

AN

✦ ILLUSTRATED ✦ WEEKLY ✦ MAGAZINE ✦

FOR THE

ARCHITECT, ENGINEER, ARCHÆOLOGIST, CONSTRUCTOR,  
SANITARY REFORMER, AND ART-LOVER.

CONDUCTED BY

H. H. STATHAM,

FELLOW OF THE ROYAL INSTITUTE OF BRITISH ARCHITECTS.

"Every man's proper mansion-house, and home, being the theater of his hospitality, the seat of self-fruiting, the comfortablest part of his own life, the noblest of his sonne's inheritance, a kinde of private princedome, nay, to the possessors thereof, an epitome of the whole world, may well deserve, by these attributes, according to the degree of the master, to be decently and delightfully adorned."

"Architecture can want no commendation, where there are noble men, or noble miudes."—SIR HENRY WOTTON.

"Our English word TO BUILD is the Anglo-Saxon Bylsan, to confirm, to establish, to make firm and sure and fast, to consolidate, to strengthen; and is applicable to all other things as well as to dwelling-places."—DIVERSIONS OF PURLEY.

"Always be ready to speak your mind, and a base man will avoid you."—WILLIAM BLAKE.

VOLUME XLVII.—JULY TO DECEMBER, 1884.

OFFICE: No. 46, CATHERINE STREET, COVENT GARDEN, LONDON, W.C.

# INDEX TO VOLUME XLVII.

JULY TO DECEMBER, 1884.

Hospital Construction and Management.\*

It is exactly a twelve-month since we commented upon the first volume of a work on the above subject, published under the joint authorship of F. J. Mout, M.D., &c., and H. Saxon Snell, F.R.I.B.A., &c. We had occasion to point out the fragmentary and somewhat confused arrangement, or want of arrangement, which characterised it as a literary effort, and deprecated the difficulty which was thus gratuitously added to the understanding of a complicated problem by unnecessary complication in its treatment.

The second part of the work just issued by the same authors is not free from the defects of the first, but, like the first, it contains much scattered information, which will repay a careful search. It is true that a general index is now added, and, so far, the reader has reason to be thankful; but, beyond this, he is left pretty much to his own resources in deducing any conclusions from the mass of miscellaneous and unrelated matter which goes to make up the book.

The authors modestly abstain from directly "formulating their own views and opinions on the questions treated" because they "demand a more profound study of the whole question than the time at our disposal admits of," and the omission will only, it appears, be supplied "if another edition of the work be called for."

Surely this is an unusual position for professional writers to take, who are presumably experts in their respective spheres. Their work amounts, practically, to this. "We give

you plans and descriptions of a great many home and Continental hospitals, some criticisms thereon, and a few extracts from the reports of various Commissions who have from time to time looked into the subject: make what you can of them, and form your own conclusions. We are too busy building and managing hospitals to have time for the profound study which should precede the formulating of opinions on so serious a matter. If, however, you ask us for a new edition of our book we will throw you an opinion into the bargain; meanwhile, we hurl at you a miscellaneous assortment of modern plans and leave you to your own devices."

The late Mr. Street once, in the heat of discussion, called a learned professor's book on domestic architecture "an illustrated shop list," and it is a pity that something of this flavour does attach to so many of the works of professional men upon technical subjects, that they leave a sort of general impression that their object is to show there is only one man who does really understand this or that particular subject, and that man is the writer of the book.

As we have more than once pointed out, the hospital architect is dependent almost entirely upon the experience of the medical profession, and he can scarcely hope to do more than give effect, in the most perfect and economical way, to the recommendations which experience in the practical treatment of disease suggests.

Unfortunately, however, medical experts are by no means agreed as to hospital requirements. The aggregation of some hundreds of patients under one roof, or their segregation in huts of small capacity; the accumulation of story upon story, or the limitation of the hospital ward to a single floor; the shape of the ward, and the disposition of the beds; natural *versus* artificial means of ventilation, or the union of the two; and many similar matters, are open

questions debated with more or less energy of advocacy and depreciation.

Perhaps the most exhaustive and valuable amongst the several published contributions to the literature of the subject is the joint official report of Drs. Holmes and Bristowe; and thus they deliver themselves on one fundamental principle of hospital planning, after a close study of the whole question of hospital construction, and personal examination of almost every example in the United Kingdom and on the Continent:—

"If all the subordinate parts of a hospital have been well constructed, the size of a hospital is a matter of absolute indifference; whether it contains 100 or 1,000 patients does not appear to exercise the least influence on the health of any individual in the hospital. At St. Bartholomew's Hospital four floors are used as wards, and no difference is perceptible between the healthiness of the different stories. Allowing that each ward is healthy, and that, say, thirty patients may be placed in each ward, we see no reason to doubt that it is safe to put 100 wards together, and accommodate 3,000 patients in the same hospital."

"No more permanent hospitals," says Sir James Simpson; and his view is supported by the opinion of many authorities. "They must be replaced by hut hospitals. The permanent hospital is the Sepulchre Hospital,—*nothing* can render it wholesome. The hut hospital, wholly or partially renewed every ten or fifteen years, *alone* possesses the hygienic conditions necessary for the abodes of disease."

And the problem receives another element of complexity in the fact that the statistics of some of the most perfectly constructed modern hospitals contrast unfavourably with others "full of every fault which can be united in the same building." Whence some writers on the subject have too hastily deduced that the construction of the hospital goes for nothing, and

\* By F. J. Mout, M.D., &c., and H. Saxon Snell, F.R.I.B.A., &c. London: Churchill & Co.

that all depends upon the administration; the records of the new Lariboisière, and others of its type, being quoted against the cleaner health hill shown by the outrageously faulty old Leeds Infirmary.

Another instance of the divergence of medical opinion is provided by the opposite recommendations of the English and Belgian Commissions on the orientation of axial line wards, the former recommending an axial line running north and south, the latter being quite clear in favour of a line running east and west.

In view of such important differences in skilled opinion the outsider can only keep cool, weigh the several reasons adduced on either side, and draw what lessons be may from such historical facts, and such clear statistics of results as lie within his reach.

The history of hospital construction and management is a sad one. The earliest hospitals were simply big houses, haphazard conglomerations of rooms without special fitness of arrangement, into which the sick were crowded indiscriminately. Such refinements as the separation of infectious from non-infectious cases, the limitation of the number of the sick to the capacity of the room, or the provision in any special way for the sick as such, were undreamt of. The pictures of neglect and suffering which rise up before us in perusing the history of the Hôtel Dieu, for example, are not only terrible, but sickening. It is almost incredible, though unfortunately but too true, that a century ago "the extraordinary spectacle was to be seen of two or three small-pox patients and several surgical cases, and sometimes even four parturient women lying in one bed." The writer's feelings get a little the better of his grammar, and he does not altogether mean what he writes; but, when due correction is made, his statement is sufficiently startling. It is known, moreover, from the official records of the time, that the unfortunate wretches were turned out of their miserable beds periodically to allow those still more unfortunate sufferers who had been waiting their turn on a ledge at the bed's foot to take their short interval of rest (?). In 1515 each of the 303 beds of this particular hospital held eight, ten, or twelve sick poor "so crowded that it was pitiable to see them." Modern civilisation has no doubt sins of its own to answer for; but the horrors of the casual ward are elegance and comfort compared to this hideous refuge of disease and destitution. So bad was the condition of nearly all similar institutions that the chances of recovery in them were less than if the patients were left untended in the public streets! And so uniformly fatal were certain surgical operations which are now performed with perfect safety that the surgeons abandoned the practice and simply left the sufferers to die.

The Rev. W. K. R. Bedford, reported in the *Lancet* of November 19th, 1881, concerning the hospital built at Malta in 1575, by the Knights of St. John of Jerusalem, says:—

"It was situated on the south-east side of Valetta; the site is the lowest on that side of the town, and all the ground falls towards it. The drains of the town were, and still are, discharged into the sea close to the building. The hospital was exposed to the sirocco, and protected from the healthy north and north-west winds. The windows in the wards were small and high, and along the seaward sides niches were arranged, one to every two beds, which were used as latrines. Some later buildings shut out both light and air from the wards. So that the hospital builders of that day were ignorant or careless of the deleterious effects of sewage emanations, a low situation, had ventilation, gloom, and the depressing influence of the relaxing sirocco."

Some of the older hospitals in this country were scarcely more intelligently planned, and many still remain in which the arrangements are almost as bad as they can be.

The abominable old Hôtel Dieu has been replaced, as every one knows, by a palatial structure, at a cost of a million and a half,—each bed costing the prodigious sum of 1,216*l.* in building alone,—and, with the cost of the land, more than double that sum. Unfortunately the money has been ill-spent. The defects

of the well-known hut unfortunate Lariboisière have been repeated and exaggerated, and the new building is, by the unanimous verdict of the medical faculty, "a magnificent structure, but a detestable hospital, absolutely contrary to the fundamental principles of hospital sanitary law."

We are not without similar examples of the mistaken application of large sums of money in the endeavour to provide for our sick, and the best way of avoiding similar mistakes in future is a full discussion in the press and elsewhere of the whole subject in its multifarious bearings.

Setting aside matters of detail, it is pretty well agreed that the following points are of primary importance, to wit:—

1. A dry, open, healthy, and ample site.
2. The proper classification of cases.
3. The provision of ample lateral space in the immediate region of each patient.
4. The provision of a sufficient cubic space or air volume about the patient.
5. The rapid and complete removal of all morbid emanations from the sick.
6. Sufficient sun-light.
7. An agreeable and steady temperature.
8. Facilities for nursing in each ward.
9. General facility of supervision and administration of the whole.

It must never be lost sight of that the one object to be attained is the speedy recovery of the sick, and that to this all other considerations should give way. And there is a preponderance of skilled opinion in favour of Sir James Simpson's dictum, that of all forms of hospital, the isolated hut is the most favourable for the end in view.

Accordingly, the practice of hospital building which abandoned the corridor type for the pavilion of many stories, although the former was not without professional defenders, is in turn abandoning that type for the hut.

In towns hospitals will no doubt continue to be built on the pavilion plan,—reducing the number of stories and increasing the intervals between the blocks as much as possible; but the hospital of the future will probably be an assemblage of one-storied huts raised upon hollow basements, quite isolated, and built either of impermeable materials or of such as may be periodically destroyed or renewed.

The new hospital at Genoa is lined with a thin brick wall for subsequent removal, and the Moabitte Hospital at Berlin has been built expressly with a view to the successive destruction of the huts of which it consists when the termination of the healthy life of each shall have been reached. It is now a well-established fact that buildings, like human beings, may be "miasmatically poisoned," and that by the absorption of the emanations from the bodies of the patients, hospital wards become positively a danger instead of an assistance towards the recovery of their occupants.

We have not, as yet, had sufficient experience to fix the average duration of such a hut as above alluded to; but it is probable that on merely economical grounds the change will be justified, for the least expensive of permanent hospitals costs 200*l.* or so per bed, whereas there are examples to prove that the hut hospital and its accessories, including the administration, can be suitably erected at a cost only slightly exceeding 80*l.* per bed.

The remarkable success of the Toilet form of hospital plan and construction, which we have several times adverted to in the *Builder*, has directed attention to this form of hospital building, and the daily increasing list of impervious vitrified building materials will, in all probability, enable architects to combine permanence with the other advantages of the hut type.

The last new thing in hospital building is the circular form of ward simultaneously invented in Belgium and England, although like many inventions pre-invented, advocated by Dr. Sanderson, Professor Marshall, and others, and carried into execution on a large scale at Antwerp, and on a small one in a few cases in this country.

It may be found easy to ventilate such a ward by a central "aspirator," and there is no doubt something to be said for the facility

afforded for destroying in a central fire, or otherwise, the disease germs which are exhausted with the effete air of the ward; but it is quite easy to ventilate the rectangular ward, and, as stated by us in our previous notice, we shall be surprised if this form of ward eventually makes its way. It is, however, a fair subject for discussion, and a profitable discussion of the matter will be helped by the experimental hospitals now being erected on this system, and we may treat the subject in greater detail hereafter. As to the Antwerp Hospital, we expressed our opinion in noticing the first portion of the present publication.\*

Although the Continental architects have in some matters bettered the instruction they have received from us, and we have much to learn from their latest works, they in turn are still far behind us in all sanitary arrangements, and even the new model Hospital at Baltimore, the result of an examination of the best modern hospitals of Europe, is far from perfect in this respect.

The principal value of the book before us consists in the careful record of what other nations are doing in hospital construction, as shown in the numerous plans and sections. Especially useful for practical men are the tables of the cost, accommodation, floor space per bed, and other particulars of the principal European hospitals. All who are engaged in hospital design and construction may learn much from the labours of the authors, and will find that it is a veritable mine of information for those who have the courage to work it.

#### STRUCTURAL AND PICTORIAL BEAUTY.

**B**N any inquiry into the question of the identity, or otherwise, of structural and pictorial beauty, it must be observed, in the first instance, that neither adjective is adequate to cover, and exclusively to cover, the group of phenomena that rank under the title. It may at first be thought that there can be little doubt as to what is meant by beautiful structure. Even as to that, however, there is something to be said. But by the term pictorial may be meant something far wider than the elements usually called picturesque,—such as beauty of landscape, of colour, or of studied adornment. In the most subtle meaning of the expressions there may, indeed, be an underlying unity. But it is rather to illustration than to definition that we must have recourse in attempting to trace a comparison or a contrast.

What we understand, then, by beauty in structure is something which appeals to the intelligence and to the judgment, as affording the most perfect appliance for carrying out a definite purpose. It is, so far as our powers of discrimination go, the evidence of design,—of the application of perfect skill to carry out a distinct object. It admits of no error, whether in excess or in defect. It displays the true method of the production, or the counter-balance, of force. If we grasp this idea, it will enable us to bring forward instances of structural beauty in which what we usually regard as structure,—that is to say, rigid structure,—is wholly absent. In the ever-varying curves of a freely-springing fountain, we trace the constant play and balance of natural forces. For no two seconds of time do the graceful forms remain the same. Yet at all times (pressure and other conditions being alike) there is a certain amount of identity. The most abstruse mathematics (we may cite the recent work of a learned French hydraulicist, M. Grief, in support of the assertion) fail to trace the behaviour of a single filament of water. And yet the eye and the mind are at once completely satisfied by the perfect manner in which nature, under such conditions, asserts the never-failing certitude of mechanical law. The same remark will apply to the grander forms of the like action, as seen in the mighty wave of the incoming tide, or in the leap of a mountain cataract. In each of these cases it is the perfect and truthful form, ever changing but ever the same,

that charms the eye. Let the sun come from behind a cloud, and span the foam of the cascade with a rainbow arch, and in the addition of colour to form we have the perfection of pictorial beauty.

We speak of the ever-varied forms of moving water, evincing, as they do, the unfeeling action of mechanical law, as an illustration of structural beauty, for the reason that this excellence is not often very easily to be detected by our powers of observation in the inorganic world. It may almost be said that it is only when motion, of a kind readily to be grasped by our senses, is present, that the term applies. It is to the organic kingdoms of nature that we must turn for the most apt illustrations of beauty of structure; and the instances that there occur are chiefly notable as being contrivances for resisting or producing motion.

The most perfect examples of structural beauty are to be found in the animal kingdom, and notably, from the mechanical point of view, among the birds. The skeleton, or rigid structure, of a swift, of an eagle, of a stork, or of an auk,—different as one type is from another,—is in each case a perfect mechanical provision for the special motion habitual to the bird. But, taking that rigid structure alone, there is a total absence of pictorial beauty. There is no waste of unseen finish or ornament. The roughness, useful for the attachment of the muscles, the elegant but perfectly mechanical swelling at the joints, the hollow shafts of the columnar bones,—all structurally admirable,—are not agreeable objects in themselves. In the human form, of which we,—perhaps not the best judges,—speak as the most beautiful of all forms in nature, the bones are a subject of undisguised terror to a child. Even when they peep too prominently from under the skin they are ever regarded as unsightly. Of all the osseous parts of the human structure but one group has any pictorial beauty. The teeth are beautiful, sometimes very beautiful, but the teeth are intended to be seen.

In the animal organisation, therefore, while the whole mechanical structure of skeleton, tendon, and muscle is admirably adapted for locomotion, there is no attempt at pictorial beauty in detail or in sum. The beauty which enchants the eye in the animal is, as it were, draped around the mechanical structure, as unnecessary to it,—for mechanical reasons,—as is the iris to the waterfall,—but yet, when produced, essentially aiding the perfection of imaginative excellence. It is thus with the texture and colour of the human skin, with the plumes of birds, even with the scales of fishes. Work,—or the power of work,—seems to have been first regarded; and when the dynamical problem has been exactly solved, the creative power of nature may be said to have indulged itself in the addition of wonderfully-varied exterior beauty.

It is one thing to trace a subsidiary utility in a beautiful form, and another to attempt to attribute all that we consider beautiful to teleological or to self-acting causes. To those who will, perforce, adopt no other than a rigidly utilitarian point of view, let us offer the compromise of physiognomic truth. That certain combinations of form or of colour suggest certain ideas to the human mind there can be, we think, no doubt. Where beauty is imperfect, admiration may be matter of individual taste. But not so where beauty is perfect. From the time when the verse of Homer glowed with the reflection of the grace of Helen, there has been no more doubt as to the charms of that fatal cause of war, or of those of Cleopatra, than there is as to the melodious quality of the notes of the nightingale.

Akin to this instinctive perception of beauty is that equally instinctive physiognomic perception which appears to be much more highly developed in children, and in animals familiar with man, than it is in the civilised adult. It is easy to understand why such should be the case. On the other hand, it is held by those who are admirers of Lavater that a truly scientific study of physiognomy is possible, the outcome of which shall nrite the keen impressionable sense of the child or of the savage with the orderly conceptions of the philosopher. How-

ever this may be, let us regard such a detail as what has been called "the actor's feature," the eyebrow. Nothing in the face, of which the will can control the expression, is more expressive than the eyebrow. The change which emotion can give to its form, slight as it is, is in the highest degree significant. The eyebrow has been spoken of as a contrivance for keeping dust out of the eyes. That in some infinitesimal manner it may so act may be allowed. But a keen ridge of bone, shading the eye like the poke of a cap, would probably, for optical purposes alone, be a far better arrangement. Again, for those who believe that there is no such thing as species in nature, but that each existing living type is only a chance item in the course of continued self-evolution, the explanation that the eyebrow is a remanet of the original hairy covering of the faces of our bestial progenitors labours under the disadvantage that the bony orbit of the brow would have been one of the first parts of the frame from which the hair would have been rubbed off by the destructive friction of daily habit, and mutual intercourse. Neither utility nor "survival" can account for the existence, the constancy, and the wonderful variety of what we may call this capricious feature. It may be regarded from the artist's point of view alone; but if it be required to add a reason beyond that of the production of pictorial beauty, it is only to be furnished by physiognomy.

One peculiarity of architecture, to which that fascinating study may probably owe no small portion of its charm, is the mode in which it combines structural and pictorial beauty. Examples of this may be taken from various styles, schools, and periods of architecture, but the most conspicuous illustration of the remark is to be found in the Classic orders. Thus we trace, first structural purpose, and then a gradually increasing mastery over durable and beautiful material, which adds all the charm of what may be called skin beauty to structural proportions that gratify the perception of weight (if that be the faculty by which we judge of stability). We may hesitate to admit the descent of Helen from a gorilla; but we instinctively recognise the filiation of the Corinthian column, perfect in the maiden graces of its proportions, from the humble timber "upright." Indeed, that idea of remanet, survival, or homologue, which we are wont to consider as special to organic life, may be traced in such architectural features as the triglyph; pictorially beautiful, no doubt, in the form which had become conventionally fixed by the age of Pericles, but none the less bearing the unmistakable stamp of its constructive and wooden origin. The structural beauty of a Greek temple may be said to result from the truthful skill with which the nobler material of marble has been substituted for the humbler material of wood, in carrying out what we may call the apotheosis of the hut. In the process of architectural change the surface beauty of which the nobler material is susceptible has been added to the grace of outline. But it has not been added as "decoration," or "appliqué work." It sits as close to the structure as does the blush to the human cheek or the iridescent plumage to the sunbird or the bird of paradise. There is a union, or rather unity, in the two elements or kinds of beauty in such a building as was the Parthenon, that holds almost more nearly to the handiwork of nature than to its feeble imitation by man.

To draw the line between the work of the engineer and that of the architect has long been a matter of delicacy, not to say of dispute. Nor must we forget, in this case, the truthful dictum of Linnæus, "*Natura non facit saltum*." Thus there is one group, and that a most important group, of buildings, of which it may be difficult to determine the character as appertaining to the province of the architect or of the engineer. We mean, of course, the lighthouse. But, as a general rule, we think the remark may be ventured that the province of the engineer is to deal with structural beauty alone, and that he may, in fact, have been wonderfully successful in the production

of a hideous, but truly mechanical, structure, such as the hollow beams of the Menai bridge. But an ugly structure, however scientifically or economically perfect, is not a credit to an architect. To the attainment, therefore, of high rank in his profession there is necessary an element with which it is not needful that his brother,—son of Vulcan as he may be,—should be endowed,—the gift of artistic taste.

NOTES.

**T**HE case of Barlow v. The Kensington Vestry, which came before the Court of Appeal on the 26th ult., alters the law in regard to the frontage of corner-houses as laid down by Vice-Chancellor Bacon in the Court below. As we pointed out (vol. xlv., p. 374) in commenting on the decision of the Vice-Chancellor, this case was of the utmost importance, because it practically laid down the law in regard to corner houses. This was, in fact, a house in Kensington-road with its front door in that thoroughfare, but it had its side not only in De Vere-gardens but also a part of the building projecting beyond the line of frontage as laid down for that street by the Superintending Architect of the Metropolitan Board of Works. Shortly put, the Vice-Chancellor's decision was that the house was not within the terms of Section 75 of the Metropolis Management Amendment Act, 1862, because it was in Kensington-road and not in De Vere-gardens, and, therefore, so long as it did not extend beyond the line of frontage in the road it was immaterial if its side extended beyond the line of frontage in De Vere-gardens. On the other hand, the Court of Appeal decided that a corner house could be in two streets, and, therefore, the fact that it was nominally in one only did not prevent it being also in another. Unless we are greatly mistaken, the effect of this decision would be, if strictly observed, to make a number of corner houses liable to be pulled down, since many appear to be built in the same manner as the house in the Kensington-road. We regard the general result of this decision with satisfaction because any judgment which increases our open space, by however small an extent, does a service to the community. On the other hand, we think the owner of this house is really to be pitied as having been the unfortunate *corpus vile* on which this useful experiment was tried, and also because the Kensington Vestry should never have allowed the house to get so far on as it did before taking legal steps. We may also commend to the notice of local authorities the remarks of the Court, that these provisions of the Act are so strict that they should be watched by judges and magistrates with great jealousy.

**T**HE Hellenic Society held their annual meeting on Thursday of last week, the Bishop of Durham, president of the Society, in the chair. While glancing at the attractiveness to scholars of Hellas proper as a field of investigation, he suggested that the ground which had actually fallen to the lot of the Society in Asia Minor was possibly even richer in matter of archeological and historical interest. He made two special suggestions,—first, the thorough investigation by competent persons of the monastic and other libraries of the East; secondly, the mapping out by the Society of subjects to be worked upon by competent young scholars, who would devote time and labour to their solution. Mr. Newton, in a subsequent speech, spoke strongly in deprecation of the apathy of the English Government and of Englishmen generally in regard to archeological investigation of this class; observing that when the German Government grant for the excavations at Olympia was exhausted, a sufficient sum was at once raised by private means to continue the work. We heartily echo the spirit of Mr. Newton's criticism, and hope that the labours of such a body as the Hellenic Society will not be without their influence on the general tone of English feeling on the subject, sooner or later. The next number of the "Journal of Hellenic Studies" will not appear till the autumn.

THE Metropolitan Board of Works have wisely determined to appeal against the magistrate's decision dismissing a summons taken out by the Board, as we mentioned a fortnight since, against a builder who proposes to build upon a disused burial-ground in Peel-grove, Bethnal-green, in which, it is stated, upwards of 20,000 interments have been made. The summons was taken out for an infringement of the By-law made by the Board under the powers conferred by the Metropolis Management and Building Act Amendment Act, 1878, which provides that no house shall be built upon a site covered with animal, vegetable, or fecal matter. The magistrate, in dismissing the summons, stated that in his opinion the Board had mistaken their remedy. In the case of the disused graveyard attached to Whitefield's Chapel, Tottenham-court-road, which was proposed to be built upon a few years ago, the parish indicted the builder for a misdemeanour; he was tried at the Old Bailey and convicted, and the building scheme was abandoned.

IN effecting certain alterations on the premises of Messrs. Tylor, at Warwick-square, near Newgate, some interesting Roman remains were discovered, which form the subject of a recent communication to the Society of Antiquaries. Mr. Alfred Tylor, the writer, is not content with describing the objects brought to light, the chief of which were a handsome stone vase, 2 ft. 3 in. high, with solid stone (porphyry or serpentine) handles and four leaden *ossuaria*, but has made them the text of a discussion upon certain points connected with the Roman occupation. He maintains that it was the metallurgical wealth of Britain which gave the island importance in the eyes of the Romans, and that the Britons had acquired considerable skill in the working of metals long before the Roman invasion. From a very early date the export of tin was a prominent branch of British commerce; steel scythes, home-made, were used, and iron was largely employed in the construction of chariots, and for other purposes. These are well-known facts; but Mr. Tylor also asserts that working in lead or plumbing is a native industry, and that it is more likely that the Romans learned the art in Britain, where the metal is plentiful, than that they taught it to the conquered nation. The *ossuaria* found in Warwick-square (about 18 ft. below the surface) are, however, specimens of Roman leadwork, and the ornamentation upon two of them is remarkable. One coffin bears a representation of Sol in his four-horsed chariot,—symbolising the passage from light to darkness,—and another has upon the inside a star of eight points, which, in the opinion of Mr. A. Tylor, has reference to the worship of Mithras. The eight-rayed star has, indeed, been claimed as a Christian emblem, and as a modification of the common symbol, Chi-Rho (X. P.); but Mr. Tylor contends that it is just the other way, and that the eight-rayed star,—Assyrian in origin,—was, with other emblems, adopted from Paganism by the early Church, and thenceforth invested with a new meaning.

IT is much to be desired that the authorities would consider the question of the ventilation of some parts of the Law Courts. During the present hot weather the windows on each side of the First Court of Appeal are open, and thus a very pleasant but very dangerous draught is caused. If the windows are kept shut, the atmosphere of the Court becomes intolerably close, so that those whose business it is to be present must run the risk of being stifled or having a sharp attack of cold or neuralgia. Again, the atmosphere of the corridors is exceedingly close and disagreeable; they rival in bad smells the worst of the old Westminster Courts, and so far from relieving the atmosphere of the adjoining Courts, they make it worse. This state of things is quite to be expected, because these corridors are crowded with persons, the seats in the windows being the scene of many consultations and conversations; they are very low and entirely unventilated, even the small windows

in them are never open. These corridors are, in fact, one of the most unsatisfactory features of the building,—they are quite dark in winter, and in summer their atmosphere is quite poisonous. Alterations to the windows, and some method of ventilation, are absolutely necessary.

THE advance of public feeling with respect to the Manchester Ship Canal was signally displayed in the House of Commons, in the short debate that preceded the second reading of that measure, on the 26th ult. One or two members, who represented the interests which have been the chief opponents of the canal, admitted that they could no longer oppose the second reading, and confined their efforts to demanding a "strong committee," a point as to which the promoters of the canal are fully in accord with the speakers in question. The probability, or otherwise, of damaging the navigable character of the Mersey by the attempt to improve it, is the sole *locus standi* to which the opponents of the Canal are now reduced,—a fact which renders the more valuable that citation of the unbiased opinions of the profession, when no scheme of improvement was on the *tapis*, to which we called attention in our last number.

THE London and Middlesex Archaeological Society's Excursion to Rochester and Strood, on the 26th ult., was very numerously attended, owing, no doubt to the favourable weather, and was a decided success. The Cathedral and Castle were described by Mr. W. H. St. John Hope, of The Vines, Rochester, Assistant-Master of Rochester Grammar School, who has recently made some interesting discoveries of the foundations of portions of the conventual buildings beyond the present cathedral precincts. The same gentleman described the Corporation regalia, and Mr. Ferguson, of Carlisle, gave an impromptu sketch of the history of civic regalia. Restoration House, the residence of Mr. Stephen Aveling, was visited, as were also the building known as Watts's Charity and Eastgate House, High-street, formerly a ladies' school, and the supposed scene of Mr. Pickwick's escapade, but now converted into a Working Men's Club. At Strood the local antiquities collected by Mr. Humphrey Wickham were described by Mr. C. Roach Smith. The company dined together in the evening at the King's Head Hotel, Rochester.

AT the approaching Church Congress at Carlisle one of the important features will be an ecclesiastical art exhibition, part of which will be a Loan Collection, intended to afford special opportunity of comparing modern with ancient work. The collection is intended to comprise ecclesiastical metal work, embroidery, wood and ivory carving, paintings, drawings, photographs, books, and MSS.; and the clergy are particularly appealed to for the loan of communion plate and any movable articles of archaeological interest belonging to their churches. Mr. William Nanson is the Local Secretary for the Loan Collection.

TWO months ago we called attention (*Builder*, April 19, p. 537) to an intended exhibition of works of decorative art in precious stones, ceramic, glass, and other wares, to be held in Paris in August next, giving the classification of objects to be exhibited. In a circular letter we have received from the Department of Science and Art we are asked to call attention to the subject again in relation to some communications which have taken place between the French Government and our own Foreign Office in regard to English co-operation in this exhibition. On the 2nd of May last M. Waddington sent a note to the Foreign Office requesting that English workers in the industries included, viz., "art objects in stone and wood, pottery, ceramic wares, enamels, glass, crystal, and mosaics" should be invited to contribute to the Exhibition. This note was enclosed by the Foreign Office to the Science and Art Department, who wish

it to be made known that the French Government are desirous of specially inviting English workers to exhibit,—an invitation which we have no doubt will be amply responded to. Those who wish for the precise statement of the classes of objects to be exhibited will find it, as before observed, in our last volume on the page given above.

AN interesting demonstration of some of the manifold purposes for which electrical energy can be utilised was given on Friday evening last, at 6, De Vere-gardens, the residence of Sir Daniel Cooper, who had invited a number of gentlemen interested in the subject to see what could be done by means of accumulators or storage-batteries. The reception-rooms were brilliantly illuminated by one hundred and fifty 60-volt Swan lamps of 20-candle-power arranged in two circuits, each worked by a storage-battery of twenty-four cells, of the Faure-Sellon-Volckmar type, which have been previously described in this journal. Each cell contained sixteen pairs of lead plates, measuring 10 in. by 9 in., and they were supplied by the Electrical Power Storage Company. The lamps had been running for several hours on the previous evening, and the accumulators had not been recharged, but there was no symptom of diminished brilliancy in the lights, which were, if anything, rather too bright, particularly in the dining-room, and all were burning with that absolute steadiness which the use of accumulators ensures. As the installation was only of a temporary character, no attempt had been made to conceal the cables or to provide special fittings for the lamps, which were attached to existing brackets and gaseliers, and, with excellent effect, to three armed candelabra in the dining-room. In addition to the lighting, several applications of the energy stored in these batteries to motive power were shown; for instance, a small fountain was worked, a lathe was driven, and a miniature tramcar made Lilliputian journeys in the library with regularity and despatch. There were also exhibited an incubator in which the proper temperature was maintained by the electric current, and two forms of *calorifères*, invented by Mr. Sellon, of which one was in the shape of a foot-warmer. The fact of no engine whatever being required ought to make these accumulators in great request for temporary installations at balls and banquets, as the batteries can be placed in any out-of-the-way corner; but for general purposes the weight of the cells is undoubtedly a drawback, as the cost of carriage for any distance to or from a dynamo-machine for the purpose of re-charging must be heavy.

THE House of Commons having thrown out the Thames Crossings Bill, so far as it related to the proposed subway between Nightingale-lane and Bermondsey, the Board at their meeting last week received a report from their Parliamentary Committee recommending that the portion of the Bill relating to steam ferries at Greenwich and Woolwich should be abandoned for the present. The logic of this decision (for the report was adopted) it is not easy to understand. Most people would see in the circumstance an additional reason for proceeding with the ferries scheme, which is the most rational and practical portion of the whole.

THE case of "Wright v. The Midland Railway Company" occasioned some remarks from Mr. Justice Field the other day, which railway travellers would do well to make a note of. The case was one arising out of a fatal accident from the deceased person having apparently walked over the line in front of the train he was waiting for, and which it was admitted he knew was coming, as he crossed the line because he heard it approaching, and was on the wrong side for it. The Judge observed that while railway companies were bound to take all proper steps for securing the safety of their passengers, the latter were "not expected to part with their common sense and care upon a railway." This is a side of the relation between railways and the public which is apt

to be forgotten. From the evidence in the case referred to we should say that the unfortunate man met his death through want of the most ordinary common sense in walking straight before a train without looking how far off it was or how fast it was coming; and the fact is that the travelling public on railways are, in these matters, "mostly fools." We hinted one day to a porter who had twice drawn our attention to the fact that a train was coming (while waiting to cross the line), that we could see a train as well as he could. He replied, "There's a many of 'em that can't, sir!" and that is about the truth of it. But it is hardly reasonable that grown-up persons should expect to be taken care of on a railway as if they were babies.

THE "Cathedral of St. Finn Barr, Cork" has not much appearance of architectural antiquity. It was mainly rebuilt between the years 1725 and 1735. The choir is lighted by a fine Venetian window. The interior, 97 ft. by 57 ft., has a richly-pannelled ceiling which rests upon ranges of Ionic pillars of scagliola. The north and south galleries are supported by Doric columns. A usually well-informed illustrated contemporary has the assurance to print the above for the edification of the Philistine, under date June 28th, 1884. Shade of Burges! Shall the hard measure dealt out to thee during life pursue thee beyond the grave?

IN our usual list of meetings for the week will be found the announcement of a remarkably interesting course of papers which are to be read next week at a Conference at the Health Exhibition under the auspices of the Royal Institute of British Architects, on the 10th, 11th, and 12th of the month (Thursday to Saturday next week). On each day there will be two short papers and a discussion, commencing at 2 p.m., and a further paper and discussion commencing at 4 p.m. The names of the presidents and the readers of the papers include, as will be seen from our list, some of the most eminent and able of the members who take an active part in the proceedings of the Institute. The subjects to be treated include sanitary arrangement of houses past and present, drainage, impermeable construction of roofs and walls, collection and storage of water, &c. We hope there will be a good attendance both of professional and non-professional hearers, who will certainly learn something of value from the papers and discussions.

THE SUAKIM-BERBER RAILWAY.

It is difficult to reconcile the conflicting statements put forward in regard to this proposed railway. Early last week it was announced in the House of Commons that no decision had yet been arrived at as to its construction, while a few days after it was said that the first ship-load of railway plant for Suakim had sailed from Woolwich. While the matter remains thus avowedly unsettled it may be useful to reconsider the expediency of selecting this particular route even for the purpose for which it is ostensibly to be undertaken. The expressed intention seems undoubtedly to be the construction of a purely military line for a temporary purpose, and without any ulterior prospect of allowing it to become a permanent line of communication suitable for either strategic or commercial purposes. It has been described as a light narrow-gauge railway provided with correspondingly light rolling-stock and engines, while its construction is to be entrusted to men of the Royal Engineers, supervising whatever native labourers can be found or transported to the locality, and it is anticipated that the whole will be finished within six weeks, or at a rate of four miles per day. In face of the physical difficulties to be encountered in regard to climate, want of water, sparseness of population, and hostility of the tribes through whose territory much of the line must pass, the expectation of such a speedy rate of construction appears to be somewhat sanguine. But assuming that all possible contingencies have been thoroughly considered, and effectually provided against, it is still open to doubt whether, after all, the route from Suakim to Berber is the best that could be selected for

even the immediate object in view, that of facilitating the transport of an expeditionary force for the relief of Khartoum. Leaving aside, however, the military aspect of the question as not within the province of the *Builder* to discuss, the possibility, if not the certainty of the construction of a trade route with the Soudan becoming an absolute necessity, ought to have an important bearing in the selection of a line of communication which probably will involve an expenditure of two millions of the public money. Commercial requirements must in the end override political interests, and an interchange of mercantile operations, following a development of its resources, will be better calculated to effect the desired end of pacification and to consolidate the future government of the Soudan, than a maintenance of military demonstrations after the present disturbances have been quelled. If this view be correct, then the country to be benefited by the outlay, and on whom its burden will ultimately fall, being Egypt, that route which will most effectually assist the transport of its produce and develop its trade should unquestionably be preferred. It can scarcely be gainsaid that the valley of the Nile is the route which the trade will take. Produce from the Soudan and territories through which the White and Blue Nile run is now carried on these rivers to Khartoum and Berber, whence, if there must needs be a transshipment, it should at all events take the direction of Korosko rather than Suakim. The length of land carriage in either case is the same, but the route to Suakim lies through utterly unproductive country, whereas either terminus of the Korosko line abutting on the Nile would be useful for its entire valley, and all down-produce shipped at Korosko would be carried without breaking bulk, either to the warehouses in Alexandria, or direct to the ships' sides in the harbour. All the important towns between Cairo and Korosko would then be opened to trade with the Upper Soudan, Kordofan, Darfour, and the countries bordering the great lakes; but they would derive no benefit whatever from the Berber-Suakim line. The mere fact, too, of access to the splendid harbour of Alexandria, with its temperate climate, ought, in itself, to be sufficient to decide the question, for before Suakim could be converted into a useful harbour, a very large outlay would be necessary, and even if practicable at a moderate cost, its excessively trying climate, unendurable for several months of the year, renders it unfit as a place of permanent habitation for Europeans.

As, notwithstanding all existing obstacles and argument to the contrary, the Nile must and will remain the great highway from the interior to the coast, just as the great rivers in India and America still are, in spite of all the railways which have been, or ever will be, constructed, the attention of all those concerned in the welfare of Egypt should be directed to removing or overcoming the existing impediments to its effective navigation.

Pending the carrying out of works for that purpose, nothing could better serve intermediately as an auxiliary than a railway from Korosko to Berber, unless it be a temporary line carried along the river as far as "old Dongola," and thence across to Khartoum or Berber, distant 180 to 200 miles respectively. One advantage of the parallel line would be to facilitate the construction of the works for overcoming the present obstacles between the first rapid at Assuan, and the last between Shendi and Khartoum, while it would meanwhile carry not only the traffic arriving at the latter place for the coast, but also the produce of the country between Khartoum and Assuan. If, therefore, a temporary railway has under any circumstances to be constructed for military purposes, and the advantage of being in close proximity to not only water but to a tract of country from which inexhaustible supplies could be drawn will not be questioned, ought not the likelihood of its being ultimately required for commercial purposes to aid in determining its direction? There can be no question but that, if it is to be undertaken in the interests of Egypt alone, the Government of that country would pronounce in favour of the line which would serve as a trade route after it had fulfilled its military purposes. If Egypt is unable to pay the cost of construction, there would probably be little difficulty in getting a syndicate of capitalists in this country to take it over and work it. It would

be well, therefore, that whatever route be selected, our Government should bear in mind the important fact that however useful and necessary their proposed railway may be for military operations, it will be still more useful afterwards for commercial purposes, and that it should therefore be so constructed to meet that end as far as is consistent with its primary object.

A FRENCH ARCHITECT ON THE COMPETITION QUESTION.

THE following is a part of the paper on Competitions, read by M. Paul Wallon at the recent Congress of French architects. Some of his remarks will be found suggestive by our readers:—

"Having given a brief summary of some long and serious disquisitions, we have now before us the views, many times expressed, on the subject of public competitions.

After this enumeration of the principal items in the grand total what, in my turn, shall I say?

People have spoken to you of resolutions, of decrees even, to obtain for the future a uniform regulation of competitions over the whole of France. Well, gentlemen, I venture to say, in regard to this official regulation of public competitions, these resolutions and decrees, and so on, I do not believe in them and do not wish to see them at all.

Every one must be master in his own house, whether an administration, a commune, or a constituted society, and I cannot imagine a Minister or a President of the Republic consenting to intervene between competitors and organisers in a competition.

