Sir Charles) thought the local authority would manage to make the position such that the official would find it impossible to hold it. Therefore he did not think that arrangement would be desirable, or that the Local Government Board should interfere, except, perhaps, in the case of a very near division and a close minority. Generally speaking, and judging from what he knew of the feeling throughout the country, he did not think, whether the Government in power was Liberal or Conservative, that anything like increased central control would be given to any department. He had, however, considered the expediency of there being some representative county authority which might be constituted a court of appeal from the smaller local authorities. In conclusion, he should like to allude to one or two other points upon which it might be desirable that legislation should take place. He had no doubt that the Royal Commission to which he had alluded would recommend legislation upon various matters, but he did not anticipate that they would recommend any violent or sweeping changes. The recommendations would more likely be in the direction of the enforcement of existing legislation than in the extension of it. Formerly Governments had more power for legislation than individual members; but now things were changed, and many Bills were opposed and stopped simply because they were

the measures of the Government. He therefore advised the Association not to look to interference from the Government on the matters which had been brought under consideration, but to see whether they could not get some private members to take up matters on their behalf.

Mr. W. H. White (Oxford) spoke of the difficulty of getting satisfactory by-laws adopted where the sanitary authority was distinct from the corporation, and where the latter owned a quantity of old property, crowded upon a small space, which could not be rebuilt in the same way if proper by-laws were in force. He suggested that, in such exceptional cases, the Local Government Board should not be so strict in insisting upon the adoption of their Model By-laws, but should approve of the best code that could be carried. He objected altogether to the suggestion of Professor Robinson, that the Local Government Board should act promptly on the complaint of individual ratepayers. There was far too much of this at present, and there was often a great deal of troublesome correspondence about trifles that could readily be explained. He expressed strong doubts as to the value of any certificate of examination, and said he had had several men in his office who had passed such examinations very satisfactorily, and he was not far wide of the mark when he said that the men who had come out the best in examinations were of the least use in the office. He should like to see the surveyor strengthened, as his position was frequently a most difficult one; but he held that the only true and permanent remedy was to educate the constables by whom local authorities were elected. Until they were sufficiently educated to elect men solely because they were well fitted to look after the public health, he feared they should not get efficient sanitary work done.

Mr. Lemon (Southampton) said the conflict between local and district surveyors must be got rid of, because the result was that the supervision over buildings was very inefficient. He suggested that the payment of fees should be to the local vestry direct, instead of to the district surveyor, and that from the fees the latter should be paid a salary, and men to exercise proper supervision should also be provided. He believed the principle of allowing Boards of Guardians to act as sanitary authorities was altogether unsound, as they practically neglected the business. If, as Mr. Chadwick had suggested, the sanitary areas were enlarged, many difficulties would be got rid of, and more efficient officers would in many instances be employed. He also condemned the practice of paying heavy compensation for old ruinous property, and endorsed the suggestion that the landlord should not be allowed to receive rent for property that was in an unsanitary condition.

Mr. Pritchard (Birmingham) said the consensus of opinion, both on the part of the readers of the papers and those who had joined in the discussion, was that local government was in some respects defective. He believed the questions of the qualifications and the protection of officers would be settled by increasing the area of districts, and the formation of county boards as had been shadowed forth. Having spoken of the satisfactory way in which the rural sanitary authorities of Solihull and Aston discharged their duties, Mr. Pritchard briefly referred to the epidemic of typhoid at Kidderminster, and to the "slums" which exist there, and concluded by again expressing his preference for enlarged sanitary areas and county boards.

Mr. Jerram (Walthamstow) and Mr. Gamble (Grantham) having spoken,

Mr. Fowler (Manchester) said the difficulty he felt with respect to examination was that experienced by practical old George Stephenson,—"Who is to examine me?" He sharply censured the practice of the "popular" members of local governing bodies, who, for the sake of apparent economy, sacrificed efficiency.

Mr. Angell and the readers of the other papers then replied, and the meeting closed with votes of thanks to Sir Charles Dilke for taking the chair, and to the gentlemen who had read papers.

**The Sanitary Congress at Dublin.**—The paper on House Drainage in connexion with town sewers was read by Mr. Geo. B. Nichols, of Birmingham, not "J. B. Nicholls."

#### SHALL PARIS HAVE HER SOUTH KENSINGTON MUSEUM?

This was the question which seemed to meet with something like a solution on Thursday, the 9th, at a banquet given by the "Union Céramique et Chaufoûnière" to M. Jules Ferry and to M. Antonin Proust, who is president of the "Union Centrale des Arts Décoratifs," to the members of the Jury of the Exhibition at present open at the Palais des Champs-Élysées, and to the press. But we may as well touch on the day's history,—the conference before the banquet.

At two on the same day, then, M. Bandot, member of the Commission des Monuments Historiques and Inspecteur-Général des Édifices Diocésains, delivered, in one of the halls of the Exhibition (the one decorated with the Gobelins tapestries) a lecture "On the Employment of Polychromatic Materials in Construction, and on Ceramic Work in general." M. Bandot has employed ceramic work largely in the new Lycée now rising in the outskirts of Paris, of which he is the architect; and as the completing architect for the restoration of the Château de Blois, commenced by the late M. Duban (see *Builder*, June 28th, p. 342), and the favourite pupil of Viollet-le-Duc, to whom he owes his official position, M. Bandot has every qualification for speaking with authority on so important a subject. He addressed a numerous audience, where by the side of Government architects and members of the "Société Centrale" were crowded the manufacturers of the "Union Céramique" and members of the Académie des Beaux-Arts, including M.M. Ballu and Garnier, architects, M. Guillaume, sculptor, M. Lauth, director of the manufactory at Sèvres, M. Lameire, the brilliant decorative painter, M. Didron, artist in stained glass, and others. The paper, of three-quarters of an hour long, read by M. Bandot, did not, however, speak very well of the progress of ceramic art in France. Certain veiled sarcasms against his professional brethren who employed too much stone in their buildings or who did not make sufficient effort to harmonise the various materials they used; certain not very definite bits of advice to those more sober and serious minded ones who looked for the decoration of the buildings to ceramic art alone; a very warm eulogium of the Union Céramique et Chaufoûnière, from the point of view at once of industrial and social, we might almost add of national, advancement,—such are the main points of the address which remain in our memory. Two special recommendations may, however, be mentioned: one was, the necessity of raising a *tarif* on foreign ceramics imported into France, in order to provide a better market for French work (a very questionable principle, M. Bandot); and the second was a special eulogy of Viollet-le-Duc, to whom was due a considerable portion at least of whatever progress had been made in ceramic art in France, through his researches and practical experimenting in the judicious employment of these materials.

M. Bandot also put a question in regard to his eminent master, to which we feel moved to suggest an answer. How was it, he asked,—though it was true that no one is a prophet in his own country,—how was it that the work of Viollet-le-Duc was so much more appreciated in foreign countries than in his own? Without calling to mind here how, by the side of his admirable work of restoration, Viollet-le-Duc has too often crowded against the magnificent cathedrals of France little parasitic modern-thirteenth-century edifices which harmonise ill with the old work, one may find an easy answer to the question. For two centuries, as Mr. W. H. White has well shown in his interesting work on "Architecture and Public Buildings," France has possessed a vast network of institutions, inwoven one with another, under the comprehensive title of "Académie d'Architecture," or "Académie des Beaux-Arts," "École des Beaux-Arts," "Académie de France à Rome," "Conseil-Général des Bâtiments Civils," and "Inspections Générales" of all branches of architecture; and they have maintained as a special and fundamental law of being, that all, or nearly all, official architects should have a competent knowledge of the art of Greece and Rome, and even of Egypt; while in other countries, in England especially, architectural education has been exceedingly unskilled, and hence the tendency to regard Mediæval architecture, much more than

in France, as the specially national architecture; and this tendency has given a special value to the works of Viollet-le-Duc, in which he laid down, with the authority derived from thorough knowledge, the principles, the elements, and the manner of development of the "architecture ogivale" and the arts which cluster round it, as well as the varied resources which it offers to the artist.

Some hours afterwards, many of those who had listened with interest and applause to this lecture, found themselves at the aforesaid banquet, and drawn together by a subject of great interest, for the "Union Céramique et Chaufoûnière" was really a pretext for putting the great question,—the vital question for French art-industry; the presence of the President of the Council (M. Ferry) furnishing an opportunity for asking once more for the institution of a "Musée des Arts Décoratifs" on a large scale, as the centre for instruction in the industrial arts. M. Proust, the spirited president of the Union Centrale, has pursued this object perseveringly for several years, and on this occasion terminated his speech by demanding, amid the applause of the company, the use of the ancient Palais du Conseil d'État for exhibitions, partly permanent, partly annual, of decorative art.

We believe that M. Ferry, though his official responsibility did not allow him to accede to such a request on the instant or in a formal manner, has promised more or less officially to the Senior Minister of Arts, who is appointed Commissary-General for the Exhibition of 1889, to give fair play to the proposition, and that having remarked that "we must re-establish the system of apprenticeship, that admirable institution of our forefathers," he was understood to say that he would do all in his power to facilitate the creation of a museum where the production of future masters in the industrial arts would be preserved. It is to be hoped the movement may prosper, for all French or foreigners, will be the gainers by such an enterprise; but the palace on the Quai d'Orsay, enclosed by streets which limit it in every direction, could hardly become other than a museum for the fashionable quarter, and seem ill adapted for the installation of a great school of industrial arts, decorative and other. But it is, at all events, a question to which it will be of interest to return at some other time.

#### THE ASSOCIATION OF MUNICIPAL AND SANITARY ENGINEERS AND SURVEYORS.

On Thursday, October 9th, a special meeting of the members of the Home Counties District of the Association of Municipal and Sanitary Engineers and Surveyors was held in the Jury Room at the Health Exhibition. There was a large attendance. Mr. H. G. Lawes (Newcastle-on-Tyne), president of the Association, occupied the chair in the early stage of the proceedings, but subsequently resigned the position to Sir Charles Dilke, M.P. Among those present were Capt. Douglas Galton and Mr. Edwin Chadwick, C.B.

The business having been commenced by the Secretary (Mr. Thomas Cole) reading the minutes of the last meeting, which was held at Ealing.

Mr. O. Claude Rohson (Kilburn) was, on the motion of Mr. C. Jones (Ealing), seconded by Mr. Hall (Torquay), unanimously chosen District Secretary for the ensuing year.

Mr. Lewis Angell first read a paper explaining the origin, the constitution, and the objects of the Association. Mr. Angell urged strongly that the erection of new houses should be strictly supervised by a staff of special officers, who should be remunerated by fees paid by the builders for the necessary supervision. Such powers had been obtained by Eastbourne and West Ham by private Acts of Parliament, but he argued they should be extended by a Government measure to the whole of the Kingdom. The reason why the erection of new houses was not efficiently supervised was that the local surveyor had so many diverse duties, and was not provided with an adequate staff. He also referred to the want of building by-laws outside of the metropolis, and said that, even where adopted, they were frequently not properly enforced. The laying of drains should be made one of the first things done; and the law relating to the dedicating of private streets to the public, a subject bristling both with practical

and financial difficulties, needed considerable amendment. After pointing out other defects in the existing Public Health Act and the by-laws framed under it, Mr. Angell referred to the obstruction offered to sanitary improvements by interested members of local authorities,—men who had secured their return to promote their own personal interests and protect jerry builders and small property owners from their natural enemy, the local surveyor. It was impossible to speak out on this subject, because surveyors had not the protection which the Local Government Board extended to workhouse officials. He urged that such protection was not only needed, but was desirable, and that the status and functions were quite as good and as important as those of a poor-rate collector, over whom the Government spread its protecting wings. Passing to the qualification of sanitary officers, Mr. Angell said:—

"It must be admitted that the charge of inefficiency has had some force with regard to some of the smaller towns, and even to larger towns which make small appointments. Sometimes these positions have been given as a reward for local party services, or out of charity,—to a local builder, for instance, a 'practical man,' who had failed in his jerry speculations. There is on record the case of the appointment as surveyor, by his fellow townsmen, of a bankrupt linen-draper, 'because he had been used to measuring.' But such things, if not very remote, are becoming things of the past. The greatest difficulty is in small places, and with boards of small members, the remedy would appear to be in county government. The action of recent public opinion has resulted in the demand for and offer of better inducements to sanitary engineers and surveyors of professional standing and experience. Among our number are many members of the Institution of Civil Engineers, and of the Royal Institute of British Architects, and I think it may now be safely asserted that every important centre of population has the services of a fully-competent sanitary surveyor, although he may be hampered in his work in the ways I have previously indicated.

A society, junior to our own, is seeking to impose on local surveyors an examination of competence, of which they, the Sanitary Institute of Great Britain, shall be the judge and dispenser of certificates. I think the members of our Association would, in their own interest, generally assent to the principle of examination. We would even extend the principle further, and apply it to the members of local authorities. In a profession like ours, practical experience is of far more value than the cram and book-work which may qualify for a certificate, but not for the responsibility of office. But, admitting the examination who are to be the examiners—a newly-constituted society of persons having themselves no guarantee of qualification, or some of the older chartered professional bodies which have our confidence? Our own Association is senior to the Sanitary Institute, and composed exclusively of, so to say, picked men,—that is, sanitary engineers and surveyors by profession, each selected from a large number of other candidates to fill a public office, without which qualification no one is eligible as a member of our Association. If it be objected that we should not give confidence by examining ourselves, then we have the Institution of Civil Engineers and the Royal Institute of British Architects, having charters half a century old. The latter body, of which I have the honour of being one of the Board of Examiners, is charged by Parliament with the duty of conducting examinations for the office of District Surveyor under the Metropolitan Building Act, and the Institute has extended the examination to the office of local surveyor. The diploma of the Royal Institute of British Architects would certainly carry greater prestige than that of a newly-formed non-professional society. There are also the Universities, or the Civil Service Commissioners, or a joint examining board might be formed of some of these bodies. We have no antagonism to the general objects of the Sanitary Institute, of which body, indeed, I am a Fellow; we wish the Society every success in educating the public in promoting sanitary progress, but, as professional engineers, we decline to admit the claims of a new dilettanti society to examine us."

Professor Henry Robinson, M. Inst. C.E., followed with a paper on "Sanitary Legislation and its Enforcement." He said,—The Public Health Act of 1875, and the Metropolitan Local Management Act of 1855 (the latter Act constituting the Vestries the sanitary authorities for the metropolis), contain provisions for the protection of the public from avoidable sanitary dangers, which if vigorously put in force would remove many evils which call for drastic treatment. If these Acts were framed now, they would doubtless be drawn with less of the optional or permissive and more of the compulsory element than is found in them. At the time, however, when they were passed, public opinion was not nearly so alive as it is now to the consequences attending sanitary neglect. It is a fact that in many respects

even the existing mild legislation is not put into operation. This arises from two causes, one being the ignorance or indifference of the sanitary authority to carry out the powers confided in them, and the other being the legal difficulty and expense which an individual ratepayer has to meet in order to compel his sanitary authority to exercise their powers when they had failed to do so. Take one point which is of very common experience. The sanitary authority is either apathetic or obstinate as to remedying a condition of things which is injurious to health. The evil and the remedy are both obvious. The Acts prescribe that the course of action is by representations to the officers of the authority. But these officers may be the offenders themselves, either by neglecting to take the matter in hand, or by being unable to obtain from their authority the necessary permission to rectify it. This neglect or want of appreciation of the evil by the authority is of constant occurrence, and is due to the fact that a very large number of those who compose the corporations, local boards, and vestries are deficient in zeal for the public good, as regards health, and in many instances have vested interests directly antagonistic to any action being taken.\* Where the desire to suppress inquiry exists it is difficult for it to be brought about. The officers are all appointed by the board. A too zealous official soon gets removed. The remedy, we think, is for the Local Government Board to take prompt action on the memorial of an ratepayer, and to take the necessary steps to immediately remedy the evils complained of. Further, the sanitary inspectors and similar officials should not be wholly dependent on the sanitary authority. It is also very necessary for all officers of health to be subjected to an examination in test of their fitness for the duties they seek to discharge. In my experience most unfit and incompetent persons are appointed by local authorities to administer the Public Health Act. Having acted for some time as one of the Examiners of the Sanitary Institute of Great Britain in granting diplomas for surveyors and inspectors of nuisances, I have had opportunities of testing the fitness of many men holding important positions of this kind. A great amount of preventable mortality arises from houses being occupied which do not conform to the most elementary rules of house sanitation. A fruitful source of mischief arises from defective drains, water-fittings, and plumbers' work, which being hidden from sight is often performed by unskilful or dishonest men. This class of work requires the most stringent regulations to ensure its proper execution. We would require every man engaged in it to be certificated and registered, as we are confident that without such a system to protect the public, the existing bad work and consequent mischief will continue. We might advantageously copy the example which has been set us by the City of New York. In the year 1881 an Act was passed to secure the registration of plumbers and the supervision of plumbing and drainage in the cities of New York and Brooklyn. This Act was the outcome of a public movement which was set on foot by those who appreciated the evils we have referred to. Amongst the most prominent of these reformers, and the one to whom the passing of the Act is chiefly due, was Mr. Henry C. Meyer, the proprietor of the *New York Sanitary Engineer*. It should be mentioned that in the Health Exhibition there is an exhibit of Mr. Meyer for the purpose of showing to the British public how the State of New York has dealt with some of the sanitary evils with which we are grappling.

Mr. H. Percy Boulnois, M. Inst. C.E., Borough Engineer of Portsmouth, read a paper showing "The Effect of Municipal Government upon Sanitation." The water-supply, he held, should always be in the hands of the local authority; but often this was not the case, from the fear of interfering with vested interests, or the first

\* One of the latest illustrations of this fact is reported in the *Pall Mall Gazette* of Wednesday last. A member of one of the Metropolitan local vestries or district Boards of Works is the owner of some property which, on the showing of the sanitary officer, is in so insanitary a condition that there is "eighteen inches of sewage in the kitchen." The Sanitary Committee have the courage to act upon their own responsibility when the matter is brought before them by the officer during the vacation, and, as the owner of the property refuses to put it into proper condition, they order the work to be done. When the report of the Committee comes up before the Board, there is, apparently, one of those scintillating and recriminatory "scenes" which have done so much to bring small local authorities into contempt, and, in the end, the Board adjourns without having adopted its Committee's report.—En.

cost of acquisition. In some instances there was worse neglect, by permitting an insufficient or impure supply of water to be used, instead of providing a pure and sufficient supply. The sewerage of a district, which must of necessity be in the hands of the local authority, was second only in importance to the water supply. Permissive legislation led frequently to nobbling being done, and the difficulties connected with the removal and disposal of sewage were made the excuse for inactivity. The supervision of house-drains was generally inadequate and a mere form, and it would require a far larger staff of officials to attend to it properly than a local authority is at all likely to supply. With respect to defective house-drainage, some easier and less cumbersome mode of procedure than than afforded by section 41 of the Public Health Act is required, to secure a prompt remedy. The delay entailed rendered action almost useless in such cases, and a few authorities had been obliged to obtain private Acts. Scavenging was also a most important duty. The duty was often greatly neglected, and the practice of storing large heaps of house refuse, to effect a sale of some portion, and thus bring in a small revenue, was much to be deprecated. Some improvement was needed where new streets are required, as great cost for compensation has frequently to be incurred. Mistakes as to soil and position were often made in the selection of cemeteries, and as population increases, cremation will doubtless have to be substituted for the present system of burial. He also strongly urged that all public works should be of the best and most substantial kind, but frequently a false economy resulted in the lowest tender being accepted.

The discussion which took place upon these papers, including an important speech by Sir Charles Dike, will be found in a special report on another page of this week's *Builder*.

Additional papers were read by Mr. Robert Godfrey on "The Removal of House Refuse," by Mr. S. C. Trapp on "The Destruction of Excreta," &c., and by Mr. George Winship on "Some Advantages and Results of the Supply of Water by Meter in Domestic Consumption." To these we may return.

#### THE ALBO-CARBON LIGHT.

AMONGST the numerous claims for the best illuminating medium, whether gas or the electric light, we venture to think that the albo-carbon light will "hold its own" in either case. The recent successful application of this system at the new Brompton Oratory has demonstrated its capability to bring out clearly the architectural features of our churches and chapels, and those who will take the trouble to visit the Oratory at night cannot but be much impressed with the effective appearance of that vast building, due to the brilliant, yet subdued light thrown over its area. The fathers of the Oratory are not only satisfied with the effect produced at night upon their gorgeous ritual by the albo-carbon light, but really seem to think there is almost more light than absolutely necessary,—a good fault, seeing that there are only eight twelve-light, two six, and two four-light clusters in the whole building, lofty as are its proportions.

On the ground of comparative economy, as against the ordinary system of gas-lighting, some interesting experiments have recently been made,—in the one case with a single light by Professor Keat, and in the other by Mr. F. W. Hartley (the gas engineer), with a cluster-light burner. With a single light it was found that by a consumption of 5 cubic feet of gas per hour, an illuminating power was produced of 307 candles, whilst one eight-light cluster, burning 307 cubic feet of gas, gave an illuminating power of 2715 candles. These figures speak for themselves, but in addition to the greatly enriched power of the flame produced is the fact that with the increase of light there is a very considerable diminution of heat, which is a most important feature, and indeed, is one of the chief recommendations of this very beautiful system of lighting.

**The Dairy Show.**—At the ninth annual show of the British Dairy Farmers' Association, held at the Agricultural Hall, London, the first premium and silver medal have been awarded to Messrs. Clark & Moscrop, architects, Darlington, for the best plan arrangements for model dairy farm-steadings. There were fourteen sets of drawings.

Illustrations.

THE NICHOLSON INSTITUTE, LEEK.

THIS Institution, which was opened this week with much ceremony, and of which we give a view as well as the two principal plans to a small scale, occupies a very central site in Stockwell-street, facing south to Market-street, whence an imposing and effective view of the grand entrance, with its lofty domed tower, is obtained. This view is diversified by one of the ancient houses of Leek, stone-built and ivy-clad, "with many blinking windows, row on row," which, by the removal of a neighbouring modern building, it has fortunately been found practicable to preserve. With its quaint garden of sunflowers and bollyhocks it imparts a charming old-world flavour to the whole scene, and contrihutes very largely to the success of the *tout ensemble*.

The style of the new buildings is a somewhat severe form of Classic Renaissance, and the materials used are thin, hard-fired local bricks with hack joints, dressings of red Roche and mottled Alton stone, and Broseley tiled roofs. All the windows are glazed with faintly-tinted antique glass in lead quarries.

The leading feature of the front is the tower, which rises to a height of about 100 ft. from the street. This has the spacious principal entrance doorcase at its base, supporting in the same composition the great staircase window with pedimented crown with carved urns; and large elliptical lights in each face of the upper stage. The domed roof and lantern are covered with sheet copper, which in a few years will, no doubt, assume the green *paten* which strikes one so often sees on such features in the old Dutch and other Continental towns.

The façade between the gable and the tower has a stone balustrading with urns, and contains a large window lighting the hall. The fanlights contain the effigies of four eminent men, representing the four last centuries, carved in high relief in stone from models by Mr. Stephen Wehh, which are hung in the building. Tennyson stands for Literature and the nineteenth century; Sir Joshua Reynolds for Art, and the eighteenth; Sir Isaac Newton for Science, and the seventeenth; while Shakspeare for the sixteenth century may be said to reflect *Humanity in toto*. Above these "animated busts" a carved scroll supported by griffins carries these words of John Milton's "Areopagitica":—"A good hook is the precious life-blood of a master spirit, embalm'd and treasur'd up on purpose to a life beyond a life."

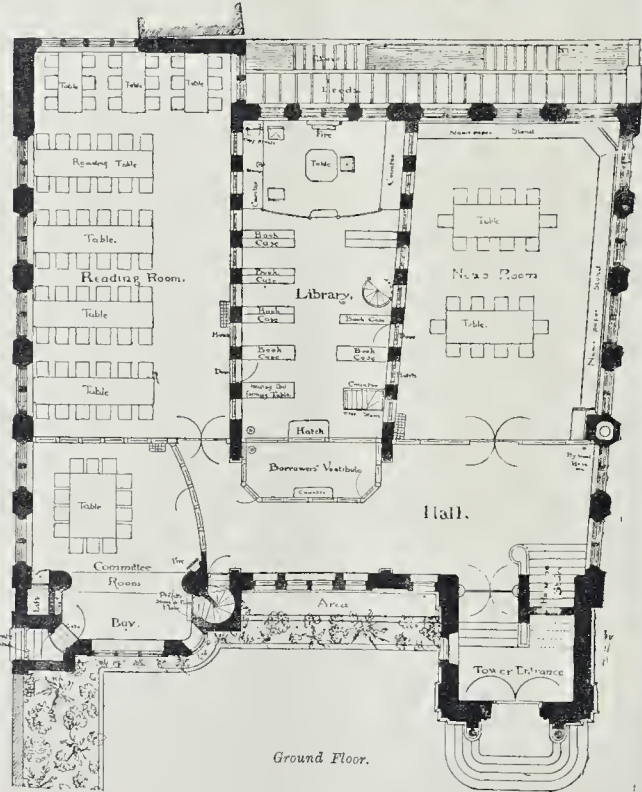

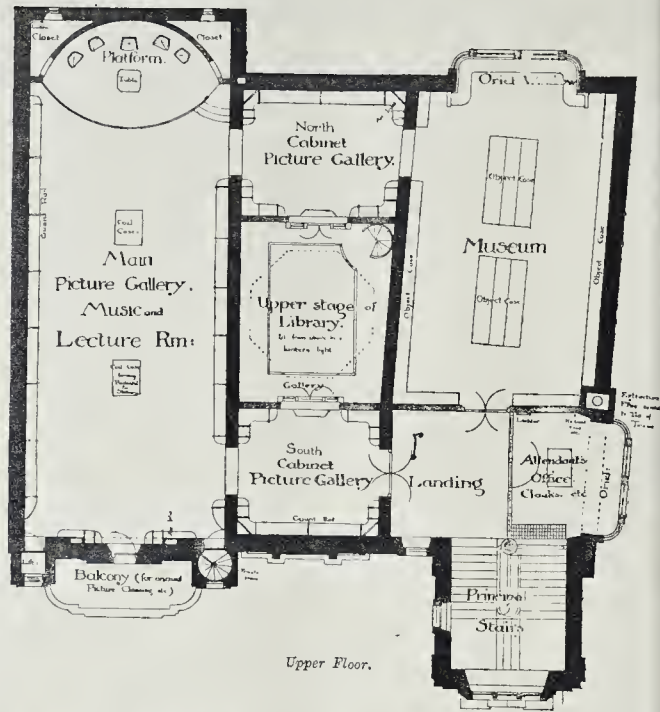

Internally the building consists of three floors, the central one elevated some 9 ft. above the street. On this floor the various reading-rooms, &c., are located; the floor beneath it contains the School of Art, &c., and that above the museum, picture galleries, &c.

The first floor is lighted by clearstories, or vertical lights on each side, with a solid ceiling intervening between them: the effect of which is certainly comfort and substantiality,—to be infinitely preferred to the flat glass shed roofs now so largely adopted in picture galleries. The height of the large rooms is 33 ft., and this enables the glazing to be kept high enough from the floor to prevent any possibility of "glitter" from refracted light upon the pictures. The gas-lighting, which is by continuous jets, is similarly arranged; and in such a way that it lights the gallery by night at about the same angle as the day-light enters.

Every precaution has been taken against fire. The floors throughout are of iron and concrete, paved solidly with thick wooden blocks, laid parquet-wise in hitumen; and on each floor are hydrants with leather buckets and branch pipes and hose, slung on rings and chains, ready for immediate connexion.

The ventilation has had special attention. Fresh air supplies abound; and the over-heated and vitiated air is drawn off from each room at a high level, and conducted by shafts to a large flue in which the air is artificially rarefied. This flue discharges from the louvred lantern at the top of the tower. The warming throughout is by the low-pressure system of hot water, by which a constant and genial heat is secured, and the deterioration of the atmosphere attendant on so many other methods is avoided.

The School of Art comprises an elementary school, 25 ft. by 37 ft.; an advanced room, 20 ft. by 32 ft.; and an antique and life room, 25 ft. by 25 ft., with bead-master's office and

stores, entrance vestibule, male and female cloak-rooms and lavatories, &c. These rooms have been very tastefully and completely furnished by the committee of the Leek School of Art, and are well appointed in valuable casts and copies from South Kensington, &c. The head-master is Mr. Joseph A. Kean, late head-master of the York School of Art. Sloping north lights are secured in the principal rooms, and at night ventilating sun-lights are used.

The whole of the works, including all details of decoration and furniture, have been carried out to the designs and under the superintendence of Messrs. William Sugden & Son, architects, Leek.

The following firms have been engaged upon the various branches of the work, viz.:—The builders, Messrs. H. & R. Inskip, Longton, whose assiduous foreman, Mr. Johnson, has very satisfactorily superintended the progress of the structure; Mr. Edwin Phillips, Leek, for the plumbing, painting, &c., and the duresco decorations of the interior; the heating, &c., by Messrs. Haden & Sons, Trowbridge; Mr. Roger Lowe, Farnworth, the iron and concrete and wood block flooring and waterproof concrete flats; the Gateshead Stained Glass Company the lead-quarry glazing; Messrs. Minton, Hollins, & Co., Stoke-on-Trent, the tile floors; Messrs. Balfour & Co., Longton, the perforated tiles in coil cases; Mr. Millson, Manchester, the wood and stone carving and the sculptured medallions (the latter from models by Mr. Stephen Webb); Mr. Robert Hird, Shipley, the iron staging and spiral stairs of library,—the gun-metal patent casements and the guard rails in galleries; and Mr. Woodhead, Leek, other castings; Messrs. Elgood Bros., Leicester, the wrought-iron entrance-gates, and all the bronze door-handles and metal fittings throughout, except such as were provided by Messrs. D. Cartwright & Son, Leek; Messrs. T. Brawn & Co., Birmingham, the wrought-iron and other gas-fittings; Messrs. Young & Glover, Wolverhampton, the locks, &c.; Messrs. W. Tonks & Son, Birmingham, the patent hook-shelf fittings; Messrs. Brady, Liverpool, the copper covering of tower dome; Mr. Black-horn, Nottingham, the lightning conductor; Mr. Hindshaw, Manchester, plaster modelling; and Mr. John Shaw, Bowdon, the planting of quadrangle and approach. The furniture of the Institute was supplied by Messrs. Inskip, Longton; Messrs. Kendall, Milne, & Co., Manchester; Mr. A. Overfield, Leek; and Messrs. Eckstein, Birmingham; that of the School of Art by Messrs. Mackrell, Nixons, & P. Tomkinson, builders, of Leek.

The whole outlay in connexion with the undertaking has been generously borne by Mr. Joshua Nicholson, a silk manufacturer, of Leek, and a citizen for many years prominent in every local or general movement for the popular good.

DESIGN FOR ADMIRALTY AND WAR OFFICES.

BY MESSRS. MAXWELL AND TUKE.

We give this week the Whitehall front and, as in other cases, the two principal plans, of Messrs. Maxwell & Tuke's design as submitted in the second competition. Of the plan we have already observed that it is in some respects one of the best, if the normal objection to a not very wide closed quadrangle be put on one side; the rooms are well grouped in reference to their respective uses, and the traffic lines of the plan reduced to the greatest simplicity. There is, however, the defect which it shares with some others of the plans which are otherwise praiseworthy, viz., the employment of long and narrow rooms with one not over large window at the end. At some times of the year in London such an arrangement would practically render one half of the room useless for work except by artificial light. The design we cannot care for much: the spirit of Manchester seems very predominant in it, and this is the more emphasised by comparison with the Horse Guards building, to which the new building claims to accommodate itself in any way. The following extracts from the architects' Report may assist in rendering clear their intentions:—

"We desire to call attention to the disposition of the central quadrangle with its three surrounding glass-covered courts, its open court near to the Horse Guards, and the four spacious courts lighting the secretaries' messengers' rooms and cross corridors.

The quadrangle is 280 ft. long and 113 ft. wide, and hountfully lighted most important

offices on three sides and a corridor on the fourth side, and by means of areas 15 ft. wide it renders the basement offices on both sides as valuable as if on the ground level.

The chief approach to the quadrangle is by three broad archways from Whitehall; the central one being for carriages and the sides for pedestrians. The total width of this entrance is 43 ft.

The second entrance to the quadrangle is from Spring-gardens after passing through the Admiralty Court. The width of the carriage entrance in Spring-gardens is 3 ft. wider than the central entrance to the quadrangle of the new Government Offices in Charles-street.

It will be observed that five principal entrances to the Admiralty and War Offices open into the quadrangle, that under the loggia to the west being the principal entrance for the chief of the staff on the War Office side as well as for the Lords of the Admiralty. The two entrances on each side of the quadrangle give direct access to important sections of the War Office and Admiralty.

The glass-covered court upon the Admiralty side is in reality a spacious hall, 90 ft. by 60 ft., in addition to the arcade on two sides on the ground-floor, and the surrounding corridors on the upper floors. There are four entrances to the Admiralty from this court, leading at once to the feet of the four principal staircases, and it will be observed that no office of any importance opens directly into the open court, but that all the office doors open from the corridors.

It will be seen that this system of lighting gives splendid results, not only to the corridors, but also to the adjacent offices, which will thus be as well lighted at the rear as on the window side.

The two covered courts to the War Office are intended really to be entrance-halls, and, there being no carriage-way traversing them, will be much warmer than the Admiralty court. For this reason we have not thought it necessary to isolate the offices on the ground-floor by means of corridors.

The court near the Horse Guards is open down to the basement-floor, and forms here a sort of horse-yard for the dwellings surrounding it. There are cloisters on two sides, and an approach out of the Horse Guards Parade.

It will be seen that, with the exception of the messengers' lobbies, not a single office obtains its light from the covered courts. These are devoted solely to the illumination of the corridors, messengers' lobbies, waiting-rooms, committee-rooms, libraries, lavatories, and stairs.

The eastern end of the great quadrangle is devoted, on the upper floors, to the lighting of the corridors, but with this exception the whole of the quadrangle, Whitehall, St. James's Park, Horse Guards, and Spring-gardens fronts are devoted to offices, and no portion of these valuable frontages is wasted upon water-closets, staircases, or other secondary purposes.

Whilst referring to this portion of the site we had better explain the leading idea dictating our arrangement of the pavilions flanking the Horse Guards Parade:—We observe in the block plan applied to us certain dotted red lines indicating proposed new buildings on the south side of the Horse Guards Parade arranged in such a way as to form a noble square, of which the old Horse Guards would be the centre. In designing the Park and Parade fronts we have, therefore, assumed that the features of our design, if successful, would be repeated on the opposite side of the square, and this consideration has determined the position and design of the massive sentinel-like pavilion at the south-west, or Secretary of State corner, as well as the two slighter pavilions commanding the Horse Guards, which will form so conspicuous a feature in driving up Whitehall.

The style of architecture appears to have been dictated to us by the existing new buildings in the immediate locality, as also by Messrs. Inigo Jones's beautiful hotel in Whitehall.\* (!!) It appears to us that any building not in perfect accord with these examples would destroy the unity of the grouping which we have studied to maintain."

TOMB OF LORD TREASURER BURGHLEY, IN ST. MARTIN'S CHURCH, STAMFORD.

The tomb stands on the north side of the chancel, and is a fine specimen of late sixteenth-century work. The recumbent figure of the Lord Treasurer is in alabaster, and represents him in rich armour, and bareheaded; decorated with the insignia of the Garter, and holding the wand of office.

The different marbles in now faded colouring combine to enhance the effect of the whole. The drawing, which was in the last Academy exhibition, is by Mr. G. C. Horsley.

SKETCHES BY A DISTRICT SURVEYOR.

I.

Vitré.—The strangest and most bizarre of all the old streets are the Rue Poterie and the Rue Bondreiric. A confused mass of projecting wooden houses with penthouse roofs covered with thick slates, the ground floor being occupied by porches with a sort of square pillars supporting superstructures and forming covered galleries, into which open miserable shops. In some cases the buildings are ornamented by statuesque sculpture.

Dol.—This and some other sketches which will appear are intended to assist the register of quaint buildings in this old town, which are from time to time being swept away under pretext of embellishment.

In the chief street are many old bones which preserve its Mediaeval physiognomy the moulded woodwork of which, and variety of columnar design, will repay the trouble of noting. The example chosen has some such columns which support the superstructure, and form a public covered way.

Dinan.—The old house at Dinan, by the side of the river, was, in its day, probably of some importance, and its moulded woodwork, so characteristic of Brittany, may be studied with advantage. In the interior of the town are many streets which have conserved their original features, and on several of the buildings are figures of saints, mythological and grotesque subjects.

St. Malo.—The sketch of part of old house at St. Malo was made to exhibit the abominable arrangements of the place for disposing of house-

refuse of every kind. Outside the window of each story (the house being let out in tenements) is fixed a receiver, siphoned after a fashion, and connected with a vertical stack of badly-jointed earthenware pipes.

#### THE ARCHITECTURAL ASSOCIATION CONVERSAZIONE.

The opening conversation of the Architectural Association was held on Friday, the 10th inst., in the Galleries of the Royal Institute of Painters in Water Colours, Piccadilly. There was a large attendance of members and their friends, but the crush was not so great as on the last occasion, for, as Mr. Cole Adams, the President, explained at the outset of his address, the Committee had, owing to the growth of the Association (which now numbers 395 members), been compelled to limit the number of invitations sent out to other than members of the Association. There was, as usual, a good display of drawings in illustration of the work done in the classes in competition for the various prizes; and there were numerous exhibits of "art-furniture," upholstery, decoration, paperhangings, &c. Mr. Alfred Newman had on exhibition some good modern ironwork, as well as an interesting collection of old Flemish and German specimens.

The greater number of the company having taken their seats in the Prince's Hall (which was very draughty and chilly, by the way), the President, Mr. Cole A. Adams, proceeded to distribute the prizes. The following is the Prize List:—

**A. A. Travelling Studentship.**—Studentship and Medal taken by Mr. G. J. Oakeshott. Second prize, value £12, taken by Mr. G. G. Woodward. Honourable Mention made of Messrs. W. H. Bidlake, G. G. Wallace, and E. H. Selby.

**Association Medal.**—Taken by Mr. Arthur Sykes. **Class of Design.**—First prize, value 3l. 3s., taken by Mr. C. C. Bradley. Second prize, value 2l. 2s., taken by Mr. F. S. Granger. Honourable Mention made of Mr. W. Dewes.

**Elementary Class of Design.**—First prize, value 2l. 2s., taken by Mr. F. M. Day. Second prize, value 1l. 1s., taken by Mr. A. H. Hart. Honourable Mention made of Mr. Ferguson.

**Colour Decoration Class.**—First prize, value 3l. 3s., taken by Mr. A. W. Hennings.

**Architectural Union Prize.**—Not awarded.

**Class of Construction and Practice.**—First prize, value 3l. 3s., taken by Mr. S. H. Seager. Second prize, value 2l. 2s., taken by Mr. Frank Nassie. Third prize (presented by Class), value 1l. 1s., taken by Mr. H. P. B. Downing.

**Class for Study of Planning and Specification Writing.**—First prize, value 3l. 3s., taken by Mr. Ernest A. W. Barnard. Second prize, value 2l. 2s., taken by Mr. M. Collins.

**Sketch Book Title-page Prize.** value 5l. 5s., taken by Mr. William A. Pite.

**Essays.**—First prize, value 5l. 5s., taken by Mr. E. P. Tector. Second prize, value 3l. 3s., taken by Mr. Lionel Littlewood.

**Lectures on Construction.**—First prize, value 3l. 3s., taken by Mr. A. C. H. Sibbett. Second prize, value 2l. 2s., taken by Mr. Herbert S. Saunders. Third prize, value 1l. 1s., taken by Mr. J. W. Stenhold.

**Lectures on Architecture.**—First prize, value 3l. 3s., taken by Mr. G. T. McCombie. Second prize, value 2l. 2s., taken by Mr. H. Abraham. Third prize, value 1l. 1s., taken by Mr. Norman C. H. Sibbett.

The President then proceeded to deliver an address, in the course of which he said,—

It is one of the obligations of the office of president to deliver an address on the occasion of the annual conversation, and one of the obligations you have entered into this evening by the attendance you have honoured us with is to listen to it. I see no escape for either of us. I will endeavour, however, to be as brief as possible, so as not to weary, and you, on your part, will kindly extend to me your patience for a short time, before adjoining to lighter and more congenial amusement. You have just witnessed a ceremony which, I hope, has interested you; the rewards of merit have been made more valuable to the gainers of them by your generous applause, and that touch of sympathy which every one values. The ceremony of bestowing the prizes has been a very short one, but it has taken a year's work to win them. On the walls of the gallery above you will see something of the labour involved, and I hope you will not leave this evening without at least a glance at them. You will see how much labour it takes to win distinction, and obtain some idea of the study required to make an architect. What you will there see is but a fraction of what is necessary for that purpose. The Architectural Association was established several years ago for the object of mutual improvement and instruction in the art of architecture, and upon a voluntary basis. The senior members impart instruction to the juniors, who, in their turn,

become teachers. We have lectures, classes, discussions, and exhibitions, for the study of design and construction, and in our ranks are all sorts and conditions of men, who go to make up the profession. Among these are those who are in practice, but who retain their names on the list of members from the affection they bear to the society which has added them in their work, and their desire to keep touch with those who yearly join it, and many remain in the ranks to render help in the work carried on. Others, and a large proportion, are in offices as assistants, anxious to avail themselves of the instruction to be obtained at a very small cost; and lastly, we have yearly drafts of young men who are serving their articles, and have just entered on the duties of the profession they have selected. The advantage of this chain of connexion from the first link in the professional chain to the last is obvious, and helps the creation of an esprit de corps and kindly sympathy which is most advantageous. We claim that the Architectural Association is a unique body, doing valuable service to the public and to the profession, breaking down the barriers of little jealousies, and forming that union which is strength. . . .

To those who have given any attention to the study of architecture, the progress that has been made of late years must be apparent. A glance only at the exhibits in the galleries represents so kindly and generously lent to us for this evening, and contributing so largely to the enjoyment of it, will go a long way to prove this assertion. These exhibits, it is true, are only accessories to architecture, but they are the outcome of the improvement which has taken place of late years. Many of the objects on view are designed by architects in practice who are members of this Association, and all the exhibits will repay your careful examination. It is too much the fashion to sneer at modern architecture and those who practise it; but let any one whose eyes are not hopelessly blind examine with care and attention the buildings, both ecclesiastical and civil, which have been erected during the last quarter of a century, and one may go further back than that. The Gothic revival has produced men who have covered the land with churches and buildings, many of which are masterpieces of design, and which I venture to think, future generations will do greater justice to, and treasure them as precious legacies. The works that will live are the creations of minds which have devoted their lives to the study of their art, men who have unceasingly toiled to learn their craft, and who have ransacked the treasures of the past with an absorbing love for the work, which is above praise. There are very few old buildings in this country, or on the Continent, that have not been visited, and careful drawings made of such parts which would serve for study and be useful in practice. That the result of this should be a too close resemblance to ancient architecture, justifying the charge of forgery in many cases, is natural, but in the works of the best masters and by their works progress in modern architecture should be judged. You will always find originality and a distinct adaptation of forms to modern usages, and any one well acquainted with old work will at once distinguish and appreciate the merits of the modern. The old Gothic architects were just as much copyists as the modern ones, or else how is it that the same plans, the same features, the same forms, and the same mouldings may be traced in buildings, from one end of the country to the other, and in far less variety than you see now in modern work.\* The great advantage the old builders possessed over ourselves was that they were happy in living in an age when they could practice their art in one style, and so bring it to greater perfection. Changes came very slowly to them, and men were left more to the quiet contemplation and development of their art, and to practice it free from the competition, rush, whirl, and excitement that attend upon us moderns. So much of the charm of old work lies in its antiquity and in the sentiment that surrounds it. Time is a skilful artist, and with loving hands colours the walls and roofs, gently tones down the interior, darkens the woodwork, knocks off sharp edges, softens and refines any crude contrasts, and produces generally that charming ensemble we call picturesque. There are many old buildings which, if the magic wand could pass over them and change to what they

\* Does Mr. Adams seriously mean to say that he does not perceive the enormous and radical distinction in principle between the two kinds of "copying" to which he refers?

were when the builders left them, would be passed by as unworthy of notice. Do not think for one moment I am drawing comparisons to the disadvantage of the past; far from that is my intention; but I plead for a fairer and more honest examination and judgment upon the work of the present, and for greater discrimination. I do not assert that the Gothic revival has produced work so grand and noble as the source from which it has sprung; the wonder is that such progress towards perfection has been made amidst difficulties which only those who adopt our profession can have any distinct knowledge of. What has been done in time past it is possible the world may see again, and with the progress that has undoubtedly been made of late years is it too Utopian to hope that buildings shall yet arise which shall be a delight and wonder to coming generations? The hope of modern architecture rests much with the public. It is sad to the enthusiast to find how people, as a rule, care little for architecture at all, and yet how lavish many are in expressing their opinion about it. The facilities for travelling afford opportunities for visiting edifices which are the admiration of the world; but they are not studied by the mass; hasty judgments are formed, and opinions expressed, borrowed from writers good, had, and indifferent. Such people fail to see the lesson taught by what they have visited, and to analyse the reasons for their likes and dislikes. Education is making rapid strides in every branch, and, may be, in time a more intelligent reasoning will take the place of the indifference to the study of architecture which characterises us a nation. Should that time come, when architecture shall be studied with delight, then the sure outcome of this will be a revival which shall eclipse all our previous efforts. If, as the wheel of time goes round, men will turn to the study of architecture, they will become more critical in their judgment, and demand a higher standard of design and workmanship than they do at present. They will seek out for employment only those architects who are architects in deed as well as in name. In time, perhaps, a diploma will be granted to architects who are able to satisfy the examiners that they are men skilled in the art. Such a course would be a guarantee to the public, and shut out men who have no sort of right to be trading on the ignorance of their employers. A step in this direction has quite recently been taken, and no man can now become an Associate of the Royal Institute of British Architects without passing an examination; make it compulsory that no man shall practise without this test, and improvement will take place. Such a step might not produce all the results hoped for from the artistic side; that difficulty must one day be met by a college of architecture presided over by distinguished professors; but from the practical side great good would follow. Buildings would be erected that would be better in construction and planning, and in that most important condition, better in their sanitary arrangements. With the responsibility which a legal status would give, some obstacles would be raised up against speculative building which, as at present practised, is such an absolute disgrace in too many instances to the architecture, if it may be called so, of this country. As long as the public are content with the present state of things, there is no remedy possible, but in all fairness they should be discriminating in their censure of architects and their work, and not judge the architecture of their time from the houses most people are compelled to inhabit, which are, for the most part, the creations of men absolutely ignorant of design and plan. Let a taste for architecture be cultivated, then a demand will arise for good and intelligent design, and there is the material always at hand to meet the supply.

**Clocks.**—The church at Great Houghton, Northampton, has just been enriched by having a large new clock fixed in the tower, which strikes the hours on a large bell, and shows time on two dials, each 4 ft. diameter. Messrs. John Smith & Sons, Midland Clock Works, Derby, have carried out the work. They have also erected the large new clock at Wootton Church, near Bedford. It strikes the hours on a large bell, chimes the ding-dong quarters, and shows time on a copper dial 5 ft. in diameter. It is fitted with all the latest improvements.

THE VENTILATION OF PRINTING OFFICES.

THE necessity for the efficient ventilation of printing-offices must be apparent to many who have had occasion to frequent them, if not always to those who own them or work in them. No doubt the difficulties in the way of providing ventilation, without objectionable draughts, are great, especially in some of the older offices, although in some new buildings of the kind the means of ventilation are either inadequate or inconveniently primitive. As everybody knows, the production of a newspaper entails much nightwork, and, in the composing-rooms especially, a good light is essential. Hence the plentiful, not to say profuse, use of gas, and the consequent rapid vitiation of the air. Much improvement in this direction may be hoped for from the use of the electric light, but we believe it to be a fact that the lighting of composing-rooms by electricity has not yet proved altogether successful where it has been tried. However, whether gas or electricity be the illuminant of the future for printing-offices, ventilation will always be needed to remove the products of respiration thrown off by the large number of compositors and other workmen, and to bring in fresh air, warmed when necessary. In this connexion we are glad to be able to call attention to the fact that, with laudable consideration for the health of their employes, the proprietors of the *Daily Telegraph* have just had their composing-room ventilated by means which appear to be eminently successful, viz., by the *Æolus* water-spray ventilator, which appears to have been successfully used for ventilating the Life School of the Royal Academy, and many other public buildings. In the composing-room of the *Daily Telegraph*, 170 compositors work throughout a great part of the night, and seventy Argand burners light the "cases." Under the advice and direction of Messrs. Arding, Bond, & Buzzard, the proprietors have put a new and lofty roof, which is covered by a lantern along its whole length, the windows on both sides of the lantern opening in two divisions by lever bars at each end of the room. This provides an ample outlet for the vitiated air in summer time, or in calm moderate weather, when open windows are unobjectionable. Fresh purified air, either cold or warm as may be required, is driven in by a 16-in. *Æolus* Water-spray Ventilator fixed in the basement. The fresh air is delivered into the room by a series of fourteen 3-in. tubes, rising 5 ft. from the floor, and each, as shown by tests with the anemometer, capable of sending 630 cubic feet of air per minute into the room, without draught. In warm weather the cool fresh air is used to keep down the temperature to an agreeable point, while in winter the fresh air can be raised in a few minutes to a temperature of 100° by simply lighting the gas-burners around the tubes through which the fresh air passes. A continual supply of fresh air, equal to five times the cubical contents of the room, is thus afforded every hour, and of a temperature adapted to the sensitiveness of men engaged in sedentary occupations. Returning to the subject of extraction, when the weather is such as to render open windows undesirable (and in this climate of ours such an objection obtains for several months out of the year), the vitiated air is drawn off by two 16-in. *Æolus* water-spray ventilators, which have their communication with the composing-room through two panels occupying the position of two of the side-lights of the lantern; these are continued by 16-in. galvanised shafts outside the roof, which enter the composing-room again through the roof by the plate and descend through all the floors into the basement. In each of the last 6 ft. lengths of these shafts a waterspray is fixed, and by simply turning the tap a powerful exhaust is immediately set up, dragging down the vitiated air from the composing-room into the basement. A continual change of atmosphere is thus ensured for the composing-room, although doors and windows be tightly closed. Another peculiarity in this application of the waterspray as an exhaust is the fact of the upper part of the shaft, falling down the slope of the roof, being exposed to the action of the cold atmosphere outside; this condenses the carbonic acid held in suspension in the heated air, which by its own gravity assists the downward current.

We understand that the new offices of the *Daily News*, now in course of erection in

Bonvic-street, Fleet-street, and of which we lately gave some particulars, will also be ventilated by the *Æolus* Water Spray Ventilator.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

211, Improvements in Exhaust Ventilators. George William Webb, Reading.

In this invention, a novel pattern of exhaust ventilator is made by fixing guards or plates in a peculiar manner at the angles or corners of a cowl. Perforated zinc or wire gauze is used instead of the ordinary louvre or shutter. The air rushing through the slits exhausts the vitiated air from the up-take pipe, and discharges it in the ordinary manner. The claim is really the arrangement of the shutters, which form four partitions around a central chamber.

1,533, Improvements in Metallic Sash Lifts. Charles Showell, Birmingham.

The improvement consists mainly in manufacturing metallic sash-lifts from sheet metal. It is principally adapted to such fixings as have a ring or loop in the centre, in which the finger is placed to lift or cover the sash. One piece of metal only is used, and from a T-shaped blank worked in a press or stamp, a loop of the ordinary pattern is made.

9,018, Improvements in the Manufacture of Fireproof Blocks or Slabs for Preventing the Transmission or Radiation of Heat. C. Toope, London.

This invention relates to the manufacture of hard coherent fireproof blocks or slabs from silicate cotton, asbestos fibre, and a solution of silicate of soda and pipe-clay. The fireproof blocks or slabs, when made of the proper shape, are especially adapted for protecting the joists of buildings; but they may also be used for covering steam-boilers, gas-pipes, wooden structures, and preventing the radiation and transmission of heat generally. The blocks or slabs may be composed of either the silicate cotton or asbestos fibre alone, in conjunction with the silicate of soda and pipe-clay, or they may be composed of a mixture of silicate cotton and asbestos fibre in any suitable proportion in conjunction with the mineral ingredients already mentioned, the proportion in which they are employed depending in either case upon their quality. In manufacturing the blocks or slabs, 8 lb. of pipe-clay are mixed with about one gallon of silicate of soda, and then sufficient silicate cotton or asbestos fibre (or a mixture of the two) is added, to form a plastic mass. The whole is then thoroughly incorporated in a pug-mill or otherwise. Afterwards the material is rammed into moulds of the desired shape, and the blocks or slabs turned out are baked in ovens at a temperature of about 175 deg. Fahr. until they are thoroughly dry. The blocks or slabs may be coated with asbestos sheeting or asbestos paper to give them a smooth surface, and this may either be done after the blocks or slabs are produced in the operation of moulding. In the latter case sheets or strips of the asbestos sheeting of the proper shape are laid in the moulds before the introduction of the plastic mass of composition, which is then filled into the mould and adheres to the sheeting or paper. In the former case the sheeting or paper would be cemented to the blocks, &c., after they have been baked by a cement composed of pipe-clay and silicate of soda in suitable proportions.

APPLICATIONS FOR LETTERS PATENT.

Oct. 3.—13,119, F. Mason and J. Conqueror, Sunderland, Manufacture of Rolled Plate Glass.—13,124, G. W. Elliott, Liverpool, Improvements in Axes, Hammers, Spades, Shovels, and other Tools.—13,143, H. Tall and C. R. Mathews, London, Water-waste Preventers, especially applicable for Flushing and Disinfecting Water-closets.—13,147, R. Oakley, London, Ventilating and Warning Buildings.—13,148, W. H. Lindsay, London, Improvements in Bridges.—13,152, T. Parsons, London, Boring Apparatus.

Oct. 4.—13,160, J. Law, Balsall Heath, Portable Hall Lantern Frame.—13,164, R. H. Perks, Birmingham, Self-closing Water-preventing Valve for Flushing Cisterns.—13,181, J. Rogers, London, Fire Partitions.—13,183, J. M. Stanley, London, Construction of Furnace, Boiler, and other Fireplaces.