It is by persuasion and appeal to the public that one must work, by interesting them in our cause and showing them that it is at the same time their own and that it is by advising them as well as in defending ourselves that we hope to obtain better results.

Declarations of principles have had their day, official inquiries and communications have done their work. Leave on one side, if you please, vague forms, Platonic views, and mere theory, and enter more strictly on the real question; put our finger on the sore, and, by example, counsel, and energetic action when needed, let us write day by day the history of public competition up to the point when no scandal can be possible, and when a corrupt municipality will recoil before public opinion.

Do not suppose that I deny the influence of statements of principles, or of those lengthy debates which we have just passed in review. I hear people say, 'Oh, the competition question. They have been discussing that backwards and forwards for years, and what comes of it all?' But all these discussions have not been useless, we may be sure. They have not resulted in 'arrêtes' or 'décrets'—certainly, but in something more important, — the formation of public opinion. The principle of competition is firmly established now, without any movement of great administrative machinery; it has entered into our life by the mere force of circumstances. I would even venture to say, and it will be my sole criticism against the institution, that there is a certain exaggerated desire for competition, on every hand. Every village wishes to play 'la grande ville,' and each little building is immediately thrown open to public competition. It is often an electoral question. The situation of the 'architecte de département' is not improved by it. For him, public competition is a source of perpetual danger, and, in case of failure, of humiliation before his fellow-townsmen, especially if the building in question should chance to be one of small importance, which he could, perhaps, have carried through far better than his unknown competitor, a stranger to the district, and simply either more fortunate or backed by stronger interest.

Now, it is of considerable importance that the position of 'architecte de département' should be sought after and occupied by those members of the profession who have spent their youth in studying at the École des Beaux Arts and under our greatest masters, and who are anxious to return to the provinces and to place their talent and knowledge at the service of their department. If the position is to be acceptable, it must be protected.

The 'architecte de département' must win his post by competition, and then it may fairly be conceded that he possesses the knowledge

necessary for the construction of schools, town-halls, and other municipal buildings without having recourse to competition at all.

The present, gentlemen, is no longer a time when (as M. César Daly wrote in 1861) the number of public competitions may be reckoned by that of the reigning dynasties in France; on the contrary, we may be said to suffer from a surfeit of them.

It is true, and the fact is to be deplored, that great public institutions still escape the salutary impulse given by competition; but this is an exception which will become more and more rare as time goes on. The question for us is not now whether competition will prevail, but by what guarantees it can be protected from injustice.

The morality of public competition,—that is the gist of the whole subject. I must allow at the outset that the phrase has been greatly abused. Every decision must create some malcontents, and the anathemas and accusations hurled at the judges by those against whom the decision has gone are often not merely exaggerated, but altogether unjust. It is but human to cherish illusions with respect to a work that one has begotten, nourished, and caressed through long months of application, and the rude awakening of an adverse judgment is often very hard upon this paternal fondness.

Nevertheless, instances of injustice do not seldom occur, and in accordance with the plan I have laid down for myself in this address, I will now venture to draw your attention to some that have come under my own observation."

M. Wallon then proceeded to narrate, with considerable irony, and amid signs of approbation from his hearers, the particulars of a somewhat recent scandal *à propos* of the election of an "architecte de département," and the curious fact, to say the least of it, of an architect who, on applying at the *Mairie* for the particulars of a certain building put up for competition, received instead an offer of collaboration, not gratuitous, but obligatory, from an "agent-voyer" (trustee of roads), who, upon this condition, promised his powerful interest to gain acceptance of the candidate's designs. M. Wallon also reminded his hearers of the open competition in 1880 for the construction of a police barracks at Oran; and, on the other hand, of the case in which, first the *Conseil de Préfecture* of the department, and then the *Conseil d'État*, condemned the town of Charleville (Ardennes) to pay the competitor whose designs for the construction of a college and library had been classed first, but not chosen for erection, his fees at a deduction of five per cent. from a certain sum for the cost of superintendence.

A similar decision was given in 1883 on the occasion of the construction of a group of school buildings at Puteaux (Seine).

M. Wallon continued, "It must not be imagined that similar abuses accompany competitions for such buildings as the Opera, or the *Hôtel de Ville*; the judges in such cases are men of the nicest conscience, of the most absolute impartiality, and the competitors find themselves face to face with a public opinion which it would be dangerous to displease." M. Wallon then drew attention to some erroneous ideas on the subject of public competitions, and discussed those recently set forth in a pamphlet by M. Charles Morin, architect of the department of the Bas-Rhin and of the town of Strassbourg before the German invasion; he amused his hearers by two anecdotes; one of a country mayor who mistook a Louis XVI. design for a toilet-table, all over Cupids and nymphs, for a church altar, and another of a "Conseiller Général" who took a tracing of some drainage tiles on a plan of a basement for the elevation of a clock-tower.

Drawing attention to what he believed himself entitled to demand and to obtain, M. Wallon continued:—

"Gentlemen, the State has far too many subjects in hand, far too many general interests to defend, to be able to occupy itself with a question so special, so variable, so difficult to formulate as that which we are considering. One may almost say that for every fresh competition there is a fresh way of organising its conditions, either in the details of the programme or in the composition of the jury. Do you intend to appeal to the Government on every occasion of difference? Who will blame it for turning a deaf ear to your appeal? If you have a grievance, there are the courts of

law; we have just seen that they are not appealed to in vain. But, you will say, it is not every one who can engage in a law-suit, a hundred objections of time, of expense, &c., may arise to prevent it. During next Friday's session, gentlemen, you will have an opportunity of listening to a remarkable report, drawn up by M. Hermant, in the name of a special Committee, assisted by the Judicial Council of the Society, for the creation, under the auspices of the Central Society of Architects, of a mutual defence fund in cases of liability. The proposition emanates from the International Congress held at Nice at the beginning of this year.

Does not the question of public competition naturally fall within this scheme? By this means we can provide for our own defence, and for the repression of abuses and illegal proceedings.

Together with this federation for defence you must form a centre for information and advice. Here, again, it seems to me the *role* of the *Société Centrale* is pointed out.

It must be made known to all municipalities, public bodies, and committees that competitions will not be undertaken under certain inadmissible conditions; they must be convinced that these conditions will deprive them of the assistance of many architects of merit, of every architect who is desirous not to have his reputation placed in incapable hands. Those who are organising competitions must themselves come to us frankly, and say, We have full confidence in your powers, in your good sense, in your independence, and in your justice: give us your advice. Here is our programme in its main features; we rely absolutely on you to settle its details, to appoint the jury, to award the premiums. All our decisions accepted beforehand, we shall only appear to put them into execution. Do you believe, gentlemen, that any society, whatever it might be, consulted in this way, would not consider itself bound in honour to do its duty, and nothing but its duty? Do you think that a public authority could place its interests in safer hands than these?

And do not imagine that I am over-credulous or over-hold in speaking thus! Public authorities will be found only too ready to receive advice which they will be the first to profit."

Here followed two instances that we shall content ourselves with quoting on the authority of M. Paul Wallon: one, of the good influences exerted in 1877 by the "Conseil Général des Bâtimeurs Civils," with regard to the open competition for the construction of an *Hôtel de Ville* at Rodez, and the other the influence exerted recently by the *Société régionale* of the architects of Northern France with regard to the competition for the construction of the *Palais des Beaux Arts* at Lille.

"Well, gentlemen," continued M. Wallon, "let all provincial societies imitate upon occasion their valiant sisters of the North. Let the central Society of Architects in Paris, in accordance with its principles of joint responsibility and co-operative union, create in its midst a centre of information, of publicity, of defence. Let there be a permanent, renewable Commission, bound to follow every phase of the question, to give every information, to receive all protests, and to refer all cases of interest to the members of the Mutual Defence Committee of the Society.

This protective province of the Society has already been recognised on more than one occasion under the direction of its president, Victor Baltard. A letter was written to the Mayor of Bagnères de Luchon on the subject of the open competition for the erection of a Casino in that town; and another to the Prefect of the Department of the Morbihan on the competition for the post of architect to the department.

I should like to see this assistance of the Central Society continued and extended; its wide reputation, its well-deserved influence would enable it to repair many errors, and to render great service to the general good, more especially in this question of public competition."

After further arguments, winding up with a moving appeal to national feeling, M. Wallon concluded, amid general applause, in these words:—

"Gentlemen! the discussion in which you are now to take part should be made known to all, to administrative bodies, to the public in general, as one that has a higher aim than the interests of any individual, of any school, of any corporation; its aim is the triumph of the artistic pre-eminence of France, the greatness of our nation!"

## GEOLOGY AT THE HEALTH EXHIBITION.

ON Saturday, the 28th June, several members of the Geologists' Association, with their president, Dr. Hicks, F.G.S., &c., and secretary, Dr. Foulerton, F.G.S., visited the International Health Exhibition, for the purpose of seeing the various objects relating to their special study. They were met in the Water Companies' Pavilion, at 4 p.m., by Colonel Sir Francis Bolton, C.E., Water Examiner to the Local Government Board, who conducted the party round the Pavilion, outer corridor, and the outside annex, pointing out and explaining many of the principal exhibits. Amongst these were noticed the modes of filtering the water obtained from rivers in the vicinity of London, for which purpose glass cases have been erected showing in descending order:—1, Very fine sand; 2, coarser sand; 3, pea grit; 4, small sub-angular flints; and 5, larger flints. When water is poured on the top of such a filter as this, it percolates through, leaving the impurities behind on the uppermost layer of sand, whilst a pipe inserted in the lowest stratum carries off the filtered water.

In the outer corridor, to the left of the main entrance to the pavilion, is a unique exhibit, being a case lent by the Aqueous Works and Diamond Rock-boring Company, Limited, of London, containing a collection of cores of different strata, obtained in artesian and other borings by the diamond drill. In the following, which were particularly observed, the geological formation is mentioned, giving the depth at which the specimen was procured and the locality of the bore-hole. Chalk marl, 780 ft., Meux's Brewery, Tottenham Court-road; upper greensand, 860 ft., Albion Brewery, London; upper greensand, 610 ft., New River Company's boring at Ware; new red sandstone, 550 ft., from bore-hole for salt at Middlesbrough.

Other cores in the corridor are, gault, with impressions of pecten, ammonites, and pieces of lignite, 966 ft., Turford, Herts; three examples from Devonian, 933 ft., 855 ft., and 1600 ft. respectively, Turford. In the core from 955 ft., spirifer, with other fossils, were seen. Upper greensand, 585 ft., Ware; two specimens of Wenlock shale, 800 ft. and 827 ft. respectively, Ware. Borings for water and other economics in the south-east of England show that a ridge or chain of Palaeozoic rocks runs under London to the Continent. These borings are of considerable interest, both commercially and scientifically, for they indicate to a certain extent the position of building-stones, &c., which, it might be added, are too deep-seated to be profitably worked in the London area. At Messrs. Meux's brewery, at 1,064 ft., Devonian purple and green shales were met with. At Crossness, new horing, after passing through river drift, 39 ft.; Woolwich beds, 47 ft.; Thanet sand, 51 ft.; chalk, 631 ft.; upper greensand, 65 ft.; and Gault, 170 ft. Red sandstones and marls are met with, which may probably be of Triassic age. At Burford, Oxon, the borings show:—Surface blue clay, 35 ft.; lower oolites, 110 ft.; lias, 598 ft.; rhaotic, 10 ft.; new red marls, 291 ft.; red sandstone, 137 ft.; coal measures, 225 ft. In the Carboniferous beds a coal seam of some thickness was passed through. A boring at Richmond, Surrey, recently described by Prof. Judd, proved the presence of oolites, and at the base of the hole red-rocks occurred which he thinks might be of Poikolitic age. The celebrated sub-Walden boring at Netherfield, near Battle, clearly demonstrated that Jurassic rocks are of great thickness in that region, as nearly 2,000 ft. of them were bored through, and Palaeozoic rocks were not reached. In this experiment valuable beds of gypsum were found which have since been turned to commercial advantage.

The outer corridor also contains many boring tools. There is a diamond drill boring-crow, 22 in. in diameter, showing five diamonds ready for use. The rough black diamond or carbonado, which is a peculiar form of carbon, is used for this purpose. It was discovered in the diamond gravels of Brazil in 1842, and appears to furnish a transition from the ordinary diamond to graphite. A diamond-drill core-extractor, used for breaking off and raising the cores, and a hand iron chisel, are also exhibited.

In the outside annex are large mains, from 13 in. to 48 in., used by the water companies, with water meters and hydrants. Examples of stone, wooden and concrete pipes, of olden times, were particularly noticed, side by side with iron mains of modern times.

At this point the President, Dr. Hicks, thanked Sir Francis Bolton for the great trouble and pains he had taken during the afternoon in explaining the various objects to the members of the Association, and the party then proceeded to the Belgian Court under the direction of Mr. C. E. De Rance, Assoc. Inst. C.E., F.G.S., of H.M. Geological Survey of England and Wales.

There, various rock specimens, maps, and charts are exhibited, to show the manner in which geology and geography are taught in the elementary Belgian schools.

The following are amongst the principal objects which claimed attention:—Tin, which is almost exclusively obtained from Cassiterite, or tin-stone, a peroxide of tin containing nearly 80 per cent. of metal; antimonite, a tersulphide of antimony; a fine collection of calamine,—carbonate of zinc,—from the celebrated Vieille Montagne, or Altenberg deposits. These mines are situate in the Belgian, Prussian, and neutral territories, between the towns of Aix-la-Chapelle and Verviers. The calamine there has been worked since 1435 as an earth to make brass; but it was not until the beginning of the present century that it was found to contain any metal. Zinc-hiende or sulphide of zinc. Galena,—sulphide of lead,—a most important ore, which usually contains various other metals, and it is probable that neither silver nor gold is ever absent from galena. Iron pyrites,—a bisulphide

MASON & SWANN'S  
AIR-HEATING APPARATUS.

An improved air-heating apparatus for warming buildings is being introduced by Messrs. George Swann & Co., of Portobello-road, North Kensington. The apparatus (which is the subject of Patent No. 3,540 of the present year, 1884) appears to be well adapted for warming churches and other public buildings with economy and without the unpleasant sensation of the air having been hurried, which is but too often apparent where hot-air apparatus is used. Messrs. Swann & Co. claim for their apparatus that it supplies fresh hot air; that it presents greater heating surface with less consumption of fuel and attention; that a hot-water apparatus can be fixed and worked from the one fire of the apparatus for warming any building adjoining, or for supplying hot water to baths, lavatories, &c.; and that it is simple in construction, having few flues, these being ascending and easy of access. The furnace-chamber is constructed of fire-lumps and is closely embraced at the top and two sides by series of inverted U-shaped air-heating pipes, which serve to hold the fire-lumps together. These pipes (B, B') can be made square in section as well as circular (the method shown in the engravings). We quote further description from the complete specification.

Figure 1 is a transverse section of the apparatus. Figure 2 is a horizontal section of the same. The furnace-chamber A is constructed of fire-lumps *a*, and is closely embraced at the top and two sides by series of air-heating pipes, B, which serve to hold the fire-lumps together. These pipes are

together. By this sectional construction of the air-heating pipes B and flues D, the furnace and apparatus may be readily constructed of any required dimensions and air-heating capacity by employing a greater or less number of the said sections.

The apparatus is enclosed between front and back settings of brickwork or iron F, which leave the pipes B and flues D exposed to permit the free radiation of heat. The apparatus is provided at one end with a furnace front, having fire-doors and cleaning out doors.

The air to be heated enters the air-flues C at C, and rises in the series of air-heating pipes B, wherein it is heated by conduction and radiation from the walls of the furnace chamber, and is brought out under the horizontal flues D, D<sup>1</sup>, D<sup>2</sup>, where it is still further heated by radiation therefrom.

It will be observed that the air to be warmed is kept from contact with highly-heated surfaces of iron.

ART-EDUCATION IN BELGIUM.

A SERIES of two conferences on primary education in Belgium was held at the International Health Exhibition, on June 27th and 28th, under the presidency of Lord Reay, chairman of the Educational Committee of the Exhibition. The first was given by M. Slnys, Director of the Normal School at Brussels, on the subject of "The Reform of School Methods," introduced into Belgium in 1879 by M. Germain, the Director-General of Education.

FIG. 2.

FIG. 1.

Mason & Swann's Fresh Hot-Air Apparatus.

of iron,—is not so much a source of iron as of sulphur. Limonite or brown iron ore. Quartz crystals, chalcedony, agate, melaphyre, &c. Pebbles, and bottles containing sand, such as quartzose glauconitic sand, &c.

Amongst the rock specimens may be mentioned porphyries, granites, anthracites, ordinary bituminous coals, lignites, peats, limestones, sandstones, clays, shales, a series of slates, marbles of various descriptions, Cambrian schists, &c.

Calamites, lepidodendron, sigillaria, neuropteris, and peccopteris are some of the fossil plants from the coal-measure shales, and products, atrypa, belemnites, lima, peecten, sharks' teeth (lamna, &c.) are examples of the very few other fossils exhibited.

It is noteworthy that in many instances in the case of metals the raw material was placed with the manufactured article, and the name of the specimen, the locality whence it was obtained, with its "usage," were written on small labels, attached to the majority of examples in cases.

Many maps are seen on the wall, on some of which the contour of the mountains, abysses of the sea, with ocean currents, are beautifully shown.

Mr. De Rance gave a short account of the Belgian coal-measures.

The party then adjourned to the fountain display, and finally broke up in the grounds.

each composed of two vertical pipes B at either side of the furnace-chamber, united by a transverse pipe B'. The vertical pipes B rise from chambers or passages C below, with which they communicate for the admission of air to the air-heating pipes B, the entrance to said chambers being at C' at the opposite end of the apparatus to that at which the furnace-chamber is situate. The furnace-chamber A is provided with a suitable grate, and communicates by a flue A' with a series of large horizontal flues D D<sup>1</sup> D<sup>2</sup> at the upper part of the apparatus immediately above the horizontal or transverse portions of the air-heating pipes B, the products of combustion passing through these flues D D<sup>1</sup> D<sup>2</sup> successively in the order named on their way to the chimney. For this purpose the flue A' leads into the rear end of the flue D which communicates by a chamber *c* at the front end with the middle flue D<sup>1</sup>, which communicates by a similar chamber at the rear end with flue D<sup>2</sup>, which communicates at the front end with the chimney.

A partition in chamber *c* prevents communication between flues D<sup>1</sup> and D<sup>2</sup> at their front end. The air-heating pipes B open out at B<sup>2</sup> immediately beneath the flues D; D<sup>1</sup>, D<sup>2</sup>, and they are placed closely together side by side, and to allow for expansion and contraction, their adjacent sides are fitted together by tongue and groove joints formed in ribs *b* cast on the sides of the pipes, and the whole series of pipes are tied together by the bolts *b'*, passing through flanges *b*, cast on the outer sides of the pipes.

The horizontal flues D, D<sup>1</sup>, D<sup>2</sup>, are constructed in short sections, tongue and groove jointed together at *d*, and cast with flanges *d'*, through which tie-bolts *d''* pass from end to end to hold the sections

At the second of these Conferences (both of which were held in the Lecture-hall of the Central Institution of the City and Guilds of London) a lecture was delivered by M. de Taeye, Director of the Academy of Fine Arts of Louvain, his subject being "Artistic Teaching in Belgium and its Application to Industry." Among those present or taking part in the proceedings were Sir P. Cunliffe Owen, M. Couvreur, ex-vice-president of the Belgian Chamber of Representatives, M. Lenders (Belgian Consul), Mr. Ahlett, and other English and foreign educationists.

M. de Taeye, who spoke in French, commenced his lecture by expressing his regret that he could not have at his side the collection of teaching exhibits in the Belgian Section of the Exhibition, for by reference to the various objects it contained it would have been much more easy to illustrate his lecture. The subject of art-teaching was excessively subtle, but it was also of the greatest importance for the workman,—the population *ouvrière*. The education of the artistic sense was not only a necessity for the due development of a pupil's powers, but was an important element in the wealth of nations. To conceive an idea was nothing, but to put it into practice,—there was the difficulty. Industry had been long travelling in a path absolutely false. All countries taking their cue from England,—especially two leading industrial nations of Europe,—had followed England in the pursuit of that

which was cheap. A man of profound perspicacity was the first to perceive the falsity of the situation. It was a prince of England (the late Prince Consort). He had a true inspiration. He created the Great Universal Exhibition of 1851, which brought all the different nations of the earth together. Then it was revealed to the world for the first time that cheapness was not the most important thing. England astonished the nations by her extraordinary wealth of machinery and tools, and another country impressed every beholder with the fine æsthetic sense of the beautiful which pervaded her productions,—it was France. There followed Persia, Japan, and China with their products, which were the admiration of all. It was before these that the crowds gathered and stopped to gaze. Why? It was the artistic sentiment, the feeling of the beautiful, governing all other sentiments. It was determined that the unfortunate direction which industrial art had taken should be abandoned, and the leader in this movement was again Prince Albert. He was followed by others. A report of the Exhibition held in England in 1851 was drawn up by Count Laborde, who enunciated a truer sentiment,—“L'art!” said he, “est la plus puissante machine de l'industrie.” (“Art is the most powerful engine of industry.”) The true path was now entered, for the love of the beautiful was natural to man. It existed among some semi-civilised races perhaps in a purer form than among the nations that stand at the head of civilisation. We saw the wilder peoples imbued with the sentiment of the beautiful when they had not the wherewith to cover themselves. It was now clearly apprehended that it was by the development of the beautiful that we must emancipate ourselves, but the question came, How was it to be done? It was to answer that question that he (the lecturer) was there that day. None but a few rich persons occupied themselves seriously with the matter, and it was necessary for each seeker to search within himself to find the true solution. Three countries appeared to have entered upon the search, following parallel lines. England, it was natural to remember in that place, led the way by the creation of the Museum of South Kensington—a model for Belgium to follow, as it was for France. There art found a shelter where it could popularise itself to the eyes of the nation. France, possessed with a sense of the beautiful, sought further to develop that fine æsthetic sentiment which already belonged to the race in a richer degree than to the rest of Europe. In Belgium, with its love of family life, love of the practical, love of method, the efforts made in the common direction had to encounter almost insurmountable obstacles. The chief obstacle arose out of a vicious principle of teaching then in vogue,—a method detestable,—he referred to the “drawing copy.” The wretched thing was put before the pupil with the command, “reproduce what you see before you.” The copy was, so to speak, thrown at the pupil's nose. Galliano, in Belgium, proclaimed the doctrine that all drawing should start from a basis of science, but not being a very practical man, he did not show how it was to be done. Under what form was it to be founded upon science? There were two distinct kinds of drawing,—picture-drawings and (what were called in English) “designs.” The real question was, under what form was the teaching of drawing to be put within the reach of all in our primary schools? The denunciation of the evil of copying was set forth, and an answer to this question at the same time suggested, by Herr Von Müller, Minister of Public Instruction in Prussia,—a man of real erudition,—in a letter of instructions on the organisation of professional schools. “The teaching of drawing,” says the Minister, “must remain within school limits. Its purpose is not to produce artists, but much rather to exercise the pupils in the elementary practice of art; to enable them to acquire the knowledge of form, the rapidity of a sure eye, accuracy of measure, and firmness and lightness of hand. It is of less import that what is drawn should be picturesque than that it should be exact.” And the Minister adds impressively “The method must be organised in such a manner that every capable teacher may be in a position to successfully teach, according to it, the elements of drawing; and that from it should be rejected every copy lacking in ideas, and above all those mechanically executed productions of images which are so well known to everybody.” Herr Hellart, a famous Austrian

educationist,—a veritable Fröbel in his way,—also demanded that an immediate remedy should be found to overcome the same difficulty. The remedy consisted in the rejection of the “copy” and the flat outline from the early lessons, and the substitution of objects from nature or forms in relief. This substitution brought drawing at once into the category of subjects to be taught in the primary schools by the logical process of developing the intelligence. It only remained to put it into the hands of the teachers, but the question then arose at what age the child's instruction in drawing should be commenced. M. Couvreur was of opinion that it should commence at the same period as reading and writing. In that way could best be secured the development of the hand. Thus the hand would be rendered supple and the eye sure. It was thus that the famous Horace Vernet, trained by an intelligent father, became able to answer more readily with his pencil than his tongue. When asked to tell the name of a person he had seen, young Vernet, to save himself the trouble of remembering names, would take a piece of paper, and, after making a few possible lines, would hold it up, and say, “That is the man.” The lecturer then described the programme in detail, which had been incorporated into the reformed system of primary education in Belgium in force since 1879. The instruction was given in four stages,—I. (the first year's course), for children aged from six to seven; II. (second year's course), for children of seven, eight, and nine; III. (third year), for children of eight, nine, and ten; IV. (fourth year), for children of ten, eleven, and twelve years, and in some cases to thirteen and fourteen years. In the first year's course, after the child's intuitive notions in regard to points had been developed by dots placed in all positions with regard to each other, they were combined in denser and denser formations to develop the notion of intensity of tones. The intuitive notions of colour were then expressed, with a view to discover as early as possible the existence of “Diatonism.” Before proceeding to straight lines, which were regarded by M. de Tæye as far from simple things, when combined in certain ways, certain common objects in solid and natural forms were treated, the instruction forming in all cases the foundation on which further instruction at each step was based. The first year's course finished with the combinations of straight lines and drawing from memory. All the exercises at this stage were done on paper ruled in squares, or on slates or black boards marked in the same way. They were, of course, freehand drawings. The second year's course commenced with the study of curved and mixed lines, followed by exercises in shading and colours, the complementary principle in colours being now introduced. Gothic letters and figures, and the drawing of common objects from nature, followed, lines interlaced, and the application of lines to ornament and drawing from memory concluding the second year's course. The third year's course was directed particularly to quickening the eye of the pupil, and to developing firmness of hand; geometrical figures were now introduced, but instruments were used, and the exercise-paper was plain, except that on the sides a scale in divisions of the metre was figured. In the fourth year, projection and perspective were treated, geometric drawing with instruments was taught, and in freehand drawing natural objects were selected as models, offering all possible complexities of form. The exercise-paper was quite plain, no help of any kind being supposed to be necessary. M. de Tæye concluded his lecture with a few general observations, couched in earnest and eloquent language. The Belgian system of teaching drawing, as well as other subjects, was founded upon the maxim of Herbert Spencer, “The intention to learn ought to precede the instruction.” The details of the system resembled the German models from which they were adopted, and it might be hoped that they would be found equally worthy. Their youths on leaving school were fitted for noble toil, and, without indulging in the language of exaggeration, he declared that to give the workman a knowledge of graphic form was of greater necessity than to teach him to read. We were very far from having assimilated our conditions as regarded artistic knowledge with those which existed in the Middle Ages. All our true workmen were in the past, but we were at last ready to follow in their footsteps. What would be the result? Naturally the workman would have acquired a

correct taste, and insensibly they would be able to draw him more and more out of the workman to turn him into the artist. Each individual would receive the instruction which best befitted him for his work, and the sentiment of the beautiful would necessarily generate the sentiment of morality, and we should, therefore, possess in him an element of moral, material, and intellectual progress.

Sir P. Cunliffe Owen (speaking in French) proposed a vote of thanks to M. de Tæye for what he described as “the splendid, the admirable, lecture,” they had just listened to. With regard to the question of “art applied to industry,” it was one which had been agitated in many other countries, and it concerned every country, but in none had it been more persistently considered than in Belgium. It was very remarkable to see a young country pursuing with such ardour a subject so large, and it had astonished many. Belgium wanted something new, but to secure for herself the advantage of a good system; she was willing to show everything to those who might be adverse. In 1879, drawing became a compulsory part of the primary education in Belgium. That step set a great example which would be followed by all countries. But to what purpose would they have taught drawing if they had no models to put before the workman? In the South Kensington Museum here we had a million visitors annually, and the loan collections distributed from the Museum in different parts of the country attracted from two millions and a half to three millions of visitors in the provinces. It was in that direction he wished to see Belgium, and even France, rise to the level of the occasion. But the possession of a museum of art models would not be sufficient unless it was open in the evening. The people were not for them. They would say the museums were not made for them, but that they (the people) were made for the museums. They would not succeed in propagating science unless they had good models, and until they put those models within the reach of the people. The Belgians were a social race. They could always find plenty of amusement. If they saw three Belgians together they were sure to be a merry company. They must direct this characteristic to the advantage of the people. That was what he asked of them above all. The King of the Belgians, in 1873, and again in 1877, expressed to him his desire to establish a museum on the model of that of South Kensington. He expressed his conviction that a museum could not succeed if it were not open in the evenings.

Mr. Ablett, in seconding the proposition, said he did not quite agree with setting up a knowledge of form in primary schools as the most important matter. Other subjects had a claim to be studied before drawing. He quite agreed as to the necessity that for teaching drawing satisfactorily it should be done in a room specially adapted for the purpose.

Lord Reay said he had listened with much pleasure to M. de Tæye's admirable address. It was an excellent thing for Belgium to have organised such a method of teaching drawing. As M. Couvreur had pointed out, the improved methods in teaching drawing improved the chances of getting higher places for the children taught in their schools. While listening to the lecture it seemed to him that they were trying to find our way again after having lost it. It was not the dark Middle Ages that were dark, but the modern times, and it was re-asserting to find that we were trying to regain the light of the Middle Ages. The same thing appeared to be going on in all countries. He spoke not only of Holland, but of Germany, and those who would pay a visit to the exhibits from the school of Karlsruhe in the German section would see what the Germans were doing. The French were now importing from Germany certain classes of goods of which France had formerly almost the monopoly. That was a fact, and not simply an oratorical statement. He hoped the lecture would be published and sold in the Exhibition in order that it might address itself to a much larger audience than they could expect to get at these conferences. He thanked M. de Tæye and also M. Couvreur for the valuable assistance they had rendered in making the conference successful.

The vote of thanks was carried by acclamation, as was also a vote of thanks to Lord Reay and the Educational Committee, on the motion of M. Couvreur.

CAN THE NEW GOVERNMENT OFFICES BE DURABLE?

SIR,—This, at the present moment, is such an important question for Her Majesty's tax-paying subjects that I do not doubt its consideration, ere it is too late, will be generally welcome should you be able to grant a little space for it. It will not be the first time you have allowed me to urge it in your columns; but, as you are well aware, all innovations,—even the best,—require much reiteration before they are adopted.

When the late Dr. Ansted, some years ago, was delivering some Cantor lectures at the Society of Arts he remarked,—after lamenting the rapid decay of the public buildings of London, whether constructed of limestone or sandstone,—that quartz rock was the only material to be rolled upon. It is true that he added the words, "too hard to be chiselled," which, at that time, was a fact, but is now no longer so. The ingenuity of our countrymen has overcome all difficulty in this respect, so that the hardest volcanic stones can be surfaced at the speed of a square foot in about five minutes, and as the patent has just lapsed, there are no royalty charges to pay. Hence a great step in economy. And burnishing, by which process alone the natural and characteristic beauty of porphyry, serpentine, and granite can be developed, is now so simple a matter that it may be done by boys.

In the face, then, of these facts,—the rapid decay of all freestone buildings, the absolute and proved durability in London of volcanic stone, and the facility and economy with which it can now be converted into useful building material,—is it too much to hope that the First Commissioner of Works and the architect of the above important national structure, whoever he may prove to be, may find it possible to abandon the use of the perishable freestones hitherto in favour,—for no better reason than that as they are so easily carved and modelled a building may be enriched with abundant meretricious ornamentation at little cost? Surely, Sir, we have had enough of this. A purer and simpler style, with better construction, would be a welcome innovation. A highly-ornamental facade of Bath or Portland stone may, of course, be the most beautiful product of architectural art; but, *cui bono*, if it fall to pieces, like the east front of Buckingham Palace, before the workmen depart, or be changed from white to nearly black by soot absorption, like the Royal Courts of Justice, before the contractor delivers up the keys?

There are good reasons for believing that it would be economical to make the change I venture to propose; for what can be more costly than to be compelled, as we are, to be constantly repairing the soft porous stone of our public buildings? Twenty years ago the elaborate sculptured exterior of our grandest national edifice, that was to last for ages, and the stone of which had been selected by a Royal Commission costing nearly 20,000*l.*, was showing signs of crumbling to dust. Since then it has been necessary for the Government to invest about 70,000*l.* sterling to provide a yearly sum of 2,500*l.* for the constant renovation of the stonework of the Houses of Parliament. At the present moment the facade of the Treasury is in the hands of the masons, at a cost of 8,000*l.* at least. Lambeth Palace has been restored at the earnest appeal of the late Archbishop. The Dean and Chapter of Westminster, the Ecclesiastical Commissioners, and the Government are now anxiously discussing the ways and means for a thorough restoration of the Abbey, has been decayed, if not dangerous, condition of which has been fully reported upon by Mr. Pearson. This, although hundreds of thousands have been spent in restorations since Wren's time. At St. Paul's a column of one of the porticoes gave way and has been replaced with new stone, and other repairs are much needed, but must wait for want of funds. The Travellers' Club in Pall Mall, and Buckingham Palace, are painted annually to preserve the stone.

But enough, Sir, of examples that might be multiplied indefinitely. I think it will be admitted that they sufficiently prove that building with freestone in London,—and this is entirely and emphatically a London or town question,—is a very costly proceeding indeed.

The materials I have referred to are mostly very common. As we pave our streets and form the edges of our footpaths with them it cannot be a very great step in advance to construct the

fronts of our more important buildings with them.

Aberdeen may be called "a granite city." The inhabitants allow no meaner material to be used. It is true that it is upon the spot, and, therefore, comparatively cheap, but why, for Government work for which we all have to pay, should not an Admiralty transport be employed to reduce carriage? Nearly all the ancient churches of Cornwall and Brittany are of granite. It was the constant use of these enduring materials that has saved to our times all that conquerors have spared of the edifices of ancient Egypt, Greece, and Rome.

Of course, in constructing a modern building of granite and other volcanic materials neither an economical nor a beautiful result would be secured without an intelligent study of their nature and capabilities. Like precious stones, their beauty is only revealed by burnishing, but this process is just that which renders them supremely suitable in the fuliginous climate of London. The hard impenetrable surface is cleaned down by every shower. I have passed the Crimean monument, Westminster, frequently during past years, and I perceive no change whatever in its polished granite shaft,—no decay, no dirt. Not so the freestone canopy, which is black with absorbed soot and other defiling *debris*.

An experience of twenty years gives me great confidence in asserting that a building constructed with the simplicity of detail necessary to exhibit the natural beauty of these materials would entail little if any extra cost. There need be no elaborate mouldings or deeply-cut carvings. As we all know, some of the noblest structures of ancient times are strikingly simple in their details. Their architectural effect would be utterly ruined by increased richness. A few splays of larger or smaller size were all sufficient for perfect work in those days. The old buildings of Burgundy show what excellent architectural effect may be obtained by simply applying two or more materials in masonic construction.

Working upon these lines, a careful comparative estimate by a well-known surveyor, prepared from detail drawings of the front of a bank,—one of richly carved Portland stone, the other of burnished granite, porphyry, and serpentine,—gives three per cent. only in favour of the former, which as we have seen would require much subsequent outlay in repairs, while the latter would entail none.

The too common use of polished granite in combination with dull freestone is, to my mind, an inartistic proceeding. As well put new cloth into an old garment. But I will here try to describe a newedifice. Comparatively small stones should be used, so that decoration may be almost entirely dependent upon construction. The bulk of the building should, I think, be of white, or nearly white, granite from Cheesewring, Gannislake, Par, Okchampton, or Kemnay, with the lines of construction emphasised with dark grey Dalbeattie, green Portlesco serpentine, rose syenite from Montsouris, and black basalt from Cleve Hill or Rowley Regis.

These colours are all of subdued character. Indeed, they are tints rather than colours. As none of the primaries exist, a gaudy effect would be impossible. Thus treated, the facades would require little additional ornament. A little mosaic of the choicest of the materials in spandrels, panels, and strings would probably satisfy the most refined taste.

A simpler treatment would be to have one colour only for the ornament on the white ground of the general surface, similar to the exterior of the duomo of Monreale in Sicily.

It would be departing from the simplicity of this proposal to hint at such a mosaic frieze as that to the exterior of the New Museum, Berlin.

I have said nothing of architectural style, because this is mainly a question of construction, and is more or less applicable to any style.

If such an edifice as I have ventured to suggest could be realised for the New Government Offices, it would not only be truly economical from its extraordinary durability, characteristic of this scientific age, and, doubtless, of sufficient architectural beauty; but it would at once and for ever do away with the reproach of the foreigner that Englishmen,—practical Englishmen,—are unable to cope successfully with a practical difficulty,—the erection in London of a really durable building. Surely such a national benefit is well worthy of the administrative powers of the First Commissioner of Works.

H. TRAVIS.

INTERNATIONAL HEALTH EXHIBITION.

VENTILATING APPARATUS FOR DWELLINGS, WORKSHOPS, AND MINES.

In the Western Gallery, along with various other mechanical appliances, are to be seen some ventilating apparatus, the exhibitors of each claiming some speciality in connexion therewith. With rival schools of ventilation, and claimants asserting priority of invention in regard to certain principles, it is difficult, perhaps, to steer a safe course; but we will endeavour to be just without being invidious in our criticisms. We must be candid at once in saying to all, or nearly all, the exhibitors of ventilating appliances, that though improvements in details are manifold, and though useful modifications have been introduced, ventilation, as a system, has not made such rapid progress within this century as many persons imagine. We will first describe a few of the appliances on view, and further on we will allude to what was accomplished long years ago, but which seems to be ignored by our rival schools of the present day. It may be possible that exhibitors save an odd one or two, are not posted up in the history of modern ventilation, or are in ignorance of what was attempted and accomplished many years before they were born.