Oct. 6.—13,125, J. Kretschmann, London, Water-closet Valves.—13,231, F. C. Hustler, London, Window-sash Fasteners.—13,237, J. W. Matteson, W. J. Chapman, and T. G. Matteson, London, Manufacture of Portland Cement.—13,238, R. Hunter, London, Improvements in Kitchen Ranges.—13,243, Sherwood & Co., London, Manufacture of Cathedral Glass.

Oct. 7.—H. J. Allison, London, Improvements in Brick Kilns.—13,270, R. Entwistle, London, Water-tap.—13,273, J. C. Hudson and T. Bayley, London, Improvements in Locks.—13,284, F. George, London, Compositions for Lead or other Hiko Pipes.—13,302, W. R. Lake, London, Machines for Manufacturing Wood Screws.

Oct. 8.—13,314, W. Lester and W. R. Lester, Glasgow, Glazing Bars or Astragals.—13,325, G. Moore, Lewisham, Combined Steam-fitting and Hand-actions

for Water-closets, Urinals, &c.—13,332, J. T. Green and J. Green, London, Latching Mechanism for Swing Doors and Gates.—13,335, G. Richards, London, Machine for Grinding Planer Knives or Cutters, and similar Edge-tools.—13,338, M. Sugar and L. Hildveghy, London, Apparatus for Stamping and Setting Stone Paving and other Blocks.—13,339, J. S. Bruce, Birmingham, Opening and Closing Ventilators.  
Oct. 9.—13,350, J. W. Chalk Webb, Worcester, Kilns and Stoves.—13,355, W. Smith, Dublin, Waterproof Cement.—13,364, A. A. Joy, London, Sash-fastener.—13,375, J. A. R. Main, Glasgow, Iron or other Metallic Roofs.—13,377, J. Kemp and F. Fissi, London, Improvements in Earthenware Pipe Connections.—13,379, A. Cuff, London, Improvements in Balconies.—13,380, J. J. Barclay, R. Allison, and J. Barclay, London, Kilns and Apparatus for Burning and Drying Bricks.—13,381, W. Wright, London, Mounting, Balancing, and Securing Window-sashes.

PROVISIONAL SPECIFICATIONS ACCEPTED.

4,763, G. Macfarlane, London, Flushing Apparatus for Water-closets, Urinals, and Drains.—11,722, J. Hamilton, Derby, Wood Planing Machinery, and Cutters for same.—12,067, E. V. Bailey, Birmingham, Attaching Knobs to the Spindles of Locks and Latches.—12,368, J. Tottenham, London, Improvements in Hoists for Raising Materials for Buildings in course of erection.—12,459, G. H. Conch, London, Covering Roofs and other Parts of Buildings with Tiles.—12,531, B. Warburton and G. H. Warburton, Manchester, Planing and other Wood-working Machines.—12,619, J. H. Sams, London, Improvements in Mantel and Chimney Pieces.—12,765, W. Day, London, Kilns for Burning Bricks and other Articles.—12,780, W. J. Hinit, Birmingham, Sewer-gas Interceptors for Drains.—12,875, W. J. Stokes, London, Improved Sash-fastener.—10,834, J. B. Fidler and T. B. Fidler, Wolverhampton, Lever Locks and Latches.—11,855, A. Lawrence, London, Decorating Glass.—11,931, W. Morrison, New Swindon, Chimney-tops.—12,356, C. Cowney, Birmingham, Improvements in Closets and Urinals.—12,625, W. H. Chubb, Birmingham, Lever Locks.—12,701, C. D. Douglas, London, Improvements in Locks and Latches, and securing Knobs and Handles to the Spindles thereof.—12,821, T. Robinson, Bristol, Water Meters.—12,850, G. Trice, London, Lock Protector.—12,881, J. Menzies, London, Apparatus for Cutting and Sharpening Stone.

COMPLETE SPECIFICATIONS ACCEPTED.

Open to opposition for two months.

15, J. A. Walter, Rainham, Kent, Improvement in Locks.—84, J. D. Tucker, Bromley, Sliding Window-sashes.—411, E. V. Bailey, Birmingham, Converting and Adjusting Door-knobs to their Spindles.—1,798, R. Stanley, Nuneaton, Manufacture of Terra-cotta and other Clay Goods.—2,474, A. Shepherd, Birmingham, Machinery for Painting the Laths of Venetian Blinds.—125, A. Clark, London, Hydraulic Lifts.—512, J. Dean, Oxford, Self-acting Open Fire Ranges.—1,553, R. Wright, Richmond, Preventing Smoke in the Combustion of Coal in Open Fireplaces.—2,524, G. C. Davies, London, Improvements in Inspection or Access Pipes for House-drains and Soil-pipes.—7,610, G. H. Chubb and H. W. Chubb, London, Improvements in Latch Locks.—10,596, Hans A. Hansen, Christiania, Improvements in Saw Saws.

THE DECORATION OF ST. PAUL'S.

SIR,—I addressed a few lines to your readers on the subject of the decoration of the dome of St. Paul's shortly after Mr. Pullan's paper at the Institute.

And I then took occasion to draw attention to some of the methods of decorating domes which had their internal concave finished as a smooth surface, and not constructed with deep coffers,—the majority of cases being treated as if there were no dome at all, but a vision of the heavenly host intervening; its very existence was a thing of the imagination only. And, further, I asserted that if it was desired to retain the form of the dome as an opaque concave roof covering, this could only be done by rejecting the impossible architectural forms introduced into Thornhill's paintings; for, though their incongruity might not be painfully apparent while executed in sepia only, when done in bright colours it would be absolutely unbearable.

I felt I was but repeating a generally accepted truism, but to my surprise Mr. Seddon and Mr. Cave hold a different opinion; and I am constrained to repeat my own. Sir James Thornhill depicted what Sir Christopher Wren declined to construct; that is to say, he represented the inner dome pierced with a series of lofty arches, through which the observer is supposed to see a tableau illustrative of the life of St. Paul, painted on the walls of the intermediate cone which sustains the lofty stone

lantern surmounted with the gilded ball and cross.

Now, it cannot be questioned that the continuation of a great picture round the lower half of the dome was a fine idea, and one surpassing all others from a pictorial point of view. But the obvious falseness of the architectural environment was unworthy of a palace of truth, and is objectionable to the taste of an age wherein the real is daily becoming more popular than the unreal.

Moreover, it would be shirking the problem and confessing our failure to compass it. While to assert that the nineteenth century can do no better than the seventeenth, and that, therefore, we should be content to sit at the feet of Sir Christopher (whose opportunities of study were comparatively limited), and be afraid to act upon the increased knowledge and artistic power of our time—to assert, I say, that this is what we are to learn from the example of the Renaissance architects, is a most singular conclusion to arrive at.

The Medieval architects would have scorned to repeat in the fourteenth century the efforts of any preceding century; they trusted to themselves, and looked for inspiration from within or from above, to excel all that had been previously done, which is characteristic of true genius. But this was before the new birth of literature, when we were supposed to have gained all knowledge of good and evil; and straightway lost our power of independent action in the fine arts.

The late Mr. Stevens has, however, left behind him suggestions for the treatment of St. Paul's dome, which we may now see worked out in the rival designs exhibited on opposite sides of the dome itself,—both of which embrace his idea based on the fact that every plain section of a sphere is a circle. And this suggestion expressed Stevens's desire to preserve the representation of the true form of the great concavity. Mr. Stannus has carried forward Stevens's idea with the same object, and has knit together the circles by ribs, rising from the blocking over the unpierced piers of the peristyle. These ribs also express the form of the dome, and diminish proportionately as the circles diminish as they reach the summit of the cupola. Raised mouldings may be implanted on the ribs and the frames or stiles of the circular panels, provided always that their flat treatment is maintained, but no painted cornices or false construction is admissible.

The conditions of the problem have never been more nearly met, or more effectively and reasonably rendered, than by the design thought out by Mr. Stannus. Nevertheless, there is room for further study of the details and accessories, of the tone of the colouring, and the scale of the pictures, which can only be settled satisfactorily *in situ*.

It is imperatively required that whatever is designed shall be treated broadly, and be suited to the position it is to take in scale and colour. It is much more an architect's province than a painter's to determine the leading lines and framework of the composition, and to prescribe the limits and scale of the decorations and pictures.

The plain wall below the peristyle, or podium behind the gallery-railling, seems to call for more decidedly flat treatment, in warm secondary colour. The ornament in relief and in bright colours would be better replaced by a band of figures, like that surrounding the Albert Hall externally, with seated figures at the four points of the compass, their broad outlines being well seen from below, their low-toned details being appreciated from the gallery.

The blocking-course over the peristyle is too much cut up and too low, especially when compared with that over the main order below, from which spring the domical ribs of the eastern apse.

The angle at which the light strikes the upper part of the cupola causes the gold mosaic to look brightest there, and so brings down the centre and dwarfs the total height, and apparently flattening the apex of the dome. This will have to be overcome, but, for my own part, I would rather see the whole done in marble mosaic: this would lower and soften the whole tone of the decoration, and give distance and haziness.

But in all these points the accomplished architect of the cathedral, Mr. Penrose, will doubtless be eventually consulted, whatever is done.

EDWD. C. ROBINS.

Sir,—Mr. Clayton's special pleading must not divert us from the main object of the contention, and that is, to preserve Thornhill's admirable general arrangement from being overlaid and effaced by a scheme that will not bear critical analysis, and which, if carried out, would ruin the dome as an architectural feature. To carry out the complete decoration of St. Paul's, it may be admitted that Thornhill's monochromes cannot be retained intact. But when their utter annihilation is threatened, I say, no! We are bound upon principle, not only out of respect to the artist, and to the architect, but also in recognition of the general appropriateness of Thornhill's scheme, with some admissible alterations, to retain them. I never contemplated that process of effacement by overpainting, which so exercises Mr. Clayton's imagination: my proposal is to use Thornhill's works as *cartoons* for mosaic, just as it is proposed to use the experimental designs. Would Mr. Clayton consider the translation into mosaic of the work of Sir Frederick Leighton and Mr. Poynter, as the effacement and ruin of those eminent painters' designs? Would not the mosaic be virtually their designs still?

In so far as the preservation of early work is concerned, Mr. Clayton must very well know that, in the progress of sculpture in Greece and of painting in Italy from their infancy to their maturity, the earlier, imperfect works were, in the main, preserved, or we should have been in ignorance of the characteristics of that evolution. A few exceptions do but prove the rule. We moderns, too, are bound to cultivate a similar kind of reverence for the disproportions inevitable in the past, and of this virtue we should have expected to find Mr. Clayton an exemplary exponent.

W. CAVE THOMAS.

October 10th, 1884.

#### "CROSIER" AND "PASTORAL STAFF"

Sir,—An editorial note to above relating to the curved summit of the Sacraments-Halslein at Nuremberg draws a distinction between an "archbishop's crozier" and a "bishop's pastoral staff." May I be permitted to say that this is an error? The archbishop's processional cross is quite distinct from his crozier. This latter, which belongs to him as bishop, not as primate, is nothing more than the crook or pastoral staff common to all his episcopal brethren.

This erroneous distinction, which is very prevalent, is based on false etymology. The connexion between "crozier" and "cross" is apparent only, not really, except so far that both words are ultimately derived from the same root. "Crozier," or "Crosier," is really synonymous with "crook," and is derived from the Celtic root, *krog*,—a hook, a head, an angle,—from which also a considerable number of very familiar words descend, *e.g.*, crotch, croquet, cricket, crunch, crouch, encroach, &c.

EDMUND VENABLES.

The Precentory, Lincoln.

\* \* \* When the difference of opinion lies between two such learned authorities as Dean Hook, whose words were quoted in the note referred to, and the Precentor of Lincoln, the controversy must be approached with due deference to each. The latter, however, admits that "cross" is ultimately derived from the same root as "crozier"; in order, therefore, to avoid confusion amongst the many derivatives from "krog," there may be some convenience in distinguishing the pastoral office of a bishop by speaking of his "pastoral staff." The French have somewhat similar, but distinct, words for crook, crozier, and cross, namely, *croc*, *croisse*, and *croix*.

It would certainly seem that there was in Medieval times a distinction between the archbishop's crozier and the bishop's pastoral staff. Dr. Lee, in his *Directorium Anglicanum*, describes the archbishop's crozier as a cross borne on a staff, the lower end of which is pointed (as in the pastoral staff). He goes on to say, however, that it is never carried by the archbishop himself, but by one of his chaplains. No authority is quoted for this negative assertion, whereas in MSS. of the thirteenth century we find drawings of archbishops who are represented as holding in their hands croziers exactly answering to Dr. Lee's description. This seems to prove the existence of a cross-headed staff peculiar to archbishops, and distinct from the pastoral staff as well as from the processional cross.

#### EGHAM SCHOOL BOARD COMPETITION

Sir,—In response to the advertisement inserted in your issue of the 13th of September, I received applications from 103 architects and other persons desiring further information re new schools, in order to prepare designs. Of these applicants, forty-nine have forwarded complete sets of plans and specifications. As the larger portion of these have evidently been prepared at considerable cost, the Board consider that it will be only just towards the competitors that a corresponding amount of pains should be expended, and competent assistance sought in making a selection. This will, of course, involve some little delay in adjudication of premiums. Will you allow me, through the medium of your widely-circulated paper, to inform those gentlemen who have sent in designs that arrangements have been made for the plans to be exhibited in the large hall of the Egham Literary Institute, for the better examination of the designs by the Board, and that on the 24th and 25th of October, between the hours of ten a.m. and four p.m., the plans will be open, under certain restrictions, for the inspection of any ratepayer or other person interested in the education of the young. Should any of your readers, including the competitors, like to avail themselves of this privilege, I shall be pleased to hand them admission tickets to the hall on their communicating at once with me.

BENJAMIN TICE,  
Hon. Clerk, Egham School Board.

#### SEA-SAND FOR MORTAR.

Sir,—Will any of your readers be kind enough to inform me whether any objection exists to using sea-sand in mortar for house-building purposes? I am now building a house at the sea-side, and being under the impression that the mixing of sea-sand with the mortar tended to produce dampness in the walls in damp weather, I specially requested the architect to insist on the contractors using other than sea-sand with the mortar. The architect, however, does not share my prejudice against sea-sand, and assures me that it is not open to the objections above stated.

A reply from any one having experience on this question will greatly oblige.

\* \* \* Our correspondent does not state whether the architect compelled any process of washing or cleaning the sand from salt. It turns mainly on that. Mechanically, sea-sand is often one of the best sands that could be used for mortar, owing to its sharp and crystalline character; chemically, it is always hazardous at the best, owing to the difficulty of clearing it from salt, a very small percentage of which is sufficient to prevent the mortar setting properly, and to cause dampness and efflorescence on the walls.

#### SCREW-DRIVERS.

Sir,—In the last number of your journal [p. 511, *ante*] I noticed an interesting description of a novel screw-driver.

The many years that screw-drivers have been in use I have never seen one that has been properly adapted to fit the modern screws; they either have a tendency to split the head of the screw, or to slip out of the screw-cut. The form that I have made for my use is one with the end rounded and more rounded. The groove in screws as now made is cut with a small circular saw; and I have found that a screw-driver made to fit the screws is all that can be desired. The screw-driver can be used at any angle with the screws, and will always bite, and is always inclined to keep in the centre of the cut.

W. R. BOUSFIELD.

#### LIQUID REFUSE.

Sir,—An injunction has been served upon a club, restraining him from turning liquid refuse from printing and dye works into the public sewers.

Can you, or any of your readers, suggest any method of clarification, or point out any examples of successful treatment in such cases? A. B.

A Festive Gathering.—On Monday evening last, Mr. James Forsyth, architectural sculptor, Finchley-road, gave a supper to the men in his employ, on the occasion of the majority of his eldest son, Mr. James Forsyth, jun. On the cloth being removed, Mr. Meadows, foreman of the wood department, rose and said he had a very pleasing duty to perform, and which was to call upon Mr. Williams, foreman of the stone department, who acted as vice-chairman (Mr. Forsyth himself acting as chairman), to present to Mr. Forsyth, jun., on behalf of the men, as a token of the respect and esteem in which he was held by them, a handsome dressing-case. Mr. Forsyth, in acknowledgment, said he regarded the kindly feeling which had prompted the gift, not only as a great compliment to himself, but also to his father. A very pleasant evening was passed.

The Student's Column.

ON THE CONSTRUCTION OF FLOORS.

THE girders of a framed floor have to carry the whole weight of the floor on one, two, three, or more points, according to the number of the binders framed into them, and the distance apart of the binders, as described in a former article, so that the load can hardly be said to be uniformly distributed along the beam. When the girders are placed 10 ft. apart the scantling may be found by the following rule, which will be found sufficiently near to suit all cases. Divide the cube of the length (in feet) by the breadth (in inches), and multiply the quotient by 6 for ordinary floors, and by 18 for those of warehouses, the result is the cube of the depth (in inches).

For example, if the length of bearing is 20 ft. we have the cube of 20 is 8,000, and if we assume the breadth to be 10 in., 8,000 divided by 10 is 800, which multiplied by 6 gives 4,800 as the cube of the depth, the cube root of which is nearly 17 in., the depth for ordinary floors; if multiplied by 18 we get 14,400 as the cube of the depth for warehouses, the cube root of which is nearly 24 in. If the breadth is 12 in. then, by this rule, the cube of the depth is 4,000 for ordinary floors, of which the cube root is about 15 in.; for a warehouse floor the cube of the depth is 12,000, the cube root of which is about 22 in. the depth required.

With a bearing of 30 ft. let the breadth be 15 in., the cube of 30 divided by 15 gives 1,800, which multiplied by 6 gives 10,800 as the cube of the depth, or 22 in. for the depth of a girder for ordinary floors; and 32,400 as the cube of the depth for a warehouse, or 32 in. for the depth. In this case it would be almost impossible to obtain a solid beam of fir of the required depth, and a built-up one might be used of the pattern described in a former article and shown by fig. 6; or a trussed beam of less depth might be used of the description shown by fig. 5. (See p. 475, ante.)

Girders should be made to rest at their ends upon stone templates not less than 2 ft. long by the full thickness of the wall, on which they should bed at least 9 in., so as to distribute the load over as large a portion of the wall as possible. A space of 1 in. or 2 in. should be left round the ends to allow a free circulation of air and prevent dry rot.

With very long timber girders that have to carry a heavy load it is advisable to introduce a support in the middle, by which its strength is more than quadrupled, and a smaller depth of timber can be employed. The weight that a pillar placed at the centre will have to support may be taken as half the load which rests upon the girder, and the sectional area of a long square pillar may be found by the following rule:—Multiply the weight in tons by  $\frac{1}{4}$  for fir, and by  $\frac{1}{8}$  for oak; multiply the square root of the product by the length in feet; the result is the sectional area of the pillar. For example, suppose a girder 30 ft. long has to support a load of 45 tons, and that half of this, or 22½ tons, is thrown upon a central pillar of oak, whose length is 12 ft.; 10-11ths of 22½ is 20.45, of which the square root is 4½, and this, multiplied by 12, gives 54 square inches for the sectional area, or nearly 7½ inches square. The girder ought not to rest immediately on the head of the pillar, as it is liable to be bruised thereby, and a 3-inch template of oak, about 2 ft. long by the width of the girder should be placed on the top of the pillar, which should also be tenoned into the template.

Timber girders may be greatly strengthened by the addition of a plate of iron in the following manner:—The beam is sawn down the middle and reversed, as described in the former article, and a thin plate of rolled iron, the exact depth and length of the beam, is placed between the two halves or flitches as they are called, and iron bolts are passed through the timber and iron, which has previously had holes drilled to receive them, so as to hold them all firmly together. This is termed a *flitch-girder*, and, if the flitches are each 5 inches thick and the iron  $\frac{1}{2}$  inch thick, the strength of the composite beam will be about double that of the timber without the iron plate. This arrangement enables us to reduce the depth of the girder while retaining the required strength, and the cube of the depth need only be half what it should be when there is no iron plate, for the same breadth and length. Thus we have just

seen that for a length of 20 ft. and breadth of 10 in., the cube of the depth is 4,800, or the depth nearly 17 in.; but, with a  $\frac{1}{2}$ -inch iron plate, the cube of the depth will be 2,400, or the depth 13½ inches, the proportions being as 4 to 5.

Where there is not sufficient depth to allow of a double-framed floor with timber girders, binders, and joists, the space can be economised by using rolled iron beams of I section, as G in fig. 7, in place of the timber girders, the ends

Fig. 7.

of which may be made to rest upon stone templates in the walls at intervals of 10 ft. or 12 ft.; the joists, J, are cut the same depth as the iron beams, and their ends fitted into the space between the flanges and resting on the lower flange, as shown in the figure. The floor, F, can be laid on the top of the joists in the usual manner, and the ceiling laths, C, nailed to their underside. For ordinary floors a rolled iron beam, 12 in. deep and 5 in. wide, weighing 42 lb. to the foot, will form a girder sufficiently strong to carry a floor over a span of 20 ft. For warehouse floors two such beams placed one on the top of the other and riveted at the flanges, as in fig. 8, should have

Fig. 8.

four times the strength of the single beam; the greatest strength of the girder is, however, in this arrangement placed at the middle of the depth where the strain is the least, so that there is a considerable waste of material which adds to the load without increasing the strength; and such a beam can hardly bear more than three times the load of the single beam. As, moreover, its depth of 24 in. might prove inconvenient, a better arrangement is to place the two beams side by side with a  $\frac{1}{2}$  in. plate 12 in. wide riveted on the top and bottom, as shown by fig. 9,

Fig. 9.

where the same strength is obtained with little more than half the depth; the greatest strength in this form of beam being placed at the top and bottom where the principal strains are exerted.

Instead of letting the joists rest upon the lower flange of the iron beam, as at J in fig. 7, it would be better to use binders rather less than the depth of the girder, and lay light joists across them to carry the floor and ceiling as shown in fig. 4 of the last article. This plan would require less timber, and the depth would be nearly the same.

Hitherto we have confined our attention to the use of timber in the construction of floors, since by far the larger number of dwelling-houses, as well as other buildings, have their floors made of that material. The use, however, of iron as a constructive material has of late years so greatly extended, that its application as a support for the floors of buildings claims a large share of our attention. The form in which iron is now most commonly employed for flooring purpose is that of the rolled joist of I section, as described in our last article, and shown in figs. 7, 8, and 9. These joists can be obtained in a great variety of sizes and weights, from 3 in. to 20 in. in depth, and weighing from a few pounds up to nearly 1 cwt. per foot of length. Joists of I pattern are also made, but these do not possess so much strength for the same weight of metal as those of I section, although in some cases they are more convenient to use.

The load in tons that can be safely distributed over the length of a rolled iron joist of I section, can be approximately calculated by the following rule, where the length between the supports is taken in feet, and all other dimensions are to be expressed in inches.—Multiply the cube of the full depth by the breadth of the top or bottom flange; then multiply the cube of the depth in the clear between the flanges by the breadth less the thickness of the web or vertical part; deduct the latter quantity from the former, and divide the remainder by one and a half time the product of the full depth into the length of span. The quotient is the safe distributed load in tons that may be laid on the beam; but if the load is all placed at the middle, the strength will be reduced one-half. For ordinary floors we reckon the load at 1 cwt. to every square foot of surface, or half a ton to every foot length of a girder, where the girders are placed 10 ft. apart. For warehouses, three times the above must be taken as the load. For example, we will take the case of a rolled beam of I section having a span of 20 ft., and carrying the joists directly on its lower flange, so as to distribute the load uniformly, as described in fig. 7 of the last article; the depth being 12 in.; the width, 5 in.; the thickness of web,  $\frac{1}{2}$  in.; and the clear depth between the flanges, 10½ in. Then the first quantity, by the above rule, is 5 times 1,728, or 8,640; the second quantity is 4½ times 1,158, or 5,211; the difference of these two quantities is 3,429; the third quantity is  $\frac{1}{2}$  time 12 times 20, or 360; and 3,429, divided by 360, gives 9½ as the number of tons that can be safely distributed over its length of 20 ft., which is very nearly half a ton to each foot of length. For a warehouse floor, we may use two such beams placed one on top of the other, as shown on fig. 8 of the last article, by which means the strength is increased threefold, and the stiffness to a still greater degree; or we can place two joists side by side, and rivet a plate on the top and bottom, as shown at fig. 9 (see last article). The same rule will apply in this last case as in the former one for calculating the strength.

For example, let the span be 20 ft., and two joists, 12 in. by 5 in., placed side by side, with a  $\frac{1}{2}$  in. plate 12 in. wide, riveted on top and bottom. The full depth is 13 in.; the breadth, 12 in.; the clear depth, 13½ in.; and the clear breadth, 11 in. Then the first quantity, by the above rule, is 12 times 2,197, 26,364; the second is 9 times 1,158 or 10,422, plus twice 1,728, or 3,456, making altogether, 13,878. Their difference is 12,486, which, divided by  $\frac{1}{2}$  time 13 times 20, or 390, gives 32 tons as the safe distributed load, or a little over  $\frac{1}{2}$  ton per foot of length.

As it is important that we should know the amount of deflexion a given load will produce on a beam, we can calculate it by a rule similar to that given above for the strength, only the quantity there used as the numerator is inverted and becomes the denominator in this case. Multiply the cube of the length (in inches) by the load to be laid on the middle of the beam (in tons); divide this by the remainder found in the last rule multiplied by 40,000; the quotient is the deflexion in inches. But if the load is uniformly distributed the deflexion will be five-eighths of the above.

Thus in the example given above of the I joist 12 in. by 5 in. and 20 ft. long, with a load of 9½ tons, the dividend is 9½ multiplied by the cube of 240; the remainder is 3,429, which multiplied by 40,000, is the divisor; the quotient

is .96 the deflexion in inches when the load is all at the centre; but, as in this case, the load is supposed to be distributed over the length of the beam, we take five-eighths of the above, or .6 in. as the deflexion in the middle, which is rather more than one-fortieth of an inch to every foot as prescribed by Tredgold for the maximum deflexion of floor beams, being, in fact, one thirty-third of an inch for every foot length of the beam.

In the example of the double-beam, given above, we have 32 multiplied by the cube of 240 for the dividend, and the remainder 12,480 multiplied by 40,000 for the divisor; the quotient is .88 in. as the deflexion if the load was all at the centre, five-eighths of which is .55 in. when the load is distributed, or nearly one thirty-sixth of an inch to every foot of length.

A girder suitable for a warehouse floor of 30 ft. span can be made with two beams of I-section, each 16 in. deep and 6 in. wide, and weighing 62 lb. to the foot, placed side by side, and connected with a  $\frac{1}{2}$ -in. plate 14 in. wide at top and bottom, or else two  $\frac{1}{2}$ -in. plates at the top, and one  $\frac{1}{2}$ -in. plate at the bottom. By the rule given above it is found that this girder can be safely loaded with 45 tons distributed over its entire length, or 14 ton to each foot.

For a warehouse floor of 40 ft. span we should require to use two beams of I-section, each 19 $\frac{1}{2}$  in. deep and 7 in. wide, weighing 100 lb. per foot, placed side by side, and united by a 1-in. iron plate 15 in. wide riveted to the top and bottom flanges, the thickness of the web being 2 in., and of the flanges 1 $\frac{1}{2}$  in.; such a beam will be found by the above rule to be capable of bearing a distributed load of 60 tons, or 14 ton per foot of length.

When the span of the warehouse exceeds 20 ft. it will generally be found economical to support the middle of the girder on a cast-iron column, by which means the strength is increased fourfold, while the stiffness is increased in a much greater degree; so that beams of much lighter weight can be employed. With a span of 30 ft. we may consider that the column has to bear a load of 22 $\frac{1}{2}$  tons; if the length of the column is 12 ft., then the diameter must be at least 5 $\frac{1}{2}$  in. if solid, and 7 in. external diameter if hollow, with  $\frac{1}{2}$  in. thickness of metal. If the length of the column is 18 ft., its diameter if solid must be at least 6 $\frac{1}{2}$  in., and 8 $\frac{1}{2}$  in. external diameter if hollow with  $\frac{1}{2}$  in. thickness of metal.

#### MEETINGS.

MONDAY, OCTOBER 20.

Plumbers' Congress at International Health Exhibition. 11 a.m.

FRIDAY, OCTOBER 24.

Architectural Association.—The President's Address. 7.30 p.m.

#### Miscellaneous.

**Architecture in relation to Landscape Gardening.**—Mr. G. Richards Julian delivered the second of his course of lectures at the Crystal Palace on Wednesday afternoon last. The subject of this lecture was "Roman and Romanesque Architecture." The lecturer commenced with an explanation of the relative positions of the Etruscans and the infant Rome, drawing attention to the fact that the Romans derived the semicircular arch and the circular plan for temples and tombs from the ancient Pelasgic inhabitants of Etruria, or Tuscany. The absence of any architectural development during the existence of the Republic, and the enormous activity of the Roman emperors in building, not only in Rome itself, but in all her subject provinces, were then pointed out, notice being taken of the fact that while almost all the remains of Grecian architecture are to be found in temples, the Romans have left behind them not only temples, but baths, amphitheatres, basilicas, forums, and triumphal arches and columns. The effect on the Romans of the conquest of Greece, in the adaptation of the Greek orders as decorative features applied to the arched construction derived from the Etruscans, was described, and a detailed account of the various modifications made in the orders followed. Passing to Romanesque architecture, the characteristics of the early Christian basilicas were noted, and a short digression to point out the rise of the Byzantine style in the East, and some of its leading features, was made. After this the lecturer glanced at the round-arched architecture of Lombardy, of the Rhine valley, and of France.

**Liverpool Engineering Society.**—The ninth meeting of the season was held on the 8th inst., at the Royal Institution, Colquhoun-street, Mr. R. R. Bevis, jun., in the chair, when a paper, entitled "Inland Navigation Works Abroad," was read by Mr. R. L. Tapscott. The author, in treating of his subject, dwelt on the accomplishment of the great canal works of recent years as a result of the improvements in the various mechanical appliances now substituted for hand labour, and the benefits thence arising; instancing the successful maintenance of the Suez Canal as the forerunner of the many suggestions for inland navigation now brought forward. Admitting the difficulties of the Panama Canal to be considerable, he held that they were yet of a similar nature to what have been overcome before; but, all taken together, presented an unparalleled series. Whatever the cost, however, the work had every appearance of proving a financial success. Passing on, the Amsterdam Canal was instanced as illustrating the surmounting of difficulties which the early part of this century dare not approach. Amongst the other works and schemes mentioned were the entrance to the Mediterranean by means of the Garonne River, the flooding of the Sahara, the draining of the Zuyder Zee, the improvement of the Neva, and the piercing of the isthmuses of Malacca, Florida, and Corinth.

**The Operation of the Artisans' Dwellings Act** was discussed at the last meeting of the Board of Works for the Whitechapel District, when replying to the Rev. Mr. Billing, Mr. Muoro (of the Metropolitan Board of Works) said the delay in covering the cleared areas under the Improvement Schemes arose from the land being unmarketable under the conditions attached. As regarded the areas in Spitalfields, new plans were now being submitted to the Home Secretary, and awaited his approval. The Metropolitan Board would, in fact, be glad to let the land at almost any price so as to get the spaces rebuilt over. There had, probably, never been an Act of Parliament so differing in intention and operation. Intended to be a benefit to the poor, it had been a source of misery to them; and of all the people evicted from the Whitechapel District, probably not ten had returned to the new homes built for them at so enormous a cost. The Dwellings' Improvement Act was, in fact, a measure for benefitting certain portions of the middle-class, and the tenements in such places as Royal Mint-street were occupied by persons for whom they were never intended.

**Enlargement of the Wimbledon Sewage Farm.**—In consequence of the rapid rate at which the population of Wimbledon is increasing, the Wimbledon Local Board have found it necessary to increase the area of their sewage farm for the disposal of the constantly-increasing sewage of the district, which they have found to be very profitable as applied to the land. The area of the Board's farm at present under cultivation is upwards of sixty acres in extent, and land for the purpose having been purchased by the Board immediately adjoining the present farm. This land is situated on the main road from Merton and Wandsworth, lying between the River Wandale and the South-Western Railway. It has for some time past been occupied as the Wimbledon and Wandsworth brickfields, and last week, in consequence of the Local Board requiring immediate possession of the land for their sanitary works, the whole of the brickmaking plant and machinery on the ground was sold by auction. In illustration of the expansion of the district within the area of the Local Board, it may be stated that during the present year upwards of 1,000 new houses have been erected, whilst in addition large numbers are now in progress. Several land companies have recently purchased estates in the locality, including the British and the Birckbeck companies, and the last-named company has just laid out upwards of one hundred building sites in Queen's-road, South Wimbledon.

**The Plumbers' Congress.**—As will be seen by an advertisement in another column, arrangements have been made for the holding of a conference in connexion with the Plumbers' Congress, at the Technical Institute, Health Exhibition, South Kensington, on Monday next. The mayers of forty of the principal towns in England have already accorded their co-operation to this object, and many of the leading practical plumbers in and about London are giving their assistance.

**Lifts.**—Judging from the frequency with which we receive particulars of new lifts and lifting machinery, that branch of mechanical engineering is in a prosperous condition. That it is likely to remain so may be inferred from the ever-increasing height of town-buildings, which renders the use of lifts an absolute necessity. Amongst the firms who have "laid themselves out" for lift-work are Messrs. Archibald Smith & Stevens, of Queen's-road, Battersea, and the American Elevator Company, of 35 Old Jewry. Messrs. Smith & Stevens have just completed two sets of hydraulic lifting-machinery in connexion with the Hydraulic Power Company's mains,—one at Messrs. Spencer Wicks & Co.'s new premises in Watling-street, E.C., and the other at Mr. A. Steddall's premises, Adde-hill, E.C. This new system of public supply of hydraulic power is, we are told, finding very extended application. The same firm have also in course of construction for the Mont Doré Sanatorium, Bournemouth, two hydraulic passenger lifts upon Stevens & Major's patent suspended principle. America is renowned for its lifts, which were in general use in the States while they were only to be occasionally met with in this country. The development of lofty buildings used as residential flats, in New York especially, would probably never have been attained to without the aid of the system of lifts which is in vogue in America. The American lifts differ in some essential points from those in use in this country, and the American Elevator Company, believing that its productions will commend themselves to English architects, are introducing them here. The Company has lately received an order for one of their "Standard" hydraulic lifts for passenger service, and especially for the use of invalids, to be erected in the London Temperance Hospital, Hampstead-road. The American Elevator Company claim that their New York and Chicago houses (Messrs. Otis Bros. & Co. and W. E. Hall & Co.) have produced more than half of all the elevators "running" in the States.

**The last of Sion College Buildings.**—In a few days the last remaining buildings in connexion with old Sion College will have finally disappeared. The hall has already been taken down, as well as several other buildings belonging to the college estate, and the whole of the site of the college having now been let on building leases, Messrs. Fox & Bonsfield last week sold the materials of the library, and the ancient gatehouse in London Wall,—the sale of the library, in addition to the building itself, including the bookcases, book-shelves, and fittings. In taking down the library, arrangements have been made for the preservation of the stone in the Philip-lane frontage which records the circumstances under which the college was originally founded, together with the re-erection of the college buildings after their destruction by the Great Fire of London. We understand that this stone is intended to be placed in the new college buildings now in course of erection on the Thames Embankment. We also learn that the valuable collection of books forming the library will be deposited in temporary premises in Aldergate-street, pending the completion of the new hall and library. The new buildings to be erected on the site now being cleared are all of a commercial character with frontages in London-wall, Philip-lane, and Aldermanbury-avenue.

**Surrey Archaeological Society.**—At the ordinary monthly Council meeting of this Society, at S. Dane's Inn, held last Wednesday, the 15th inst., two new members were duly elected, viz., Colonel de Cetto and Mr. John Pettit Griffith. After the Council meeting was over, a special general meeting of the members of the Society took place, Mr. Granville Leveson Gower, F.S.A., presiding, when the following resolution was unanimously adopted:—"That Rule 13 be altered in such a manner that the annual general meeting be hereafter held in the month of January or February, instead of the month of June or July, as at present."

**The Fine Art Society.**—The following exhibitions will be held by the Fine Art Society during the autumn:—(1) Sketches in France, Italy, Spain, and other countries, by Ernest George (to open on Monday next); (2) The works of Linley Sambourne; (3) Venetian and Italian Drawings by the Russian painter, Count Roussoff; (4) Pictures and Drawings by J. D. Linton.

**Messrs. Farebrother, Ellis, Clark, & Co.'s New Premises in Fleet-street.**—For several months past the premises in Fleet-street, nearly opposite St. Dunstan's Church, which for some years were occupied as the West-end offices of the Norwich Union Insurance Company, have been undergoing extensive alterations. The building, which contains five floors, with an elevation to Fleet-street upwards of 60 ft. in height, is faced with grey and red polished granite and Portland stone, in which a profusion of carving and sculpture is introduced. The whole of this frontage has been cleaned, and, where necessary, re-faced and restored. Internally the building has been re-constructed and entirely re-arranged, and enlarged in the rear by the construction of new buildings about 100 ft. in depth, extending to the boundary of Goldsmiths-court and the Temple Church. The whole of the interior has been fitted and arranged for Messrs. Farebrother, Ellis, Clark, & Co., the well-known auctioneers, surveyors, and estate agents. The ground-floor, extending from the Fleet-street entrance to the rear of the building, has been arranged in several separate departments, and contains, amongst others, the general office, also the office for the sale and letting of houses and estates, cashier's office, accountants' office, estate and drawing office, London and Country Sales offices, waiting-room, and other offices. Sir J. W. Ellis's private office and waiting-room are on the first floor, facing Fleet-street, and at the rear of this floor are the architect's office and the drawing-office. The second floor is appropriated to agency in connexion with landed estate and estate sales. The third and fourth floors are set apart as the housekeeper's residence. In the basement are several strong-rooms and lavatories, also a gas-engine for working the dynamo for the electric light by which every apartment in the establishment is lighted.

**The Steel Square.**—Pliny says that Theodorus, a Greek of Samos, invented the square and level, but this cannot be, for the square figures in the represented designs of the Tower of Babel, one of the earliest known structures. The city of Babylon was a perfect square, and the bricks used in its buildings and walls were square; so probably were those in Babel. Now, to form small squares correctly, and to introduce them in endless combination into buildings, it needed a guiding instrument of some kind. So the square, as a constructive tool, came into use. Among the ruins of Babylon, Nineveh, and Petra, it is said to have been found represented. There are pictures and sculptures from the ruins of Thebes, in Egypt, showing the square in the hands of the artisan. Evidence of its use are also to be seen in ruins in India, which are thought by some to ante-date those found in Egypt. Among the ruins of the Aztecs, or the people before them, in Peru and Brazil, it has also been found; and though tools of stone and flint, such as axes, hatchets, hammers, &c., were the first used by primitive man in these ruins that date back beyond history, the square is found, and specimens may be seen in the British Museum.—*Iron.*

**Building at Tulse Hill and Dulwich.**—In connexion with many other suburban localities, building has been proceeding at a rapid rate during the last few years in the neighbourhood of Tulse Hill and Dulwich, and with the view of still further developing building operations in the district, a new company has just been formed for the purpose of purchasing the Tulse Hill Park Estate, and also the Manor House Estate at Dulwich, consisting of several acres, and stretching a considerable distance in the direction of Sydenham. Some two or three years ago this estate was laid out for building upon, when the old Manor House was demolished. The capital of the new company is 150,000*l.* in 10*l.* shares.

**The Association of Municipal and Sanitary Engineers and Surveyors** is to hold a Northern District meeting this day, Saturday, the 18th of October. The members will assemble at the Town-hall, Stockton, at 10.30 a.m., so that the ordinary business may be transacted in time to leave the Corporation Wharf by steamer, at 11 o'clock sharp, to inspect the lighthouses, breakwater, and other river works at Tees Mouth. Mr. John Fowler, M.I.C.E., Engineer to the Tees Conservancy Commissioners, will explain the river works.

**New Bridge at Bsdford.**—The works in connexion with the construction of the new iron roadway bridge and approaches over the River Ouse, for the Corporation of Bsdford, are now nearly completed, and preparations are being made for the opening, which will take place on Tuesday next, October 21st, the Right Hon. Earl Cowper, K.G., performing the ceremony. The works have been designed and are being carried out under the superintendence of Mr. John J. Webster, A.M.I.C.E., of Stephenson-chambers, Liverpool, the contractors for the masonry and brickwork, &c., being Messrs. S. W. Pilling & Co., of Manchester, and for the ironwork Messrs. Goddard & Massey, of Nottingham.

**Ensilags at Eastwll Park.**—The ice house silo of H.R.H. the Duke of Edinburgh was opened about three weeks since. The result has been in every way satisfactory, and a very marked increase has been noted in the yield of milk from those cows fed on the silage. The patent mechanical pressure of Messrs. F. W. Reynolds & Co., of Acorn Works, Edward-street, Blackfriars-road, London, was used in this silo.

**Akeley.**—The four-light east window of Akeley Church, near Buckingham, has just been with Munich stained glass by Messrs. Mayer & Co. It represents the Birth of Christ, His Baptism, the Angel at the Tomb, and the Supper at Emmanus.

**COMPETITIONS, CONTRACTS, & PUBLIC APPOINTMENTS**

*Extrane of Advertisements in this Number.*

### The Hellenic Society.

**T**HIS Society, whose full title is "The Society for the Promotion of Hellenic Studies," has now been in existence for, we believe, something over four years, and held its first meeting for the present autumn session on Thursday afternoon last. Though the Society includes in its list of members not a few distinguished names, and has put forth a Journal which, for weight of matter and beauty of illustrations, stands high among European archaeological publications, its existence and its doings seem in England to attract but little notice beyond the circle of those specially-informed people who make up its not too numerous ranks. A report of its annual meeting appears, perhaps, periodically in the leading daily paper, and the "general reader" wonders why people should get together and discuss with such apparent interest the paintings on an ancient jar, or an unexpected discovery of an inscription in some out-of-the-way corner in Asia Minor. And had there always been Hellenic Societies and British Museums, we should not so much require them now. But whole centuries passed away, during which it was forgotten that people called Greeks ever lived on European soil, and left behind them the brightest legacy of perfection in art and literature that any race of men has left. Their exquisite buildings have been allowed to go to ruin, or have been wantonly defaced and destroyed by violence; much of their glorious literature has disappeared, never to be recovered; and now, when it is all but too late, the modern educated world has awakened at last to the fact that all remnants of that age of joyous artistic insight and achievement are precious, either for their intrinsic beauty, or, in the case of archaic work, for the light which they may throw on the early history of Europe, on the development and race-connexions of the Greeks themselves and of contemporary peoples, on doubtful points of philology and archaeology, and on the genesis of the European art of which the Greeks are the founders; and the cry among those who appreciate the interest of such relics is, "Gather up the fragments that remain," that at least nothing be lost of what remains to find, which may prove to be more than we can at present estimate.

The objects of the Society for the Promotion of Hellenic Studies, as stated in their "Rules," are (1) to advance the study of Greek language, literature, and art, and to illustrate the

history of the Greek race in the ancient, Byzantine and neo-Hellenic periods, by the publication of memoirs and un-edited documents or monuments in the journal of the society; (2) to collect drawings, transcripts, photographs, &c., of Greek inscriptions, MSS., works of art, and ancient sites and remains, inviting the co-operation of travellers in communicating notes of what they have observed; and (3) to organise means by which members of the society may have increased facilities for visiting ancient sites and pursuing archaeological researches in countries which at any time have been the sites of Hellenic civilisation. A considerable portion of this programme, as the Journal and illustrations for the past year sufficiently prove, is in the way of being realised. A further object which the society has much at heart, and which was specially referred to by the President, the Bishop of Durham, at the annual meeting in June last, is the establishment at Athens of a British school or institution for Hellenic research. Until, the President observed, there was such a centre of work established on Greek soil, Hellenic studies in England would be at a decided disadvantage. In an article not long since we referred to the melancholy fact that at Rome the archaeological visitor knew only too well that it was to the German Archaeological Institute that he must betake himself to have the latest and best news of archaeological exploration. The want of interest in such subjects evinced by the English Government is but too well seconded, in the negative sense, by the indifference of the British public. Men who are supposed to represent both culture and wealth will spend disproportionate sums on curiosities in china ware, which are of comparatively recent date and inferior artistic worth, but can find nothing to bestow in assisting such a research as that of Mr. Wood at Ephesus, after the poor pittance granted by the Government had been exhausted. An increased membership of the Hellenic Society, a wider circulation of its publications, and a more general public recognition of its objects and of the work it is doing, might do something to break through the apathy of even the educated portion of Englishmen on this subject. The increased attention which has of late years been paid to archaeology in our universities, more particularly at Cambridge, will no doubt have its effect in time; and, as Mr. Newton said at the annual meeting before referred to, the hope is that young men are now being trained at our universities who will be in time competent to carry out the work of exploration. For twenty years past, he observed, there had been in France and Germany a constant succession of young scholars, first sent to the schools at Athens, then upon

special missions, and in course of time promoted to chairs of archaeology at the different universities; and it is a significant fact, as was observed in our columns not long since, that German is now almost the recognised language of archaeology.

Looking through the last volume of the Society's Journal, we observe that architectural subjects do not at present occupy a very large portion of its attention; and in connexion with this fact we may observe that the name of the author of the most valuable work on Athenian architecture that has ever appeared is not on the list of members. Whether this is because the Society does not know Mr. Penrose, or that he does not know the Society, we cannot say; but either way the omission is to be regretted. But we rather fear it is with Greek archaeologists as it is with other people,—architecture is one of the last subjects connected with the arts in which interest is felt. It may be added, perhaps, that Greek architecture has been a great deal studied and illustrated already, while the systematic study of Greek sculpture is only of recent date, and there are many very interesting problems connected with it at present demanding solution. There is a passage of arms in the Journal between Professor Sayce and Dr. Jebb in regard to Hissarlik, in which the latter sums up to the effect that while the large pre-Iliad settlement, of which remains exist at Hissarlik, "may be that town the capture of which at an unknown date gave rise to the legend of Troy, the data of the Homeric poems for the site of Troy cannot be really reconciled with any one site in the Iliad. Some of them suit Bunar-bashi only; others suit Hissarlik best. The town adumbrated in the Iliad is, in all its architectural details, purely poetical. . . Homer's Troy, in the sense of an actual town, described by a poet recording historical fact, has not been found at Hissarlik, and will never be found anywhere." To which we may say, with Sancho Panza,—"God hless me, did I not tell you so?" But the contributions on subjects specially architectural are interesting, though brief. One is a description, accompanied by very full drawings, of a small prehistoric building near Salamis, which has been measured and drawn by a German gentleman, Herr Ohmfalsch Richter. It is a chamber of about 35 ft. by 20 ft., of Cyclopean masonry, and with a circular barrel-vault and a small chamber leading out of it cut in the rock, which latter has been roofed by an immense monolith, flat in the first instance, but from which a sloping roof, gable-shape, has been worked half out of the soffit of the stone and half out of the rock on which it rests. Though the main chamber is rectangular, the resemblance of the whole construction, in general idea and plan, to

those of which the "treasury of Atreus" is the best-known example, is certainly striking. It has been supposed by some to be a tomb, but there is a hollow cut inside in the ponderous stone lintel, communicating with a kind of porticulis groove in the lintel and jambs, which was evidently a provision for closing the opening with some kind of door from inside; and, as Herr Richter pithily says,—"Dead men cannot close a door." A communication by Dr. Waldstein, curator of the Fitzwilliam Archaeological Museum, on "Views of Athens in the year 1687," is of considerable interest. It is in relation to two sketches in the library of the late Sir Thomas Phillips at Thirlestone House, Cheltenham. These views, from an old book of sketches done by some unknown Italian visitor, show the distant Parthenon in the fourth period of its consecration, as a Turkish mosque,\* with a tall minaret added, which figures conspicuously in both sketches. The Parthenon was a mosque from 1458 to September 26, 1687, the ill-fated day when the Venetian mortars succeeded in sending a shell into the temple and igniting the powder stored there. There are letters extant showing that among the officers concerned in the attack were some who had an interest in art, and it is conjectured that the drawing published in the Journal was a sketch from a distance by one of these officers before the event of the bombshell. The larger sketch is a kind of half plan, half view, of Athens, with the fortification of the Acropolis shown, and the city on the sloping ground below; the Temple of Theseus, the Piræus, and the long walls, are indicated. The vignette from the same book of sketches is also given, showing a kind of picture-frame design, with a roughly-sketched head-piece in which are represented the owl in the centre, and Athene and Poseidon seated on the slopes of the frame on either side; below, in the square centre-space, is the sketch of the Acropolis alone, from nearly the same point of view as the other. The sketch is on a very small scale, but there is an attempt to indicate something on the roof, more than mere straight lines, which is deserving attention. Dr. Waldstein refers to a drawing by Herr Von Duhn in the *Mittheilungen* of the German Archaeological Institute at Athens, in which three small "opæia" are visible in the centre of the roof, and refers to the possible bearing of these indications on Mr. Ferguson's theory of the lighting of Greek temples. There are on the little frontispiece sketch published in the Journal certain dots along the roof, to which Dr. Waldstein does not refer, but which must mean something. They may be only an attempt to indicate the effect of the *antefixa*; but it seems a question whether the *antefixa* could be prominent enough, at the distance from which this sketch must have been taken, to attract the notice of a draughtsman making a rough sketch on a small scale.

Among the most interesting of the papers bearing on ancient art generally, in one on two archaic sarcophagi found at Clazomenæ in 1882, the designs on which are reproduced both by cuts in the text and by a finely executed monolithograph among the larger separate plates; and there is a paper by Mr. Percy Gardner on a very beautiful statuette of Eros, of gilt terra cotta, which was presented by the King of the Hellenes to the Princess of Wales, and which Mr. Gardner believes to be probably a copy of a modification of a design of Praxiteles. A very interesting and thorough article by Miss Harrison, on "Monuments relating to the Odyssey," deals with certain representations in vase paintings of the escape of Ulysses and his companions from the cave of Polyphemus. Miss Harrison is proposing, we observe, to classify the existing illustrations of "the whole series of myths of the Trojan cycle"; such a compilation from so thorough an investigator will have a lasting value. The finest illustrations published among the separate plates are, however, the chromolithograph reproductions of the paintings of the sarcophagus found at

Corneto in 1869, and now in the Egyptian and Etruscan Museum at Florence. The lithographs are by Steinbock, of Berlin, and are alone sufficient to make the album of plates worth possessing; the figures, though all partly obliterated, are very fine and powerful in action and expression, and the execution of the plates is splendid. Plate xxxvi., where a very beautiful Amazon turns round on her horse to strike at the man behind her, is especially noticeable. These paintings, which belong to a late period of Greek art (probably about 300 B.C.), are far more pictorial than the conventional and more decorative vase paintings which are generally associated with the idea of Greek painting; the features and figures being delicately modelled and shaded.

Since the previous remarks were written we have learned that the Committee for Promoting the Formation of an English Archaeological School at Athens, which is officially a separate body from the Hellenic Society, have received a free grant of a piece of land for the purpose from the Greek Government, the enclosure of which will be carried out immediately, and that they have collected 4,000*l.* towards building and enclosing the proposed institution. This, of course, is not a fifth part of what will be required, but we have got thus far on the way; and it is to be hoped that others who are able to do so will give speedy and substantial assistance to enable England to take as honourable a place in the strife for knowledge as Germany has already taken.

Of the meeting of the Society on Thursday afternoon we can necessarily only speak very briefly. Mr. Newton occupied the chair, and a very interesting paper was read by the head-master of Eton, the Rev. E. Warre, on the raft built by Ulysses to escape from Calypso's island. Mr. Warre, who joins a knowledge of boats and boat-building to Greek scholarship, went, in a very detailed and practical manner, into Homer's workmanlike description of the construction of the raft, and illustrated his remarks by a model, showing the conjectured shape and method of construction, and by some copies of Egyptian drawings, showing certain forms of tools, of which also models had been made, reproducing the ancient tools in actual working form. This paper was followed by one from Mr. Ernest Gardner on some of the objects found in tombs at Kertch, and now in the new museum at Oxford. The special value of these is that they serve to represent, to those who have not been to St. Petersburg to inspect the rich collection of archaeological treasures from Southern Russia, the type of work which is mainly characteristic of the Hellenic remains in that part of Europe. The paper was illustrated by several pages of lithographed plates, which will, we presume, eventually form a portion of the Society's Journal, and which represent a good many beautiful bits of decorative work in the way of personal ornaments (found in the tombs of women), almost purely Greek in style and feeling, though presenting some special peculiarities which added to their interest. Mr. Gardner remarked on the extreme delicacy of the gold-work in many of these ornaments, the gold being only a thin sheet *repoussé*, and in some cases ornamented with minute spirals of gold wire made separately and applied to the surface. Of course all who are familiar with Greek gold work are aware of this characteristic of the sparing and delicate use of the metal, and we have often commented on the contrast between this and the goldsmith's work of to-day, when the object seems to be to have as much bullion in proportion to the real art work as possible.

We hope the Society for the Promotion of Hellenic Studies will ere long enlarge its borders, and also that it will be able to take up and throw additional light upon some of the interesting questions concerning ancient Hellenic architecture, which should receive its due proportion of attention among the other branches of archaeology which are included in the field of Hellenic study.

## THE LIFE OF SIR HENRY COLE.\*

 ALF a century of genuine work is something for the doer of it to look back upon with satisfaction, and it must be conceded that Sir Henry Cole was fairly entitled to indulge in this feeling. There may be more than one opinion as to the character of some of his work, but all will agree that it was executed with energy. Energy, indeed, when it shows itself in the form of restless desire to set things and people straight, is apt to make a man fussy and self-important, and if, in addition, he be a little too conscious of his own merits and a little too fond of the smile of the great, the shafts of hostile criticism are likely to fall pretty thickly around him. But, happily for himself, Sir Henry had not the sensitive nature of a poet, and so the remarks in which Saturday Reviewers indulged, and which were often "tartarly" enough, seldom ruffled his temper and never provoked a retort.

"Populus me sibilat, at mihi plaudo  
Ipse domi."

He went his own way, displaying ever a cheerful optimism which neither hard words nor hard work could impair.

Cole had done substantial service to the State in more than one department before the Great Exhibition of 1851 brought him into public notice. He helped to organise the Public Record Office, and was associated with Rowland Hill in the reform of the General Post-office. Quick to see anomalies and abuses, and fertile in plans for their removal, his aid was most acceptable to those who were fighting the battle of progress. He knew, too, the value of ridicule, and, notably in the contest about Railway Gauges,—employed it with signal success. A good cartoon or a page of pungent satire from the pen of a Thackeray could, he thought, influence public opinion a hundredfold more than infallible figures or the most logical arguments.