Messrs. R. W. Hale & Co., Chalton-street, N.W. (Stand 1,125), exhibit registered air-pump ventilators designed for the inlet of fresh-air and the exhaustion of vitiated air. We are told that these are applicable to all classes of buildings, hospitals, schools, factories, ships, sewers, &c. The ventilator on this stand comprises a series of cones fixed at an angle of forty-five, divided by what are termed haffle-plates. The ventilator is not still in calm weather, but keeps in motion as if there was a stiff breeze, though not, perhaps, with such quick action. Down-blow is prevented by the arrangement of the haffle-plates. The inlet ventilator is constructed with a sleeve acting in telescope manner, to suit the thickness of any wall. The air, before it enters the room, has to traverse a conical tube, where the stream or current is converged to a focus. It then impinges on the air contained within a second cone, thus acting as a "cushion," so called. The current of air becomes broken up, as it were, and is then distributed through a perforated grating into the room "without impact and without draught." As far as we could test these ventilators and examine them by the light of experience in regard to similar appliances, we were favourably impressed by their construction. The exhibits include inlet chimney-breast and extraction ventilation. Chimneys have often been capped, but if the exhibitors' "chimney caps" do their work effectively from all points of the wind, they will indeed be a blessing to perplexed householders, who have more sad experience of draughts than pleasing ventilation. Messrs. Robert Boyle & Son, Holborn Viaduct and Glasgow (Stand 1,126), exhibit, among other appliances, patent air-pump ventilators, chimney-cowls, and soil-pipe ventilators. The well-manufactured appliances of this firm have been more than once described in these pages. We may briefly say the action of these ventilators is continuous, the hot vitiated air is extracted, the fresh air being admitted through louvre openings. The current is scarcely perceptible, and down-draught is prevented. It was well understood long since that hot air naturally ascends, being the lighter body, but some of our recent exhibitors, though apparently knowing this, allowed the current of cold air entering the room from above to force down again the foul air to be rebreathed, by not adapting their system to meet admitted wants. The chimney-cowl is composed of a cylinder set into, and in prolongation of, the brickwork of top of the flue. This cylinder has a varying diameter according to different circumstances, being made to enlarge or swell into a large circular box formed of two truncated cones inversely joined, the aperture of the upper one being of a diameter equal to that of the cylinder. Surmounting this construction is another truncated cone held up a certain height from the lower structure by suitable uprights, and finally the whole is crested or crowned with a hollow conical cap, also supported a few inches higher by uprights. The action is as follows:—The smoke ascending the flue strikes before escaping from the inside of the top cap, then passes into the conical box, which is at once heated

by connexion, so that a comparative vacuum is formed there, sucking up and creating the desired continuous draught. Mr. B. B. Stirrat, Newcastle-on-Tyne (Stand 1,129), shows steam radiators, steam heating combined fresh-air warmer and ventilator, indirect steam-heating coil, return water feeder, and plans of buildings heated by steam. The radiators are simple in their action, taking the water from the coils and returning it without waste of heat. There is economy of fuel and ease in attendance. The appliances are applicable to breweries, sugar refineries, paper-mills, &c. Mr. James Howarth, Victoria Works, Farnworth, near Bolton, shows a large assortment of ventilators of all kinds, suitable for rooms, public buildings, and workshops. In point of manufacture the exhibits are good. The patent chimney-breast ventilator for ventilating rooms by means of the flue from the fireplace appears to be a very serviceable appliance. Mr. George Segrave, Wellington Buildings, Chelsea, S.W. (Stand 1,133), displays his hot wind generators for ventilating hospitals, houses, and heating the same, also for disinfecting, deodorising, flushing, and drying. Stewart's patent high-pressure blower, shown on this stand, for accomplishing the ventilating and drying process, is a differential blower, its action being derived from two blades, within a cylinder revolving with varying velocities around a central shaft, concentric with the axis of cylinder. The velocity is controlled by the eccentric cross-head acting upon the crank arms outside the cylinder. The advantages are double-action, the charge of air (or other fluid) being delivered twice each revolution; there is no gearing, no valves, no dishing composition needed, and finally the action is positive and in no way dependent on high speed. Driven in the opposite direction the outlet becomes the inlet port, and vice versa, the action being reversible, applicable alike to exhausting and blowing. Messrs. J. L. Bacon & Co., Gloucester-place, N.W. (Stand 1,137), have on view several excellent exhibits in relation to heating and ventilating, but the chief of these we have recently described. It is needless to say that the manufacture is good, and, judged by present standards, the articles merit adoption from their suitability. The hot-water heating apparatus of this firm has met a public want, as is shown by the number of public buildings into which it has been introduced. Messrs. Hill & Hey, Halifax (Stand 1,168), present models of their patent Excelsior Syphon, or double-current ventilators, for buildings and workshops, &c., without other means of inlet, wall ventilators, and others for roofs, and dining, drawing, and bed rooms. The double-current ventilators are intended for outlet or exhaust, "enabling the arrangement of inlets below to be dispensed with." Fresh air is here stated to be brought in, and vitiated air extracted efficiently. An excellent induction mine and colliery exhaust ventilating fan is shown by Messrs. Henry Aland & Son, Commercial-road, E. (Stand 1,171). In fans of the kind the blade travels double the speed of the air, hence a great vacuum takes place behind the blades. Here, however, the vacuum is filled with air by openings in the side plates or cones of the revolving propeller. The intake of the fan is increased to nearly the diameter of the revolving impeller itself. The fan can be used for a large volume at low pressure or a restricted volume at high pressure. These ventilators are applicable to buildings and factories as well as to mines, and can be fixed in any position. We consider the triplicate mine and colliery exhausting fan a very efficient apparatus. The single and double geared hand ventilating fans are also very serviceable ventilating appliances. The first-named fans are made in sizes from 3 ft. to 12 ft. in diameter, the latter being of sufficient capacity for the largest coal-pit works. The Blackman Air Propeller Ventilating Company, Fore-street, E.C. (Stand 1,173), display a number of their appreciated propellers. The special feature consists in the construction of the blades towards the periphery, so arranged to prevent the radial escape of the air, but causing a directly increased current over the large area created. The propeller is adapted for the removal of heated or foul air, or dust, and in drying processes.

If the reader keeps in mind some of the principles put forward in connexion with the ventilating systems and apparatus above described, and compares them with what we state presently, he may be inclined to say that in our grandfathers' days, or even previously,

men knew something more of ventilation than we give them credit for. In the last quarter of the eighteenth century, M. Le Roy, member of the Royal Academy of Sciences, Paris, in his observations on the construction of hospitals, which were accompanied with plans, made some very pertinent suggestions on the subject of ventilation. The general construction of hospitals in his day was objectionable, because the majority of the wards did not admit of perfect ventilation, the air passing from one patient over another, as it does still in several of our British hospitals. M. Le Roy held that a large hospital should consist of distinct and separate buildings, each forming one ward, crested upon arches or columns, at a considerable height from the ground, and ranged at a distance from each other like the tents of an encampment. The ceiling or roof of each ward was directed to be formed with a number of spherical arches, according to its size, the crown of each arch being in the middle of the breadth of the ward, and opening into a funnel like a common chimney, which should be supplied with a vane [or cowl], so that it might be always open to leeward. In each floor, midway as to height, there was to be a row of holes of suitable distances from each other, to admit air from below, so constructed that the quantity of it might be regulated at pleasure. In consequence of this structure M. Le Roy says,—"There must be a constant change of air; for that which is in the lower part of the ward, being warmed by the patients and nurses and the necessary fires, will ascend, and in consequence of the spherical construction of the roof will be directed to the openings in it, and flow through them, while the holes in the floor will afford a constant supply of fresh air, which will move rapidly as it enters the room so low." Then follow directions for placing grates or stoves over the holes in the floor, for warming purposes, and other arrangements for quickening the circulation of the air. Verily some of the representatives of our rival schools of ventilation must have been flitting the brains of dead men, or is it that congeniality of thought produces similarity of expression? Let us appeal to history again. Up to 1782, of 17,650 infants born alive in the Lying-in Hospital, Dublin, 2,940 had died within the first fortnight, nearly every sixth child, or 17 in the 100. The disease was known then as the *black fits*, another form was known as the *white fits*,—forms of convulsions and wasting respectively. Dr. Clarke, the master of the hospital, came to the conclusion that the disease was owing to the following causes:—(1), Foul air; (2), neglect of keeping the children dry and clean; (3) the irregularity in the manner of living of their mothers, more especially in the abuse of spirituous liquors. The first cause appeared to be the principal one; for there was lack of proper ventilation in the hospital. To remedy the serious defect, Dr. Clarke carried out a number of alterations for the better ventilation of the hospital. Apertures of considerable size were made in the ceiling of each ward, which were after some trial changed for air-pipes of 6 in. diameter. Three holes, of 1 in. diameter, were bored in an oblique direction through each window-frame at the top. The upper part of the doors entering the gallery were also perforated with a large number of holes. By these means an easy inlet was given to the air through the wards at all times, and so executed as to put it out of the power of the nurses or patients to control. The beds were reduced in number in the large wards, and more cleanly and airy arrangements were made. The result of this simple method of ventilation a century ago was shown daily in the fits of the children becoming less frequent. By 1789, of 8,033 children born after the new system of ventilation was adopted, only 419 died, or a little over one in fifteen. See what ventilation did in the saving of human life even in days when men were scarcely credited with knowing anything practically about it. Our advance, after all, is not very great in the principle of ventilation or the science thereof, though it must be admitted our appliances have largely increased for admitting fresh air to our dwellings, workshops, and mines, and extracting the foul air therefrom. There is growing a manifest tendency in our midst to ignore the labours of our social and sanitary pioneers and reformers, which should be combated. Water, said the poet Pindar, is the best gift of Heaven, but what would it be in the absence of pure air in our workshops and dwellings?

## HEALTH EXHIBITION LECTURES.

## HEALTHY HOUSES.

On the 24th ult. Mr. T. Prigdin Teale, F.R.C.S., delivered a lecture at the International Health Exhibition on "Healthy Houses."

Mr. F. S. Powell, in the absence of Captain Douglas Galton, C.B., through indisposition, presided, and in the course of his remarks observed that the lecturer held high rank in his profession, but his industry had not been confined to the duties of his profession, strictly so-called. He had given great attention to the application of science to the domestic arrangements of a home.

Mr. T. Prigdin Teale said that there were 24,000 medical men in the United Kingdom whose lives, abilities, and energies were devoted to the preservation of health and the cure of disease, and yet until the last few years there was scarcely a house in the kingdom which was not at times a source of illness, and there were very few households who knew, or appeared to know, whether their houses were not manufactories of disease. When, some years ago, he expressed his conviction, in the course of a lecture he delivered before the Leeds Philosophical Society, that very few houses were safe to live in, he was looked upon as an enthusiast; but now such a statement would be looked upon as a truism, so great had been the progress in the diffusion of sanitary knowledge and in the identification of sanitary facts. Sir James Paget had lately spoken of the diminution of preventible diseases during the last ten years, and this progress had been more the result of greater knowledge of sanitary matters on the part of the public than of legislative interference. Much remained to be done, but a great deal could be effected by the carrying out of the sanitary laws we possessed. The basis of all true sanitary progress must be the spread of sanitary principles among the people. Every old house in the kingdom should have its sanitary arrangements revised on the principles adopted in recent years, and every new house could be made perfectly healthy, which would be done if those interested in its construction made themselves acquainted with improvements in sanitation. Proper arrangements were more simple and economical than faulty ones. The lecturer described the horrid state of the kitchen of his father's house when he, a little boy, saw the floor taken up in consequence of the place being overrun with rats, a foul drain running beneath the house. The scullery-sink was some distance from the outside of the house, and the contents of the sink went into an old-fashioned drain, which emitted a very foul smell. Perhaps the simplest and most universal of our sanitary arrangements was the sink, and if people knew what a sink really ought to be they would have made considerable progress in sanitary education. The sink carried away the refuse of a house, but as long as it was connected with drains carried under the house so long would there be risk of disease. A true sanitary maxim to be followed in building a house was to let no drain be under any part of it, to disconnect all waste-pipes and all overflow-pipes from the drain, and to place the soil-pipes outside the house and ventilate them. It was a great thing to get the refuse as quickly out of the house as possible. The principles he had just mentioned any one might make himself acquainted with and carry out. The lecturer referred to baths, lavatories, and closets generally in connexion with the principles he had laid down, insisting strongly on the importance of disconnecting the houses from the drains. He also alluded to the fact that some of the faults of construction of the houses were due to ignorance, while in other cases they were to be attributed to rascality. There was a very reprehensible practice of putting in "seconds" pipes,—the effect of which was to make faulty drains, merely because the builder found these "seconds" pipes cheaper than sound ones. The lecturer illustrated his meaning by reference to diagrams arranged on the walls. He was afraid there were thousands of houses which had untrapped sink-pipes passing into the drains. The lecturer proceeded to make some practical remarks in regard to the necessity of the isolation of the sick in the cases of infectious diseases, and dilated on the importance of keeping out dust and dirt from the larder. He also insisted on the necessity of a good water-supply, of good

ST. PAUL'S CATHEDRAL.

Copy of full-sized Cartoon for proposed Mosaic Decoration of the Dome. Designed by Mr. E. J. FOYSTER, B.A.  
The central circular compartment by Sir F. LEIGHTON, P.R.A.

...ation, and on economy and cleanliness in use of fuel, quoting the following passage in a leading article in the *Times*: "Sir Henry Acland took a very proper tone when he reminded the Conference of the necessity of economy and simplicity. Common sense would lead upon striking a rough balance of risks and costs. It was important, therefore, to keep down the cost whether in money or trouble, and Sir Henry Acland said it was astonishing how little was often required to make a house decent and safe without imposing on the owner or upon costly things which it was difficult to cure, and complicated things which it was difficult to maintain." A vote of thanks to the lecturer and the chairman terminated the proceedings.

ANGLO-SAXON FOOD AND DRESS.

This was the subject of a lecture delivered at the International Health Exhibition on the 1st ult., by Mr. J. Frederick Hodgetts. The lecturer commenced by observing that he intended to bring before his audience a brief sketch of what was known in reference to the food, dress, and dwellings of their own predecessors. In dealing with questions having a social and historical bearing we were often led by the absurd bias of writers to trace the origin of all that was great and good which was foreign to ourselves and to our progress as a nation. Our true ancestors, from whom we derived everything English, were somehow shuffled off. The history of England, therefore, according to many authorities, commenced with the appearance of the foreign conqueror, who was called erroneously the first king of England. One glowing writer began his history with another foreigner, the third William. The advent of the first William never came too much dwelt upon. The English never came Norman. The few hundred Normans, these self-styled rulers of this land, never affected the English language nor modes of thought, although eight centuries ago there were jobs who copied those in power and spoke French. But that died out. The Norman sounds had nothing in common with the English language. Professor Max Müller, of Oxford, had pointed out that language could not be mixed. Words might be introduced, but the true spirit of a language could not be affected by them. Our early ancestors came from Scandinavia in the fifth century, and they remained Pagans until Rome sent missionaries to these shores and converted them to Christianity. They never were conquered by Rome; they took her Christianity, of her. Then came the monasteries. The monks wrote their books in Latin, but left our English pure. The English speech was a plant of Northern growth. This language and our early history should teach us, when a question arose as to English thought and style, the authority of the Latin school. The freedom of speech, the customs and modes of thought which we cherished, were all of Scandinavian origin. The Romans were never our ancestors, but the Romans tried to stamp us out. He came to say something which would sound unfamiliar. Our early home was Scandinavian; we were from the South of Scandinavia proper. Therefore some of the roots of our words would be found more like those of the Germans than if we had dwelt farther north. Of course, in tracing the early history of a people, the effects of climate and religion in forming habits of life had to be borne in mind. The people of Scandinavia were accustomed to cold and hunger and thirst, and they had to contend with wolves and bears and other wild animals. The first requirement of man was food, and accordingly our ancestors manufactured rude weapons with which to slay the animals, the flesh of which was to yield them food. In the far north there was a preference for the flesh of boars, but in the south and far east the swine was an abomination. Our forefathers had soups of the most appetising and nutritious kind, made from the flesh of birds, rabbits, venison, &c. They were also in possession of the knife and the perforated spoon, a refinement that showed them to advantage. In Scandinavian homes of the fourth century, halls for the refectory of warriors by great chieftains were numerous, and in early representations of a meal, we found the knife, the spoon, and plate laid on the table. Our forefathers came to Britain as people now went to New Zealand, and our nation was more rich than the Anglo-Saxons in tales of the past. In the centre of

the hall stood the hearth, which was never absent from the great houses of our ancestors of the sixth century. They had smoked meats and batten fish, puddings, oyster patties, loaves large and small of various kinds of bread, eggs, cheese, and butter. From very early times the table-cloth was in common use. Our ancestors had various kinds of drinks, and wine was imported from Italy. They had the swan, duck, water-fowl, salmon, eels, pilchards. All food that required it was sweetened with honey. There were pears, peaches, melons, plums, cherries, and altogether the Anglo-Saxons were well provided in the matter of food. The lecturer made copious extracts from Sharon Turner's "History of the Anglo-Saxons," which, he said, had never been approached for accuracy by any other work on the subject. From the almost innumerable articles of food and drink mentioned by him, it was evident that the Anglo-Saxons by no means fared badly. Friar Tuck, although a portraiture of a later age, was alluded to as not being a bad sample of the Anglo-Saxon of the tenth and eleventh centuries, as far as good living was concerned. The lady of the house had her special seat when she was present. On some occasions the ladies sat side by side with the warriors. Coming to the next branch of his subject, Mr. Hodgetts observed that of course in the matter of dress woman reigned supreme. The Anglo-Saxon ladies were distinguished by the wimple or hood. Their dresses were very long, covering the feet; they were loose, the sleeves being tight at the wrist. There was no attempt at distortion of the body in order to make a waist. The mantle was also a part of their attire. The costume of the females in those days was characterised by greater simplicity than that of the males. The true Englishwoman was in the sixth century as she was now, modest, proud, and good. The warrior was certainly rather "loud" in his attire. Woman's dignity supplied that attraction which men had to borrow from dress. Let us be proud of our English mothers and honour them in their descendants. The Normans were not English, so his remarks did not apply to them. The lecturer proceeded to say that dyes of various colours were in common use, and alluded to a variety of specimens of ornaments worn in Pagan times; these ornaments could be inspected in the British Museum, and would be found interesting. Ladies had bracelets, necklaces of amber, exquisite beads, &c. The hair was worn plaited behind or round the head like a coronet. The mantle was richly edged with gold. There was one mantle worn for ornament, and a larger one well lined with fur to keep out the cold. The boots were neatly made. It did not appear that since the introduction of Christianity very great progress had been made in the matter of female costume. After some further remarks, Mr. Hodgetts said that he found he had not time to enter upon the history of Anglo-Saxon houses, as he had intended, but on a future occasion he might have an opportunity of going fully into the subject.

The Chairman (Mr. Morgan) expressed regret that Professor Hodgetts had been compelled to leave out the third part of his lecture, but he had given them a very interesting account of the language, food, and costume of the Anglo-Saxons, and he was sure the ladies would join him in cordially thanking the lecturer. No doubt many of them would take an opportunity of inspecting the specimens of ornaments which had been referred to as being in the British Museum.

Captain F. S. Dumaresq de Carteret-Bisso agreed with the lecturer that for beauty there was nothing to compare with the pure English language. As regarded the female dress in early periods of history being a loose one, he happened to have been at a lecture given on English dress by Mr. Lewis Wingfield, at which a breast-plate like a piece of armour was exhibited as worn by Queen Boadicea.

The lecturer, in acknowledging the vote of thanks, remarked that there never was a breast-plate worn by a lady or anybody else in the fourth century. Agam, Boadicea was not an English woman. If she had a tight-fitting dress our female ancestors had none. The proceedings terminated with a vote of thanks to the chairman, moved by Mr. Trendell.

The Proposed New Battersea Bridge.

It is stated that the Metropolitan Board of Works have decided to construct a temporary foot-bridge across the Thames during the building of the new Battersea Bridge.

Illustrations.

DESIGN FOR THE DECORATION OF THE DOME OF ST. PAUL'S.

WE publish this week a small copy of the coloured cartoon of the proposed mosaic decoration for the dome of St. Paul's, designed and executed by Mr. E. J. Poynter, R.A.; with the exception of the larger circular panel, which has been designed and executed by Sir F. Leighton, P.R.A. The illustration is from a coloured drawing specially made for us at Mr. Poynter's studio, and with his permission, by Mr. Raimbach. We add also larger illustrations in monochrome of the two subjects in the large circular panels, "Christ in Judgment," by Mr. Poynter, and "The Sea gave up her Dead," by Sir F. Leighton. These are reproduced by the "ink-photo" process, from photographs taken by Mr. Bedford Lemere, and are therefore absolutely correct, as far as drawing and design.\* We have thought that many of our readers, professional and non-professional alike, would be glad to have a carefully-executed representation of a work which is of national interest, and which is likely to excite much attention at present.

It was expected that by this date the cartoon would be fixed in its place in the dome and exposed to public view; and we had not intended, in fact, that our publication of the design should anticipate the exhibition of the original; but we understand that unforeseen difficulties in fixing the cartoon, as well as other causes, have retarded the preparations longer than was expected, and it will probably not be open to public inspection for a few days yet.

From a memorandum furnished to us by Mr. Poynter we collect the following statements as to his ideas in regard to the design. When he was first consulted on the subject the idea was that Alfred Stevens's design should be carried out, the subjects in the large circular panels and the seated figures below alone being changed. Stevens's design illustrated the Old Testament; he only designed half the dome, and it is not clear what his intentions were in regard to the other half. The work he actually did covers about the same ground as the ceiling of the Sistine Chapel. The Committee thought these subjects unsuitable for that part of the cathedral, and preferred that the subject should be taken from the Book of Revelations, and that the figures of prophets below should be replaced by the figure of St. John the Evangelist and those of the bishops of the Seven Churches of Asia,—not, to our thinking, a very happy idea, as the eight figures in the eight compartments of the dome certainly should all be of equal importance; the architectural conditions offer no suggestion for making one figure predominate over the rest, as St. John certainly should predominate over the bishops. However, this was the idea; the general lines of Stevens's design were to be followed. Sir F. Leighton was commissioned to paint the subjects of the eight large circles, and Mr. Poynter was commissioned to draw out the whole design, and to design the subjects of the smaller circular compartments above. Stevens's design divided the dome into eight compartments, by what might, for want of a better name, be termed ribs, answering to the eight blocked-up windows or solid piers of the drum, each compartment containing two circles, the upper one necessarily smaller than the lower. The "ribs" are built up of figures and architecture; above each pedestal which forms the base are three magnificent nude figures, an imitation of Michelangelo in style, but of which Mr. Poynter observes that Michelangelo himself perhaps never did anything finer. The reasons for putting aside this fine work were twofold. Some of the committee thought nude figures unsuitable,—an objection which, considering the entirely abstract and ideal character of the figures, we should call merely a truckling to the Philistine; but a more logical objection was that these living figures supporting a mass of architecture were performing a perpetual acrobatic feat, and it was impossible to avoid the feeling that if one of them made the slightest movement the whole thing would come toppling down. It was obvious that it was necessary to give to the whole "rib" a truly architectural character, and that the retaining of Stevens's figures would render this

\* We are indebted to the courtesy of the Dean and Chapter for the opportunity of photographing Sir F. Leighton's painting, which had been for some time completed and under their charge.

Church of St. Mary, Portsea.—Plan. Scale, 32 ft. to 1 inch.

an impossibility, so that there was no alternative but to abandon them. Accordingly the ribs were designed as an architectural framework, as seen in the present illustration, with figures riched in them; and it occurred to Mr. Poynter that these figures should be brought into relation with the Apocalyptic subjects in the main compartments. The most suitable way of doing this seemed to be to represent in these figures the chorus of praise, "Worthy is the Lamb" (Rev. iv., 12, 13), and thus give to these otherwise merely decorative figures a distinct meaning. He therefore replaced Stevens's upper groups of three struggling figures by three angels singing, and who are supported by the architecture instead of supporting it; and with these it is proposed to alternate groups of martyrs who also surrounded the throne. Above, instead of the single angel who supports the cornice in Stevens's scheme, are placed two youthful cherubs, seated singing (in the style of the old Italian pictures), and for the group of nude figures (finally and regretfully set aside), Mr. Poynter has substituted groups representing saints on earth, each accompanied by an angel, these groups being also designed to illustrate some appropriate text from one of the Psalms of Praise. In a circle above all, which was run round under the lantern, will be the "Four-and-twenty Elders," and it is proposed to continue the illustration in the lantern with "the four beasts" (as the word is quaintly translated in our Bible), and the Agnus Dei in the centre at the top of all.\* There will be thus a consistent scheme for all the figures external to the panel subjects, beginning at the top with the Lamb to whom praise is sung, and continuing downwards in proper order of progression through the four beasts, the four-and-twenty elders, and the angels and martyrs, to the saints on earth receiving inspiration from angels, and lowest of all to the seven churches, who are the embodiment of Christ's church, with St. John as the central figure. The portion now designed includes the figure of St. John hearing the voice saying "What thou seest write in a book"; the voice being symbolised by the angel descending and putting a pen in his hand; a cherub holds the book. The lower group on the rib illustrates the verse "Ye holy and humble men of heart, bless ye the Lord"; and appropriate texts in the same spirit will be found for all the others which are to be executed hereafter. The subjects of the panels are prescribed by the Committee, and are sufficiently noted in the titles to the illustrations. The upper one Mr. Poynter has kept as simple as possible, owing to the great height at which it will be seen, and the same feeling seems to have influenced Sir F. Leighton in the composition of his panel.

Thus the general disposition of Stevens's design is retained; the panels and the ribs

\*The drawing of these so as to have an intelligible appearance to the eye from below will be, we should say, a curious and rather tough problem in perspective.

remain where they were, and the groups of figures remain in the same places; but the meaning and detail of the whole is changed. Indeed, it may be said that Stevens's design in many of its features, grand as it is, has little or no meaning, which is certainly a serious critical objection to it.

We have confined ourselves to description at present; when the actual cartoon is visible *in situ*, so that its effect as seen from below can be judged of, we may have further remarks to make. We may add here that a good deal of gold will be introduced into the mosaic design, but it has not been thought advisable to use actual gold in our small illustration, as the effect would be quite different on a small scale. The two circular panels in our larger illustrations are shown the same size; their actual relative dimensions can be seen from the general illustration.

#### NEW PARISH CHURCH OF ST. MARY, PORTSEA.

This church is designed to take the place of the present one, which is an unsightly and inconvenient structure.

The new church will be built in sections, of which it is proposed first to undertake the nave and aisles, affording accommodation for 1,400 adults on the floor. It is intended that the completion of the church should, if necessary, be spread over several years, and that nothing should be done to curtail or mutilate the original design permanently. The tower will probably be the last section to be built.

The walls of the church will be constructed with an outer casing of flints, stone ashlar within, and between these a filling in of Portland cement concrete. A dado of red terracotta will be carried round the walls internally. Doulton stone will be used for the external stonework and Bath stone within. The roofs will be of open timber, except that over the sanctuary, where there will be a ceiling of groined stone covered externally with leaded roof of flat pitch.

The view of the church is reproduced from the drawing which is at present in the Architectural Room at the Royal Academy. We propose to give the sections of the church in a subsequent number, as the interior design presents some details that are unusual and interesting. The whole church promises to be an exceptionally fine one when completed.

#### PRAYER-DESK, HOARWITHY CHURCH, HEREFORDSHIRE.

THE prayer-desk which we illustrate this week has been executed by Mr. Harry Homs from the designs of Mr. J. F. Seddon, for Hoarwithy Church, near Ross, Herefordshire, of which Mr. Seddon is the architect. The prayer-desk is devoted, as far as its sculpture subjects are concerned, to the illustration of the legend of St. Dubricius, who is traditionally supposed

to have had a large monastery almost upon the site where stands the present church. The right panel of the front of the desk represents the birth of the Saint, whose mother was condemned to be burned alive, and was found the next morning sitting on the funeral pile with a new-born babe in her arms, the future St. Dubricius, who is represented in full canonicals in the adjoining panel. The side panel on the right in our illustration shows the Saint casting out the Devil from a woman (an achievement which has tasked the efforts of saints in various ages), and on the panel seen on the left he is setting to rights an unfortunate monk who was accused of having stolen wine from the cellar of the fraternity, a charge which was satisfactorily but rather illogically disposed of by the Saint, who blessed the barrels and caused wine to flow from them again. It is to be hoped the brother was really wrongfully accused, and that the Saint was not *particeps criminis*.

Whether it is worth while, or even in every sense suitable, to decorate a modern church with these rather foolish legends, to which it will be observed, no moral whatever attaches, is a question we do not discuss, and which we should, perhaps, be told was out of our province. We give the desk merely as a good piece of work in design and execution, rather inclining to wish that both architect and carver may on another occasion light upon an historical subject better worth treating.

#### THE MURRAY TOMB, ST. ANDREW'S, WELLS-STREET.

As something special was said at the recent Conference of Architects about the late W. Burges and his works, we need not apologise for illustrating a very pleasing design of his, executed a good many years ago, but which, we believe, has not been published hitherto. It is a monument in St. Andrew's, Wells-street, and is a remarkable example of Burges's large and bold treatment of Gothic detail. It is photo-lithographed from a pencil drawing by Mr. J. Attwood Slater, which has its interest also as a good example of architectural sketching.

By an unfortunate oversight, this was named in an advertisement last week as from an original sketch by Burges himself; a mistake arising out of the fact that we were arranging for the publication of some original pencil sketches by the late G. E. Street, and a phrase intended for the one item in the advertisement was inadvertently applied to another. The publication of the Street sketches was not announced, as their reproduction in lithograph presented some difficulty, and rendered their immediate publication doubtful. This has been surmised, however; and in place of one original sketch by Burges which was promised, we are able to give two by Street which were not promised, which we hope will be regarded as restoring the balance of accounts between ourselves and our readers.

THE LATE WM. BURGESS, A.R.A., ARCHITECT.

TWO SKETCHES BY THE LATE  
G. E. STREET, R.A.

THESE two sketches at Bonrres are two out of half a dozen pencil sketches by Street which his representatives have placed in our hands for publication. They show at once what they are; the rapid sketches of an architect, seizing the main outline and effect in a few comprehensive lines, and filling in as much of the detail as was necessary as a memorandum. The others of the series we hope will follow, but it depends somewhat on fate and sunshine; pencil being a doubtful and capricious medium for reproduction by photo-lithography.

THE WORK OF MEDIEVAL AND  
MODERN CRAFTSMEN.

THE SOCIETY FOR THE PROTECTION OF ANCIENT  
BUILDINGS.

THE seventh annual meeting of this society was held on Tuesday afternoon in the Hall of the Society of Arts. The Hon. R. C. Grosvenor, presided, and, in moving the adoption of the report, observed that the committee had been much assisted in their work by their secretary, Mr. Thackeray Turner, who was a gentleman thoroughly competent to look at a building and see at a glance whether it was worthy of being preserved; and since they had had the advantage of his services the committee had been able to act with greater vigour and success than previously.

Mr. H. W. Brewer seconded the motion, and the report was adopted unanimously.

Mr. William Morris then read a paper on "The Essential Difference between the Work of the Medieval and the Modern Craftsman." He commenced by observing that the members of that society, at least, knew the beauty of the weathered and time-worn surface of an ancient building, and they had all felt the grief of seeing that surface disappear under the hand of the restorer, but though they all felt that deeply enough, some of them might perhaps be puzzled to explain to the outside world the full value of that ancient surface. He was sure that, as members of that society, they could not doubt that in one way or another the surface of an ancient building,—that was, the handiwork of the old handicraftsman,—was most valuable and worthy of preservation, and he was sure also that they felt instinctively that it could not be reproduced at the present day. The attempt at reproduction not only deprived them of a monument of history, but also of a work of art, and he had to attempt the task of showing that this impossibility was not accidental, but was essential to the conditions of life at the present day,—that it was caused by the results of all past history, and not by a passing taste or fashion of the time. Consequently no man or body of men, however learned they might be in ancient art, whatever skill in design or love of beauty they might have, could persuade, or bribe, or force the workmen of today to do their work in the same way as the workmen of the time of King Edward I. did theirs. It must be admitted that every architectural work was a work of co-operation. The very designer, be he ever so original, paid his debt to this necessity in being in some form or other under the influence of tradition. Dead men guided his hand even when he forgot that they ever existed. But, furthermore, he must get his ideas carried out by other men; no man could erect a building with his own hands. In all co-operative work, the kind and quality of that work,—the work of the ordinary handicraftsman,—was determined by the social conditions under which he lived, which differed very much from age to age. Let them try to see how they differed, and glance at the results to art of that difference, during which inquiry they would have much more to do with the developed Middle Ages, with which the work of their Society was chiefly concerned, than with any other period. In the Classical period, industrial production was chiefly carried on by slaves, whose persons and work alike belonged to their employer. It was natural that, under such circumstances, industrialism should be despised; but under Greek civilisation at least, ordinary life for the free citizens,—the aristocracy, in fact,—was simple. The climate was not exacting of elaborate work for the purposes of clothing and shelter; the race was yet young, vigorous, and physically beautiful. The aris-

toocracy, therefore, freed from the necessity of rough and exhausting work by the possession of chattel slaves, and little oppressed by anxieties for their livelihood, had both inclination and leisure to cultivate the higher intellectual arts. Well, the ideal of art established by the intellect of the Greeks with such splendid success lasted throughout the whole Roman period also, in spite of the invention of the arch in architecture, or rather in building. The open-mouthed contempt for the results of industrial production expressed by the pedant Pliny, whether it were genuine, or artistically deduced from the conventionalities of philosophy, well illustrated the condition of the slave-produced lesser arts of the later classical period. Meantime, and while Pliny was alive, the intellectual arts of classical times had long fallen from their zenith, and had to wade through weary centuries of academicism, from which they were at last redeemed by the break-up of classical society itself, which involved the change of chattel slavery, the foundation of classical society, into serfdom or villeinage, on which the feudal system was based. The serf in the earlier Middle Ages was, however, in a very different condition from the chattel slave, for certain definite duties being performed for his lord he was (in theory at least) at liberty to earn his living as he best could within the limits of his manor; the chattel slave, as an individual, had the hope of manumission, but, collectively, there was no hope for him except in the complete and mechanical overturn of the society which was founded on his subjection. The serf, on the other hand, was, by the conditions of his labours, forced to strive to better himself as an individual, and collectively soon began to acquire rights amidst the clashing rights of king, lord, and burgher. Also quite early in the Middle Ages, a new and mighty force began to germinate for the help of labour,—the first signs of secular combination among freemen, producers, and distributors. The guilds, whose first beginning in England dated from before the Norman Conquest in all probability, had their roots in that portion of the European race who had not known of Rome and her institutions in the days of her temporal domination. England and Denmark were the foremost countries in the development of the guilds, which took root latest and most feebly in the Latinised countries. The spirit of combination spread, and the guilds, which had at first been rather benefit societies or clubs than anything else, soon developed into bodies for the protection and freedom of commerce, and rapidly became powerful merchant guilds. In the height of their power there was formed under them another set of guilds whose object was the regulation and practice of crafts in freedom from feudal exactions. By the beginning of the fourteenth century the supremacy of the craft guilds was complete. At that period their constitution was thoroughly democratic. Pure journeymen there were none; the apprentices, as a matter of course, took their places as masters of their craft when they had learned it. The craftsman of that day lived far easier than his successor now. He made his wares himself and sold them himself to the man who was going to use them. Some of the rarer goods, such as silk cloth, did come into the chaffering market, but even these were made primarily for home consumption, and only the surplus came into the hands of the merchant, who was not a mere gambler in the haphazard of supply and demand, but an indispensable distributor of goods. The people were good judges of manufactured wares, and consequently adulteration was scarcely known. The freemen of the guilds had their share in the pasture lands of the country. Port Meadow, at Oxford, for instance, was the common pasture of the freemen of that city. The English craftsman of the fourteenth century was not a priest-ridden or down-trodden savage, but a thoughtful and vigorous man, and in some sense free. He worked not for the profit of a master, but for his own livelihood, which he did not find difficult to earn. He had a good deal of leisure, and being master of his time, his tools, and his material, he could afford to amuse himself by giving artistic finish to his work. That artistic finish was not venal,—it was given freely to the public, who paid for it by interest in, and sympathy for, the work itself. What is called in modern slang the wages of genius were much neglected by the holders of ancient buildings; for art, as Mr. Thorold Rogers

justly said, was wide-spread; the possession of some skill in it was the rule, and not the exception. As a rule, those who could afford to pay for a building were able to do the necessary planning and designing, obviously because they would naturally find help and harmonious intelligence among the men they had to employ. For instance, the tower of Merton College, Oxford, was carried out by ordinary masons under the superintendence of the Fellows of the College. Judging from the wretched tinkering that the present Fellows had allowed to be perpetrated on their beautiful little house at St. Alban's Hall, he would not venture to trust them with such a work now. When they heard it said that extra money payment was necessary under all circumstances to produce great works of art, they could appeal to the witness of those lovely works still left to them, whose unknown, unnamed creators were content to give their talents to the world with little more extra wages than their pleasure in the work and their sense of usefulness in it. Well, it seemed to him that a body of artificers so living and so working with simple machines, of which they were complete masters, had very great advantages for the production of architectural art. But as the towns grew bigger, and population flowed to them from the enfranchised field-serfs and other sources, the old craftsmen began to form a separate and privileged class in the guilds, with their privileged apprentices, and the journeyman at last made his appearance. After a while the journeymen attempted to form guilds under the master crafts, as the latter had done under the merchant guilds, but the economic conditions of the time, tending towards manufacturing for a profit, beat them, and they failed. Nevertheless the conditions of work did not change much, until the first quarter of the sixteenth century, during which England, from being a country of tillage, cultivated for a livelihood, became a grazing country farmed for a profit. This had a very direct influence upon the conditions of life and manner of work of the artisans, for the crafts were now flooded by the crowds of landless men who had nothing but the force of their bodies to live upon, and were obliged to sell that force day by day for what those would give them who certainly would not buy the article labour unless they could make a profit by it. The Reformation itself was but one of the aspects of the new spirit of the time produced by great economical changes which dealt with Art and its creator Labour far more completely than any series of accidents could do. Though there was still a good deal of what might be called domestic manufacture, the workmen in the towns became more dependent on their employers,—more and more mere journeymen,—and a great change was coming over the manner of their work. Division of labour now began, and speedily gained head. Almost all goods, except those made in the most domestic way, had now to go through the market before they reached the user's hands; they were made for sale, not primarily for use. The division of labour had so worked that instead of all workmen being artists as they once were, they were divided into workmen who were not artists and artists who were not workmen. This change was complete, or nearly so, by the middle of the eighteenth century. The gradual degradation of the arts from the fifteenth century to this point was steady and certain. The picture-painters, what few of them were aught else than mere pretentious dabblers, were turned into courtly flatterers of ill-favoured fine ladies and stupid supercilious lords. As for the architectural arts, what could be expected from a set of human machines,—co-operating, indeed, but only for speed and precision of production, and designed for, at best, by pedants who despised the life of men, and, at worst, by mechanical drudges little better in any way than the luckless workmen? Whatever might be expected, nothing was got but that mass of foolish toys and costly ministrations to luxury and ostentation which had since those days been worthily continued under the name of upholstery. But that was not the end of the degradation of the arts. At the close of the eighteenth century the manufactures in England were still secondary to her merely country life, and mixed with it. In fifty years more England became the manufacturing country of the world; the "workshop of the world," often so called with much pride by her patriotic sons. This strange and most momen-

ious revolution was brought about by the machinery which the chances and changes of the world forced on the population. Whereas under the eighteenth-century division of labour system a man was compelled to work for ever at a trifling piece of work in a base mechanical way, under the system of the factory and the almost automatic machines of the present day, he might change his work often enough. He might be shifted from machine to machine, and scarcely know that he was producing anything at all. In other words, under the eighteenth-century system he was reduced to a machine; under that of the present day he was the slave to the machine. The machine workman had to be well skilled, at least, in his contemptible task; the slave to the machine needed but little skill, and, as a matter of fact, his place had been taken by women and children, and what skill was needed in the work was in the overlooking of the labourers of these latter. In short, the present system of the factory and its dominating machine tended to do away with skilled labour altogether. They set their slave to the machine to do the work of the free Medieval workman, or of the man of the Transition period, indifferently. They had learned the trick of masquerading in other men's clothes, and carried on a strange hypocritical theatrical performance, rather with timid stolidity than with haughty confidence, determined to shut their eyes to everything seriously disagreeable, nor heeding the silent movement of real history which was going on around and underneath their rare show. Surely such a state of things was a token of change,—speedy perhaps, complete certainly,—of the visible end of one cycle and the beginning of another. The society of today, anarchical as it was, was nevertheless forming a new order, of which the members of the Society he was addressing, in common with all those who had the courage to accept realities, were and must form a part. They were contending for the reality of art; that was to say, the pleasure of the human race. The tendency of the commercial or competitive society which had been developing for more than 300 years had been towards the destruction of the pleasure of life. But that competitive society had at last developed itself so far that its death was approaching. When society was so reconstituted that all citizens would have a chance of leading a life made up of due leisure and reasonable work, then would all society resolve to protect ancient buildings from all damage, wanton or accidental; for they would begin to understand that these were a part of their present lives,—a part of themselves. That would come when the time was ripe for it; for at present if people knew of their loss they could not prevent it, since they were living in a state of war,—that was to say, of blind waste. Surely the members of that society had had this truth driven home practically often enough. They had often had to confess that in the destruction of an ancient monument of art and history was a matter of money it was hopeless striving. Let them admit that they were living in a time of barbarism, betwixt two periods of order,—the order of the past and the order of the future,—and then, though there might be some of those who thought, as he did, that the end of that barbarism was drawing near, and others that it was far distant, yet they could work together to preserve what relics of the old order were yet left them for the instruction, the pleasure, the hope of the new.

A vote of thanks was given to Mr. Morris for his address.

**City of London Society of Artists.**—On the evening of the 27th ult., on the invitation of the Lord Mayor, a large number of ladies and gentlemen assembled at a *conversazione* in the Library of the Guildhall, to meet the members of the City of London Society of Artists, which was established four years ago. The object of the Society was to form a permanent Gallery and an Academy for the instruction in the higher grades of the Fine Arts, as well as to sell or otherwise dispose of pictures, sculpture, or other works of art exhibited from time to time by its members. So successful has the project proved that the Society now consists of 67 members of the Royal Academy and other eminent artists, 107 Fellows and Guarantors, and many members of the Corporation.

#### SANITARY LEGISLATION.

CONFERENCES AT THE HEALTH EXHIBITION.