The special work, however, with which Sir Henry Cole identified himself from an early date was the application of the Fine Arts to the manufactures of the country. He saw that while English productions had a high reputation for cheapness and intrinsic excellence, they were deplorably deficient in beauty of design, in symmetry of form, and harmony of colouring. What, then, he set himself to do, and what he urged the Society of Arts to take in hand, was,—in his own words,— "to wed high art with mechanical skill, or to bring about the union of the artist with the workman." It was in furtherance of this idea that the International Exhibition of the products of industry was set on foot. At the outset very little else was proposed than a merely National Exhibition, but Prince Albert very quickly saw that the object which they had in view would be best secured by gathering together under one roof the productions of all countries, thus bringing into high relief our neighbours' excellences and our own defects. The marvellous success which attended the execution of the idea has been somewhat lost sight of in the crowd of events that have since happened. It is one of the advantages of this memoir that it brings together, in very readable fashion, contemporary records of all that occurred in connexion with the Great Exhibition of 1851. We may, perhaps, demur to Sir Henry's statement that "no event comparable to it in its promotion of human industry is to be found in the history of the world," but at least it must be allowed that it gave an impetus to English manufacture which is still felt, and did much to promote that union between "high art and mechanical skill" on which the enlightened mind of the Prince Consort was largely set. It is amusing at this distance of time to read of the various panics which the scheme created in men's (and women's) minds. The public were assured by the Astronomer Royal that Paxton's glass house must by demonstration infallibly fall to pieces.

\* As most of our readers know, the Parthenon has been successively a temple of Athene, a Greek church, a Roman church, and a Turkish mosque.

\* "Fifty Years of Public Work of Sir Henry Cole, K.C.B., accounted for in his Desks, Speeches, and Writings." Two vols. London: G. Bell & Sons. 1884.

The Duke of Wellington brought 10,000 additional troops into the neighbourhood of the metropolis to deal with apprehended disturbances. Colonel Sibthorpe, in the House of Commons, prayed that hail or lightning might descend from heaven to defeat the ill-advised project. Telegraphic arrangements were made between the Executive Committee and the Police Commissioners, to deal at any moment with the unruly mob; but, adds Sir Henry Cole, "these curious devices were never employed; and it may be said that the great building, even with 93,000 persons in it at one time, was never so crowded as a lady's successful *sobriété*."

As to the results of the Exhibition we have Cole's own opinions, as given in a lecture delivered in December, 1852. He expressed his belief that in the domain of art England had learned most from the Eastern exhibits, while in mechanical appliances America had taught her some valuable lessons. Insular prejudices had been lessened, competition in new fields of labour had been suggested, and the inter-communication between countries by a general postage system had been largely promoted. The lecturer would have done wisely if he had contented himself with these conclusions, and abstained from the perils of prophecy. Unfortunately, he went on to say that the Reform of the Patent Laws would be a speedy result, that open councils would be substituted for secret diplomacy, and that nations would be kept back from going to blows as hastily and foolishly as they have been accustomed to do. From the last and happiest result we seem to be as far off as ever, but its realisation then seemed possible to many minds. Lord Macaulay expressed the prevailing opinion when he said,—"This will long be remembered as a singularly happy year of peace, plenty, good feeling, innocent pleasure, national glory of the best and purest sort."

With the later exhibitions of a similar kind both at home and abroad Cole was necessarily much associated. He advocated the adoption of an arrangement of "like objects with like objects" as being more scientific and technically useful than the geographical system. But it involved more cost and labour, and was neither so picturesque nor so popular. The exhibitions held in 1871 and the three succeeding years were financial failures, though each was, so far as manufactures were concerned, an improvement upon its predecessor. But as the quality improved, the novelty wore off, and, however technically instructive they may have been to the few, they ceased to be attractive to the many.

Sir Henry Cole's services at the Science and Art Department and South Kensington Museum were of a more enduring character. The former was rather the consolidation of a number of existing institutions than the creation of an absolutely new one. The oldest of these institutions,—the Royal Dublin Society,—had been in the receipt of an annual public grant from the year 1800, and elsewhere there were numerous schools and museums which were practically without control, though nominally under the Commissioner of Public Works or the Board of Trade. All these, re-organised and developed, were placed under the Committee of Council of Education, and no little credit is due to Henry Cole for the share which he bore in carrying this arrangement into effect. A genuine interest in technical training, immense industry, a clear head for details, and excellent health, were the chief qualifications which Sir Henry possessed for the posts which he occupied, and that they were occupied with credit to himself and with advantage to the State these interesting volumes abundantly testify.

As an artist and an architect Sir Henry will not be remembered; indeed, if the "Brompton Boilers" were in any degree his work,—and his son assures us that they were not,—it were well that he should be forgotten. His letters and lectures on architecture, which are re-published in these volumes, are chiefly useful for certain practical suggestions, but whether the appointment of a Council of Taste to advise on public buildings be one of these is, to say

the least, a question to be asked. The establishment of a permanent Minister of Arts we have often advocated; but that is not quite the same thing.

#### WHAT THE HOUSEKEEPER REQUIRES FROM THE ARCHITECT.

**T**HE rapid increase in the number of inhabited houses in England is a fact as noticeable from a financial as it is from a pictorial point of view. As to the latter, the up-growth of houses in many districts traversed by our great railway lines is such as to force itself even on the attention of the traveller, who may, perhaps, be limited to an annual survey from the windows of a flying train. Land which a few years ago was waste is now dotted with houses. Villages are growing into towns. Towers, and spires, and cupolas pierce the sky; and red brick "Queen Anne" houses are toning down so as to assert an imaginary antiquity. The gross estimated annual rental of England, for 1881, as valued for the poor-rate, exceeded that of 1850 by no less than 4,894,000*l.*; and although this was an exceptional spring, due in part to new valuation, the rental of 1881 exceeded that of 1871 by upwards of 38,000,000*l.*

Activity of all kinds concurs in this rapid planting of brick and mortar. Here we see the commodious mansion, reared, regardless of cost, under the eye of some magnate of the architectural profession. There we see the questionable, or even the unquestionable, work of the speculative builder. Distinct from either of these, in very different parts of the country, rise what may perhaps best be described as amateur houses,—that is to say, dwellings reared, often by retired or well-to-do tradesmen, either for their own abode or as a means of investing their savings. Many of these are built with scant aid from the architect. Sometimes a young man may be induced to act on reduced terms. Sometimes a successful foreman will develop into a builder, who asks no advice but his own. Sometimes a clerk of the works is employed by the owning builder.

It is chiefly in cases of this kind that a very serious inconvenience is arising, and in some places rapidly increasing. This is the practical unacquaintance of the builder with the requirements of family life on different scales. In every well-ordered establishment, great or small, a certain organisation exists, which ought to find its counterpart in the plan of the house. Probably the best scale by which this organisation is to be determined is that furnished by the number of servants. A house intended to be kept in order by two or three servants is not to be converted into one proper for the employment of seven or eight merely by adding two or three sleeping-rooms. The whole theory of the building differs. And in the amateur houses to which we refer, not only is there a want of keeping in this respect, but very often two or three good reception-rooms are combined with such stinted accommodation for offices of all kinds as to make a house, for which the rental proper for a family of some considerable status is asked, totally unfit for the daily requirements of such a family.

We are no believers in the hand-book system, when it is regarded as the means of enabling the purchaser to act for himself, without taking proper advice. Quackery in architecture is likely to be little less disastrous than quackery in medicine. The well-known qualification of the man who is his own lawyer may generally be taken to apply to the man who is his own architect. But with that caution, we cannot but think that there is room for some such guide for the builder as that which the Italians have devised for the railway engineer. The normal dimensions of platforms, ticket-offices, refreshment-rooms, and other station accommodation for railways of different capacities for traffic are now laid down, on the Italian lines, with accurate prevision. It would be of no little use to the young architect if he could refer to a like outcome of experience as a guide to the plan of a house.

As to the rooms that come *en évidence*, dining-room, drawing-room, study, or morning-room of some kind, sleeping chambers, hall, staircase, and kitchen, there is, probably, little to be said. Every one,—or, at least, every one who can "drive a gig," may, perhaps, have a right to indulge his or her own taste so far. But the above-named apartments do not form a house, though they often compose what goes by that name. First we should be disposed to rank among neglected specialities the arrangement of nurseries. A certain elasticity, no doubt, is here proper. But then the need for that elasticity should be kept in view from the first. Leaving an ordinary bed-room unfurnished is not the way to provide that essential to the healthy growth of children,—a light, airy, sweet, dry nursery. A room may be suitable for a servants' bed-room which will be very unsuitable for a night nursery. The combination of the two, that is to say allowing the children to live and to sleep in the same room, is a source of permanent mischief, which would be well avoided at the cost of sacrificing a boudoir, a study, or a morning-room.

Again, the want of a servants' hall is a very serious defect if (say) more than three servants are kept. So is the absence of a second staircase. So of the want of housemaid's pantry, china-closet, butler's pantry, linen-room, laundry, dairy, box-room, knife-room, coal and wood stores, scullery, and all the other requirements of the inmates of the kitchen. Health, economy, and comfort are as much involved in the ordering of this series of domestic conveniences as in the arrangement of those rooms of which the number and size are duly advertised.

A sort of rough normal specification, based on the number of servants that the house demands for its thorough keeping, might be so constructed as to be of no little value. In this not only the actual number of rooms required, but some rules for their convenient area, might be given. Thus a distinct step should be made when it is intended to lodge men-servants within the house. The size of the servants' hall should be in proportion to the number of servants. Of stable and coach-house we have not spoken, as they should not come under the general roof; but here proportionate accommodation should be indicated. And if the actual arrangements of houses known to be fully adequate to the comfort of their occupants were cited as examples, we think that a very valuable work might be written on the theme of "What the Housekeeper requires from the Architect."

#### NOTES.

**T**HE verdict in the case of the disastrous gas explosion in Bermondsey seems to us a remarkably feeble one. The Coroner, indeed, appears to have commented strongly on the conduct of the Board of Works in not sending any representative to the inquiry, as it had been stated that the leakage of the gas-main was in the first instance due to the insufficient support over their own sewer works; and the jury "censured" the gas company for not seeing that the main had been properly replaced by the sewer contractor,—a matter in which their interest, as well as their duty, might have been thought to be concerned. But when we come to the direct cause of the explosion, viz., the search for the place of escape by the gas company's servant with a naked light, a proceeding the rashness and folly of which has been condemned over and over again, and is apparent to the commonsense of even untechnical persons, mere "censure" is far below what the case calls for, and a verdict of "accidental death" is what we call little short of a miscarriage of justice. How can we expect that such gross carelessness and stupidity can be put a stop to, when death caused thereby is regarded by the law as an "accident"?

**A** CORRESPONDENT asks the meaning of "prime cost" as mentioned in specifications. Paperhangings are troubling him as they have so often troubled others. He

wishes for decisive information,—whether the price marked at the back of the pattern by the manufacturer, or the net price charged to the trade at the warehouse is really the “prime cost.” It is to be feared that the answer cannot be given as desired. In view of this difficulty architects,—who do make prime cost provisions in their specifications for stoves, chimney-pieces, gasfittings, ornamental glass, ironwork, &c.,—generally put an explanatory sentence of this sort: “prime cost prices are to be understood as the actual cash payments made by the contractor to the manufacturers, and the contractor is to make his own provision for profit, carriage, packing, &c., and fixing, in the preparation of his estimate.” Frequently, in order to make things very clear, the paperhangings have a special note in addition. The discounts, amounting to one-third or one-half (and even three-fourths in the case of old machine-made papers), are answerable for this amplitude of explanation; and the note probably runs thus, “the prices of paperhangings are to be understood as being the current nominal retail prices of good manufacturers.” Without these precautions the question is sure to be raised, and to be slurred over in a spirit of compromise, or decided by an arbitrator who tries to gather from the documents and by evidence the real intention of the parties to the contract. Many architects dislike such explanations, looking on them as cumbersome, and, in the case of prime cost being defined as actual cash payment, having a tendency towards looking unduly behind the scenes, and controlling the contractor's skill in buying and paying, and denying him the little advantages which he can secure by special bargains and cash payments. These architects, therefore, content themselves with providing sums, and the goods selected will cost those sums at retail prices; the contractor may then make his own terms and pay accordingly. If the architect finds that the employer is not likely to get good value at a place selected by the contractor, another place will be selected, and better value obtained,—always for the retail prices. Unfortunately the system of trade discounts is much misunderstood. Judges on the bench have in our hearing protested against the discounts, thinking them the same thing as “secret commissions,” and thus looking on them as one might on the receipt of a consideration to do evil. They are, in fact, allowances to constant customers who do a fair amount of business, and are served at less cost, and with more satisfaction, than chance customers who buy one thing and never come again.

THE interesting and varied series of water-colour sketches by Mr. Ernest George, which are now being exhibited at the rooms of the Fine Art Society in Bond-street, should be attractive alike to architects and amateurs. They represent many phases of Medieval architecture on its picturesque side. The work of an able architect, the drawings will be regarded with confidence by architects as likely to be trustworthy in detail, while to the amateur they represent that view of architecture which all persons with a cultivated taste for what is characteristic and picturesque can appreciate, even without any knowledge of architectural history and construction; though, of course, such knowledge will add very much to the interest of the collection. In one sense only the drawings differ from what a painter, as distinguished from an architect, would have produced; for Mr. George, looking mainly to architectural form and character, works with a restricted palette and with apparently little regard to effect of climate and atmosphere, so that the Scotch and Spanish subjects, which are side by side, seem to belong to the same climate. The drawings, which number nearly 300, and are, we understand, only the work of brief holiday periods, show a remarkable facility of work, in addition to the artistic power and effectiveness of many of them. They afford also a very interesting comparative view of the characteristics of picturesque architecture in the various countries of Europe. We come from the Château de Chambord (25),

with its mixed expression of refinement and tyranny, to the old street at Vitre (43), with its piers and beams made before the day of competition estimates; from San Gemignano with its brutal chimney-like towers, emblems of ferocious warfare only, to the elegant campanile of the Renaissance and the octagon towers of Spain; and so on through a score of significant contrasts. All architectural students should look at the collection.

MR. RUSKIN commenced last Saturday at Oxford his series of lectures on “The Pleasures of England,” which, in other words (for Mr. Ruskin happily never says anything like other people,—“for which relief, much thanks”), means a sketch of the art history of England, regarding art from the people's side, as representing what they really took “pleasure” in at various times. Of course Mr. Ruskin looks at the subject from a moral and not from a merely “art-critical” point of view. His opening lecture was on “the pleasures of learning,” by which we presume he means the period when early Saxon England was slowly learning an art from the vague and half-forgotten hints which had made their way from the fields of the dead Classic art. Curious, as Mr. Ruskin suggests, to consider what we might have been “if no Roman missionary had ever passed the Alps in charity and no English king in pilgrimage; what the clay of the Isis might have yielded if it had never been touched by the spear of Pallas and the rod of Agricola.” The course of lectures will probably be of great interest and full of brilliant suggestions, but we regret to observe that the concluding one, on the mechanical age of to-day, is entitled the “Pleasures of Nonsense.” It is regrettable that any one of Mr. Ruskin's earnestness and eloquence should deliberately refuse to see how much of greatness, of energy, of healthy influence there has been in that era of machinery which he despises, partly because he does not understand it.

FEW artists, even among those of marked ability, will bear the trial of having a large number of their works exhibited together, and Mr. Ernest Parton is not one of the few. A number of oil studies from nature by this artist are now on view at Messrs. Dowdeswells. Seen separately, they would impress us, as Mr. Parton's finished pictures do, as the work of an artist with a true feeling for nature, and a style at once broad and delicate in its translation of natural beauty through the medium of oil painting. But the collection of 100 of his studies together shows that, beautiful as they are in style, the artist's powers move within rather narrow limits. Nature is always the same colour to Mr. Parton, whatever scene he paints, and at whatever time of day; and except one or two sunsets (rather crude), he seems practically to have only one effect. It is a very good one, but—*toujours perdrix*. Some small drawings by Mr. Chas. Robertson, of coast scenery, in the same room, are worth attention. In some of them Mr. Robertson seems to have been emulating the style of small finished water-colours, pictures in miniature, which Turner did for engraving.

WE regret to hear that Mr. G. H. Birch, who designed and superintended the erection of the old London Street which has unquestionably been the central attraction to an immense number of those who have visited the Health Exhibition, has had but a very meagre recompense for his labours, having had to pay out of his own pocket the clerk of works' salary and other incidental expenses, amounting to more than 25 per cent. out of a fee somewhat inadequate to begin with. Surely the committee for carrying out the work should have been aware that the clerk of works' salary, at least, is always paid by the building owner, not by the architect. Mr. Birch has further had the pleasure of seeing an illustrated guide to the “street” brought out by a large publishing firm, without any consultation with him, swarming with mistakes and describing houses that are not in the street at all. Mr. Birch has every right to feel proud of his work, which has given pleasure and interest

to many thousands of people, but, apparently, virtue is mainly its own reward in this case.

MR. DOBBS, the champion of the consumer against the water companies, has published an audited statement of accounts of the money subscribed by public bodies and private individuals to arm this modern St. George for his conflict with the dragon. The costs have been somewhat heavy, but, says Mr. Dobbs, “Bearing in mind that not only the annual income, but the capitalised amount to be paid under any compensation, is affected by the case; and considering that this has been accomplished by an expenditure of less than 800*l.*, I think the result will be satisfactory to London; and I may look back on my three years' work and anxiety without regret.” Mr. Dobbs proceeds to draw attention to the still unsatisfactory state of several matters connected with the metropolitan water supply, such as the increased charges lately made for water rate on business premises, the want of any decision of the Courts of Law as to the proper method of supply to such premises, the state of the law as to charges for stable and coach-house supply, the regulations as to fittings for constant supply, and, of greatest importance, the unregulated power of cutting off supply as the readiest means of compelling acquiescence in doubtful claims.

AMONG stray exhibits at the Health Exhibition which deserve mention is a model showing “Quayle's Patent” for a new way of connecting guard-bars with window-sashes, the bars being attached to the under-side of the bottom bar of the sash and rising through the sill when the sash is raised. A simple means of disconnecting the bars at pleasure is provided, but this can also be locked by a key working in the sash bar, so as to prevent any but the master hand from disconnecting them. This provision for the security afforded by bars, without their unsightly appearance as a permanent screen to the exterior of the window, ought to be very useful in such buildings as lunatic asylums and hospitals, and also in the nurseries of private houses.

FROM a Melbourne paper we notice that an interesting lecture was given before the Adelaide Chamber of Commerce, by Mr. T. W. Chambers, hon. secretary to the River Darling Navigation Company, on making the Darling navigable all the year round, and that a committee had been formed to co-operate with that company in their endeavour to carry out the project. It appears that the New South Wales Government is desirous of diverting the trade of the district of Riverina from Melbourne and Adelaide to Sydney, whereas its natural outlet is by the rivers Darling and Murray; but owing to an insufficiency of water, the former is often closed for more than six months in the year. It seems that though this state of things has repeatedly been brought to their notice, the New South Wales Government refuse to apply any remedy. Mr. Gordon, “the well-known Victorian hydraulic engineer,” reported that it would be possible to lock the Darling from Wentworth to Wilcannia, so as to make it permanently navigable, for 310,000*l.*, and that the annual cost of maintenance would be only 7,250*l.* The scheme, if carried out, will yield, it is estimated, a return to the shareholders of 8 per cent., and be of immense advantage alike to Riverina, Victoria, and South Australia.

PREVIOUSLY to 1829 the angle formed by the north transept and choir at St. Giles's Cathedral, Edinburgh, was occupied by a building of several stories, having a domestic aspect, and which may have been the residence of the sacristan. In order to make this building correspond in outward appearance with the chapel of St. Eble, which occupies a similar position to the west of the transept, Mr. Burn caused large three-light tracered windows to be inserted in the outward walls to the north and east, although internally there was only a room of about 11 ft. square cut off from the choir by a solid wall. This room was

fitted with a flat plaster roof, and was used as the vestry up to the time of the restoration undertaken by the late Dr. William Chambers. The architect of the restoration, Mr. W. Hay, proposes to open up this chamber towards the choir by forming a boldly moulded arch, stripping off the lath and plaster from the walls and substituting a stone groined roof for the plaster one. The walls would be faced with stone, the floor paved with marble and screened off by a wrought-iron railing similar to those of the other chapels. It was suggested that the chapel thus formed should serve as a memorial of and be occupied by a recumbent figure of the restorer. Instead of the effigy the Lord Provost's Committee have expressed a preference for filling the windows of the chapel with stained glass, but this it is thought might be left to private donors, who, as experience has shown, are ready to undertake this part of the work.

**THE** "Union Centrale des Arts Décoratifs" continues with varying success its course of meetings and lectures. After M. Baudot on ceramic art, followed M. Appert on glass-work, and M. Ph. Burty with another critique on ceramic art, but on that of Japan and the far East more particularly. A lecture by M. Paul Sédille on contemporary architecture in France and the rest of Europe is expected to be given shortly.

**THE** annual public meeting of the "Académie des Beaux-Arts," in Paris, which took place last Saturday, went off with more than usual éclat. The musical performances, consisting of an "Ouverture Symphonique," composed by M. Brontin, a "pensionnaire" student at Rome, and a "scène lyrique" by M. Debussy, the holder of the first "Grand Prix" for musical composition, are spoken of as exhibiting qualities beyond those of students' compositions generally. In the discourse of the President, M. Guillaume, the unity and relationship of the arts seem to have been especially recognised in a passage which is in other respects sufficiently suggestive for quotation.—"Le point essentiel est toujours de savoir si ce que l'on peint, si ce que l'on sculpte, si ce que l'on chante est l'exacte expression de ce qu'il y a de plus profond dans le sentiment, si l'on ne sacrifie rien de cette vision, invisible à tout autre, que l'on porte en soi, si on ne lui donne pas une forme mensongère, si l'on ne se trahit pas. Cas de conscience perpétuel, dirai-je, travail d'honneur que l'artiste doit faire sur lui-même, et qui, dans l'élaboration mystérieuse de son œuvre, est le seul dont il ait le secret."

**THE** Metropolitan Board, at their meeting on Friday last, declined to grant a certificate under the Metropolitan Management and Building Act (Amendment) Act, 1878, in respect of the large concert-room (to be called Connaught Hall), at the west end of the Albert Exhibition Building, Prince of Wales's-road, Battersea Park, on the ground that the building does not comply with the Board's regulations with regard to places of public entertainment. The building in question has, however, been licensed by the Surrey magistrates apparently without waiting for the Board's certificate.

**THE** Joint Committee of the Metropolitan and Metropolitan District Railways have sent us a formal announcement that in consequence of numerous suggestions they have altered the name of "Eastcheap" Station on their new length of line to "Monument Station." One name seems to us as good as the other for practical purposes, and "Eastcheap" goes much further back in the history of London than "Monument." It would be more to the purpose if the directors would direct their minds to the "numerous suggestions" they have received as to the necessity of accelerating the traffic on the line. That we should arrive at a station in decent time is of more importance to most of us than what name we shall find it called by when we do arrive.

NEW LIGHT ON THE HERMES OF PRAXITELES.

THE German excavations at Olympia are long since closed. It is scarcely possible that the deserted plain will give up a new statue by Praxiteles, or even a fresh fragment of a pediment by Pæonios. But when the actual discovery,—the excavator,—ceases from his labour a new work sets in scarcely second in importance. Discovery is over, interpretation begins. Only a few can discover, the field of interpretation is open to all. The mass of material remains the same, but from time to time this or that monument is lighted up with fresh light,—an unexpected link binds the known to the unknown,—an unmeaning, isolated detail wins by a right juxtaposition its right significance. Dr. Purgold, in his "Olympische Weihgeschenke," has made no new discovery; but, in a wonderfully ingenious way, he has seen the meaning and relation of two or three old ones, and by so doing has incidentally given us a more secure foothold for dating the famous Hermes of Praxiteles. His ingenuity, though equally great, might have won him less applause had it involved any statue less widely popular.

We all know where the statue was found, and what Pausanias said of its surroundings when he noted it in the Heraion. In this ancient sanctuary, "more museum than temple," as it has been happily called, his admiration was aroused by the great number and beauty of the archaic works of art there gathered together, the old chest of Cypselus and a host of other curious works in gold and ivory. But, as he passed out of the Heraion, he noted three other works standing within the cella, works which had been added later. These were the well-known Hermes and an Aphrodite by Kleon; and, further, in front of the Aphrodite, the statue of a naked boy gilt over, which, Pausanias adds, was the work of Bœthos of Carthage. The Aphrodite we may dismiss, only noting that it was the work of Kleon. We know that he made another statue for an Olympian shrine about 384 B.C., so that he may quite naturally have been still at work about 360 B.C., the date we shall seek to establish.

It is on this other statue of the naked golden child or babe *païdion* that Dr. Purgold has expended his ingenuity. It has puzzled archaeologists a good deal. The fact that Pausanias leaves it unnamed and unexplained has led many to suppose that it was a mere *genre* composition of no mythological significance, and, relying on this theory, Dr. Overbeck has sought to identify it with the famous Capitoline "Boy extracting the Thorn." But Dr. Purgold has something better to offer us. He starts naturally from the assumption that a statue, occupying an important place in a shrine so important as the Heraion, would have some well-defined and weighty significance. He happily recalls that in a terrible crisis of the affairs of Olympia a very significant part was once played by a naked child. Pausanias himself tells the story (vi. 20, 4 and 5). But he tells it not *apropos* of the child in the Heraion, but when describing the sanctuaries of Sospolis (saviour of the State). The Eleans, the proper owners and defenders of the Olympian plain and its sacred games, were hard pressed by the Arcadians; the boy Sospolis was as yet a child at his mother's breast, and the mother dreamed that the child should save the Elean host. They placed the child naked in front of their battle array, and as the Arcadians came up, the child was changed into a snake, and, panic-stricken at the omen, the Arcadians broke and fled. The Eleans consecrated a shrine in their capital to their deliverer, Sospolis, holding it near to the temple of the goddess Tyche (Fortune). In the shrine was a picture of Sospolis,—he was represented as a child dressed in a chlamys, spotted with stars (no doubt to indicate the metamorphosis into a snake), and in one hand he held the horn of Amaltheia. Another picture of him was exhibited on the actual spot where he was said to have appeared.

No record is left us of a statue of the saviour-child, and yet what more probable, what more almost certain, than that such a statue existed. And if it did exist, what place more likely for its exhibition than the Heraion? The shrine proper of Sospolis was only accessible to the priestess. It stood on the Kronion-hill, at the foot of which lay the Heraion, ready to hand for a commemorative statue.

The question of the identification of this child statue by Bœthos with Sospolis is in itself of great interest, but it gains double interest from the fact that it forms one of the group of statues "added later," to which the famous Hermes belongs. If we can date this Bœthos statue, and if it be Sospolis, it follows that we can date the Hermes.

But supposing we grant that the child statue represents Sospolis, how do we securely date it? When by the help of the child Sospolis, the Arcadian host was driven back, the Eleans in their gratitude dedicated not only the shrine we have mentioned, but also a colossal bronze statue of Zeus himself, the largest that the sacred altis contained. Its height was 70 ft. The statue has, need we say, perished; but near the east front of the Temple of Zeus, on the north side, a fragment of a huge bacchion, or statue base, has been found, the dimensions of which would suit just such a colossal statue, and happily the inscription remains in part. "Of the Eleans, concerning their treaty (*quavaiac*)." In this inscription the retention of the digamma, and the irregular characteristic form of the letters, specially the N, lead epigraphists to date it as not later than the first half of the fourth century B.C. It is just at this time that the event falls to which almost without doubt the inscription refers, i.e., the Arcadian invasion. The terms of the inscription are peculiar, and can scarcely refer to any other event; the colossal bronze statue was not an anathema of the ordinary sort, not made out of the spoils of a conquered foe, but it was *πρωι θηραιων*, concerning a union or treaty only temporarily disturbed. The Arcadians themselves felt that the struggle was an impious one,—religious scruples led to dissension in their camp. The sacred festivals could only prosper when conducted by the chosen tribe of the Eleans. Accordingly, the war ended rather in treaty than defeat, and the bronze Zeus may have been even a joint offering to symbolise unity restored.

Gathering together, then, the scattered threads of our evidence, we shall not be far wrong if we closely associate together the little group of statues added later, which Pausanias saw in the Heraion, and add to them the inscribed basis of the Zeus colossus. About 360 B.C. occurred the Arcadian disaster. The invasion had devastated a great part of the altis, and from the position of the memorial temple we may suppose that the Heraion suffered exceptionally. Architecturally, it is plain enough that before the statue of the Hermes was set up the building had undergone restoration, the cella had been rebuilt, and the statues added later, i.e., the Aphrodite, the Sospolis, and the Hermes, are placed with a view to the new restoration. Immediately after the repulse of the Arcadians we may then picture to ourselves an energetic restoration of the devastated altis and an eager dedication of new temples and statues. The Heraion is rebuilt, and in the restored building is placed the Aphrodite, possibly a successor of some destroyed statue; the Sospolis, in honour of the saviour of the State; and the Hermes, carrying the child Dionysos. Dionysos was a child held in special reverence by the victorious Eleans,—his childhood was thus represented in the Heraion, while by the same artist Praxiteles, and, probably, in honour of the same victory, there was set up at Elis a statue of Dionysos full-grown. It seems possible, though Dr. Purgold does not suggest this, that the infant Dionysos in the Heraion may have been suggested by the infant Sospolis.

Not only was the old Heraion restored, but the new shrines to Sospolis and Tyche were built, and possibly to the same date belongs the Metroon.

Such a period of restoration, religious enthusiasm, and artistic activity would well accord with the political unity and strength brought about by the Theban supremacy. Anyhow it gives to a statue which has hitherto stood somewhat solitary in its fame, a background and a fitness of circumstance which, once conjectured, we should be loth to forego. It also accords well with Professor Brunn's view that the Hermes belongs to an early period of the activity of Praxiteles.

Dr. Purgold's ingenious essay forms a very fitting part of the birth-day volume dedicated to the great Olympian discoverer, Professor Ernst Curtius, on his seventieth birthday,—a work we may notice on another occasion.

## LONDON WATER SUPPLY.

The fourth annual statement\* by Mr. Alfred Lass, comprising an analysis of the accounts of the Metropolitan Water Companies has just been published, and will, no doubt, be scanned with interest by not only those who are interested in their welfare, but by many who feel that the prosperity of the companies is obtained at the expense of their customers. As it may not be in the power, however, and still less in the inclination of many to pay 15s. for a copy of the statement, we propose making a short abstract of the principal facts and figures recorded in it. The public generally are little aware of the enormous duty which the several water companies have to perform in order to supply the wants of the metropolis. During the past year 654,102 houses have been furnished with an average of 226 gallons daily, and a population of 4,913,513 persons have received 30.31 gallons each per day, the supply varying from 42 gallons by the Chelsea works to 26.11 gallons in the West Middlesex district, inclusive of all purposes, while the consumption per head for domestic purposes only has ranged from 30.41 gallons in Chelsea to 20.89 gallons in the Middlesex district, giving an average of 24.25 gallons. Of the 654,102 houses 237,826, or a little over one-third only, are furnished with a constant supply, notwithstanding that during the year 35,353 houses have received that boon; but, as during the same period 29,688 additional houses have had to be supplied with water, it must necessarily take some time before the constant supply can be made general. The aggregate quantity of water contrived throughout the twelve months by the several companies amounts to the enormous volume of nearly 53,000 million gallons.

The finance of the companies stands as follows:—Of the total authorised capital of 14,483,774*l.*, nearly 13,297,000*l.* have been raised, leaving a balance of 1,375,328*l.* yet to be called up. The total sum expended amounts to 13,317,582*l.*, giving as the capital cost for the supply of 1,000,000 gallons 248*l.* 5*s.*, or nearly 5*s.* per 1,000 gallons.

The gross income is comprised of receipts under the two main heads of water-rates and miscellaneous items, the first of which amounts, after allowing for empty houses and bad debts, to over 1,611,000*l.*, yielding a rate of from 9*8*/<sub>10</sub> pence in the New River system to 4*4*/<sub>10</sub> pence in the East London works, and an average rate of 7*2*/<sub>10</sub> pence per 1,000 gallons, or 12 per cent. on the capital outlay. The cost of maintenance, inclusive of all items, is stated to be 205 pence per 1,000 gallons, or 28.19 per cent. of the gross income; but of this 836 pence are on account of pumping and filtration, which are scarcely items of maintenance, as that is a term more generally implying the outlay necessary for an effective upkeep of the various parts of a system together with the cost of supervision. The maintenance of the reservoirs and mains amounts to 5.17 per cent. of the gross income, and the salaries of engineers, &c., to 3.36, rates and taxes to 7.41, while the balance is made up of miscellaneous charges. To these expenses has to be added the cost of management, which includes the fees to directors, auditors, secretaries, and other officials, to collectors, the general establishment, and law and Parliamentary charges, the total amounting to 123,522*l.*, or 7.60 per cent. of the gross income. The combined expenses of maintenance and management reach the large total of 581,708*l.*, and form a charge of 35.79 on the gross income, thus leaving a sum, inclusive of a few other sundry items, of 1,049,438*l.* as "gross profit." From this latter sum has to be deducted interest on loan capital, Debenture and Preference Stocks, amounting to 151,481*l.*, leaving a net profit of 897,957*l.*, equal to 4*d.* per 1,000 gallons, and yielding an average dividend of 9.35 per cent. on the stock and share capital. The West Middlesex and New River Works produce the highest dividend, viz., 11.50 and 11.29 per cent., while the Chelsea Works yield only 7.24. The net profit per 1,000 gallons is greatest in the New River and Kent Companies, being over 6*d.*, while that on the East London and Southwark and Vauxhall is less than half that sum. The rates charged by the same companies are 10*6*/<sub>10</sub>*d.*, and 7*6*/<sub>10</sub>*d.* in the one case, and 4*6*/<sub>10</sub>*d.* and 6*6*/<sub>10</sub>*d.* in the other. These figures tend to show the inequality in the rating, while

\* Analysis of the Accounts of the Metropolitan Water Companies, 1883-84. By Alfred Lass, F.C.A. London: Walter King.

the great excess of profits accruing to the companies which charge the higher rates shows that such rates are not necessarily called for by any increase of first cost or subsequent maintenance. The prices charged are unquestionably much higher than should be believed for such an absolute necessity of life, but, until the question of water supply is taken up and dealt with as a whole by some central authority, the public must continue to suffer from the loose legislation which placed such great powers in the hands of the metropolitan companies, from whose exactions not even the judgment, delivered in the Dobbs case seems likely to afford much relief. The preparation of the statistics contained in Mr. Lass's pamphlet must have involved a vast amount of time and labour, but it is to be regretted that its price has been pitched so high; for it cannot but limit the sale considerably amongst a numerous class of householders to whom the information it contains would be very acceptable.

## STOVES, GRATES, AND GAS STOVES AT THE HEALTH EXHIBITION.

We this week conclude our notice of the contents of the East Arcade, but, before referring to the exhibits of firms which have not yet been mentioned, we revert for a moment to our former notice (p. 487, *ante*), in which we inadvertently omitted to call attention to a grate shown by the Coalbrookdale Company which, in the opinion of some architects who have seen it, possesses qualities that are likely to secure for it a foremost place among the best types of ventilating grates. It is claimed for it that without infringing any patent it is so constructed as to combine all the advantages of the best-known grates, including the "slow-combustion,"—minus the "fire smothered in its own ashes." This grate is named "Crane's improved ventilating grate."

Stand 619 is occupied by Messrs. Smith & Co., of Osborne Works, Blackheath, who exhibit a kitchener, the "Blackheath," which possesses some good points.

Gas cooking and heating stoves are shown in great variety and abundance, and in many of them marked improvements are visible. The great convenience and cleanliness of most of these appliances will, without doubt, as time goes on, do much to make their adoption general for at least a portion of the year. In them the supporters of the smoke-abatement movement will find much help in the crusade against soot and dirt. Among the exhibitors of gas stoves are Messrs. John Wright & Co., of Birmingham (Stand 620), who show their "Eureka" gas cooker, which is very conveniently arranged. By lining the interior with a non-conducting substance, the consumption of gas is diminished, it is asserted, by as much as 40 per cent.

Stand 621 is occupied by Mr. J. B. Pether, of Yeovil, with his very ingenious "Nautilus" grate, which has now been before the public for some time, and has met with much approval. In cross-section the grate, which gives a pleasant open fire,—resembles a nautilus shell. In summer the grate may be lifted out and the fireplace recess filled with plants and flowers.

Mr. Edward Bingham (Stand 622) exhibits dog-grates, slow-combustion stoves, and ventilating and warm-air chamber stoves.

At Stand 623 Messrs. Fredk. Edwards & Son, of Great Marlborough-street, exhibit their "Economic" slow-combustion tiled kitchener, with loose ash-plate for stopping the supply of air to the under-grating, and with plate to close in front of the fire, so that the fire could be kept in continuously if required. The same firm also show their improved slow-combustion and smoke-abatement grates.

Mr. T. J. Constantine, of Fleet-street (Stand 624), shows his "Treasure" ranges, and utensils used in connexion therewith.

At Stand 627, Messrs. Benham & Sons, of Wigmore-street, show (besides their ventilating globe-light as improved for use in hospitals), the "Wigmore" range, Edwards's smokeless grate, and Benham's ventilating kitchener.

Messrs. H. & C. Davis & Co., of Camberwell (Stand 628), are exhibitors of a very good gas cooking-stove, the "Metropolitan," which appears to be both convenient and economical. The same firm are exhibitors of the patent "Thermo-hygenic" heating and ventilating stoves, in which gas is the heating agent; the heat is utilised in the most economical manner,

and the products of combustion cannot pass into the apartment to be warmed.

Mr. James Keith, of Arbroath (Stand 629), exhibits his "open-fire hot-water apparatus," and his patent sectional "Challenge" boilers for hot-water heating. These boilers are constructed of sections placed one above another in such a manner as to give about ten times the heating surface of ordinary saddle boilers, and they are complete in themselves, requiring no brick setting, the fire being wholly "water-jacketed." The construction is very ingenious, and the arrangement and form of the sections are such as to ensure the minimum amount of fire to produce a given effect. An interesting exhibit at this stand is a model of the oil-gas apparatus which Mr. Keith is now erecting for Ailsa Craig Lighthouse, upon the recommendation of Messrs. D. & T. Stevenson, the engineers to the Commissioners of Northern Lighthouses.

At Stand 631 Messrs. Brown & Green, of Luton, exhibit a smoke-consuming kitchener burning common coal.

Messrs. Martineau & Smith, of Birmingham (Stand 632), exhibit some useful steam kettles or water-boilers, as used by the Birmingham Coffee-House Company. By the aid of one of these kettles, 20 gallons of water can be boiled in three minutes from the time the steam is admitted to the steam jacket.

At Stand 633, Messrs. W. & S. Deards, of Harlow, exhibit the "Princess Louise" open-fire coil-grate, in which the fire-bars form parts of coil-circuits which pass round the room. It appears to be well adapted for warming school-rooms, &c.

Messrs. Deane & Co., of King William-street (Stand 634), exhibit a variety of gas cooking and heating stoves, patented by Mr. Fletcher, of Warrington, with his "solid-flame" burners for boiling. These will repay examination, and the same may be said of the numerous workshop stoves made by Mr. Fletcher for use in various technical processes.

At Stand 636 Mr. John Bell, of Southwark-street, exhibits asbestos as applied in gas-stoves, &c.; he also shows an asbestos fire-proof plaster.

Mr. William Hellier (Stand 637) exhibits a "water-heater," as well as a simple arrangement for heating conservatories, greenhouses, &c., by the gas or oil fuel, without the possibility of the fumes of the gas or oil escaping into the apartment to be warmed.

Stand 638 is occupied by Jaffrey's Patent Grate Company, of Charing-cross. The grate which they exhibit is constructed to burn ordinary coal, and has an arrangement for consuming its own smoke. The fire produced by it is very bright and cheerful, and radiates a considerable amount of heat, while it is economical in its consumption of fuel. It will burn either bituminous coal or anthracite.

At Stand 651, Messrs. Wm. Sugg & Co. Limited, show their "Charing-cross" Gas Kitchener,—a convenient apparatus combining facilities for roasting, boiling, frying, grilling, and baking.

Messrs. Davis & Sons, of Bath (Stand 653), exhibit some well-made gas cooking stoves.

Dr. W. H. Stephenson, of Blackburn (Stand 654), exhibits his portable gas-heating water coils, which are constructed of a series of double copper tubes, 4½ in. in diameter, placed one above the other, and connected at each end. An ingenious automatic heat-regulator is shown in action by the same exhibitor.

At Stand 655 Messrs. Pugh Brothers, of Highbury, show a new gas-fire fitted with prepared asbestos fowl.

Mr. R. E. Cox, architect, of High Holborn (Stand 656), exhibits his patented improvements in grates. These improvements are well worthy of notice, for it is claimed that in virtue of them an ordinary grate can be converted into a smokeless slow combustion stove at little expense. We have not space to describe them in detail, but we may say that they are shown applied to a common register stove, so that if Mr. Cox's invention be all that Professor Ayrton's report upon it would seem to indicate, there is hope of obtaining efficiency and economy in our domestic fireplaces.

Mr. H. H. Hazard (Stand 657), of Knightsbridge, exhibits some gas cooking stoves of novel arrangement, patented by M. Ubarrier, of Paris. One of these stoves is specially designed to be placed on the top of a disused coal-burning kitchener during the summer months. All these stoves appear to possess considerable merit, the roasting and broiling burners giving

a bright radiating flame, whilst the burners for boiling (which are on the atmospheric principle) exhibit novelty of arrangement and construction, whereby they can be instantaneously taken out and washed.

At Stand 660 Messrs. Edward Davis & Son, of York-street, Westminster, exhibit some gas-cooking stoves which have their ovens lined with white tiles.

Messrs. Charles Wilson & Sons, of Leeds (Stand 661) exhibit gas-cooking and heating stoves, bath-heaters, and a new patent gas-fire.

Mr. J. G. Wagstaff, of Dukinfield (Stand 662), shows some patent saddle and cylindrical boilers, coils, coil-cases, &c.

Messrs. Musgrave & Co., of Belfast (Stand 663), exhibit one of their admirable slow-combustion ventilating double-chambered stoves, which will burn for several hours without attention. The fireplace is lined with fire-clay, and holds sufficient fuel to last for from eight to twenty-four hours. It is fed through a door on the top or front, and there is another door in front which admits the air for combustion, and allows the ashes to be removed. It is also provided with a hot-air chamber, through which the cool air of the apartment passes. This stove, if placed in the hall, will keep up a supply of warmed fresh air for the whole house.

Mr. Alfred Curchman, of Fulham (Stand 665), exhibits a new asbestos gas fire stove, with a special arrangement for regulating the amount of heat.

Messrs. J. Nettleton & Co. (Stand 666), of Sloane-square, exhibit their patent open and close fire heating-stoves, constructed with a view to supply warm fresh air to buildings. It is claimed that by the use of these stoves the warm air supplied is unburnt. The stoves will burn for from six to nine hours without attention.

At Stand 670, Messrs. Geo. Wright & Co., of Queen Victoria-street, exhibit Dyer's patent front fire-bars for domestic stoves. The improvement consists in arranging the bars *louvre-fashion*, the lower edges of the bars being towards the fire, so that the bars slope upwards and outwards. It is claimed for them that by their use firebrands are rendered unnecessary, that cinders and dust cannot fall out in front, and that the radiation of the heat of the fire is much improved.

The Eagle Range Company (Stand 671), of Regent-street, show their speciality, which has been mentioned by us on previous occasions.

Messrs. Beynon & Cox, of Torquay (Stand 672), exhibit gas-cooking stoves so arranged as to prevent the fumes of the gas from coming in connexion with the food placed in them.

At Stand 674 Messrs. Adams & Son, of the Haymarket, exhibit Captain Warren's patent cooking apparatus, as adopted by H.M. War Department.

Mr. D. O. Boyd (Stand 678), of Maddox-street, shows his patent Hygienic "Fisheries" grate, so named, we presume, because it was used at the "Fisheries" Exhibition. It affords an admirable means of warming and ventilating hospitals, schools, and all large rooms requiring an abundant supply of warmed fresh air.

Messrs. Hearder & Son, of Plymouth (Stand 679), exhibit a slow-combustion improved Arnott stove.

Mr. Henry Masters, architect, Bristol (Stand 681), exhibits a method of heating by gas tubular condensing and evaporating apparatus. The apparatus consists of two hollow pedestals connected together by twenty horizontal tubes, all made of sheet metal, and it is so arranged that the products from two gas-burners, one at the base of each pedestal, shall circulate through the pedestal and the whole of the tubes, backward, then forward, and then pass out of an aperture or chimney. The distance travelled by the gas in this apparatus is about 15 ft., and the heating surface about 40 ft. The inventor says that, in his experience, he has found that if the products of burned gas be made to pass through a horizontal tube 16 ft. long, the quantity of moisture deposited upon the inside of such tube at its end checks the flow of the gas products, so much so that it becomes nearly stagnant, and the difficulty of carrying off the fumes by a fine or pipe is retarded. He therefore allows the products in his apparatus to be checked at about 14 ft. by striking against a plate, which he names a condenser; the moisture is here partly collected and passes through tubes which convey it to evaporating troughs,—one over each burner, and it is dried

up and leaves a deposit in the troughs which may be cleared out readily.

At Stand 683 Mr. Harry Hunt, of Newington Green, exhibits the "Crown Jewel" stove and the "Hygiene" ventilating hall stove. They are both American productions, the latter being an improvement upon the former. The stoves are made to burn coke or any kind of smokeless fuel, anthracite in particular. The "Hygiene" stove can be left without attention for twenty hours. The same firm are exhibitors of what are called "the patent gas-fumes neutraliser stoves,"—a very awkward name,—in which it is sought to neutralise the fumes or products of combustion by means of layers of silicated cotton and carbon. It is claimed for them that as no fire is required the whole of the heat generated is utilised. A cooking-stove on this principle, which is shown, consists of two separate parts, the top or hob, and the oven, either of which can be used independently.

In conclusion, we would only refer to the unsatisfactory lighting of this important section of the exhibition by night.

#### THE PLUMBERS' CONGRESS.

This Congress was opened on Monday at the Technical Institute, South Kensington, under the presidency of Mr. George Shaw, Master of the Plumbers' Company. There was a very large attendance.

The Chairman, in commencing the proceedings, recapitulated what he had said at the preliminary meeting at the Guildhall (reported in the *Builder* three weeks ago, p. 472). He referred to the old ordinance of Edward III., which nearly covered the whole of the subjects they were to discuss, and said that they should endeavour to discover means by which the public would be protected from the serious evils arising from defective plumbing, by enforcing personal responsibility against those doing bad work. This could only practically be done by establishing a standard of excellence in work and material. He hoped their deliberations would tend in this direction. The Court of the Plumbers' Company were fully disposed to take action in the matter; and it was satisfactory to find that at last such a general movement was taking place.

Mr. Ernest Hart read a paper in support of the extension of the existing statute law as to house drainage in order to provide for the more efficient regulation and registration of plumbers. He referred to the carelessness of householders generally with the question of drainage until the matter was brought home to them by the occurrence of disease in their houses; and he pointed out that many cases of ill-health short of actual disease had their origin in the exhalation of sewer gas. After summarising the existing laws on the subject, he quoted Mr. Rogers Field's statement that he had only found three sound drains in the course of his eight or ten years' experience, and the figures recently announced by the London Sanitary Protection Association, as proofs that as a matter of fact the number of houses that could be regarded as safe from the irruption of sewer-air was very small indeed. Our public buildings did not set a good example in this respect, for one of the most flagrant cases of bad drainage ever seen had been observed at the office of the Local Government Board, the chief sanitary authority in the kingdom. He thought that much might be done by encouraging lectures to plumbers on the plan recently adopted by the National Health Society, and by affording opportunities for the systematic instruction of plumbers in their craft through the Plumbers' Company, or in some other authoritative way. His suggestions as to legislation were, that the powers of rural and urban authorities should be assimilated; that the principles of the Model By-laws as to new streets and buildings should be embodied in a Building Act to have universal application. All drainage works should be executed in accordance with plans and specifications previously approved by the local authority. No drainage works should be covered until passed by the surveyor, and all drains should be tested before being passed. No new house should be allowed to be inhabited before being passed and certified by the surveyor. All plumbers should be registered and licensed, no work being allowed to be done by unlicensed plumbers, and no licence to be given except after examination. The licences should be re-

newed from year to year, and a list of licensed plumbers published annually. The reasonableness of these regulations he supported by what was being done in the chief American cities.

The first subject for discussion was "The Technical Instruction of Plumbers." On this subject,

Mr. W. Eassie, C.E., read a paper in which he contended that plumbers were often to blame for having fallen from the high position which the craft occupied in ancient times. The healthy conservatism of the trade had degenerated into unhealthy radicalism. Mere manual skill was not sufficient to make a finished workman, and he would not honour with the name of technical education the mere use of tools. It was to be regretted that the bulk of the literature of the trade had been of too elementary a character. In his opinion a technical knowledge of plumbing should consist not simply of using certain metals for certain purposes, but of a knowledge why they were so used. It should consist of being able to apportion the metals in case the plumber found himself in a new colony; of being able to sketch in minute detail any appliances; and of not only being able to execute work, but also to measure it up. There should also be sufficient knowledge to tell whether work would fail if carried out in the manner directed, and to provide a remedy. Architects and clerks of works were sometimes to blame in dealing with plumbing work, and showed a total lack of technical knowledge. The inexperienced architect specified that a soil pipe should be fixed inside the house, when it was usually to be found outside; the clerk of works passed it; the huilder erected it; the surveyor measured it up; and yet the arrangements betokened a lack of the necessary knowledge. So things would continue until the status of the trade was raised, and until the plumber reached a stage which would enable him to become a teacher of his craft, and to refuse any ill-conceived work. The manual education of the plumber would be secured during his apprenticeship, and much practical work learned besides, but there was a great want of technical education, and the question was how this could best be imparted. It must be derived more or less from books. The mere seeing and handling of lead would not teach all its properties and applications, any more than a knowledge of the bones taught the practice of surgery,—hence the institution of the City and Guilds Institute, and of the various technical schools. There should be not only a written but an oral examination, besides a practical demonstration of the capabilities of the metals. He would be inclined to follow more or less closely the system adopted by the National Health Society in the plumbing competition inaugurated by Mr. Shaw; and would accord no medal in the first year to any but those who passed the ordeal with commendable credit. It would repay the candidate for coming a long distance to receive such a medal, as it would place his thorough competency beyond cavil.

Mr. C. T. Millis (of the Technical College, Finsbury) read a paper on the same subject, in which he urged that the instruction requisite for the plumber of the future should be divided into the following heads:—Mechanical drawing for the trade; practical work of the trade; and physics of the trade. Under the first head he would place practical geometry appertaining to the trade, including pattern-cutting, or the development of surfaces, and the making of working drawings from dimensioned rough sketches, to be done by the student from models of plumbing appliances and fittings. The second head included the manipulation of sheet-lead, elementary sheet metal work, and instruction in the various kinds of joints; while the third head comprised instruction in the physics of the trade, with laboratory work, by the aid of lectures and experiments. This latter would include the properties of metals and alloys, the composition of solder and the like, and the action of air and heat on molten metals. It was not to be expected that men who had reached middle age, or who had family or other ties, would take up the course of instruction put forward by him as needful for the plumber of the future. By the very words "of the future," young men were necessarily indicated, and it would be no heavy call on a young man to attend a course of instruction spread over (say) two years. When this was done, a plumber

would be as much trusted and praised as he had been abused of late years.

Mr. J. W. Clarke, a teacher of plumbers' work under the City and Guilds Institute, read a paper in which he contended that the meaning of technical education was not clearly understood by the London plumbers. No man could learn a trade by reading books or attending lectures. Technical education, as commonly understood, was not practical experience, and would never take its place. At the same time it was often asked, what was the good of a knowledge of technology? It might as well be asked, what was the good of brains? The plumber who knew something of the nature of the metals he used would take the precaution of protecting the public from injurious contact with noxious matters, and would know what should be used for each special purpose. A knowledge of hydraulics and hydrostatics, however elementary, was of great help to the plumber. He had never known an architect who gave detailed drawings for the plumber to work to, and the remedy for this was that the plumber should educate himself so that the architect would have confidence to advise with him personally. The plumber should know how to make drawings so as to be able to submit them to those in authority. It was necessary also that he should educate himself to prevent his being pushed aside by the sanitary engineers. The best solution of the problem was the establishment of trade scholarships. Through the munificence of the rich City Companies, schools could be opened in any place where a few plumbers were got together; but the plumbers themselves had not taken up the subject as they might.

Mr. E. G. Mawbey (Borough Surveyor of King's Lynn), in a paper read by him, stated that it was frequently found more difficult to convince the plumber than the owner of the necessity for modern sanitary arrangements. Plumbers, instead of opposing, should, in their own interests as well as for the benefit of the public, support the suggestions of experienced surveyors and sanitary inspectors. There was not so much difficulty in securing the technical education of plumbers in large cities and towns as in small towns and districts. This might, however, in the latter cases be effected to a great extent by holding plumbers' district meetings for the reading and discussion of papers, and the medical officers, local surveyors, and sanitary inspectors might be invited to take part therein, and the papers, &c., printed and circulated. The example of the Sanitary Institute might with advantage be followed by instituting examinations for plumbers and granting certificates to competent men.

In the discussion which followed, Mr. Smeaton (London) maintained that the plumbers knew very well what they had to do. They had to get a living. A specification was put into their hands by a person who knew little about plumbing. The plumber was ordered to carry out his instructions and to mind his own business. The honest plumber was too often put on one side, and any one who could write on sanitary science came to the front. Competent plumbers only should be employed in connexion with technical instruction for the trade.

Mr. P. J. Davies (London) said that what was required was a number of duly registered instructors of the plumbers' trade. There should be an examiner in each district, and then there would be no difficulty in getting good plumbers. He was certain that members of the craft would never tolerate licences.

W. P. Buchan (Glasgow) contended that no man could learn the plumbing trade out of the shop. When a journeyman he had often to refuse to answer the questions of clerks of works, when under the master's order he had put on 5-lb. lead piping instead of 6 lb. lead. A knowledge of drawing lay at the root of the whole question of the education of the workmen.