On Thursday and Friday, the 26th and 27th of June (as mentioned in our last, p. 953), conferences were held on the above subject under the auspices of the National Association for the Promotion of Social Science. Sir Richard Temple, bart., the President, occupied the chair, and opened the proceedings by calling upon Mr. Francis S. Powell to read an introductory address.

Mr. Powell, in the course of his paper, stated that the Statute-Book bore record that during many centuries the nation was in some measure, according to the knowledge of those times, alive to the necessity of protection against nuisances and other conditions dangerous to health. It was, only, however, since the commencement of the present century that Parliament had passed Acts of wide range. This country, indeed, must always be remarkable for the rapidly-increasing density of the population; for the insanitary conditions incident thereto; for the energy and knowledge applied to the diabolical and removal of those conditions; and, lastly, for the stringency of the statutes dealing with this class of evil. The visitations of Asiatic cholera were, no doubt, a principal cause of the mind of the country being aroused to the necessity, as well as the duty, of thoroughly investigating and legislating upon matters relating to public health. The General Board of Health, the first central authority, was established in 1847, and this was followed by a series of general statutes and by Lord Norton's Sanitary Commission, which recommended various valuable reforms. These reforms were sanctioned by Parliament, and in 1875 Mr. Selater-Booth's Public Health Act was passed. Few statutes had so long and so well stood the test of public criticism. Under that Act much that was permissive was made compulsory, and there was but one authority, for public health purposes, in every place, whilst one central authority presided over both the Sanitary and the Poor Law Authorities throughout the country. Complaints had been made of want of powers, but it was by no means certain that this was well founded, if the 340 sections of the Act were well enforced. Experience had taught him that powers which were necessary in dense populations would be intolerable in rural districts. The statute contained a provision for conferring urban powers on rural authorities, thus enabling districts to obtain the advantages without experiencing the inconvenience of urban powers. It was a satisfaction to him (Mr. F. S. Powell), as the author of this provision, to observe the results. Before May, 1883, 444 orders conferring those urban powers had been issued, and those districts had thus obtained by a simple procedure the benefit of any urban power which the circumstances required. The sections of the Public Health Act which would first demand reconsideration were probably those which related to offensive trades. Meanwhile, the Alkali &c. Works Regulation Act of 1881 imposed severe restrictions on the conduct of alkali works, and what might, in general terms, be described as chemical works. By the operation of this Act 976 works were registered up to the close of 1882, and there was good reason to hope that the sections of this Act, and the action of the inspectors under it, would restore vegetation to wide districts which were blighted by noxious emanations, and render them once more such that the inhabitants might dwell therein without suffering inconveniences destructive to comfort and the enjoyment of life. Mr. Powell next referred to the Act for the Prevention of the Pollution of Rivers, passed in 1876, remarking that the most difficult problem,—that of the Thames Valley,—was still not satisfactorily or finally solved. Although the question of watersupply had occupied much of the attention of the Legislature for ten years past, it could not be regarded as certain that the people of this country were duly impressed with the necessity of obtaining an ample supply of wholesome water, or of guarding from contamination the water when supplied to each house. He thought there was much reason to regret that the Legislature had not made general the principle embodied in many local Acts which enforced the notification of infectious disease. Public attention was at length aroused, and was fully directed to the most complicated question of the homes of the people, but it was premature to further remark upon this matter until the

issue of the Report by the Royal Commission. It should not be forgotten, however, that the homes of the people depended upon the people themselves, and that neither cubic space, nor sound construction, nor sanitary arrangements, would attain their end if indolence suffered dirt to remain; if neglect failed to make due use of the best appliances; if reckless, almost savage, violence destroyed that which was provided for the comfort, nay, even the safety of life. Education itself, unless due regard were paid to the conditions of youthful life, was proved to be a danger.

Mr. H. H. Collins, F.R.I.B.A., then read a paper entitled "What Conditions are essential for a Healthy Dwelling, whether in an Urban or in a Rural Locality; and how far is it desirable that they should be rendered Compulsory by Legislation?" The substance of this paper was printed by us last week (see p. 953, vol. xlv.).

After a few remarks from Mr. F. S. Powell, in which he expressed grave apprehensions as to the system adopted in the building of lodging-houses in London,

Mr. Board, steward to the Duke of Bedford, moved a vote of thanks to Mr. Collins for his very able paper. The question of housing the people was one of great importance to the inhabitants of the metropolis, and every effort should be made to get rid of insanitary dwellings, and to put a stop to the practice of overcrowding. As regarded lofty houses he agreed with the observations of Mr. Collins, and he must say he had viewed with much concern the disposition to raise such buildings without sufficient areas around them. Instead of being a benefit to the working-classes he was afraid these lofty buildings were likely to prove a curse. He doubted the necessity of crowding particular neighbourhoods with artisans' dwellings, because he thought that many of the trades carried on in London could be as well removed into the country, or, at least, into the suburbs. If they ensured workmen and work-women employment in their trades they would readily follow their employers into the country. Until we could educate the people properly in sanitary matters we must compel them to act up to the law.

Mr. Stanley Bird mentioned instances in which cesspools had been found under in excavating for the foundations, and urged that there was a great necessity for compulsory legislation. While speaking with all respect of sanitary engineers, he thought there was too strong a tendency amongst some of them to expend their energies in the invention of traps and such like appliances which should be connected with their names as the inventors.

Mr. Arnold spoke of the deficiency of powers to provide for efficient ventilation.

Mr. Craig thought it was very desirable that Parliament should appoint a Mission of Health. Mr. J. H. Bridges, M.B., was then called upon to read a paper, the subject of which was, "What, if any, restrictions in the interests of health should be enforced in connexion with the employment of girls and women in workshops and factories?" He pointed out that the most important extensions of factory legislation that had been proposed were:—1. Restriction on the employment of mothers, namely, that it should be illegal to employ them for a period of six weeks after childbirth. 2. Extension of the Workshops Act to domestic occupations. 3. Extensions of it to various wandering occupations; as to chimney-sweepers (already under special, but possibly insufficient control), errand boys, street performers and musicians, news-boys, match-sellers, &c. 4. Restriction of hours of labour in retail shops. It was evident that a strong case might be made out in favour of each of these proposals. The arguments in favour of the first was obvious. It was admitted that women in Lancashire frequently returned to work within a few days of their confinement. When they remembered that work with these women meant incessant watching of four looms, through each of which the shuttle passed three times a second for ten hours a day, and that during those ten hours they could never once sit down, every one might imagine, though no one but a medical man could fully appreciate, the enormous, the atrocious, imprudence of such an act as this. In view of the inevitable miserable consequences, the question was, should women be protected in this matter from the pressure put upon them, sometimes by brutal and drunken husbands, sometimes by stupid and greedy overlookers? Should their freedom of returning to work be curtailed by

law? Should it be an offence knowingly to employ any woman within six weeks of childbirth? This prohibition had been enacted in Austria, and, he believed, in Switzerland. After considering the arguments for and against, he had come to the conclusion that a case was made out for legal prohibition. The second change he would advocate was the assimilation of factories, so far as sanitary inspection was concerned to workshops,—that was to say, their subjection to the Health Authority of the district, whose officer should be instructed to visit them, in the ordinary discharge of his duty, and not, as at present, on the special invitation of the Inspector of Factories. Those two changes excepted, he had but little hope for the remedy of the grievous evils connected with the condition of women in workshops, and above all the domestic workshops, from a further extension of minute inspectorial supervision. The real and practical remedy for the evils complained of would seem to be an organised concentration of public opinion on the condition of low-paid labourers, such as would lead a skilled workman to refrain from ordering his clothes at a slop-shop, or a fashionable lady from changing her fashion rapidly, or ordering her dress in a hurry. He did not despair of a time arriving when through the wide diffusion of sound principles on this matter, the skilled mechanic and the rich lady, and every one of them rich and poor, would be restrained by the unwritten law of conscience from purchasing any article for which there was reason to believe that the maker of it had not been duly paid, or had been unduly worked.

The Chairman having invited discussion, Mr. John Arnold wished to remark, on behalf of the very unfortunate class of girls who worked in dressers' shops, whose case had been touched upon by Mr. Bridges, that the hours these girls were employed, frequently in close and unhealthy shops, were excessive, and the girls were on their feet all day long.

Mr. Edwin Chadwick said it had been proved that there was nothing gained by the long hours of work in the factories of Lancashire, and he thought workshops should be visited once a week by medical officers of health.

Professor de Chamont observed that it appeared to be thought by some that legislation was the panacea for all evils. He sympathised with the overworked girls and women in shops whose hardships had been referred to by Mr. Arnold, but the difficulty of applying legislation to their cases was very great.

After a few words from the Chairman the meeting adjourned.

At the second meeting of the Conference, held on Friday, the 27th, Sir Richard Temple again presiding, papers were read by Mr. G. W. Hastings, M.P., entitled, "Is it desirable that Notification of Infectious Disease should be Obligatory?"; and by Mr. A. H. Brown, M.P., on "Is it desirable to Legislate further respecting the Duties of Medical Officers of Health?"

Mr. Hastings, M.P., in the course of his paper, observed that the question of making notification of infectious diseases was first brought forward in a paper read at Brighton in the year 1875, and since that time, in thirty-eight towns, some system of compulsory notification had been adopted, while during the present session several others would receive similar powers. It was, therefore, too late to say that notification should not be made obligatory because the results could not be foreseen. The real question was whether notification should be made universal, and if so, under what conditions? He might mention the case of Edinburgh, where the system was in force, and had been attended with the most satisfactory results. The duty of giving notice of the existence of infectious disease there devolved on the medical attendant, and no objection had been raised to it. Dr. Littlejohn, the Medical Officer of Health of Edinburgh, had reported that from the year 1879, when the system was introduced, up to the end of 1883, he had received notifications to the number of 21,710, of the existence of typhus, typhoid, diphtheria, scarlatina, and small-pox. Notification had been attended with the happiest consequences in checking the spread of those diseases. Similar testimony had been given by medical officers in other towns, and as applications for compulsory powers were constantly coming forward, it seemed desirable that a general Act should be passed enabling every town or district to apply such measures without

having to go to the expense of a special Act of Parliament.

Mr. James Bailey and Mr. William Young both protested against compulsory notification as an interference with the liberty of the subject.

Alderman Pollard, of Halifax, remarked that compulsory legislation in the matter of infectious diseases had been in force in that town for two years, and he was convinced that it had been the means of saving many lives. He believed the death-rate arising from zymotic diseases was lower in Halifax than in any of the large towns the returns of which had been published by the Registrar-General.

Dr. Dudfield also strongly advocated the adoption of compulsory notification of infectious diseases.

Dr. Wallace, of Greenock, expressed the opinion that without compulsory notification they would not be able to do very much in the way of preventing the spread of infectious diseases. He had not the slightest doubt that the mortality of all towns or districts would be greatly diminished by the adoption of compulsory notification by medical men.

Prof. de Chamont thought the objections urged against compulsory legislation on this question were not well founded. There was no doubt that such legislation was necessary, but great care and tact must be exercised in bringing compulsory notification into general practice. He was as great an advocate of the liberty of the subject as any one, but he could not understand how opposition to a measure having for its object the prevention of the spread of infectious diseases, could be maintained on that ground. He wished to get rid of the idea that this movement for official notification was got up for the aggrandisement of the medical profession, for the small fees that were charged were not likely to be a great temptation.

Mr. Hastings, in the course of his reply, said this was a question which chiefly affected the poor, and he did not understand that "liberty of the subject" which would allow disease and death to go on unchecked. He had heard the objection as to the interference with the liberty of the subject brought forward in the House of Commons, and there was, in fact, no nonsense too great to be talked in that assembly of the collective wisdom of the nation, simply because the members would not take the trouble to acquaint themselves with the real facts.

Mr. A. H. Brown, M.P., then read his paper, in which he discussed the question, "Is it desirable to legislate further respecting the duties of Medical Officers of Health?" The various conclusions which Mr. Brown arrived at in his paper may be summed up as follows:—First, that combined districts, giving large areas to medical officers, were advisable; secondly, that the areas should be of such a size and population as to occupy the whole time of a medical officer in his public duties, and therefore he should not have a private practice; thirdly, that the medical officer should be approved by the Local Government Board, because it made him more independent for the term of his appointment; and the term of his appointment should be lengthened. With regard to this latter point, the Local Government Board, in their twelfth annual report, made the remark that hitherto it had been the practice to appoint the officers employed for single districts for short terms, usually not exceeding two or three years; but with the experience which had been gained, since the passing of the Public Health Act of 1872, of the nature and the extent of the duties devolving upon those officers, it appeared to the Board that under certain circumstances they might now not improperly assent to a somewhat more extended term of office. Fourthly, that it was not advisable to give medical officers any independent authority, nor was it advisable to give them any power of appeal from the Local Boards either to any proposed new authority, or to the Local Government Board; fifthly, that the principle of making the medical officer of health a county officer and paying him out of the county rates, would not get over the difficulty, for any expenditure for sanitary purposes must be local expenditure, and would be opposed on the same grounds as now. Finally, that the best means of promoting sanitary improvement and awakening Local Boards to their duties, was by the force of public opinion, by public discussion, and by conferences similar to the present.

In the course of the discussion which followed,

Mr. E. Chadwick remarked that Mr. Brown had rendered good service in the cause of sanitation, and he hoped he would continue his exertions in the cause.

Dr. Saunders was of opinion that until medical officers of health felt themselves secure in their appointments, and that they could not be arbitrarily discharged, their hands could not be so strong in the performance of their duties as they ought to be.

Dr. Wallace corroborated the view expressed by the last speaker as to the necessity of security of tenure in their appointments as medical officers. They ought to feel that they could not be removed except by the Secretary of State. It was absurd that in a large town or city a medical officer of health should be liable to removal at the caprice of a local body elected annually. One of the greatest difficulties medical officers had to contend with was the securing of healthy homes for the working classes.

Mr. Dudfield was of opinion that medical officers required to use discretion in putting in force the powers which they possessed, but he thought it absurd that there should be so many defects in sanitary arrangements, while there were such powers as at present existed for their removal.

Mr. Brown, in replying on the discussion, observed that some local Boards did their duty very well, but he must say that in many instances they did not properly support their medical officers of health in the matter of sanitation. He was quite of opinion that the term of appointment should be lengthened, and that medical officers of health should not be liable to removal, except by the Local Government Board. They would thus become more independent, and their opinions would have more force. It appeared, from a paper supplied by the Local Government Board, that out of 577 Rural Sanitary Authorities, the medical officers of 527 were paid by Parliament to the extent of one-half their salaries, and with the condition that they could not be removed by their Local Boards for the term of their appointment except with the consent of the Local Government Board. There were 947 Urban authorities, and the same remark applied to the medical officers of health of 579 of them. It would be understood that of these last figures were the number of authorities, not the number of medical officers; for one officer often superintended several districts.

The Chairman, in closing the discussion, observed that the papers read had been written with remarkable ability, and were inspired by humane and enlightened principles. He trusted the result of the Conferences would be satisfactory, not only to those of the public who were interested in sanitary matters, but to the officials of the National Association for the Promotion of Social Science, under whose auspices the Conferences had been held.

On the motion of Mr. Edwin Chadwick, a vote of thanks was accorded to the President, who briefly acknowledged the compliment, and the proceedings terminated.

#### ARTISTIC TAPESTRY PAINTING.

MR. EDOUARD RISCHGITZ, of 42, Linden-gardens, W., has opened what purports to be the first English Exhibition of Painted Tapestries. The quality which a painting upon any textile fabric must have to make it worth the attention of those who look for a principle when they set about decoration is permanence. And this quality Mr. Rischgitz claims for his work. The "Compagnie des Peintures artistiques" who exhibited their work in London two or three years back were the first to discover this secret of giving absolute permanence to paintings executed upon woollen or animal fabrics (on a vegetable fabric it is said this cannot be done). But the secret of the "Compagnie des Peintures artistiques" rests with them, and Mr. Rischgitz has had to discover his method for himself. In all painting of this kind acid is used with the colours. This acid must afterwards be removed by a process which gives, at the same time, fixity to the painting,—a process which, by way of analogy only, may be compared with that of firing in china-painting. Mr. Rischgitz's painted tapestry will wash, and, generally speaking, may be submitted to any cleaning process not injurious to the fabric itself. It thus appears to be a genuine and legitimate industry, and not to be ranked in

## CHURCH BUILDING NEWS.

**Mevagissey.**—A meeting has been held to consider proposals for the restoration of the parish church, which the vicar describes to be in so dilapidated a condition that it is in danger of being blown down. An effort was made for obtaining funds for the work some eight years ago, but unsuccessfully. It is stated in a local paper that plans and specifications were then obtained from Mr. St. Anby, architect, and Mr. Henderson offered to restore the body of the church for 1,000*l.*, erect a tower for 2,000*l.*, and extend the chancel for 100*l.* Total, 1,300*l.*

**Bromley Common.**—Holy Trinity Church, Bromley Common, was re-opened and a new apse consecrated by the Archbishop of Canterbury, on the 23rd ult., after having been closed during restoration. The old building was erected about forty years ago, and was built on a very awkward plan, having a very shallow chancel, no organ-chamber, and inadequate heating apparatus. The present additions consist of an apse giving greater depth to the chancel, an organ-chamber with space underneath for Grundy's hot-air apparatus, choir-stalls, an oak and stone pulpit, &c., the chancel being raised above the level of the nave floor, and projecting into the body of the church. New seating in pitch-pine has been substituted in place of the old straight-backed pews. These improvements were carried out in memory of the late Mr. George Warde Norman by his family, and a memorial tracery window of four lights, filled with stained glass by Messrs. Clayton & Bell, has been put in by the children of the late Mr. Henry Norman. The total cost of the restoration, including an organ by Mr. Henry Jones, of the Fulham-road, will be under 2,000*l.* Mr. William Smith, of Bromley Common, was the builder employed, under the direction of Mr. C. Pemberton Leach, architect, 31, Spring-gardens.

**St. Stephen's-by-Lanuceston.**—The ancient parish church, dedicated to St. Stephen, at St. Stephen's, near Lanuceston, has for some time been in the hands of the restorers. St. Stephen's is the mother church of Lanuceston. The church stands upon high ground, and consists in plan of a nave, north and south aisles, chancel, north transept, and a south porch with parvise and tower. The edifice is generally of grey granite, but polyphant the beautiful soft finely-grained stone of the district, has been largely introduced into the new masonry. The restoration of the church has long been felt to be most desirable, and at length the task was entrusted to Messrs. Hine & Odgers, architects, Plymouth. From the plans of these gentlemen the work is being carried out by Mr. Henry Burt, builder, of Newport, Lanuceston. The new roofs assume the ancient wagon type so prevalent in the West. They are covered with lead outside, and within are of pitch-pine, and enriched by carved oak bosses. The stalls are of oak, and have sculptured angels in attitudes of adoration carved upon their ends. These are by Mr. Harry Hems, of Exeter, who has also done the carving appertaining to the new roofs. The new Perpendicular windows are of polyphant stone, and are glazed with cathedral-tinted glass. The plastering has been stripped off the walls, and these are now neatly pointed. There is no pulpit and no seating in the body of the sacred edifice. It is the intention to use chairs,—at least for the present. An exceedingly handsome feature in the chancel is the new reredos, which is erected immediately under the east window. It is, in the main, of Bath stone with polished Devonshire marble columns. The sculpture is of Caen stone. The crowning feature is a high crocketed gable springing from supporting and pinnacled buttresses, whilst at either side are three panels, containing fleurs-de-lis, and surmounted by a cornice of carved worked and pierced masonry. The central panel contains a sculptured representation of the Crucifixion, each figure in the group standing out in high relief. This is also the work of Mr. Harry Hems.

**Newcastle-on-Tyne.**—A new church, to be called St. Jude's, is to be built in the district of Shieldfield, Newcastle-on-Tyne. Mr. Arthur B. Plummer, A.R.I.B.A., Newcastle, has been appointed the architect.

**Gateshead.**—On the 27th ult., the ceremony of laying foundation stones of the Church of the Venerable Bede, at Sunderland-road, Gateshead, was performed by Mrs. Edward Joyce and (in the absence of Lady James) by Sir Walter James. St. Bede's is one of three

churches to be built under the Gateshead Church Extension Scheme, which provides for the erection of between twenty and thirty new churches throughout the diocese. The general arrangement of the new church, the contract for the erection of which has been let to Mr. Alexander Thompson, is in the form of a Latin cross, and consists of a nave, north and south transepts, chancel, vestry, and organ-chamber. The nave is 29 ft. wide and 89 ft. 6 in. long; the north transept, 32 ft. 6 in. by 17 ft. 6 in.; the south transept, 32 ft. 6 in. by 20 ft.; the choir and sacristy, 32 ft. by 24 ft.; the vestry, 19 ft. 6 in. by 13 ft. 6 in.; the organ-chamber, 18 ft. by 13 ft.; and the north porch, 14 ft. 6 in. by 19 ft. As there are no aisles, and consequently no nave arcade, every one will be able to see the preacher. The entrance doors will open outwards, and the whole of the walls will be built of stone, faced with sneck walling, the thicknesses of the walls being based upon the scale of dimensions required by the Ecclesiastical Commissioners. When finished, the building will accommodate 624 adults. The cost will be 5*l.* a sitting. Messrs. Oliver & Leeson are the architects.

## STAINED GLASS.

**Westminster Abbey.**—At a meeting held last week in the hall of the Institution of Civil Engineers it was decided to erect in Westminster Abbey a memorial window to the late Sir W. Siemens. It was resolved, in order that the tribute should be of a truly representative character, to limit the amount of subscription to 1*l.* from each person. An executive committee was appointed, consisting of the president and two members of each of the five societies represented at the meeting. Mr. James Forrest was appointed secretary and treasurer.

**Paramatta.**—There have been placed in position in the eastern wall of St. Patrick's Church, Paramatta (says the *Cumberland Mercury*), three stained glass windows, presented by Mr. T. H. Rawlings, as a tribute to the memory of the ability, zeal, and worth of the late prelate of the Catholic Church, Archbishop Vaughan. The design,—by the donor,—has been faithfully and tastefully executed by Messrs. Ashwin & Falconer, of Sydney. It embraces full-size representations of St. Benedict, in the habit of his order; the Crucifixion,—showing at the foot of the cross, in group, St. John, the Virgin Mary, Mary Magdalene, and St. Thomas.

**Columbia Market.**—According to Mr. David Scott, of 94, Commercial-street, E., this costly gift to the East End of London has a more fortunate career before it than for a long time, seemed probable. Mr. Scott, in a letter to the *Morning Post*, writes:—"Six months ago the fruit and vegetable department of this market was opened by the twenty-six salesmen who were compelled by law to remove from the Great Eastern Railway Depot at Bishopsgate to Columbia Market, and it is not too much to say that the efforts of the salesmen have been rewarded with the most complete success. This once unlucky place is growing in importance every day, and would grow still faster and be a greater means of benefit to food consumers if some half dozen or so of those who send their produce to Spitalfields would avail themselves of the undoubted advantages offered by Columbia Market, relieving themselves of the high tolls and charges and want of accommodation, the prevailing features of Spitalfields Market. The idea of failure in connexion with Columbia is a thing of the past, thanks to the generous liberality of that noble-hearted lady, the Baroness Bardett-Contts, and the business tact and hearty co-operation of Mr. Bardett-Contts."

**Truro Cathedral.**—On Sunday last the Bishop of Truro gave the second portion of an address in St. Paul's Cathedral on the claim that the Truro Cathedral has on the entire country. His lordship stated that unless 15,000*l.* was forthcoming by the beginning of August a beautiful design would be spoilt by having to place a temporary roof on unfinished walls. His lordship urged those who had abundant wealth and every luxury to give, say, an organ, a pulpit, or a reredos, to the cathedral of the west, besides helping to find the 15,000*l.*

## The Student's Column.

**T**HOUGH our columns are professedly intended for and addressed to proficient in the artistic and practical branches of the architectural profession, we have always had every desire to give assistance or information to beginners who have asked for it, as not a few have from time to time. It has occurred to us that, without modifying in any way the main character of the literary and critical matter of the *Builder*, we may be able to furnish our younger student readers, those who are commencing the study of the rudiments of architecture and professional practice, with a page or two written especially for them, and addressed to those who are only just learning, and not assuming on the part of the young reader the existence of anything more than elementary knowledge of the outlines of the subject.

We propose, in this Student's Column to carry on successive series of short articles on artistic and practical subjects, by various contributors specially qualified to treat such subjects. We have found the idea has excited considerable interest both among some of our old and tried coadjutors, and among others who are offering us their hearty and valued co-operation for the first time in this endeavour to add a specially educational feature to our pages.

By way of beginning at the beginning, we give this week the first of a short series of comprehensive lectures on the study of architecture, going over the characteristics of the various styles and their historic and artistic relation to one another. These lectures, as they may be called, have already in substance been delivered to the students in connexion with a well-known architectural society, some of whom will, perhaps, recognise what they will be glad to have a record of in permanent form; and we could hardly begin better than by giving wider circulation to what has already been found useful and interesting by a small circle of students. These will be succeeded by other series on such subjects as foundations, drainage, wood-work, iron-work, construction generally, and various other subjects connected with the endless interests of professional architectural work.

We may add also that we shall be glad to make this column a medium for answering questions such as young students may often have occasion to ask during the time when they are first brought face to face with the very various problems which the study of architecture suggests.

## HINTS FOR THE STUDY OF THE HISTORY OF ARCHITECTURE. I.

Most buildings, up to the date of what is known as the "Renaissance," three or four centuries ago, are clearly referable, by the evidence of their own appearance, to some particular date and locality. Photography places them, as it were, in our very hands, and the great charm and pleasure to be derived from a study of the History of Architecture lies in the being able to assign such date and locality to any example. The pleasure is, of course, enhanced by visiting the locality and there ascertaining the date.

A sketching trip, even in our own country, affords a range of several centuries for this interesting amusement, for it really amounts to that, when one holds the threads that give the one to be followed out.

The Renaissance, which closed up certain recognisable styles of architecture, has, after all, only acted like a finger placed on a drop of quicksilver, and has merely dispersed it into countless smaller drops, making the synthesis a more laborious and more interesting task.

The whole history is like a web, composed, at first, of a few strands into which other strands, from time to time, are woven; and, supposing them to be of different colours, the predominance of any particular colour would indicate the prevalence of a style. Here and

there we should find a blending of several colours, harmonious enough, and in effect as different from those of the component strands as green is from blue or yellow. Other strands will pursue their own course, forming, as it were, a fringe that clings to the edge and forms a pattern of its one colour beautifully varied in texture only, and never mingling with the rest. Another strand of fierce colour will suddenly appear and dart off to permeate the web, and, by its very brightness, absorb its neighbours until they have sufficient energy to reassert themselves and to drive it back.

Now the results of these weavings, as evidenced by the buildings themselves, while they are interesting to the literary student, are far more instructive to the intending practitioner, who will see why certain architectural features have been adopted and improved upon, and perhaps discarded. He need, as a consequence, become no mere archaeologist, still less the slave of any one particular style; on the contrary, he will see that beauty is correlative to fitness, and, without making ridiculous attempts at originality, will produce buildings as typical of our time as the most ancient buildings are of theirs. His studies must be started in books, and, as he cannot be always visiting libraries, he will require some general authority constantly at his elbow for reference.

Although there are several excellent hand-books, put into as condensed a form as possible, and moderate in price, it will be worth the student's while to start with Fergusson's "Handbook of Architecture," and to have it bound in one volume. As one turns over the thousand and four pages of this work, the entire range of architectural history, down to the time of the Renaissance, is laid before one; the views are represented by excellent woodcuts; and the plans, sections, and elevations are drawn to uniform scales; while the letter-press is both historical and descriptive. There is only one thing wanting to complete the utility of the book, and that is a date to each illustration. The student can, however, by reading the context, add many of these dates himself, and derive much benefit from the process.

Fergusson's "History of Architecture" is an amplification of the former work, and proportionally more valuable; but the "Handbook," as the one most within the reach of a student's purse, is the work that will be generally referred to.

For those who can read French, Ramée's "Histoire Générale de l'Architecture," in two octavo volumes, will be found a very comprehensive work, and it is especially valuable on account of the lists of books on the various styles, given at the beginning of each chapter.

Rosengarten's "Handbook of Architectural Styles" is another octavo volume that, in addition to the ancient styles, includes Renaissance and Modern Architecture, and, with larger print and a greater proportion of illustrations, disposes of the whole in 509 pages; that is to say, in the English version edited by Professor Roger Smith. While proving very useful to those who cannot afford to purchase Fergusson's Handbook, it is also a valuable companion to it on account of the many and varied kinds of illustrations contained in it.

Another book, which is likely to be in the hands of students, is Gwilt's "Encyclopedia of Architecture," in which the first 226 pages are devoted to the History of Architecture, besides an appendix on Gothic or Pointed architecture.

Smith & Slater's "Classic Architecture" which was preceded by a work by the first author, and Professor Roger Smith's "Gothic and Renaissance;" these form a pair of useful hand-books, of which a notable feature is the analysis of each style.

For those who enjoy ingenious theories, treated by a man possessed of the most varied information and the most consummate skill as a draughtsman, Viollet le Duc's "Habitations of Man in all Ages" will open their eyes to many hitherto obscure forms and features. It has been translated into English by B. Bucknall. This wonderful and indefatigable author's other works will be alluded to in due course.

A book that is frequently referred to as a standard authority is Hope's "Essay on Architecture," the illustrations of which are in outline and bound separately from the text.

Another work which is devoid of all illustrations, excepting a frontispiece, is Freeman's "History of Architecture," devoted, however, chiefly to the honour and glory of Gothic architecture in distinction from previous styles.

Without pretending to exhaust the number of handbooks on the subject, the above will be found accessible to most students, and with the help of larger books, such as Gailhabaud's "Monuments Anciens et Modernes" and the works of d'Agincourt, du Sommerard, &c., will give him a fair notion of the various styles.

Fortunately, in London, we need not trust only to books for our studies, for the British Museum, the South Kensington Museum, the India Museum, and the Architectural Museum, in Tufton-street, contain many actual examples; and full-sized models of the architecture of all ages, and surely no Architect will begrudge his pupils the time to visit these collections with paper, pencil, and 2-ft. rule in hand.

Groups of two or three students will, by mutual assistance, get through an astonishing amount of measuring in a short time, being careful to take turns in measuring and plotting to scale, and making perspective views of the examples, otherwise he who is always plotting will not learn to handle his 2-ft. rule, and he who is always measuring will not realise the appearance of the object laid down in outline; while he who lays down the outline will not appreciate the light and shade of the object.

The Architectural Courts at the Crystal Palace will, to a certain extent, assist the student in realising the actual appearance of the originals; but, after all, there is nothing like visiting the originals themselves.

The air, the atmosphere, the smell,—often the dirt,—the people, the sounds, the journey,—all the surroundings of Architecture visited on the spot, exert their influence on the impressions produced by it. It is better to run down to Rochester or to St. Alban's or to Waltham or to Eltham, or to Windsor on a Bank Holiday, and to bring back a sheaf of, perhaps grimy, measured drawings, than to sketch in comfort at the Crystal Palace with a sense of hand and lungs and coffee pervading the place.

The same remarks are still truer of a week's trip across the Channel, or of a fortnight's trip to, say, Lombardy, or of a month's trip, say, to Greece or Sicily; but the longer the trip the greater the cost, and as the study of the history of architecture must begin at the beginning, and as that beginning is to be found a long way from England, English students must be content to make their first measured drawings from the collections above named.

Now, there are some styles of architecture which, although they cannot be put at the beginning of a consecutive series, like the threads that come to be woven in with other threads in the web, have still a decided colour and texture of their own. These are they which may be said to cling to the edge of the web, forming a fringe. Possibly future discoveries may prove a connexion between them and the consecutive styles; meanwhile, we may follow the example set by Fergusson in his "Handbook of Architecture," and dispose of "Indian," "Chinese," "Japanese," "Mexican," and "Peruvian" architecture as styles exerting no influence upon the other known styles.

NATIVE INDIAN.

Fergusson, in his Handbook, begins with the native architecture of this country, not because it is by any means the most ancient of the known styles, but because the country is such a long way off that the great conquerors of the world could not get at it, and consequently it kept itself to itself, and, with one exception that will be pointed out, the Architecture of its native religions neither influenced nor was influenced by the styles of other countries.

In illustration of this separate existence of India it is worth while to study such a book as Keith Johnston's work on "Geography, Physical, Political, and Descriptive," published by Stanford. In it may be seen a chronological series of small maps of the known world at twelve various periods, with the respective States and Empires indicated by different colours on them. In most of these, India sticks to its own colour, that is to say, until it carries the colour of the British Empire. Other writers also give India a separate chapter unconnected with other styles. Fergusson has, indeed, devoted a separate volume to the subject, published in 1876.

As a brief summary of the style, it may be said that it is divided into two classes. The earliest is devoted to the worship of Buddha, a religion that not only continues to exist, but, if we may believe the description on the model of the Sanchi Tope at the India Museum, now numbers more followers than the Christian

religion, though, curiously enough, none of these are in India, the land of its origin.

The other class of architecture that was developed in India is called Hindu or Brahmical, from the Brahmins or priests belonging to its two great sects worshipping Siva and Vishnu. Then there is Jainia architecture, a kind of offshoot from Buddhism, which appears to exist side by side with Hinduism.

After reading up these subjects in the books referred to, it will be worth while to visit the India Museum (on the opposite side of the road to the South Kensington Museum, and closing at four p.m.), and to measure the gateway and railing of the Sanchi Tope. These, although of stone in the original, are curiously suggestive of wooden construction, and the voluted ends of the cross beams should be borne in mind when the Ionic volute to be considered, later on, as referable to a wooden origin.

Another kind of tope, in the form of a column, may also be seen, namely, a pillar from Amravati, octagonal in plan, the alternate faces of which are delicately incised with a running leaf ornament, quite as well worth study as Medieval or other more recognised examples usually followed.

There are also some oil paintings representing the rock-cut Temples, which are curiously like the nave and aisles and apsidal ambulatories of a Gothic church, though there can hardly have been any connexion between the two.

Another point to study is the form of the pillars left to support the roofs of these temples; at first square, then with the corners cut off to form an octagon, then with sixteen sides, and gradually back to the square again, and supporting an evident imitation of wooden girders, binders, and joists!

Many other native peculiarities may be studied, but there is one class of examples to be found both at the India Museum and at the British Museum (on the staircase near the main entrance), which form the one exception to the exclusive character of Indian art. There are the "Græco-Buddhist" carvings from Peshawar, anciently known as the Bactrian colony of the Greeks, whose influence on the details and carving it is most interesting to observe.

BUILDING PATENT RECORD.\*

APPLICATIONS FOR LETTERS PATENT.

- June 20, 1884.—9,246, F. W. Coons, St. Louis, U.S.A., Engraving Marble and Stone.
- June 21.—9,263, J. Hobbs, Bristol, Chimney-caps or Wind-guards.—9,272, A. Kolvie, London, Clamp Window-blind.
- June 23.—9,303, W. Blackshaw, Birmingham, Cart for collecting pans containing night-soil, &c.—9,308, G. W. Chambers, Rotherham, Converting ordinary Grates into Slow-combustion Grates.
- June 24.—9,330, J. Parsons, Carlton, Joint for Sewage-pipes, &c.—9,331, Catlow, Burnley, Venetian Blinds.—9,332, J. Napier, Kirkcubright, Cooking Ranges.—9,335, E. R. Widgecombe, London, Safety Sash-fastening.—9,372, W. Rockliffe, Sunderland, Latches and Locks.
- June 25.—9,379, H. Shelmerdine, Liverpool, Construction of Soil-pipes, Rainwater-pipes, &c.—9,381, W. Glassey, Liverpool, Dadoes.—9,392, H. Knowles, Woodville, Kilns for Burning Bricks, Tiles, &c.—9,402, F. J. Nibbs, London, Roofing Tiles.—9,405, W. H. Luther, Glasgow, Sash Bars or Astragals.—9,414, J. C. Bromfield, London, Compound for Making Paving and Building Blocks, Slabs, &c.
- June 26.—9,441, G. Pollard, London, Union Joints for Pipes, &c.—9,450, M. Tohin, Uxbridge, Ventilating Buildings, &c.

SPECIFICATIONS ACCEPTED.†

- June 24.—32, H. H. Lake, London, Compound for Plastering or Stucco Work. Com. by H. E. Scales, Newton, U.S.A.

ABRIDGMENTS OF SPECIFICATIONS

Published during the week ending June 29, 1884.

- 4,944, A. C. Kennard, Falkirk, Heating Stove, (Oct. 17, '83, price 6d.)
- Above the fire-box are a series of vertical chambers, through which the products of combustion ascend and descend consecutively on their way to the flue, whereby all the heat therein is retained.
- 5,167, E. E. Allen, London, Portable Buildings. (Oct. 31, '83, 2d.)
- The frame-work of these buildings is made of wood, and between the two parts of each frame are secured sheets of corrugated metal. Double sheets may also be used, filled in between with sawdust, silicate cotton, felt, dry earth, peat, &c. (Pro. Fro.)

\* Compiled by Hart & Co., Patent Agents, 186, Fleet-street.  
† Open to public inspection for two months from the dates named.

5,281, J. L. Stevens and C. G. Major, London, Spring Hinges for Doors, &c. (Nov. 8, '83, 10d.)

To the heel of the door is secured a shoe, which has a short vertical spindle below, on which are two areas enclosed in a box below the floor. Each arm is connected to a piston travelling in a cylinder placed on each side of the spindle, and springs back on the pistons, which tend to force them to the further ends of the cylinders. The cylinders have two diameters, the smaller of which, at the further ends, exactly fit the pistons, and the heads of the cylinders are open. The box is filled with liquid, and when the door is opened one of the pistons is drawn out along its cylinder, the liquid passing freely round its periphery in the larger diameter of the cylinder, while the other is being forced back, compressing the liquid behind it in the smaller diameter of the other cylinder. Then the liquid acts as a cushion, and prevents any jarring or sudden motion of the piston, and therefore of the door.

7,329, J. N. Mocratti, London, Domestic Fire-places. (Nov. 10, '83, 1s.)

Above the fire on each side are air-mixing chambers, into which the smoke, &c., from the fire is drawn by several curved tyre-mouths opening just above the coal. These chambers are connected together by a number of horizontal pipes arranged to form a basket, in which are placed lumps of asbestos, and the smoke, &c., issues through holes in the pipes, and comes in contact with the asbestos, whereby it is consumed, to assist which process also there are other tyre-mouths, which draw in air from the room into the chambers, and thence to the pipes.

5,385, W. Walker, Birkenhead, Exhaust Ventilator. (Nov. 15, '83, 6d.)

A corrugated shaft is fitted on the top of the chimney, above which are one or more conical corrugated hollow truncated cones, one above the other, and a corrugated conical cap surmounts all. The wind striking these corrugations, passes up these cones, inducing a draught up the shaft.

5,421, E. Hurley, Birmingham, Closet-pan Apparatus. (Nov. 17, '83, 2d.)

Below the upper pan, which is the receiver, is another similar pan, into which the neck of the upper pan passes. The lower pan is connected to the drain, the outlet thereof being governed by a valve. (*See* *Proc.*)

5,435, T. E. Bladon and W. Matthews, Birmingham, Apparatus for Ventilation. (Nov. 17, '83, 2d.)

A fan is used, which has inclined vanes, which when the fan is revolved drives the foul air away through a tube.

#### MEETINGS.

WEDNESDAY, JULY 3.

Parkes Museum of Hygiene.—General Meeting, to receive report from Council, 8½ p.m.

THURSDAY, JULY 10.

International Health Exhibition (Conference of the Royal Institute of British Architects).—At 2 p.m. (1) Mr. George Atchison, A.R.A., on "The Impermeable Houses with regard to Sanitary Arrangements"; (2) Mr. Fred. W. H. Hunt on "The Sanitary Arrangement of Houses in London during the last Eighty Years." The discussion upon these papers to be opened by Prof. Kerr.—At 4 p.m., Mr. S. Flint Clarkson on "Drainage under Dwellings." The discussion upon this paper to be opened by Mr. Theo. Worthington.—Mr. Ewan Christian, Chairman for the day, Mr. Charles Barry, Vice-chairman, Association of Municipal and Sanitary Engineers and Surveyors.—Annual Meeting, to be held in the Town-hall, Newcastle-Tyne, 11 a.m. (1) Annual Report. (2) President's Address. (3) Paper by Mr. J. F. Spencer, F.R.S., on "Inspecting and Testing the Sanitary Arrangements of Houses."