Mr. Matkin was in favour of licensing plumbers.

Mr. Scott-Moncrieff (London) thought that the meeting should do something in the way of passing a resolution in favour of technical education. The day had nearly gone by when any plumber could take refuge under the failure of other tradesmen in connexion with the sanitation of a house.

Mr. Humphrey (Nottingham) considered that plumbers' work was not of the offensive character that should necessitate its being buried

out of sight. The work should be open for inspection, and be thoroughly good work of its kind. The architect should be the ruling spirit in building work, but he should consult the men who had devoted their lives to particular branches of trade.

The chairman here suggested that some such resolution as the following should be passed:—

"That, in the opinion of this Congress, it is desirable that in future architects should not include plumbers' work in builders' contracts."

This was received with great applause, and was proposed by Mr. Clutterbuck, who said they had a right to protest against builders taking every kind of business in hand. Contracts should be divided, and so should the responsibility. The plumber would then receive 10 per cent. more for his work and the public be better served.

Mr. Firth (Kensington) seconded the resolution.

Mr. F. C. Penrose (architect) expressed his adherence to the separation of the plumbing work from builders' contracts.

Mr. Lane opposed the resolution, believing that divided responsibility would end in no responsibility.

Mr. Wandsborough contended that the action of the architects in including plumbers' quantities in building contracts had done more than anything to damage the trade. The architects would be serving the public better by conferring with practical men in their various spheres of work. If the work were divided it would open up facilities for the development of education, which masters at present could not afford to carry out.

The resolution was carried with one dissentient.

The next subject discussed was "Apprenticeship, the duration and condition of indentures suited to the present state of the plumbing trade, and to the modern system of technical instruction."

Mr. W. R. Maguire (Dublin) read a paper, in the course of which he said that the apprenticeship of plumbers should not be reduced to a shorter period than seven years, as of old time.

The object should be not so much to induce apprentices to come in, as to insure that when they went out they should take with them a well-taught, well-learned, and well-practised handicraft for public benefit. Payment to apprentices should be formed more in accord with their value to their masters, than was now the case. Even if paid little in the first year there should be a tangible payment and steady advance of wages year by year. Employers being as different in character as workmen were, the Congress might frame some suggestions on the subject which would be accepted as a good guide by both employer and employed.

Mr. Frederick Fell (Worcester) followed with a paper on the same subject. Never in the history of the mechanical trades had so great a necessity existed for an apprenticeship of long duration and strict in its terms. Where the master confined his business strictly to plumbing, all that was needful might be learned in six years. He would like to see introduced into the indentures clauses compelling the apprentices to attend classes at properly-constituted Science and Technical Schools, and to pass at least two examinations during their term. The first of these should be simple and mainly practical, and the second one of a more searching character. No tradesman should be allowed to assume the responsible position of master, unless qualified to be one.

Mr. Smeaton in a paper contended that apprenticeship should be for at least five years, the most suitable time for which would be between the fifteenth and twentieth year. One or two evenings a week should be devoted to the study of the theory of plumbing, including drawing, geometry, water supply, heating, drainage, and the roofing of dwellings. The apprentice must be allowed, by mutual consent or arbitration, to have one master, and finish his term with another for the purpose of improving his knowledge of the trade. It would also be well if the indentures were endorsed as to the conduct and ability of the apprentice.

Mr. Scott-Moncrieff thought that five years would be a good period, with perhaps another two years as a term of probation in other workshops. He moved:—

"That, in the opinion of this Congress, it is desirable that the apprenticeship system should be continued, and

modified, if necessary, to suit the improved course of technical education."

This was seconded by Mr. Stolder, and agreed to.

The third question discussed was, "The establishment of Metropolitan and Provincial Boards of Examiners of Plumbing Work."

Mr. P. J. Davies opened the subject with a paper, in which he advocated that a Metropolitan Board of Plumbers should be established, with head-quarters at the offices of the Plumbers' Company. The duty of the Board would be to examine plumbers both in theoretical and practical plumbing, and to grant to successful candidates a certificate and registration, which latter should qualify for the office of district examiner of sanitary plumbing work. If necessary, sub-committees should be established in large provincial towns to carry out the work in conformity with the laws and regulations established by the Metropolitan Board of Plumbers, or by Parliament. The Committee should be made up of certificated plumbers.

Mr. E. Knight (Southwark) maintained that by the establishment of such boards, owners of houses would obtain certificates as to the proper sanitary condition of their dwellings. The advantage of this was manifest in connexion with the letting and selling of houses, and it would at once strike at the root of defective sanitation. The Board of Examiners should, if possible, be invested with some local authority, and should at all events hold a well-defined and acknowledged position. They would work in connexion with the parochial authorities, being careful at the same time not to usurp the duties of the inspector of nuisances. The charge for reports should be a small one. A board might be formed in the first instance from members of the Court of the Plumbers' Company, assisted perhaps by one or two professional gentlemen.

In the discussion which followed, Messrs. Moore, Underwood, and others took part. Dr. Vacher proposed:—

"That this Congress is of opinion that in the event of the establishment of Provincial Boards of Examiners of Plumbing work, such Boards (firstly) should be affiliated with a Metropolitan Board; (secondly) should consist chiefly of trained working plumbers; and (thirdly) should be in connexion with the provincial schools of plumbing."

Mr. A. B. Clarke seconded the resolution, which was carried.

The fourth subject was "The Registration of Journeyman Plumbers."

Mr. R. Smith (Bermondsey), who read a paper, was opposed to the proposed registration, as it would open up a field for many abuses, and ultimately do great harm to the trade. Any board of examiners would consist largely of members with theoretical qualifications, and such a class of judges would in time exclude the practical man. There were means in their midst for obtaining properly-qualified plumbers, viz., the trade societies. There was a prejudice against these, but he would ask what were the Plumbers' Company and the other guilds but trade societies? Plumbers were the only competent judges of plumbing, and the young man who joined a trade society had the benefit of the experience of the older workmen.

Mr. Smeaton advocated the granting of some such certificate as was given in America.

Mr. Houghton thought that if the masters were registered first it would have the effect of keeping linen-drappers and others from undertaking plumbing work.

The Chairman remarked that the registration would be a mark of high honour, showing that the person registered was a competent craftsman.

Mr. Swales said that in Melbourne plumbers had to pass an examination.

The Congress then rose for the day.

On re-assembling on Tuesday, again under the presidency of Mr. Shaw, the following resolution in continuation of the previous day's business, was passed:—

"That, in the opinion of this Congress, the registration of master plumbers and journeymen plumbers is expedient."

Mr. Webb read a paper on "The suitability of materials used in plumbing, and particularly of those materials recently introduced as substitutes for lead." There was, he said, no known substance to equal lead for wear. Properly laid, not condensed, well dripped, and with all the expansion possible, he contended it was the best. But they must adapt themselves to circumstances. In model dwelling-houses,

with drying-grounds at the top, it would be entirely out of place to use anything else but asphalt or cement and coke breeze. Turning to another substitute, viz., zinc, although much improved in the laying, it had no superiority over lead, being a hard metal without expansion, and liable to crack from the action of the acid in the process of soldering. With regard to cisterns he gave the preference to galvanised iron ones. In lead cisterns, and especially in certain districts, the action of water affected the weakest point of the cistern, viz., the outside of the soldering, and when the cistern was not frequently cleaned out small portions of the lead were liable to be imported into the system. Slate cisterns, as a substitute, would not stand the test; he had found in cleaning them out a slimy vegetable matter adhering to the sides, and there was a liability to leakage from vibration. With respect to soil-pipes he gave his allegiance to lead, and asked whether it was possible to make a caulked joint with iron lasting for any length of time? Shrinkage would occur in the cement of the joint, and the smell would exude. Turning to the question of closets, some good-looking pieces of porcelain had been introduced, but these were complicated in construction, and dirty from a sanitary point of view. He still adhered to the valve closet adopted by Bramah, but very much improved, for all private dwellings where supervision reigned. A very old servant, the pan-closet, had been harshly treated of late. Though long since condemned, it was still to a large extent in use, and would live as long as some of its contemporaries as a hard-wearing closet.

In the discussion which followed, Mr. Davies said he considered the ordinary pan-closet was the filthiest thing in buildings.

Mr. Stolder affirmed that no cistern should be left for more than three months without cleaning.

Mr. Smith was not opposed to iron soil-pipes if they could be made sound. Iron and lead pipes did not always join well together; in a comparatively short time there was a crack in the joints, and the foul air would escape.

Mr. T. H. Court thought that plumbers should be allowed to use their discretion very much as to which was the best material to be used.

Mr. Underwood believed there was a great opportunity for plumbers to push lead as against zinc. For internal soil-pipes a good strong lead was the best, fitted neatly and well. Dr. Vacher remarked that glazed earthenware was suitable for cisterns in country districts.

Mr. Smeaton was of opinion that lead was the most suitable material for soil or any other pipes, because good lead would stand the action of any amount of acid or air. He did not believe glazed earthenware used in water-closets or urinals would last more than twenty years. He had seen portions of the lead piping of the ancient conduit in Cheapside, and which was as good as on the day it was laid down. In the case of Glasgow, the engineer would not allow anything but lead to be used for the water-pipes, except for the large mains. He believed they all agreed that lead was the best material.

Mr. Buchan (Glasgow) read a paper on "The desirability of fixing upon a system by which uniformity in the quality of materials used in plumbing may be insured." In the course of it he said that the idea of enforcing uniformity in the materials used in plumbing was not new, as articles in connexion with the water supply of London and Glasgow had to bear an official stamp. No regulations, however, existed for roofing materials or soil-pipes. The practice of fixing thin cast-iron rain-water pipes inside houses, and especially to do duty as soil and waste-water pipes, should be prohibited. In many cases it was customary to discharge hot-water waste-pipes for hats and wash-basins into the soil-pipe for the closets. This was a bad plan, causing the soil-pipe to stink worse than with only cold water going through it. In addition to condemning thin iron pipes he objected to the way in which their joints were often made, viz., by merely plastering a little putty round the top of the joint. When the joints were not caulked and run with lead or sulphur, they should be rubbed with red lead, and the joints made with hemp dipped in red lead and twisted round the spigot end of the pipe. When in position the hemp should be rammed down and the joint run full with red lead.

In the discussion which followed, Mr. Coles remarked that a standard of the quality of

materials should be fixed upon, to be specified in the tender.

An extra paper by Mr. Poole, of Norwood, on the same subject having been read, Mr. Tidman proposed,—

"That the Congress is of opinion that it is expedient that the system of sealing or marking lead and solder of standard weight and quality be revived by the Plumbers' Company, and that the Plumbers' Company should be requested to consider whether the materials used in plumbers' work as substitutes for lead are suitable, and whether standards of quality for such materials could be advantageously fixed on and verified by a recognised mark."

Mr. Smeaton seconded the resolution, which was carried.

Mr. F. Wells (Worcester) opened the question of "the formation of district associations of plumbers to investigate and secure, as far as practicable, correction of evils and abuses arising in connexion with the trade." If the formation of such associations would correct the evils of insanitary plumbing it would be a strong argument in their favour, and would effect a lasting good. Insanitary plumbing was the cause of a great amount of illness and death, and yet this sort of work was not only accepted, but sought after on the plea of cheapness. If district associations could be formed to correct these abuses, and carried on effectively, they would in the first place be the means of securing wholesome dwellings, and would give the honest tradesman his legitimate place in his trade.

Mr. Emptage (Margate) in a paper said that though much had been done through the labours of sanitarians and sanitary societies, it was small in comparison with what would be accomplished. Our American cousins had grappled ingeniously with the evils, and by the aid of a stringent plumbing law had almost regenerated the trade. In some places the law was carried out with great rigour, and he found that a plumber in New York was fined fifty dollars for putting in a dummy vent-pipe to a trap in the basement of a house; a master plumber was fined 150 dollars for allowing two dummy vent-pipes to be fixed; while another was fined 250 dollars for bad plumbing work in new buildings.

An unregistered plumber lost the day in an action against a builder to recover his account for work done, because he was not registered, and was therefore working contrary to law. On the other hand, the permissive nature of our laws in regard to sanitary matters too frequently resulted in the presence upon our local boards of unscrupulous builders, and interested parties who used their position to silence the surveyor. The American law had been in force for more than three years, and seemed to work well. It protected the plumber to a great extent from dangerous competition, and enabled him to do honest work. There would be considerable difficulty in getting such a stringent law passed in England, but they might, with a good chance of ultimate success, aim at obtaining Parliamentary powers whereby all plumbing work in connexion with sanitation would be carried out under the strict supervision of properly appointed and duly qualified persons, upon certain fixed and sound sanitary principles.

Mr. John Bailey thought it would be better to form associations to remodel their craft, than to allow it to dwindle into mere tinkering. He would call attention to the fact that the general public when they had cause of complaint against the trade were not aware that the plumbers did not design their own work, but were in reality carrying out other people's ideas of sanitation. It was his opinion, after forty-five years' experience, that it was necessary to form metropolitan and provincial associations, not simply for themselves, but for the registration of journeymen plumbers.

Mr. T. H. Court, in a paper, referred to the necessity which existed for an investigation of plumbers' work. Architects in some instances, and the medical profession, were now giving more time and attention to the laws of sanitary science than at any previous period. He was sorry to say he had been compelled to condemn a large portion of the work he had seen in different parts of the country. They would all agree that there was the greatest necessity existing for a thorough investigation of plumbers' work for the correction of evils and abuses. This should be done by associations formed for the purpose. It would not be a trade which was second to none in importance, for upon the plumber's work more than upon that of any other trade did the health of

the nation depend. The associations should be composed of plumbers, as the work to be inspected would be plumbers' work.

Mr. Allam (Eastbourne) proposed:—

"That the resolutions and conclusions set forth in the preceding paper be referred to the Plumbers' Guild, with a request that they will confer thereon, with a view to take such action as may seem best."

Mr. J. Murrell (Norwich) seconded the resolution, which was agreed to.

The Chairman, in summing up the work of the Congress, expressed the hope that it would result in the formation of a representative committee to carry out the recommendations and suggestions that had been made. He congratulated those who had attended the sittings on the practical character of the discussions and the general manner in which they had been carried on, and thought it would only be the beginning of what would be an ultimate and general success.

A cordial vote of thanks to the chairman and to the Plumbers' Company closed the proceedings.

#### GLASGOW INSTITUTE OF ARCHITECTS

The annual general meeting of this Institute was held on Wednesday, Mr. Jas. Thomson, F.R.I.B.A., president, in the chair. Mr. William Maclean, the secretary, read the annual report of the council.

The report contained the following passages:

"The Committee (Mr. Sellars, convener) appointed to consider the Rules and Regulations for the Measurement of Mason-work in this district, or wherever the Glasgow mode of measurement is adopted, have completed their work, and reported to the Council. They had before them the draft Rules prepared by the Institute, those prepared by the Institute of Measurers, and by the Master Masons' Association. After careful consideration of the three sets of Rules, the Committee found that, except in a few instances, there are no serious differences in the rules as prepared by the three bodies, and they recommended that representatives of the two Institutes and the Master Masons' Association should meet to discuss and, if possible, agree on one set of rules, so that uniformity of practice in regard to this important matter may be secured in the future. In order to facilitate the work of this proposed conference, the Committee prepared a statement showing in parallel columns the rules applicable to the measurement of each department of mason-work as suggested by the three bodies. Representatives from the Institute have been appointed, and the Institute of Measurers have been communicated with, but their reply has not yet been received. The Table of Fees issued by the Glasgow Institute of Measurers has also been considered and reported on by the Committee of Council.—Mr. Sellars, convener, appointed for that purpose, and a communication has been sent to the Institute of Measurers."

"At a meeting of the Alexander Thomson Memorial Trustees, held in October, 1884, it was reported that a suitable investment had now been found for the Trust funds, and Mr. John Shields was appointed Factor and Secretary to assist the Trustees in the administration of the Trust."

Mr. William Landless, the treasurer, submitted the financial statement.

On the motion of the president, seconded by Mr. M'Gibbon, the report and treasurer's statement were unanimously approved of, and ordered to be printed and circulated among the members. On the motion of the president, seconded by Mr. Campbell Douglas, the following gentlemen were unanimously elected to be members of council for the ensuing year, viz., Messrs. James Sellars, jun., William Landless, Hugh Barclay, John Gordon, John Murdoch, Robert Turnbull, F. L. Watson, David Thomson, James Thomson, Alexander Skirving Wm. F. M'Gibbon. On the motion of Mr. Campbell Douglas, a cordial vote of thanks was awarded to Mr. James Thomson, the retiring president.

At a meeting of council, held after the general meeting, the following were elected as office-bearers, viz., Messrs. James Sellars, jun., 265, St. Vincent-street, president; Hugh Barclay, 135, Wellington-street, vice-president; William Landless, 227, W. George Street, treasurer; John Burnet, 167, St. Vincent-street, auditor; William Maclean, 81, Bath street, secretary.

#### Amsterdam Exchange Competition.

—We have already noted the constitution of the jury for deciding this important competition, and that Professor Kerr had been appointed to represent England. We regret to learn that in consequence of recent ill-health Professor Kerr has been obliged to relinquish the appointment. The Municipality have appointed in his stead Mr. R. Phené Spiers, — one of the best substitutes they could have chosen.

#### The Late Archbishop of Canterbury.

—Messrs. Young & Co., of the Eccleston Works, Philadelphia, have just completed a bust in bronze of the late Archbishop of Taik, by Mario Raggi, sculptor, to be placed in the Edinburgh University. It has been subscribed for publicly.

## BAS-RELIEF: "THE SONS OF CYDIPPE."

BY MR. GEORGE TINWORTH.

**T**HIS bas-relief, executed in terra-cotta by the artist, and which has been exhibited, along with other terra-cotta work from Lambeth, at the Health Exhibition, is interesting, to those who know Mr. Tinworth's previous work, as a work in a style entirely different from what he has previously done. Hitherto Mr. Tinworth has treated mainly Biblical subjects, in a manner which may be called Gothic; high relief,—often throwing the figures entirely up from the ground,—energetic action, and force of light and shade, having been the characteristics of his design. Here we have a purely classic subject treated in delicate bas-relief, a style, we may observe, not so well suited to clay as to marble or bronze. The work represents, of course, the well-known story of Cleobis and Biton, the pious sons of Cydippe, the priestess of Juno, who themselves drew her car to the temple when the sacred oxen were not forthcoming or were recalcitrant, and for whom the mother implored the greatest blessing the gods could grant, a prayer which was answered by their falling presently into a deep sleep from which they never awoke. Mr. Tinworth varies a little from this version of the legend, as he represents Cleobis and Biton as falling in death at the moment of their mother's prayer, and on the very steps of the temple. The work was produced, we understand, with direct reference to a poetical version of the legend by Mr. Gosse, the prayer of Cydippe, at the moment of action chosen by the sculptor, being thus rendered by the poet:—

"Hear me! and grant for these, my pious sons,  
Who saw my tears, and wound their tender arms  
Around me, and kiss'd me calm, and since no steer  
Stay'd in the byre, dragg'd out the chariot old,  
And wore themselves the galling yoke, and brought  
Their mother to the feast of her desire;  
Grant them, O Heav'n, thy best gift of gifts!"

In a later replica of the work, Mr. Tinworth has draped the right arm of Cydippe, which, as in the original design here shown, stands out rather harshly, and seems to need something to connect it with the adjacent parts of the composition.

## DESIGN FOR ADMIRALTY AND WAR OFFICES.

MESSRS. MALCOLM STARK AND J. LINDSAY, ARCHITECTS.

We give a small view and some details of this design, and one plan only, the authors having preferred the publication of the sheet of details to that of the second plan. The plan appears to us inferior to most of the nine, but the design is a pleasing and graceful one in general grouping. The following are the architects' notes, sent to us in explanation of their views:—

"The authors have adopted architecture of a Palladian type, as being best adapted for a large public building, and being in perfect harmony with the surrounding structures, while it also in its treatment admits of ample light. The block-plan of the buildings has been carefully studied, and with a view to give the maximum of light and air, and direct and dignified entrances from Whitehall to Spring-gardens. It was the opinion of the authors a T-shaped form of quadrangle was most convenient. In the arrangement of corridors, a plan of the most direct and simple form was adopted. On each flat the arrangement would be repeated. One of the features of the design is one large staircase for the War Office and one for the Admiralty for the principal departments, entering from the grand quadrangle. Entering from Whitehall, one large public staircase for the War Office and one for the Admiralty was considered necessary.

The use of Portland stone was recommended for all the external walls, and Scotch granite for the basement walls to the level of the base course."

## HOUSE NEAR TUNBRIDGE WELLS.

This house has been erected from the designs and under the personal superintendence of the architect, Mr. James Neale, F.S.A., of Bloomsbury-square, London. The lower story is of red brickwork, with cut brick sills, arches, and dressings. The upper story is of half-timber work and tile hanging. The roof is of red tiles.

ST. JOSEPH'S R.C. CHURCH,  
MAIDENHEAD.

This church, the nave of which is now being erected, stands on a commanding site on the Cookham-road, and will, when complete, with presbytery, &c., form a pleasing group, harmonising agreeably with its site and surroundings. The materials of the neighbourhood are as far as possible being used in the construction of the building, flint and brick forming the walls, with Bath stone introduced where necessary in windows, buttresses, &c., and red tiles for the roof. Inside the building the walls are of red brick, with stone bands, and the roof is an open-timber one, with double principals. The screen at the west end supports an organ, and will also form an internal porch. There is to be, as shown on the plan, a chapel on each side of the chancel, also two sacristies, one of which will communicate with the presbytery. The works now in progress are being carried out by Messrs. Silver, Sons, & Filewood, of Maidenhead, under the superintendence of the architect, Mr. Leonard Stokes, 31, Spring-gardens, London.

## SKETCHES BY A DISTRICT SURVEYOR.

The old church Notre Dame sons Dol, which has been much ill-used and untended, is finished with square chevets. The bays of the nave date from the eleventh to the twelfth century, the tower the fourteenth century. The building is now used as a corn-market.

The courtyard of the Hôtel Notre Dame is more attractive on paper than in reality. The external galleries, on to which the room doors open, are reached by a large wooden staircase fixed in what is now used as a kitchen. Wooden huts are said to be more healthy than buildings of brick or masonry as air cannot be excluded,

a truth I experienced when in residence at this ancient fabric.

St. Malo has fortifications of great strength, and in the midst rises up the horse-shoe shaped tower (illustrated), which Queen Anne of Britany caused to be constructed. There is a tradition that she directed her engineer to adopt as his model for the highest forms of this tower the driving-box of a coach with a seat on each side, the mast and ropes doing duty, I suppose, for whip; and as the lady appears to have had a will of her own, after her little quarrel with the Bishop Bricout about her legal rights, and the placid-tempered motto she had engraved in relief on one of the towers flanking the entry to the chateau,—“Qui qu'en grogne, ainsi sera c'est mon plaisir”—it may very well be taken to express her regal determination to drive through all obstacles.

The other sketches are from Dol, and were generally referred to in last week's number.

T. E. KNIGHTLEY.\*

War and Admiralty Offices.—In reference to a note on their report in our last, Messrs. Maxwell & Tuke write to say that “Messrs. Inigo Jones's hotel” was a copyist's error. Of course we did not suppose it was the architects' own mistake; but the deliberate insertion of the “Messrs.” was rather startling.

## COMPETITIONS.

Schools, Redruth, Cornwall.—In the competition for the new schools at Trewizgie, for the Redruth School Board, the Board have accepted the design of Mr. John Robert Nichols, architect (of the firm of Messrs. Geo. Berry Nichols & Sons), of Colmore-row, Birmingham.

Vestry Hall, Chelsea.—At the meeting of the Chelsea Vestry on the 14th inst., the Works Committee presented a report,—

“Recommending that three architects be invited to submit competitive designs, together with specification, and estimate of the cost, for the enlargement of the Vestry-hall, and with that object, that the same information be furnished to all three competitors. . . .

Recommending that competitive designs be invited from the following architects—Mr. Ernest Flint, A.R.I.B.A.; Mr. Zephaniah King, A.R.I.B.A.; Mr. J. T. Wimpey, F.R.I.B.A.; and that they be requested to submit the same by the 1st of December next.

Recommending that the architect whose design is selected be entrusted with the supervision of the works, upon the usual remuneration of 5 per cent. upon the cost of the works; and that, provided the two next best designs comply with the conditions issued to the competitors, the architects submitting them be paid a fee of 50 guineas each, the drawings to become the property of the Vestry.”

After two or three amendments had been proposed and discussed, the Vestry decided to have an open competition.

## CHELSEA SURVEYORSHIP.

THERE were eighty-two candidates for this appointment. They were reduced, first to twelve, then to six, viz., Mr. George R. Strachan, of Chiswick; Mr. Charles Clegg, A.M.I.C.E., of Colchester; Mr. E. Latimer Rumble, of Plumstead; Mr. Walter G. Scoones, of Brixton; Mr. Joseph Swarbrick, A.M.I.C.E., of Withington, Manchester; and Mr. James P. Norrington, of Birmingham.

At the election on Tuesday last, these six gentlemen were seen by the Board, and voted upon by ballot, with the following result, viz., Strachan, 30 votes; Clegg, 10; Norrington, 3; Rumble, 2; Scoones, 1; Swarbrick, 0. Mr. Strachan was declared to be elected.

The salary is 400l. per annum.

We learn that Mr. G. H. Stayton, the retiring surveyor, will hand over his duties to his successor at the end of this month, prior to his departure for Australia on the 12th prox. A farewell dinner to him took place on Thursday evening last at the Holborn Restaurant, when the members of the Chelsea Vestry presented him with a testimonial.

The Nicholson Institute, Leek.—In the list of contractors for this building given in our last (p. 539), the name of Mr. John Stones, of Ure Mills, Ulverston, who supplied the lift, should have been included.—The wood block flooring was laid by Mr. R. L. Lowe, of Farnworth, Bolton, on his improved system. The blocks are only 1½ in. thick, 1 ft. 3 in. long, and 3 in. wide, laid parquet-wise in Mr. Lowe's patent composition, not in bitumen. Floors laid on this principle are spoken of very favourably by those who have used them.

\* The signature was omitted by mistake last week.

## NOTES FROM BIRMINGHAM.

Few, if any, towns in the United Kingdom will be so well supplied with public buildings as Birmingham, when those which are projected and in progress are completed. In this respect, at least, the borough has well sustained its motto "Forward." Its town-hall is one of the finest-proportioned Classic buildings in the world, and although its interior is now marred by a decoration altogether foreign to the character of the building, it is to be hoped that when the time comes that this interior requires redecoration, it will be placed in the hands of a competent Classic architect. The Crompton-Winfield electric lighting of this great hall, under the direction of Mr. Lea, has been a great success, and is much appreciated. Its cost alone prevents its being used on all occasions when artificial light is required. This the promoters assure us will be much lessened when the area for which they have a provisional order, and which is bounded by New-street, High-street, Bull-street, and Colmore-row, is also lighted on their system.

The new Council-house and Art-Gallery is also a noble monumental building taken as a whole, although the latter portion, now approaching completion outwardly, is marred by one or two very decided blemishes. This building (the Art-gallery part) completes the block surrounding a quadrangle, and is being built at the entire expense of the Gas Committee of the Corporation out of the profits arising from that department, and will provide offices on the ground-floor towards Edmund-street for the transaction of their business (which will then be removed from the old offices in the Old-square), and an Art-gallery and Museum above, the entrance to which will be in Congreve-street, opposite the Dawson Statue, and which is emphasised by a colonnade and pediment, to be filled with figures. Adjoining, on the angle of the building, rises a lofty square clock-tower, having pediments over the clock faces, and surmounted with a truncated pyramidal roof, with dormers, and covered with red tiles and iron cresting. This is blemish number one. Another consists in the indiscriminate employment of cylindrical ventilators, with conical tops, of which there are no fewer than nineteen visible from Edmund-street and three from Congreve-street. One would have thought that having a lofty tower at hand it would have been used to further the ventilation, and that part of an architect's business not be relegated to a patentee, whose aim would possibly be to use as many of his own productions as possible, without regard to their effect upon the elevation of the building. A third blemish is the employment of large areas of skylight in the plane of the roof which is very flat, and well seen from the street. Apart from these little matters, the building is a noble one, and reflects honour upon the architect and the town. By the terms of the contract it ought to be finished by this time, but there is probably another twelve-month's work yet to be done before it can be opened to the public.

The new Liberal Club, which is rising to the third story above the street, at the other corner of Congreve-street, will be a lofty and imposing building in red brick and red terra cotta, supported towards the Memorial-square by massive circular red granite columns on the ground floor, and having its main entrance on Congreve-street. It is in the Gothic style, and has boldly-projecting oriel windows on the angle and Congreve-street side, and balconies on the other side. Its progress has been much retarded, waiting for terra cotta.

Lower down Edmund-street, adjoining the Medical Institute, the new School of Art,—a red brick building, with red terra cotta and Horseley Castle stone dressings, also in the Gothic style,—is up to the roof, now going on. This building is another instance of the public spirit of Birmingham citizens. The land has been given by Mr. Colmore, and 10,000*l.* each has been given by Miss Ryland and the Bros. Tangye, and the latter have also undertaken to bear any additional expense incurred in completing the building. On the other side of the Medical Institute are the new offices of the Birmingham School Board, now occupied; and adjoining them is the still incomplete block of new parish offices, with its lofty clock tower a very prominent object in the view, and its main entrance below. This is a fine building in the Italian Renaissance style, having frontages to three streets, and containing, besides the neces-

sary offices for the transaction of the business of the guardians, a large and lofty reception-room or hall-room, and its being there seems to imply that, however hard the times may be, the guardians and their friends are indisposed to allow such considerations to prevent them from enjoying social intercourse at the ratepayers' expense. So much, indeed, is this felt, that one of the guardians recently moved of a resolution that the new offices be disposed of, but he obtained little support. The workhouse at Winson Green is being almost constantly enlarged, in spite of its already capacious size.

So many old-fashioned residences, which were occupied formerly by medical men, having been pulled down in this neighbourhood, a new block of residential chambers has been erected in Edmund-street, opposite the new School Board offices, and is now nearly completed. Its front is of red brick, and white terra-cotta dressings and strings (with an effect decidedly "streaky"), supported on the ground-floor by cast-iron columns, having over them small semicircular white terra-cotta arches.

Lower down Edmund-street, on the same side, and at the corner of Church-street, we have the new Eye Hospital, in red brick and stone dressings, in the Queen Anne style, recently completed and opened. This is a very imposing building, having frontages to Edmund-street, Church-street, and Barwick-street. Some considerable delay was caused in its progress by the bankruptcy of the contractor.

Another instance of the public spirit of Birmingham has recently been shown by the announcement that Mr. Jaffray, J.P., one of the proprietors of the *Daily Post*, who had taken an active part in the management of the General Hospital, and, therefore, knew well its wants, had determined to build and present to the use of the public, with the freehold, a convalescent hospital at Erdington, a very salubrious suburb, and invitations were sent out to the public to contribute to an endowment fund. This was liberally responded to, and some 23,000*l.* subscribed. The hospital is now in progress, and will be a red brick building, covered with red tiles, consisting of an administrative block, with two wings, and arranged so that two other wings may be added afterwards. The ornamental grounds will be also of considerable extent. Some extensive additions have recently been made to Oscott College in this neighbourhood, and further enlargements are contemplated.

A large block of shops and offices is now going up on the corner of Bull-street and Corporation-street for that "general provider," Mr. Lewis, of Liverpool and Manchester, and in Corporation-street adjoining, a further block for Messrs. Jerons & Mellor, in extension of their very handsome new premises just completed in the French Renaissance style. A new block of warehouse buildings on the opposite side of the street is noticeable chiefly for having all the windows above the shop rectangular in one sheet of plate glass opening on a vertical axis, and the whole of the outside of the sash gilded. Another block of shops and offices, with a frontage in the Queen Anne style, is being completed at a new corner formed by continuing London Apprentice-street (now Dalton-street) into Bull-street, by abolishing the Old Coach-yard. Here the architect has made all his bay windows the full height of the building above the shops, in wood, and painted them a pale green. Adjoining these in Bull-street, the Messrs. Sonthall, chemists, have had their premises remodelled, and a new front built, and at the back in the Lower Priory an extensive range of warehouse building for their wholesale trade. The old chapel at the back of the Conservative Club in Union-street is to be removed as soon as a new one can be built on vacant land adjoining the new Grand Theatre in Old Square. It is understood the architects are now preparing the plans. The new North-Western Arcade is a remarkable building in continuation of the Great Western Arcade from Temple-row to Corporation-street, and parallel to Bull-street. It is built over the tunnel of the Great Western Railway; and although a heavy and lofty building, is supported entirely on brick pillars carried down outside the tunnel to its foundation, with heavy riveted plate girders spanning the arches above on which the building rests. The shops inside the arcade have let uncommonly well, and there is a dry promenade in all weathers from Corporation-street to Colmore-row, except crossing Temple-

row: the effect has been to draw off from Bull-street the folks who go shopping, and to very materially reduce the business of those shopkeepers who have their premises there.

The Midland Educational Company, who supply most of the public and private schools of the Midlands with books and school requisites, have had built for them a large and lofty warehouse in Corporation-street, extending through to Cannon-street, and have recently removed into it. It has a red brick front with Bath stone dressings in the Italian Renaissance style, and is very pleasing and effective. Another warehouse for a wholesale and retail stationer has been built in Cannon-street, with a frontage in Cherry-street, also, in the Queen Anne style. At the bottom of Cannon-street, and in New-street, the old shop property which had been there so many years has been bought by the proprietors of the *Daily Post*, and a new block of shops and offices in continuation of the *Daily Post* block has been built, and is now fully occupied.

The very large extension to New-street Station is proceeding, and the construction of the bit of new line for the Midland from Granville-street to New-street Station, and the widening of the road from Granville-street to King's Norton Junction will, it is expected, be complete, with its double line of rails, before Midsummer next. All the Midland traffic to and from Birmingham will then pass that way, leaving the old main line for local and through traffic. The New-street Station now covers 11 acres. The new bridge across the centre of the station in continuation of the old bridge is open to the public, but some improvement ought to be insisted on at its junction with the old bridge, where the undulations of the floor are like the waves of the sea. The platform for the Harborne line is being considerably widened, and a better road made from it into Pinfold-street, and a new block of booking-offices (how that name sticks) are being built for the Midland at the corner of Worcester-street next the Market Hall. A new and handsome hotel has been built and opened at the corner of Dudley-street and Station-street, and a large block for a firm of coach and cab masters is going up. A block of new warehouses had just been completed in Hill-street, and another new hotel, close by at the corner in John Bright-street, where also some extensive half-timbered buildings are going up.

In the Bristol-road, corner of Nelson-street, the new red stone Chapel in the Gothic style for the Old Meeting congregation, whose chapel was removed to make way for the new station, is going up. The large school-room adjoining is already complete, and the services are held therein temporarily. Here the contractors have in use a Scotch crane, worked by steam power, the massive jib of which fell recently, fortunately without much damage being done,—none at all to any person, but causing considerable delay and consequent loss to the contractor. Very great care ought to be taken not only to have these cranes securely fixed upon their high platforms but also to have their chains frequently tested, especially in winter.

The new fish-market, so long delayed by the bankruptcy of the contractor, is again proceeding under another contractor. Provision has been made for cold store-rooms and ice factory by going down a double cellar into the rock, under the new portion, which is to that extent an extension of the old area. It is much to be desired that no further delay will take place with this market, for the trade is an extensive and growing one, and the present accommodation, although of comparatively recent provision, is miserably inadequate for the town. It is a curious fact that Birmingham is better supplied with fish than either London or Liverpool.

The agitation against the proposed removal of the live cattle market from the centre of the town to what is known as the Rupert-street site has, apparently, along with the proposal itself, died a natural death. It is very doubtful if we shall ever hear of the proposal again. Not only was the site objectionable in itself on account of its position and surroundings, but the fact that one line of railway enjoyed a monopoly of entry to it, which it was not willing to share with the other two lines which come into the town, formed an insurmountable objection. The town would have acted unwisely to have laid out 70,000*l.* or more under such conditions. It will, probably, never

wait for its new market until the boundaries of the borough are extended, when there will be a much better choice of sites on now vacant land. The market must be within the borough boundaries to enable toll to be collected. Meantime it is intended to cover over the whole of the present market site with roofs corresponding with that over the adjoining vegetable market, and the Markets and Fairs Committee have been authorised to proceed with it. This, however, makes no provision for a meat market to replace the very inadequate present one. For this purpose it might be well for the Corporation to acquire the whole of the site bounded by Edgbaston-street, Pershore-street, Dean-street, and Jamaica-row, which is now a most insanitary area, and by cutting a street, say 60 ft. wide, through from Jamaica-row to Pershore-street and another at right angles from Dean-street to Lease-lane, and build shops on each side with cold stores below, and cover the same with a cylindrical iron and glass roof, with a dome at their junction. This arrangement would give four entrances to a spacious market, and would disturb only 60 ft. on each of the four streets for shops and entrance gates, and would leave the present miserable market intact with its adjoining slaughter-houses until the completion of the new market. E. G.

**PRACTICAL TESTS WITH WATER-METERS AT THE HEALTH EXHIBITION.**

AMONGST the various questions affecting the future water-supply of the metropolis or elsewhere is that of the registration of the quantity of water supplied either in bulk or to individual houses. The expediency of introducing any system of meter into the supply of a town has, as our readers know, been the subject of much controversy; indeed, Mr. Hawksley has expressed an opinion that "the effect of supplying water by measure would be exceedingly detrimental to the health of the population," and

character, and the executive Council having adopted Messrs. J. Tylor & Sons' inferential meters for the registration of the quantity of water consumed by the fountains, we are induced to give the following facts in connexion therewith.

The water for the fountains is supplied by the West Middlesex Company. In close proximity to the basin are constructed two oblong pits, lined and paved with glazed bricks,—which contain in one a nest of three 8-in. meters and in the other a 12-in. meter. The former is shown in the accompanying illustration, fig. 1. Upon the occasion of a recent visit, during a period of half an hour the three 8-in. machines registered 4,000, 4,100, and 4,000 gallons respectively, whilst the 12-in. meter recorded 8,500 gallons,—showing that in this interval of time, which is usual, upwards of 20,000 gallons of water had been projected into the air. Having had an opportunity of minutely examining the whole of the operations of these displays, both by watching the meters during play and in the operating-room under the fountains, we are able to express a confident opinion that these meters have been subjected to a very severe test, with very satisfactory results. Indeed, we are given to understand that Sir Francis Bolton has stated that he is surprised to find they have stood so well, as the recoil during the shooting of the high jets must be very great; at such periods the pressure-gauge has recorded 220 ft. It should here be stated that attached to the nest of meters at each end is fixed one of Bourdon's and Smith's pressure-gauges respectively, whose registrations are almost identical.

Only those who have visited the operating-room during a display can form any conception of the severity of these tests, and we were well repaid for the inconvenience and discomfort of the experiment; and whilst upon this subject we would suggest that if the authorities decide to continue these very popular displays at succeeding exhibitions, it would

effects of the present cramped, inaccessible, and badly-ventilated cell.

We pass from the meters attached to the fountains to one fixed in the East Central Gallery, where may be seen the registration of the quiet and steady flow of water under small pressure. A willow ball may be observed to be sustained upon the slightest jet of water passing through a meter, attached to which (equally with those in the ground) is one of Tylor's "Patent Waste-detecting and Registering Clockwork Apparatus," as shown in the accompanying cut. It will be noticed that this apparatus consists of a pencil, A, fitted with leads or dye to mark on the paper; B, B, are rollers giving motion to the paper; C is the pendulum of the clockwork, adjustable by means of a screw; D is the dial of the clock; E, a roll of paper sufficient to last six months; F, a rim to support the metal cover; and G, a lever connecting the pencil to the meter, which is disconnected at H, when the registering apparatus is removed. By this ingenious machine the quantity of water passing through the meter is recorded every hour upon the paper strips, in illustration of which we reproduce three diagrams taken at the Houses of Parliament, upon the occasion of important debates on the 20th, 22nd, and 23rd of June, 1880, whereon will be seen that each vertical jump of the zigzag line represents 500 gallons,

Fig. 1.

Fig. 2.

after giving numerous reasons against the adoption of house-meters, concludes by saying, "After long experience on the subject, I am utterly opposed to the often-suggested plan of supplying water for domestic consumption by measure." Whether this judgment be right or wrong, however (and we are disposed to question it very much), the recent experiments and tests with water-meters at the International Health Exhibition are of a very interesting

be very desirable to enlarge the operating-room, and connect it with the mainland by a subterranean passage, it would facilitate matters, as we have no doubt that large numbers of the general public would willingly pay a substantial fee to have an opportunity of witnessing the manipulation of the various appliances used in promoting their pleasure and amusement, added to which is the paramount necessity of reducing the very exhausting

so that the quantity passing during the hour will be shown by the number of jumps and fraction of 500 gallons. The water in this case is used for driving the ventilating machinery of the House, as well as for other purposes, which accounts for the large quantity registered; and it is somewhat amusing to find the heated temper which gave rise to a crowded house and a warm (in every sense) discussion, thus mechanically registering itself by meter.

ARCHITECTURE IN RELATION TO LANDSCAPE GARDENING.

In the third of his course of lectures delivered at the Crystal Palace on Wednesday afternoon last, Mr. G. Richards Julian dealt with Norman and Gothic architecture. He pointed out that the Norman style, when once planted here, soon exhibited a growth of features by which it was easily distinguished from that form of it which prevailed in Normandy, and proceeded to enumerate in detail the characteristics of the English variety. After a few words on the domestic architecture of the period, the lecturer called attention to the Natural History Museum at South Kensington, designed by Mr. Waterhouse, of which he said that if it be not a revival of the Romanesque style, it is, although freely treated, imbued with much of its spirit, and ornamented with many of its details. He recommended the students to take an opportunity of observing the balustrades of the staircase and of the gallery in the great hall, from which excellent suggestions for the appropriate treatment of balustrades and piers in harmony with Romanesque buildings might be obtained.

Passing to Gothic architecture, Mr. Julian mentioned the various theories as to the origin of the use of the pointed arch,—firstly, that it was suggested by the Norman intersecting arcades; secondly (Mr. Fergusson's), that it was devised to lighten the weight on the crown of a barrel vault; thirdly, that it was introduced by the Crusaders, who had met with the form in Saracenic buildings in the East; fourthly, Sir Digby Wyatt's opinion that the Normans of France got it from the Normans of Sicily; and lastly, the theory (which Mr. Julian adopted) that the pointed form was introduced to overcome a constructional difficulty, namely, the tendency of large semi-circular arches to spread, and so flatten at the crown. On this view of the matter he quoted some passages from the Academy lectures of Sir Gilbert Scott, delivered in 1860.

Mr. Julian deferred until next week the subjects of the domestic architecture of the Medieval period, and the appropriate treatment of garden architecture in connexion with Gothic buildings.

PROTECTION FROM FIRE IN THEATRES.

MARYLEBONE THEATRE.

THE owners of the above theatre, situate at Church-street, Marylebone, were summoned by the Metropolitan Board of Works for that they, between the 25th day of February and the 9th day of July, neglected to make certain alterations necessary to remedy structural defects in the theatre by which danger from fire might result to the public, after having been served with notice to do so.

Mr. Grain, instructed by Mr. Thos. Burton, appeared on behalf of the Board; and Mr. Besley represented the owners.

Mr. Grain stated that the requisitions served were seventeen in number, and the owners had neglected to carry out ten of them, some of these being of a most important character. The proceedings were taken under the 41 & 42 Vic., c. 32, s. 11, which imposed a penalty of 50*l.* in case of default, and 5*l.* for every day during which such default continued. No notice of appeal having been served, the requisition became binding upon the owners, and Mr. Hebbs, Assistant Architect to the Board, was called in support of the Board's case.

Mr. Besley, for the defence, contended that the requisition of the Board had been complied with as far as was practicable, and called Mr. Verity, an architect, in support of his statement.

Mr. De Ruzen said the Act of Parliament was a most important one, and ought to be strictly carried out. He had nothing whatever to do with deciding whether or not the requirements of the Board were necessary. His duty was merely to impose a penalty to show owners of such places as theatres that the requisitions of the Board must be complied with in the interests of the public. He should not impose the full penalty of 50*l.*, but a mitigated penalty of 10*l.*, including costs.

**The Alho-Carbon Light.**—We are asked to state that the lighting of the Brompton Oratory by the Alho-carbon light (as described in our last, p. 521, ante) was effected by the Sanitary Engineering and Ventilating Company, of 115, Victoria-street, Westminster. We hear that this method of lighting has also been successfully applied by the company to several West End Club-houses.

THE DOME OF ST. PAUL'S.

SIR,—Notwithstanding Mr. Robins's own valuation of Thornhill's scheme of decoration, there is the hard-and-fast fact, a fact patent to all who have studied this question, that Sir Christopher Wren sanctioned that scheme, and that it was carried out immediately under the eye of the great architect. The architect and the painter were in favour of colour in the figure compositions, but the Puritanism of the times would not permit such blazonry; any colour would have been then exaggerated into positive scarlet, and any golden overlaying would have been rated as tinsel.

To say that we are in the nineteenth century, and that therefore we ought to do better than in the seventeenth, does, at its first statement, appear to be reasonable, but facts prove that this is not a necessary consequence. We cannot do as well as the architects and artists at a much more distant date than the seventeenth century, and, although in recent years considerable progress has been made in the refinements of art, we have not surpassed the examples of the English Renaissance architecture of the seventeenth century, and neither modern architects nor artists have had any considerable practical experience of the pictorial decoration of such buildings. As an artist who has made mural painting a study, I affirm that, side by side with the experimental projects, Thornhill's is, in architectonic arrangement, immeasurably their superior. Mr. Robins says:—"It is much more an architect's than a painter's province to determine the leading lines and framework of a scheme of decoration." Let this he conceded for the nonce; then I say Mr. Robins's condition has been fulfilled, for Thornhill's architectonic arrangement was designed under no less an architect's supervision than that of Sir Christopher himself,—which of the living architects would Mr. Robins appoint to overrule Wren's sanction?

That the new projects are based on "the fact," as Mr. Robins puts it, "that every plane section of a sphere is a circle," condemns the schemes as being designed on radically wrong principle. The only position in which a circular plane can be appropriately introduced into the decoration of a dome is in the crown of the hemisphere. There are several optical reasons against the introduction of circular plaques elsewhere on its surface. But what shall we say to a project suggesting that no less than fifty-six of these, of various sizes, shall be distributed over its surface? Was this scheme, one almost feebly tempted to inquire, designed in the interests of the spectacle-makers?

The Renaissance admits of exuberance in decorative display,—of altar-pictures in frames, and of hangings in chapels, of hold and daring flights in decoration, of a prodigality of ecclesiastical furnishing, but there must be a method in this noble rage. It is for this that our painters of interiors set up their easels in St. Peter's, and elsewhere, where they are astonished to see how art was flung about in picturesque profusion, instead of being *finicked* on in small quantities, by mere chamber decorators.

The Renaissance, then, is not a pure but a picturesque style of architecture, admitting of considerable latitude of treatment, of redundancy in decorative display. To talk about shams in reference to St. Paul's, when we know that purists are never tired of pointing out various shams in its construction, is quite useless. It is the opportunity that the style affords for a Titanic hurling of masses,—for, as it were, a reckless surcharge of treatment that conduces to its grandeur. It was the necessity for this largeness of treatment that changed the early tenor of the great Italian mural painters. Gothic proportions, and perpendicularity, were found to be incongruous with the huge developments of the Renaissance. It is for these reasons that Thornhill's arrangement is seen to be more congruous with the architecture of St. Paul's than any weaker and more subdivided project, and although Wren had never been in Italy, and may not have been able to express the reasons of this congruity, the great architect, as a born artist, felt that it was.

W. CAVE THOMAS.

SIR,—I had not intended again to trouble you on the subject of the St. Paul's decoration. I am induced now to do so only to reply to the question which in your last issue Mr. Thomas puts as crucial. He asks "Would Mr. Clayton

consider the translation into mosaic of the work of Sir F. Leighton and Mr. Poynter as the effacement of those eminent painter's designs? Would not the mosaics be virtually their designs?"

The reply is obvious. The mosaics, thus produced, would be not virtually but actually their designs, and this for the reasons which would be fatally wanting in a like rendering of Thornhill's monochromes. The cartoons of Sir F. Leighton and Mr. Poynter are those of living men who expressly made them for mosaic, in effects of gold and colour which were, *ab initio*, part and parcel of their designs. Mr. Thomas cannot cite these or any such conditions to justify a translation of Thornhill's work into colour, which could be none of his, and into gold backgrounds, which were abhorrent to his art.

The one plea upon which Thornhill's work has been condoned, has been its generalised vagueness of effect arising from its monochrome throughout. By the proposed translation of this result into unnoted gold and colour for the pictures within the arcade, the latter would be developed into disastrous and undesigned prominence, while the paintings would become a chromatic fiasco in eight parts. This, too, in the name of Thornhill, and in homage to his memory!

JOHN R. CLAYTON.

Oct. 22, 1884.

SEA-SAND FOR MORTAR.

SIR,—In reply to the query of your correspondent "F. L." in your last number [p. 542], as to the use of sea-sand in mortar, may I say that I have often wondered why this (as I consider) important question has never, to my knowledge, been set at rest.

Speaking from a long experience in the use of sea-sand, I beg to say I should never hesitate to use it in preference to any other, either inside or outside of any building. As a matter of fact, I built four houses twenty-five years ago without using a particle of any other than unwashed sea-sand, either in brickwork or plastering, and I never had a single complaint from the occupiers about dampness. I have also frequently used it in large houses without discovering any ill effects from its use, either under paint or paper.

Permit me to say a word as to its value for strength in brick mortar. A few months ago I had to cut away a portion of a two-brick wall in an hotel built eighteen years ago, close to the sea. This wall was built with sea-sand mortar, and I never in my life had a stiffer bit of work to deal with in regard to hardness of mortar.

I should like to see the chemical side of the question settled by a few tests. First, to ascertain the quantity of chloride of sodium it may contain, by sand, after standing a day or so to allow the salt water to drain from it; and, further, whether the action of the lime neutralises the effect of the small quantity of saline matter left in the sand when used in the usual way.

H. L.

\* If our correspondent has used *unwashed* sea-sand with these results, our impression is that he has been very lucky.

SUPPORT OF ADJOINING HOUSES.

SIR,—As so many of your readers are engaged in cases which involve the question of the right of support to houses, permit me to call their attention to a decision of the Court of Appeal, which gives a new and surprising illustration of the rule of law on this subject.

A, the owner of two adjoining plots of land, let one plot to B, to make a private road to his cricket field. He afterwards let the other plot to C to build a house upon it. C built the house, and assigned the lease to D. After D had bought and paid for the house, A, at the request of B, made a drain through the private road, and close to the flank wall of D's house. The trench was considerably deeper than the foundations of B's house. No means were taken by A or B to support D's house while the trench was open, and no notice was given to D to enable him to take such means himself. The effect was that the flank wall of D's house began to slip and crack. The house was rendered uninhabitable. D was obliged to underpin the flank wall, and repair the house, at the cost of several hundred pounds. To recover this outlay, he brought an action against A. Mr. Justice Manisty and Mr. Justice Watkin Williams held he was entitled to recover, the right of support for the house being "a necessary easement," which the law implies.

The Court of Appeal has now reversed that decision and given judgment for the defendant A. The court held that D had no better title than C, and C had no better title than A, and after the lease A could not have prevented the issue of the private road from letting down the house, as he had not in the lease "reserved" the right of support. As the

Master of the Rolls said, if the parties had been asked at the time if they intended that the house should have the right of support they would have answered in the affirmative; but this did not avail the unfortunate purchaser. The right of support was not "necessary" in the strict sense of the word, for by underpinning as deep as the drain, the house could have done without the support of the adjacent soil.

Lessees of houses which have not stood for twenty years may learn from this case that another and serious risk has been added to their property, and one which no previous inquiry or precaution would have enabled them to avoid.

The freeholder who builds his house close to the boundary knows that he runs the risk of his churlish neighbour letting it down; but up till the present time few lessees have been aware that the adjoining lessee who holds under the same landlord may, merely on the ground that his lease is earlier in date, have the right to let down his neighbour's house.

This novel application of an old rule of law will perhaps surprise some of the lessees whose wrongs are said to require remedial legislation. R.

ST. PANCRAS MORTUARY COMPETITION.

Sir.—May I be allowed to say a few words in answer to the letter of Mr. H. H. Bridgman in your issue of the 11th inst. He tells us that an Act of Parliament prevents the Vestry from building the mortuary on the site for which competition drawings were asked (Feb. 2, 1884); hence the delay in decision. He also inserts a copy of a letter showing that his drawings are one of the (six) selected for further consideration when the new site is found. In my opinion, it is unfair to make any selection under the above circumstances, as totally different designs would have been sent in on another site. I think as the old site is not to be used that fresh competition drawings should be asked for. It would be as well if the Vestry said whether drawings were to be under motto or otherwise in future competitions, as a great many signed their drawings.

J. C. WATSON.

HIDDEN DANGERS.

Sir.—Any person passing the Royal Palace of Justice lately must have seen a yawning chasm in front of the building, leading under the Great Hall; and right into the midst of the wall bases, foundation arches, and so on, have the authorities placed two (or more) huge steam boilers, just where they could do most mischief if they were to give way. A veritable Samson would such a steam generator prove if it went, as boilers do go at times in factories and ships of war. If both were working when one exploded, the chance of the other going too might be reckoned on with some certainty. How many more of these bottled earthquakes are there about under our best buildings? Why not put such dangerous things in an outside shed, which need not be ugly? BANG.

The Student's Column.

ON THE CONSTRUCTION OF FLOORS.

WE now pass to the subject of Fire-Proof Floors. The risks of being destroyed by fire to which large warehouses are subjected from the combustible nature of the materials they contain, has drawn the attention of architects to the means which might be adopted to prevent the spread of a fire and confine its action to the story on which it commences. The intense heat that is generated in a large warehouse when a fire takes place, renders the construction of floors that shall be perfectly fire-resisting a matter attended with considerable difficulty, as many substances which will resist a tolerably high temperature become either completely destroyed or else their strength reduced to such a degree as to become practically useless, when exposed to the heat produced in a burning building.