FRIDAY, JULY 11.

International Health Exhibition (Conference of the Royal Institute of British Architects).—At 2 p.m. (1) Mr. Edward C. Robins, F.R.S.A., on "The Impermeable Construction of Roofs, Walls, and Basement Floors, with thereto"; (2) Mr. John F. Sullivan on "The Construction of Chimneys." The discussion to be opened by Mr. C. Forster Hayward.—At 4 p.m., Mr. Horace Jones on "A Suggestion with regard to the Construction of Doors, so as to afford opportunity of Escape from Fire; and another on an Economical Mode of Fireproof Construction adopted in several Instances in Public and Private Buildings." The discussion to be opened by Mr. Henry Dawson, Mr. George Godwin, F.R.S., Chairman for the day; Mr. Alfred Waterhouse, A.R.A., Vice-chairman. Association of Municipal and Sanitary Engineers.—Meeting at Newcastle, continued, 10 a.m. (1) Mr. James V.C., on "Sewage Disposal." (2) Lieut.-Col. Jones, "The Cost of Local Government and the Distribution of the Funds."

SATURDAY, JULY 12.

International Health Exhibition (Conference of the Royal Institute of British Architects).—At 2 p.m. (1) Mr. George Atchison, A.R.A., on "The Sanitary Aspect of Internal Fittings and Decoration in Houses." The discussion to be opened by Mr. T. W. Cutler.—At 4 p.m., Mr. Thomas H. Watson on "The Collection, Storage, Management, and Distribution of Water, for Domestic Purposes, within the House." The Right Hon. A. J. B. Hersford, M.P., Chairman for the day; Professor T. Hayter Lewis, Vice-chairman of Water, for Association of Municipal and Sanitary Engineers.—Meeting at Newcastle, continued, 10.30 a.m., Closing Business, 11 a.m., Visits to various works.

#### Miscellaneous.

Tiverton Drainage.—After considerable delay the Town Council of Tiverton (acting upon the report of Mr. E. Pritchard, M. Inst. C.E., to whom the competition drawings were submitted) have awarded the premium of 25l. to Messrs. Gotto & Bealey, of Westminster, for their scheme for the disposal of the sewage of the town by irrigation, at a cost of 3,500l.

**Society for Improving the Condition of the Labouring Classes.**—The fortieth annual meeting of this society was held at Willis's Rooms last week, under the presidency of the Earl of Shaftesbury. The report of the committee showed that the society was the first to step into the gap to provide improved dwellings for the poor, and although their progress had been slow, their efforts had been crowned with beneficial results, as the report upon the condition of the society's houses showed that the tenants were in good repair, and the superintendent's reports were very satisfactory. It also stated that the model dwellings in Street-ham-street, Bloomsbury, for fifty-four families, had been fully occupied. Portpool-lane model houses, for twenty families and 128 single women, reported as a rule all the houses and rooms let; the public washhouse returned 23,000 washers. The Dyoit-street (late George-street), Bloomsbury, lodging-house, for 104 single men, returned an average of ninety-eight. Macklin-street lodging-house, for seventy-two single men, had averaged sixty-four nightly inmates. The renovated dwellings, Wild-court, Drury-lane, fifty-two rooms had been fully tenanted. Clark's-holdings, St. Giles, for seventy-eight families, returned an average tenancy. Great St. Andrew-street, St. Giles, renovated houses for families, reported generally good occupation. The rate of mortality throughout the houses was 15 per 1,000. The report having been adopted, Lord Shaftesbury said that the society was an admirable institution, and if its work had been carried on as originally intended, many of the evils would have been removed. Although the condition of the London poor was far better than formerly, there still remained much to be done. If the people were better housed their whole condition would be improved. In the course of a few years London might be made to present a very different aspect if capitalists would advance money for building purposes, and be content with a return of four per cent.

**The City Companies Commission.**—The report of the Commission of Inquiry into the Livory Companies of the City of London has now been presented to Her Majesty. After detailing the history of the various companies, the report concludes with "Suggestions as to Reform," among which are the following:—"4. We recommend the appointment by Act of Parliament, of a Commission, which shall undertake, pursuant to the terms of such Act, (1) the application of a portion of the corporate incomes of the companies respectively to objects of acknowledged public utility; (2) the better application of the trust incomes of the companies; (3) should it prove practicable, the re-organisation of the constitution of the companies. 5. We are of opinion that by the terms of such Act 'objects of acknowledged public utility' shall be defined as follows:—(1) Scholastic and scientific objects, i.e., elementary education, secondary education, classical education, scientific research. (2) General public purposes, e.g., hospitals, picture galleries, museums, public libraries, public baths, parks, and open spaces. (3) The improvement of workmen's dwellings, and where the companies represent trades, subsidies to the benefit societies of such trades. 6. We are of opinion that, having regard to the facts that (1) the companies are connected with the municipality of London; (2) their wealth is in the main the result of the remarkable progress of London, the objects of acknowledged public utility to be promoted should be mainly metropolitan objects, but that, in cases in which a trade formerly carried on in London has established itself elsewhere, similar objects connected with the present place of trade may properly be included."

**An Island for Sale.**—An estate in a rifenge has always been esteemed a desirable acquisition, but at the present time the unusual opportunity is offered of purchasing an estate entirely bounded by the sea, inasmuch as the island of Herm, which is about a mile and a half in length by three-quarters of a mile in breadth, and contains about 400 acres, is announced to be sold by auction on the 29th of July by Messrs. Debenham, Tewson, & Co., who have sent us particulars of the property. It is one of the smallest of the Channel Islands, and enjoys a delightful climate. The purchaser will at once become "monarch of all his surveys," and will have about forty subjects on his island.

**Destruction of the Theatre Royal, Edinburgh.**—The Theatre Royal, in Broughton was, on Monday last, destroyed by fire, happily without loss of life or other serious catastrophe. The fire broke out at midday in the property-room, at the opposite end from the stage, but how it originated does not appear. The progress of the fire was very rapid, and so speedily did it get a firm hold of the building that the efforts of the fire-brigade were directed mainly towards saving the adjoining property. The Roman Catholic pro-cathedral, which adjoins the theatre to the north, had a narrow escape, having twice caught fire, but by the prompt attention of the firemen, the flames were prevented from getting firm hold. By the exertions of the clergy and other willing assistants, the valuable properties in the church (including the "Dead Christ," by Vandrey, valued at 5,000l.) were saved. The theatre was destroyed at about 13,000l., and the estimated damage to the adjoining property to be about 18,000l. or 20,000l. The site of this theatre was during the first quarter of the century occupied by a concert-hall, under the direction of Natali Corri; in 1820 it was converted into a theatre known as the Adelphi, which was consumed by fire in 1853. Re-constructed in 1855, under the name of the Queen's Theatre and Opera-house, it was again burned down in 1865; re-built the following year, under the designation of the Theatre Royal, it was a third time burned down in 1875. Upon the occasion of the last fire, the elevations of the building remained intact, and the interior was fitted up under the direction of Mr. Phipps.

**The Crypt of Hexham Abbey Church.**—Some of the passages of this ancient crypt, which have previously been unopened, have been cleared of the debris which hid them from view, and laid open to inspection. The steps by which the crypt was entered from the outside (on the west side of the church) have been brought to daylight; and in the crypt many stones of Roman masonry have been found from the Saxon cement which covered them, which adds still further to the interest of this underground chapel. One of the passages which has just been opened evidently led back to the building above, known as St. Wilfrid's Church, but the point of egress is at present covered by the base of the massive pillars of the tower and the aisle in the transepts of the present church, so that it would appear that the priests had a separate door by which they could enter the crypt, and that there were other doors by which other persons not so privileged could enter. Perhaps the most interesting Roman stone in the crypt is that which formed part of a Roman altar, and from the inscription upon which the name of the Emperor Geta was erased at the command of his half brother, the Emperor Caracalla, after the assassination of the former.—*Newcastle Chronicle.*

**The Parkes Museum.**—A general meeting of the members of the Parkes Museum will be held in the Museum, 74s, Margaret-street, Regent-street, on Wednesday evening next, July 9th, at five o'clock, p.m. His Grace the Duke of Westminster, K.G., vice-president of the Museum, has intimated his decision of being present. The following is the business to be transacted:—1. To receive report from Council on general work of the museum; 2. To receive statement of accounts; 3. To elect vice-president: **George Buchanan, M.D.**, proposed.

**Mr. W. H. Dalton,** the last of the original members of the Metropolitan Board of Works, died last week at the age of seventy-five. At the time of his death he was the representative at the Board of the parish of St. Martin-in-the-Fields, which parish he had represented since the formation of the Board in 1856.

**The Forestry Exhibition, Edinburgh.**—The opening of the International Forestry Exhibition took place on Tuesday last, under somewhat unfavourable circumstances, the arranging of the exhibits being, as is too commonly the case on similar occasions, greatly in arrear.

**The New Bridge at Putney.**—At the meeting of the Metropolitan Board of Works, on the 27th ult., it was announced that the Prince and Princess of Wales had consented to lay the foundation stone of Putney Bridge on Saturday next, July 12, at four o'clock.

**The City and Southwark Subway Bill.** The Committee of the House of Lords, presided over by Lord Romilly, passed, on the 27th ult., the London (City) and Southwark Subway Bill, authorising a subway under the river from King William-street to the Elephant and Castle.

The Water Supply of Venice.—That ancient cause of grumbling among residents and holiday tourists, the undrinkable water of Venice, appears, from the report of our Vice-Consul, Mr. De Zuccato, to be now at an end. Eight years ago a concession for bringing water from the mainland was granted to an association of English capitalists, who subsequently transferred it to a French company, by whom the project has just been brought to completion at a cost of five millions of francs. The great aqueduct passes under the Lagoons. By the terms of the arrangement the municipality pays the water company 100,000 francs a year for the supply of good water to the 120 public wells in the city, which are to remain open three hours a day; but after sixty years the whole of the waterworks will become the property of the city. Private families are supplied with water at the price of about sixpence (60 centesimi) per thousand litres, equal to about 240 gallons.—Daily News.

Roman Remains at Woolstone.—In the course of his researches on the site of the lately-discovered Roman villa at Woolstone, Mr. R. Walker, of Uxington, has found what he believes to be "a depository for the remains of the dead previous to cremation, similar to the

exquisite archaeological treasure now moved to Oxford." He has discovered indications of three distinct houses, and has also marked the traces of at least half a dozen others, including one with indubitable tokens of the bathroom. In another locality he has found no less than six or eight houses, nearly parallel, as if forming a street east to west, the foundations of which are clearly discernible. Beyond this other fields are disclosing glass, pottery, iron, and what Mr. Walker "noted as an interesting fact in the Church Field," the presence of a large deposit of oyster shells (real natives),—denoting a luxury of living, and the probable chance of finding rich pavements on a thorough search."—Reading Mercury.

Disused Burial-Grounds as Public Gardens.—The Metropolitan Public Garden and Playground Association deserves well for its efforts to add to the pleasures and improve the stamina of city children. The conversion of old and disused burial-grounds into open spaces for recreation, which is one of its leading principles, has much that can be said in its favour and is open to no valid objection. It implies no neglect or desecration of those whose remains formerly rested there, inasmuch as their elements have years ago become part of

the dust out of which they came. Their very memorials in many cases have perished, as they must at length, crumbled away by the hand of Time. Neither does hygiene require that these spots should continue to be the neglected abode of rank grass and weeds alone. Let it be granted that urban burial-grounds were a mistake of a former generation; they have wrought their evil, doubtless, and have ceased to be effective long before now. The period which has intervened since the abolition of intramural graveyards is sufficient to have purified by disuse the most unwholesome of them.—Lancet.

The Ashmolean Museum, Oxford.—Mr. A. Evans, M.A., of Brasenose College, has been elected Keeper of the Ashmolean Museum, in the place of the late Mr. J. H. Parker, C.B. The keeper is now required to deliver lectures as well as to superintend the collections of the museum.

International Health Exhibition.—A Grand Evening Fête, under the immediate patronage of their Royal Highnesses the Prince and Princess of Wales, who have announced their intention of being present, will be held at the International Health Exhibition, on Wednesday, July 23rd, in aid of the Fund for the London Hospitals.

COMPETITIONS, CONTRACTS, AND PUBLIC APPOINTMENTS.

Epitome of Advertisements in this Number. COMPETITIONS.

Table with 10 columns: Nature of Work, By whom required, Premium, Design to be delivered, Page, Nature of Work, By whom required, Premium, Design to be delivered, Page. Includes entry for Daily Hometown.

CONTRACTS.

Table with 10 columns: Nature of Work, or Materials, By whom required, Architect, Surveyor, or Engineer, Tenders to be delivered, Page, Nature of Work, or Materials, By whom required, Architect, Surveyor, or Engineer, Tenders to be delivered, Page. Includes entries for Blinds, Crofton Infirmary, North-Easton Ry. Co., etc.

PUBLIC APPOINTMENTS.

Table with 10 columns: Nature of Appointment, By whom Advertised, Applications to be in, Salary, Page, Nature of Appointment, By whom Advertised, Applications to be in, Salary, Page. Includes entries for County or District Surveyors, Road Foreman, etc.

TENDERS.

For building sessions court, police-courts, &c., for the Corporation of Birkenhead. Messrs. Thomas D. Barry & Son, Liverpool. Quantities by Mr. George T. Atter, Birkenhead.

Table of tenders for building sessions court, police-courts, &c. in Birkenhead. Lists names like S. & W. Pattinson, Ruskington, and amounts.

For Cullum House, Lime-street. Messrs. N. S. Joseph & Pearson, architects. Quantities by Mr. Stephen Barton Wilson.

Table of tenders for Cullum House. Lists names like Conder, Williams, Bywaters, etc., and amounts.

Accepted for repairs to Nos. 1 to 5, Oliver-road, Leyton, Essex. Mr. William C. Livermore, surveyor. Quantities by A. Nicholls, Leytonstone. £185 0 0

Accepted for reinstating house and warehouse, damaged by fire, at 4, Cable street, St. George's-in-the-East. Mr. William C. Livermore, surveyor. Quantities by A. Nicholls, Leytonstone. £435 0 0

Accepted for the construction of brick and pipe sewers, and laying down new granite carriage-ways and York stone footways in the streets embraced in the Pear Tree-court, Clerkenwell (Artisans' Dwellings) Scheme, for the Metropolitan Board of Works. £2,599 0 0

For alterations to the "Bodden Company's" premises, High-street, Borough. Mr. W. Macie Leir Seaman, 3, Chancery-lane, architect. Quantities prepared by the architect:—

Table of tenders for alterations to premises at High-street, Borough. Lists names like Drew & Cadman, Holborn, and amounts.

For rebuilding premises in High-street, Shermesson-Sea, for Mr. D. Frosser. Messrs. P. P. Perry & W. Macie L. Seaman, architects, 3, Chancery-lane. Quantities prepared by Mr. W. Macie L. Seaman:—

Table of tenders for rebuilding premises in High-street, Shermesson-Sea. Lists names like Ham Hill Stone Dressings, and amounts.

For painting, whitewashing, &c., at the St. Marylebone Infirmary, Notting-hill, for the Guardians of the Poor of the Parish of St. Marylebone. Messrs. H. Saxon Snell & Son, architects, 25, Southampton-buildings. £1,600 0 0

Table of tenders for painting, whitewashing, &c. at St. Marylebone Infirmary. Lists names like Smith & Saunders, J. H. Jolliffe, etc., and amounts.

For making up, metalling, and channelling of roadway, and tar paving of pathways, at Manor Park-road, Harlesden, for the Willesden Local Board. Mr. O. Claude Robson, engineer:—

Table of tenders for making up roadway at Manor Park-road. Lists names like Pizzey, Nowell & Robinson, etc., and amounts.

For erecting fifty labourers' dwellings, on the Cann Hall Estate, Leyton. Mr. G. H. L. Stephenson, architect:—

Table of tenders for erecting dwellings on Cann Hall Estate. Lists names like Evans, Read, Wilson, etc., and amounts.

For constructing 1,400 ft. brick sewer, in Bridge-road, Hammersmith, and 3,200 ft. brick sewer, at Stamford Brook East, near Willesden Junction, for the Metropolitan Board of Works:—

Table of tenders for constructing sewer at Stamford Brook East. Lists names like George Felton, Iverson-road, N.W., and amounts.

For alterations and additions to "Coleyhurst" Bath-road, Reading, for Mr. Thos. Rogers. Mr. W. Ravenscroft, Reading, architect. Quantities by Messrs. Cooper & Sons, Reading and Maidenhead:—

Table of tenders for alterations at Coleyhurst. Lists names like Wheeler Bros., Reading, and amounts.

For the erection of a new tobacco factory, for Messrs. W. D. H. O. Willis, Bedminster, Bristol. Mr. Frank W. Willis, architect:—

Table of tenders for tobacco factory. Lists names like A. J. Beaven, Bristol, and amounts.

For alterations and additions to "Coleyhurst" Bath-road, Reading, for Mr. Thos. Rogers. Mr. W. Ravenscroft, Reading, architect. Quantities by Messrs. Cooper & Sons, Reading and Maidenhead:—

Table of tenders for alterations at Coleyhurst. Lists names like Wheeler Bros., Reading, and amounts.

Accepted.

For completing six houses, Roselyn-gardens, Hampstead for Mr. T. A. Amos. Messrs. Spalding & Auld, architects:—

Table of tenders for completing houses at Roselyn-gardens. Lists names like L. H. & R. Roberts, and amounts.

Accepted, but reduced to 15,710l.; the lowest but one of nineteen tenders received.

For alterations to 10, Pelham-street, Nottingham, for Mr. A. Steadall, Mr. George Edwards, architect.—

Morrison .....	£1,150 0 0
Hind .....	947 0 0
Woodson .....	850 0 0
Martin, Walls, & Co. ....	790 0 0
Bell & Son .....	790 0 0
Simpson & Co. ....	713 0 0
Scharen & Williams (accepted) ..	694 0 0
Victors (exclusive of dog and railings) ..	690 0 0

For cold water tanks, at the New Wandsworth and Clapham Workhouse, Mr. Thos. W. Aldwinckle, architect, East India-avenue, E.C.—

Thames Bank Iron Company .....	£987 10 0
Z. D. Berry & Sons .....	850 0 0
Appleby .....	810 0 0

Accepted for erecting six cottages, and workshop in rear, situate in Grove street, Deptford, for Mr. Frank Barnes, Mr. Henry Roberts, architect and surveyor.—

Hubble & Trott, Deptford. ....	£1,195 0 0
Workshop .....	87 0 0
[Except bricks.]	

For the erection of cemetery chapel, for the Corporation of St. Alban's.—

F. W. Austin, St. Alban's .....	£535 0 0
W. Sparrow, Kettering .....	518 10 0
C. Chamberlain, St. Alban's .....	515 0 0
Marcus Holland, St. Alban's .....	513 0 0

Special Notices.—Lists of tenders frequently reach us too late for insertion. They should be delivered at our office, 46, Catherine-street, Strand, W.C., not later than four p.m. on Thursdays.

TO CORRESPONDENTS.

W. A. C. (parcel received).—H. P.—W. W. L.—W. W. N.—J. T. C.—W. H. B. G.—If we will not send a parcel of books into the matter, but can do nothing this week.—C. F. A. V.—E. J.—E. W. R.—G. B. S.—W. W. G. It is in a matter of supply and demand, and will take care of itself.

All communications regarding literary and artistic matters should be addressed to THE EDITOR; all communications relating to advertisements and other exclusively business matters should be addressed to THE PUBLISHER, and sent to the Editor.

All statements of facts, lists of tenders, &c., must be accompanied by the name and address of the sender, not necessarily for publication.

We are compelled to decline pointing out books and giving addresses.

NOTE.—The responsibility of signed articles, and papers read at public meetings, rests of course, with the authors.

We cannot undertake to return rejected communications.

Letters or communications (beyond mere news-items) which have been duplicated for other journals, are NOT DESIRED.

PUBLISHER'S NOTICES.

THE INDEX and TITLE-PAGE for Volume XLVI. (January to June, 1884) will be given as a Supplement with our next Number.

A COLOURED TITLE-PAGE may be had, gratis, on personal application at the Office.

CLOTH CASES for Binding the Numbers are now ready, price 2s. 6d. each, also

READING-CASES (cloth), with Straps, to hold a Month's Numbers, price 2s. each.

THE FORTY-SIXTH VOLUME of "The Builder" (Annual), will be ready shortly, price Twelve Shillings and Sixpence.

SUBSCRIBERS' VOLUMES, on being sent to the Office, will be bound at a cost of 3s. 6d. each.

CHARGES FOR ADVERTISEMENTS.

SITUATIONS VACANT, PARTNERSHIPS, APPRENTICESHIPS, TRADER, AND GENERAL ADVERTISEMENTS.

Six lines (about fifty words) or under ..... 6s. 6d.

Each additional line (about ten words) ..... 6s. 6d.

Terms for Series of Trade Advertisements, also for Special Advertisements on Front page, Competitions, Contracts, Sales by Auction, &c. may be obtained on application to the Publisher.

REVOLUTIONS WANTED.

FOR LINES (about THIRTY words) or under ..... 2s. 6d.

Each additional line (about ten words) ..... 6s. 6d.

PREPAYMENT IS ABSOLUTELY NECESSARY.

\* Stamps must not be sent, but all small sums should be sent by Cash in Registered Letter or by Money Order, payable at the Postoffice, Covent-garden, W.C. to DOUGLAS FOURDRINER, Publisher.

Advertisements for the current week's issue must reach the Office before THREE o'clock p.m. on THURSDAY.

The Publisher cannot be responsible for DRAWINGS, TESTIMONIALS, &c. left at the Office in reply to Advertisements, and sent.

TERMS OF SUBSCRIPTION.

"THE BUILDER" is supplied gratis from the Office to residents in any part of the United Kingdom at the rate of 10s. per annum, payable by the quarter in advance, and 5s. for each extra copy. Remittances payable to DOUGLAS FOURDRINER, Publisher, No. 46, Catherine-street, W.C.

SPECIAL.—ALTERATIONS IN STANDING ADVERTISEMENTS or ORDERS TO DISCONTINUE same, must reach the Office before TEN o'clock on WEDNESDAY mornings.

PERSONS Advertising in "The Builder," may have Reprints addressed to the Office, 46, Catherine-street, Covent-garden, W.C. free of charge. Letters will be forwarded if addressed envelopes are sent, together with sufficient stamps to cover the postage.

### Old Halls in Lancashire and Cheshire.\*

THE work brought out under this title by Mr. Henry Taylor, whose "Notes on Sketching Tours" we formerly had occasion to notice favourably, is one of those that is, or should be, as interesting to the generally cultivated reader as to the architect. The general reader, especially if he be of an antiquarian turn of mind (a supposition which perhaps takes him out of the "general" catalogue), cannot fail to find interest in the history and illustration of so many old family houses, connected in some cases with names that have been eminent in English domestic history, and perhaps in public history also. The architect finds here interesting examples of effective and picturesque planning, and still more interesting suggestions in architectural grouping and effect; suggestions which are capable of adaptation and modification in styles of building and with materials widely different from those which are here illustrated.

To have illustrated every old hall of the kind in the two counties named would have been, we can well believe, a too onerous task for any one who had not his whole time to give to it. The author tells us that he has therefore selected for description a limited number of interesting or typical examples, and endeavoured to trace the architectural history of the several buildings in such a manner as to illustrate as much as possible the development of English domestic architecture in general. This latter aim is, perhaps, hardly carried out, and hardly could be in the course of separate and rather brief notes in reference to a number of structures possessing many leading traits in common; but some degree of generalisation is effected in regard to a portion, at least, of the subject.

Mr. Taylor commences, for instance, by giving some block plans of what he recognises as the leading types of plan in the houses of which he is speaking. Six types are thus distinguished, of which, however, one or two seem little more than variations resulting from economy. The tendency of the buildings to form some portion of the sides of a quadrangle

is obvious in nearly all of them. In the earliest and simplest type given, where parlour and kitchen departments form the two wings, connected by the hall as an intermediate "curtain," we have what seems the embryo suggestion of the quadrangle plan, the two wings just sprouting into arms which, if extended, would make the second and third sides of the "quad." Then we have the three-sided quadrangle, with open space on the fourth side; the two-sided, in the shape of the letter **t**, sometimes the result of the pulling down of a formerly existing third side; and we have the complete quadrangle, that picturesque, comfortable, but (on a small scale) distinctly unhealthy form of planning, forming in hot weather a central reservoir for the air to stagnate in. The dates of these buildings are mostly between the Late Gothic and the Jacobean period; a few remnants going as far back as the fourteenth century. The other generalisation which the author gives us is in regard to the sites of these old dwelling-houses; and here he touches upon a point which is the more interesting because it is commonly overlooked. Although we have descended, in our present study, below the age when the castle dominated everything, we are still in times very turbulent and deficient in police as compared with our own, and the houses of the period are built not without regard to the defensibility of the site; indeed Mr. Taylor suggests that this was a matter much more thought of, and more carefully looked to, than any consideration of picturesque effect, and there is no doubt that in this respect he is right. The idea of placing a house picturesquely is probably an essentially modern one; the ruling motives in the fifteenth and sixteenth centuries would be much more convenience of water-supply and security from attack except with considerable advantage of position to those attacked. The author divides the sites, as regarded in this light, into those naturally defensive, such as those on the brow of a hill or within the sharp bend of a river; those which are naturally defensive but improved by art; and those which are made defensive by art alone, such as moated houses on flat sites. The latter are, however, the most numerous class; the sites which required isolating by a moat and drawbridge being, probably, the most convenient of access for friends, and the moat offering a sufficient stumbling-block to foes. The author also draws attention to the "folds" which word represents, in the districts of which he is writing, a small collection of farmhouses, grouped together in a quadrangle for mutual defence and security; the doors of

separate tenements all opening inwards on to the quadrangle, which thus displayed only one vulnerable point at the general entrance. This defensive element in the arrangement of ancient homesteads, whether manor-houses or farms, is overlooked by many, but it is an interesting item in the study of old English domestic architecture.

The real interest of these old English houses to the architect, however, lies in their picturesque treatment and arrangement, and the numerous suggestions which they offer to the designer. A large number of the buildings given here belong wholly or partially to that half-timber manner of building which offers so much natural opportunity for varied and effective arrangement of materials; but there are others which, without this extra source of effectiveness, present nearly as varied and effective a treatment with a more solid method of building. In order to give as complete an illustration as possible of the whole disposition of these buildings, they are mostly shown in bird's-eye views. On any other scheme a considerably increased number of drawings would have been requisite to show the whole building, and the expenso of production, as well as the bulk of the book, materially increased. The object has been, in fact, not to make pictures in the first instance, but to convey a correct idea at a glance of the disposition and arrangement of the buildings, for which the only expedient is a bird's-eye view.

Among the more solidly built of the examples which are thus exhibited to the reader, in which the half timber method is not used, one of the most interesting and characteristic is Houghton Tower, as the author describes it, "a picturesque, sturdy-looking pile of buildings, situated on the summit of a lofty eminence, midway between Preston and Blackburn, which is a conspicuous object in the landscape for many miles around," and appearing, on closer inspection, "more like a village than a private residence." On three sides the ground slopes away rapidly, on one side being precipitous; on the fourth side, where the ground is more level, the whole is defended by a battlemented gatehouse and angle-towers, the fenestration of which, by the way, is much more symmetrical than is often found in such buildings. The gatehouse gives access to a large court, flanked by buildings for stabling, kitchens, and retainers, and on the further side is the entrance to the mansion proper, up a flight of semicircular steps and through a gate flanked by massive piers with the favourite stone ball decoration at the top, leading to a

\* Old Halls in Lancashire and Cheshire; including rider on the ancient domestic architecture of the Counties Palatine. With numerous illustrations. By Henry Taylor, Architect. Manchester: J. E. Cornish, 1884.

second enclosure, and along a kind of causeway and up a further flight of steps to the actual house, which again forms a quadrangle enclosing a square court. In the angle is the chapel (or the remains of it), which in the desire for correct and honest ornamentation was canted somewhat askew from the main lines of the building. The further side of the quadrangle included "King James's rooms," where James I. stayed in 1617 with Sir Richard de Hoghton, and had a fine time of it in hunting and feasting. In the arrangement of this fine and interesting old house we seem to see, in a more quiet and picturesque form, and with less gloomy expression, the same idea which presents itself to the great French châteaux; the defensive part of the house without, in the shape of massive towers, and the real habitation within the lines of these defences. Enough is shown of the inner or house court in the view, though on a small scale, to let us see that this is one of those examples of picturesque expression, in the grouping of windows and other features, which renders these old English houses such a series of studies for the architect.

This quality of effective and expressive grouping, in fact, is that which always interests us most in this class of buildings. It is difficult to say how far this kind of effect was really intentional on the part of the builders, how far it was merely the result of a *naïve* and unpretending way of building. The plans of the large dining-halls, for instance, are charming examples of effective planning of rooms, with their large bays added often transept-wise, showing how directly social distinctions and the desire to seclude one portion of the party a little from the other, found their direct and natural expression in the architecture. The bays, Mr. Taylor says, were partly used for the effective display of plate, partly also, he thinks, and we should be disposed to think so too, as places of collection for the ladies, a little apart from the more mixed company that would often have filled the hall. In some cases all the window treatment, if one may use the expression, seems concentrated on these bays, the rest of the hall having smaller windows at some distance from the floor, the bay alone having a large extent of window brought nearly to the floor, sometimes being almost entirely one great window. The height of the windows from the floor, in many of the principal rooms, is a point of difference between ancient and modern house building to be remarked; in these days of low windows it is difficult to realise the difference of living in a house where one could not see through the windows without climbing on a chair; but blinds were not in use then, and high windows were desired for privacy. Mr. Taylor finds in the high windows another advantage, that the effect of the interior lighting is better; the shadows fall in a natural manner, instead of being cast upwards from below. How many people in the present day would give up the opportunity of looking through the window for the sake of getting the light to fall rightly in the interior, we cannot say; we are not among those enthusiasts for *stare* and logical *chiaroscuro*. But the plans of the large dining-halls, of which several are grouped together on one plate, are delightful; with their great angle-nooks, large bays added in different ways and at different parts of the room as fancy dictated, and the elaborate carved screens which in many of them separated the hall from the entrance passage, they represent the poetry of room-planning.

The ball was the great feature of the interior; but everywhere throughout the exterior of the houses shown in this volume, as well as in others of a similar class and date, we are struck with the prevalence of that feeling for accentuation, whether conscious or unconscious, which makes the great distinction between old and modern house-building, with the exception of recent special efforts in that direction. Of late some people have learned the lesson and repeated it by rote, probably in a far more conscious spirit than it was done by our forefathers; but even this intentional and antiquarian expression is not very often to be found in modern country houses or "halls."

The note of modern house-building is said respectability, an absence of expression; one window like another, or one row of windows, at least, like another; nothing to fix the eye on this or that point, or to indicate that the builder or architect took a pleasure in concentrating architectural treatment on any special feature. Now the reverse of this is what especially strikes one in turning over the pages of a book of illustrations of old houses like the one before us. Everywhere we find incident in the buildings, a grouping of the features, a marking out of some points by a special treatment. More especially is this shown in the arrangement of the windows, the eyes of a house, on which so much of its expression depends. So also in regard to the use of half-timber work, which a little while since, at least, was regarded as in itself, and in any form, a receipt for the picturesque. But it is not used in this blind haphazard way in the old buildings. It is either the method employed for the whole building, and treated with great breadth of effect; or it is concentrated where it has special convenience or meaning, constructively or architecturally. Thus, in Ageroff Hall, the whole building is half-timbered, but in a plain and utilitarian manner on the exterior, with the chimney piers alone built solid and running up unbroken through this mass of post and pan work, like the main supporting skeleton of the building. On the inner side, next the quadrangle, the character of the half-timber work is altered, and becomes more ornate. In Ordsall Hall, on the same page, the varied arrangement of bays and projections is charming, and completely expresses the difference between the show portion and the working portion of the interior. In Royle Hall and Gawthorpe Hall we are almost as much pleased by the simplicity of the architectural treatment, the windows put just where they are wanted, without pretence of systematic arrangement. In "The Lodge, Royle," we see the millioned windows carried into the horizontal bands right round the three sides of a square projection; and in Belfield Hall the arrangement of the millioned windows in long groups gives a special and most charming expression to a building which is constructed architecturally out of the simplest materials.

Among other interesting points in the book may be specially named the representations of the remarkably sumptuous wood-work in Rufford Old Hall, and the geometrical drawings of the timber framing (plate xxx.) in Smithells, Baguley, and Garret Halls. This should have a scale, by the way. The author draws attention to the great size of the oak pieces used at Baguley; "it will be seen that the head of the east doorway is cut out of a piece of oak nearly 3 ft. wide, the main upright posts out of timber 2 ft. 6 in. wide." It is not "seen," because there is neither scale nor figured measurement, though we take the author's word for it. He remarks that this building "affords a proof of the great durability of oak, for the timbers here are in splendid condition." Speke Hall, one of the finest and most sumptuous of the Lancashire halls, is inadequately illustrated by a very small bird's-eye view; it would have been worth while to have given more space to it. However, we may thank Mr. Taylor for a charming and very valuable book, and may conclude by giving further publicity to one recommendation in it, namely, that local antiquaries might do great service if they would follow the example of Mr. G. H. Rowthorn, who has kept for some years an album for the collection of engravings, sketches, and documentary evidence of every kind relating to Ordsall Hall, in his neighbourhood. Similar collections in regard to other such old houses would have great and increasing value, as the progress of time and decay bring about inevitable alterations and repairs.

**Kilburn.**—Mr. J. Avery's tender for the ornamental wrought-iron grilles, gilt and completed, for the Church of St. Augustine, Kilburn, according to the designs of Mr. J. L. Pearson, R.A., has been accepted, at the sum of 325l.

#### THE SANITATION OF TOWNS AND DWELLINGS.

N ably composed manual\* on the elementary principles of sanitation as applicable to towns and dwellings has been recently issued by the publisher, Baudry, of Paris, compiled by M. A. Wazon, who takes for his motto the aphorism of Pasteur,—"It is within the power of man to extirpate diseases of parasitic origin." The work is divided into six parts, and treats of water supply and distribution; surface drainage; public ways; sewers, and the utilisation of sewage. In the words of the author, "Taking pure water from its different sources of supply we distribute it in the various parts of a dwelling, then following this water when fouled by domestic use we discharge it upon the public way, where it is joined by the foul water from surface drainage; we follow this admixture of polluted water into the network of the public sewers; we carry the sewage to the places where it is utilised and purified; and, finally, after undergoing process of purification, we restore the water to the river in a condition of purity closely approaching that which it possessed primarily, applying thus continually the cardinal principle of constant circulation."

The first portion of the work is devoted to a consideration of the water supply of towns and dwellings in which the principles which should guide the arrangements of this most important branch of sanitation are set out with great perspicuity, with references to the best authorities, English and foreign. It is a satisfaction to find that among these authorities, English and American authors are those most frequently cited. The injurious effects upon health through the contamination of water by public cemeteries are pointed out, and the evils resulting from the use of water from shallow wells, and the storage of water in cisterns, are clearly demonstrated. Artesian wells, as a source of supply, are held to be unsuitable for towns on account of their cost and the fluctuations in the yield, temperature, and composition of the water furnished from these wells which renders it unfit for general use. A constant supply of water from fully-charged mains is considered by most authorities as the only provision suitable for large towns. As regards the minimum quantity of water necessary for health our author fixes the amount at 180 gallons a head a day, which is considerably in excess of what has been hitherto considered to be requisite. The total quantity of water from all sources available for Paris is stated to be about 100 millions of gallons per diem. In 1876 the population of Paris was about 1,988,000 inhabitants; in 1881 it was 2,240,000, or nearly 2½ millions, showing an increase of 232,000 in five years, and if this increase should continue in the same ratio, it is probable that in 1886 the population will be about 2½ millions, and unless the present water supply is increased, there will be then only 40 gallons of water per head. Marseilles appears to enjoy an abundant water supply, the provision being equal to 180 gallons per head a day. The London water supply is at the rate of about 33 gallons per head a day. About 110 millions of gallons are daily pumped into London, but of this amount it is probable only about one half is consumed, the rest being wasted.

The total quantity of water obtainable in the case of a state of siege in Paris is stated to be 90 gallons per head a day, from which it would appear that Paris, in the time of war, is nearly three times better off as regards water supply than London in a state of peace. In New York it is proposed to construct an aqueduct for the purpose of bringing the Croton water to the city, at a cost of 3 millions sterling. This work, when completed, will, it is estimated, give a daily supply of 180 gallons a head.

The present water supply of Paris is condemned by the author as inadequate. The

\* Principes techniques d'Assainissement des Villes et Habitations suivis en Angleterre, France, États-Unis et présentés sous forme d'Études sur l'Assainissement de Paris, par A. Wazon, Ingénieur-civil. Paris: Baudry, éditeur. 1881. 8vo., pp. 364.

use of lead for pipes and linings to cisterns is inhibited, and even when lined with zinc lead pipes are considered by him to be open to objection, and iron pipes lined with some material which will resist the action of salts in water are preferred. Coal tar is recommended by the American engineer, Ripley Nichols, for coating the inside of pipes, but the most perfect results are obtained by the Barff process. As regards filtration, the employment of animal or vegetable charcoal as a filtering medium is now generally discarded on account of its liability to develop animal germs, and spongy iron or carferal are considered to be the only effectual means of filtration. One of the defects of spongy iron as a filtering medium, namely, that it produces filtered water containing particles of iron in suspension or solution is pointed out, but this defect can, it appears, be remedied by passing the water after filtration through a layer of powdered gypsum. Carferal is said to be composed of alumina, iron, and carbon, and to form a very efficient filtering medium; the composition, however, is a secret, and being also very costly, it is not likely to be generally adopted. It is stated to be largely adopted in the construction of filters for the English navy. The *filtré rapide* of M. Maignen, which is on view at the Health Exhibition, is praised for its simplicity, but upon all points a filter invented by the French engineer Chanoit is preferred by our author.

The pollution of water by water-closets is alluded to, and the necessity of the entire separation of the water required for culinary purposes from that required for flushing is strongly insisted upon, and the various inventions for effecting this separation, and preventing waste, are described and illustrated, the English methods occupying a prominent place. The author is of opinion that the 2-gallon flush, which is required by the Paris regulations, is insufficient, basing his opinion upon the experiments made by Mr. Hellyer, who considers that a minimum flush of 3 gallons is necessary to effectually cleanse the traps. It is strange to find that, while we are grumbling at our system of rating for water supply, the author prefers the English plan of charging for water according to the ratable value of a dwelling, and gives an illustration to show that the price of water is greater in Paris than in London.

Turning to the essay on the removal of refuse, it appears that before the siege of Paris in 1870 household refuse was permitted to be placed upon the side walks from seven in the evening until seven in the morning, and the result was that the atmosphere was tainted with pestilential emanations. Since 1870 household refuse is not allowed to be placed upon the public way, but must be carried to the dust-carts which pass between five o'clock and seven o'clock in the morning. The author considers that the system at present adopted in Paris is inefficient from a sanitary point of view, and recommends that every house should be provided with a dust-shoot fixed on the outside, and delivering into a receptacle, which should be emptied every morning by the *employés* of the municipality.

The use of valves for water-closets of all kinds is strongly condemned. With regard to syphons, all syphons with valves or balls, whether filled with water or mercury, are stigmatised as dangerous, Renk's syphon and Peitenkofer's syphon being denounced by name. Mr. Hellyer is praised for his investigations with reference to what for want of a better name has been called syphonage; but to the American engineer, E. S. Philbrick, the author gives the credit of having been the first to point out the importance of ventilating syphon-traps. The water-closets in use in Paris are declared to be greatly inferior to those in use in England and the United States. The principle of the English pan-closet which, until recently, was preferred on account of its simplicity, and cheapness is examined by our author, and the construction of these closets as well as of the "wash-out" closets (which are much used in America), is pronounced to be unsatisfactory. The hopper closet of Jennings and Rhoad, and the Carmichael closet, the Vortex

closet, and the Artisan's closet, all of which are British or American manufacture, are mentioned with approval.

The provision of cesspools to dwellings, which was made obligatory in Paris by a decree of Parliament under date of the 13th of September, 1533, and confirmed by an edict of Francis I., dated 1539, was an immense step in advance, and was destined to put an end to the deplorable condition of the streets, which were encumbered with all kinds of filth. But the improvement was slow, in spite of the severe punishment inflicted upon delinquents. Up to the year 1668 these cesspools were frequently only holes dug in the ground, and the liquid portions of their contents filtered through the adjacent ground and poisoned the wells, as may be observed to the present day in the streets near the Hôtel de Ville, where the well-water has a perceptible odour of sewage which has percolated from old porous cesspools. This state of things continued until the year 1809, when an Imperial decree was promulgated regulating the construction of these important sanitary accessories. Notwithstanding the improvements that have been recently effected in regard to cesspools, the author agrees with Professor Vallin that they should be entirely abolished. In the year 1881 the Commissioners for the Sanitation of Paris proposed as a temporary measure the use of metallic cesspools containing from 60 ft. to 200 ft. cube to be emptied by the pressure of the air. These cesspools would require emptying once a week, and the cost of this work, at the rate of 8 francs per cube metre, as estimated by the author, would amount to the enormous sum of 200 millions of francs, or eight millions sterling per annum. This amount is irrespective of the cost of providing and fixing the temporary cesspools, which is calculated to amount to nearly fifteen millions sterling, and this for a mere temporary expedient. The total expenditure of the Metropolitan Board of Works for main drainage works up to the end of the year 1883 is under six millions sterling.

The different systems that have been proposed from time to time for disposal of the sewage of Paris are analysed, and illustrations are given of the apparatus to be employed, but the conclusion arrived at is that the water-carriage or English system is upon the whole to be preferred for populous towns, and it is pointed out that in nearly every instance the dissemination of zymotic disease which has occasionally occurred under this system has been traced to defects in matters of detail, which do not affect the integrity of the principle adopted.

The old streets of Paris were unpaved, and it was not until the time of Philip Augustus that the paving of the principal streets was commenced. Before this time the public way was covered with a thick layer of mud, traces of which are sometimes found in carrying-out sewer works. Belgrand, the engineer, constructed a map of these layers of mud, which were in places several yards thick, and the old streets are easily distinguished from the modern streets by the depth of their strata. The condition of the streets, even when paved, was not much improved. The gutter was in the middle of the street, and one wheel of the carriages was always kept in this gutter, spattering the roadway with mud and moisture. The interstices of the paving allowed the filth of the streets to pass through, which infiltrated the soil and penetrated under the houses. About the year 1830 the substitution of a convex surface for the pavement of streets led to a great improvement in the condition of the public ways in Paris, which are now watered twice daily, the paving is fairly maintained, and the mud penetrates less readily into the soil.

The first materials employed for paving the streets were cubes of stone, at first of large size, and then gradually reduced; this system was succeeded by that of Macadam, which is now discarded in favour of paving of wood and asphalt. Wood paving has the advantage of being almost noiseless, but it is costly to maintain, porous and unhealthy, especially in dark and narrow streets, where the wood decays rapidly. It is related, on the authority

of Douglas Galton, that the wood paving in Regent-street, London, was obliged to be removed on account of the ammoniacal exhalations with which it was impregnated, which tarnished the plate in the jewellers' windows; a statement which was alluded to some time since in our columns and which we have no doubt is correct. After passing in review the different systems of paving at present in use, the author declares himself in favour of cement and asphalt, although he acknowledges that these materials are costly and require frequent repairs.

As regards surface drainage the good effects produced by the drying of the soil is recognised, and the testimony of Dr. Buchanan is cited, who has shown that the mortality from phthisis has diminished in some instances, nearly one-half in some English cities since the execution of drainage works; at Banbury 41 per cent., at Rugby 43 per cent., at Ely 47 per cent., and at Salisbury 49 per cent. The same causes have led to a considerable diminution in the death-rate in the United States, notably in the city of Philadelphia.

Among the improvements, which in the opinion of the author are desirable in the public ways, is the provision of public water-closets, which he considers should be gratuitous, and might be placed under the superintendence of the officers of the public hospitals, a box being placed for voluntary contributions.

Some interesting details are given with regard to the removal of household and street refuse in Paris. The total quantity of this refuse amounts, it appears, to 2,000 cubic metres, or about 54,000 feet cube daily, and its removal is effected by 600 carts. A rate is levied upon all buildings abutting upon the public way for the expense of cleansing and removing the street refuse, according to the extent of the frontage, the amount of the rate, varying from about 1d. to 7d. per lineal yard. In 1880 this rate produced 104,000*l.*; the cost of cleansing, &c., amounted to 212,000*l.*, leaving a deficiency of 108,000*l.*; which, we presume, is made good out of the metropolitan budget.

The river Seine, the Bièvre, and the rivulet of Ménilmontant, were from the earliest times the natural means of drainage of Paris, and it was towards these three streams that the ancient inhabitants directed the rain-water and household refuse water by means of ditches formed across the garden ground with which the city was surrounded. Later on the moats of the fortifications erected by Philip Augustus and Charles VI. received a portion of the surface drainage. These ditches were open, and as the city increased in size became offensive and injurious to health. About the year 1374 Hugues Anbriot, mayor (*prévôt des marchands*), constructed the first sewer, properly so-called, by covering in the ditch which conveyed the drainage from Montmartre into the brook of Ménilmontant, already polluted from changes near its source. This sewer, which was called the great circular sewer, was reconstructed by Turgot, the then mayor, in 1740. Under the First Empire the improvement of the sewers was looked upon as the necessary corollary of the introduction of the water of the Ourcq into Paris, which was intended by the engineer Girard for the purpose of flushing the sewers, the total length of which, in 1806, was only about 23,000 yards. In consequence of the increase in the volume of water supplied to the city, the Ménilmontant sewer, which was only about 10 ft. wide, was soon found to be insufficient; and when, in the year 1830, the city engineers were desirous of further developing the system of sewerage, they laid the inclination of their new sewers, not towards the Ménilmontant sewers, but towards the Seine. The result of this step was to re-establish the inconveniences which former generations had sought to remedy; and it was not until 1856, when the engineer Belgrand was appointed, that he succeeded in organising a complete system of common sewers and intercepting sewers, which is now partly finished.

By a decree of the Council of State, dated the 22nd of January, 1784, no communication was permitted between dwelling-houses and the public sewers, and an order of the king,

dated the 30th of September, 1814, confirmed this decree, with this exception, that buildings which were too low to deliver their waste water into the kennel, were allowed to deliver it into the sewers. This permission, however, was only of a temporary character, and was limited to certain old houses which could not be rebuilt without stopping up all communication with the sewers.

At the present time every house in Paris is obliged to deliver the rain-water and household waste into the sewers. The municipality thus admits the necessity that every street should be provided with a sewer of sufficient dimensions: a street less than 60 ft. wide must have one sewer, and a street more than 60 ft. wide two sewers, one upon each side of the street. An interesting description of the system of sewerage adopted in Paris is given, and the various methods suggested for cleansing and ventilating sewers are discussed at length, and with signal ability, the systems of ventilation applied to the towns of Eastbourne and Gloucester being selected for approval. The ventilation of the Frankfort sewers is also referred to,—which work was carried out by the English engineers, Messrs. Gordon & Lindley,—and was declared by Sir Robert Rawlinson to be superior to any sewerage works, public or private, in England or elsewhere.

Toucing the purification of sewage, the opinion of De Freycinet is quoted, that hitherto all attempts to purify sewage by merely chemical means have been unsuccessful. In Belgium the same conclusion has been arrived at, and in France the partial success of the schemes in operation at Clichy and Combeville do not affect the general principle. The results of the experiments at Rheims are, it would appear, even less favourable than those obtained at Paris. The number of patents for purifying sewage taken out in England between the years 1856 and 1876 was 421. The whole of these processes, which are more or less complex, may act as clarifiers, but they have a very limited effect upon soluble matters.

After passing in review the various processes suggested for purifying sewage, the author concludes that the principle of downward intermittent filtration possesses the marvellous property of completely purifying sewage, but that, as is admitted by the inventor of the system, it is a costly process, and offers no possibility of reconment.

#### NOTES.

**T**HE current number of the *Archaeologische Zeitung* contains an interesting discussion on the metopes of the east end of the Parthenon. The sculptures still remain *in situ*, but severely injured by time and weather that their individual explanation has been regarded as a well-nigh hopeless problem. It is, however, generally accepted that these represent a *giganto-machia*, and since the discovery of the Pergamene *giganto-machia* frieze every monument embodying that myth has been studied with redoubled interest. Dr. Robert now brings together all the available material,—the drawings made by Stuart, those published by Labouche and Michaelis, and the descriptions and notices of Leake, Stephens, Cockerell, and others; to these he adds a consideration of the general typography of the myth on black and red figured vase-paintings, and relying on these data he explains the fourteen metopes as follows:—I. Hermes; II. Dionysos; III. Ares; IV. Hera; V. Chariot of Zeus, with Nike or Iris; VI. Zeus; VII. Chariot of Athene, with Aglauros; VIII. Athene; IX. Herakles; X. Chariot of Herakles, with Iolaus; XI. Apollo; XII. Artemis; XIII. Poseidon; XIV. Chariot of Poseidon, with Aphrodite. This arrangement has the advantage that it places in a central, conspicuous position Zeus, Athene, and Herakles, always in the *giganto-machia* the three most distinguished combatants, while the remaining gods and goddesses fall into natural pairs on either side. The arrangement is ingenious, and shows how much can be done

with scanty material. But, surely untainted though they are, these metopes deserve to be carefully cast before time and weather entirely complete their ravages.

**T**HE Prussian Imperial Archeological Institute has in hand no less than five serial publications which are of the highest importance to archaeologists and artists: 1. A continuation of the great work of E. Gerhard on Etruscan mirrors. Since Gerhard's day much new material has been added and some new light thrown on these somewhat mysterious Greco-Etruscan designs. The first issue of this continuation has appeared. It is edited by Klügmann and Körte. 2. A collection of antique terra-cottas, intended, so far as possible, to be a complete series. The second volume of this publication will shortly appear. The whole is under the management of Otto and Kekulé. 3. The collection of Roman sarcophagi, arranged by Robert, of which a few specimen-plates are prepared and will be shortly published. 4. A continuation of the series of Etruscan ash chests by Körte. 5. A continuation of the collection of Greek grave-reliefs, the Attic part of which is just about to be published by the Academy at Vienna. It will be seen that all these publications have one common aim, *viz.* to bring together material. This material is at present scattered far and wide, often only accessible to a few, and that by an almost impossible expenditure of time and money. When these five publications are completed we may hope for a flood of light on difficult questions connected both with mythology and the chronology of art. Only by juxtaposition can come comparison; only by the comparative method comes secure elucidation.

**T**HE absorption of the two small gas companies, called the Woolwich Consumers' and the Woolwich Equitable, by the South Metropolitan Company, is a step that appears to be in the interest of all concerned, and primarily in that of the public. The total capital raised by the two small companies (according to Mr. Field's Analysis) consists of 67,814*l.* for the first, and 22,500*l.* for the second: items that form but a small proportion of the South Metropolitan raised capital of 2,211,510*l.* The character of the gas manufacture, and especially the mode in which, owing to its extreme lightness, the manufactured product is conveyed from the works, are such as to render concentration of work a source of greater economy in gas, than in perhaps any other industry. Thus the working expenses of the two small companies for last year came respectively to 15*l.* 7*d.* and 19*l.* 9*d.* per 1,000 cubic feet of gas sold, while those of the South Metropolitan Company were 13*l.* 8*d.* Thus the reduction of 2*d.* per 1,000 in the price of gas may at once be secured to the customers, to say nothing of the advantage of the further extension of the sliding scale. The account given of the terms of amalgamation, indeed, speaks of a reduction from 3*s.* to 2*s.* 8*d.* per 1,000, as well as of a rise in illuminating power; but the charge of the South Metropolitan for 1883 was at the rate of 2*s.* 10*d.* per 1,000. For the net cost of coal and all expenses, last year, the small companies paid 21*l.* 6*s.* 3*d.* and 23*l.* 4*s.* 7*d.* respectively, and the South Metropolitan 18*l.* 20*s.* per 1,000 cubic feet sold. It is only by grasping facts of this nature that the question whether concentration is advantageous, or the reverse, can be really decided.

**T**HE Turks, we have been recently told, concern themselves with the present only, the future is in the hands of Allah, the past is unprofitable. With such a creed it is much if they do not destroy any such relics of this unprofitable past as they possess. It is much more that they have allowed an unbeliever to classify and catalogue the antiquities now exhibited in the Tehnli-Kiosk. This work was undertaken by M. Salomon Reinach, a member of the French School at Athens. It gives a somewhat hasty but most valuable description of the treasures of this museum. He found the monuments heaped together in the utmost disorder, and with unbappily no

clue to their identity excepting occasional loose labels. The catalogue was completed in 1882. It is now being followed up by publications from photographs of certain selected monuments of particular interest. Three appeared in the May-June issue of the French "Bulletin" with explanatory text by M. Henzey. 1. A very remarkable archaic head which M. Henzey attributes to Rhodes, and to which he devotes a searching analysis. 2. A beautiful stele from Macedonia, representing the nude figure of a young warrior with helmet, spear, and shield,—a work probably of the early part of the fourth or latter half of the fifth century B.C. 3. A large bronze Hercules, standing with the club over the right shoulder, the lion's skin over the left arm, and some uncertain object in the left hand. This bronze is remarkable for its size and the novelty of its motive, but is somewhat dry in execution.

**S**IR CHARLES DILKE is reported to have said in the House of Commons last week (the 4th) that property was assessed much higher in London than in other towns. What is the fact? Taking the only towns with which any comparison can be instituted, *viz.* those of upwards of 200,000 inhabitants each (the whole of which, taken together, make up only about half the population of London) we have the following comparison. In London the ratable value is 82.5 per cent. of the gross rental; in Liverpool it is 90 per cent.; in Manchester and Salford, 84.7 per cent.; in Leeds, 83.4 per cent.; in Birmingham, 83.6 per cent.; in Bradford, 83.7 per cent.; and in Sheffield (alone lower or so low as in London) 75.9 per cent. For all England the ratable value is 82 per cent. of the gross rental. These facts are as important to the Londoners with regard to their present proportional rating, as they are with reference to the health of the metropolis. It should be considered indispensable to ascertain the actual facts of a case before setting to work (in the absence of such knowledge) to improve it.

**T**HE first meeting of the Société des Amis des Monuments Parisiens, after that which was held for the purpose of organisation, took place on the 29th of June, and was occupied by the reading of a paper by M. Maurice du Seigneur, relating to some sculptured stones, work of the last century, to which M. Ch. Lucas had drawn attention, and which must have formed part either of one of the three former *frontons* of the Panthéon (before those by David d'Angers), or of the bas-reliefs formerly decorating the façade of that building. The Society has commissioned MM. du Seigneur and Lucas to pursue their researches on the history of this sculpture of a century old, and we shall probably be able to state the further results of their investigations in due course.

**T**HE competition organised in connexion with the national manufacture of Sévres, in which first and second prizes are awarded to French designers only, will have for its subject this year, "Une cheminée de boudoir et la garniture pouvant faire corps avec la cheminée." The work which receives the 5,000 fr. prize will remain the property of the State, and will be executed at Sévres at Government expense. Why will not some other Governments take example?

**O**N Wednesday evening the Executive Council of the International Health Exhibition, represented by His Grace the Duke of Buckingham and Chandos, K.G., and the Council of the Society of Arts, represented by Sir Frederick Abel, C.B., F.R.S., &c., received at the "Healtheries" a vast concourse of visitors, and provided for their entertainment every imaginable form of delight. The grounds never looked so much like fairyland, and were the subject of unstinted and universal admiration. "Old London" under the combined influence of a bright moon and the electric light was charming. The shops were kept open, and smiths and braziers in their quaint costume worked away and explained with never-failing suavity and patience the mysteries of their several crafts, while the

hand-hell ringers from a balcony discoursed the kind of music most familiar to the scene represented. In only one point the resemblance to the original failed, for Old London never witnessed such a crowd of gaily-dressed and handsome women as on that night thronged its streets from dusk till midnight. Perhaps the chief of the attractions was the Chinese department, opened for the first time on Wednesday evening. The Chinese have had the entire control of the building and decoration of their court, and wonderfully light and pretty they have made it. Benign Celestials dispense "real Bobea," and smile serenely when questioned in a language they unfortunately "do not understand." We admire a great deal that belongs to the Celestial Empire, but we cannot admire their music. The hand performed at intervals, and the programme comprised some remarkable solos. As to the singing, it was the nearest conceivable approach to catering-wailing. There is reason to believe that the themes were serious, and that "The Seal of Longevity" and "The Ladder of Happiness" were not comic songs, notwithstanding the loud and immoderate laughter with which they were received. The calm philosophic Celestials smoked their long pipes in the intervals of their programme, and no doubt set down our misappreciation of their efforts to the general benightedness of our condition. As we pass out the strains of the Coldstream Guards band swell upon our ear, and it will take a good deal to persuade us that Chinese music is the real thing.

**T**HE verdict of the jury on the fatal accident on the New Augarack Viaduct (Great Western Railway) can hardly be accepted as satisfactory. Two men were lowering a stone of 22 cwt. with a crane when the "spill," a piece of iron by which the weight was suspended at the top of the "jacket," broke, and one of the men was killed by the consequent fall. The piece which broke was wrought iron, and was supposed to be safe at a load of 30 cwt., and the evidence went to show that nothing unusual occurred in lowering the stone. The verdict merely recorded the facts, without expressing an opinion. Unquestionably either the limit of safety was too low, or the iron was defective. It is an accident that ought not to have happened.

**T**HE important case of Yassie v. Baker, an action by a tenant against his landlord for bad drains, which was partially heard and adjourned some weeks ago, ended in a *fiat* on the resumption of the case on the 4th ult., the jury being unable to agree, in the face of very conflicting evidence. The case turned on whether the pipes had originally been badly laid or not, about which it is hard to come to any conclusion on the evidence. Lord Coleridge, in his summing up, laid it down that the plaintiff having taken the house after an assurance that the drains were in proper order, the landlord was undoubtedly liable if the contrary were proved to be the case.

**T**HE unsanitary condition of the House of Commons, we are sorry to see, occupied the attention of Mr. Lowther and the Speaker on Wednesday evening. It appears that the effluvia from a sewer which runs outside the gates of the Westminster Palace, at the corner of Parliament-street, makes itself felt in the House, under certain atmospheric conditions. If the sewer is the real originating cause of the odour, we do not see what the ventilating arrangements of the House itself have to do with it, as the Speaker seemed to imply. It is the sewer that wants ventilating, not the House of Commons,—at least in regard to this special evil.

**A**S we stated a long time ago, the project for concentrating the Thames Valley sewerage at Mortlake would, if the sewerage were properly treated according to the best mechanical and chemical processes, have probably resulted in the discharge into the river only of an effluent which would have been practically innocuous and imperceptible, and we were noting the other day with satisfaction that our previous

opinion was supported by the evidence of Dr. Frankland, Professor Dewar, Mr. Crookes, and other scientific men whose opinion on such a subject is of special value. Suddenly, on Wednesday of this week, came the news that the Special Committee had quashed the scheme. The particular reasons for this unexpected result are at present only on hearsay; they are said to be commercial rather than sanitary. At all events, there seemed a near prospect of something being done, and now all is at sixes and sevens again. Fifty rowing clubs, it appears, gave evidence of their dread of the effluent. But what was the value of their combined scientific experience? or which do they prefer in a river, a "treated" effluent or raw sewage? There is plenty of the latter in the Thames at present, at all events.

**B**Y the way, the question not only of what we run into the Thames, but of what we take out of it, is likely to become of increasing practical interest. People seem at last to be getting made painfully aware of the fact that you cannot go on pumping so many millions of gallons per diem out of a river of moderate size without producing visible and unmistakable effect on the contents and condition of the stream. So much water is abstracted from the Thames now that in dry weather there is not enough coming over Teddington weir to cover the bed of the river. One consequence of this is that there is less stream to carry away the impurities which now find their way in, and the Thames above Richmond is unquestionably more muddily and offensive at low tide this year than it has ever been before. As you can't both have your cake and eat it, so you can't both have your river and drink it.

**T**HE Select Committee on the Thames Communication question have delivered their report. As was to be expected, they have negatived the utterly unpractical idea of the Duplex Bridge, but report that two crossings are immediately necessary,—a low-level bridge at Little Tower Hill, with two openings, each about 100 ft. wide, spanned by a pivot swing-bridge; the other a subway at or near Shadwell, which they consider would best meet the wishes of the inhabitants in the more eastern part of London. We believe the latter will be a useful work, inevitable sooner or later. Concerning the swing-bridge we feel much more doubt. Two vessels arriving from opposite directions can pass at the same time, but then vessels will not always be so obliging as to come at the same time, and then the bridge must be kept open to wait for the later one. The time of detention for vehicles crossing will thus be considerably lengthened; and, as we have said before, a bridge which may at any moment be open, and which is sure to be open just when you are in a hurry, is hardly worth calling a bridge, for the practical purposes of a large traffic.

CAMPS, CASTLES, FORTIFICATIONS,  
AND EARTHWORKS OF  
WARWICKSHIRE.\*

BRINKLOW EARTHWORKS.

THE village of Brinklow is situate on the Roman Foss-way eighteen English miles from Leicester, the Ratis of Antonius, and six miles south of Claybrook, or Venonis, the Roman centre of Britain, where the great Roman British military roads the Foss and Watling-street crossed each other. Its mound or tumulus is a most conspicuous object for miles round, and the camp in which it is situated is upon the terminating point of a ridge of elevated land stretching thence in a north-easterly direction. Dugdale, in his "Antiquities of Warwickshire," says, "This place has its name from that eminent tumulus whereon the keep or watch-tower of the castle, which long ago was there, did stand, but whether it was because this little hill, by our ancestors termed a low, stood upon the edge or brink of the natural ascent overtopping the rest of the country thereabouts, or from the British word 'brynn,'

which is the same with *collis* in Latin, 'tis hard to say. Leaving my reader, therefore, to his own fancy, I shall first consider the ruins of that quondam castle, concluding that had it been a work since the Norman Conquest our public records or some other authorities would have taken notice thereof. But that it was more ancient the diversion of that noble Roman way, viz. (the Fosse), for the raising such a fort does no less argue than the extent of that pool which, from the said road, covered the adjacent valley even unto the skirts of Newbold Revel. How he it, in Domasday Book there is no mention of it, for as much as it was then involved with Smit, and so consequently part of the possessions which Earl Alberic had." When the Roman General Ostorius, in the year 50, invaded Mid-England, the forest of Arden covered the greater portion of Warwickshire; he met some slight opposition from the natives, who, however, were unable to repel the invasion of their territories, and therefore submitted to the conqueror. They appear to have had a perfect chain of fortresses upon the hills hereabouts,—at Burrow-hill, near Daventry, Edgehill, Brinklow, Breedon-hill, Corley, Brownsover, Oldbury, and elsewhere,—to which they could retreat and defende when their lands were invaded. These fortresses were on the frontiers of the British tribes and upon the borders of the country of the "Dobuni" and "Carnabi," and from them communication was no doubt given of an enemy's approach, by means of watch-fires, to the dwellers of the neighbouring hills and forests.

The Romans probably found this spot fortified on pushing their military road southward from Venonis, for slight traces of old rude earthworks existed amongst the small inclosures and gardens towards the village. Having carried the position by force, and thinking it too good to give up, it would appear they constructed a camp for their own occupation to the north-east of that of the native tribe. As a rule the Roman engineers chose level low-lying ground for their camps, where supplies of wood for fuel, and water for horses were plentiful; but policy often dictated otherwise, for, desiring not entirely to extirpate their opponents or their defences, they gradually caused camps of the square form to be built adjacent to the British ones, and thus the inhabitants, mixing with themselves, acquired Roman ways and manners, became useful members of the State, or attended the imperial armies to other lands and conquests as soldiers or servants under the ensigns of the empire. The remains of the Roman or parallel line camp consist of a double row of ramparts and ditches facing the south-east and creating the summit of the hill on that side; they are not straight, however, but had a entrance nearly at their centre, and probably some other defensive work existed at this spot. At the foot of the hill there is a corresponding drip or cutting from the fosse to the land, which seems evidence that a road to the camp existed on this side; the rampart is returned at the angle, and shortly dies into the natural slope. A ridged track is perceptible on this side, and is said to have formed a road to the camp. The rest of the earthworks of this earlier camp are not now discernible; probably a stockade or wooden fence existed on its ramparts. It would see an engagement during the turbulent hundred years 450 to 550, when Britain, no longer held by Roman arms, was invaded by bands of Saxons, Jutes, and Angles, who overran the country and destroyed much of the Roman defences in the Midlands.

In process of time the Saxon, finding the remains insufficient for defence against the Danes (during the period 840—1040), and near the houndaries given to that people to settle in, built the camp anew, or rather erected his castle upon what was left. The works being unwieldy, he divided them into haileys or courts, raising more extensive ramparts and defensive ditches from the ridges of the hill sides, and terminating in the Roman inclosure at the north-east, in which he placed his mound or castle keep, armoured with round wooden or rude rubble stone dwelling (similar to the representation shown in the Bayeux tapestry and contemporary illuminated MSS.), for the use of himself and family, and around which a constant guard was kept against invasion and the sudden approach of a stealthy foe; whilst his soldiers and immediate attendants occupied the haileys in time of peace, living in rude wooden thatched dwellings; and the whole population of the district assembled therein in times of war

\* The illustrations are all to a scale of 6 chains to an inch.

### DECLINE IN THE TRAFFIC OF THE SUEZ CANAL, AND FRENCH AND ENGLISH VIEWS OF THE CAUSE AND THE REMEDY.

So far as the proceedings of the Directors of the Suez Canal, at their meeting on the 1st current, have been permitted, or rather arranged, to transpire, the first half of 1884 has witnessed a marked decline in the traffic. That such was the case may have been the suspicion of many persons who have noticed the accounts of daily transport published in the morning journals, although but few will probably have taken the trouble to carry the items to account day by day. The MM. de Lesseps are said to regard the check as only temporary. From the opening of the Canal in 1869 the increase in the number of ships that passed was steady until 1875, and then fluctuated for four years, the number for 1879 being seventeen fewer than that for 1876. The tonnage and the traffic receipts, however, rose till 1877, but were less in 1879 than in 1877 by upwards of 20,000. From 1879 the rise in all these items was rapid and continuous till the close of 1883, when the receipts were rather more than seven times the amount received in 1871, although the expenditure of 1882 was less than that of 1870 by more than 20,000.

A check in the traffic, therefore, would not give much cause for alarm but for its connexion with facts that hardly lie within the purview of the French directors of the Canal. In the year 1881, for the first time since the publication of the statistical returns of our shipping, the shipping tonnage of the United Kingdom declined in amount. The present state of that important trade is very serious. The imports and exports of the United Kingdom were 4 per cent. less for the half-year, and 20 per cent. less for the month of June, in 1884, than in 1883. The last report of the Tyne Commissioners states that the number of steamers now laid up in the river is 104, with a total tonnage of 90,000 tons. At Jarrow, at Witton Park, and at Middlesbrough, "the streets are full of unemployed men." For a vessel classed A 1, well engined, and guaranteed fast, valued at 20,000, no higher bid was obtained on the 23rd ultimo than 12,000. Whether it be the case, as the shipping interest appears to consider, that this panic is due to the introduction of the Government Shipping Bill, in part or in whole, or not, of the paralysis there can be no doubt.

Under these circumstances it is not matter for wonder if the French directors of the Suez Canal are desirous to postpone the reduction of 50 centimes per ton, which was arranged to commence this month, and which would amount for the six months to something like 70,000. The seven new English directors have not yet been able to take their seats, the requisite change in the statutes of the Company not having yet been authorised by the Egyptian Government. But it is not a question of a tax of this amount (some 75 per cent. of which would be borne by English bottoms) on our Indian trade which most claims the attention of the country. To ascertain the real cause of the check in one of our most important industries is a matter of far more moment than is an addition of 4d. per ton to the freight of a long voyage; and if it be true that the shipowners and shipbuilders of Germany are not struck by any similar check, but are, on the contrary, thriving on our discontinuance, it would seem as if the reply to the question, "What is the cause of the shipping decline in England?" ought to be as ready, and as distinct, as it is virtually important to the country.

The question of the mode in which the necessary increase of accommodation for the ocean traffic through the Isthmus should be provided appears to have been set at rest by the three nights' debate on the subject of "Speed on Canals," on the 5th, 12th, and 19th of February, 1884, which is reported in the seventy-sixth volume (just issued) of the Proceedings of the Institution of Civil Engineers. Out of thirty speakers who took part in that debate,—including civil engineers, shipbuilders, and naval men,—but one was found to advocate the scheme of a second canal, and his remarks only brought into fuller relief the advantages to be derived from widening the existing channel, rather than attempting to cut a new one. When it is borne in mind that each vessel that passes through the Canal pays a total of nearly 800*l.* (in 1883, 3,307 ships paid on an average 796*l.* each) while the total expenses of maintenance,

transit, and administration only amounted to 74*l.* per ship, it is tolerably clear that the customers of the Canal have the right to expect that those measures which, as pointed out in the debate in question, would reduce the time needed for the passage of a vessel from the actual allowance of 53 hours 41 minutes, to a maximum delay of 12 hours, should be taken without further procrastination. According to the reports taken from the French papers, the hope is entertained in Paris that the new English directors will themselves propose to defer the reduction of 50 centimes per ton that should come into operation during the present month. It is much more rationally to be expected that the influence of these gentlemen will be thrown into the scale with the view of making an enterprise that earns that enormous proportional profit really available for the requirements of navigation, which, at the present moment, cannot properly be said to be the case.

Since the above was in type we have ascertained from official sources that the decline in the receipts of the Canal Company from navigation has been 14.7 per cent. in May, and 21.1 per cent. in June, 1884, as compared with the same months in 1883.

### SALE OF PRINTS IN THE FOUNTAINE COLLECTION.

SIR ANDREW FOUNTAINE was born in a fortunate day for collectors, and he made good use of his time. The fact that he should have been able to gather treasures together enough to take Messrs. Christie & Manson eight days in the selling, says much for his energy and discrimination. The aimless crowds who came flocking when the falience was sold, to extaticism over clumsy candlesticks, and kitchen utensils of Urhino, or Nevers, or Palissy ware, are happily absent from the rooms when a great collection of engravings is to be sold. The strength of the collection lay in the works of the "little masters" of Germany, and of the great master, Dürer; in the etchings of Vanöyke, and the Marc Antonios; and the interest was fairly spread over the whole four days of the sale. The splendid set of Aldegraver's work was the feature of the first. No reason, by the way, is given by Bartsch, or any other writer with whom we are acquainted, for distinguishing, as Bartsch does, the "Master of the Monogram, A.G.," from Aldegraver himself, or some fraudulent copyist of him. The date of Aldegraver's death is placed speculatively at 1558. May not the fact that this "master" (or fraudulent possessor of) "the monogram A.G." puts 1562 to many plates, suggest for his demise a later date? Be this as it may, the collection was a very fine one, containing the "Parable of Dives and Lazarus" (in five prints), and the set of the "Wedding Dancers," 1538, and other things which Duplessis holds up to especial admiration. The work of the two Behams, Barthel and Hans Schald, was distributed in more than 120 lots, out of which it would be hard to particularise. No. 192, "The Portrait of an Emperor," from Sir Peter Lely's collection; No. 217, "The Musicians"; No. 240, "The Little Jester"; and No. 245, "The Two Genii," in the first state, all by Hans Schald Beham, are works of the greatest rarity.

A great many of the choicest prints of Sir Andrew seem, by the way, to have come to him from Sir Peter Lely. That had painter was no mean connoisseur, and the plain P. L. within a circle, which denotes his ownership, does nothing to prejudice a print with an experienced buyer. The name of Baccio Baldini is one which commands more respect than his artistic merits seem to allow. His association with Botticelli on the famous 1481 Dante, accounts in some measure for this. So long as the early history of typography and wood-cutting is explored, Baldini's name will not die. Narford Hall had nothing much of this artist to show,—only a set of the "Prophets" (wanting ten out of twenty-four), and these not in their most valued state. Duplessis thinks that in the "Prophets" also he can trace the design of Botticelli. It is rather surprising to find but one Rembrandt in the collection. Others, perhaps, were sold at some earlier date; or perished in that cruel conflagration at "White's" which destroyed so many of Sir Andrew's treasures. The rage for Rembrandt is pretty old, whilst that for the little masters is

comparatively new. Sir Andrew Fountaine, however, was a very surprising person. We have seen already how wisely he went to work collecting Limoges enamels and majolica, and medals of Pisano and Sperandio, whilst his silly countrymen were raving over had copies of the "Eclectic" school, and over broken fragments of Roman "antique." A desire to be original in his line may account for his leaving Rembrandt upon one side. To make up for it, however, he made a fine collection of Dürer's prints, and gathered together a splendid lot of Vanöyke's most treasured etchings. It may be remarked that the ardour of any amount of cult is determined more often by the amount of scope which it offers to pure connoisseurship, than by the attractiveness of the subject from a merely artistic point of view. Between the plate-mark of an etching and its margin there may be matter for a study no less minute, though it may well be less profitable, than that which the etched subject itself demands. Vandyke's etchings, whilst their splendid artistic qualities give them rank only second to Rembrandt's, present also infinite varieties of state and condition which make them a specially popular subject of study. If any unthinking person wants to be finally convinced that the last "state" of a plate, as of unregenerate manhood, is worse than the first, he has only to be shown those brilliant portrait-heads in their first or second states, as they came fresh from the needle of Vandyke, and then shown the later states of the same, in which his own work may be antonched, but the backgrounds have been filled in and various circumstantial details superadded. Under Vandyke's death his plates came into the hands of his friend Van den Enden, and by him were republished; later, again, they were purchased by Gillis Hindrix, whose abhorred initials (O. H.) seen below the plate-mark cause the heart of a collector to shiver within him. Looking over these portfolios we had rare opportunities of studying and comparing the "states." Space does not permit us to treat at length of other matters. A vast number of portrait engravings after Vandyke would interest chiefly the historian. Hollar was fairly represented, but no more than a highly-skilled mechanic; yet, even so, some masterpieces of the etcher's craft would have been unknown to the world had it not been for his patient point. Such a piece of work was 616, "A Muff"; such, too, were his famous "Shells." A very rare portrait of "Vandyke with a Sunflower," in perfect condition, was among the finest of Sir Andrew's Hollars. Of German masters, we have made no mention of Burgkmair, nor of Brosamer, nor of the "little master," Jacob Binck, who, much to his advantage, has been confounded with the "Master I. B." Why the said J. Binck should have chosen to sign himself H. B. (H. C. B.) whilst his own proper initials were thus sent a-begging, is a point we must leave men wiser and better to determine; and with only a glimpse at a complete set of Hogarth, and the remark that one may fail to be deeply impressed by the heavy work of Raimondi, and yet be in excellent company, we take leave of a collection which ere now has taken final leave of us.

### THE INTERNATIONAL FORESTRY EXHIBITION, EDINBURGH.

THIS Exhibition, which is the first of the kind ever held, owes its origin to the Arboricultural Society of Scotland. The Society felt that the education of this country in the science of forestry had been very much neglected, and that, however much we might be in advance of other nations in many respects, in this one point we were far behind most of the other nations of the world. This was all the more to be regretted, seeing that we possess to a larger extent than any other nation, forests in every quarter of the globe, a fact which in itself implied that these are of varied character, and required different treatment. Owing to the difficulty in obtaining a site for the requisite buildings, it was not until March last that the plans of the building now erected were accepted, and these buildings are universally admitted to be well adapted for the end in view. The effect of this delay, however, has been that the time was insufficient, not only for the thorough completion of the building and its accessories at the period fixed for the opening, but it has deterred some in-

tending exhibitors from coming forward, and the exhibits of others were behind time. The result may, on the whole, be considered satisfactory, and the exhibition is really a very interesting one.

The Marquis of Lothian, in the opening address, expressed a hope that out of the exhibition might come a School of Forestry, and, if possible, that it should be located in Edinburgh. They had their Botanical Garden, their Arboretum, and their University, and they had the Highland Society, which had taken an interest in forestry matters, and they had abundant opportunities in the country for students learning practical and theoretical forestry. During the few months the Committee had worked very hard, and had done their best to make the exhibition practically useful and also attractive, but he was not so far from being without attraction did not go for much money, but let them hope that before long money would be forthcoming, and that they might see a School of Forestry in Scotland. The Lord Provost referred to the interest which the Town Council had, during the last three hundred years, taken in the University, and to the important duty they had performed in recently acquiring ground for an arboretum at a cost of about 20,000*l.*, and placing it at the disposal of the Government for the purpose of improving the education of the students, and ultimately with the object of providing a School of Forestry.

The building, designed by Mr. Robert Moreham, City architect, is simple in its arrangement and mode of construction, and is admirably adapted for its purpose. The only attempt at internal decoration has been the colouring of the arched principals which support the roof pale blue tint with stencilled ornament thereon. This is either too much or too little, and the effect would have been better had these beams been left uncoloured like the rest of the woodwork.

The first object that attracts the attention of the visitor on entering the building is a section of a "Californian redwood tree," 13 ft. in diameter, which forms a small apartment hung with photographs, showing the operations of the lumberers in the forests. In the adjoining transept are examples of the wood as applied to different articles of furniture, polished and unpolished, carved and inlaid; for all of which purposes the wood seems to be well adapted. The wood is generally of a deep red colour, but it varies considerably both as regards hue and grain. These trees are the grandest productions of nature's vegetation, sometimes having a diameter of 20 ft. and a height of 200 ft. before a branch is thrown out. The grove of these trees in the Yosemite Valley has been frequently described by travellers, but to see the tree in perfection and the forest in its most sublime aspect, the lover of nature must penetrate to solitudes whose depths have seldom or never met the gaze of civilised man. The outskirts of these forests are for a distance of about half a mile fringed by spruce and smaller trees, with here and there a few redwoods. It is in the depth of the forest that the true grandeur of the redwood is found, and where it usurps the entire possession of the ground. At first it is difficult to form an accurate idea of the magnitude of these monarchs of the forest, there is no scale by which they can be contrasted; tall and close together, they seek the upper light, often thirty or forty of them with diameters of upwards of 14 ft. being found upon a single acre. It is only within the last few years that the capabilities of this wood have become known, and the forests once given up to solitude and the Indian now resound with the stroke of the axe and the grating of the saw. A ready market is found for the wood in Chicago and the Eastern States, which is now extending to Europe. The wood is found to be adaptable to outside work as well as to internal fittings, and to be durable and free from shrinkage.

**Demolitions in Blomfield-street.**—The Corporation have just made a clean sweep of the buildings on the south side of Blomfield-street, extending to about half the entire length of the street, in the direction of the North London and London and North-Western Railway stations, and to a considerable depth eastward, the site thus cleared being nearly an acre in extent, which is now announced to be let on building leases.

#### GUILDFORD ART LOAN EXHIBITION.

AFTER the stimulus that has been given to exhibitions of all sorts, by the first and most brilliant of them all, that of 1851, the English public has been so often invited to visit collections drawn from the inexhaustible sources of private as well as public wealth, that it requires some special element to give to any local display the chance of success. There is, indeed, only one way in which a local exhibition, not of enormous dimensions, is likely to attract any other than strictly local notice, and that is when local associations, of historic moment, can be appealed to and illustrated. In this respect the county town of Surrey may be said to be not unworthy of its position. Its structural memorials go back to a date long antecedent to the Conquest. The "strips" on the tower of its most ancient church savour of Saxon building; and the small double-splayed windows of that part of the sacred edifice appear to have been constructed to keep out the sacrilegious invader. It was down the Wey that the bier of the fair Elaine floated; Guildford Castle, with its ancient herring-bone brickwork, has traditions of Alfred; and the spot is identified with the Astolat of the poet. In the neighbourhood are such historic sites as Wotton, still held by an Evelyn; Sutton, with its noble chapel, occupied the first floor of an entire wing; Loseley, with its Elizabethan windows, and its memorials of the Mores. The monuments, plate, pictures, and other articles of interest, from houses such as these, the regalia and records of the corporations of Guildford, Godalming, and Farnham; and the objects of interest lent by the houses of Percy, of Onslow, and other neighbouring families, are such as to make this loan exhibition worthy both of visit and of record.