A method commonly adopted at one time of forming what was deemed a fire-proof floor, is shown by fig. 10; cast-iron beams of the section

Fig. 10.

shown at G, were laid across from wall to wall, about 10 ft. or 12 ft. apart, and between them were turned two or three rings of brick arches in cement, the contour of the arches being very flat segments of a circle, so as not to take up

more depth than could possibly be avoided. The haunches of the arches were filled with concrete, C, and the joists, A, laid thereon. To prevent the arches from thrusting out the walls or displacing the girders, wrought iron rods were generally passed through the lower part of the girders, as at T in the figure, being secured with nuts and screws. Experience, however, has shown that when subjected to great heat, the cast-iron beams either broke in pieces or became fused, and allowed the whole floor to fall in. Ordinary bricks also split up under the action of fire, only those made of fire-clay being able to resist a high temperature. Wrought-iron beams have been tried in place of the cast-iron ones, but these become twisted and weakened when exposed to the fire, although they will not fuse as cast-iron does; the longitudinal expansion of the iron is also liable to endanger the walls.

As it is scarcely practicable to make a fire-proof floor without using iron, it becomes an essential point to completely protect the metal from becoming strongly heated, by encasing it in some material capable of resisting the action of fire. A method shown in section by fig. 11,

Fig. 11.

which has been successfully used to a large extent, consists in laying rolled iron joists across from wall to wall of size proportioned to the span; close boarding is temporarily fixed to the underside of the joists, and on this is placed a layer of cement concrete, C, so as to cover up the whole of the iron, as shown in section by fig. 11. The iron joists, A, are usually from 4 ft. to 5 ft. apart, and if the floor is to be boarded, light wooden joists, a, about 2 in.

squares, are bedded on the concrete before it hardens. If a cement or asphaltic floor is required, it can be laid directly upon the top of the concrete after it has thoroughly hardened. As the concrete becomes set in twenty-four hours, the planking below can be removed at the end of that time, and the under-surface will be ready to receive the usual coating of plaster, if it is desired to form a finished ceiling. If the joists are placed 5 ft. apart, the following sizes may be used for ordinary floors according to the span,—for 10 ft. span, the joists may be 5 in. by 3 in. wide; for 12 ft., 6 in. by 3 in.; for 15 ft., 7 in. by 4 in. Or if joists of L section are used, they may be 4½ by 4 for 10 ft.; and 5½ by 5½ for 15 ft. The floors of corridors which are not more than 6 ft. wide can be made of concrete 5 in. or 6 in. thick without the employment of any ironwork, if well bedded on the walls, or York landings 4 in. or 5 in. thick may be used and will be equally impervious to fire. This kind of floor possesses far more rigidity than one of timber, and is also more sound-proof; and although the weight that it throws on the walls is much greater, yet this is, to a great extent, counterbalanced by the absence of vibration which is often so injurious to the walls of a building.

In warehouses and other buildings of wide span it is necessary to use iron girders and binders as in the manner described for timber floors, and shown on figs. 12 and 13. If a

Fig. 12.

Fig. 13.

single rolled iron beam cannot be obtained of sufficient strength, then the girder G may be formed of one on the top of the other, as pre-

viously described and shown by fig. 8; or they may be placed side by side as shown by fig. 9. This latter plan is, perhaps, better, as it is easier to encase the girder in fire-resisting material, which must always be done when iron is used. Rolled iron joists, B, are laid across from girder to girder in the manner of binders, resting on the lower flange of the girder and being riveted thereto with angle plates as shown at T. Between the binders are laid light wrought-iron joists, b, of L section, and on these are laid the concrete, C, in the manner before described, so as to fill up the space between the binders. Light wooden joists, a, can be laid on the top of the concrete to receive a wooden floor. Fig. 12 shows the section of the floor across the girders, and fig. 13 is the section across the binders, at right angles to the former.

As the concrete itself weighs about 140 lb. per foot cube, a thickness of 6 inches will add 70 lb. a foot superficial to the load on the girder, the strength of which must be regulated accordingly. For a span of 18 ft. a single iron joist 19½ in. deep by 7 in. wide, will make sufficiently strong girder for a warehouse floor constructed in the manner above described. For a span of 26 ft. a pair of rolled joists, 16 in. by 6 in., with ½ in. plate 14 in. wide, riveted at top and bottom, as shown by fig. 9, will serve the purpose of a girder.

Another method of employing concrete and iron for a warehouse floor is shown by fig. 14,

Fig. 14.

where G is the iron girder, C the concrete which is laid upon centering to give it an arched soff. By this means the whole of the iron can be encased in the concrete, which is made thicker at the springing than at the crown. A concrete in which sulphate of lime is used in place of Portland cement has been much employed for arches of this description, which are often made of considerable span without any iron being used between the girders. The floor is laid on the top of the concrete in the manner previously described, upon joists bedded thereon if a wood floor is required, or a cement floor may be laid directly on the concrete and covered with tiles or asphalt.

If iron columns are employed to support the girders they should be cast solid, as being more capable of resisting the action of fire than hollow ones, which split up into pieces when exposed to great heat, especially if water comes in contact with them when red-hot. It is, however, always advisable to case the iron columns round with some fire-resisting material, such as fireclay, to prevent any risk of their becoming so weakened by the action of fire as to give way under the superincumbent load.

When a floor of stone, tile, or asphalt is to be laid on the level of the ground, the top soil is first cleared away and the earth raised to the required level by means of a layer of broken brick, lime-core, or ashes, upon which the stone flags can be bedded in mortar, their surface being tooled or rubbed and the edges dressed square before being laid. Where asphalt or tiles are required, a bed of concrete 3 in. or 4 in. thick is first formed, and rendered as nearly level as possible; on this is floated a thin coating of cement, which is allowed to harden, and the tiles, asphalt, or other material laid thereon; tiles being bedded and jointed in cement, and asphalt poured on in a semi-fluid state, fine sand being sifted over the surface while still soft.

As a flag-paving if laid on the ground is liable to become damp, it is best to build sleeper walls 3 ft. apart from centre to centre, and to lay the flags across from wall to wall, bedding them thereon in mortar. In this case the flags must be cut to the exact length of 3 ft. By this arrangement the damp is prevented from striking up from the ground, and the floor is kept dry. Ventilation can be maintained under the floor by means of air-bricks in the outer walls.

Sir.—In your "Student's Column" this week is there not an error in giving the clear depth of a double iron beam for warehouse floor as 13½ in.?

so, is there not a discrepancy between the rule... example for finding the deflection? The rule... "multiply the cube of the length (in inches)...

JOHN A. MARSHALL. Prospect-road, Child's Hill, N.W., Oct. 18, 1884.

"13" was a misprint for "10." As to the word "discrepancy," if the writer had read on he would have seen there was none, as it is stated that a quotient is .96 the deflection in inches when the load is all at the centre; but, as in this case, the load is supposed to be distributed over the length of the beam, we take five eighths of the above, or .6 in. as the deflection in the middle."

Books.

On Implements and Machines. By Professor JOHN SCOTT. London: Crosby Lockwood & Co. 1884.

OWING to the constant and increasing competition in everything appertaining to agriculture, to secure in this country even a moderate return on investment, it has become necessary to conduct farming operations on an improved, or, we may say, a more scientific basis than has hitherto been the practice. The recent advances made by America in reaping and binding and other agricultural machinery, and the progress made by some of the Continental nations,—notably Hungary with regard to milling machinery,—have, with other causes, rendered successful competition by English oat-growers a matter of extreme difficulty. The issue, therefore, by Messrs. Crosby Lockwood & Co. of a series of farm engineering textbooks, by Mr. John Scott, must be considered very *apropos* at the present moment. To one before us "Barn Implements and Machines," No. 5 of the series, we do not content altogether so worthy of commendation as one that have preceded it. Some of the chapters,—particularly those relating to water, steam, gas, and hot-air powers,—are crude, and a matter not by any means new. In several cases they smack very much indeed of the *ade* catalogue.

We cannot agree with the author's conclusion at "an engine which is merely a portable, and not a traction, engine is now of comparatively little value on the farm." In point of fact, is,—owing to hills, bad roads, small fields, and other causes,—only a moderate proportion of the farms in this country that can use a traction-engine profitably, to say nothing of its largely increased first cost. The author remarks that the best makers give 20 ft. of beating surface to the boiler for each nominal horse power. We do not say in what type of boiler; we presume, however, he refers to tubular boilers. To think on inquiry he will find that this amount of beating surface is exceptional, and in the case of the larger tubular, Cornish, Lancashire, and vertical boilers, this statement requires very considerable modification.

The latter part of the book is a great improvement on the first, and the author appears to be much more at home with his subjects. The best chapters are those relating to thrashing-machines, the arrangement of barn machinery, and dairy appliances, and these alone are well worth the price charged for the whole.

Coûtures en Ciment de Bois. By CHARLES S. HAESLER. Hanover: Th. Schäfer. 1884.

This is a pamphlet describing a woody cement or the construction of flat roofs, which is said by the author to have been largely introduced into Southern Germany. The cement is a viscous and bituminous paste, of which the basis is wood, and is stated to be flexible and noncombustible; it is put on warm, and becomes when cold metallically hard. The roof is arranged horizontally, or with a very slight rise, and the wood covered with a thin bed of fine sand (about three millimètres); this, again, is covered with alternate layers of prepared paper and wood cement; and, finally, with powdered coal or fine furnace slag dust; on this is placed sand and gravel, which is well rolled, the object being to protect the cement from the deleterious action of the atmosphere. Amongst the advantages claimed for this roof by the inventor are that it is as cheap as an ordinary roof, weighs very little more, is fireproof and weatherproof. The roof has been

designed specially to allow of it being used as a garden or playground, and the book contains some illustrations of such gardens, the appearance of which in London would be, to say the least, refreshing. A number of illustrations of different designs for the construction of roofs in wooden cement are given.

The composition of the cement not being stated, we are unable to form an opinion as to the likelihood of its durability: the method of fixing certainly appears rather troublesome, and we should imagine that its success would depend largely on the skill with which the roof was laid, and protected from moisture by proper ventilation, say by free currents of air passing beneath it.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

3,057, Improvements in Balancing Apparatus for Railway-carriage or other Window Sashes. J. A. Adams, Liverpool.

This device is chiefly for railway-carriage windows and to obviate the defects of the present system. The windows are at present generally lowered with a strap. This strap necessitates an expensive holder and strap, with a stud or holder, and a defect of a more serious kind is the open space between the inner and outer middle rail or cross-bar of the door, down which space or opening rubbish of various kinds, and occasionally lighted matches or fuses, are thrown. The removal of these is only effected with great expense. In this invention cords or wire-rope are used, and the weights for balancing the sash are placed out of the way. The opening is also covered by a thin strip of wood. The balance-weight or weights preferably take the form of an iron bar, which is fixed, stretching from side to side of the hollow panel or pocket of the door. This bar has india-rubber buffers at each end to deaden the shocks or concussion.

11,509, Improved Process for the Production of Monumental Designs, &c. A. J. Boulton, for F. M. Nicholls, of Chicago.

The designs for building monumental or other work are varied by the interchange of blocks or cards with parts of designs cut upon them, and comprising in all but a very few pieces of finished structures, an endless variety of designs by mere mechanical operations may be produced.

11,614, Improved Wheel-barrow. Browne & Co., for Jules George Dreyfus, Paris.

These metallic wheelbarrows are made with the body stamped out of a single piece by a die, and the bottom of the barrow is also stamped from a single corrugated piece of iron or other metal. The frame, too, is corrugated, and the inventor claims lightness and strength, combined with cheapness in manufacture.

1,290, Improvements in the Arrangement, &c., of Receptacles for Coals, &c., in combination with Chimney-pieces or Fireplaces. Arthur Foley, Salisbury.

Into the chimney-breasts, jambs, hoods, or sides, receptacles are introduced for holding coal or other fuel. These are so arranged as to slide in or out, or to move to and fro on hinges, open sideways, fall over, or as convenient for storing and emptying the fuel. The hoppers or drawers are hidden from sight by the fittings, and in an improved form a projection is made at the base of the jamb, which is very convenient for holding coal.

342, Improvements in regulating the Height of Desks and Seats. W. H. St. Ruth, Manchester.

The desk or seat rests on a round, oval, square, or triangular column or shaft, with parallel or with tapering sides, placed in a cavity with a wedge thin end downwards. When the desk or seat is lifted, the wedge prevents its return. When the wedge is lifted, the desk or seat descends. The wedge is moved by a handle working freely in a slot. This method of fixing the adjustable column is the claim of the patent.

APPLICATIONS FOR LETTERS PATENT.

Oct. 10.—13,388, H. Smith, Coventry, and D. Smith, Birmingham, Improvements in Window-sash Fasteners.—13,390, W. W. Cunningham, London, Improvements in Lock Furniture.—13,556, A. C. Carver, London, Improved Window-sash Fastener.—13,552, H. H. Lake, London, Lifting Jacks, parts of which are applicable for other purposes.—13,553, W. Hussall, London, Fireplaces or Furnaces for Heating Pottery, Bricks, and like Kilns or Ovens.

Oct. 15.—13,602, D. Allport, London, Improved Paving for Carriage-ways.—13,605, H. Nance, Liverpool, Locks and Latches.—13,621, R. G. Kirton, London, Chimney-top and Ventilator.—13,626, E. Wood, London, Composition for Washing, Renovating and Reviving all kinds of Stone Work.—13,634, C. De Bourbon, Gonzaga, London, Application of Veneers of Wood or other Substances to Cloth, Paper, or other flexible Material, for decorative purposes, and to Wood with Waterproof Glue and Cement.—13,636, F. Howcroft, London, Automatic Sash Lock.—13,646, H. G. Gilchrist, London, Gasfitters' Pliers.

Oct. 16.—13,656, E. H. Booth and F. N. Dyer, Manchester, an Improved Sanitary Appliance.—13,668, S. Willett, London, Improvements in Door-handles and their Spindles.—13,672, H. G. Appleford, Birmingham, Burners for Heating purposes.—13,684, S. Pooley, London, Machinery for Sawing Timber.—13,690, J. Waller and B. Farrington, London, Raps and Coaks.—13,691, G. Nobes, London, Supplying Disinfecting Fluid to Water-closets and Urinals.—13,692, A. F. Dennison, London, Machinery for Cutting Wood of various Shapes for Marquetry and Parquetry Work.—13,699, H. G. Harris and G. Beavis, London, Improvements in Bakers' Ovens.—13,700, G. Coultas, London, Improvements in Pipe-joints.

PROVISIONAL SPECIFICATIONS ACCEPTED.

11,926, G. Cresswell, Brighton, Improvements in Pipes for Water-closets, &c.—11,957, S. P. Pochin, London, Improvements in Structures of Iron and Concrete, or equivalent Material.—12,143, B. P. Harris and A. Stagg, London, Kins or Drying Floors.—12,237, J. Bartlett, London, an Improved Lift.—12,257, J. Partridge, London, Window-blinds, applicable also to Partitions or Screens.—12,364, J. Rawlings, London, Cutters for Wood-planing Machines, and an Appliance for Grinding same.—12,486, T. Freeman, Jun., and E. Easley, Haxley, Machinery and Method of Manufacturing Hollow Bricks and other Hollow Clay or Plastic Building Materials.—12,607, W. L. Wise, London, Ventilating Apparatus.—12,747, W. Shaw, Glasgow, Stoves and Cooking-ranges.—12,750, S. B. Sutcliffe, London, Construction of Wooden and other Chimney-pieces.—12,767, W. D. Curzon and G. Jones, London, Manufacture of Pigments.—12,816, J. Stephens, Stonehouse, Heating Apparatus.—12,816, S. Peacock, London, Improvements in Ovens.—12,833, H. J. Hadden, London, Drying Kilns.—12,907, E. Smith, Birmingham, Appliance for Opening and Closing Windows.—12,973, H. K. Bromhead, London, Kitchen Ranges and Stoves.—13,083, S. Coombs, London, Improvements in Doors, springs.—13,089, R. Hodges and J. Archer, London, Sash Fastenings.—13,112, T. S. Worthington, London, Producing Imitations of Wood and Marble on Painted and other Surfaces.—13,136, G. Grey, London, Appliance for Locking the Levers of Window-catch Fasteners.—11,113, J. Rosenthal and C. M. Rosenthal, Vienna, Fireproof Curtains.—11,844, Theatres, Warehouses, and other Buildings.—11,844, W. Caron, Birmingham, Adjustable Holding and Regulating Cramp.—12,538, W. Mangnall, London, Improvements in Water-closets.—12,736, J. Blacka, Toomorden, Pointing Tool.—12,771, H. A. Stuart, Fenny Stratford, Screw Lifting-jacks.—13,033, L. Dathis, London, Bakers' Ovens.—13,143, H. Tuff and C. R. Mathews, London, Water Waste-venters for Water-closets.—13,147, R. Oakley, London, Apparatus for Ventilating and Warming Buildings.—13,231, F. C. Hestler, London, Window Sash-fasteners.

COMPLETE SPECIFICATIONS ACCEPTED.

Open to opposition for two months. 108, T. Jones, London, Improvements in Ventilators.—139, W. H. Barclough, Edgubaston, Apparatus for Flushing Water-closets, &c.—259, H. H.

Bridgman, London, Improved Girder and Fire-proof Floor.—260, H. H. Bridgman, London, Fireproof Floors.—326, J. Smith, Liverpool, Improvements in Fireplaces and Grates.—407, F. T. Bond, Gloucester, Stoves for Warming and Ventilating Purposes.—2381, C. Walton, London, Machine for Separating Clay or other Materials from Stones or other Hard substances.—10,853, J. Brendon, jun., and Geo. D. Brendon, Cullington, Cuphead Fasteners.—209, F. Smith, Birmingham, Raising, Lowering, and Securing Window Sashes.—519, J. Petrie, Rochdale, Heating Rooms and Buildings.—571, H. M. Ashley, Ferrybridge, Kitchen Range.—661, E. Woolfenden, Rochdale, Improved Ventilator.—723, S. Smith, Smethwick, Cooking Ranges.—887, S. Reeve, London, Warming and Ventilating Apartments and other Places.—1,046, H. Sutcliffe, Halifax, Water-closets and Apparatus connected therewith.—1,339, J. Hodgson, Birkenhead, Window Sash or other Fasteners.—9,744, T. Telford, Newcastle-on-Tyne, Chimney-tops and Apparatus connected therewith.—12,476, J. E. Hopkinson, London, Improved Roller Blind.

## MEETINGS.

MONDAY, OCTOBER 27.

*Inventors' Institute*.—Mr. E. Guest on "Universal Visible Speech," 8 p.m.

TUESDAY, OCTOBER 28.

*St. Paul's Ecclesiastical Society*.—Mr. Hugh Standen on "The Decoration of St. Paul's," 7.30 p.m.

WEDNESDAY, OCTOBER 29.

*Institution of Carriage Manufacturers*.—The Taxes on Carriages (public meeting, Westminster Town-hall), 8 p.m.

## Miscellaneous.

**Third-class Passenger Traffic and Railway Profits.**—The returns which have just been issued show that railway shareholders continue to be mainly indebted for their dividends to third-class traffic. The total number of first-class passengers who travelled on all the railways now opened for traffic in the United Kingdom, during the half-year ending on the 30th of June last, was 16,115,749; second-class, 25,814,099; and third-class, 241,739,085; the number of third-class passengers being more than 500 per cent. in excess of first and second-class passengers combined. The relative amount of receipts is in equal proportion, those from first-class passengers being 1,658,977*l.*; second-class, 1,402,459*l.*; and third-class, 7,281,213*l.* The difference applies to all the lines in common, as a reference to the traffic on the London and North-Western and other leading lines shows. Thus, on the London and North-Western line the number of first-class passengers was 1,139,500; second-class, 1,946,000; third-class, 22,841,751; and the receipts from first-class passengers, 241,534*l.*; second-class, 172,710*l.*; and third-class, 1,007,950*l.* The figures given in connexion with the traffic on the Great Western, Great Northern, Great Eastern, Midland, South-Western, and the whole of the other lines having their termini in the metropolis show similar results. The North London line returns are especially striking, the receipts from first and second-class passengers being 16,768*l.*, whilst those from third-class passengers amounted to 128,590*l.*, or about 800 per cent. more than from first and second-class combined. Within the period named the Metropolitan and Metropolitan District Companies and the North London Company carried upwards of 50,000 passengers, to which must be added, as showing the enormous traffic within the area of the metropolis, that of the Great Eastern, London, Chatham, and Dover, London and Brighton, and the South-Western and South-Eastern companies, a large portion of which is purely metropolitan.

**The Nineteenth Century Art Society.**—Saturday, November 1st, has been appointed for the private view of the Autumn Exhibition of the Nineteenth Century Art Society at the Conduit-street Galleries, and the Exhibition will be open to the public on Monday, November 3rd.

**Inventors' Institute.**—The opening of the session will take place at Lonsdale-chambers, Chancery-lane, at eight p.m. on Monday next, when, after a brief address by Admiral Selwyn, Mr. E. Guest will read a paper on "Universal Visible Speech," introducing, in illustration, one of Farini's dwarf Earthmen, from the *Aquarinn*.

**The Surveyors' Institution.**—The first ordinary general meeting of the Session will be held on Monday, November 10th, when the president, Mr. T. Smith Woolley, will open the Session with an address.

**New Office Buildings in Basinghall-street.**—An extensive and striking block of new buildings is at present in course of erection in Basinghall-street, having a frontage of 62 ft. to that thoroughfare. The buildings are Flemish in style, and are faced with Dumfriess stone and Portland cement. They contain six floors above the ground-line, and a deep basement. The main elevation, containing four of the floors, is 50 ft. high, the extreme height to the apex of the stepped gable in the centre of the frontage being 76 ft. The buildings are being erected in two divisions, and under separate contracts, one of the divisions being now almost completed and ready for occupation. The ground-floor of this division has two spacious windows on each side of an entrance 11 ft. in width, which is very elaborately treated. This portion of the frontage, up to the top of the first floor, is constructed in a recess about 4 ft. in depth to the rear of the main face of the building. Immediately over the entrance is an enriched moulded cove in fibrous plaster, containing work in relief, specially designed and modelled by Messrs. Daymond & Son, of Vauxhall Bridge-road. Immediately above the entrance, within the recess already named, there are octagonal piers alternately in Dumfriess stone and Portland cement surmounted by hoods or turrets, and above these, on a level with the upper part of the second floor, there is a central arch in Dumfriess stone. The treatment, architecturally, of the building within the recess is a special feature in the structure. The several floors have two and three-light mullion windows, and in the glazing and other details the character of the style of architecture adopted is maintained. The interior is arranged in suites of offices, of which there are a large number, admirably lighted from the rear as well as from the front of the building. All the offices are fitted with slow-combustion stoves, supplied by Messrs. George Wright & Co. Mr. R. M. Roe, A.R.I.B.A., of Basinghall-street, is the architect, the contractor for that portion of the block now nearly finished being Mr. J. Grover, of the Wilford Works, New North-road, and for the other portion, Messrs. Larke & Son, of Fore-street, E.C. The cost of the entire block will be about 8,000*l.*

**Technical Education for Carpenters and Joiners at the Health Exhibition.**—Some instructive diagrams and models in wood, joinery, are exhibited in one of the rooms containing the Finsbury Technical College exhibit, by Mr. Staynes. The drawing and model of a splayed lining to an "ellipse on circle" frame shows all the working lines for the construction of this difficult piece of work. A very difficult case of raking moulding is shown. The angle between the walls is an obtuse angle; both mouldings are on the rake, and the rake of one is greater than that of the other. The drawing and model of a piece of handrail show the theory of the tangent system of handrailing, the drawing giving the tangents, pitch of the plank, face mould, bevels, the thickness of the plank, and the width of the cutting-out mould, while the model shows the application of moulds and bevels, and it can be taken to pieces so that the manipulation can be clearly illustrated. The model of a piece of "circle on circle" work, made by one of the first-year students of Mr. Staynes at Finsbury College, shows, at the different stages of construction, the application of the various moulds and bevels.

**New Public Hall and Assembly-rooms at Streatham.**—The great expansion of which has been going forward during the last few years, has led to a determination to erect a new public hall in the parish, which is about to be carried out. Three large estates in the neighbourhood have been laid out for building on two of these upwards of 600 houses have already been erected. Upon a third estate, the Manor Park Estate, recently laid out, building is at present actively going forward. About 100 houses have already been built. In one of the main roads of this estate, and conveniently situated near the railway station, the public hall is to be erected. The building will contain a large public hall and assembly-rooms for public meetings and entertainments, with reading-room, smoking-rooms, chess-rooms, committee-rooms, &c. The ground-floor will consist of shops. Messrs. Wheeler & Holland, of Chapside, who have designed the buildings which have so far been erected on the estate, are the architects.

**The Width of Streets.**—Much advance has been made during recent years in securing increased space about inhabited dwellings, and modern regulations require that a certain minimum of space shall be given in the rear of houses, and also to the front, the width of the street being taken into account as regards the latter space. But in the State of Illinois the excessive width of the streets is reported as having of itself become a source of nuisances or of danger to health. Sixty feet and more are ordinarily given to new streets, even in the smaller towns; 8 ft. on each side are paved and devoted to pedestrians, and the remaining space, varying usually from 44 ft. to 54 ft., is devoted to carriage traffic. The result is that this wide carriage-road, so often in excess of the requirements of the vehicles that have to travel over it, becomes a source of such expense as to forbid its being properly paved, cleaned, and channelled. The street, consequently, is soon turned into a vast surface of dirt mixed with filth, horse droppings, and other refuse, and when the weather is so dry that dust is formed, the air which is inhaled as the dusts about is calculated to bring about diseases as well as discomfort, instead of promoting the health of pedestrians. Dr. Gregory, in bringing forward this subject, fully concurs in the great importance of providing wide thoroughfares, and of keeping the number of inhabitants to each acre down to a proper maximum, and hence he declares that he would not on any consideration diminish by a single foot the width of the streets. But he would curtail the width of the roadway, so that it shall only suffice for the proper demands of the carriage traffic; and between that limited space, which could then be properly kept at a reasonable cost, and the footpaths, he would plant trees and lay down grass, so as really to provide in towns and cities such freshness and greenness as would go far to induce people to take that form of exercise which is most conducive to health.—*The Lancet*.

**Wellington College.**—The Governors of this College have recently completed extensive sewerage and water-works schemes at the above. An entirely new system of sewer and rain-water pipes has been laid. The sewage gravitates to the purification works, consisting of mixing-basins, precipitating-tanks, and silt-pits, about one mile and a quarter from the College, where it is dealt with by the Native Guano Company under their patent process. The rain-water is collected in a large underground reservoir, near the recently-erected laundry, and is used for washing purposes. The water-supply is now also completed; the water is pumped to Edge Barrow-hill, about three-quarters of a mile from the College, where circulating reservoir filter-beds and clean water storage-reservoir have been constructed. The existing well has been relined with iron cylinders, 6 ft. in diameter; the well is about 250 ft. deep. Extensive sanitary alterations in the interior of the College have also been executed. The engineer was Mr. Baldwin Latham, C.E., F.G.S., &c. The resident contractor was Mr. Sydney Lowcock. The contractors were Messrs. B. Cooke & Co., of Battersea, whose contract amounted to about 12,000*l.*

**Messrs. Chubb & Son and their workpeople.**—The new building for the coffee-tavern and workmen's dwellings in connexion with Messrs. Chubb & Son's Safe Works, Glangall-road, Old Kent-road, London, is now advanced, and will be completed by Christmas. We are pleased to note that arrangements are being made to form a large and complete library for the workpeople and their families; and the first book presented to it is a copy of the Queen's latest work, which Her Majesty sent to the workmen quite unolicited, the title-page bearing an inscription with her autograph. We are told that the building contains several novel features of interest, so that it will, complete, repay a visit to those interested in such matters. The architect is Mr. Elijah Hoole, of Great Russell-street; and the builder is Mr. Edward Edwards, of Leighton-road, Kentish Town, N.W.

**Dublin Artisans' Dwellings Company.**—The secretary of this company writes, in reference to a remark in our leading article of the 4th inst., that it is incorrect that any members of the Corporation of Dublin are shareholders in the Artisans' Dwellings Company. We of course made the statement on what we believed to be trustworthy information.

**Association of Municipal and Sanitary Engineers and Surveyors.**—A meeting of members of the northern district of the Association of Municipal and Sanitary Engineers and Surveyors was held at Stockton on Monday last. Mr. Laws, M.I.C.E., city engineer of Newcastle, and president of the Association, presided. The mayor heartily welcomed the members to Stockton. Mr. J. W. Tomson, of Willington Quay, was unanimously elected hon. secretary to the district. The president briefly addressed the meeting, and urged that the Association should apply for a charter of incorporation to enable them to conduct examinations and grant certificates. If they should not take this step, he thought the local Government Board would institute examinations. As to the suggestion that sanitary engineers and surveyors should not be liable to be discharged without the consent of the Local Government Board, he disapproved of it, because through a powerful association would be able to protect its own members if they were committed. After visiting the Tees conservancy works the members dined together.

**St. Austell.**—The parishioners of Holy Trinity Church, St. Austell, Cornwall, have erected a four-light Munich stained-glass window, by Messrs. Mayer & Co, to the memory of the late Rev. Fortescue Todd, vicar from 1838 to 1881.

**Richhill (Co. Armagh).**—A window has been erected in the transept of Richhill Church, in memory of the late Mrs. Bacon, by the friends, parishioners, and tenantry. It is a three-light window in the Perpendicular style of architecture, with a number of openings in the tracery. The subjects chosen in the upper part of the design are figures representing "Faith," "Love," and "Hope," with typical subjects in the base of "The Marriage Feast at Cana," "Our Lord healing the Sick in the Temple," and "Our Lord raising the Widow's Son." In the upper part of the tracery are "Angels holding emblems of purity," "Angels in prayer," and in the centre an angel holding the celestial crown. The work has been executed by Mr. James Cameron, of Wigninstown, London.

**Pulpit, St. John's Wood.**—A circular pulpit, in alabaster, to the memory of the late Mr. Edmund Robins, has recently been erected in All Souls' Church, St. John's Wood. The work has been executed by Messrs. Farmer & Brindley, of Westminster Bridge-road, from the designs of Messrs. Wadmore & Baker, of 35, Great St. Helen's, London.

**West Hartlepool.**—Plans for considerably extending the business premises of Messrs. J. Backhouse & Co. have been approved of by the Commissioners, Mr. G. G. Hoskins, F.R.I.B.A., of Darlington, being the architect.

For the erection of a villa at Goring, Oxon., for Mr. E. H. Baydon, Mr. J. S. Dodd, architect, Reading:—

**PUBLIC APPOINTMENTS.**

Nature of Appointment.	By whom Advertised.	Applications to be in.	Salary.	Page.
urveyor, &c.	Wantage Improvement Commissioners	Nov. 1st	100 <i>l</i> . per annum	xvi.

**TENDERS.**

For laundry to be erected in the rear of Ebenezer Terrace, Kennington-road, for Mr. C. Zierenberg. Mr. Banister Fletcher, architect:—  
 Blyton..... £917 0 0  
 Mills..... 876 0 0  
 Parker..... 789 0 0  
 Towner & Patten..... 765 0 0  
 Burman & Sons..... 749 0 0  
 Buchanan..... 695 0 0  
 Andrews (accepted)..... 679 0 0  
 Aldridge & Jenvey..... 673 0 0

For additions to "Anglebay," Woodchurch-road, West Hampstead, for Mr. Banister Fletcher:—  
 J. Mansbridge (accepted)..... £220 0 0

For shops to be erected in Brent-street, Hendon. Second contract. Mr. Banister Fletcher, architect:—  
 J. Ellacott (accepted)..... £1,400 0 0

For the erection of a house in the Royal-road, Kennington, for Mr. C. Zierenberg. Mr. Banister Fletcher, architect:—  
 Smaller House. Larger House.  
 Mills..... £800..... £940  
 Towner & Patten..... 795..... 937  
 Parker..... 791..... 890  
 Blyton..... 795..... 900  
 Burman & Sons..... 765..... 767  
 Aldridge & Jenvey..... 640..... 719  
 Andrews..... 698..... 671  
 Buchanan..... 664..... 695

For alterations to No. 44, Fish-street-hill, E.C. Mr. Edward Pover, architect, 16, King William-street, E.C.

Quantities by Mr. W. Barret	
B. E. Nightingale	£1,507 0 0
R. Conder	1,395 0 0
Burch & Co.	1,367 0 0
J. R. Hunt	1,249 0 0
J. & J. Greenwood	1,212 0 0
J. Dover	1,200 0 0
Fuller (late late)	1,120 0 0
W. Shurmer	1,158 0 0
Hill & Berridge	1,150 0 0
J. O. Richardson	1,059 0 0

For alterations, &c., at Richmond-road, Barnsbury, for Dr. Wilkinson. Mr. W. Smith, architect.

Wood	£205 0 0
Oldis	201 0 0
Matthews	183 0 0
Lark	180 0 0
Hewitt	177 0 0
Dearing & Son	176 5 6
Dunson & Lang	169 0 0
Stevens	158 0 0

Accepted for the erection of storehouse, coachhouse, stables, &c., being the first portion of new brewery stores, London-road, Hatfield, for Messrs. Savill Brothers, Mr. Frederick A. Ashton, architect, Stratford.—

J. Hearle & Son	£750 0 0
-----------------	----------

Accepted for the erection of committee-rooms, classrooms, and caretaker's apartments (Contract No. 2), for the Building Committee of St. Barnabas's Schools, Homerton. Mr. E. Witts, architect. Quantities supplied.—

Stimpson & Co.	£1,530 0 0
----------------	------------

For converting three houses into shops near Clapham Junction. Mr. Thomas Spearing, surveyor.—

J. Munday	£750 0 0
Samuel Rice	730 0 0
Jones & Edwards	590 0 0
E. Book	480 0 0
Robinson & Miller	460 0 0
Howard	444 0 0
Saunders & Co.	405 0 0
Rand	400 0 0
Thompson & Co.	388 0 0
W. Ellis	390 0 0
F. Warr	360 0 0
R. Smith	350 0 0
Hughes & Davis	348 0 0
Baker	330 0 0
Scharier & Williams	317 0 0
Coussons & Simmons	295 0 0
Fewart & Co (accepted)	243 0 0
C. J. Rand	225 0 0

For alterations, &c., at No. 480, Kingsland-road, for Messrs. A. & W. Flatau. Mr. T. E. Knightley, architect.—

Greenwood	£717 0 0
Ashby	698 0 0
Staines & Son	584 0 0
Staines & Son* (reduced estimate)	352 0 0

\* Accepted.

For alterations and additions to the Wesleyan Sunday Schools, Ramsgate. Mr. E. L. Egar, architect.—

Hugden	£455 0 0
Smith	437 10 0
Port	420 0 0
Martin	419 10 0
Grumman	370 0 0
Bowman	339 0 0
Miller	310 0 0

For alterations to wine cellars, and building chimney-shaft, for Messrs. Wat-wal & Co., Ramsgate. Messrs. Hinds & Son, architects:—

Smith	£1,365 0 0
Miller	893 0 0
Bowman	879 0 0
Newby Bros.	576 10 0
Hone	565 0 0
Grumman	554 0 0
Martin (accepted)	532 0 0

For heating with hot water Hepe Church, North Wales. Mr. J. Oldrid Scott, 31, Spring-gardens, London, architect.—

Messenger & Co., Loughborough	£95 17 6
-------------------------------	----------

\* Accepted.

For erecting cement concrete sea-wall, groynes, and other works, for the Commissioners of Highways, on the shore near the Granite fort, Sandown Plains, Isle of Wight. Quantities by the surveyor, Mr. E. Humphreys, East Medina District.—

T. Hall, Portsmouth	£918 15 0
T. B. Hayton, Portsmouth	835 0 0
T. Jenkins, Newport	799 0 0
G. Hayes, Shanklin	695 0 0
T. Hayden, Sandown	625 0 0
E. Pritchard, Sandown (accepted)	615 10 0
J. White, Sandown	723 0 0
T. Barton, Ryde	594 10 0

[Mr. Barton's tender was first accepted, but was thrown out on account of not naming surtees at the time of tendering, in accordance with specification.]

For two new shops, Brixton-road, for Mr. F. Bird. Messrs. Fowler & Hill, architects. Quantities supplied:—

W. King & Son	£2,900 0 0
W. Brown	2,855 0 0
Jas. Carpenter	2,386 0 0
John Dickson	2,690 0 0
Pack Bros. (accepted)	2,473 0 0

Accepted for storage water-tanks, &c., at the Ipswich Borough Asylum. Mr. E. Buckland, architect. Mr. Crisp & Smith

	£251 0 0
--	----------

[Amended price for 3 1/2 in. tanks]

For works to Cabden-road, Sevenoaks, Kent, in forming, metalting, kerbing, channelling, storm-water drains, gullies, &c., for the Sevenoaks Local Board. Mr. James Mann, surveyor:—

H. Owen, Sevenoaks	£561 16 6
W. J. Botterill, Sevenoaks	405 0 0

[Surveyor's estimate, 496.]

For the construction of 109 lineal yards of glazed earthenware pipe sewer, with manholes and lamp-hole, in a portion of the Gordon-road, Sevenoaks, Kent. Mr. James Mann, surveyor:—

H. Owen, Sevenoaks and London	£35 0 0
H. J. Botterill, Sevenoaks	2,236 0 0
Chas. King, Sevenoaks	62 9 0
H. Robbins, Sevenoaks	62 9 0
H. Owen, Sevenoaks (accepted)	53 7 6 0

[Surveyor's estimate, 70.]

Special Notice.—Lists of tenders frequently reach us too late for insertion. They should be delivered at our office, 48, Catherine-street, Strand, W.C., not later than four p.m. on Thursdays.

PUBLISHER'S NOTICES.

CHARGES FOR ADVERTISEMENTS. SITUATIONS VACANT, PARTNERSHIPS, APPOINTMENTS, TRADE, AND GENERAL ADVERTISEMENTS. Six lines (about fifty words) or under ..... 2s. 6d. Each additional line (about ten words) ..... 6s. 6d. Terms for Series of Trade Advertisements, also for Special Advertisements on front page, Competitions, Contracts, Sites by Auction, &c., may be obtained on application to the Publisher.

SITUATIONS WANTED. FOUR Lines (about THIRTY words) or under ..... 2s. 6d. Each additional line (about ten words) ..... 6s. 6d. PERSUASION IS ABSOLUTELY NECESSARY. \* \* \* Stamps must not be sent, but all small sums should be remitted by Cash in Registered Letter or by Money Order, payable at the Post-office, Covent-garden, W.C. to DOUGLAS FOURDRINER, Publisher, Addressed to No. 46, Catherine-street, W.C.

Advertisements for the current week's issue must reach the Office before THREE o'clock p.m. on THURSDAY. The Publisher cannot be responsible for DRAWINGS, TESTIMONIALS, &c., left at the Office in reply to Advertisements, and strongly recommends that of the latter COPIES ONLY should be sent.

SPECIAL.—ALTERATIONS IN STANDING ADVERTISEMENTS OR ORDERS TO DISCONTINUE SAME, must reach the Office before TEN o'clock on WEDNESDAY morning.

PERSONS Advertising in "The Builder," may have Copies addressed to the Office, 48, Catherine-street, Covent-garden, W.C. free of charge. Letters will be forwarded if addressed in envelopes are sent, together with sufficient stamp to cover the postage.

TERMS OF SUBSCRIPTION. "THE BUILDER" is supplied direct from the Office to readers in any part of the United Kingdom at the rate of 9s. per annum, in advance. To countries within the Postal Union, 10s. per annum. Remittances payable to DOUGLAS FOURDRINER, Publisher, No. 46, Catherine-street, W.C.

TO CORRESPONDENTS.

E. and R. (our advertising columns are open)—J. W. B. (find our mark)—W. G. S. Exors. (amounts should be sent)—R. T. (late for this week)—F. C. F.—J. C. G.—H. H.—J. H.—W. J. W. G.—W. C. All statements of facts lists of tenders, &c., must be accompanied by the name and address of the sender, not necessarily for publication. We are compelled to decline pointing out books and giving addresses. Note.—The responsibility of signed articles, and papers for public meetings, rests, of course, with the authors. We cannot undertake to return rejected communications. Letters or communications (beyond mere news-items) which have been duplicated for other journals, are NOT DESIRED. All communications regarding literary and artistic matters should be addressed to THE EDITOR; all communications relating to advertisements and other exclusively business matters should be addressed to THE PUBLISHER, and not to the Editor.

Best Bath Stone. WESTWOOD GROUND, Box Ground, Combs Down, Corsham Down, And Farleigh Down. BANDELL, SAUNDERS, & CO., Limited, Corsham, Wilts. [ADVT.]

Box Ground Stone. Is the Best for Use in all Exposed Positions, being a well-known and tried Weather Stone. 50,000 feet cubo in stock. PICTOR & SONS, BOX, WILTS. [ADVT.]

Doubling Freestone and Ham Hill Stone of best quality, in blocks, or prepared ready for fixing. An inspection of the Doubling Quarries is respectfully solicited; and Architects and others are CAUTIONED against inferior stone. Prices, delivered to any part of the United Kingdom, given on application to CHARLES TRASK, Norton-sub-Hamdon, Ilminster, Somerset.—Agent, Mr. E. WILLIAMS, 16, Craven-street, Strand, W.C. [ADVT.]

Doubling Free Stone For prices, &c., address S. & J. STAPLE, HAM HILL STONE, Quarry Owners, Stone and Lime Merchants, Stoke - under - Ham, Ilminster. [ADVT.]

Asphalte.—The Seyssel and Metallo Lava Asphalte Company (Mr. H. Glenn), Office, 38, Poultry, E.C.—The best and cheapest material for damp courses, railway arches, warehouse floors, flat roofs, stables, cow-sheds and milk-rooms, granaries, tun-rooms, and terraces. [ADVT.]

Asphalts. Seyssel, Patent Metallo Lava, and White Asphalts. M. STODART & CO. Office: No. 90 Cannon-street, E.C. [ADVT.]

J. L. BACON & CO., MANUFACTURERS OF IMPROVED STEAM AND HOT-WATER APPARATUS, FOR WARMING AND VENTILATING Private Houses, Churches, Schools, Hospitals, Manufactories, Greenhouses, &c. OFFICES AND SHOW-ROOMS:—No. 34, UPPER GLOUCESTER PLACE, DORSET SQUARE, LONDON, N.W. And at DUBLIN, BELFAST, GLASGOW, and NEWCASTLE. Illustrated Pamphlet on "Heating" post free.

CHAPPUIS' PATENTS FOR REFLECTING LIGHT. DAYLIGHT REFLECTORS OF EVERY DESCRIPTION, ARTIFICIAL LIGHT REFLECTORS.

WHY BURN GAS?—CHAPPUIS' REFLECTORS DIFFUSE DAYLIGHT.—They are exclusively adopted by and fitted at Buckingham Palace, all H.M. Government Offices, Houses of Parliament, H.M. First Commissioner of Works, the Metropolitan Board of Works, British Museum, South Kensington Museum, Royal Institution, Guildhall Museum, on board H.M. Ships, also Railway Companies' Offices, Hospitals, Institutions, Banks, Insurance Offices, Manufactories, Private Houses and generally from Noblemen's Mansions to Artisans' Workshops. 30,000 in use in London alone. Patronised by leading Architects, Engineers, Contractors, &c., &c.

N.B.—For Prospectuses and Diagrams, address Stamped Envelope to P. E. CHAPPUIS, Patentee and Manufacturer, 69, FLEET-STREET, LONDON.

NOTICE.—The POLYGONAL REFLECTOR (Latest Patent) FOR ARTISTIC and PICTURE GALLERIES. Its construction allows of the angle of light being readily altered so as to reflect in any desirable direction. N.B.—On View at HEALTH EXHIBITION (Eastern Gallery).

# The Builder.

### On Structural Analogies in Nature and Art.

THAT the sculptor and art-student may feel the want of a guide to the proportions of the human form is avouched by the repeated attempts which have been made in ancient and modern times, and even by artists who

themselves had the best claim to be independent of any assistance, to establish and supply it. A translation, with reproduced plates, of the "Polycletus" of the Prussian sculptor Schadow is the most recent recognition of this want; it is published by the authority of the Committee of Council on Education,—so we read on the title-page,—and "is intended more for the advanced art-student and draftsman (draughtsman) than for those who have not attained a certain proficiency in drawing the figure." Credit is taken for care to preserve very closely the character of the original lithographs, but we are warned not to regard them otherwise than as mere diagrams explanatory of the text. They are certainly not likely to be mistaken for anything more ambitious; the notice is only not superfluous because otherwise it would not be unreasonable to suppose, from the reputation of the sculptor who drew them, that he had naturally taken pains where pains would have been appropriately bestowed, and fancied that he had succeeded. As it is, the truth must be told, that whether we turn to examples of the average human figure, or to an Apollo or a Venus, the object which is presented to us in illustration of the laws of beauty is scarcely less repulsive and repugnant than those marvellous types with which Albrecht Dürer was satisfied for his treatise on human proportions. The Berlin of our own day would seem, if we are to trust these specimens, not more fortunate in its models of form than the Nuremberg of four centuries since.

Few who have given attention to that book of Dürer's will disagree with the brief verdict of Michelangelo thereon,—"*poca e debole cosa questo libro*." We are obliged to ask ourselves seriously how far the same may not apply to the "Polycletus" of Schadow. The very title-page provokes a challenge, and we ask, will sculptors and art students derive much guidance in the matter of proportion by "measurements in feet and inches of full-grown figures of both sexes and of various ages"? and, indeed, of figures not full-grown? for the measurements begin with the new-born infant, "which can only be taken with accuracy

when the nurse stretches out by force the arms and legs." It is only in the fourteenth double plate that we reach the full-grown example; earlier plates exhibit front, back, and profile measurements for years and half-years of progress up to seventeen. To an eye not unused to the scrutiny of living forms it is not pleasant to scan representations which the author may excuse as mere diagrams, but which on their own part evidently would be characteristic if they could, but cannot. We may fairly give credit to the measurements having been accurately made and recorded, but what interest they have very clearly does not belong to art, but to anthropometry. From the latter point of view, it may be of interest to record and classify the measurements of the entire population of a German town, man, woman, and child; but what an artist may be thankful for would be the measures of such select individuals as he recognises independently for beautiful or characteristic examples; for this recognition he does not want guidance, but he will welcome and be thankful for the discovery of any proportionate relations between dimensions or between masses which can be shown to conduce or be essential to the expressive result. It was a saying of Michelangelo that a sculptor should have his compasses in his eye; but this by no means amounts to the repudiation of the precision of measurements which proportion implies; he would have the perception by sight of proportionate magnitude so perfect that the application of compasses would not correct his report. It was only his mistrust, according to Condivi, of his literary faculty that withheld him from putting into form a better theory, matured between his anatomical studies and practice of art; it is unfortunate that the notes which Cosdovi made of his observations (*molte cose rare e recondite*), upon the body of a beautiful Moorish youth were never given to the world.

The explanation of these plates is preceded by a chapter headed,—"*The History of the Science of Proportion*"; but the substance of this is rather a bibliography arranged according to the nationality of the authors who have treated the subject. Even so it is necessarily incomplete, as the first edition of the Polycletus dates half a century back, and no note is given of even German writers,—Ziesing and others,—who have treated of the subject since. No attempt is made at definite summaries of the systems and principles of the different writers, nor are we supplied even with any general indication of what is most necessary,—the distinction between a truly scientific view of the subject and the many varieties of unscientific, with which the literature of it is encumbered. We can scarcely concede to the translator that

Dr. Schadow himself has ably treated the science, though he claims only,—it is said "with the characteristic modesty of his erudite countrymen" (it is as well to remember that Schadow was writing in 1834),—only to have extended the researches of others,—and even so claims too much.

The treatment of the subject fails indeed of a scientific character above all in this respect, that the consideration of Proportion in the true sense,—the comparison of elements having definite functional relations by reference to definite ratios,—is deserted easily for a simple comparison of particular measurements. For the subject of the proportions of the human figure to be dealt with satisfactorily it is necessary, in the first instance, to acquire a distinct conception of what are the concrete phenomena of which we seek an explanation; what are the combinations of which we require the elements.

The concern of the artist is with expressive form,—with form that has a clear and definite characteristic expression,—whether of sublimity, of beauty, or of any subordinate modifications of such qualities, as even of prettiness or grotesqueness, and thence to well-marked varieties of the repulsive and the ugly. Now, to take the most familiar illustration possible, the heads of an Apollo, a Jupiter, and a Hercules all agree in essential features and their general arrangement, but special characteristic beauty is conferred by special proportions. When we extend our comparisons to the entire figure the same rule holds with limbs as with features. The beauty of each figure is a birth of the artist's poetic imagination. But if science presumes to meddle with the matter, we are entitled to demand of science an exposition of the contrasted governing principles which induce such contrasted results. Contrasted as two beautiful forms of a youthful Apollo and a youthful Hercules may be, they fall into direct comparison in two respects. The elementary limbs, members, features, are identical as such, in either form; and either form has a relation, but a relation of its own, to a common primary type; they may be regarded as diverging from this in different directions and degrees, but each at last presents itself as a strictly self-consistent and specific unity. The attainment of such well-defined specific character can only be accounted for on the assumption of the divergence from a common and primary type being subject to some regulative principle.

Such characteristic differences are matters, therefore, not of difference of parts but of relative dimensions of parts that in themselves are of the same nature; not of quality, but of quantity; not of what general kind of limbs, for instance, are combined in an organism, but

of what proportions are assigned to them severally, and on what principle.

The most important variations of specific character, then, it is clear, must depend upon modifications of the most important proportions, and it becomes a matter of leading interest to decide what are the seats of these, and what modifications they are susceptible of without being utterly lost and vitiated. We are just at present only concerning ourselves with the human figure, the highest of natural organisms, but have to bear in mind that if the principles which we arrive at are just, they must equally apply to characteristic variations of artistic types,—and notably of all the orders of Greek and all the styles of Gothic architecture. The determination of the proportions of the human body in a general way may be compared to that of the scheme of proportions among the notes of the diatonic scale; to have ascertained these would be a limited advantage indeed, but that it introduces us to the command of the re-arrangements which constitute the entire list of varied keys, both major and minor, with all their diversified characteristics in alternation and transition.

To deal with a human figure of an average type, we may say that when it is erect the total height is divided equally at the *symphysis pubis*; the upper half is then again equally subdivided at the line of the nipples, and the lower half just below the patella. But two of these lines of division at least have not exact structural or functional coincidence; and mere subdivision by what an ancient would call continued dichotomy, into a mere series of equalities, is essentially defective in power to express energetic consolidation. For proportional adjustment to fulfil its true office it must be applied to bringing into orderly relation those parts or functions which, in themselves, present the greatest contrast, and which therefore may seem liable to introduce confusion or fall into antagonism.

Here we have a problem for analysis, in the treatment of which we sometimes get our best clue from nature, and sometimes from perfected art. In a Greek portico we have no difficulty in recognising that the primary contrasts are between the comparative heights of the vertical and horizontal members in the first case, and then between the voids and solids,—that is, between the diameters of the columns and their interspacing. In the less developed stage of architectural art, but long after all the Doric members and details were decided, the principle of applying an exact proportional relation between the height of the column and the joint height of the horizontal members above and below them, seems to have been unrecognised. At the next stage, in cases when true proportionate exactness was applied, the column was at best allowed only half the height of the elevation; very frequently an effect of more than cumbrousness,—of clumsiness,—was the result of the height of the column being made the minor term in the comparison,—being made less than half the full height, however, in some precise proportion. To Athenian taste, study, and insight it appears to have been due at last that the architect recognised the superior, the animating effect, of assigning superiority of elevation to the column; and then not only of making this height precisely proportional to that of the horizontal members jointly, but adhering to a proportion of very low numbers, and to a proportion again of the simplest character, as having a difference between its terms of unity only. In the appendix to Mr. Cockerell's work on *Ægina* and *Bassæ* will be found an example. The height of the column of the latter temple compares with the joint height of stylobate, entablature, and pediment, in the ratio of 7 : 6. Here it is evident that we obtain a principle which may be stated in rigid terms, and yet is susceptible of varied characteristic application. These ratios, to which the geometers have given the name of super-particular ratios, may be arranged in series, as their terms gradually approach to equality. The columns of the *Theseum* have the lighter proportion of 5 : 4, and those of the *Parthenon* the severer 10 : 9 (= the series  $\frac{5}{4}$ ,  $\frac{6}{5}$ ,  $\frac{7}{6}$ ).

We turn now again to the erect human form,

and ask ourselves where would the Greek look for the leading contrast which demanded a primary proportional adjustment? What members or groups of members might he be expected to declare the exponents of a predominant antithesis, and to which of the terms selected would he assign a preponderance between themselves? If we take upon ourselves to follow out the suggestive analogy supplied to us by the architect, we may find no difficulty in assuming that the massive trunk constitutes one term of a comparison with the joint height of the free lower limbs and the head and neck above, as the other. Accordingly it proves that the typical proportion, which we thus obtain, is 1 : 2, the simplest of all. That is to say, the massive body or trunk may be taken as exactly one-third of the height, the other two-thirds being divisible between the upper and lower completions of the full stature. This is a single, simple, and comprehensive proportion between terms which are naturally antithetical, and the natural effect and consequence of it is to convey an instinctive impression of unity, concert, combination, and breadth of effect.

As the lower extremities are equal to half the full height, there remains on this assumption one-sixth for head and neck, and it will be found by observation that the proportions which result have a satisfactory appearance both in art and nature; namely, head and neck, one-sixth; body, two-sixths; legs, three-sixths; equivalent to a proportion for the body of two-sixths to complement of full stature, four-sixths, or 1 : 2.

As we turned from architecture to Nature here, we may now in requital proceed in our comparison, by tracing how the hint obtained from Nature is applicable to architecture. "The perfection of proportion, as of many other things, was reached," says Fergusson, "in Westminster Abbey. Here the whole height of a bay is divided into two equal parts, and the upper subdivided into three, of which one is allotted to the triforium, and two to the clearstory." It will be observed that in this distribution, as in the typical human body, we have an exact division of height into halves, associated with a further subdivision of one half, resulting in a triple division, which followed the simple arithmetical series, 1 : 2 : 3. But the triforium, by its structural relation, groups preferentially with the arcade below, and the connexion is emphasised by continuousness of decoration; thus wrought conspicuously together, they form a compound term of comparison with the height of the clearstory in the ratio 2 : 1, the height from the pavement to the string-course above the triforium being just double the height of the clearstory, which asserts its distinct and independent office above.