Among the paintings ascribed to "Old Masters," which head the Fine Art Section of the catalogue, are a few of undoubted authenticity and merit. Such are the portrait of Cardinal de Retz, after his return to France on the death of Mazarin, by P. de Champagne; a small, but beautifully-distinct view of London, by Canaletti; portraits of the regicides Bradshaw and Cromwell, by Dobson; of Lord Walpole, of Wolterton, by Denner; of Charles I., attributed to Vandeyck; of Horace Walpole, by Hogarth; and a wonderful head of an old woman, from the Orleans Collection, by Denner. The claims of the portraits of Edward VI., of Sir T. More, and of Wolsey, to be from the pencil of Holbein, may perhaps be better avouched by the records of Loseley, whose owner lent them, than they would seem to be at first sight. One portrait is in itself enough to repay the cost of a visit to the exhibition. It is a head of Dr. Johnson by Gainsborough, the property of Sir J. Whittaker Ellis; a portrait that goes far to show the nobler and more tender aspect of a rugged character which has been obscured by the incense of Boswell.

Of the collections of modern oil pictures, crayons, and water-colour drawings; of the groups of works by Morland and by Russell, the latter a local celebrity; of the deeds, MSS., &c.; of seals, autographs, coins, and medals; of ancient printed books and manuscripts; of porcelain and pottery; of needle-work, embroidery, and tapestry; of articles of plate and bronze; of neolithic and palæolithic stone implements; and of miscellaneous articles, we have no room to speak. Under each head are ranked very interesting specimens. The sword left by Charles I. at Weston, the seat of Sir Richard Halford, the night before the battle of Naseby; two ivory chairs taken from Tippoo Sahib's tent; and some fine bronzes are lent by her Majesty the Queen. A case contains a selection of silver and gold plate vases and other objects from the wedding presents to their Royal Highnesses the Duke and Duchess of Albany. The Guildford Corporation plate, comprising an ebony staff with silver top, presented to the town by Queen Elizabeth; a silver mace presented by the High Steward,—one of the Howards,—in 1663; and another mace, of great but unknown age (which the occurrence of a single plume, like the centre feather of the three in the Prince of Wales's plume, may, perhaps, enable the expert to fix), and other objects, are lent by the Corporation. But, whether it was due to the good lighting or to the excellence of the sculpture, nothing has lingered longer on the memory of the writer

than two marble busts lent by the Duke of Northumberland,—one of Mr. Spencer Perceval, thoughtful and delicate; and one of Lord Melville, the forcible classic features of which recall to mind the lines,—

"In whom  
The ancient Roman honour more appears  
Than any that draws breath in Italy."

#### THE EFFECTS OF FROST ON BUILDING STONE.

THE study of the above question has led to many detailed investigations, without precise and definite results having been arrived at. The only indications of any exactness are those which have proceeded from lengthened observations of materials employed in climates and under circumstances analogous with those for which it is proposed to draw inferences from practical experience.

In bringing forward, in the *Revue Industrielle*, some connected details upon various branches of this subject, M. Braun remarks that nothing definite is proved by the statements made at a certain period respecting sulphate of soda. It has often happened that stones which have resisted expansive force, have later on given way under the influence of frost, while the contrary has sometimes been remarked. It must not, however, be concluded if stone has for a length of time resisted the effects of frost, that it will do so for an indefinite period. The case of the stone bridge at Borrège, cited by Vicat, is a striking proof bearing on this point.

After calling attention to the fact that the effects of frost are often confounded with other causes of deterioration to which stone is liable, M. Braun endeavours to define in an exact manner the question under discussion, asserting that a stone is affected by frost when its resistance to longitudinal traction is less than the force of expansion of the water contained in its pores at the moment of its transformation into ice.

The *Journal du Céramiste et du Chaufournier* remarks that this theory requires certain modifications in practice. It is, however, admitted that, supposing this definition to be exact, it furnishes a provisional solution of the problem, and would allow of the resistance of a stone to frost being ascertained without exposing it to a practical test. According to mechanical theories, a kilogramme (2½ lb.) of water in freezing develops an amount of mechanical labour equaling 33681 kilogramme-mètres (24351 foot-pounds). This knowledge of the force developed by water at the moment of its changing its condition would enable the resistance of a stone to frost to be estimated if there were also known,—1, its density; 2, its porosity; 3, its resistance to longitudinal traction. Thus, if the quantity of water contained in a cubic centimètre (.061 cubic inch) of a stone does not produce in congealing a force superior to its resistance to traction per square centimètre (.15 square inch), the stone would not be affected.

Unfortunately, however, matters are not so simple in practice. The principal elements of perturbation are (1) the want of homogeneity in stones; (2) the state of superfusion of water, which is often produced in the interior of stones; (3) the chemical action of the waters of the quarry. The first point is too well known to call for detailed reference. The capacity for absorption of water which is possessed by stones from the same quarry (or even from the same part of it) varies to such an extent as to render it difficult to fix *a priori* what is the quantity of water the expansive force of which in congelation has to be estimated.

The circumstances under which the longitudinal traction takes place must not be lost sight of. M. Braun, relying upon Hodgkinson's experiments, considers that the figures arrived at in the tests of traction should be reduced by one-third. As the complete rupture is always preceded by a disaggregation which is indicated by fissures, and as these fissures are generally produced under a burden which varies between one-third and one-half of that necessary for the total rupture, it would be necessary, in view of these facts, to introduce a new co-efficient of reduction, comprised within the limits indicated. This *co-efficient of broken equilibrium*, as M. Braun designates it, must be always attended by uncertainty in its determination, according to the opinion expressed by the journal already mentioned. As a

summary of his investigations, M. Brann gives this formula:—

$$(C + C_1) R = 33.681 A.$$

- C = The co-efficient of reduction as deduced from Hodgkinson's experiments.
- C<sub>1</sub> = The co-efficient of broken equilibrium.
- R = The average burden per square centimetre, which determines the rupture under the action of longitudinal traction.
- A = The quantity of water contained in a cubic centimetre of stone and expressed in grammes.

When the first number of the above is superior to the second, the stone is fit for building purposes. When the contrary is the case the stone should only be used in situations where it is not exposed to frost.

It is admitted, in conclusion, that M. Brann's ideas are both new and original, displaying, at the same time, such an amount of probability as to render it possible for them to mark a new point of departure in experiments bearing upon the subject under discussion, notwithstanding the speculative nature of some of the principles enunciated.

Illustrations.

DESIGN FOR A MODEL THEATRE.

THE fundamental principle of this design for an ideally perfect theatre, which obtained the first prize at the Berlin Health Exhibition of 1883, has been the arrangement of the building in detached groups, allowing of an easy and general supervision. The advantages of such a disposition would seem to be,—1, The separation, as far as possible, of the auditorium and the stage; 2, The provision of easy and rapid modes of entrance and exit for the audience; 3, In cases of fire facilities for localising the flames and attacking them from all sides at the same time; 4, The external lighting of the auditorium, the staircases, and most of the rooms belonging to the stage; 5, Economy of space both on the stage and in the auditorium.

The central point of the whole design is the circular auditorium with its three staircases. It gives access to open courts on four sides, and beyond these it is surrounded by the main vestibule and the foyer in front, by three rehearsal rooms, the manager's room, &c., on the two sides, and by the stage behind. The stage is so arranged that only the most necessary apartments are actually contiguous to it. The dressing-rooms, property-rooms, and workshops lie on either side, but they are isolated by means of corridors. The painting-room is above the back of the stage, and in the further corners of the building are two large storerooms, separated from the stage by small open courts.

The principal entrance to the theatre leads direct into the main vestibule, which communicates easily with the smaller vestibules on either side of the auditorium, intended for the use of the gallery portion of the audience.

The staircase leading from the main vestibule is intended for the use of the audience in the area of the theatre, and on the first and second tiers of boxes. The two side staircases lead to the galleries. The staircase from the vestibule, however, also goes up to the top gallery, in order to afford easy communication between the upper stories and the foyer, and to be used by the gallery audience in case of panic. Extra staircases, to be used in cases of emergency, are approached from open loggias on each floor and lead down to the four open courts, and thence through passages direct into the street.

The auditorium is thus seen to be completely isolated, surrounded by four detached groups of buildings, giving access on four sides into open courts provided with extra staircases for the safety of the audience. The open loggia, extending along the side of the courts on each floor, serve to disperse the audience as far as possible in cases of panic, and in summer they can be used as places of refreshment; each of them is capable of containing 200 persons.

The front area of the auditorium seats	368 persons.
The back	274 "
The first tier above	142 "
The second	244 "
The third	354 "
The fourth	370 "
Total	1,759 "

Access to the stage is given as follows:—

The staircases for the actors, singers, &c., male and female, are in the group of buildings on each side of the stage, and completely separated from the entrances for the workmen, machinists, and scene-painters, which lie behind the stage.

The entrance to the manager's room and offices are in the second group on the right of the auditorium. Extra staircases for the actors open from the galleries in immediate proximity with the dressing-rooms.

The stage is 24 metres long by 17 metres deep and 34 metres high. Corridors extend along either side partly as means of communication with the stage, partly as convenient and protected posts for the firemen and their machinery. The stage is roofed in by a dome constructed of panicles, and covered with a second roof of iron. This device affords, in the opinion of the designers, a security against the falling in of the roof, by providing, in any case of fire, a cool current of air between the dome and the iron outer roof. The central opening on to the stage serves for ordinary ventilation, the four side openings for the issue of heat and smoke should fire break out on the stage.

The flies, consisting of four stories, have grated floors, and a considerable open space is left above, calculated to check the progress of fire and to diminish the danger of the falling-in of the roof.

In providing for the separation of the stage from the auditorium in case of fire, the authors of this design have kept in mind the danger attendant on the use of an iron drop which, as soon as it becomes heated above a certain point, falls and leaves free passage to the flames. They believe they have obviated the danger by designing the construction of two iron drops, a lighter one as an act-drop, and a heavier one for use at the conclusion of the performance, each completely independent of the other, and under the direction of a fire-inspector. The fire-inspector's room is between with the fire-engines and the water supply, so that in case of need the iron curtains can be continuously sprinkled with water, and their over-heating prevented.

The front stage is separated from the back by an iron wall, which is hollow and filled with water, and can be raised and lowered by hydraulic pressure. There are, of course, doors in all the three drops for use in case of need.

The storerooms are in two stories and very strongly constructed. They are in easy communication with the back stage and the painting-rooms above.

The ventilation and heating of the theatre are designed by Herr J. Strebel, engineer, of the firm of R. O. Meyer, Hanburg. They are on a very complicated and perfect system of hot-air and steam-pipes, and provision is made for the introduction at an equable temperature of hot air, moistened by steam. The stage, property-rooms, dressing-rooms, corridors, &c., are each provided with stoves or coils, for steam or hot water, and the whole apparatus is so constructed as to be easily under control in case of fire or accident. The boilers and steam-engines are located in the basement for the better safety of the building. The employment of steam both as a purifying and a heating medium renders this isolation of the machinery and apparatus possible, since it loses but little either of heat or pressure by its passage through any length of pipes.

The design for ventilation cannot be explained in detail without the aid of diagrams. It provides for a change of the air on the stage every half-hour, and for an hourly supply of 25 to 35 cubic metres of fresh air per head in the auditorium.

There is an abundant water supply with separate systems and cisterns for the ordinary purposes of the building, for the extinction of fire, and for use on the stage, all of which could be utilised at any given point within a very few minutes.

SKETCHES BY THE LATE G. E. STREET, R.A.

THESE are photolithographed from two others of the set of pencil sketches by the late Mr. Street, of which we gave two last week. They are reproductions of the lines of the originals, though the peculiar texture of pencil work cannot be reproduced in lithography.

PULPIT IN CHURCH OF SAN LORENZO FUORI LA MURO, ROME.

The lithograph of this effective example of inlaid work in marble is from a drawing of it made on the spot by Mr. R. Barratt. The design, with its hard straight lines and flat surfaces, is thoroughly suited to that class of work, and it is judiciously raised on a plain solid base of masonry which sets off the inlay work above and, at the same time, prevents the whole from appearing too slight or deficient in monumental character.

SILSDEN MECHANICS' INSTITUTE, YORKSHIRE.

THIS building, of which we give an illustration, is now in course of erection, by local contractors, and is intended to be opened in September.

On the ground floor are a reading-room, 19 ft. by 19 ft.; news-room, 24 ft. by 16 ft.; conversation room, 24 ft. by 14 ft.; lavatory, shop, and living room.

On the first-floor are an assembly or lecture room, 48 ft. by 30 ft., and retiring or classroom, 19 ft. by 19 ft.

The contractors are,—for masons' and brickwork, Mr. Joshua Tillotson, Silsden; joiners' work, Mr. Frank Cowling, Silsden; plasterers' work, Messrs. Laycock, Silsden; plumbers' work, Mr. B. Newbould, Keighley; slaters' work, Messrs. Hill & Nelson, Bradford; and painters' work, Messrs. Tillotson & Harrison, Keighley.

The stone is fine sandstone from neighbouring quarries,—the ashlar being toolled and the wall stones fine hammer-dressed. The joiners' work is all of the best red deal, and will be painted plain colours. The rooms are intended to be warmed by a low-pressure hot-water apparatus by Messrs. Clapham Bros., Keighley.

The architect is Mr. W. H. Sugden, of Keighley, who has contrived, we think, to give a good deal of character to a simple and inexpensive building.

**Cholera and Cowardice.**—It is a most deplorable proof of the weakness of human nature that it is at all times prone to fall into a state of panic when brought face to face with the inevitable. We must all die, and we are not ignorant of this our destiny; nevertheless, the instant a danger to life is recognised, we fly from the peril with the impetuous haste of crazy and cowardly creatures, forgetful alike of duty and decency. It is vain to argue in favour of self-possession. Philosophy has no charm for, or power over, the man who impulsively turns his back to the enemy. Nothing we could urge would have the slightest weight with the multitude bent on escaping from the ports and cities which are just now supposed to be rife with infection of cholera. These flying crowds, on safety all intent, must be left to their own devices. It is manifest that they will spread the malady, and it is scarcely less certain that they will, many at least, lose their lives in trying to save them. With regard to these matters, however, it is useless to speak. Suffice it to point out that, although in the presence of an epidemic of cholera, there is always and unquestionably some personal peril of contracting the disease, it is by no means certain that this is increased by remaining in association with the sick, or that the danger is to be avoided by running away. During severe epidemics it has been noticeable that the mortality has not been, by any means, greatest in the very centre, so to say, of the disease. In the hospitals and among the cholera patients scattered throughout the population, medical officers and nurses have gone about doing their duty with no greater mortality than that of those who have kept aloof. Indeed, it is probable that a certain amount of immunity from disease has been enjoyed by those who have not feared the danger of infection. The great secret of success in warding off disease is the preservation of health. We mean that if, heedless of danger, men and women do their duty to those around them,—keeping up a cheerful temper and a trusty spirit, neither abusing the good things of life nor avoiding them,—in short, living as all should live, whether in the midst of a healthy population or in the presence of an epidemic,—they have a far better chance of escaping disease than by falling into a state of panic and "hastening to leave."—The Lancet.

HEALTH EXHIBITION LECTURES.

FOUL AIR IN HOUSES.

A LECTURE was delivered by Professor Corfield at the International Health Exhibition on the 4th inst., on "Foul Air in Houses." Dr. Heron presided, in the absence of Sir P. Cullifife Owen.

The lecturer introduced his subject by observing that it was one in which all should take an interest. He then proceeded to show the result of breathing air highly contaminated by the respiration of human beings, referring to the catastrophe of the Black Hole at Calcutta on June 20, 1756, where 146 persons were confined for ten hours at night, and 123 were found dead in the morning, while twenty-three of the survivors were covered all over with boils, and in what was called a high putrid fever. Typhus, or gaol disease, was a characteristic of places where there was overcrowding. There was another disease prevalent under such circumstances, namely, consumption. Dr. Guy mentioned an instance of printing-works in which the workers had only just 200 cubic feet of air each, and they died of consumption as fast as if they had had typhus fever. Now, what was the reason why air that had been breathed was unfit to be breathed again,—why rooms that contained air that had been breathed over again were so injurious to health? Was it the diminution of oxygen in the air? The amount of oxygen in badly-ventilated rooms was 2,080 or 2,075 parts in 10,000 of air. The instances were very rare where it was reduced below 2,070. So that the diminution of oxygen was very small. Then that was not sufficient to account for the deleterious results he alluded to, and neither was the increase of carbonic acid, although poisonous. The prevalence of typhus fever and consumption was undoubtedly attributable to the foul organic matter, and the excessive moisture in the air. They were able to estimate the amount of air required by each individual in an hour. That amount was 3,000 cubic feet, so that if he remained in a room seven hours, he would require 21,000. He could not get that in any ordinary-sized room, and so the air required changing. If the atmosphere of a room was in such a condition that a disagreeable sensation was experienced on entering, that was evidence of the presence of putrescible organic matter. The results observed from the entrance of air from drains into houses, whatever way it got in, was the appearance of certain diseases, such as sore throats, diphtheria, scarlet fever, diarrhoea, typhoid fever. Foul air got into houses from had appliances or from defective arrangements of good appliances, from using things that were out of order, and still more from the disuse of things. New drains were often made of porous materials, which allowed foul water or foul air to pass out. They were frequently made of bricks and mortar, which were very improper materials for such a purpose. The presence of rats was to be regarded as a serious sign, and as a sign that in all probability the drains were out of order. Besides, these rats took some amount of filth from the drain, and very likely they got into the larder. But rats might get into a house through the imperfections of the drains of neighbouring houses. A serious instance of this occurred in a house in which the pipes were imperfectly joined together. A layer of concrete was used by the occupants to cover up the pipes instead of making them out altogether. The rats made their way into an adjoining house in which the drains were in an excellent condition and made their place under the hearthstone, where they lived and died, and whence they ran all over the house, and had a very nice time of it. When the hearthstone was taken up there were found the remains of thirty-six rats in various stages of decay. That was a curious instance in which a man who did not attend to his own drains might be a nuisance to his neighbours. Foul air often got into houses from pipes which were not properly made. Not infrequently the pipes were laid the wrong way. Instead of being laid with the socket upwards they were laid with the socket downwards, and thus the water ran out and the drains were stopped up. If the pipes were joined with cement that was an excellent plan, but it might be done inefficiently; for instance, the cement might be put round the top of the joint and nothing underneath. Dust-bins were too

frequently placed near the walls of houses, and thus foul air passed into the dwellings, first into the basement and next into the upper rooms. Very often connexions were made with the drains from the floor of the house. Openings were made in the drains and they were provided with some kind of trap. A very common trap was the bell-trap, which, a few years ago, was to be found in every house in London. This was a kind of trap which should not be tolerated inside of a house, especially if connected with a drain. Soil-pipes were the pipes into which water-closets discharged. They were very frequently placed inside houses, and often not ventilated. One of the best materials for them was lead; but lead was not the best material if they were not ventilated. Foul air had a propensity to eat through solid lead where the pipes were not ventilated, and thus the foul air escaped into the house, and sore throats and other diseases were the consequence. Dr. Corfield showed examples of soil-pipes which had been eaten through by foul air, and went on to say that they should be ventilated at the top. Ventilators of soil-pipes were not infrequently carried near to windows of sleeping-rooms, and disease was the result. Where there was a foul smell the best way was to throw down some oil of peppermint into the suspected drain. In the case of one country house he knew of, this had been tried on a soil-pipe in which, in spite of the escape of peppermint, no defect could for a long time be found; but ultimately the wall was opened, and one portion of the pipe was found there which had been struck by a workman with his chisel, and a hole left in it, through which the foul air escaped and wandered through the floors into quite a different part of the house. The most common kind of closet used in houses was the pan-closet, but that was about the worst form of sanitary arrangement ever put into a house. They might have the best arrangements for ventilation, but if there were a pan-closet there was sure to be a nuisance, especially if they had a D-trap under it. This form of apparatus should not be tolerated anywhere. There should be syphon-traps on the soil-pipes; and waste-pipes should not be connected with soil-pipes. Rain-water pipes were frequently placed inside houses; they passed through the bedrooms, perhaps through the drawing-room, through the dining-room or hall, and through a room in the basement to the drain. Proper care was not taken to see that the joints were made air-tight, because they were only the joints of rain-water pipes. But foul air from the drains came up from the rain-water pipe through such leaky joints and passed into the rooms. Lead rain-water gutters were not infrequently taken from the outside of a house through the top rooms. He had known cases of disease caused by rain-water gutters passing under the floors of rooms. Waste-pipes of cisterns were not uncommonly connected with drains or soil-pipes, and so foul air got into the cistern. The best plan was to cut off the waste-pipe and make it discharge into the open air. Foul air frequently travelled about houses by means of tubes through which the bell-wires ran. This was a fact which was not so much attended to as it should be. He had known instances where the rooms had become uninhabitable from the foul air passing through those tubes. Foul air was not uncommonly produced by a slight escape of coal gas, through the gasfittings not being perfectly air-tight. The smell caused by this was very peculiar, and it was not easy to detect. Whenever there was a doubt as to a peculiar smell in a room the gas-pipes should be tried. He did not mean that they should try with a light, for the escape would be too slight for that. Coal gas contained carbonic oxide, one of the most poisonous of gases. It was through this slight escape of coal gas that headaches were often produced. Foul air from drains sometimes got into larders, and so affected the food. It was not uncommon for soil-pipes to pass downwards through the larder. Milk rapidly absorbed foul matter from the air and became poisonous. It was exceedingly dangerous to have in a house sanitary apparatus not in use. Foul air came in through them. Dr. Corfield mentioned a case, by way of illustration, of a large school-house formed by two houses being thrown into one. The sanitary arrangements were thought to be perfect, but in one of the houses was a sink that was not wanted. The scullery was not used, and the foul air that

came through the sink and from the hell-trap was "enough to turn a windmill."

A cordial vote of thanks was passed to the lecturer.

THE PARKES MUSEUM.

THE annual report of this valuable Institution, adopted at the general meeting held at the Museum, 73a, Margaret-street, Regent-street, on Wednesday last, observes that "the first year of the occupation of its new premises by the Parkes Museum has been honourably marked by the death of the President, H.R.H. Prince Leopold, Duke of Albany. This event has been an incalculable blow to the progress of the Museum.

The able address which His Royal Highness delivered at the opening of the Museum in May, 1883,\* was an evidence alike of the sympathy which he felt for Sanitary Science, and of the importance which he attached to the diffusion of that branch of knowledge through the country. The Council feel that in losing His Royal Highness they have lost a President who had the interests of the Museum deeply at heart, and who would have spared no effort to render it worthy of the objects for which it was established. The Council have carefully considered the question of electing another President, but they think that it is undesirable to take steps in this matter at the general meeting of this year. The Council have the satisfaction of being able to report that the Museum has made a considerable advance during this, its first year in the new building.

In January of this year, Dr. Louis Parkes, nephew of Dr. Parkes, in whose memory the Museum was founded, was appointed honorary librarian, and he has since his appointment devoted himself to a more regular classification and complete labelling of the books, reports, and pamphlets contained in the library, so that any volume sought can now be found more readily than had hitherto been the case; in addition to this, the work of cataloguing the library has been taken in hand, and is now in an advanced state of preparation. Numerous and valuable presentations have been made to the library during the last year; but to mention here even a few of the names of the munificent donors would occupy more space than could be spared in this report. The total additions to the library since June, 1883, have amounted to about 530 volumes; and the present collection, in point of numbers and of extent of subjects embraced, forms a very valuable library of sanitary literature.

The library and reading-room, although now open to the student on the payment of the small fee of 5s. a year, has not been so largely frequented as might have been anticipated, when its numerous advantages are considered. The Council are deeply indebted for many services rendered to the Museum by its honorary officers.

During the year the Sanitary Institute of Great Britain and the National Smoke Abatement Institute have been provided with office accommodation in the building, and a space in the Museum has been set apart for the exhibition of smoke abatement apparatus. Although these two societies have not in any way amalgamated with the Museum, it is felt that, their field of labour being so similar, this association of offices will be beneficial to all, and will also prove an advantage to the public generally.

Since the opening of the Museum in its present premises, the number of members has largely increased. The members numbered 99 on the 30th of June, 1883, just after the opening of the Museum. They now number 260. During the year the Museum has been visited by 6,870 people.

The financial position of the Museum is not as yet so firmly established as the Council could wish; but they feel assured that if the members would evince their interest in the Museum by bringing the good work that it is accomplishing under the notice of all the various people with whom they are brought into connexion, both in business and otherwise, so as to add to the number of members, they have reason to hope that the income of the Museum would be sufficient to carry out its objects with even more usefulness than at present.

All things considered, the Council are able to look back upon the first year's work of the Parkes Museum with considerable satisfaction.

The utility of the Museum has increased month by month. The Museum has clearly

\* Reported in full in the *Builder* at the time.

met a great public want, and the Council would again strongly urge upon the members, and upon all who are interested in sanitation, to use their personal influence, so to increase the number of members and life members that the future of so valuable an institution may no longer be a matter of doubt."

#### ACTION FOR THE RECOVERY OF ARCHITECT'S FEES.

TOMLINSON V. BARNETT.

On Tuesday last, this case came up for judgment before Mr. Justice Field.

The plaintiff, an architect, of 35, Great James-street, Bedford-row, W.C., brought an action for the recovery of fees for plans, &c., for erection of houses at Sutherland-gardens, Maidal-vaie, and for further sum promised him for extra supervision, in consequence of the failure of the builder to perform his contract. The total sum claimed was 167*l.* 7*s.*, and the defendant, who described himself as an engineer, put in a counter-claim to the amount of 2,000*l.* for alleged negligence. The defendant had by order previously paid into Court 100*l.*, beside the sum of 27*l.* 11*s.* obtained by the plaintiff on account, and it having been agreed that the plaintiff was entitled to the sum of 91*l.* 7*s.* for plans, &c., and a fair sum for extra supervision from the time of the builders leaving the works until completion. Mr. Henry Hunt, of 45, Parliament-street, Westminster, was appointed referee to report on this and upon the counter-claim. The evidence showed that the plaintiff had been put to considerable annoyance, having been held responsible by several firms for goods supplied to the defendant's houses. Mr. Hunt reported that the plaintiff was entitled to the sum of 20*l.* 5*s.* for extra services, and that the defendant was not entitled to anything on his counter-claim. His lordship entered judgment, with full costs, for the plaintiff accordingly.

#### CASE UNDER THE METROPOLIS MANAGEMENT AND BUILDING ACT AMENDMENT ACT.

A CASE of considerable importance to builders was decided at the Surrey Sessions on Tuesday last. A Camberwell builder, Mr. James Hampton, had laid out for building a plot of ground in the rear of some houses in Chiswell-street, and had erected thereon six blocks of combined dwellings, approached by a street only 16 ft. wide, without having first obtained the approval of the Metropolitan Board of Works. The Vestry of Camberwell complained to the Board, who thereupon directed proceedings to be taken for an infringement of the 8th section of the Metropolis Management and Building Act Amendment Act, 1882, 35 Victoria, ch. 14, which requires that where it is intended by any person to lay out any road, passage, or way for building, as a street for foot traffic only, such person shall give notice to the Board of his intention, and the Board may, on the receipt of such, approve of the formation of such street, either with or without conditions, or may decline to approve of the same, and in the event of the road not being approved, it cannot be lawfully formed. The defendant in this case, on proceedings being commenced, placed gates at the entrance to the street leading to the houses built by him, and contended that the public not having the right of access to the street it was not subject to the provisions of the Act. The case was heard before Mr. Chance at the Lambeth Police Court on the 29th of May last, when the defendant was represented by counsel. After a lengthened discussion the magistrate convicted the defendant, and imposed a penalty of 20*s.*, and costs, the maximum fine being 40*s.*

The defendant appealed to Quarter Sessions against the conviction, and the case was again argued on Tuesday last, the 5th inst. Mr. Horace Ivory, instructed by Mr. Thos. Burton, appearing for the Metropolitan Board of Works, the respondents, in support of the conviction; the appellant being represented by Mr. Besley and Mr. Ernest Bagdaly.

After hearing the evidence the magistrates dismissed the appeal, with costs, subject to a case being stated for the opinion of the Superior Court (which will probably be the Court of Queen's Bench) as to whether the street in question is "a road, passage, or way" under the meaning of the 8th section of the Metropolis Management and Building Act Amendment Act, 1882.

**The Reform Club, Liverpool.**—The Liverpool Reform Club, which has for some weeks been closed for repairs and redecoration, has been again opened for the use of the members. The work has been done from the designs of Mr. Edmund Kirby, architect, and under his direction. Messrs. Wannop & Son, of Renshaw-street, have done the painting and decoration, and the panelled dado to the dining-room is the work of Messrs. Norbury, Upton, & Paterson, all of Liverpool.

#### DISSENTING CHURCH-BUILDING NEWS.

**Hoylake.**—The foundation-stone of a new Congregational Church at Hoylake was laid a few days ago. The site of the new church is at the corner of Station-road and the road to West Kirby. It will not only afford space for the present building, but for a much larger church at some future date, when the edifice now to be erected will be used as a lecture-hall and class-room. The present building will be constructed of brickwork and covered with Welsh slates. Messrs. Smith, builders, of Hoylake, are the sole contractors; and Messrs. W. & J. Hay, of Liverpool, are the architects, from whose designs and under whose supervision the work will be carried out. The cost of the building will be about 1,650*l.*

**North Shields.**—The Free Methodist Church, North Shields, which was designed by the late John Green, of Newcastle, something like forty years ago, and is in the Italian style of architecture, is about to undergo considerable alterations and improvements, including the introduction of an ornamental pulpit-platform in place of the present pulpit, together with a re-arrangement of the galleries. The church is to be newly painted and decorated throughout. The committee have engaged Mr. J. J. Lish, architect, Newcastle-upon-Tyne, to carry out the works.

**Newcastle-on-Tyne.**—The design of Messrs. S. Oswald & Son, of Newcastle, has been selected in the limited competition for a new Wesleyan Chapel to be erected at Heaton. The chapel will seat 900 to 1,000 persons; and adjoining it there will be a lecture-hall for 350, besides five class-rooms and vestries. The style adopted is Early English.

### The Student's Column.

#### HINTS FOR THE STUDY OF

#### THE HISTORY OF ARCHITECTURE.—II.

**A**FTER examining the books and examples referred to last week on the subject of Native Indian Architecture, and postponing, for the present, the consideration of Indian Saracenic Architecture, the student will do well to learn something of the architecture of two other distant parts of the globe, namely, of Mexico in one direction, and of China and Japan in another direction.

China is treated of in Fergusson's Handbook, at page 133, and in his History, in vol. ii., at page 733; and he remarks that the Chinese differ from all European nations, not only in the objects they propose to attain by their arts and in the forms in which they seek to embody their conceptions, but also in the processes by which they carry them out. Their largest works belong rather to engineering than to architecture, as evidenced by their bridges and embankments, and, last but not least, by their Great Wall, said to be about 1,400 miles long and over 20 ft. thick.

With regard to their more architectural works, Rosengarten, page 54, says that Indian art made its entrance into China with the worship of Buddha, and he points out the use of bracket construction in place of a capital for the support of the architrave, owing probably to the use of wood, added to the cravings of a restless fancy. They were not satisfied with ordinary straight lines, but curved their roofs about, especially at the eaves and at the feet of the hips, in a distracting manner. Such treatment, when sobered by the effect of repetition in their many-storied pagodas, is not unpleasant. (A pagoda may be seen at Kew Gardens.) In their gateways, a similarity to the construction in the Sanchi Top, mentioned last week, is pointed out by Fergusson, with the exception that the ends curl upwards instead of downwards.

Some idea of Chinese Domestic Architecture may be gathered from the wonderful models of houses, with their surrounding pleasure-grounds, at the South Kensington Museum, and no doubt their minute accuracy would admit of their being enlarged without much loss of correctness. The frequent use of the *fret* should be noticed in Chinese art.

The adjoining country of Japan possesses some interest for us now that we have so many specimens of its wonderful art in our midst, but until recently we have not had much information about its architecture. This want has now been admirably supplied in Dr. Dresser's

"Japan," illustrated with many views of buildings, in addition to drawings of the smaller objects with which we are now familiar. On p. 102 is represented the old wooden building in Nara, where the Mikado's treasures have been preserved for 1,200 years. The roof has been restored, but the body is probably the oldest wooden building known. Here the eaves and hips are straight. The whole building is raised on posts clear of the ground, which may account for the preservation of the wood for this astonishing number of years. Although many instances are given of roofs with a hollow curve from ridge to eaves, there is not much of that curling up of the hips so common in Chinese architecture. At the same time, most elaborate bracketing is used. The treatment of columns and the general proportions of buildings are quite different from anything that we are accustomed to think correct.

On page 148 will be found an interesting example of a tie-beam roof, the beam being used, as in many of our English examples, to steady the walls and to support the roof posts rather than to hold together the feet of the principal as in a truss.

There is given on page 201 a pagoda at Nikko, which is much more embourbed than the Chinese examples, and also much less curved up at the hips of each tier of its roof. Both in this view and one of the end of a wall, on page 113, should be noticed the jointing of the masonry at the angles of such walls. These are tilted up, but probably for a very different reason from that in the case of the roofs, namely, for preventing the quin stones from getting loose. This should be borne in mind when Egyptian walls come under consideration, though there was probably no connexion between the two countries.

The Temples at Oaska, illustrated on page 140, bear a stronger resemblance than do the Chinese gateways to the before-mentioned gateways of the Sanchi Top; the wooden construction is further emphasised by the keys driven through the posts to tighten the cross beams, the upper ones of which are curved upwards throughout their whole length, and the under ones straight.

A journey across the Pacific to Central America introduces us to styles of architecture that are yet further removed than any of the above-named to the *sequent* styles. Here we come to the architecture of Mexico and Peru, which offer ample subject for study and food for thought, and for this reason, that they bear such a tempting resemblance to the styles of other countries that it is difficult to believe that there has been no exercise of influence between one and the other; but after enumerating the various theories by which Mexican architecture has been ascribed to the influence of Egyptians, Babylonians, Moguls, and—at great length by Lord Kingsborough—to Jews, Fergusson, page 147, concludes that, on the whole, we may safely exclude all such considerations, and treat of the architecture of Central America as complete in itself and unconnected with any known style.

The best books in the library of our Instituto to study on this subject,—though not found in the catalogue under the title of "Mexico,"—are by J. Stephens, and beautifully illustrated by F. Catherwood. They are "Incidents of Travel in Central America, Chiapas, and Yucatan," 2 vols. Svo., New York, 1841; and "Incidents of Travel in Yucatan," also 2 vols. Svo., New York, and published two years later, in 1843.

The peculiarity of the Mexican temples consists in their being built on the top of substantial pyramids, and in being of very massive construction with slanting roofs, constructed with oversailing corners of stone. Some light is thrown upon the necessity for this method of construction by the description of an earthquake which the author experienced, and which are said to be of frequent occurrence. In many of the temples the external walls are divided horizontally, the lower portion being essentially massive stonework and the upper part all in stone, but copied from wooden construction; indeed wooden lintels are actually found in some buildings, and the fact of their not having yet utterly decayed, in spite of an unpropitious climate and neglect (as compared with the Japanese example), points to the possibly modern date of these structures.

Fergusson's chronological table ranges over a short period, from the arrival of the Toltecs in 648 A.D. to the arrival of the conquering

Spaniards in 1519, during which this curious out-of-the-way style attained a very high degree of artistic merit. In support of this statement, a visit should be paid to the collection of sculpture, &c., formerly at Mr. Franks's, in Victoria street, and now at the British Museum. A type of head will be found, showing a technical knowledge of modelling and a grasp of character very much in advance of most antique sculpture,—excepting, of course, that of Egypt, Greece, and Rome.

There are a great many stone idols carved on upright monoliths in which so much space is allotted to the head above the head, that the face itself comes about a third of the way down the stone; the surmounting head-dress consisting of a conglomeration of confused ornament. In vol. ii, however, of Stephens's earlier book, facing p. 343, an idol or statue is represented in which this head-dress is distilled, so to speak, into a grand and simple form that is wonderfully suggestive of the colossal Osiride figures in Egypt.

The frequent use of hieroglyphics covering a great portion of the wall-space supplies another point of resemblance to Egyptian art; but both facts are probably mere coincidences, showing how different people may arrive at similar results.

There is another feature which can hardly be anything but a coincidence, and that is a trefoil-headed opening not unlike those that are found in Gothic work! An example of this will be found facing p. 344 in the volume last mentioned.

The use of the fret as an ornament has probably never been carried to such gigantic proportions as in Mexican work. It has been noticed above in speaking of the Chinese, and would there seem to have been suggested by the rectangular lattice framing of their carpentry and joinery. In Mexico, on the contrary, the first indications of it may, perhaps, be found in the system of making some of the facing stones to project beyond the rest, which produces a number of shadows in irregular directions,—now along the wall, now down, now back again twice as far, now up again, and so on.

As regards the surface sculpture generally, as applied to buildings, it is of the class best described as "bogey"; but the broad pilasters which separate the openings leading into the temples are sometimes ornamented with bas-reliefs of gods or priests, executed with extreme delicacy and refinement. These priests are represented with flattened foreheads and long noses of the Aztec type, and do not differ much from each other; whereas the other heads, carved about in various positions, have the appearance of individual portraits, and the element of caricature is conspicuous.

The almost neighbouring country of Peru is a degree more puzzling than Mexico, so far as regards the origin of its architectural style; or this does not even bear any resemblance to that of its neighbour: on the contrary, whereas the Mexican style revels in sculptured decoration, the Peruvian buildings are austere, severe, and are examples of masonry rather than of architecture.

Ferguson, on page 154, attributes a very short existence to the stylo, namely, from the time of a godlike man, known as Manco Capac, in the thirteenth century of our era, to the conquest of the country by Pizarro in 1534, during which short time he notices great progress to have been made in the art or science of masonry. Curiously enough, this Peruvian work, which can hardly have had any connexion with that of Europe or Asia, presents two features that are characteristic of the Pelasgi and (perhaps we should say, or) the Etruscans, of whom more will be said in the proper place. But after all, this is only one of the proofs that architecture is primarily a matter of construction, for both these people had to construct with the same kind of materials, huge tones of irregular shape forming the masonry known as Cyclopean (or such as might have been put together by the fabulous one-eyed giants known as Cyclopes), which masonry led to another point of similarity, namely, the openings in such walls narrowing upwards, so as to reduce the work of the stone hater. Even their skill in masonry had improved, the taper form of the openings survived, and was employed in buildings of the most refined construction, and the result is a most striking resemblance to the European style known as truscan.

A more curious coincidence is pointed out by Ferguson in describing the walls or fortifications enclosing Cuzco, the ancient capital of the kingdom; for here we find a series of walls, one behind another, arranged in the form adopted by modern military engineers to withstand the assault of firearms, and it is extremely improbable that the use of gunpowder was known to the builders of the walls of Cuzco.

It is possible that other hitherto unknown countries may be discovered, exhibiting recognisable styles of architecture, either detached from or linked on to the chain which we have next to consider, and before taking leave of those already mentioned, attention should be drawn to the ingenious manner in which these ruins have been restored and re-inhabited by the rich fancy of Viollet-le-Duc, in his work on the "Habitations of Man in all Ages."

Ethnology is no mean factor in the study of architecture, and, even if the same climate and the same materials be given, a distinct impress will be added by the temperament of those who build.

We will now take leave of the fringe of the world (to use the simile adopted last week), and endeavour to grasp the beginnings of those threads which can still be traced in architecture of our own day.