It is by no means as a matter of unlicensed fancifulness that again we recognise an analogous relation in the human figure. The test of this is to put to proof whether the point assigned as boundary of the divisions which are made terms of comparison, has or has not a natural propriety, to the full as positive and distinct as that which regulates the limit of the clearstory in the architectural examples.

When we contemplate the human form at the same time that we are possessed with a lively sense of its varied relations, the same distinction among them naturally declares itself, which is traceable as pervading the philosophical reflections of Prince Hamlet:—"Noble reason" and "infinite faculties" are correlative to "expressive and admirable form and movement,"—the action as of an angel, to apprehension as of a God. Even so, consciously or unconsciously, we are impressed by the correlation of what, with no meaning of disparagement, may be called the servile division of the body to the noble division. Even those who are least inclined to consider their bodies to be what they mean by themselves, will be apt to recognise a nearer relation of their intellectual, imaginative, and moral nature and functions, to the head and that upper portion of the trunk which houses the heart and lungs,—the organs most immediately concerned with and affected by sensation, thought, and emotion. There are vessels of honour and

vessels comparatively of dishonour, and the organs which directly subscribe animal growth, digestion, and locomotion, are on a different line of dignity to the immediate instruments of our highest endowments, from the organs of speech to the all-accomplished hands. The line which marks this division below the chest gives to the upper nobler division, as in the case of the Westminster clearstory, exactly half the height of the lower and subject or subordinate division of our marvellous frame. But, as Cicero is fond of interposing, *hæcenus hæc*,—so much for this part of our subject. Still more definite application may follow.

#### REFORMS IN PLUMBING.

SOME members of the Plumbers' Company deserve to be congratulated on the effective Congress recently held at South Kensington,—the proceedings of which were reported at length in last week's *Builder*.\* The company is not one of the great guilds;—it has no hall, and presumably its members are not stimulated so frequently as in some companies which have their palaces and use them royally. Plenty of work was, however, cut out for the members by the speakers and movers of resolutions. If what was asked of them is undertaken, all lead and solder of standard weight and quality will be sealed or marked; and as this was asked for by Scotch and Irish people in company with Londoners and visitors from country towns in voting for the resolution, that alone will prove a considerable task. They were also asked to consider whether the materials used in plumbers' work as substitutes for lead are suitable,—there being a very strong suspicion in the minds of some of the plumbers who were present that there was nothing like lead; and that iron pipes must for up, have bad joints in themselves, and join other pipes awkwardly; that the best specimens of earthenware will have but a short life; and that zinc should have its character pronounced in an authoritative way. Still, if these claimants for notice made good their claims, then the company was requested to consider whether it would not be a good thing to fix standards of quality for those materials, and settle on marks by which the standards should be easily recognised.

When these tasks with reference to materials have been duly performed, the journeymen and master plumbers, their education, status, remuneration, and rewards, remain to be dealt with; and all these subjects with others allied to them,—and some a little wide of them,—were treated of at the Congress, in a number of short papers, and by plenty of speakers, before a large and appreciative audience. It is true that the order of things was not just as we, for the reader's convenience, have stated it. The materials were talked of nearly at the end; and the Congress had resolved without one dissentient at the beginning that plumbers ought to be properly paid. Observers have drawn very favourable conclusions from this fact. The resolutions seem to mean business, say these students of men and things, when the business element takes a decent prominence. If the members of the company, and the plumbers who are not members, had not been in force this practical appeal, they say, to sensibilities would not have been made. The "professional men, and men whose social position enables and entitles them to support the credit of the body and to advance its usefulness" (thus the worthy master commended his colleagues), who lend support to the mystery of plumbing would hardly have been so very much in earnest on this topic. The decision was put in these terms:—"It is desirable that in the future architects should not include plumbers' work in builders' contracts"; and the meaning of it was that general contractors are not fair to the plumbers,—that they pay them as little as possible for as much work as possible,—and that plumbers must either lose work, or work at too small profits, or do inferior work. Good general contractors, and many plumbers who

\* See p. 553, ante.

work with and for them, would, no doubt, put a different complexion on some parts of the case; and the other sort of contractors need very slight consideration.

The system of lump-sum contracts by one contractor has taken pretty good hold, at least in the south,—and in the main good and honest work is produced under it,—in plumbing as in other trades. The effect of the clause against sub-letting in ordinary contracts is frequently misunderstood, or, at any rate, misrepresented. One common form is, "The contractor shall not sub-let or assign this contract, or any part thereof, without informing the architect and obtaining his written consent"; and then it is observed that, notwithstanding this, and without intimation or written consent, the architect will be well aware that a number of sub-contractors are at work on any large building. This looks like remissness, but is really judicious. The sub-contractors are not formally recognised unless they are inefficient,—then the contractor must employ them no longer. If they are underpaid, the feeling will be in the air, so to speak, and detected by a vigilant architect and a capable clerk of works without prompting. When the general contractor selects and employs other people, a better concert may be hoped for than where two equal powers,—or one that should, and another that wants to, rule,—are contending for precedence. It is difficult and often impossible for work to be carried on without little adjustments among the workpeople; the right men will not be available till next week; cannot something be done to make this suit? There are a dozen similar reasons, and others concerning employers besides, which lead people to look with favour on the system, even though they are unable to call it perfect. Still there is a case on the other side. The increased attention given to these matters by the more intelligent sections of the population will help the plumbers if they are reasonable and politic, as well as resolved. They may compel the world to make exceptions in their favour, and use their power so wisely when they get it as to make everybody confess that the change is an improvement.

The example of the Rochester (New York) master-plumbers was not quoted at the Congress, but it may supply a precedent for other people who have sufficient unity of purpose and resolution. Early in this year the leading people in the trade there,—about twenty employers,—resolved that they would, after the end of March, refuse to submit tenders for plumbing work, except directly to owners or architects. Their reasons were that "the practice of including plumbing and gasfitting work in builders' contracts has developed many evils. It has been a simple matter to foist upon the owner poor material and poorer labour,—the entire system of skin work,—and our trade has been branded as incompetent and dishonest. . . . Some builders secure work with the estimate of one firm of plumbers, and then begin to play us off against each other, and thus cut down the price to be paid to the plumber who is actually employed to do the work; or they perhaps drop the plumber entirely, and buy the material and set a tinker to do the work." The stringent plumbing laws in some American towns, with such fines as 250 dols. for bad plumbing work in new buildings, and 150 dols. for putting vent-pipes which only pretended to be vent-pipes, and were worthy to be classed with wooden nutmegs or stage properties, may have rendered things possible there, for which the necessary education has probably not yet been gone through on this side of the Atlantic.

Perhaps there is still less preparedness here, for the institution of Provincial Boards of Examiners of Plumbing Work, consisting chiefly of trained working plumbers, all in connexion with the provincial schools of plumbing, and affiliated with a Metropolitan Board. The Board in a country town, it was maintained, should be invested with some local authority, hold a well-defined and acknowledged position, work in connexion with parochial authorities, and at the same time not usurp the duties of any of the municipal officers. Put forward as a little

committee of trade experts, assisted by the knowledge and trained skill of professional architects, there might be a field for reports for small fees, and a good deal of useful work might be done in a quiet way. To carry out laws and regulations, and put in force compulsory powers, under Parliamentary authority, would be another thing,—requiring, indeed, something more than the education of the general population which would call for and favour such control. "Sanitary plumbers" have not yet proved, in any considerable number, that they could wisely be trusted with these powers,—that their superiority to fads and crotchets is so complete that their superiority to preferences for their own specialities and to dislike of other people's, is so evident that a self-respecting Sindbad should quietly allow such a weighty burden to seat itself upon his shoulders once for all.

Certificates to journeymen, who had proved their competency, was pointed to as one of the special duties which such Boards could well perform. Every one must sympathise with a tradesman's preference for a workman who has come in at the front door, who has been admitted regularly, and been kept steadily in contact with actual work under an experienced master. It was decided that the apprenticeship system ought to be continued,—modified if necessary to suit the improvements in technical education. The old term of seven years some think too long,—keeping a young man from earning money for himself when he might well be doing so, if clever and well-taught. Five years was advocated as a more suitable time, perhaps from the fifteenth to the twentieth year; if finishing at nineteen there might be two years of probation added in other workshops. Strict apprenticeship for a sufficient time, and a scale of payment bearing some relation to the services of the apprentices to the master, will apparently be offered in times to come to the young plumber who wishes to qualify for being a useful servant of the public. Antecedents and character ought to go for a good deal,—for more than they always do now,—in securing employment; and the granting of a certificate which could be obtained by the right man, and which the wrong man could very rarely manage to secure, would be a step in the right direction. Such a testimonial to the serviceableness of a workman should be given for his qualities as a workman; for his skill of hand, trustworthiness, and so on. He should, of course, know the real purpose of the appliances which he spends his life in putting upon and into buildings, and his understanding of how to use them should obviously not be limited to the mere power of handling them in a good traditional way; nor, still more obviously, to merely correct knowledge of the theory. Perhaps in some of the speeches the value of knowledge, as an instrument for finding fault skilfully, was insisted upon too firmly. The working plumber, it was argued, ought to know whether work would fail if carried out in the manner directed; and one speaker went the length of stating that he should be able to refuse to work, when he thought he knew better than the people who were setting him to do it.

There is always a trifle too much fun made of the ignorant architect when drainage, soil-pipes, traps, and water-closets are being talked about. The architect,—that is, putting all the profession together and writing of it as an individual, several thousand single gentlemen rolled into one,—knows quite as much about those matters which are within his province, as the individual (comprising (by the same figure) any other profession or trade, knows about the province under his professional or tradesman-like care. We are, it may be, inclined to show some sensitiveness on this point, when taking no notice might seem more politic; but the time must come for making it clear that a bad joke is not improved by endless repetition. However, at a Congress there is a happy tendency towards throwing blame on the absent, as well as on those whom it is difficult to honour. *Après* the registration of journeymen, it was pleasantly suggested that if masters were registered it might have the effect of keeping

linen-draper and others from undertaking plumbing work; and, stung probably at the recollection of specialist assumptions, another speaker blurted out his complaint that "the honest plumber was too often put on one side, and any one who could write on sanitary science came to the front." This sort of thing may be useful, but Mr. Bullitude had actually to change his identity before he profited duly by this kind of discipline.

The congress was certainly an interesting one; and will prove more so in looking back, if the recommendations are carried out to practical results. We hinted above that the Plumbers' Company will have its hands full; but hope it will make haste slowly, and manage to go bravely to and through all the workings;—that it will take the leadership, and get plumbers to do the best of work when it is required of them, to train themselves very thoroughly, to look after their apprentices, and find good workmen constant employment, and that somebody will at the same time be taking pains to make it clear that the materials are as good as the work upon them.

## NOTES.

At a special meeting of the Court of Common Council last Tuesday, at the Guildhall, to discuss a report of the Bridge House Estates Committee in relation to the erection of a low-level bridge over the Thames, from Irongate Stairs to Horselydown, it was unanimously resolved to adopt the report. The recommendation of the Committee was for a bascule or lifting bridge, rather than a swing-bridge, in which we entirely concur; of the two it is likely to be the more manageable, though probably the more expensive at the outset. (The estimated cost is 750,000*l.*) There will be only two piers, occupying together 80 ft. of the waterway, leaving a clear passage of 200 ft. We shall watch the result, if powers are obtained for it, with the greatest interest, but the statements on the subject at present are too *couleur de rose*. It has been asserted, for instance, that the average time occupied in the passing of vessels will be only about three minutes, and that in regard to the average number of vessels passing this will not involve the stoppage of the bridge traffic for much more than an hour during the day. We feel certain that the average time from the raising to the lowering of the bridge will prove to be more than that, especially when it is remembered that, taking into account the swiftness of the tide current in the Thames, a very large margin will have to be allowed for an approaching ship, to insure perfect safety. Then the stoppage of a bridge for a number of short intervals, amounting in the aggregate to an hour, is a very different thing from its stoppage for one hour at a specified time. The latter could be reckoned on in the traffic arrangements, the former cannot. We are glad to see that our often-repeated recommendation to try well-appointed ferries for intercommunication is to be acted upon, and the Board of Works will go to Parliament for powers to establish such ferries, free of toll, between North and South Woolwich, and between Greenwich Pier and Barque-street, Poplar.

IN one of the roughly-fenced inclosures in front of the South Kensington Museum there are now lying the *disjecta membra* of a very interesting work of modern art, which on every account deserves very different treatment. These are the ponderous carved stones of a gateway executed in the Hindoo style by modern Hindoo workmen for the recent Calcutta Exhibition, at the cost of the Maharajah Scindia of Gwalior, and subsequently sent over by him as a gift to the South Kensington Museum. The idea of encouraging modern native workmen to execute a work in emulation of their ancestors originated, we believe, with Major J. B. Keith, who was commissioned by Sir Lepel Griffin to look after the work. Having been engaged in the work of conserving the ancient monuments of Central

India, it occurred to Major Keith to give the work a practical significance, as showing that the descendants of those who had executed the massive carved gateways of the Gwalior district retained something of the same cunning. The native art-workmen threw themselves into the work with enthusiasm, and executed it in the space of six months, a very short period, considering the massive character and the elaboration of the work. The arch (so-called) alone is a solid piece of eight tons weight, the spandrels and jambs being covered with delicate carving. Well, this piece of work, executed by the men of our great Indian dependency as an example of their skill, presented to our national museum by an Indian dignitary, has been for some months lying, in pieces swathed in haybands, in a back-yard, as one may say, of the South Kensington Museum. The arch-shaped doorway is set up to see how it looks, apparently, and it seems that a considerable number of the bud-like pendants of the soffit have been knocked off in transit. The jamb-columns and capitals are uncovered, lying on the ground, and show beautiful workmanship. The whole thing would be of the highest interest, and it is left lying on the ground, like another Burlington colonnade business, because the authorities cannot make up their minds where to put it. Is this creditable?

AS our readers must be aware, we never meddle with party politics, not wholly from want of interest in the subject (though it seems to tend just at present more and more to a paltry game of "beggar my neighbour,") but because it is out of the proper scope of this journal. Architecture is of no politics. But in the interests of public order we must say that the attitude taken by the Home Secretary on the opening night of the session, in regard to the complaints of Members who were impeded in their passage to the House by the great anti-House-of-Lords procession, was most unsatisfactory, not to say absurd. If it is a standing sessional order that "the Commissioners of Police do take care that during the sitting of Parliament the passages through the streets leading to this House be kept free and open, and that no obstruction be permitted to the passage of Members," it is the simple duty of the authorities in power at the time to see that this provision be carried out. One honourable Member, who, it may be admitted, is rather prone to make the most of things, declared positively that he could not have got to the House but that his club enjoyed the special convenience of a subterranean passage thereto; and the leader of the Opposition, who is certainly not given to inordinate grumbling, stated that on entering a cab at Waterloo Station to drive to the House, he was forbidden to cross Westminster Bridge (which, in fact, he would have found impassable on that day,—*experts credit*),—and was told to go round by Lambeth Bridge. If this is not "obstructing the passage of Members to the House," what is it? It is against all common sense for the Home Secretary to pretend that he has no power, or that it is an injudicious interference, to forbid to a popular procession a route the use of which must involve the abrogation of one of the very orders which it is his own official duty to see carried out. We make the comment without prejudice, seeing that our politics, if we had any, would not be those of Sir Stafford Northcote and Mr. Chaplin. But this is a question not of politics, but of police; and we hold that the objectors were perfectly right, and that such an obstruction ought not to be allowed to become a precedent.

THE recent meeting in the City in favour of a code of arbitration law was a practical attempt to assist the passing of a useful measure. Perhaps of all the branches of municipal law there is none of greater interest to those who are connected with building matters than that which is concerned with the law of arbitration. It will be very satisfactory if a plain and clear digest of this subject can be published. But we should be sorry to see any regular Court of Arbitration grow up.

The law courts are in themselves one kind of courts of arbitration, and what are popularly termed arbitrations are only required when the matter to be inquired into is full of so much detail that it is not possible to enter into it in a court of law. It is also quite a mistake, as many of our readers are well aware, to suppose that arbitrations are really cheaper than actions. The expenses of witnesses, of preparations for the encounter, of arbitrators, have all to be incurred. The cheaper the law is the more useful it is to the community at large, but we entirely deprecate setting up courts of arbitration side by side with the law courts. But this objection in no way prevents us from expressing a desire to see a code of arbitration law speedily in the Statute Book for the use of all those who may have to give their attention to this subject.

MR. RUSKIN'S Oxford lectures on the various pleasures of England, though they were announced as art lectures, seem to turn mainly on what may be termed moral lessons derived from history. The second one, delivered on Saturday last, on "The Pleasures of Faith," and embracing the period from Alfred to the Confessor, was, in fact, a religious exhortation for the most part, and as such in many points most stirring and admirable; but into that side of his subject we do not here profess to follow Mr. Ruskin. There were one or two bright gleams of light thrown on the artistic side of the subject, however, as when the lecturer appealed to the coinage of Alfred as part of evidence of what London was like in the ages of faith. The character of a coinage, he urges, is quite conclusive in national history; there is no great empire but tells its story in beautiful coins. True, as far as it goes, no doubt; but it hardly goes quite so far as Mr. Ruskin makes out. Then there were the Saxon war-ships "bright with banner and shield and dragon prow," lying at London's strand, more beautiful, it is implied, than anything to be seen there now. We should like to draw Mr. Ruskin's attention, by way of looking at the other side, to the enthusiastic and picturesque meditation on the London docks and shipping by Mr. Richard Jefferies, which appeared some time ago in the *Pall Mall Gazette*, and part of which we reprinted and commented on at the time.\*

THE exhibition of the Turners' Company at the Guildhall, though it includes a good deal of very neat and some very finished workmanship, does not seem to have satisfied the judges, who have declined to award the highest prizes because the combination of high finish with excellence was not found in any article submitted in the competition; though, as the number of exhibits was 121 and the number of prizes of some kind awarded is 44, the minor guerdons seem to have been distributed with a tolerably liberal hand. The exhibits were classed under three heads: wood, pottery, and the cutting of precious stones; the subject of turning including mechanical manipulation of various descriptions. Now, in regard to the artistic side of the matter we must say that the exhibition confirms what we have always felt and occasionally said,—that turning does not seem to be a branch of work which by any means tends towards artistic development. Neatness, cleverness, what may be called sleight of hand, it promotes no doubt; but there seems to be something in the very nature of lathe operation which deadens the artistic sense. Nearly all the more elaborate exhibits in wood show indifference to, or want of feeling for, pure beauty and expressiveness of form; the outlines are essentially mechanical; the object is to execute little *tour de force* in minute turned ornaments stuck on over the larger turnings, &c. The only things that have some of the salt of art about them are some of the larger plain, but freely-shaped, pottery exhibits, with their fine flowing lines. The eye for form seems to be cultivated by these; by wood-turning it seems only to be deteriorated; the wood will not take the fine flowing sweep of

the clay, and the result is "a thing of shreds and patches," the exhibition of ingenuity rather than art.

AT the General Meeting of the Egypt Exploration Fund on Wednesday last, Mr. Flinders Petrie gave an interesting description of the excavations he has been recently conducting at the Temple of San, which he illustrated by a large series of photographs shown by limelight. The great area of the temple presents the appearance of a long disused quarry, which, in a sense, indeed, it may be said to be, though no stone was naturally there craggy-looking masses of granite, parts of broken obelisks, colossi, and columns with their lintels lie scattered on the ground, a few stones of a distant pylon alone being left one upon another. Mr. Petrie has cleared away the accumulated rubbish and sand from the remains, exposing some fine carvings and hieroglyphs, but, beyond an interesting shrine of limestone, a very fine colossal head of Rameses II. when young, and a few exceptional treatments of the sculptured figure, there is little to be seen at present that throws fresh light on the art of ancient Egypt. But who shall say what treasures for the archaeologist may lie hidden under that *débris* of ages which cover the wide and unexplored ground yet to be worked? Mr. Petrie proposes to return to Egypt next year to resume his works outside the wall of the Temple.

THE Council of the Institution of Civil Engineers have forwarded us the list of subjects on which they invite original communications, for the best of which various premiums, arising from funds bequeathed for the purpose, will be awarded. The list is large and various, including forty-three different subjects. Among those which bear more or less upon our own class of subjects may be mentioned:—

"Improved Instruments for Surveying and Levelling."

"Machines and Measuring-Apparatus for Testing Metals, and the Equipment generally of Mechanical Laboratories."

"The Mechanical Properties of Cold-Rolled Metal, as compared with Hot-Rolled Metal, and on the Cold-Rolling of Iron Shafting, as practised in America."

"The Manufacture, Strength, and other Properties of Castings of Malleable Cast Iron and Cast Steel."

"The various systems of Brickmaking by Machinery."

"The Principles involved in the Conservation or Improvement of any Tidal River or Estuary."

"Promenade and other Piers, with reference to the effect of Sea-water on Wrought and Cast Iron Structures, and the best Means of Preserving the same."

"The Ventilation of Sewers, with a Summary of Experiments as to the Motion, Pressure, &c., of Gas in Sewers."

"Filter Presses for separate Fluid in Semi-fluids, particularly for the treatment of Sewage Sludge."

"The Transmission and Distribution of Electricity over large areas for Lighting and for Motive Power."

MR. ROBERT L. STEVENSON, a member of a family honourably known in the annals of the civil engineers of Great Britain, justly complains, in the columns of a contemporary, of the ascription, in a popular publication, of his grandfather's noble work, the Bell Rock Lighthouse, to Rennie. That distinguished engineer would have been the last person to claim either the design or the execution of the sea tower in question. Not only have the Stevensons reared, it may be almost said with their own hands, some of the grandest and most serviceable monuments that stud the stormy shores of our island, but they have further served their profession by the literary memorials they have put on record, such as the "Life of Robert Stevenson," by David Stevenson, published in 1878, which gives a full and most interesting account of the building of the Bell Rock Lighthouse. It is disheartening to find achievements of this nature, when referred to in popular literature, so imperfectly treated, that the author cites a second-hand reference to part of a newspaper correspondence as what he calls "authority" for very grave misstatement. Mr. Stevenson has done well to protest.

\* "The Picturesque of To-day," *Builder*, Nov. 10, 1883.

**A SUGGESTION** made by Mr. Nicholas Whitley, C.E., for utilising the water power of the Nile for the purpose of forcing a supply, through a 12-in. pipe, from the Fifth Cataract to Suakin, deserves more than a moment's glance. Under reserve as to the resistance afforded by the friction of 240 miles of 12-in. pipe, and by the height to be overcome between the Nile and the Red Sea (which we leave to the responsibility of Mr. Whitley), the main difficulty involved would appear to us to lie in the guarding of the line. The height of the water in the Nile at the junction of the Atbara is given by Mr. Baker as 1,148 ft. above the Mediterranean; and the force of the cataract, or rapid, could probably be easily applied by a turbine or turbines. The quantity of water to be derived, which is an important consideration, would not be such as to raise serious objections. On the whole, it would be well to see Mr. Whitley's proposal put into the form of definite hydraulic computation.

**WE** are glad to observe that at a meeting of the General Purposes Committee of the Manchester Town Council at the end of last week, notice was given of a motion in opposition to the resolution of the town's meeting some little time previously in favour of making a grant out of the city rates in aid of Parliamentary expenses. Mr. Alderman King said it was unfortunate that many of the ratepayers had not been afforded the opportunity of expressing their objection to the resolution at a poll of citizens. We commented at the time on the very undesirable precedent that would be set if such a use of rating powers were sanctioned.

**THE** completion of the new Turkish baths in Northumberland-avenue, planned and designed by Mr. R. Walker for Messrs. Nevill, the proprietors of the London Bridge and Aldgate Turkish Baths, has been one of the architectural events of the week. The building includes baths both for men and women, the entrance to the former being from Northumberland-avenue, that to the latter from the other end of the building next Craven-street. The interior arrangements and fittings are carried out in a very complete manner, and the general effect of the rooms is pleasing. The actual baths are in the basement, and the interior includes a large central hall or divan, with a gallery running round it. We reserve further details till we can accompany them with an illustration.

**AT** the meeting of the St. Paul's Ecclesiological Society, on Tuesday last, Mr. Hugh Stannus delivered a lecture on the decoration of the dome of St. Paul's, describing, in a very clear and lucid manner, the principles of treatment which he regarded as correct, including the "articulation" of the dome design with the architectural substructure. Mr. J. P. Seddon occupied the chair; and a short discussion followed, in which Mr. Micklethwaite, Mr. G. H. Birch, and Mr. Statham took part. Mr. Micklethwaite urged, in a very practical spirit, the desirability of first settling the future arrangement of the cathedral for worship, and its complete furniture (in the widest sense) for that purpose, before deciding on the treatment of the culminating point in the decoration. Mr. Statham differed from Mr. Stannus in recommending a rib treatment of the dome in eight partitions; such a treatment being rather suited to an octagon dome, such as that at Florence, and being, in fact, a contradiction of the actual architectural structure of a hemispherical dome, and tending to weaken its effect of space and mystery, and reduce the dome from poetry to prose. He certainly did not, however, as Mr. Stannus in his reply seemed to think, recommend what may be called "Corregiosity" in dome decoration, but only the homogeneous treatment of the spherical surface in a purely decorative manner. Mr. Seddon summed up, if we understood him rightly, rather in favour of this latter view. Mr. Stannus has gained an honourable position in relation to the experimental decoration of St. Paul's by the energy and ability which he has

brought to bear upon it; but we may suggest that he should not refer to Mr. Poynter as his "colleague" in the matter,—a phrase which hardly represents the true state of the case.

**THE Pall Mall Gazette** published on the 28th five small and rough outline illustrations of the designs submitted for equestrian statues for Blackfriars Bridge, submitted in the second competition by Messrs. C. B. Birch, Hamo Thornycroft, T. Brock, and R. Belt ("Que diable faisait-il dans cette galère?"). It is difficult to judge at all of the merit of the works from these rude illustrations; one or two of the statues look as if they might turn out something. The *Pall Mall* sets out, we observe, with the statement that Blackfriars Bridge "is without doubt the handsomest structure of its kind in London." It is, without doubt, the most tawdry, pretentious, and vulgarly-designed bridge ever put over the Thames; but that is the kind of thing which is usually called "handsome" in amateur architectural criticism. What must be the architectural perceptions of a critic who can look on such a piece of clapp-net as Blackfriars Bridge, and on Rennie's grand work a little lower down the river (not to speak of Waterloo, which has great merits), and then deliberately characterise the first-named as "the handsomest" of our bridges? We quite agree with the *Pall Mall* that the competition has been much mismanaged, and that the sculptors ought at least to be remunerated for their labour (for it seems nothing is to be resolved upon even now), but for the rest we wish our contemporary "all manner of prosperity, with a little more taste."

#### PUBLIC HYDRAULIC POWER.

**SCHEMES** having for their object the distribution of motive power to the public have been frequently brought forward, but, with the exception of the work we are about to describe, no practical results have followed, so far as the metropolis is concerned; unless the introduction of the gas engine may be said to have constituted the gas companies distributors of a source of motive power. A year or two ago a system was in operation in New York by which steam was generated in large central establishments, and carried underground through suitable mains, to be supplied to the public in the same way that gas and water are ordinarily laid on. The scheme, however, was a failure, and we understand that the company which promoted it has suspended operations. In England power is now being supplied by means of hydraulic pressure, the town of Hull having had such a system in operation for the last nine years.

Within the past twelve months the General Hydraulic Power Company (Limited) has been engaged in carrying out an extensive system of power distribution which has been elaborated by Messrs. Ellington & Woodall, M.M. Inst. C.E., of Palace-chambers, Westminster, who are engineers to the company. The work already done, and the success attained, appears to leave little doubt that the system will become a leading feature in the metropolis, even if it does not spread to other large towns. London, however, offers an especially favourable field for an enterprise of this nature, inasmuch as it is the great depot of the nation. Hydraulic power is especially well adapted for the production of rectilinear rather than rotary motion, and the numberless cranes and hoists of various kinds used in the metropolis for the transshipment and warehousing of goods require just such a motion as water pressure is best adapted to give. In addition to this, the great value of land in London renders it always desirable to economise space as much as possible, so that the room occupied by an engine and boiler is generally an object of considerable importance. The higher rate of wages in London is another feature that tends to the same end, the ordinary attendances and necessary repairs to machinery costing far more in the metropolis than in any other part of the kingdom.

From an engineering point of view, there is not a great deal that is new in the operations now being carried on, if we put on one side their magnitude, and the distances through which the power is conveyed. In most docks, and in the large goods depots of different rail-

way companies, hydraulic systems identical in principle have been in operation for so long that the venture of the present company is no experiment so far as engineering practice is concerned. The only point that had to be solved was whether the public would give sufficient support to the scheme to make it financially a success, and although it has not been in operation for a twelvemonth, the promoters consider that an affirmative answer has already been given.

The central pumping station of the company is situated at Falcon Wharf, close to the Blackfriars Station of the London, Chatham, and Dover Railway Company. The water required for the service is taken from the river below ordinary low-water mark. The intake consists of a 10-in. pipe, which has large stones placed over the inlet so as to keep out as much mud as possible. On the wharf there is one of the Pulsometer Company's No. 9 Pulsometers, and in the engine-house are two of Brotherhood's centrifugal pumping engines. These are used for lifting the water from the river to tanks placed on the top of the engine-house. There are three tanks, or, rather, one large tank is divided into three divisions. The total size of this three-fold tank is 44 ft. 3 in. by 49 ft. 6 in. by 4 ft. deep. It is composed of cast-iron plates bolted together, the joints being planed to surface. Into one of the compartments the water from the river is lifted, and is there allowed to settle for a time so as to get rid of the heavier particles of matter held in suspension, after which it is run into two double "Thames" filters by the Pulsometer Engineering Company, which are placed in the engine-house below, and which are calculated to pass 5,000 gallons per hour each. This description of filter consists of a cast-iron cylinder lined with copper. In this are two pistons composed of opened gratings covered with wire gauze. The piston-rod, which is cased with gun-metal, passes through a suitable stuffing-box in the cylinder cover, and is attached above to a small hydraulic ram, by means of which the necessary motion is given to the pistons. Above each of the latter is a perforated diaphragm, and the space that lies between is filled with sponge, which forms the filtering medium. The water to be filtered flows by gravity from the tanks above, and rises through the mass of sponge, by which matters held in suspension are retained. So far the action is very similar to that of an ordinary filter, but it is in the cleansing arrangement that the novelty lies. When it is required to clear the filter the pistons are caused to move up and down by the hydraulic power. This action alternately compresses the sponge and releases it from pressure. The current of water is at the same time reversed, so that clean water flows downwards through the mass of sponge. The operation effectually cleanses the sponge, the working it receives from the pistons acting in the same way as the hand-squeezing one usually gives to a domestic sponge when it is necessary to free it from any foreign matter. By this ingenious arrangement the great difficulty that has hitherto been experienced in large filters,—that of cleaning them,—has been satisfactorily overcome. From the filters the water rises to another series of tanks which are placed over the boiler-house. These are at a lower level than the first set, so that no further pumping is required. The combined length of the latter tanks is 66 ft. They are 29 ft. 6 in. wide and 4 ft. deep. In one corner is a charcoal filtered bed 14 ft. 9 in. long by 12 ft. 6 in. wide, through which the water first flows.

Arrangements have been made for doubling the tank capacity by erecting another tier above those tanks now in position, and it appears likely that this increase will soon be required. The first three months of this year three and a quarter million gallons of water were raised; last quarter the quantity registered was five and a quarter million gallons, and that the rate of increase will be more than maintained for some time is, we believe, insured by the installations already asked for. The company is empowered by its Act to take from the river one million gallons a day. This would be equal to a power of 800 horses continuously supplied for ten hours, but as the demand is always intermittent the capacity is estimated at from 2,000 to 3,000 horse-power. From the tanks last referred to the water is taken by the main pumps, of which

\* In the ordinary single filters there would be only one piston.

there are two sets already at work, and which have been supplied by the Hydraulic Engineering Company of Chester. Another set similar to those now in operation are ready for erection, and will be under steam before long. These latter are the pumping-engines we made reference to in our recent notice of the meeting of the Iron and Steel Institute at Chester when describing the works of the Hydraulic Engineering Company (see p. 451, ante). The foundations are also laid for a fourth set of engines, and there is room for two more sets in the building. These, it is anticipated, will be soon wanted. The engines are of the inverted compound condensing type, and are supported on wrought-iron standards, the condenser also forming part of the framing. They have three cylinders, one high-pressure, 19 in. in diameter, which supplies steam to the two low-pressure cylinders, which are each 25 in. in diameter. The stroke is 2 ft. The Correy type of valve-gear is used. In this the expansion valve is forced down by the pressure of steam in the valve-chest acting on the valve-rods, which are made of large section for the purpose. The valve is released at the right moment by trigger gear, which is actuated by a cam. By shifting the cam the cut-off can be arranged for any desirable part of the stroke, and a very sudden closure of the part is also obtained. The stopping and starting of the engines is automatically performed by means of a governor and an attachment made to the accumulators, so that as water is drawn away in the course of work the pumps are immediately started to make up the deficiency. The pumps are 5 in. in diameter, and the plungers are driven directly from the steam pistons, there being forked connecting-rods for driving the crank-shaft. The two engines now at work will give an aggregate of about 300 to 320 indicated horse-power, and will each deliver 240 gallons per minute with the accumulator at a pressure of 800 lb. per square inch when using steam at 50 lb. pressure.

There are three steel boilers of the Lancashire type, each 28 ft. long and 7 ft. in diameter. They are fitted with Green's economisers, which consist of a series of vertical tubes placed in the flues in the path of the escaping gases. Through these the feed-water flows, and its temperature is raised by the waste heat. The great difficulty in the application of all feed-water heaters has been to keep the soot and tarry products from depositing on the cold pipes. In the present instance this is got over by having fitted to each pipe an annular scraper, which is worked automatically from the outside. The economiser is said to give very good results in the present instance. The stoking is carried on by means of a mechanical stoker by Messrs. T. & T. Vickers, of Newton-le-Willows. The fuel, which consists of breeze, the small refuse coke from gasworks, is fed into hoppers, and is automatically and continuously charged into the furnace, where it is constantly carried on towards the back end of the fire-bars, by a reciprocating motion which is given to the latter. The clinker is broken up at the same time and is removed by hand. The good results obtained in these boilers with such a poor fuel as breeze would seem to indicate that these mechanical stokers are also a success. The trunk mains are of hydraulic pipe, 6 in. in diameter. They are in 9 ft. lengths, and are tested to 2,500 lb. per square inch at the works. The joints are formed by spigots and sockets, turned and bored. They are packed with india-rubber washers, and held by two 14 in. bolts passing through oval flanges. At intervals of from 400 to 500 yards there are stop-valves, which can be used in case of damage to the pipes, or for the purpose of localising a leak in the system. In most cases each main can be fed from either end, so that an accident in any one spot would only shut off the length of 400 or 500 yards between the two nearest stop-valves.

The area over which the company is empowered by the Act of Parliament to lay their pipes extends on the south side of the Thames from the Surrey Commercial Docks to Vauxhall Bridge, and goes back a distance of 600 yards from the river bank for the whole length on the Middlesex side; the district comprises all land that lies between the West India Docks and Vauxhall Bridge, within a distance of 1,200 yards from the river. Several miles of mains have already been laid, and these are being added to as fast as the work can be done. On the north side two large mains pass down Cannon-street and Upper and

Lower Thames-street respectively. On the south side the pressure has been carried east as far as Crucifix-lane. The quantity of water used is ascertained by a meter, and the consumers are charged, at the registered rates, only for the amount consumed. The following is the scale of charges:—

	Per Quarter.
Under 3,000 gallons .....	£1 5 0 per machine.
Above 3,000 " not exceeding 5,000 gallons .....	0 8 0 per 1,000 gallons.
" 5,000 " " 10,000 " .....	0 7 0 " "
" 10,000 " " 20,000 " .....	0 6 0 " "
" 20,000 " " 50,000 " .....	0 5 0 " "
" 50,000 " " 100,000 " .....	0 4 0 " "
" 100,000 " " 200,000 " .....	0 3 0 " "
" 200,000 by special terms.	

There is a charge of 5s. per quarter for meter. We understand that at the highest rate the cost for power is less than half that charged by the water companies for an amount of water at the company's pressure capable of doing similar work. In many cases the cost of lifting by the Hydraulic Company's power is as low as  $\frac{1}{2}$  p. per 50 foot-tons.

The many uses to which the hydraulic power may be put will readily suggest themselves; we will, however, give a few details of some of the principal installations that we have lately met with. The first we will mention is that at the Lead Works of Messrs. Grey & Marten, which adjoin Southwark Bridge. Here the original motive power machinery has been entirely done away with, and that from the Hydraulic Company's main only is taken. The presses for producing solid-drawn lead pipe are one of the principal features in the plant. A water pressure of about 5,000 lb. per square inch is required for working these, and, as the Hydraulic Company's pressure is not much above 700 lb., a machine, known as an intensifier, is used. This consists of a double ram, the two areas not being the same. The pressure from the main is admitted beneath the larger ram, and in this way a considerably higher pressure can be obtained upon the smaller one, the final pressure being proportional to the difference in areas. At the large grain warehouses of Mr. George Doo, situated at St. Mary Overry's Wharf, near London-bridge, the Hydraulic Company's power is extensively used. Here there are several cranes, elevators, and conveyors, all especially designed for handling grain in bulk. With these appliances and by the aid of a Priestman's bucket, it is astonishing how quickly a large load of wheat or maize is transferred from the craft to the warehouse floor. The cranes are on the double-power principle, so that with light loads there is a smaller quantity of water required. There is also a hydraulic pump used for draining the basement. The whole of the work here is of considerable interest, and has been executed by the Hydraulic Engineering Company, Limited, of Chester.

On the north side of the river the most instructive application of the system is that which is to be found in the large block of new warehouses in Wood-street. These buildings have been erected in the place of those destroyed by the memorable fire of December the 8th, 1882. In Messrs. Foster, Porter, & Co.'s really gigantic establishment the whole of the lifting and transporting of goods is carried on by power supplied by the Hydraulic Company. Here there are several cranes, together with lifts and elevators of many varieties, including those for goods, passengers, coals, &c. There is a separate lift used for carrying hooks from the counting-house to the various floors, and another working in connexion with the kitchen. In the same block of buildings Messrs. Silber & Fleming, and Messrs. Rylands & Sons, Limited, are also using the power of the company for handling their goods. In this densely crowded neighbourhood the convenience of having a source of power always available without requiring thought or trouble are very highly appreciated. Carts are quickly unloaded, and the traffic in the narrow tortuous streets is much relieved. But in the particular instances we have under consideration, no doubt there were even stronger inducements to adopt the system. Putting aside the actual loss arising from a great fire in merchandise and buildings, which can be covered by insurance, the damage done to a business by being thrown into a state of utter confusion is a most serious matter, and has been keenly felt in the instances in question. In addition to removing a source of danger by doing away with the necessity of steam

boilers on the premises, the application of the hydraulic power enables powerful hydrants to be placed in any required position where the hydraulic service is laid on. It is well known that, in a jet of water used for fire extinguishing, force of impact is almost as desirable as volume. By the use of the injector hydrant, which was

designed by Messrs. Greathead & Martindale, and is being manufactured by Messrs. Sir W. G. Armstrong, Mitchell, & Co., both volume and impact can be obtained. In this apparatus a small jet of water from the high-pressure service is injected through a nozzle into a chamber through which flows a larger volume of water obtained from the water company's mains, or from any other convenient source. By the lateral inductive action of the high-pressure water, the slowly-moving stream has the required velocity imparted to it, and the whole is forced through a nozzle in the ordinary way. It has been found by experiment that with a high-pressure service of 700 lb. to the square inch, which is that carried in the Hydraulic Power Company's pipes, and a low pressure service of 20 lb. per square inch, it will require 32-4 gallons of high-pressure water to throw a jet of 150 gallons per minute through an inch nozzle, and to a height of from 75 ft. to 84 ft. This would be equivalent to the pressure due to 100 ft. head at the back of the nozzle. The hose is taken to be 200 ft. long and is the ordinary  $2\frac{1}{2}$  in. brigade hose, the resistance of which may be considered as equivalent to 3 in. head per foot of hose. With pressures in the Water Company's mains of 60, 50, 40, and 30 lb. to the square inch, 3, 7, 10-9, 18-1, and 25-2 gallons of high-pressure (700 lb.) water would be required respectively, the remaining conditions being as before stated. The difficulties attendant on fire extinguishing, as at present carried out, are constantly receiving too many practical and melancholy proofs to require urging here; the superiority of fixed hydrants, always on the spot and at any time ready for immediate service, over an engine that has to be brought from a distance, and may possibly be engaged elsewhere, is apparent; supposing, of course, the hydrants are sufficiently powerful for the work required from them. We, in London, have never yet had to deal with two fires of great magnitude at one time, although we have more than once been very near having to do so. It taxes all the resources of our present fire brigade to limit the ravages of a conflagration such as that of last December twelvemonth, to the confines of one block of buildings; the result of two such fires occurring on a breezy night might be little short of the disasters of Chicago or Boston.

There is a further point worth noticing in connexion with the Wood-street installation. The warehouses last referred to were outside the Parliamentary limit of the company at the time these pipes were laid down, and the local authorities had, therefore, to be petitioned before the streets could be opened up. In spite of the very great inconvenience that is inflicted on the owners of warehouses in this overcrowded part by the stoppage of a thoroughfare, nearly the whole of them signed the petition in question,—a fact which speaks strongly of the estimation in which the Hydraulic Company's labours are held.

The company has a pumping-station in Philip-lane. Here there are two 20-hp. locomotive boilers by Robey & Co., and two pumping engines by the Hydraulic Engineering Company, of Chester, with 8-in. cylinders and 12 in. stroke. The accumulator is 13 in. diameter by 20 ft. stroke. It has not been found necessary yet to have recourse to this machinery, as the engines at Falcon Wharf have been found sufficient for the purpose. In this case the source of power is nearly two miles, in the line of the mains, from where it is used, but we understand that there is no appreciable loss of power or unsteadiness in working. This is no more than might be expected, for the loss in friction is less than is generally supposed. Sir Frederick Bramwell has put on record that power can be conveyed through pipes of small diameter at a speed of

one foot per second with a loss of only 2 per cent. per mile. The actual experience in the present case will, however, be of value in convincing those who doubted the practicality of conveying power at high pressure for public use through long distances.

#### THE WORK OF THE ARCHITECTURAL ASSOCIATION.\*

Those who were present on the corresponding night to this last session will, perhaps, remember that we considered the various statistics furnished us by the Brown Book, which, *en passant*, I rejoice to see has returned to its true colour this session. These statistics were not so encouraging as could have been wished, nor are those now before you this new year. It will be well as briefly as possible to consider the facts just presented to us. In the Elementary Class of Design there is a falling off of sixty-eight attendances and seventy designs submitted; on the average eight less attendances, nine less designs submitted. The Class of Design is, however, encouraging,—forty-four more attendances, fifty-four more designs submitted; on the average five more attendances, seven more designs submitted. Again, in the Colour Decoration Class, progress has been made. Last session no statistics were forthcoming. Comparing this one with that of 1881-2, we find thirteen more attendances, seven more sketches; on the average three more attendances, two more sketches. Turning to the Class for Study of Planning and Specification Writing, seventeen more attendances, eleven more sets sent in; on the average three more attendances, two more sets sent in. Class

Construction and Practice, thirty-four less attendances, eighty-one less papers; on the average five less attendances, ten less papers. Advanced Class of Construction, seven less attendances; but on the average two more than the previous session. The Surveying Class shows a decrease of five members below the two previous sessions. The lectures in connexion with classes of design gain by two attendances, those for construction by twelve, on the average one. The library report shows a falling off of nine in the number of readers. You will see, therefore, that though the annual report is right in pointing to "some advancement in the work of the Architectural Association, and some improvement in those respects which were referred to as being unsatisfactory, especially in the case of the Colour Class," still it is not so great as we all hoped and expected, especially if you consider the large increase of members. The falling off in the Elementary Class of Design is very noticeable, but some consolation may be gathered from the encouraging increase in the Class of Design, and Mr. Stammis, the president of this class last session, must be congratulated on this fact. The Colour Decoration Class has, I rejoice to see, shown fresh signs of life and vigour. There is also an encouraging improvement in the Class for Study of Planning and Specification Writing.

Then we are met face to face with a very serious falling away in the Class of Construction and Practice, and that for the Advanced Class of Construction is not much better. Referring to the latter, the report of the secretaries points out that six out of eight meetings advertised were held, four out of seven papers promised were read, and these were by members who contributed the previous session; but it should be noted that the average of attendances was higher. Lastly, the reports of the teacher of the Surveying Class and the librarian are not such as could be wished. Taking all the above facts into consideration, I think it will be admitted that the appointment of a special committee "to inquire into and report upon the present system of education as carried on in the various classes and lectures of the Architectural Association, with the object of rendering them, if possible, more efficient, and in other ways considering how the quality of the instruction and work done in the Architectural Association might be raised" has not been undertaken too soon, and that we must not one day devote our energies to finding some means for altering this state of things by taking a new departure. This special committee has not been idle. Their first business consisted in sending out a series of questions for the purpose of eliciting opinions, facts, and suggestions from those considered

best acquainted with the working of the Association, and from others competent to advise. The result of this has been a mass of most valuable information, which has been duly tabulated by the honorary secretary of the committee, Mr. Frederick E. Bales, in a very thorough and comprehensive manner. This information has been, so to speak, boiled down, and the essence drafted into a report, which, early this session, will be brought before the special committee, and, when passed, laid before the general committee to undergo further revision. Then the whole result of these deliberations will be presented to you. The gist of the questions issued in the first instance I will briefly summarise, in the hope and expectation that those members who, from inadvertence, were not applied to, and others who have the care of solid advancement at heart, may be induced to lend their help and forward their views at the very earliest day possible to Mr. Bales, who will, I feel sure, welcome any contributions, despite the further encroachment it may make upon a busy life. Briefly, then, the questions run thus,—and I shall restrict my summary to those upon which we most used information, and in any answers you may favour us with, kindly make them in the order in which I put them. The numbers here given agree with the printed paper to which your attention was called. (1) Is the system of education the best one? In what way do you think it can be improved? (2) What are your views of the quality and amount of work done in the classes with which you are best acquainted? (3) What are the points of failure, causes, and means of obviating them? (4) Would it be advisable to reduce the amount of work set down for each class meeting, with a view of making it more thorough? (5) Would you advise any test for admittance to the advanced classes? (6) Is it desirable to limit the period of members attending the elementary classes? (7) How can the advantages of the Association be extended to country members? And, lastly, in No. 9 we asked, in what other ways do you consider the usefulness of the Association might be extended?

That last question opens up a wide field, and, like the postscript to a letter, is, perhaps, as important as any of the previous questions. I hope that all those who are in this room to-night, and who feel that they can do something to make our machinery turn out more work and better, will answer to this call, as well as those who may chance to read my address in the professional journals. It is not out of place here to say how very much we are indebted to the editors of these papers for the large amount of space they give us; the compliment is a very high one, and I feel sure I may, as your President, convey our best thanks to these gentlemen for the courtesy extended to us,—a proof of the interest felt in our proceedings, and their continued record of them goes to prove that our doings outside these walls are carefully watched by our professional brethren, and an interest taken in our welfare. Were it otherwise, we should not see, at meeting after meeting, the faces of the reporters, now so familiar and so welcome to us. We owe the press this recognition of their valuable and useful services.

With the exception of the advanced Class of Construction and Practice, and the Class for the Study of Planning and Specification Writing, all the other classes which meet in this building have this rule, "Each member must contribute to the work of the class whenever he attends." A glance at the statistics given in the Brown Book will prove that this rule is not enforced. The attendances during past sessions have largely exceeded the work submitted in the various classes. It would probably be very difficult, indeed, to enforce a strict observance of this very salutary regulation; the frequent and constant disregard of it is, however, very discouraging, and shows how many drones we have in the hive. What remedies can he devised to meet this difficulty will doubtless form an important subject for discussion in the special committee. The real solution of the difficulty must, after all, remain with the members themselves, and I hope when the next Brown Book is issued we shall see some improvement. To contribute work will materially assist you; do not fear criticism: you may not succeed so well as you could wish, but you will certainly be the gainers by entering boldly into the contest.

Last session a sub-committee was appointed

to consider whether the time had not arrived when the Architectural Association should publish the lectures delivered in this room. No action has as yet been taken although some statistics of probable cost have been collected together. The expense of such an undertaking could not fall, I think, upon the funds of the Association, nor could members expect to be furnished *gratis* with copies considering the small annual subscription they now pay. Whether the scheme ever takes definite shape must depend upon your own wish. If a sufficient number of subscribers could be guaranteed the experiment might be made, and I think some index of the feeling of our community might be ascertained if members would be good enough in the course of a week or two to send a post-card to the honorary secretary of the committee, Mr. H. W. Pratt, one of our vice-presidents, stating whether or not you are in favour of the work being undertaken. The cost, if a fair number of subscribers could be got together, would not be large, and no one will be committed to any subscription who is good enough to comply with this request. This proposition of publishing the lectures is not a new one, but, as we are considering a revision of our work generally, the present seems a fitting time to come to some decision upon this point. One strong argument against the necessity for publishing the lectures is that they are so well reported for nothing in the professional journals. This is so, and most highly should we value this boon; but then, on the other hand, no journal can be expected to publish our papers *in extenso* except when they have less claims upon their space, and, year by year, demands upon that are made from all quarters. Again, it is next to impossible to edit the productions with the exactness which a careful author would wish. When a man sees his composition in print it generally reads differently to him, and needs careful revision and some re-casting. Though the journals give all the time they can to the authors, it frequently happens that the printer's boy has instructions to wait while the proof is being corrected, and so it cannot be done with that thoroughness which such work requires, and only practised writers can hurriedly bring their thoughts to bear on the work before them. Another drawback is that the papers are holed up with the other parts of the journal, and are not nearly so handy for reference, as they would be holed up separately. It is also urged against the proposed scheme that we should find a difficulty in getting the younger men to contribute papers if they had to face the ordeal of this special publishing. I think that objection may be dismissed. I believe it would have a contrary effect, and that we should procure even better and more carefully thought-out papers, and that the honour of reading one would be more highly coveted. The publicity which the press gives to our meetings is surely a more trying ordeal than the one proposed. Again, it is urged that the discussion took place among us as students, and that the ideas evolved from a discussion are hardly worth perpetuating. To this it may be replied, that the committee appointed for the editing and publishing of the papers would in the natural course of things have discretionary powers. I have dealt at some length with this question, because I think it is an important one; and before leaving it I will again beg of you to let the committee know what your own views are upon the matter, for the decision rests solely with the members.

The judges of the Essay Prize recorded with satisfaction the success achieved by the recipient of it last Friday week, but the committee of prizes felt themselves compelled to notice how very little interest is felt in essay-writing, and they go the length of suggesting that it should no longer be advertised in the Brown Book. I hope this will not become necessary. I think the fact that students do not care to compete in literary work is a sad and serious one. Let us for a few minutes consider the matter. It should be our desire to fit ourselves for any position in our profession and in society; but to do this we must possess those literary attainments which a learned profession and society demand from those who seek to take up a position in it. To write a good essay is not within the ability of many, but to endeavour to do so is in the power of most. To write an essay at all demands an acquaintance with the subject set down for competition, and this necessitates looking up facts and perusing works on the

\* Opening address, delivered by the President, Mr. Cole A. Adams, at the meeting on the 24th ult.

subject. The necessity for a logical order, careful composition, and neatness of expression and diction, affords most valuable discipline and teaching, and the result of the sacrifice of time to this pursuit cannot but result in good to the student. One satisfaction will be, that with practice he will find his thoughts will run more naturally to tongue and pen, and assist him largely in addressing meetings, committees, or public bodies, or in writing reports.\* Again, the pursuit of references must needs open up studies which will be of use in ways little dreamed of at the time, and probably foster a love for reading and research which cannot fail to achieve as a result a cultured mind, which, I take it, is the *raison d'être* of the Essay Prize. I fancy when the profession was not so crowded as it is at present, and when good draughtsmanship was not so much thought of and practised as it is now, that *bona-fide* architects had, on the whole, a better right to the distinction of being called "learned." Previously to the Gothic revival, men devoted more time to the literature of the art, and what they learned was more thorough. With the Gothic revival came that improvement in draughtsmanship which has been so marked of late years, but I fear in too many instances the love of this charming occupation has shut out of sight the need for literary studies, and the fascination of being a good sketcher in perspective has been detrimental to that more solid good to the student which comes from measured drawings. It needs no very high order of intellect to be a clever draughtsman, and a too close devotion to this pursuit must debar the student from storing his mind with that knowledge of the literary and scientific part of his profession without which he cannot hope to hold his own with *savants*, or take that place in his profession, and in society, which should be his lawful ambition. Every year education makes strides, and we can only maintain our position in the world by showing we are worthy to do so; to neglect all efforts at culture, and the scientific side of our work, is simply suicidal. I do not think I have taken an exaggerated view of this question. Believing it to be of the utmost importance, I have made these few remarks; test the soundness of them for yourselves, and take counsel with those men who are best qualified to direct your studies. Give a little less time to draughtsmanship and making pretty sketches, a little more time to mastering the literature of your profession; go beyond this as opportunity presents, and study literature in other branches, and pleasure and profit will be the result.†

**Society for the Promotion of Hellenic Studies.**—As our article on this subject last week has brought us some inquiries as to the Society, it is well to add that the Hon. Secretary of the society is Mr. G. A. Macmillan, 29, Bedford-street, Covent-garden. We may also add that the leading European archaeological periodicals of the day, and other works the property of the society, can be seen and consulted by members at any time on inquiry of Mr. Vaux, at 22, Albemarle-street, where the meetings of the Hellenic Society are held. The journals taken include the publications of the Archaeological Society of Athens, the *Mittheilungen* of the German Society at Athens, the "Bulletin de Correspondance Hellénique," the Berlin "Archäologische Zeitung," the publications of the Russian Imperial Archaeological Commission, &c., &c.

**Leeds and Yorkshire Architectural Society.**—On Saturday afternoon the members of the above Society paid a visit to York on the invitation of the President and Council of the York Architectural Association. Mr. Geo. Bradley, the residuary clerk of the works of the Cathedral, conducted the party round the building, and in the crypt Mr. Bradley read a long and interesting paper, in which he clearly traced the architectural history of the buildings which have preceded, and some of which now form part of the present cathedral. The restoration works now being carried on under the direction of Messrs. Fisher & Hepper, architects, at St. Crax Church, Pavement, York, were next visited, and Mr. Hepper conducted the party over the works and explained to them the nature of the restoration.

\* If Mr. Adams could see some of the letters that we receive from the architects, sometimes of works of considerable importance, full of errors of grammar, and even of the most extraordinary mistakes in spelling, he would think they added to the force of his exhortation.—Ed.

† The remainder in our next.

### ST. MICHAEL AND ALL ANGELS, STOKE NEWINGTON COMMON.

**T**HIS church, which is fast approaching completion, is planned to seat 750, including the choir. The church consists of chancel, nave, north and south aisles (the south chancel aisle forms a morning chapel), organ-chamber, clergy and choir vestries, and a tower. The walls are faced externally with red brick, internally they are unadorned, the arches and all quoins being of red brick. A feature of interest in the building is cast concrete (Albion Concrete Company), which is used in every case where stone would ordinarily be used (including a tracery east window), except for the columns. The church is being built by Messrs. Holliday & Greenwood, of Loughborough Junction, whose tender for the work was 5,212*l.*, without the tower. The architect is Mr. J. Edward K. Cutts, of Southampton-street.

### DESIGN FOR WAR AND ADMIRALTY OFFICES.

BY MESSRS. SPALDING AND AULD.

WE give this week the Park view of Messrs. Spalding & Auld's design and plans, as usual, of the two principal floors. There are some fine points in the arrangement of the ground plan in regard to the disposition of the entrances, but a number of the rooms on both floors must surely be very insufficiently lighted. The architects send us the following statement in regard to their views in drawing up the design:—

"In the preparation of this design due consideration has been given to the matters especially dwelt upon in the conditions for the first competition, and emphasised more particularly in the revised instructions issued for the final competition.

In working out the scheme of plan the relative positions of the several sub-departments, the situation of the rooms on the various floors, and the order of their arrangement are all in strict compliance with the suggestions embodied in the official schedule, and follow as far as possible the sequence laid down therein.

The greatest simplicity has been aimed at in the block plan, which follows closely the natural outline of the site, the main object being to secure an ample provision of light and air and a general cheerfulness throughout. Small enclosed courtyards have been avoided, there being but two quadrangles, and these of large areas.

The space at command being limited for the accommodation required, the frontage to these quadrangles is appropriated to the official apartments, so that all rooms have a cheerful outlook to large open spaces, and the staircases and waiting-rooms are centrally disposed between the outer and inner ranges of offices.

Direct carriage communication between Whitehall and Spring-gardens is provided in compliance with special instructions.

The principal public entrances to the War Office and Admiralty are in the quadrangle next Whitehall, and are accessible from Spring-gardens by the carriage-ways above-mentioned.

Subsidiary entrances are provided for direct access to the various sub-departments. Private entrances also are given where required by the conditions.

Staircases are grouped near entrances, both being overlooked by messengers' lobbies, and having waiting-rooms in immediate proximity.

For convenience of access the repositories in connexion with ground and first floors are in basement, whilst those belonging to the second and third floors are in the attic over.

The warming, ventilation, and sanitation of the buildings, having to be specially provided for, a careful and complete scheme was submitted with this design.†

### MANSION, WEST HARTLEPOOL.

This drawing, which was one of those hung in the present year's Academy Exhibition, represents a house to be erected at West Hartlepool, on the designs of Messrs. Banks & Townsend, architects. The plan, in connexion with the list of references, sufficiently explains itself, and shows some unusual and agreeable points in planning.

### SKETCHES BY A DISTRICT SURVEYOR.

III.

AMBOISE is celebrated as having been the scene of an interview between Clovis and Alaric before the battle of Voulon, and it was to this castle during troublous times that the Guises fled from Blois with the young Francis II. After the assassination of the Duc de Guise, the chateau became a state-prison, and in it were from time to time confined a cardinal, archbishop, princes, and other persons of importance. Abd-el-Kader was detained there for five years.

In the contests between Protestants and Catholics Amboise was the scene of most horrible atrocities, in which the whole court of Francis II. took part as a recreation after the latter had crushed the Protestants. Twelve hundred gentlemen of family were hanged, and the executions were witnessed by the king, who ordered them to take place after dinner for the delectation of the ladies. These religious wars devastated the country so much that the neighbourhood lapsed into a desert. The poor, driven from their homes, fled like wild beasts; bread could scarcely be found, and was made largely of walnut-shells; families eating roots and herbs hoiled with remains of dead animals. The death-rate was frightful, and in one parish the return was "no more inhabitants."

The chateau building of the fifteenth to sixteenth centuries internally is much dilapidated; externally it has been reinstated partially. The Renaissance wing stands on one side of the court which has been converted into a public garden.

In the grounds were two chapels, one dedicated to St. Hubert, and in the other (St. Florentine) was buried Leonardo da Vinci in 1519, but this was destroyed subsequently, and in 1869 a small monument was set up on its site to the memory of the great artist.

The large building to the right and at the foot of the chateau is the Hotel de Ville.

THE CHÂTEAU D'AMBOISE

M. Castle St. Holborn London E.C.

## THE WATER FAMINE IN BRADFORD.

The water famine in Bradford is a matter of extreme significance, not only as regards the inconvenience to that populous centre, but as throwing incidental light on the unsatisfactory position of the entire question of urban water supply. Bradford, in the year 1882, contained a population of 183,050, on an area of 7,222 acres in the borough, and of 180,960, spread over 68,676 acres in the out townships, making a total of 364,040. Under nine Acts of Parliament the Bradford Corporation, in January, 1883, had expended 1,869,737*l.* on their water-works. The supply of water obtained was, for domestic use, 25 gallons per head per day; and within the borough 3,096,000 gallons were daily supplied for other than domestic purposes. It was estimated that the daily waste amounted to 15 or 20 per cent. of the total daily supply of 8,800,000 gallons.

The charges for supply are high, ranging from 7*s.* per cent. on annual value up to 20*l.*, to 5 per cent. on the annual value exceeding 100*l.* There are extra charges for extra supply; and for trade purposes the water is sold at from 3*d.* to 1*s.* per thousand gallons. In the summer, it is significantly added, the charge is 20 per cent. additional.

The sources of supply are from mountain drainage areas, springs, and streams, in the valleys of the rivers Worth, Aire, and Wharfe, the water being conveyed to Bradford by conduits and pipes, and supplied by gravitation. Fourteen reservoirs were at work, one was in course of construction, and several others were authorised by Parliament, at the date of the return on urban water supply in 1879; and no information on this head was asked for or supplied in the Parliamentary returns of the 9th of November, 1882, and the 2nd of April, 1883.

Three distinct services are described by the Rivers Pollution Commission as in use in Bradford, viz., a high-level service from the millstone grit; an intermediate service, derived partly from springs; and a low-level service, partly from this formation and partly from limestone. The area of the watershed is, in all, 13,250 acres. As the area to be supplied varies in its elevation from 300 ft. to 1,400 ft. above the level of the sea, the water has to be collected at great altitudes and led from considerable distances. The rainfall in 1879 ranged from 28.02 in. at the Exchange to 30.73 in. at Hewenden Reservoir, 700 ft. above the sea. Owing to the mode of collection, the working expenses incurred for the water supply are low, being little more than half those incurred in London, and considerably lower than those of any town in England of first-rate magnitude, except Leeds. But the rates are twenty per cent. higher than in London in proportion to the rateable value of the property, and the water revenue of the Corporation, per million gallons supplied, is higher than in any great town in England, with the exception of Liverpool, Sheffield, Manchester, and Birmingham.

Of the different methods of procuring urban water supply, it will be seen that the Corporation of Bradford have adopted that which is most easily affected by a season of drought; and that they are now suffering in consequence. The incident is a strong illustration of the importance of a complete hydraulic survey of England, and of the division of the country into great hydraulic districts, each under complete supervision. While the collection of surface water is generally regarded as the cheapest and readiest mode of obtaining a supply, it should be remarked that Bradford, increasing its area of collection by little and little, has managed to arrive at a cost, per million gallons of supply, higher than that incurred for the works of any other town in England, of above 100,000 inhabitants, with the sole exception of Sheffield; where the cost has been rendered formidable owing to the unfortunate catastrophe of the bursting of a great reservoir. A water famine after a single dry season, and notwithstanding so considerable an expenditure (amounting in 1881 to 5-13*s.* per head) in the construction of works, is not reassuring as to the success of a municipal arrangement in providing a water supply, or in providing that prime necessary of life at a moderate cost. The plan of charging half as much again, in percentage on the rent, on a

20*l.* as on a 100*l.* house, has the effect of putting the highest charge for water supply on the poorest of the population.

## THE ARCHITECTURAL ASSOCIATION.

The first ordinary meeting of session 1884-85 was held on the 24th ult., at 9, Conduit-street, Mr. Cole A. Adams, the president, in the chair.

It was announced that the president had been invited to join the committee of welcome in connexion with the American Exhibition, proposed to be held in London in 1886. This invitation had been accepted by the president, and he had now been asked to communicate with their architectural brethren on the other side of the Atlantic, with a view to making the exhibition as interesting as possible.

On the motion of Mr. Conder, seconded by Mr. Gotch, the balance-sheet, as printed in the Brown Book, was adopted.

The President then delivered his inaugural address, which we give on p. 587.

In the discussion which ensued,—

Mr. Aston Webb, in proposing a vote of thanks to the President for his excellent address, thought that he had, perhaps, taken too melancholy a tone in thinking that the members did not work so well as they used to, and that there was not so much *esprit de corps* as in the earlier days of the Association. He believed for himself there was really a great amount of vitality in the classes, and as much interest now manifested in the work as ever had been. He congratulated Mr. Adams on being president for the second time, an honour which he deserved from the manner in which he conducted the work, and for the reforms he had suggested. The Association had undoubtedly outgrown its work, and required great extension, or its prosperity might bring about its overthrow. Their president had now become, as it were, a member of the House of Lords, and in that capacity they looked upon him as their representative in the solemn assembly upstairs. The members would be glad to hear some expression as to the way in which he proposed to represent their interests. Up to the present the results had been sparse; but he expected now to see the desired reforms rapidly carried through; therefore the meeting would be pleased to hear from their president that he was an ardent upholder of the Franchise Bill before the Institute, and that he would not allow the solemnity and chilliness of that august assemblage to interfere with the energy he had displayed in the lower house.

With regard to sanitary science, he believed that architects knew all about it, and that there was no necessity to press the matter upon their attention. The President had touched upon the higher parts of the profession, and on an evening like this, which only came once a year, it was the point which should be more especially dwelt upon. The troubles and worries of ordinary workaday life were apt to engross their attention, to the detriment of the delights and charm of their profession; but there was no doubt that to produce good work they must ever have a high ideal before their eyes. They should look to art and not to science for the excellence of their work, not neglecting science, but recollecting that science without art would never produce a thing of beauty.

Mr. H. L. Florence considered there was a general improvement in the quality of work done in the classes. It should be remembered that the working strength of the Association could not be expected to be more than one-fourth of the whole number, therefore the proportion contributing to the classes could not be considered as unsatisfactory. At the same time he would like to impress upon the members the great advantages of the classes. It was impossible to obtain in an office that comparison of knowledge which was obtained in competition with others. He could speak on this point from experience, for he had learned more there than in any office he had been in. With regard to the system of education in this country and abroad, in the word "system" lay the whole secret of the case. In this country each one was left to work individually, and although in some instances it gave rise to great originality, yet the condition of architecture in England was not as artistic and complete as it was on the Continent. Mr. Florence seconded the vote of thanks.

Mr. J. A. Gotch remarked that one of the most important subjects which had been touched

upon was the education of the architect of the future. The system of pupillage had answered to a certain extent, because it had produced all the architects we boast of; but, at the same time, it was very imperfect. Architects should not be compelled to seek their education in their spare time only, but should be able to devote the daytime to a regular system of education. The young architect too frequently occupied the whole day in doing little or nothing, while in his spare time he had to come there to acquire the often disagreeable rudiments of his profession. The question of the profession becoming a protected one was of the greatest importance; but he did not believe they would gain their point by merely appealing to the feelings of other people. What was requisite was to persuade the public that they were necessary to their health and comfort. It would be a pity to withdraw the competition for the Essay Prize, and he hoped that in future years they would get more and better essays.

Mr. Brodie hoped that more attention would be directed to the question of pupillage. He knew instances of men, with little or no work to do, taking five or six pupils, which he considered was obtaining money by false pretences.

The vote of thanks having been carried by acclamation.

The President thanked the members for the compliment they had paid him. With regard to his appointment on the council of the Institute, he had always been somewhat of a free lance, but it necessarily happened that the freest of lances, when he got into office, had to be reticent as to what he said in public. From the first time he took his seat at the council, however, he had been listened to with the utmost courtesy. He had been asked what he was going to do with regard to the important question of the franchise, and upon that point he had no reticence whatever. The Associates of the Institute ought to have a vote, and to the best of his ability he would argue this. No evil would result from their having this vote, but a great deal of good; and he believed there was really no opposition to it. With regard to sanitary science, it was necessary to view this matter soberly, if they were to maintain their position with the public. What was required was that the artistic man should become practical, while the practical man should strive to become artistic. Upon the correct writing of the quantities depended a knowledge of their work.

## HEALTH EXHIBITION AWARDS.

The following awards have been made of the prizes offered by the Society of Arts at the International Health Exhibition:—

Joint Stock Prize, a Society's Gold Medal, or 20*l.*, for the best example of Sanitary Architectural Construction, Classes 20, 28, 29, 30, 32:—

Messrs. Doulton & Co.

Shaw Trust, a Society's Gold Medal, or 20*l.*, for the most deserving exhibit in Classes 41, 42, 43, and 45 (relating to Industrial Hygiene):—

Compressed Lime Cartridge Company. (In Class 45.)

North London Exhibition Trust, a Society's Gold Medal, or 20*l.*, for the best set of specimens illustrating the Handicraft Teaching in any school:—Classes 49 and 50:—

M. Germain, on account of the Collective Exhibit from the Belgian Normal Schools for Women Teachers. (In Class 49.)

Fothergill Trust, two Gold Medals (or two sums of 20*l.*), one for the best exhibit in Class 27 (Fire Prevention Apparatus), and one for the best exhibit in Class 26 (Lighting Apparatus):—

Messrs. Nobel Brothers. (In Class 26.)

Trevelyan Prize, five Gold Medals (or five sums of 20*l.*), for the best exhibit in each of the following Classes,—2, 3, 6, 7, and 11 (all comprised within Group 1, "Food"):—

San José Fruit Company. (In Class 2.)

Mrs. Charles Clarke, of the School of Cookery. (In Class 6.)

M. Pasteur. (In Class 7.)

John Moir & Son, Limited. (In Class 3.)

Messrs. J. & E. Hall. (In Class 11.)

The "Siemens" Prize, a Society's Gold Medal, or 20*l.*, for the best application of gas to heating and cooking in dwellings, Class 24:—

Thomas Fletcher (for Articles supplied by Messrs. Deane & Co.).

The "Stacy" Prize, a Society's Gold Medal, or 20*l.*, for the best exhibit in Class 30 (objects

\* From latest accounts it appears that the difficulty is for the present practically at an end.

for Internal Decoration and Use in the Dwelling; (fittings and furniture) :—

Messrs. Collicott & Lock.

\* \* In reply to several correspondents who have written asking us to mention that a medal had been awarded to them, we beg to say that we will print a synopsis of all the awards that have been made in regard to work connected with the building trades, and with sanitation and other subjects coming directly within the scope of this journal; but pressure on our space compels us to defer this till next week.

#### BUILDERS' ACTIONS.

CULLEY v. YATES.

In this action, at the Aylesham County Court, on Oct. 16 (before Mr. Julian Robbins, Deputy Judge), which had been adjourned from time to time, the plaintiff, a builder residing at Aylesham, sued the defendant, the Rev. E. T. Yates, for 19*l.* 5*s.* 4*d.*, balance due for work and labour done.

Defendant pleaded a counter-claim for 40*l.*, moneys alleged to be due to him from plaintiff.

Mr. Linn represented plaintiff, and Mr. Chittock appeared for the defendant.

Mr. Chittock said the action, which came on at a previous Court, was brought to recover the sum of 19*l.* odd, and defendant then pleaded a set-off of 50*l.* Plaintiff sued for work done, and he had also set down timber that belonged to the defendant. He sold the timber, and was indebted to the defendant for all moneys received. They charged him in the set-off for moneys received on account of defendant which had not been given credit for. This was a short history of the transaction.

After hearing further argument, his Honour gave judgment for 25*l.* 2*s.* 3*d.* in favour of defendant, and costs.

#### THE DOME OF ST. PAUL'S.

My respect for the talents of Mr. Cave Thomas disinclines me to do more than express my own opinions and leave them side by side with his for the judgment of experts. As an architect I have spoken, as an artist he has replied.

But since it is most important that all argument on the subject should be based on a foundation of fact well authenticated, I venture to give my reasons for not accepting the statement which Mr. Thomas makes, that "Thornhill's architectonic arrangements were designed under Sir Christopher Wren's personal supervision, and that he not only sanctioned the scheme, but that it was carried out immediately under the eye of the great architect," who, by the bye, must have been about eighty years of age when it was done by Sir James Thornhill.

On page 441 in Dean Millman's "Annals of St. Paul's" it is stated that "The painting of the cupola had been taken out of his hands; it was now made over, contrary to his wishes, to Sir James Thornhill."

Again, in a letter by Sir Christopher to the Commissioners, dated January 25, 1710-11, he says:—"As for painting the cupola, your lordships know that it has been long under consideration that I have no power left me concerning it, and that it is not resolved in what manner to do it, or whether at all."

In fact, the directing of it had been taken out of his hands, to his great annoyance. See Longman's "History of St. Paul's," page 130.

I may say that I agree with Mr. Clayton that it would be unjust to the memory of Sir James to translate his bold design for a monochrome treatment (for which only it is adapted) into a brilliant polychromatic representation.

EDWARD C. ROBINS.

#### CROSIER AND PASTORAL STAFF.

Sir,—I quite thought that your last issue would have contained some reference to the opinions expressed by Canon Venables on this question, first raised in the "Student's Column," and I was disappointed at finding that it did not.

In favour of the distinction which you say exists between a crozier and pastoral staff there is the authority of several well-known writers. Mrs. Jameson, in her "Sacred and Legendary Art," page 684, says, "what is properly the crozier, the staff surmounted by a cross, is borne by archbishops." In a "Manual of Monumental Brasscs," published by Parker, of Oxford, it says:—"The crozier and the pall were peculiar to archbishops. The former was a staff ending in a cross or crucifix instead of a crook." In the "Liturgical Reason Why," page 251, it says:—"Crozier, the pastoral staff

of an archbishop, which terminates in a cross, whereas a bishop's staff terminates in an ornamental crook."

Webster's Dictionary (a less reliable authority, perhaps) gives *crozier*, from *crois*, now *croix*,—*cross*. "The official staff of an archbishop terminating at the top in a cross." I have no doubt that besides these (and Dr. Lee whom you have quoted) there are other learned authorities who describe the crozier as a staff terminating at the top in a cross, and it would be of interest, I think, if some of your correspondents would make them known. Perhaps the best proof of the existence of a crozier or cross as peculiar to archbishops and distinct from the pastoral staff is to be found in examples of Medieval times. In Westminster Abbey, upon the monument of Robert Waldeby, archbishop of York (1397), the crozier or cross is represented in the archbishop's left hand. In the chapel of New College, Oxford, is a brass representing Archbishop Cranley (1417) holding a crozier which originally had as its head a crucifix. Many other instances could doubtless be produced, but these, I think, suffice to show that Canon Venables is in error in supposing that the cross peculiar to an archbishop was a processional cross, for the instances which I have named prove that the crozier (*i.e.*, a staff surmounted by a cross) was borne by an archbishop just in the same way that a pastoral staff (*i.e.*, a staff surmounted by a crook) was borne by a bishop.

There are instances amongst Medieval monuments where an archbishop is represented as holding a pastoral staff and not a crozier, but these do not interfere with my contention, the pastoral staff being the proper emblem of authority over the flock within the diocese in which the archbishop exercises the office of bishop. The Monument of Archbishop Walter de Grey, in York Minster, affords an instance of this, the Archbishop being represented as holding a pastoral staff in his left hand, but it is to be noted that he does not wear the pall over his chasuble, and that, therefore, he is represented as the bishop of the diocese, and not as archbishop of the province of York.

S. SLINGSBY-STALLWOOD.

#### Reading.

#### SEA-SAND FOR MORTAR.

Sir,—No one who knows anything about mortar or limes would recommend salt, and no architect who knew the practical part of his profession would allow sea-sand to be used without its being washed.

If "F. L.'s" architect allows sea-sand to be used that is taken below high-water mark, the impression on his mind will end in a reality; but if the sand used is what is called "blown sand,"—that is, sand that has been blown up above high-water mark, and has been subject to rainfall,—it can be used without fear of unpleasant results. For example, at Exmouth, there are mounds of sea-sand, covering several acres, which are not subject to the tide, which the sea never reaches, and which can be used without washing; while, on the other hand, sand taken from Dawlish or Teignmouth beaches must be washed, as it is covered by the salt water every six hours.

The plan adopted at my coast-towns in Devon is to store the sand and expose it to rainfall before using. The rain-water passes through the sand and carries away the salt as it passes off at the base of the heap. Sand treated in this way can be used without fear of bad results.

CHARLES PINN.

Exeter, Oct. 27th, 1884.

Sir,—I quite agree with the remarks of "H. L." in your last number (p. 575) as to the use of sea-sand in mortar. After fifty years' experience, and having seen some of the largest works in this neighbourhood, especially at Brighton, Hastings, and Eastbourne, where the sand has been brought daily direct from the sea and used without washing, I am convinced that where damp is discovered at a building other causes must be sought for rather than the sea-sand; and in our country districts where sea-sand cannot be procured the same appearances and efflorescence present themselves.

Both the old County Prison, with its thick brick walls of great solid, and also the new County Prison, are built entirely of sea-sand, and I have never had cause to notice the slightest ill-effects from its use.

Before Portland cement was known the floors of barns, malt and coach houses, used to have a sprinkle of common salt put on them to harden the grey lime surface, and all old bricklayers will speak of the strength of sea-sand mortar over that of washed or land-sand.

HENRY CARD, County Surveyor.

Leves, Oct. 27, 1884.

Sir,—Fearing your correspondent "F. L." might be led into the serious error of using unwashed sea-sand after reading the experience of your correspondent "H. L.," I beg to offer my advice on it,

which is "Don't." I should think the unwashed sea-sand of "H. L." must have been taken far above high-water level, where it had been well bleached by the sun. I have used such without any ill effect. I have also used the sand taken below high-water level, and have found that when carelessly washed the effect on the plastering was most disastrous. It was always slightly damp in the driest weather, but during a damp season it was simply wet. When thoroughly washed it will make good mortar, neither better nor worse than good pit or river sand, but it must be washed, particularly for plasterers' work. If "F. L." must use sea-sand on the score of economy, let me advise him to see that it is thoroughly washed, or he will not be so fortunate as "H. L." There will be no danger of his having complaints, for the reason that he will find no one to occupy the houses. F. DASHWOOD.

Sir,—As the question of the suitability of sea-sand as an ingredient of mortar has been raised in your columns, and, as I notice, denounced by you, unless the sand has undergone a thorough washing, I shall esteem it a favour if you will inform me whether you consider sand obtained from some distance from the sea shore open to the same objection.

I am engaged in building a house, the mortar for which is mixed with sand obtained some 200 or 300 yards from the shore, and which probably has not been submerged for centuries. Would not the salt in this case have evaporated to such an extent as to render the sand safe for making mortar? J. S.

\* \* \* Possibly, though we opine that if "J. S." sinks a hole deep enough to come to water, 200 yards from the sea, he will probably find it salt; and that, even in this case, a cleansing of the sand would be an error on the safe side.

#### EGHAM SCHOOL BOARD COMPETITION.

Sir,—In the last number of your journal I observed a letter from Mr. B. Tice, clerk to the above Board, stating that 103 architects applied for particulars, and informing the forty-nine competitors that the Board have now decided to seek competent assistance to enable them to make a selection. Doubtless the forty-nine will be pleased at this decision; but as one of the fifty-four who applied for particulars, but did not compete, I should like to say I think it would have been much more just if the Board had decided upon this course in the first instance, before receiving designs, as I have no doubt the majority of the fifty-four were, like myself, debarred from competing in consequence of having agreed, with about 1,400 of the profession, not to compete for any work unless one or more professional assessors of established reputation are appointed to assist the promoters in adjudicating on the relative merits of the designs submitted in competition; and in this case Mr. Tice, in reply to my inquiries, stated that he was not prepared to say whether a professional assessor would be appointed.

R. T. ELSAM.

#### A WAIL FROM SOUTH KENSINGTON.

Sir,—Disgusted inhabitants of South Kensington are calling out about the exhibitions of Fisheries, Healthieries, and all the other "ries" about to take place in their locality, and very justly so; but it is of no use without suggesting some way of getting out of their difficulty. May I therefore propose that the Council of such "Exhibitioneries" should be obliged to construct a tunnel from the railway, as proposed last year, into their own grounds, and to do away with the present principal entrance to the building, making another in connexion with a large yard on their own ground, where all omnibuses, cabs, and carriages would set down and take up passengers, the police having orders to refuse those noisy penny vagabonds who annoy the neighbourhood from entering such yard or loitering anywhere about the building?

The proprietors of such a paying concern as an exhibition such as the Healthieries should keep the nuisances they cause on their own ground, and not be the means of ruining a respectable neighbourhood. G. T.

Leicester.—The Temperance Hall has recently undergone repairs and redecoration. While this work has been progressing the services of Mr. Frank Ashwell, heating and ventilating engineer, have been called into requisition by the directors, with a view of remedying the numerous draughts which have for several years past been complained of by those attending public meetings or entertainments in the building. The system adopted is Korting's patent. The main principle is to keep up a regular current of air, and by means of proper outlet shafts to provide that the foul air should be as regularly discharged, thus securing a constant supply of warm and pure air. By means of an anemometer, it has been ascertained that the whole body of air in the large room can be changed two or three times every hour.

## PROVINCIAL NEWS.

**Ashington.**—On the 18th ult. the foundation stone of a new co-operative store and of a new temperance hotel, for the Ashington Old Co-operative Society, was laid by Mr. Jonathan Priestman, J.P., of Shotley Bridge, at Ashington Colliery. The new institute about to be erected will stand at the entrance to the village, and will face the turnpike road leading direct to the First Station. The front elevation will be 118 ft. in length, and will consist of shops and manager's house, with a lecture-hall, 68 ft. long, above. Behind these there will be ample warehouses, workshops, a drapery establishment, and other departments. At the extreme east end of the front part the temperance hotel will be situated. The new building will be built by Mr. Lilburne, from designs furnished by Messrs. Oliver & Leeson, architects, Mosley-street, Newcastle.

**Oxford.**—On Thursday, the 16th ult., a public inquiry was held in the Council Chamber, by Captain Hildyard, R.E., one of the engineering inspectors of the Local Government Board, with reference to an application by the Oxford Local Board, for sanction to borrow a sum not exceeding 2,000*l.*, for the sewerage of New Botley, and connecting the same with the Oxford main drainage system by pumping. The only persons present were the Chairman and Clerk of the Local Board and Mr. W. H. White, engineer. After taking evidence upon the financial and engineering features of the scheme, the Inspector visited the site of the intended works, and afterwards inspected the Sewage Pumping Station and Farm, at Littlemore and Sandford.

**Wakefield.**—A new billiard-room has just been added to the Bull Hotel, Wakefield. The room has been erected at the rear of the hotel, and is 45 ft. long, 18 ft. 6 in. wide, and 12 ft. 6 in. in height. It is well lighted by two lantern lights, and has a flat roof constructed with iron joists and concrete, and covered with Seyssel mineral asphalt, which has been laid by Messrs. Claridge & Co.'s own workmen. The ceiling is executed in plaster, and is divided into panels containing enrichments. Attached to the room is a lavatory. The billiard-room is warmed by one of E. H. Shorland's ventilating stoves, and fresh air is also supplied by his system. On the roof are fixed three of Boyle's extracting air-pump ventilators. The floor is laid with Lowe's herring-bone wood block paving, which makes a clean, warm, and noiseless floor for such a room. The work has been executed by tradesmen of the town, viz., Messrs. Flower, Bros., C. Driver, C. Squires, E. Kirk, and C. Turner, from the drawings and under the direction of Mr. William Watson, architect. The room is supplied with two tables by Burroughes & Watts.

**Stockport.**—Navigation Bridge is now completed, and we quote the following particulars respecting it from a description given by the engineer, Mr. Thomas Mitchell, of Oldham:—To economise money as far as possible the two side girders and an intermediate one (carrying the water pipes) of the late bridge have been used in the present one. The new roadway is formed with ten intermediate box girders, each capable of carrying 400 tons, thus giving a total carrying power of 4,000 tons. These girders are 2 ft. 6 in. apart, and at right angles to them and resting on the beam ranges are transverse joists, spaced 1 ft. 6 in. The roadway to the depth of the beams and including the interior of the beams is filled up and rammed full of strong cement concrete and finished with a smooth surface at the top, on which is placed a covering of strong waterproof asphalt so as to keep the ironwork drop-dry and from atmospheric exposure. The road paving comes last, heeded in sand, and grouted at the joints with pitch and gravel. In answer to numerous inquiries, Mr. Mitchell says that the strength of the concrete is such that in this case the ironwork would be the first to yield. He thus states his reasons for filling up the box beam with concrete:—

"1st. When the beams are solid, there is no chance of corrosion from the interior.

2nd. The webs are kept rigidly apart, and, from being unable to buckle, must necessarily be stronger.

3rd. As a natural sequence to No. 2, and proved by experiment, beams when filled with concrete attain a much higher resisting strain than when empty.

4th. To increase the *dead load* at the weight of the structure is called (the beams in this case being very shallow), and thus reduce the vibration of beams during the passage of traffic."

He cites as an apt illustration of what he wishes

to explain is found in the great tidal wave which followed the recent eruption in Java. This wave broke on the American coast a few hours after the explosion, having with enormous velocity travelled some thousands of miles. "Now," says Mr. Mitchell,

"It was not the mass of water which travelled, but simply the component individual molecules, which, impacting on each other, conveyed the force imparted to them by the explosion. So, too, the rolling of a wheel gives of impacted force at each point of its circuit, and the vibration caused by a beam over which it travels is due to the molecular action, which conveys the impact to the ends of the beam, and thence to the ground. Therefore, it follows that the vibration must be greater in a light beam than when fully loaded up, and consequently possessing more molecular inertia. Of course, this proposed additional loading only applies to structures such as tibia, where the live load may be at times in excess of the dead load. Any one going under the bridge will also notice the absence of that hollow ringing sound so usual in this class of bridge when traffic is passing."

The new bridge is 2 ft. lower in the roadway than the one projected by the late borough engineer, and 6 in. lower than the original Canal Company's bridge, and by lengthening the gradients from Lancashire-hill the Highway Committee have rendered this a much easier road than heretofore. The mishap that befell an old field drain by a pile being driven into it was not altogether a misfortune. If it had happened after the bridge and roadway were complete, then incalculable damage might have resulted. Says Mr. Mitchell:—

"The drain was in some places nearly silted up with mud, and generally in bad repair, requiring only a little further time to collapse itself. From its devious course it must have followed the windings of a natural water-courant, and the man who constructed it suited the width to his passing fancy or the materials at hand. Sometimes he would make it 15 in. wide, then work it down to 9 in., and gradually pull it back to 15 in. in the most free-and-easy fashion. He evidently used no setting-out lines, and although untrammelled by a School Attendance Committee, worked it nearly into the letter 'S' where it passed under the bed of the canal. As no Local Board or Sanitary Authority took particular notice of the drain, he was allowed to be unaccounted and unknown until disturbed by the rude hand of modern improvement."

The contractors were Messrs. Froggatt & Briggs, the sub-contractors for the ironwork being Messrs. Homan & Rodgers.

**Stratford-upon-Avon.**—Provision has now been made for protecting the house in which Shakspeare was born from disaster arising from lightning. On the 9th of August last, Mr. W. T. Hawkins, manager for Messrs. W. D. Berry & Sons, electric engineers, of Huddersfield, noticed a paragraph in a Birmingham paper to the effect that a ball of fire had been seen to fall near Shakspeare's birthplace. It occurred to him that a building of so interesting a nature and containing articles of such great value should be protected from lightning, and he at once put himself in communication with the trustees through the secretary, Mr. Lever, and eventually received their instructions to erect conductors on the building according to specifications submitted. The work has now been carried out. Messrs. Berry have fixed their 1 in. by  $\frac{1}{2}$  in. solid copper tape conductors on each end of the building, and carried them direct to earth. The termination in every case is carried some feet away from the building, and the extreme end of the tape is riveted to an induction earth plate of gridiron form, made with the same material as the conductor. A third elevation rod is attached to the second chimney on the front of the building, and a  $\frac{3}{4}$  in. by  $\frac{1}{2}$  in. copper tape is connected to it and carried to a fourth elevation rod on the gable-end at the back of the house, from which a 1 in. by  $\frac{1}{2}$  in. tape runs direct to earth, and terminates with an induction plate, as before stated. Each of these plates is buried in carbon in order that the current may be more quickly dispersed.

**Exeter.**—The Exeter Town Council have accepted the tender of Mr. Samuel Pearse, of Exeter, for supplying the kitchen fittings for the new pauper lunatic asylum now being built at Exeter by Mr. H. Phillips, from the designs of Mr. R. S. Wilkinson, architect, of Farnival's Inn, London. Mr. Pearse's estimate is 654*l.* 6*s.* If a Perkin's patent steam oven be substituted for the baker's brick oven specified, however, he will receive the additional sum of 145*l.*—Extensive additions are now in progress in the rear of Mr. Harry Hems's ecclesiastical art works in Longbrook-street, Exeter. It is scarcely three years ago that he erected his present premises, and the extensions now mooted will give an entire run of shops of upwards of 300 ft. The new building has been designed by Mr. R. Medley Fulford, architect, of the Close, Exeter, who was also architect for the first portion. The new works are being carried out by Mr. Hems's own staff of men.

**Truro.**—Extensive new premises have just been erected in St. Nicholas-street, Truro, for Messrs. Criddle & Smith, house-furnishers. The architect of the new buildings is Mr. Hicks, Redruth. The contract was taken by Messrs. Farley & Battershill. The painting and decorating was entrusted to Mr. Glasson, the plumbing to Messrs. Cook & Son, and the iron-work to Messrs. Harris & Polmer.

**Pudsey.**—A new boot and shoe factory, for Messrs. Scates & Salter, is approaching completion. The premises, which are very extensive, will cost about 10,000*l.* The works have been undertaken by the following contractors:—Excavating, mason, and brickwork, Mr. Wilks Graves, Pudsey; carpenter and joiner's work, Messrs. John Thomas & Son, Idle; iron-founders, Messrs. E. & W. H. Haley, Bradford; plumber and glazier, Mr. George Lazenby, Leeds; plasterers, Messrs. J. & H. Eberington, Pudsey; slaters, Messrs. Hill & Nelson, Bradford; and painter, Mr. J. Dickinson, Bramley. The hot-water apparatus has been put in by Mr. E. Oldroyd, of Leeds, and the engines and pump are being made by Mr. R. Middleton, Leeds. Mr. J. Bennett has acted as clerk of the works, and the whole has been carried out from the drawings, and under the superintendence of the architect, Mr. C. S. Nelson, of Leeds.

**Eastbourne.**—Mr. J. P. Knight, the General Manager, and several of the directors of the London, Brighton, and South Coast Railway Company visited Eastbourne on the 23rd ult., with a view to inspect the site and definitely decide upon the plans for a new station, in accordance with the intimation recently given by the general manager at the mayor's luncheon, on the occasion of the laying of the memorial stone of the town-hall a few days since. It is intended to erect an entirely new building, and to greatly extend the present platform accommodation.

**Bedford.**—The new roadway bridge over the Ouse at Bedford, the foundation-stone of which was laid by the Mayor of Bedford twelve months ago, was opened to the public on Tuesday, October 21st, by Earl Cowper, K.G. Among those present were the Marquis of Tavistock, Lord Charles Russell, Mr. Whitbread, &c. The whole cost, exclusive of land, has been 8,000*l.*, which is within the original estimate of the engineer, Mr. J. J. Webster, of Liverpool. The contractors were Messrs. Pilling & Co., for the masonry, and Messrs. Goddard & Massey for the ironwork.

**Liverpool.**—The City Engineer of Liverpool (Mr. Clement Dunscombe, M.A., M. Inst.C.E.) has been awarded, by the Jury Commission of the International Health Exhibition, a gold medal for his designs for Artisans' and Labourers' Dwellings, and the Corporation of Liverpool have been awarded a Diploma of Honour for the exhibit. These designs embrace the Nash-grove Dwellings, now being erected by the Corporation, under Mr. Dunscombe's supervision, at a cost of 53,000*l.*, exclusive of the value of the site.

## CHURCH BUILDING NEWS.

**Birmingham.**—The church of St. Philip, to which a spacious chancel has recently been built in harmony with the original structure, has been fitted with carved oak choir-stalls, designed specially to suit the Classic architecture of the building. The whole of the work has been carried out, under the immediate supervision of the architect, Mr. Chatwin, of Birmingham, by Messrs. Jones & Willis, of Birmingham, who also made the wrought-iron communion-railings. This firm have also completed a pulpit in oak and iron for the same church.

**Sedgefield.**—The Church of St. Luke, erected at the Durham County Lunatic Asylum, Sedgefield, for the use of the patients and officers of that institution, was consecrated by the Bishop of Durham on the 3rd ult. The church is built of brick, in the Early English style, and consists of a nave, with north and south aisles, chancel, organ-chamber, and vestry (with heating-chamber below), while at each side of the west porch is provided a waiting-room and lavatory, &c., for the use of patients who may be taken ill during the service. The whole of the building, inside and out, is faced with Sherburn House bricks. The moulded strings, pilasters, and arches are of pressed bricks made by the Comondale Brick Company; and the

terra-cotta is from the works of Messrs. Doulton & Co., Lambeth. Internally, the nave is divided into six bays by columns built of Comondale pressed bricks, with terra-cotta moulded caps, bases, and hands, and small clustered shafts of polished slate, carrying arches of moulded pressed bricks. The seats in the nave and aisles, and the roof-timbers and joiners' work generally, are of pitch pine; the chancel-seats, reading-desks, and reredos are of oak; the chancel-floor is laid in Maw's encaustic tiles. The pulpit is of Bath stone and alabaster, and has been executed by the architect's designs. The organ was built by Messrs. Willis, of London. Seats are provided for 715 persons, and the entire cost (exclusive of organ) has been 3,850*l.*, or 5*l.* 8*s.* 6*d.* per sitting. The church was designed, and its erection superintended, by Mr. William Crozier, jun., son and chief assistant of the Engineer and Architect for the County of Durham. Mr. Jonathan Johnson, of West Hartlepool, was the sole contractor for the work, and he has carried out his contract in a highly satisfactory manner; the plumbing and gas-fitting he entrusted to Mr. James Laidler; and the painting and glazing to Mr. Phillips, both of the city of Durham. Mr. T. Waite, clerk of works to the Asylum, was clerk of works. The buildings have been heated throughout by hot water by Messrs. Haden & Son, of Trowbridge.

**Huddersfield.**—St. Paul's Church, Armitage Bridge, was re-opened on the 15th ult., after undergoing interior decoration. The chancel walls to a height of 4 ft. are done in a rich russet-red, over which is a diagonal diaper in a lighter shade and in gold, and surmounted by a broad border of sacred monograms worked upon a dull gold ground. The wall space above this is divided by shafting and canopy work into compartments, to allow of the introduction of figure subjects, which latter are painted in a strong outline with the addition of a little colour here and there, and backed up by a dull blue ground. The chief subjects are excerpt from the life of the patron saint. In addition to these large cartoons there are smaller ones; and on either side of the east window figures of St. Peter and St. John. Immediately above the altar are four demi-angels, each holding a ribbon text "Alleluia," and a larger ribbon is carried over the table to contain the legend, "Proclaim ye the Lord's death till He come," the whole being worked upon a gold ground upon which is displayed the "fruitful vine." Above this subject-work, the remainder of the walls are diapered in gold and colours, texts being carried over each window and arch, borders and other ornaments emphasising the salient points of the architecture. The roof panels of the chancel are decorated in neutral tints and blue, upon a light stone colour; whilst the wood rafters and principals stand boldly forth in strong and vivid colouring, red, gold, and black predominating. The whole work is from the designs of, and has been executed by, Messrs. Powell Brothers, of Leeds, under the supervision of Mr. W. Swinden Barber, architect, Halifax.

**Bishop's Canning (Wills).**—The parish church of St. Mary the Virgin, having been under renovation for the past eighteen months, has just been re-opened. It is a cruciform edifice with a fine Early English tower, surmounted by a Perpendicular spire, which is a marked feature some three miles from Devises upon the high road to Bath. The tower was very unsafe. It has been underpinned, and is now practically stronger than when first erected. The roofs are partially new, and of massive oak. The walls have been stripped of whitewash, and the masonry everywhere carefully dealt with. The avenues and approaches within the body of the building are laid with old flagstones, and the spaces under the seating with wooden blocking. The chancel has a new encaustic tiled pavement by Messrs. Craven, Durnhill, & Co. There are also some new stalls and an ornate pulpit. These are all of English oak, and by Mr. Harry Hems, of Exeter. The body of the church is filled by massive oak seating. These exhibit upwards of 100 bench-ends, all carved with different designs in figure or in foliage. These also have been supplied by Mr. Hems. The builder was the late Mr. A. Restall, of Bisley, near Stroud, who unfortunately died during the progress of the renovation. Mr. Charles E. Ponting, the diocesan surveyor and architect, of Lockeridge, Marlborough, was the architect. Some 3,500*l.* has been spent on the works.

## The Student's Column.

ON THE CONSTRUCTION OF ROOFS.

THE roof is in many respects the most important feature of a building, and its design calls forth more of the constructive skill of the architect than any other portion, as the character of the roof regulates to a great degree the strength that is given to the walls which support it. Where the roof is so constructed as to throw a horizontal thrust on the walls, either they must be made of extra thickness or buttresses must be built up against them to prevent them from being overthrown. But where there is no horizontal thrust from the roof we have only to consider what will be its dead weight, and build our supports accordingly.

The object of the roof is to form a waterproof covering that will keep out the weather from the interior of the building. There are several different kinds of material used for the covering of a roof, which is usually laid upon boards or battens nailed upon timbers called *rafters*, to be hereafter described. Rafts are generally inclined at a greater or less angle to the horizontal, in order that the rainwater may be enabled to run off freely into the gutters, and he conveyed away so as not to damage the interior; the angle of slope is called the *pitch* of the roof, and depends very much on the kind of material used for its covering. The materials in common use for this purpose are *lead*, *zinc*, *slates*, *tiles*, and *asphalte*. When either lead, zinc, or asphalte is used the pitch is generally low, but should never be less than 2°, which gives a rise of about 1 in 30. Lead and zinc are, however, frequently laid on roofs of high pitch. When slate or tile is used the angle of pitch should not be less than 27°, giving a rise of 1 in 2.

The best material, but also the most costly for roof-covering, is *lead*, which is laid upon close boarding on which rounded slips of wood, called *rolls*, about 2 in. in diameter have been first nailed from top to bottom in parallel lines 2 ft. to 3 ft. apart. The lead is cut in sheets 10 ft. or 12 ft. long and a few inches wider than the distance between the rolls. It is then laid on the boarding and the edges dressed over the rolls, each sheet lapping over the edge of its neighbour and held down by *lead-headed nails* driven into the rolls. If the pitch of the roof is not very flat, the lower end of the sheet is made to lap about 3 in. over the one below; but in very flat roofs a small step called a *drip* is formed about 2 in. deep at the bottom of the sheet, the end of the lower sheet being turned up against the drip, and that of the upper one turned down so as to lap over it and prevent the rain from driving under the lead. When there is a ridge, a similar roll is spiked to the ridge-pieces at the top of the rafters, and a narrow slip of lead is laid thereon and dressed down over the upper edges of the sheets of lead, the ridge being held down by means of lead-headed nails. The weight of the lead for roofing purposes is 6 lb. or 7 lb. to the square foot.

*Zinc* is a material frequently used for roof-covering, and has the advantage of being very light in weight, 22 oz. to 25 oz. per foot being the weight usually employed. It is laid in a manner similar to that described above for lead, but is a very brittle material and much less durable than lead.

*Asphalte* can only be used as a roof-covering when the pitch is very low; it may be laid upon flat tiles placed across the rafters, on which a layer of cement is first laid, and the asphalte poured thereon in a semi-fluid state, when the cement is thoroughly hard. Fine sand may be sifted over the surface of the asphalte while soft, so as to increase its hardness. This material forms a good roof for walking upon, for which purpose it is preferable to lead or zinc, but throws a much greater load on the rafters than either of the former.

The most usual material for covering roofs is *slate*, which is cut into various sizes for roofing purposes, those commonly used being 20 in. by 30 in., called "Countess," and 24 in. by 12 in., called "Duchess." Slates of this kind, when used as roofing, weigh from 7 lb. to 9 lb. on every square foot. In laying slates it is usual to nail narrow *battens* or *slate laths* on the rafters, to which the slates are secured by means of copper or zinc nails driven through two holes drilled in each slate about one-third of its length from the top. Each slate laps half its length plus 1½ in. or 1 in. over that next below it, and 2½ in. or 3 in. over the upper

end of the next slate but one below it, this amount of 2½ in. or 3 in., being called the *lap* of the slate.

In some parts of the country *stone slates* are used for roofing, and sometimes called *grey slates*; these are really thin flags from ½ in. to 1½ in. in thickness, and weighing, when laid, about ¼ cwt. to the square foot. They have two holes drilled in them through which pegs of hard wood are driven, and by these they are hung on to the laths.

In buildings of a superior class it is usual before laying the slates, to cover the rafters with close boarding, and lay thereon a waterproof material called "asphalted felt"; this is laid horizontally in continuous lengths, each length lapping 1 in. over the one below. On this the slates can be nailed, or, what is better, the slate laths can be laid on the felt, and the slates nailed upon them in the manner described above. The advantage of the felt is to keep out the heat in summer from the rooms immediately under the roof, as slate becomes very hot in the sun, and is a good conductor of heat. It also keeps the rooms warmer in winter. Another advantage is, that if any slates are blown off, or if snow drifts under them, the felt prevents the wet from penetrating to the interior.

*Tiling* is a common form of covering to roofs, each tile being generally made with two small hooks on the upper edge, by means of which it is hung on to the laths. There are two distinct kinds of tiles in ordinary use: those called *plain tiles* are made flat, their dimensions being 10½ in. by 6½ in.; these are laid with a *lap* in the same way as slates, and weigh about twice as much per foot. Some tiles have two holes in the upper part to allow of pins being inserted for hanging them on the laths, or for large nails to be driven through. Another form of tile is called *pan-tile*, which is curved in section, and, when laid, produces a series of ridges and valleys all down the side of the roof, each tile being made to lap over the edge of the one at its side as well as over that next below it. The weight of this tiling is but little more than that of slating. Ornamental tiles of various forms and sizes are also employed for roofing purposes.

The actual weight of the roof-covering is not the only load which the timbers of a roof have to sustain; in fact, it forms but a small part of it, for in northern countries the weight of snow is often a much heavier load, especially where the pitch is not high enough to cause the snow to slide off and prevent it from accumulating. But the chief strain which a roof has to encounter is that produced by the force of the wind when blowing strongly upon one side of it. This is much greater in a roof of high pitch than in one where the pitch is low, for if we consider the direction of the wind to be horizontal and pressing in a gale 40 lb. on every square foot of a surface perpendicular to its direction, then the pressure per foot on a roof having a pitch of 60° will be 30 lb.; on one having a pitch of 45° it will be 20 lb.; and on one of 30 lb. it will be 10 lb.; and, of course, it is nothing on a perfectly horizontal roof. Wind, however, is very capricious in its action, and does not always travel in a horizontal direction, so that at times it might act at right angles to a roof, even of very moderate pitch; and, as it presses only on one side of the roof at a time, there is no counterbalancing force on the other side, and a racking strain is consequently thrown upon the timbers. For these reasons it is recommended that a load of 60 lb. per square foot should be taken as the pressure which roofs of ordinary pitch must be expected to bear.

We shall now proceed to consider the means by which the roof-covering is supported, according to the various forms of roof which are adopted.

**Flat Roofs.**—The simplest mode of constructing a roof is to place horizontal beams across from wall to wall, cover them with boarding, and lay thereon lead, zinc, or asphalte as above described; this plan is often adopted for moderate spans, and where it is desired to make use of the roof for some purpose or other. In the South of Europe and in the East flat roofs are more common than in the Northern countries. Such a roof is constructed in the manner we have previously described for "Floors," and the same scantlings of timber may be employed. For short bearings *single-joints* may be laid across and the boarding nailed on them. For longer bearings *binders* or *girders* should be employed. The timbers must never be laid quite level, but have a fall of at least one in

erty, so as to allow the rain-water to flow freely.

When the roof has to be made fireproof, we lay rolled iron joists and concrete across opening, and finish with a coating of cement and asphalt, as we before mentioned when considering fire-proof floors.

In a flat roof the whole of the weight is borne vertically on the walls, and there is no outward thrust tending to push the walls over, so long as the beams retain their horizontal position. Should, however, the beams be too light for the load they have to carry, they will assume a curved form, as A B D, fig. 1, in which case the roof will act as a wedge to push the walls asunder, with a force R in A C and

B C perpendicular to the curved beam at A and B, and the value of R is rather more than one-half of W the load on the centre of the roof; C being the centre of curvature of the arc A D B. A very great outward thrust might thus be produced upon the walls at the part where they are least able to withstand it. This shows us the importance of making the supports of a flat roof amply strong and stiff, so as not to bend to any appreciable extent under any load that can possibly be placed on the beams.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

2904, Improvements in Ornamental Walls, &c. John Baker Gansby, Birmingham.

This invention principally has reference to the construction of ornamental surfaces for ceilings, walls, or pavements. Pieces or plates of glass, enamel, or other ornaments are fixed to the wall or other surface. Supposing a design is composed of several pieces or plates of different coloured enamels, and these pieces are of different shapes to be worked into the design. In order to connect them together, strips of brass or other ductile alloy are taken with a cross section in the form of a T; or narrow strips having something like a similar section may be employed. These metal strips have at their backs at short intervals pins, studs, or projections for the purpose of fixing the design to the wall or ceiling. The working out of the design by means of the strips, and affixing them to wood, plaster, or metal by this means, is the principal claim of the improvements.

7,546, Improvements in Open Fire-grates or Stoves. Samuel Pickersgill, Derby.

In this improvement of open fire-grates the bars at the front are so bevelled inwards as to make it impossible for the ashes either to lodge on or fall through them on to the hearth, but they will be thrown forward into the fire, where they are either consumed or fall to the bottom, which is provided with a secret ash-pan, which may be removed at convenience. By this plan perfect combustion is ensured, and fuel economised. The fireplace is made something similar to the ordinary manner, but the bottom of the fireplace is formed partly of iron bars so constructed as to allow little refuse or ash to fall between them, and partly of fire-brick. It is attached to the back, which is also of fire-brick, and is so shaped as to radiate and reflect the heat into the room. The form is convenient, and it is claimed that more heat can be got out of the fuel with less smoke than by any other form of open fire-grate.

38, Improvements in Sanitary Traps. William Henman, Birmingham.

This is an improvement in the form of traps for water-closet and for bath, lavatory, sinks, and urine waste, by which security is obtained for the inflow of sewer-gas to buildings. The outer arm of the trap is funnel-shaped, and is made with the siphon below, and with the ventilating or air pipe above. The inner arm or arms are placed at about an angle of 45 deg. to receive the connecting-pipe for the water-closets, baths, or urinals. The trap is of any suitable dimensions, and is made of glazed earthenware, stoneware, or of cast iron, or of iron or metal.

APPLICATIONS FOR LETTERS PATENT.

Oct. 17—18,713, E. Preston, Birmingham, Improvements in Planes, Spokeshaves, and in other analogous Tools or Machines.—18,719, T. W. Helliwell, Halifax, Improved Method of Securing and Fixing to Roofs, Flats, or Sides of Buildings or other Structures, Sheets of Zinc, Copper, Lead, or Corrugated Metal, &c.—18,728, W. Morris, London, J. Carruthers, Erection of Bridges.—18,738, Construction and Erection of Bridges.—18,738, London, Carlisle, Shop-window Folding Shutters.—18,750, J. M. Capell, London, Ventilation.—18,761, M. Donstedt, London, Manufacture and Preservation of Articles of Gypsum, Stucco, or the like.—18,764, R. Davidson and W. H. Wright, London, Immoveable Wood Mosaic and Block Flooring, with Pyramidical Dovetail and Fish Joints, and Stair Prevention Chamber.—18,770, P. Easley, London, Metal Frames for Casement Windows.

Oct. 18.—18,779, J. Walker, Birmingham, Attaching Door Knobs to their Spindles.—18,796, J. Smith, Peebles, Folding Tables, Forms, Chairs, Benches, &c.—18,824, E. Grach, London, Mosaic and other Artistic Work.

Oct. 20.—18,830, T. H. Angles, Blackburn, Water-closet Flushing Apparatus.—18,841, J. Ennals, West Malling, Combination Closet and Dust bin.—18,845, D. Cowan, Glasgow, Improvement in Cooking-ranges.—18,859, R. Winder, London, Castors for Tables, Chairs, &c.—18,864, A. E. Finch, London, Excluding Draughts from Doors.—18,867, A. J. Boulton, London, Manufacture of Fans for Ventilating Purposes.—18,874, G. Henderson and D. M'Neil, London, Water Waste Preventers.—18,878, W. R. Lake, London, Improvements in Bakers' Ovens.

Oct. 21.—18,890, W. Russell, London, Improvements in Stoves, Stove-ranges, Mantels, and Overmantels.—18,891, C. J. Elkin, Birmingham, Improvements in Ventilators.—18,897, E. Newman, Birmingham, Window-sash Fastener.—18,900, T. Cain, Malvern, Link Sower Ventilator.—18,912, C. G. Smith and F. Smith, Birmingham, Rack Action for Opening and Closing Fanlights, Window-Skylights, &c.—18,914, J. James and C. James, Cardiff, Machinery for Sawing or Cutting Wood or other Material.—18,915, P. Lee, Cardiff, Protective Edges of Saws and other Tools when not in use.—18,924, A. M. Clark, London, Improvements in Excavators.—18,932, J. C. Newhorn, London, Baking Ovens.—18,943, E. H. Clark, London, Floating Breakwaters.—18,947, W. R. Lake, London, Metallic Lathing.—18,954, W. R. Lake, London, Improvements in Wheels.

Oct. 22.—18,977, F. H. Harrington, Liverpool, Bodies of Wheeled Vehicles.—18,981, A. Yates and W. Smith, Halifax, Adjusting the Table of Circular-Saw Frames.—18,987, R. Eccles, Brixton, Improvements in Castors.—18,990, T. Thorley, London, Chimney-breast Ventilators.—18,991, H. Fujia, London, Apparatus for Testing the Strength of Cement.—18,999, A. J. Alderman, Bow, Furniture Castors.—14,904, V. Di Terpolina, London, Underframes for Four-wheeled Vehicles.—14,010, H. J. Cooper, London, Manufacture of Portland Cement.

Oct. 23.—14,056, J. Macdonald, London, Smoke-testing Apparatus.—14,058, S. Guinier, Bpsom, Improvements in Locks and Latches.—14,062, P. J. Watee, London, Improvements in Spammers.—14,064, A. K. Kubofer, London, Improved Construction of Domestic Stoves.

PROVISIONAL SPECIFICATIONS ACCEPTED.

10,982, H. V. R. Read, London, Automatically Opening and Shutting Gates.—11,273, M. Underwood, Devonport, a Method of Construction in Metal, Stone, Wood, or other Material, by Dovetailing.—12,615, A. Sweet, London, Improvements in Water-waste Preventers.—12,712, S. Frankenberg, London, Felt for Roofing and other purposes.—12,788, W. W. Crowder, Kensington, Automatic Bolt Lock, and Burglar alarm.—12,901, J. Budd, London, Imparting to Glass the Appearance of Marble or other Stone.—12,902, J. Budd, London, Ornamenting or Decorating Glass in imitation of Mosaic or similar work.—12,935, A. M. Clark, London, Improvements in Auger-bits.—13,076, F. W. Palmrose and J. Mellows, London, Supports for Workmen on Clazed Roofs of Building.—13,364, A. A. Joy, London, Improvements in Sash-fasteners.—13,066, H. H. Jones and B. Jones, Wolverhampton, Metallic Folding Furniture.—13,148, W. H. Lindsay, London, Improvements in Bridges.—13,238, R. Hunter, London, Improvements in Kitchen Ranges.—13,381, H. Wright, London, Mounting, Balancing, and Securing Window-sashes.

COMPLETE SPECIFICATIONS ACCEPTED.

Open to application for two months. 68, N. G. Kimberley, Tottenham, Steam Flushing Apparatus.—143, H. Thompson, London, Construction of Domestic Stoves and Grates.—352, H. Knowles, Woodville, Leicester, Ovens for Burning Bricks, Pottery-ware, &c.—526, J. H. Chavasse, Kingswinton, Improvements in Pavements, Wall Surfaces, &c.—790, G. Homewood, Cuckfield, Water Waste-preventers for Water-closets.—907, C. Clayton, East Dulwich, Finger-plates for Doors, and Means of Fixing the same.—855, A. Walker, Falkirk, Kitchen Ranges.—12,118, R. Booth and R. W. Booth, Dublin, Flooring Clamp.—12,319, G. R. Postlethwaite, Birmingham, Drill Braces.—133, J. Croft, London, Wooden Pavements.—899, F. C. Biddiscombe, Manchester, Cisterns for Water-closets, Urinals, &c.—1,360,

E. H. Baxter, Birmingham, Cupboard Fasteners.—3,998, C. J. Henderson, Edinburgh, Construction of Stoves, and Ventilating Apparatus for same.—4,804 S. Morley, Stockton-on-Tees, Whitewashing Brushes.—7,280, G. W. Potter, Hamstead, Door Letter Boxes.—9,450, M. Tohny, Uxbridge, Ventilating Dwellings and other Structures.

RECENT SALES OF PROPERTY.

Table with columns for property location, terms, and price. Includes entries like 'Minorities-1 & 4, Vine-street, 17 years, ground-rent 2800', 'Westbourne Park-36, Fernhead-road, 79 years, ground-rent 6l. 1s.', 'Oxford-street-The lease of 27, Rathbone-place, term 18 years..... 10', 'Hammermith-99, Brackenbury-road, 98 years, ground-rent 6l. .... 400', 'Peckham-225, Queen's-road, freehold..... 680', 'Stoke Newington-68 & 70, Cowper-road, 74 years, ground-rent 7l. .... 740', 'Lewisham-44, Limes-grove, 70 years, ground-rent 5l. .... 300', 'Brixton-78-86 even, Barrington-road, 39 years, ground-rent 25l. .... 3,020', 'Walworth-54, Finchley-road, 68 years, ground-rent 4l. .... 720', '146, Lorrimer-road, 68 years, ground-rent 8l., and a ground-rent of 13l. a year, term 66 years, 420', 'Portman Estate-98, Cranford-street, and 19, Home-street, 4 years, ground-rent 10l. .... 100', '59 & 60, Crawford-street, 4 years, ground-rent 11l. .... 365', 'Fateroster-row-Lovell's court, 2,593 ft., term 80 years, let at 290l. per annum.', 'Brunswick-square-Improved rents of 60l. a year, term 23 years..... 505', 'Kentish Town-129 & 133, Prince of Wales-road, 67 years, ground-rent 14l. .... 844', 'Lee-50, Church-street, 43 years, ground-rent 2l. 2s. .... 210', 'Sevenoaks-The freehold residence, Croftside ..... 800', 'Kent, Horns Cross-The residence "Barasfield", and 2a. 0r. 35p. freehold ..... 2,650', 'Two freehold cottages, with gardens ..... 710', 'Leytonstone-Ground-rent of 7l. 10s. a year; reversion in 75 years..... 165', 'Ground-rent of 6l. a year; reversion 71 years ..... 129', 'Leyton-Benham-road, a plot of freehold land ..... 160', 'Milton-road, two plots of freehold land ..... 285', 'Fleet-street, Bonville-street-A plot of freehold land, area 300 ft. .... 2,130', 'South Lambeth-road, Nos. 74-84 even, freehold ..... 6,900', 'Patney-The Platt, Clarence House, 67 years, ground-rent 8l. 4s. .... 540', 'J. ## MEETINGS.

SATURDAY, NOVEMBER 1.

Association of Public Sanitary Inspectors.—Monthly Meeting, 1, Adam-street, Adelphi. 6 p.m.

MONDAY, NOVEMBER 3.

Royal Institute of British Architects.—Opening Meeting of the Session. Address by the President. 8 p.m.  
Clovis of Works Association.—Monthly Meeting, 31, Spring-gardens. 7 p.m.

TUESDAY, NOVEMBER 4.

Society of Biblical Archaeology.—Meeting at 9, Conduit-street, W. The following papers will be read:—(1) Some Religious Texts of the Early Egyptian Period, preserved in Hieratic Papyrus in the British Museum, by P. le Page Renouf. (2) Notes on some fragments of Papyrus, exhibited by permission of the Secretary of the Science and Art Department, by Dr. Birch. (3) Notes on some Egyptian Sepulchral Tablets, principally of the XVIII. Dynasty, by E. A. Budge. 8 p.m.

WEDNESDAY, NOVEMBER 5.

Institution of Mechanical Engineers.—Meeting in the Lecture Theatre, University College, Nottingham. The following papers will be read and discussed, as far as time will admit:—(1) On the Mineral Wagons of South Wales, by Mr. Alfred Slater, of Gloucester. (2) On the application of Electro-Magnets to the working of Railway Signals and Points, by Mr. Elias A. Timmis, of London. (3) Second report on Friction Experiments, by Mr. Beauchamp Tower, of London.

Sherrin and Society (Victoria-chambers, Chancery-lane). Opening Meeting of the Session. Address by the President, Mr. Thomas Allen Reed. 8 p.m.

THURSDAY, NOVEMBER 6.

Builders' Benevolent Institution.—Thirty-seventh Anniversary Dinner, at the Freemasons' Tavern, Mr. Stanley G. Bird, President, in the chair. 5.30 p.m.

FRIDAY, NOVEMBER 7.

Architectural Association.—Mr. J. D. Sedding on "The Modern Architect and his Art." 7.30 p.m.

## Miscellaneous.

**Cambridge Antiquarian Society.**—At a general meeting of this society on the 20th of October, Mr. J. W. Clark, M.A. (president), in the chair, Mr. A. G. Wright, of Newmarket, exhibited (1878) a Roman bronze earring and a Medieval bronze signet-ring, both found at Stony Hall, Lakenheath, early in this present year; also a photograph of a rare palaeolithic implement from New Park, March. Mr. Lewis exhibited a well-preserved first brass of Marcus Aurelius, *reus*, *honoris*, with portrait of the Emperor erect, olive-branch and cornucopia (141 A.D.), which had been found in 1883 at Littleington, in this county. Mr. Browne exhibited an outlined rubbing of the Wilne font, a very intricate and elaborate piece of Early work, with twelve bold characters round the base, supposed to be Runic or Oriental, and in the latter case probably Palmyrene. The font is a portion of what must have been a very remarkable column, turned upside down, and when the rubbing is turned the other way up it is found that the twelve bold characters are the feet and ankles of six human figures, cut off at the point where the pillar was broken before it was turned up and hollowed to form a font.

**Election of a Surveyor.**—At a meeting of the Chelsea Vestry on the 21st ult., the Finance Committee reported that they had considered the eighty-two applicants for the post, and out of the number selected, six, who were now in attendance, and each, in his turn, addressed the Vestry, and answered the questions put to him. The Vestry then proceeded to a ballot, the result being the election of Mr. Strachan, by a large majority. Fifty vestrymen voted, and of these the papers of four were declared informal. A corresponding clerk was also elected.

**Proposed New Post-office at South Shields.**—The Post-office authorities have decided upon building a new post-office at South Shields. The step has been decided upon in consequence of the present building being inadequate to meet the requirements of the largely increasing business in the various departments. The new post-office will be designed on a large scale, and will contain ample accommodation for the public and officials.

**The Clock at Great Houghton Church.**—The church at Great Houghton has just been enriched by having a large new clock fixed in the tower, which strikes the hours on a large bell, and shows the time on two dials, each 4 ft. diameter. Messrs. John Smith & Sons, Midland Clock Works, Derby, have carried out the work.

**Glasgow Institute of Architects.**—At the annual meeting of the Glasgow Institute of Architects, the sixteenth report of the Council was read. It was mentioned that the draft of a proposed Building Act, separate from the Police Bill, having been drawn up and submitted by the president, a committee was appointed as to the matter. After various discussions the draft was printed, and a copy sent to each member of the Council. At several meetings of the Council the draft was gone over and revised, after which a printed copy was sent to all members of the Institute. Thereafter the draft Act was considered and adopted at a meeting of the Institute, and Messrs. James Thomson, president, Campbell Douglas, and John Honeyman, past-presidents, were appointed a deputation to wait on the Lord-Advocate and confer with him on the subject. It was agreed that while a separate Building Act would be most desirable, yet if absolutely necessary, rather than have delay they should agree to the Building Act forming part of the proposed Burgh Police and Improvement (Scotland) Act. The Burgh Police and Improvement (Scotland) Act having in the previous session of Parliament failed to pass the House of Commons, a new Bill was brought in by the Lord-Advocate in the course of last session. This Bill was found to be, so far as the architectural and other kindred clauses were concerned, substantially a reprint of the former Bill, no effect having been given to the suggestions of the Institute. The Bill was referred to a Select Committee of the House of Commons, and it was ascertained that the only way in which the members of the Institute might now have effect given to the suggestions was to forward a written statement of these to the members of the committee. A copy of the draft prepared by the Institute was accordingly forwarded to several members of the committee, but, owing to the Bill having been dropped by the Government, no legislation has yet taken place. The committee have given much attention to the examinations in architecture held in Glasgow in February, under the auspices of the Royal Institute of British Architects. The Council and the past-presidents were appointed a committee to take charge of the examination. In this they were assisted by Mr. Arthur Gates, chairman of the Board of Examiners, and Mr. J. Macvicar Anderson, honorary secretary of the Royal Institute of British Architects. The Council think that these examinations will prove very beneficial to the profession, and hope that a larger number will come forward when the next examination is held.

**Removal of Gates and Bars in the Metropolis.**—On the 18th ult. the Sanitary Committee of the Vestry of St. James, Westminster, recommended that the Vestry support the memorial adopted by a conference of representatives from various local authorities, recently held at St. Pancras, asking the Metropolitan Board of Works to introduce a Bill in the ensuing session of Parliament, for the removal of all gates, bars, &c., from the streets where the cost of paving and lighting, maintaining, and sewerage such streets is defrayed out of the rates. Mr. Bonthron vigorously opposed the proposition that the ratepayers should give compensation. Let the ground landlords do it. By what natural right had these landlords put up bars and gates? He denied their right to block up the public thoroughfares on their estates. He did not deny that the tenants were entitled to compensation; but let them get it from the landlords who had put up the gates. The Vestries should act all together in this matter, for what affected one part of London affected every other part. The motion to adopt the recommendation was carried with only a few dissentients.

**Pontefract Drainage Scheme and Street Improvements.**—The Corporation of Pontefract have just completed the whole of the drainage scheme, extending throughout the borough, at a cost of about 20,000l. The works have been carried out by the contractor, Mr. John Simpson, of Hunslet, Leeds. The outfall works are situate about two miles from the town.

**Hydraulic Power.**—Messrs. Archibald Smith & Stevens, of Queen's-road, Battersea, have just completed a new hydraulic cylinder and crane for Southwark Wharf, Bankside. This forms another set of machinery worked in connexion with the Hydraulic Power Company's mains.

**"Buried" in a Caisson.**—An accident singular in its character and most remarkable in the escape of those involved in it, is reported from Havre de Grace, Maryland. The Baltimore and Ohio Railroad Company are constructing a new bridge over the Susquehanna river, and on October 1 the outer shell or cofferdam of the caisson sunk as the foundation for one of the piers gave way. The crib and a lock shaft were flooded, and the working chamber rapidly filled. Most of the men got out safely before the accident occurred, but six men were imprisoned in the submersible chamber. The caisson in question is larger than any of the others sunk for the bridge. It is 60 ft. long and 40 ft. wide, and at the time of the accident the working chamber was 60 ft. below the surface of the water. The entrance to the caisson proper is made through a perpendicular iron shaft about 3 ft. in diameter with foot and hand holes on either side. It is divided into locks, each lock having a gate. When the men descend, the lock tender withdraws the air and the gate falls, and the men draw down lifts the gate. When the bottom gate is opened, the air rushes in, thus holding the top gate in position. The same process is repeated until the working chamber is reached, which is lighted by electricity. The air in the chamber, beyond being a little oppressive, said to be not unpleasant. The men were working under a pressure of 25 lb. at the time of the collapse, and when the lock flooded, the only entrance or exit to and from the caisson was cut off. The air apparatus, however, fortunately continued to work, and this was the men's salvation. They remained in their prison helpless until rescued by the superintendent, Mr. John O'Brien, who conceived an ingenious plan, and proceeded to put it into practice. The outer lock was 5 ft. under water, and the next lock, which was 15 ft. deep, was full of water. Mr. O'Brien made a cofferdam of boards, and caulked it tightly with oakum and cement. Then he baled out the water, descended, and raised the flooded lock and haled that out. He then descended through his rudely-constructed shaft, and successfully rescued the six men from this perilous situation, in which they had been five hours. The operations were naturally watched with the greatest anxiety.—*Iron.*

**Proposed Ferry at Greenwich.**—At a meeting of the Lewisham Board of Works, the 22nd ult., Mr. Hughes said it had been decided to have a ferry from Greenwich to the other side of the river. The original proposal was a ferry from Horseferry-road to Greenwich, but he pointed out that that would compel people to go through back streets, and that inasmuch as the Metropolitan Board would have to compensate the proprietors of the existing ferry, it would be as well to have their premises. The committee agreed to recommend the acquisition of the premises.

**The Tay Bridge.**—It is stated that important negotiations are in progress between the directors of the North British Railway Company and the city of Perth, with the view of very considerably reducing the height of the Tay Bridge. It is understood that the height proposed in the negotiations is 55 ft. at the highest part of the bridge, and that the sum to be paid to the City of Perth by the North British Railway Company in return for the concession would be upwards of 90,000l. alteration in the height of the bridge can be made without the sanction of Parliament.

**Completion of the Esk Viaduct.**—The Esk Viaduct, which carries the new line of Scarborough and Whitby Railway over the river Esk, is now practically completed, and on the 24th ult. a large party was conveyed across it for the first time, in the presence of a crowd of people. The viaduct, which is constructed of red brick, is 913 ft. long and 125 ft. high, with twelve piers and thirteen arches, an average span of 60 ft. The viaduct is the last link needed to connect Middlesbrough with the teeming population of Cleveland with Scarborough.

**Strike of Riveters on the Clyde.**—The riveters of Messrs. Robert Napier & Sons, Govan, have struck work for higher rates wages. Owing to the depressed condition of trade on the river, the strike is engaging a good deal of attention in shipbuilding circles, which is its latest development,—namely, the employment of non-unionists,—seems to have created a bad feeling amongst the operatives who are immediately interested in the event.

**New South Wales Marble.**—According to the Immigration Agent for New South Wales, several beds of very fine marble or crystalline limestone occur in different parts of the Colony, as at Wollindilly, whence one of the marbles, used in paving the great hall of the University, the Post-office, and other public buildings in Sydney, has been obtained. Much of the Wollindilly so-called "whitemarble" is of acreeam tint, variegated with pale red and light blue streaks. A slate-coloured marble, used in the same buildings, is brought from Marulan, near Goulburn. There is a beautiful white saccharoid marble at Cow Flat, near Bathurst, a brecciated slate-coloured marble streaked with white calcite occurs at Wallerawang, county Cook. Beautiful marbles occur at Mudgee and Orange; also at Wellington, celebrated for its caves. At Bangalore, on the Goulburn Plains, there is found a white crystalline marble; at Yass and Queanbeyan, county Murray; good grey and white crystalline marbles are found along the banks of the Murrumbidgee, the Belubula River and the Conomidine Creek, in the Orange District. Blue-grey limestone at Warialda, county Burnett. The outcrops of small seams of grey crystalline limestone or marble are seen exposed in the Minnamurra Creek, near Jamberoo, county Camden, interbedded with the local shale and sandstones of that district. A specimen from a 2-in. band in the Minnamurra Creek was slightly crystalline, of a grey colour, with a few thin streaks of a lighter colour. Small patches of a pale green mineral were detected in parts, something like glauconite in appearance.

**Arbroath.**—Two more three-light Munich windows have been erected in St. Mary's Church, Arbroath; one by subscription, in memory of the late Rev. W. Henderson, fifty-one years pastor, and representing the "Good Samaritan," the other by Dr. J. Traill, in memory of his brother and his son, and representing "Christ Healing the Sick." The artists were Messrs. Mayer & Co.

**Scarcity of Water in Manchester.**—Manchester is threatened with a water famine, the continuous dry weather having so reduced the stock that four of the great reservoirs are quite dry, cattle grazing on ground formerly covered with water. The gathering-ground is 19,000 acres of moorland around the Longendale Valley, between Manchester and Sheffield, and the supply is distributed not to Manchester only, but to Salford and the surrounding districts, so that a total population of 750,000 is involved. Mills, dyeworks, and other industries will be stopped unless there be rain. Thirlmere, which the Manchester Corporation obtained Parliamentary powers to purchase, is not yet available for water supply, and will not be for years. Inquiries made on Saturday, however, showed that the danger is not now so great as it was a month ago. The report then made was that there was sufficient water in the reservoirs to meet only thirty days' consumption; and upon this being made known to the committee, they ordered that watering of the streets should cease, and that the use in the parks should be restricted. It is believed that but for the fact that the Gorton reservoir allowed the storage of what would have run to waste at Longendale, there would have been a famine ere now.

**The New Liberal Clubhouse in Northumberland-avenue.**—Immediately opposite to the Hotel Metropole in Northumberland-avenue, the new building for the National Liberal Club is to be erected, of which Mr. Gladstone and Earl Derby are to lay the first stone on November 4th. Mr. Waterhouse is the architect.

**Staple Inn, Holborn.**—*Truth* says that the "ancients" of Staple Inn have recently completed the sale of their property to Messrs. Trollope, of the well-known builders, for \$0,000. If there be any truth in the rumour all lovers of the picturesque must hope that the quaint old houses and gateway at Holborn Bars are not to be removed.

For building Sney's County School, at Douling, Shepton Mallet, Somerset, for the Visitors of Hugh Sney's Hospital, Bruton. Mr. George J. Skipper, architect, Opie-street, Norwich. Quantities by the architect:—

Jones & Co.	213,713 0 0
Clarke	18,843 0 0
Gibson	13,131 0 0
Sanders	12,439 0 0
Stephens & Bastow	12,399 0 0
Clarke & Son	12,317 0 0
Davis	11,980 0 0
Green	11,980 0 0
Bull & Co.	11,796 0 0
Kraus	11,417 0 0
Hawkins	10,904 0 0
Emery, Shepton Mallet (accepted)	10,600 0 0

For the enlargement of school, Portman-place, Globe-road, for the London School Board. Mr. E. R. Robson, architect:—

F. & F. J. Wood	68,727 0 0
J. F. Sargant	8,166 0 0
Steel Box	7,843 0 0
W. Shurmer	7,758 0 0

### Current Topics at the Institute.

THE opening meeting at the Institute of Architects on Monday was an unusually full one, the attendance being, no doubt, in part augmented by the interest felt by many of the Associate Members in the question of the memorial which was to be read on their behalf in favour of what may be called an extension of the franchise, by admitting the Associates to the privilege of voting at the meetings. The memorial in regard to this subject, which will be found embodied in our general report of the meeting, was read by Mr. Richards Julian,—"Well recited, with good accent and good discretion," like Hamlet's quotation from Pyrrhus,—amid the applause of his colleagues. From the tone in which the address was received by the President we may probably assume that there is every disposition on the part of the Council to accede to the views embodied in it; and, after careful consideration of the matter, we come to the conclusion that they will act wisely in doing so, and that the proposition, provided it is not set up as a precedent for rash and unholy tampering with the charter, is both reasonable in itself and for the good of the Institute. It has been urged that to give votes to the Associates will be practically to put them on a level with the Fellows, and, in fact, to give them the privileges of Fellows for a lower subscription. But, in the first place, it may be hoped that there is something more in the position of full membership than mere voting power, more especially as the Fellows alone are eligible for election to serve on the Council, and there is no talk on the part of the Associates of asking for this privilege also. In the second place, it must be admitted that a considerable proportion of the attendance at each meeting is furnished by the body of Associates, who take a lively interest in the proceedings, and some of whom speak with ability and force in the debates; and it is likely that a good deal more interest and life will be imported into the meetings of the Institute if the large body of junior members, many of them talented men who are likely to have a considerable effect in making the future of the Institute, are permitted to express their opinion in a practical as well as a theoretical manner, instead of sitting by and merely watching the solemn but generally rather small procession of Fellows file out at one door and in at the other to make their offerings at the shrine of the ballot-box.

So far, we imagine, the House is with us on the whole; nor are we likely to encounter any material opposition of opinion when we express our cordial appreciation of the tone and style of Mr. Christian's address, characterised as it was by a sincerity, earnestness, and good sense well calculated to confirm the feeling of respect and regard with which its author is universally regarded in the profession. The sequel of the proceedings was probably not regarded with equal approval and respect by the majority of the meeting, although courtesy and the (we believe) usual precedent of not entering into any debate on that occasion, kept some members silent who might otherwise have felt inclined to enter a protest against some of the utterances of the evening, which, as it was, passed with no outwardly dissentient voice. Some of us may be inclined to ask, for instance, why it should be thought necessary to import into the proceedings, for the purpose of proposing a vote of thanks for the presidential address, the assistance of the permanent Secretary of the Office of Works, whose name, despite his official position, has no weight whatever on architectural or artistic subjects, with any portion of the public who really understand such subjects; whose attitude towards the architectural profession has always been the reverse of respectful; and whose powers of oratory did not enable him to rise to the fluent expression of even the most ordinary platitudes of the occasion. Some of us may be inclined further to ask whether it is particularly suitable that the opening meeting of the central body of architects should be made an opportunity for their being good-naturedly lectured by the First Commissioner of Works on subjects which many, if not most of them, understand much better than he does, and hearing from him, without any decent chance of reply, a statement of his entire satisfaction with his own course of procedure in regard to matters in which they are much more fitted to instruct him, and on which many of them differ *in toto* from his theory and practice alike. In one respect, indeed, we may heartily congratulate the First Commissioner. The reward of a good conscience, the sense that we have done exactly what is right in every respect, the state of perfect and sincere satisfaction with ourselves, is a blissful frame of mind to which we would all aspire, but which few of us ever succeed in realising. In this respect, at least, the name of the First Commissioner of Works may be inscribed among those of the blessed who have attained Nirvana.

Upon the subjects in regard to which Mr. Shaw-Lefevre displayed so much satisfaction he had no doubt a lead from the presidential address in the first instance. In regard to one

of these, the recent War Offices competition the President of the Institute and the First Commissioner, of course, stand in a special relation to one another, having been both acting as members of the Committee of Selection; and it was inevitable, therefore, that the president should support the award in the competition, having been himself directly concerned in determining it. And there was much in Mr. Christian's tone in speaking of this matter with which we must fully sympathise. As to his claim that the decision was arrived at in the most fair and honourable manner, and with the most absolute intention to do justice to every one, we have already expressed our full conviction on that point; we believe no competition was ever decided with more absolute purity from interested or partial motives, and we have declined to entertain or publish any suggestions to the contrary, some of which have reached us. And every one will sympathise with the kindly and generous tone of Mr. Christian in the portion of his address in which he spoke of the success which had attended the labours of two young men, solitary students in a provincial town, who were able with no special advantages to produce "so fine a plan and so good an elevation, and drawings which have never been surpassed for perfect execution." Under the circumstances now known the success achieved by the architects referred to is certainly remarkable; they are entitled to the full credit of it, as well as to the solid advantage and position which they have attained by the decision of the Committee, which is, of course, binding on all concerned. But it is at the same time rather to be regretted that the President of the Institute should have appeared to give the authority of his position to the idea that beautiful drawing is a matter of any real importance in an architectural competition. It is one of the standing complaints against the competition system that success often depends so largely upon the beauty of the drawings; and it is perfectly evident that in the present case this element has not been without its effect on the minds of even the professional judges. If these things be done in the green tree, what shall be done in the dry? If eminent professional judges cannot resist the blandishments of drawing, how can we expect it of amateur judges? We might rather have expected the President of the central Architectural Society, above all other persons, to emphasise the fact that draughtsmanship is *not* architecture: there certainly never was a period when the lesson was more needed than at present. But this is nothing to the extraordinary anti-climax made by Mr. Shaw-Lefevre in reference to the same subject. They

had gone into the examination of the drawings, he told us, with the greatest care and impartiality, and the result, he pointed out, with a smile of congratulation, was that they had brought forward two architects absolutely unknown to fame; in other words, that the carrying out of the greatest building of the day was to be placed in the hands of untried men, who are to complete their architectural studies over the edifice, at the public expense.

That the committee are bound in honour to abide by their decision is unquestionable; that the result should be matter of special congratulation is another affair altogether; and that Mr. Shaw-Lefevre should deliberately have told the meeting at the Institute, as he did, that the decision "appeared to have given universal satisfaction," is a statement which we really hardly know how to characterise. We are probably as favourably placed for forming an estimate of general opinion on the subject, professional as well as amateur, as Mr. Shaw-Lefevre, and our experience is that the result has mostly been regarded as exceedingly unsatisfactory.

One word as to the comparison between this and some former great competitions, which was suggested by the First Commissioner. We were given to understand that now at last there was to be not only a perfectly fair competition (a promise which has been fulfilled), but that there was to be one based on the practical requirements of the case, and that the best building for its practical purpose was to be evolved. We doubt very much whether the latter end has been attained, and whether there were not plans, both among the nine and among those who were passed over in the first competition, which, in important practical points, are much superior to the one selected. We doubt very much whether the mere drawing has not had an effect on the minds of the judges, beyond what they are even quite conscious of themselves. But, architecturally, the contrast between this and the last great competition is extraordinary and rather painful. In the competition for the Law Courts, not only were the leading men of the day represented, while they are all conspicuously absent from the recent competition; but there were conceptions of architectural genius about the Law Courts competition which left an impression not easily to be effaced. No one who studied that set of designs is likely to forget Burges's elevation, or Mr. Garling's powerful and original design, or Mr. Seddon's bold conception of the Record Tower; not to recall other designs which presented a total effect of grandeur and dignity, even without riveting the attention by special originality; and the President of the Institute himself took especial occasion, in the address, to defend and praise the existing result of that competition. In comparison with that, how does the recent competition look? Making due recognition of some refined detail in one or two of the elevations, of a very charming interior perspective which will be remembered as the most prominent feature of the competition, and of exceptionally beautiful draughtsmanship in the selected design, the second competition has produced nothing beyond architectural mediocrity, intermingled with absolute architectural vulgarity in some instances. We do not wish to go into personalities, but there are things among the nine favoured designs of which it may be said that the very proposition for their execution in such a situation, and for such an important building, is utterly incomprehensible, and little short of an enormity; and is this a result for the responsible Government official to blow such puffs of self-congratulation over?

Another subject on which the members of the Institute had the advantage of hearing the First Commissioner's own estimate of his work was in regard to the proposed treatment of Westminster Hall, and the modern Medievalising process at the Tower. On the subject of Westminster Hall we have already expressed our opinion strongly; and we publish, in another column, a letter from an independent witness, Mr. Tarver, who is certainly more competent to speak on such a subject than any one in the Office of Works, and who denounces what he

rightly calls "playing at architecture." Mr. Shaw-Lefevre shelters himself under the authority of Mr. Pearson, as his professional adviser in the matter; but it has been stated by the Precursor of Lincoln, in the *Times*, that to his knowledge Mr. Pearson's own wishes in the matter had been overruled; and we have never seen any contradiction of the statement.

Such a question as the treatment of the side of Westminster Hall, under the present circumstances, is, of course, both an interesting and a difficult one, and would have been well worth discussing with the official authority at a meeting of the Institute. But the official authority seems to have no notion of the kind. His attitude is expressed in the complement that opens one of the "Rejected Addresses":—

"I am a blessed Gendoveer,  
"Tis mine to speak and yours to hear."

The architects may certainly be excused if they find the position a little illogical. Friendly reciprocity between the Office of Works and the Institute is, no doubt, desirable, but we do not expect the reciprocity to be all on one side. It was the crowning point of the character of Chaucer's most model personage or "person" that—

"Gladly wolde he lerne, and gladly teche."

The First Commissioner of Works showed a great practical reverence for the latter half of the maxim. Perhaps, in addressing a body of professional experts on matters concerning which he is only nominally and *ex officio* an authority, a little more recognition of the other half of the sentiment would not have been out of place.

#### WORKMEN'S HOMES AND THEIR ADJUNCTS.

THE question which has been exercising the minds of philanthropists for half a century, and which has more lately been pressed home on the consideration of the Legislature in our own country, is a problem calling for solution more or less in every European State. Private beneficence has always led the way, and in many instances has successfully provided for the wants of immediate dependents. Wealthy manufacturers and commercial men have devoted large sums towards the welfare of their workmen and servants, as regards both their physical and moral needs. Since the enormous development of the railway system most of our great companies have recognised that there are duties devolving on them beyond the mere punctual payment of the weekly wages; and that, if only with a view to secure faithful service, money is well laid out in assisting their *employés* to maintain comfortable homes, in encouraging them to exercise habits of thrift by the creation of benefit and other societies, and in providing them with means and places for indoor or out-door recreation. But, notwithstanding all that has been done, the fact confronts us that in our large industrial centres there still exists an amount of squalor and wretchedness, with their attendant physical and moral evils, utterly beyond the ability of individual effort to overtake, and with which properly organised co-operation only can effectually deal. A precisely similar state of things is found to exist in Paris and other great cities of the Continent; and it is with a view of suggesting the various modes of dealing with this crying need of the day that M. Emile Cacheux has published his elaborate treatise on the construction and management of workmen's dwellings, *crèches*, and kindred institutions,\* which can be made to contribute to the comfort and welfare of the labouring and poorer classes of the community. He commences by observing that, according to recent statistics no fewer than 90,000 persons in France annually succumb to the pressure of want, and that, owing to the prevailing high prices of the absolute necessities of life, this number must infallibly go on increasing until more stringent efforts are made to remedy the evils which exist. Several instances of the

action taken by distinguished commercial men in France to grapple with the problem are well known to those who have similarly devoted themselves to its solution, notably that of M. Godin, the originator of cast-iron stoves, who not only erected extensive buildings for his workmen, but dwelt in the midst of them himself, and personally superintended the management of every detail. Another instance is that of the town of Mulhouse, with which the name of M. Dollfus must ever be gratefully connected, and which has attained a high degree of prosperity as an industrial centre, the more remarkable from the fact that none of the raw material used in its factories is produced in the neighbourhood, but has all to be imported from distant localities. That prosperity is said to be attributable in no small measure to the care taken of its working men, who are objects of solicitude to their employers from the cradle to the grave, and whose welfare is secured, not by an abnormal rise in wages, but by first locating them in suitable and comfortable dwellings, in next providing *crèches*, or nurseries for the infants while the mothers are at work, schools for the younger children, workshops for the elder, and training establishments for each special industry which is carried on in the town; in fact, in the words of M. Cacheux, Mulhouse gives its children a theoretical and practical education sufficient to enable them to become useful citizens, capable of earning a livelihood for themselves as long as they are able to work, and of securing a provision against the advent of old age. Owing to its excellent institutions, Mulhouse was enabled to tide over the terrible crisis of 1870, and to furnish support for its 40,000 working men. What has been done in Mulhouse, M. Cacheux would fain see carried out in Paris, where philanthropy, he laments, is confined to the distribution of money, and though it is to be had in abundance, yet no trouble is taken as to the mode in which, or the persons amongst whom, it is distributed.

The remedy which occurs to him as best calculated to put an end to the existing state of wretchedness in Paris is the formation of a Society of Public Welfare, which should search out and carry into effect the measures best adapted to attain that end. These measures he explains to be:—

1. To train up the greatest number possible of individuals so that they may be healthy, strong, and fitted for work.
2. To find for them suitable employment at such wages as will afford a livelihood for themselves and families, besides a provision against times of sickness, stoppage of work, accidents, infirmities, old age, and death.
3. To develop the moral, intellectual, and material welfare of working men by all the means hitherto adopted, and by such further measures as may seem to the Society to be conducive thereto.
4. To provide as effectively as possible for such individuals as for some cause or other have to be supported at the expense of the fellow-citizens.

The scope of such a Society, as M. Cacheux observes, is truly very extensive, and to ordinary minds it would seem almost impossible to attain the ends set before it; but he is not alarmed at the prospect, and thinks it perfectly feasible, if only existing societies and charitable individuals could be persuaded to work together with a determination to carry it to a successful issue. For this purpose he set himself the task of compiling his work, and he has certainly succeeded in treating his subject most exhaustively; for he has collected together almost all the available information regarding it, and has then added a valuable contribution towards the difficult problem which is awaiting solution. The first part of the book is devoted to the subject of workmen's dwellings, specimens of which are given in the excellent series of plans which illustrate his work, together with explanations of the methods which have been pursued in various countries to provide for their erection, and of their relative accommodation and cost, the latter varying from 100*l.* in Mulhouse to 240*l.* in Paris for a house

\* *L'Économiste Pratique: Construction et Organisation des Crèches, Salles d'Asiles, Écoles, &c.* Par Emile Cacheux, Ingénieur des Arts. Paris: Librairie Polytechnique; Baudry & Co., 16, Rue des Saints-Pères.

containing three rooms, besides kitchen and offices. The general conclusion he has arrived at is the same that has been considered to be most advantageous in England, and that is, to offer facilities such as building and land societies afford, to a tenant to become the owner of his tenement by the payment of a small annuity extending over a term of twenty years, more or less, in addition to the rent. In a paper read before the Society of Arts in February last, Mr. William Westgarth, who has proved the great interest he takes in this particular subject by offering prizes to the extent of 1,200*l.* for the best essays on dwellings for the poor, observed that he should like to see the plan tried "of giving to tenants a proprietary interest in their respective rooms or houses. A redemption fund spread over a term, say of thirty years, would add but 4*d.* to 6*d.* per week to rent." Of course, the objection to a workman buying a house in the neighbourhood of his factory is the risk of the failure of his employer; but notwithstanding this the practical result proves that working men are willing to undertake this risk, and that when the facility is afforded they take advantage of the opportunity of becoming the owners of their houses.

A section is devoted to the legislative measures which have been adopted in different countries with respect to workmen's dwellings and lodgings; those which obtain in England, especially the Common Lodging House Act, and the regulations for ensuring proper sanitary conditions being particularly approved. The failure in Paris to secure attention being paid to ordinary sanitation in furnished lodgings leads M. Cacheux to the conclusion that the only way of curing this evil is the truly Gordian solution of banishing from the capital every one who is unable to meet the expenses of living there; but as the State would not be prepared to carry out such a drastic measure, he considers that it should use every possible means to stimulate the construction of suitable workmen's habitations, by promoting exhibitions of model houses, courses of sanitary lectures, and the like, for the purpose of teaching men to realise the dangers they incur by residing in overcrowded tenements, and neglecting to observe the most ordinary laws of health. The best method of removing night soil, a necessity in France, is discussed at length, and plans are given of many ingenious contrivances for the purpose, but as they are not applicable to the existing state of drainage arrangements generally in England it is unnecessary to allude to them further. There is one proposed improvement in lodging houses, however, which seems desirable, and which has already received consideration in this country. It was alluded to by Mr. Westgarth as having been found successful in rudimentary forms in present cheap lodging-houses, and from it he considers "great social and recreational as well as economic benefits" are likely to ensue. His proposals of improvement on the modern great lodging-houses in this particular accord very much with the suggestions made by M. Cacheux, both advocating that where there are separate homes consisting of one or more rooms they should be grouped around a commodious hall or common sitting or recreation room, and should comprise a common kitchen, manager's shop or store, from which articles of food, cooked or otherwise, could be supplied. "Such a common hall when well lighted and warmed would admit of fires, kitchens, and lighting apparatus being dispensed with in the separate homes, and would likewise tend to diminish the risks from fire." Doubtless in the essays for which Mr. Westgarth has offered such handsome prizes, arrangements such as these will receive due attention, and in regard to them M. Cacheux's work contributes valuable suggestions.

The second part is devoted to the elucidation of the first of the measures which the Public Welfare Society is to take up, viz., creating a race of healthy, strong, trained men, fit for employment by the Society. As it is during infancy that the seeds are sown of that mortality and physical degeneracy from which the labouring classes suffer, M. Cacheux proceeds to examine into the causes of

infantile mortality, and to devote special attention to the *crèches* or nurseries which have been created to remedy the two principal evils from which that mortality arises, viz., the custom of parents in making over their infants to the care of paid attendants, and the absence of that watchful care which infancy needs. In these institutions the French have undoubtedly been long in advance of us, for it is but comparatively lately that *crèches* have been established in this country, and to France belongs the credit of starting them. Notwithstanding certain objections, the gravest of which is the propagation of infantile diseases, yet it is an ascertained fact that the mortality of infants has considerably diminished since the establishment of *crèches*. In the table quoted by M. Cacheux the highest death rate, with the exception of Calvados, where an epidemic of measles broke up, was at Milan, where it amounted to 18 per cent., while in the city itself it reached to no less than 40 per cent. M. Cacheux does not hesitate to assert that the State would be conferring a public benefit by encouraging and assisting the establishment of *crèches*. Such action, however conformable with Continental ideas of state functions, does not fall in with English ideas, and happily the need for it does not exist, as private benevolence has already recognised to a great extent the benefits of such institutions, a notable instance of which is cited by M. Cacheux in the case of Manchester, where, at a single meeting called by the Mayor to discuss the subject, sufficient funds for founding and perfectly equipping a *crèche* were at once subscribed. Several designs of suitable buildings are to be found in the folio of Plates, as also estimates of cost of erection and equipment, from which it appears that a *crèche*, capable of holding fifty infants, costs in Paris about 700*l.*

From *crèches* the author passes on to the subject of Infant Schools, which were commenced in France by Pastor Oberdin in 1775; but it was not till 1827 (when a Madame Millet, on her return to France after a sojourn in England, where she had studied the organisation then existing, started one) that Infant Schools took root, and subsequently came under the care of the State. Similar particulars as to the design of buildings, the management and interior economy of these schools, are entered into with great detail; but in this branch of education the system pursued in England has, after seventy years, reached great perfection, so that we have little to learn from other countries. We have more to say on the subjects suggested by this voluminous and valuable publication.

#### NOTES.

**T**HE New Liberal Club, of which the foundation-stone was laid on Tuesday, will afford some relief to the monotony and commonplace which is the characteristic of too much of the new architecture of the locality. The mere introduction of a tower will be a welcome contrast in the neighbourhood of such dull bulks of building as the Grand Hotel and the Hôtel Métropole; and in other respects the design will be one of the most effective of its architect's recent works. We defer illustrating it till Mr. Waterhouse has completed his coloured drawing of it, which we shall then have the opportunity of reproducing by a new process.

**I**N reference to the same subject, the reproduction of coloured drawings, we may here draw attention to the two illustrations in the present number, the interior of Lloyd-square Chapel and the view of some cottage architecture by Messrs. Holme, of Liverpool, which are reproduced by Messrs. Waterlow, the first from a washed drawing in Indian ink, the second from a water-colour drawing, by a process which has not, we believe, been before employed in any architectural journal. We think our readers will agree with us that, as a method of reproducing the light and shade effects of a water-colour drawing, it is very satisfactory, in regard to the cottage picture

especially; the fully coloured drawing coming out better than the monochrome one. As this was in the nature of an experiment, we purposely selected small works; but if the result is liked, we shall be happy to produce larger water-colour drawings of important buildings in the same way. We may add that this is only one of two or three other means which we have in contemplation for the more varied and effective reproduction of architects' drawings.

**W**E should hardly serve any purpose by publishing over again the distressing particulars of the terrible disaster at the Glasgow Theatre, with which all our readers are already acquainted through the medium of the daily papers. The event is somewhat removed from the usual category of such calamities, in as far as its origin is concerned, if it be really true that the man at present in custody was wicked enough to give an intentional and false alarm of fire. Putting aside that, it is an old and too-often repeated story. Given a narrow landing, upon which the traffic from the pit and gallery met together, and an iron gate to check the ingress of the audience while taking tickets, and which probably (for the evidence is conflicting on this point) acted as an additional and formidable bar to their exit,—there are the elements of a fatal calamity when once the audience are under the influence of panic. The most practical deduction to be drawn from the event is as to the great additional risk and danger incurred by turning two streams of people on to one landing. The exit from each part of the house ought to be separate and unconnected with any other; and this is even more important in the case of pit and gallery, where the roughest and least self-restrained portion of the audience are usually found, than in regard to stalls and boxes. The width of the staircase was less than it ought to have been, but additional width would not have prevented, or probably even much modified, the results in this case; and excessive width may even, as we pointed out in the case of the terrible affair at Sunderland, be an additional source of danger. But the great moral which underlies the whole matter is one which, it is to be feared, it is useless to insist upon, viz.: the weakness and folly of giving way to sudden fright. Cannot all these repeated and melancholy results of foolish and unreasoning cowardice have any effect in leading people to make an effort at coolness and courage, in such cases, instead of rushing on their own destruction, with no more sense than a flock of sheep?

**T**HE experimental opening, during the second week in October, of the great Sea Canal from Cronstadt to St. Petersburg, is, for many reasons, a very suggestive event. It shows that, however supine we may be in this country as to the improvement of our inland water ways, Russia is not so slack; but that, following the lead of Holland, France, Belgium, and Germany, she is providing for the increasing necessities both of commerce and of maritime warfare. The river Neva is shallow for the twenty miles from Cronstadt to St. Petersburg, and vessels drawing more than 9 ft. of water have been hitherto compelled to lighten their cargoes up to the capital. Not only are cost and delay thus greatly increased, but the military character of Cronstadt is interfered with by its compulsory use as a mercantile port. To remedy this a channel, 300 ft. wide and 22 ft. deep, has been dredged up for ten miles from Cronstadt, leading to a canal with two branches, narrowing from 240 ft. to 180 ft. in width, and of a depth of from 20 ft. to 16 ft. The southern branch enters the Ekaterinhoff Canal, and the northern branch, intended for the transit of ships of war, enters the Neva. In the recent trial an American-built cruiser, the *Africa*, 300 ft. long and drawing 17 ft. of water, passed up the canal without difficulty, but stranded at the entrance to the Neva. The passage, however, has been effected by three Russian ships of war, and the existence of the canal, when satisfactorily finished, will be equivalent to a considerable addition to the available force of the

Russian navy, and will effect a reduction of the cost of transport to the capital. The cost of the work thus far is estimated at 10,265,400 roubles.

THE great attraction in Mr. Wallis's gallery in Pall-mall, where the usual autumn exhibition was open to the public on Monday last, is in the collection of works painted during the last two years from studies made in the neighbourhood of Rome by Carl Heffner. It must be admitted that there is somewhat too much of picture-making in these as well as in other works by the same painter; but, accepting his art for what it is, he has surpassed most of his previous efforts in these four large works, entitled "The Campagna," "Desolation," "Solitude," and "Repose;" pictures representing that strange mingling of desolate plains with the remains of great engineering and architectural works, places haunted, as Browning says, by "Rome's ghost since her decease." Pictorially, the finest work is "Solitude," the old cemetery of Rome in the time of the Caesars; but a more interesting work in subject is, perhaps, the "Desolation," showing the columns of the temple of Jupiter and the ruins of the Castle of Ostia in the middle distance. Architecturally, however, it must be observed the columns are not as well drawn as they might be; and, if the two or three at equal distances are intended to represent part of the colonnade as it stood, the intercolumniation is certainly wider in the picture than it ever was or could have been. Despite these technical errors, and a certain hard and slightly stagy effect which hangs over Herr Heffner's work, these pictures are in themselves worth a visit. A very clever example of Professor Müller's mannered but very broad and powerful style is to be found in "Trio-trac Players" (23), and a large and exceedingly spirited painting of a "Horse Fair in Bessarabia" (109), by Professor Brandt, occupies a central position. There is a Corot or two; Windmaier, Munthe, and other old favourites, are fairly represented; and a design for a fan by Professor Kaulbach (the German painters seem all to be Professors) is a pretty bit of decorative art.

FROM the *Melbourne Age* we learn that the progress of Railway Extension in Gippsland is much retarded, and that the district in what is termed "The Garden of Victoria" is languishing in consequence. The nature of the country, it is said, renders the construction of roads very expensive, and, as the income of the shires is not adequate for the purpose, the settlers are forced to remain idle, after having faithfully performed their duty in clearing the wooded hills and valleys, and will be obliged to abandon their homesteads if some effort be not made to enable their produce to be conveyed away. The Morwell to Mirroo line, after being once commenced, had, through the failure of the contractor, to be suspended, but is about to be started again, though it will cost much more than originally estimated. Seven years ago this portion of the country was taken up, and the "selectors" brought to the notice of the Railway Minister that, unless communications were opened, it was impossible for them to achieve success; but that with a railway the wealth of the colony would be increased by 100,000*l.* a year. In addition to its agricultural and grazing resources, recent discoveries have proved the existence of a large tract of coal-bearing country,—one seam of which, 5 ft. in diameter, has been pronounced by the Government geologist to be of workable size and excellent quality. Blackwood and blue-gum timber, superior to any other found in the colonies, is there in abundance. The difficulty hitherto of finding a practicable route from the North Mirroo terminus across the Tarwin River to Stockyard Creek, and ultimately to the sea at Corner Inlet, has been surmounted by taking the Morwell line across the Tarwin, and joining it with the Great Southern Line four miles further south,—and thus the connexion between the Main Gippsland Line and seaboard will be rendered complete at the smallest cost.

PRINCIPAL Sir Alexander Grant, in his inaugural address at the opening of the winter session at Edinburgh University, on October 27, referred to the desirable object of establishing an Edinburgh Union Society, for which large funds are necessary. The Prytæneum, of 3,000 students, with debating-hall, gymnasium, reading and writing rooms, committee-rooms, and other appurtenances, must, he said, necessarily be a large building, which, with its site, would cost no less than 15,000*l.*; and of this sum, he believed, only about one-fifth had been as yet provided. The scheme, however, is such a good one, and so well worthy of realisation, that it is to be hoped it will only require to be made known in order to receive the necessary encouragement and support.

THE success which has attended the recent Forestry Exhibition has given rise to the suggestion that an International Exhibition should be held in Edinburgh during the summer of 1888. A petition to the Lord Provost and Council has been prepared and already signed by a considerable number of manufacturers, merchants, and others setting forth that a movement has been made, both in the Council and outside of it, and proposing to strengthen the hands of the Council in giving effect to efforts made in the direction referred to. It is recommended that the exhibition should not be confined to Scottish industry and art, but should be international, or should, at least, embrace the Colonies as well as Great Britain and Ireland. The initiatory steps were, we understand, taken by an old society called the Edinburgh Merchants' Association.

THE Winter Exhibition at Messrs. Tooth's Gallery includes some good works, both by well-known artists and others with whom we are less familiar. M. Leon Lhermitte's large life-size figure-picture, "La Moisson," appears to us, however, an indication that this in many ways remarkable artist is seen to more advantage on a smaller scale, an opinion which a companion of his smaller work in the same collection, "Mid-day Rest," goes to confirm. Some architectural subjects, Venetian chiefly, by José Gallegos, are worth attention; also a clever work by José Benlhuire, "Christmas Eve, in the church of Aleira, Valencia," with the chorists singing at the top of their voices, and with no very reverential manner, to the accompaniment of an ophicleide. There is a sense of giving plain prose realities in this work which gives a certain sarcastic flavour to it, and the accessory figures and architecture are well studied. The Exhibition includes works by Van Haanen, Brett, Hook, Israels, and other painters of repute.

THE "Nineteenth Century Art Society," in whose catalogue, as we have before remarked, scarcely a single name known to fame in the annals of the said century finds place, opened also their winter exhibition at Conduit-street. Except a nice bit of work here and there, the exhibition seems as hopeless a collection of mediocrities as ever, and we are at a loss to understand the reason of its existence except for the benefit of persons who cannot get their works exhibited elsewhere. Having no pictures worth looking at, the Committee adroitly seek to divert our attention by a special reference to the alho-carbon light, of which we spoke in praise a short time since, and which they claim to have now introduced for the first time as a means of lighting a picture-gallery. It is no doubt a much better light for picture-galleries, both chemically and in illuminating quality, than ordinary gas. We could contentedly accept a worse light, however, if there were better things to be seen by it.

IN the ensuing Winter Session of the University of Edinburgh, Professor Baldwin Brown proposes to deliver a course of forty lectures on the History of Architecture in Europe from the Hellenic period to the Renaissance. The origin and connexion of the principal styles will be described, and their

characteristics illustrated by representative examples. The historical aspect of the buildings will be shown to be in each epoch the outcome of certain social and religious tendencies varying according to the spirit of the times. The constructive forms embodied in each epoch, with their special capabilities, will be explained and illustrated, showing how the mode of construction affected the form and aesthetic character of the edifices. The ornamentation and decorative details of the best examples will be illustrated, showing how by their form, fitness, and position they contributed to the architectural effect of the structures.

IN Mr. Ruskin's last lecture at Oxford he stated that he was showing a Birmingham friend "the collection of antique casts which Mr. W. B. Richmond had so wisely brought to supersede 'the modern stuff of Chantrey,' and on stopping under the Athena Regina, Mr. Baker exclaimed, 'Hallo! Why there's the chopped Norman arch!' And there, sure enough (Mr. Ruskin added), it was, and I had never seen it. The chopped Norman arch and the fringe in which you young ladies delight come alike from the forehead of Athena." We can only say that we hope Mr. Ruskin's audiences will take such remarkable statements on the genesis of architectural ornament with a great many grains of salt.

#### THE QUANTITY SURVEYOR.

You at once know him to be a person of distinction by the superior fragrance of the cigar which he smokes on his morning's walk from "Victoria" to his comfortable West-end office,—on fine mornings, that is to say. When the weather is inclement the fleet Hansom protects him from the rain and deposits him dry-shod at his door. As he reposes in his well-padded arm-chair, his feet deep in the pile of a Turkish carpet, reading and docketing the morning's letters, we will try to snatch a hasty note of his character and appearance. He is past middle age. His surroundings show him to be a successful man of business, and success now-a-days comes not before the marks of age. We have no longer hoy Premiers, such as Pitt. Our statesmen are well up in years before they assume the rod, and our judges are not youths. And the professional man is no exception to the rule. A flatterer would say that our friend's hair was grey, the world might even call it white. But he is hale and lusty nevertheless. A man of less force of character than he would stoop a little in the shoulders; but he resolutely maintains an almost military bearing. His hat and hoots and gloves,—sensitive indicators all,—are works of art of their respective kinds, and his whole costume, "snitting with forms to his conceit," is most carefully designed and executed "of the best materials and workmanship." His figure inclines slightly to *emboîpoint*,—a characteristic of his class. Time was when the business of the surveyor was a good deal mixed up with elaborate luncheons, provided by hopeful builders,—days when the soundness of the after-dinner port had more to do with the financial result than the soundness of the work. These things are now only matters of history. If the surveyor, from motives of policy, occasionally prolongs the social meal which conveniently divides the day's labour, is not by way of fine and penalty upon the long suffering builder. Our friend is neither a total abstainer nor a vegetarian, but he enjoys moderation the goods the gods provide. He respects the traditions of his profession, and the result is just indicated by the "graceful head and the voluptuous swell" which the tight-fitted surcoat with difficulty restrains. He comes of a long line of surveyors, and his almost hereditary professional astuteness is partly hereditary and partly acquired. His "forebear" were renowned for skill in the dissection of builders' work, and their acquaintance with the most recondite secrets of its anatomy. They had, moreover, a practical acquaintance with one or another of the branches of the building trade, and derived thence a prestige in deal with matters which came before them, done for the most part to their successors, were strong mainly in the "hookish theory." They have, however, cultivated some collateral arts to the highest pitch. Our friend astonishes by the rapidity and precision with which