**SPECIFICATIONS ACCEPTED.†**

July 1.—976, E. Lloyd, London, Kitchens.—1,690, J. D. Mackenzie, London, Sash-bars or Astragals for Roof-lights and Window-sashes.—2,653, C. H. Riley, Huddersfield, Chimney-tops.—7,118, E. P. Gibbon, Dublin, Channel Roofing and Awnings.—8,091, F. Cuntz, Karlsruhe, Automatic Flushing Tank.—8,327, W. Smith, Barnard Castle, Owens.

July 4.—6,403, C. D. Abel, London, Converting Liquids into Spray for Ventilating Purposes. Com. by E. Oehlmann, Berlin.—7,507, H. Trott, London, Water-water Preventer and after push combined, for Water-closets.

**ABRIDGMENTS OF SPECIFICATIONS**

Published during the week ending July 5, 1884.

5,333, W. P. Kelly, Mount Brandon, Retaining and Releasing Window-blind Cords, &c. (Nov. 12, '83, 6d.)

A box is fitted in which are two wooden blocks, one of which is wedge shaped, while the other has a corresponding recess. The cords pass through the box and between the blocks, being jammed there by a spring behind one of them.

5,388, H. A. Goodall, London, Blinds for Windows. (Nov. 15, '83, 6d.)

These are made of slate, of wood crossed on each other and pivoted at their crossings, and to keep them stiffly in position a longitudinal groove is cut, extending from side to side, is placed above and another below the slats, which rails slide in the grooves of similar vertical rails the whole height of the window.

5,391, J. Warnhurst, London, Excluding the

\* Compiled by Hart & Co., Patent Agents, 186, Fleet-street.  
† Open to public inspection for two months from the dates named.

Entrance of Draughts and Rain, &c., to Rooms. (Nov. 15, '83, 6d.)

This is an improvement on Patent No. 1,690, of 1869, in fitting the strip of wood to a roller, on which is a quick pitched screw-thread fitted into a nut projecting beyond the edge of the door. A coiled spring surrounds this roller to keep the strip up in the door when the same is open, but when the door is shut the nut presses against a plate on the door-post, and the roller is revolved thereby, and the strip is pressed down on the floor.

5,467, M. Mackay, London, Plastic compounds. (Nov. 20, '83, 4d.)

This compound for ornamental architectural use, &c., is made of lac, gum sandarac, rosin, ivory black, or other carbon and asbestos.

5,576, T. H. Fielding and A. U. Jensen, Sydney, Protecting Buildings, &c., from Heat. (Nov. 29, '83, 2d.)

Metallic foil or leaf is applied to the outer surface of the building, &c., to be protected. (Pro. Pro.)

5,585, W. J. Penny, London, Window-sashes and Sash-frames. (Nov. 30, '83, 6d.)

The sashes slide in between the beads as usual, but, to enable the sashes to be turned to clean, &c., the outside thereof, either the beads are divided into two parts longitudinally, which parts are hinged together to allow the projecting part to be turned out of the way of the sash, or the side sashes are similarly divided just clear of the beads, the two parts being hinged together on one side, and on the other being secured by bolts, &c., so that when these are disconnected the window can turn like a door.

5,596, G. Greig, Harrieston, Ventilating Apparatus. (Dec. 1, '83, 2d.)

The fresh air is introduced into the room in the centre of the ceiling, and immediately under the mouth of the inlet is a circular concave deflecting plate to spread the current of air all over the room. (Pro. Pro.)

5,600, G. F. Redfern, London, Substitute for Stone, Bricks, &c., Com. by J. Stickle, Denver, U.S.A. (Dec. 1, '83, 2d.)

Moulds of the required pattern are filled with pieces of scoria, and then molten scoria is poured in to bind them together and shape the block. (Pro. Pro.)

5,824, A. M. Clark, London, Metallic Plastering surfaces. Com. by J. Stanley, New York, U.S.A. (Dec. 20, '83, 6d.)

Wire cloth is used as a plastering surface, and it is also corrugated or ribbed to stiffen it.

**MEETINGS.**

SATURDAY, JULY 12.

International Health Exhibition (Conference of the Royal Institute of British Architects).—At 2 p.m. (1) Mr. George Atchison, A.R.A., on "The Sanitary Aspect of Internal Fittings and Decoration"; (2) Mr. William White, F.S.A., on "The Hygienic Value of Colour." The discussion to be opened by Mr. T. W. Cutler.—At 4 p.m., Mr. Thomas H. Weston on "The Collection, Storage, Management, and Distribution of Water, for Domestic Purposes, within the House." The Right Hon. A. J. B. Balfour Hope, M.P., Chairman for the day; Professor T. Hayter Lewis, Vice-chairman.

Association of Municipal and Sanitary Engineers.—Meeting at Newcastle, 10.30 a.m., Closing Business. 11 a.m., Visits to various works.

St. Paul's Ecclesiastical Society.—Visit to Winchester by 9 a.m. train from Waterloo. The Cathedral and St. Cross will be visited, under the guidance of Mr. Somers Clarke, F.S.A.

Association of Public Sanitary Inspectors.—Visit to Messrs. Boulton's Potteries 10.45 a.m. Subsequently at 1.45 a steamboat will leave Westminster Bridge for the works of Messrs. Johnstone, at Bolvedere, Kent.

WEDNESDAY, JULY 16.

National Smoke Abatement Institution.—Meeting to consider the Bill now before the House of Lords to amend the Smoke Abatement Act. 3 p.m.

**Miscellanea.**

The "Sir John Gray Reservoir." Dublin. On the 26th ult. the Lord Mayor of Dublin performed the ceremony of turning the water into the new reservoir at Stillorgan, which, in memory of a distinguished citizen, who took a leading part in promoting a perfect system of water-supply for the city, has been named the "Sir John Gray Reservoir." The Lord Mayor stated that the reservoir covered 22½ acres, and it was capable of holding 88,000,000 gallons; and this, they believed, would meet any possible emergency. He need scarcely inform his fellow-citizens, many of whom he saw present, that the water of the great reservoirs at Stillorgan was collected from a water-shed of 14,000 acres, and that there was impounded in these reservoirs 2,400,000,000 gallons, which it was calculated would last the city and the suburbs 170 days. The greatest possible care was taken to convey the water supply to the city in a pure state. Great trouble was taken in having it filtered. The Waterworks Committee, through the medium of a large accumulation in the reservoir, were enabled to send a constant supply to the city and to the whole of the outlying townships, with the exception of Rathmines. The district which was embraced in the area of supply reached as far south as Bray, and in the north as far as Drumcondra and Glasnevin. Mr. Neville is the engineer.

**New Buildings in London-wall and Coleman-street.**—A new face is at present being given to a considerable portion of London-wall and Coleman-street by the erection of several new buildings on an extensive site belonging to the Drapers' Company, which has been cleared of the old buildings that until recently stood upon it. The site thus cleared covers an area of upwards of 30,000 ft., or about an acre in extent. Amongst the new buildings now on the point of completion is one in Coleman-street, immediately opposite the Armourers' Hall. It contains four lofty floors, and is faced with Portland stone, freely carved, having fluted piers and pilasters between the windows. The building has also a similar return frontage in London-wall. Mr. George Vickery is the architect, and Mr. Morter the contractor. Immediately adjoining, with its frontage in Coleman-street, is another building, much resembling this in its architectural features. Messrs. W. & F. Croaker, of Great Dover-street, are the contractors. The Coleman-street frontage of these two buildings is upwards of 70 ft. in length. In continuation in London-wall westward is another building forming a block of warehouses, with a frontage of 30 ft. in length, and extending 70 ft. in depth along an intended new street or approach to several sites yet to be built upon. This building, containing four stories above the ground-floor and basement, is faced with red brick and stone dressings, and covers a ground area of about 1,700 ft. Mr. W. E. Brown is the architect, and Mr. R. Conder the contractor. On the west side of the intended new street just referred to, and opposite the last-named building, is another extensive block, having a frontage to the intended new street of about 70 ft. in length, with a return frontage in London-wall upwards of 30 ft. long. It is 60 ft. in height, containing five lofty floors. It is faced with white Suffolk brick, having Portland stone dressings with red brick bands. Mr. Lewis Solomon, of Gray's-inn-square, is the architect, and Messrs. Patman & Fotheringham are the contractors. Beyond the last-named building another block of warehouse premises is approaching completion. They are faced with Portland stone, having polished Shap granite piers at each side of the ground floor. Messrs. Joseph & Pearson are the architects, and Messrs. Patrick & Sons are the contractors. The entire London-wall frontage of these several buildings is about 200 ft. in length. The Drapers' Company announce the sale, on building leases, of thirteen more sites on the estate, covering an aggregate of 20,000 ft., each site containing 1,500 ft.

**The Inventors' Institute.**—The annual dinner of this Institute took place on the 2nd inst. at the Health Exhibition. Admiral Jasper Selwyn presided, and about eighty gentlemen sat down to dinner. After the usual loyal toasts, the Chairman gave "Success to the International Health Exhibition" was responded. "Inventors and Inventions" was proposed by Mr. Davey, who maintained that the advancement of the interests of inventors meant the advancement of the interests of civilisation itself. Mr. J. Standfield, C.E., in replying, traced the progress of inventions during the last quarter of a century, and referred to the new patent law. Previous to the new Patent Act it had been considered by the world that the English were not inventors but improvers. He had always maintained that the number of patents taken out was controlled by the fees which were demanded for them, and his opinion had been fully borne out by the operation of Mr. Chamberlain's Patent Act which had come into force only this year. There were more patents taken out in England during the first three months of this year than had ever been taken out in England in any year before that. He ventured to predict that the number would continue to steadily increase. Those countries which gave the greatest facilities to inventors gave the greatest facilities to trade and commerce. He referred especially to the immense service rendered not only to his own country but to the interests of civilisation at large by Trevelthick. He also spoke of the important inventions of Dudd Dudley, Wedgwood, John Allen, Wm. Lee, and Arkwright.

**The Wallace Memorial, Aberdeen.**—In regard to this competition, we learn that none of the designs lodged have been accepted in their present form; but revised designs have been invited from the three competitors having for motives "Patriot," "Spes," and "Furriter."

**A New Dock at Battersea.**—A new dock which has been excavated and built on a large tract of ground adjoining the foundry works of Mr. Allan Ransome, at Battersea, was opened on Wednesday. Four flour-mills, which will be an immediate source of profit and commerce for the dock, were also opened at the same time. These mills are fitted with improved machinery by Messrs. Marriage, Neave, & Co., and are intended to compete with the American efforts to absorb the milling trade of this country. The dock entrance is midway between the Albert and old Battersea bridges, and the dock extends from the southern shore of the Thames nearly to the highway between the town and the park, and converts a large area of poor grazing land into very valuable wharf property. The gates are wide enough, and the dock deep enough, not only to take in lighters, but also sailing barges and coasting steamers. Further, the entrance has been dredged to allow the largest vessels coming through the bridges to enter and leave the dock at the top of neap-tides. Its width is over 100 ft. in the inner basin, sufficient to allow the turning of a steam-tug; and two lines of barges can pass each other in the narrowest part. The dock work has been carried out under the direction of Mr. Edward Woods, C.E., the contractors being Messrs. Cooke, of Battersea.

**The New Roof of the Royal Exchange.**—Since the commencement of April last the workmen of Messrs. Whitford & Co., constructive engineers, of the Royal Ironworks, Limehouse, who are executing the iron work for the new roof over the central area of the Royal Exchange, have been engaged in erecting the roof, which was constructed and fitted together at their works. The works have now been far advanced towards completion, the greater part of the roof being now in position. The iron work of the arched portions at the east and west ends has been fixed, and is now being painted preparatory to glazing. The works in connexion with the central dome of the roof are likewise progressing, the base of the dome having already been fixed, whilst the erection of the arched iron ribs has been commenced. Messrs. Cahill & Co. are carrying out the alterations which are required in the fabric of the building. The decorations of the roof have been entrusted to Messrs. Jackson & Co., of Rathbone-place, and the whole of the works are expected to be completed in about two months. The roof, which is being constructed from the designs of Mr. C. Barry, will cost about 10,000l. We published a large view of this roof in the *Builder* for October 13, 1883.

**Putney (New) Bridge.**—The foundation-stone of this bridge will be laid at 3 p.m. on Saturday (to-day) by their Royal Highnesses the Prince and Princess of Wales, who will proceed from Marlborough House, via Knightsbridge and Fulham-road, over Putney-bridge, to the entrance to the new bridge at the northern end of High-street, Putney. They will then enter the works and see models and plans of the bridge in a small pavilion close to the stone to be laid. After laying the stone their Royal Highnesses can, if they are so disposed, proceed for a short distance over the temporary bridge to see the piers in course of construction within the dam. Returning to the entrance where they left their carriage their Royal Highnesses will then drive back by way of Putney High-street, Wandsworth High-street, York-road, through Battersea Park, and over Chelsea Bridge.

**The New Railway Bridge at Blackfriars.**—Messrs. Lucas & Aird, the contractors for the London, Chatham, and Dover Company's new station and bridge across the Thames at Blackfriars continue to make rapid progress with the works, and on Wednesday the iron-work of the first portion of the Middlesex side arch was placed in position. With the exception of that on the Surrey side, next the land abutment, the masonry of the whole of the four river piers is nearly finished and ready to receive the iron-work, and it is expected that the main portion of all the arches will be in position in about three months from the present time. The works in connexion with the erection of the new station are also considerably advanced.

**Decoration of the Dome, St. Paul's Cathedral.**—We are informed that the modification of Stevens's design by Mr. Hugh Stannus, which is to be fixed up in the cupola on the south side, opposite to the design by Mr. E. J. Poynter, R.A. (which we illustrated in our last), will be visible in about three weeks' time.

**Bourse Buildings, Bucklersbury.**—These extensive buildings, at the corner of Bucklersbury and Queen Victoria-street, have just been completed by the erection of an angular block at the rear, faced with white enamelled brick. The Bucklersbury frontage is faced with red brick and Portland stone, the central portion of the elevation having ornamental bay windows, with fluted pilasters. The buildings throughout have been very substantially erected, all the brickwork being laid in Portland cement. Altogether the buildings contain nine floors, including a basement and sub-basement, with ground and six upper floors. There is a lift, on Hart's principle, from the basement to the top of the building. An artesian well has been sunk on the premises, from which the several offices are supplied with water. This well has been sunk to a depth of about 400 ft. below the ground-surface, and bored into the chalk 100 ft. deep. The well was sunk by Messrs. S. F. Baker & Sons. Altogether there are upwards of 200 rooms in the buildings. Mr. J. Whitcher, F.S.A., is the architect, and Messrs. E. Lawrence & Sons the contractors.

**Locks and Lock Furniture.**—Mr. James Hill, of Queen Victoria-street, has sent us his new illustrated catalogues of his specialities in this line, which have been and are being largely used, not only in private but in public buildings. The catalogues are likely to prove useful for reference. Mr. Hill has just completed a large contract for the Great Eastern Railway Station, Liverpool-street, comprising upwards of 600 locks in different suites, and governed by various master-keys, together with his patent door and sash furniture, all of which we understand were selected by the architect, Mr. Charles E. Barry.

**Gift of a Public Park to Dundee.**—At the meeting of the Law Committee of the Dundee Town Council, on the 25th ult., the clerk read a letter from Messrs. Shiell & Small, solicitors, with a memorandum of the terms in which Sir John Ogilvy's gift to the town of the Fairmuir is to be carried out. It appeared that Sir John, with the consent of his son, Colonel Ogilvy, is to convey to the Town Council and the Police Commission the Fairmuir to be a public park for the inhabitants of Dundee in all time coming, and for the playing of cricket, but subject to the present right of the town to hold the market fairs on the ground.

**Social Science Association.**—Mr. Clifford Smith, the energetic secretary of the Association, has compiled an index of the subjects and names of the authors of all papers read in the Department of Public Health of the Association since its establishment in the year 1875. It makes a pamphlet of 40 pages, and gives a remarkable idea of what the Association has done on this class of subjects, and of the extent and variety of its labours. The pamphlet forms a useful memorandum "where to turn" for special information in regard to many subjects of interest in connexion with sanitary science.

**The Frere Memorial.**—At a meeting of the Frere Memorial Committee at Marlborough House on the 7th, the Prince of Wales presiding, it was unanimously resolved that Mr. Brock should be communicated with as to undertaking the work, and a letter was read from Sir J. McCarell-Hogg stating that the Metropolitan Board of Works would be happy to give a site on the Embankment for the purpose, near the statue of Sir James Outram.

**Appointments.**—In consequence of the retirement of Mr. George Powvall from active professional practice, the directors of the Law Fire Insurance Society have appointed Mr. George Harry Downall, of No. 29, Parliament-street, and Mr. Edward Street, of No. 9, Sergeant's Inn, Fleet-street, as their architects and surveyors.

**Gemetery, Ryton-upon-Tyne.**—The Ryton (parish) Local Board are just completing their new cemetery works, at a cost of near 4,000l. Messrs. Salter & Lishman, of Ryton, are the contractors, and the works have been carried out from the designs, and under the superintendence, of Mr. J. J. Lish, architect, Newcastle-upon-Tyne.

**Kensington.**—The foundation-stone of St. Cuthbert's Church, South Kensington, was laid on the 2nd inst. by the Earl Beauchamp. Mr. H. Roumieu Gough is the architect, and Messrs. S. Belham & Co. are the contractors. A view of the church, which is one of considerable importance, is exhibited at the Royal Academy this year.

COMPETITIONS, CONTRACTS, AND PUBLIC APPOINTMENTS.

Epitome of Advertisements in this Number.

COMPETITIONS.

Table with columns: Nature of Work, By whom required, Prention, Designs to be delivered, Page, Nature of Work, By whom required, Prention, Designs to be delivered, Page. Includes entries for Liverpool and Dairy Homestead.

Architecture in Paris and London.

WITHIN the compass of a small and very neat volume of some two hundred pages,\* Mr. W. H. White, the Secretary of the Royal Institute of British Architects, has endeavoured to sum up the broad distinction between the relation of architects and architecture to the State and to educational bodies in the French and English capitals respectively.

The general purport of the book is a summary of the condition of things in the two capitals, greatly preponderating in favour of Paris; and though the well-worn mot, "They manage those things better in France," might very well have been taken as the keynote of the volume, the less hackneyed and proverbial quotation which is given on the title-page perhaps expresses the philosophy of the matter with equal point and more novelty. It is a remark of Blondel to Louis XIV., whence quoted we are not told,—"Vous savez, Sire, que nous n'avons point d'amour pour les choses que nous ignorons, et qu'il falloit que l'on connût ce que vaut l'architecture, pour estimer autant qu'elle le mérite." If the Grand Monarque required that caution at the time it was given, it has, at all events, borne fruit in the attitude and conduct of successive French rulers, monarchical or republican, towards architecture, in succeeding times down to the present day. The contrast between the attitude of public men and public bodies towards architects and architecture in France and England seems to become more marked and more obvious as time goes on. The interest in and respect for architecture on

the part of English Governments and governmental officials is continually on the decrease, till we have arrived at a point when it seems to be almost a matter of course that architectural design or architectural beauty should be contemned by popular politicians as trifles of no moment and not worth spending money upon, while indifference or absolute disrespect to the profession of architect has become a recognised tradition among those departments of Government which are most immediately concerned with matters that come within the province of architecture. Of course there remains the question whose fault this is, and whether the fault is all on one side, a matter on which, perhaps, there may be a little more to be said than our author quite recognises. But the main truth in regard to the difference of things in France and England is that to which the quotation of Blondel's remark points. To care for a subject one must know something about it, and the French Governments have taken some trouble to know something about architecture, or to appoint as its guardians those who do, whereas the English Governments, in their corporate capacity and through their individual members alike, seem really to take a certain pride in contemning and ignoring the subject.

"The contrast between the great works of architecture in Paris and London is startling, even when regarded from a material and not an æsthetic point of view. On one side are conspicuous the evidences of method, refinement, and care; on the other, of inexperience, hurry, and confusion. A superabundance of knowledge perplexes both communities, but in Paris exuberance of fancy is subordinated to scholarly judgment; in London, it is morally and materially uncontrolled. This country, it is true, has an advantage in the possession of what is called public opinion, which in all national matters, except those relating to science, literature, and the higher arts, is of value, and English public opinion, though anything but dumb in difficult questions affecting architecture, is incoherent. But even if public opinion had the power of arriving at any decision in such questions, no organisation sufficiently representative to collect its suffrages, or record the result, is at disposal in London. The authorities of Paris, on the contrary, have definite artistic views. They possess a standard of taste and a power of initiation, of which Londoners are wholly devoid; and throughout France there is an abundance of carefully-prepared professional talent at the service of the State, for the design and execution of national monuments and buildings. During my ten years' consecutive residence in Paris, the authorities seemed not only to know what the inhabitants wanted for the alteration and adornment of their city, but also to obtain for them what was wanted; during my ten years' consecutive residence in London, the authorities seemed not only to ignore the prevalent desire for improvements, but also

quite unable to carry to completion the alterations they devised,—alterations which, in almost every case, have been deemed inartistic by experts, and unsatisfactory by the public."

That this statement of the general conditions in the two countries is true cannot, we fear, be denied by any who have taken a sufficiently broad view of the subject of modern architecture to be able to stand aloof, as it were, from insular prejudices, and exercise something like a cool and impartial judgment. The sketch of the history of architectural education and what may be called architectural statesmanship in France, given in Mr. White's pages, furnishes in a brief and comprehensive manner a great deal of the explanation of the more systematic and enlightened manner of dealing with architectural subjects on the other side of the Channel.

The architects of both countries, as Mr. White observes, started on pretty equal terms. Before the fourteenth century they worked much together, and the buildings of the age, though larger, richer, and more refined in France, were strangely similar in design and execution. But in the Renaissance period France had a series of kings, to begin with, who took an enlightened interest in architecture; and none so much so as the Grande Monarque himself, who showed in his treatment of Bernini and others how highly he valued their services and their talents, and left behind him a tradition which probably was not without influence on the ruling spirits of France ever since. Wren, who visited Paris in 1665, called the Louvre a school of architecture, and noted that an academy of sculptors, architects, and the chief artificers of the Louvre, met every first and last Saturday of the month. The "Academy of Architecture," formed irregularly and by a spontaneous movement in the first instance, became a recognised institution, with a charter, some time later, in 1717. We must refer the reader to Mr. White's pages for a short but comprehensive sketch of the academic element in connexion with French art, which achieved its greatest result in the formation of the École des Beaux-Arts. But there are two special institutions now existing in France, and which have been long established and have grown up into their present condition by degrees, which are more especially important in their influence upon architectural education and architectural opinion and criticism in France. One of these is the Conseil du Bâtime, originated by Colbert, who, in 1663, suggested the formation of a small council, to be consulted by him on all matters relating to buildings, a council which should meet twice

\* Architecture and Public Buildings; their Relation to School, Academy, and State, in Paris and London. By William H. White, architect, Secretary of the Royal Institute of British Architects. London; P. S. King & Son, 1884.

a week at the minister's house. This "Council for Buildings," the principle of which was then first proclaimed, exists at the present day in a highly developed form, and in some fashion or other it has always existed in Paris since the days of Colbert. It went through various modifications, the last important one being in 1795, when the Home Minister, Benezech, organised a *Conseil d'Examen du Bâtiments civils de la République*.

"The duties of this Council, which met twice a week, were divided under three heads:—(1) To prevent the execution at the cost of the nation of any work the uses, necessity, and advantages of which had not been ascertained; (2) To insure that all works, the execution of which had been authorised, were properly carried out; (3) To inquire into the accuracy of accounts and regulate payments in regard to building works. Thus the *service* or department of *travaux des bâtiments civils*, composed of the Council before-mentioned and the *Agences* (the organisation of which was completed in 1808) for all works executed at the cost of the State in Paris and some other parts of France, or for those executed at the cost of the City of Paris and some provincial capitals, grew out of the great Revolution. It was, after all, but a constitutional development, and, at this moment, in the matter of works and public buildings in France, a Minister of State is advised thereon by a council, just as the Chief of the State is advised by a Parliament.

The new Council (11 Dec. 1795) consisted of three members, one secretary, and six divisional reporting-inspectors now called *Inspecteurs-général*. Attached to these were six surveyors of accounts, who composed what was called a central office of *vérification et règlement*. In 1798 the Council, under the administration of the Home Minister, Lestourneur, took for a time the name of *Assemblée centrale des Architectes*, consisting of seven architects, presided over by one of themselves, and until 1812 the chair was occupied by some one or other distinguished architect. Later on, a Councillor of State was appointed President, but the Vice-President was always an architect. In 1839 six young architects, chosen by preference from among the *penionnaires* or students of the Academy of France at Rome, were first attached as assistants to the *Inspecteurs-général*, and accompanied them in their tours of inspection throughout Paris and the provincial cities. By the fourth section of this Decree of 1839, the titular members of the Council were not to be permitted to design or execute any new works coming within the powers of the Administration. By the fourth section, designs submitted in competition for public buildings were referred for final judgment to the Council, the members of which had to report thereon. They had also to recommend and advise as to the selection of architects competent to design and superintend the construction of new works, and to give opinions upon works in progress.

Not much essential change has been made in this *conseil* since that period, but it was one of the first acts of the present Republic to recognise it so as to form a permanent *service d'architecture*, as thus:—

"At the present moment the supreme direction of works is divided between the offices of (1) the Minister of Public Instruction and Fine Arts; (2) the Minister of Justice and Public Worship; (3) the Prefect of the Seine; and (4) the Prefect of Police.

The Minister of Public Instruction and Fine Arts is advised, in the matter of civil buildings and national palaces, by a council, whose duty it is to examine designs and to inquire into the accuracy of estimates, to assist in the final settlement of accounts, and be present at the handing over of works when the buildings are completed. In fact, the advice of the council is asked in all matters relating to the construction and keeping in repair of civil buildings and public monuments. All the members are architects of distinction in their relative positions."

We may beg the reader to observe this last statement as to the constitution of the *conseil*. In England, on the other hand, architects are generally the very last class of men whose opinions are ever asked about great questions of public building. The professors of red-tape settle these. Now let us glance at what we are told as to the other characteristics of the condition of architecture in France, the *atelier* system, which has so important a bearing upon architectural education in France. And here again we may as well quote the author's own words, premising that the *ateliers* were first started in connexion with the State School, the *École des Beaux-Arts*:—

"And here, perhaps, I ought to describe an *atelier*, which is essentially Parisian, and in character quite foreign to this country. For instance, in the French capital, an architect of eminence, generally a student of Rome, directs a kind of voluntary school, consisting of, perhaps, a hundred or more young men, all of whom are either students

or intending students of the School of Fine Arts. At the time of the reforms under the Second Empire, some fifteen or twenty private *ateliers* of the kind existed in Paris. That of M. Questel, who is now an academicien, and also President of the *Société Centrale des Architectes de Paris*, was among the most famous and popular. The young men composing an *atelier* have almost entire liberty, and the master or patron visits his pupils, or perhaps three times a week. He sets work to be done in competition by the students, and assigns places of merit to the best of the designs and drawings submitted to him. A library of illustrated works is attached to the *atelier*, and the books are consulted by the students, who each contribute to its support. By such means young Parisians wishing to be architects get their first professional insight into artistic studies, having previously been taught the rudiments of the art in one of the many technical schools of design established in Paris and the provincial cities. The French students, therefore, instead of being left to pick up information anyhow in the office of a practitioner, as is the case in England, acquire the theory of architecture from some architect of distinction who devotes time and attention to teaching them, and they learn their art in the company of a large number of fellow-students who inevitably assist each other, and to their mutual welfare."

In connexion with this subject also Mr. White gives some interesting particulars about the French Academy in Rome, now occupying the Villa Medici,—the institution long ago set on foot to enable France to plant her foot amid the remains of the Eternal City, and send her young aspirants for architectural fame to gain inspiration from amid the ruins of a great architectural past.

The result of all this is that in France there is an established connexion between the profession of architecture and the State, and a series of grades through which an architect rises to be a trusted adviser of the Government. He enters an *atelier*, subsequently goes with the "caravan" to Rome; if he approves himself there he returns at the age of thirty, still a student, to take a humble position at the Council of Civil Buildings; then he may become the subordinate to some eminent architect who is carrying out a large work for the Government. "He may rise, if he conduct himself well, to be assistant architect or joint architect upon the same or another Government building; or by the death, resignation, or promotion of his superiors he may ultimately become the architect in chief of the very work upon which he began as an *inspecteur*. He is thus placed among the few who by careful training acquire the power to design and fitness to execute buildings erected by the State from the common fund of the nation. Meanwhile the State has entrusted him with the charge of a national edifice or of some monument, such as the *Colonne de Juillet* or the *Arc de l'Étoile*, for the good condition of which he will be held responsible. In course of time he will be summoned to take a place of councillor on one or other of the several Boards pertaining to the various administrative departments."

Now contrast all this with the state of things in England: and for the full force of the contrast we must refer the reader to details in Mr. White's pages which we have not space to reproduce or comment upon here. The systematised provision for the education of the architect, to begin with, contrasts strangely with the position of an arted pupil in England, who too often, we may even say generally, merely has the run of an office to pick up what he can. It is true that if he chooses he may learn much more of practical work in architecture during his pupillage, by making the drawings for and by visiting actual buildings, than the French student at the same age. The latter learns the theory first and the practice afterwards; both, however, in a systematic manner; the English student learns or may learn a good deal of the practice first, and may, but seldom does, learn or adopt the theory afterwards. In general, he works, eventually, in the style of the office in which he was articulated, without considering too cursorily the reasonableness or logic of such style in relation to architecture generally, and to the wants of the present day. Mr. White gives due recognition, however, to the energetic and even tolerably systematised schemes for self-instruction which have been set on foot by the Architectural Association,

and by other bodies in a less complete manner. But there is, in Mr. White's view, no such thing really as an Architectural Academy, or an architectural department of an Academy in England. The Royal Academy counts for little; its students' designs are not equal to many of those made elsewhere, and the whole interest of its exhibitions centres in the paintings.

"As far as the architects go, and they are my principal concern, I do not perceive that studentship of the Royal Academy confers any advantage other than that which is the appanage more or less of all schools, public and private, namely, the emulation afforded to industry by young men working together, and competing with each other for prominence. I have never heard that the gentlemen who design some of the public buildings of this country are selected by her Majesty's First Commissioner of Works from the Gold Medalists of the Academy, or that, when he requires "temporary draughtsmen," he employs the graduates of its architectural class; nor do I think that the typical English gentleman, in search of an architect, ever intentionally chooses from among those who have taken honours there. I have before me a record of all the premiated Academy students from its foundation to the present day, and I cannot find that the careers these gentlemen have taken at the onset of their public life have influenced, in recent years, either the public or private administrations of the country in their choice of architects. Yet I know well that the list contains the names of men who, if some feasible and worthy means had been open to them to use their talents in the public service,—had wise Minister or an unbiased citizen in her Majesty's Office of Works thought fit,—might perhaps have effected more than one blunder in the conception of recent national edifices, and mitigated public reproach."

In France, on the other hand, the whole system of architectural education is recognised and fostered by the State, and, consequently, the Government has always before it a body of rising men whose careers and capabilities are known, and who can be and are called upon to assist with their advice and ability, in an honourable manner, the architectural schemes of the Government. From among them architects are selected to represent the State in every department of the country, and the greater works, the great architectural prizes, are given to the most eminent among them. How does the State relation with architecture in England compare with this? In France there is a Government Department whose object it is to select and employ the best architects. In England there is a Government Department whose object, apparently, is to ignore architects under all circumstances, except in connexion with those very few great buildings in regard to which there may possibly be a sufficient expression of public opinion to render the employment of an architect desirable. Architecture is an art demanding special and very high cultivation for its successful practice, and an art which, because it is an art and not a mere business, it is desirable to keep out of the groove of mere official routine and red tape. But the whole interference with architecture by the State in England is in the direction of crushing out the architect, of rendering the exercise of genius on great Government works impossible, and of reducing the whole thing to a kind of surveyor's business. We will quote Mr. White again:—

"There is, it is true, a method of business in her Majesty's Office of Works and Public Buildings, but, to say the least, it is an incomplete and a topsy-turvy one. More than anything else it resembles the sort of practice in vogue among rich firms of 'Auctioneers, Surveyors, and Valuers,' who undertake architecture if solicited, and get it done by persons they take on, like extra hands at a mill; or they put it out, like washing. State protection, or rather the British compromise for it, accorded to such a system, constitutes a deterrent force. In France the State encourages the architect and aids or fosters the development of architecture. In England it oppresses him, and even competes with him, not in London alone, but in every important city throughout the United Kingdom. The First Commissioner of Works is not a disinterested agent of the State, which in these days means the people. He is a practitioner, engaged in building operations throughout England and Scotland, and he monopolises those architectural works which, in continental cities, form the prizes of professional eminence. He would be regarded in France, and, in my opinion, rightly regarded, as an enemy to the State, whose aim was to render an architectural career impossible to young men of any birth, position, or education."

If we are asked for the other side of the picture, we may add that there is another side, both in regard to architectural education and State employment of architects, but it can be briefly stated, and presents little to counterbalance the preponderance in favour of France. Educationally, the French system may and probably does tend to render architecture somewhat too Academic and "correct," and leaves less encouragement to freedom of individual fancy than our unsystematic education. Viollet-le-Duc, as we know, was opposed to the Academy system. But comparing France with England, it may at least be urged that an artistic tendency based upon system and principle is better than a multifarious set of tendencies based upon habit and fashion. French architecture, thanks to her Academic system, has a path of her own; ours has none, and fluctuates from one fashion to another. In regard to the State and architects in England, it may also be urged that some large Government buildings, by eminent architects, have not been happy in result. In the case of the Foreign Offices this was partly the fault of the Government, who selected an architect for his eminence in one style, and then forced upon him another, against his will and in contradiction to his tastes and habits. As to the case of another much larger building, the Government selected one design as the best planned, and allowed another to be carried out; and they now complain, and we fear with too much justice, that they have an inconvenient and unpractical building. What is at the bottom of the whole disappointment about the Law Courts, however (which has been somewhat exaggerated), is the sentimental wave of feeling for revived Mediaeval architecture which swept over this country of late, and which led to the sentimental side of architecture being nudily put forward to the neglect of the practical side. But it may well be that the very system by which, in France, the architect's work is allied with the work of the State, is the most powerful of all antidotes against the exaggeration of mere sentiment, and the breaking loose of the architect from the influence of those practical requirements which are the basis of all architecture. At all events, there is no question that the relation of the State to architects in France is such as to encourage and to honour all competent architects, and to place all responsibility in their hands; while the relation of the State to architects in England is such as to discourage, depreciate, and in some cases insult the profession, to regard them as people to be passed over and done without, whenever this can be managed without arousing a contrary public opinion. The co-ordinate result is that architecture also, as far as it is an art, is practically considered a thing to be done without, and, as the permanent irresponsible secretary had the assurance to say, any style that is ordered can be turned out of the Office of Works, only a few more draughtsmen being required, without the assistance of architectural genius, which is a superfluity. And to the English public it is so. If we as a nation cared about architecture, there would be a public protest against getting out buildings by red-tape. But "nous n'avons point d'amour pour les choses que nous ignorons."

We hope all those officially and otherwise interested in English architecture will read Mr. White's little book, which, though not free from minor defects of style and expression, contains many useful truths put in a trenchant and effective manner.

**A New Post Office for Clapham.**—Amongst the several properties submitted for sale at the Auction Mart last week was the Baptist Church on Clapham-common, which was submitted to competition by Messrs. McLachlan & Sons. The first offer made was 6000., and ultimately the property was knocked down for 1,0250. It transpired after the sale that the building had been purchased on behalf of the Government, and that it is the intention of the Post-office authorities to convert it into a Post-office, with spacious sorting-room and other necessary apartments, the present post-office at Clapham being inconvenient in these respects.

#### THE THAMES AND THE THAMES VALLEY SEWERAGE.

**T**HE adverse decision of the Select Committee upon the Thames Valley Sewerage scheme has come upon the promoters quite unexpectedly, for they were confident as to the merits and completeness of their measure, and, if argument could have helped their case, the opening speech of Mr. Michael, the eminent counsel, in their behalf, seemed sufficient to ensure a verdict in their favour. The proverbial uncertainty of the law has never been more truly exemplified than in this case, and the chairman of the Joint Board must, doubtless, feel greatly chagrined that the measure, over which he stated in his evidence he had been breaking his heart for eighteen years, and which was on the point of being triumphantly carried, should be suddenly consigned to a grave from which it is hardly likely to be resuscitated.

The history of the origin and progress of this ill-fated measure was very clearly set forth by the promoters' counsel, who stated that for twenty years the several districts concerned had been attempting in various ways to do away with the difficulties which beset them in respect of the disposal of their drainage, and that up to the present time, notwithstanding a sum of 50,0000. had been expended by the Joint Board, and possibly an equal sum by their opponents, nothing had been done with all the various attempts that had been made to divert the sewage from flowing "unpurified, unaltered, and untouched," into the river Thames, or to prevent it from aggregating itself in the vicinity of the houses to the injury of the health of the inhabitants of those houses. Commencing with Kingston, and followed by Richmond, Barnes, Mortlake, Kew, Esher, Heston, and Isleworth, inquiries were instituted and application made to the Local Government Board for Provisional Orders to acquire land for the purpose of dealing with the sewage in various ways. The first application was for 184 acres in Ham-fields, over which the sewage of the towns of Kingston and Hampton Wick was to be spread by irrigation; but this being strenuously opposed by the landowners and other proprietors immediately adjoining, the idea had to be abandoned at once as impracticable. This was followed by an application from Surbiton, whose authorities had been warned by the Thames Conservators that their day of grace had nearly expired, and that unless they could divert their sewage from the Thames by the specified date, they would be subjected to the penalties prescribed in the Act. Similarly all the principal towns, one after another, became liable to similar penalties, but up to 1876 not a single thing was done to carry out the purpose of the Act of 1867. In the meantime, in 1872, in accordance with the Report of the Royal Sanitary Commission, an Act was passed which conferred a sanitary jurisdiction on the whole of England, without any exception, and the whole country was divided either into rural or urban sanitary districts presided over by their respective boards. In 1876, in order to carry out the provisions of the Public Health Act of 1875, an inquiry was held by the late Colonel Cox, at Kingston, to try and get rid of the difficulties which apparently beset the acquisition of land for sewage disposal, and then it was proposed that a very large district, with a population approximating to 347,500 should be constructed. The inquiry, however, showed that the formation of so large a district as proposed by the Surbiton authorities was not feasible, but that it might be expedient to form five or six distinct groups of the several parishes interested, and that facilities might be given by the Local Government Board accordingly for combining certain of the districts for the purpose of jointly establishing works for the purification of their sewage; but Colonel Cox added, in a subsequent report, that in the event of a united district being formed, it would be undesirable to include therein such districts as were geographically remote from the centre. In 1877 a Provisional Order was granted by the Local

Government Board constituting the limited district, and in 1878 another inquiry was held on various points, and amongst them was the proportionate representation of the various districts on the Joint Board. As soon as these preliminaries were settled, the Joint Board started on their duties, and the first attempt was to form a connexion of their district with the Metropolitan system of sewers, but without success.

They then offered three premiums for the best plan for dealing with the sewage of the united districts. The first selected out of nearly twenty plans was one for irrigation, designed by Colonel Haywood, involving the purchase of over 900 acres for the purpose, but the difficulties connected with obtaining so large a tract were so great that it, in its turn, had to be abandoned. The next effort was to get a connexion with the West Kent Main Sewerage Board, but their terms were so high and the uncertainty as to the expense so great that nothing could be arranged with them. The Joint Board were then obliged to revert to a scheme propounded by the firm of Messrs. Mansergh & Mellis, one of the successful competitors, for treating the sewage chemically. These engineers recommended three sites as suitable for the operation, viz., Barnes, Ham Fields, and Mortlake, the last being the site eventually selected, and for which the application for the Bill was made, and which has called forth so much opposition. The cost of the scheme as finally elaborated was estimated at 274,0000., no small sum in itself, but its sufficiency has been called in question, for in order to carry out the works it was necessary to purchase fifty-five acres of land, the value of which, being suitable for building purposes, is annually increasing.

Considering the position of Mortlake and its proximity to the Metropolis, it is, of course, not surprising that so much opposition has been manifested to the location of sewage works there.

The experience that has been already gained in the treatment of sewage no doubt goes far to justify the expectations of experts; but the result of careful experiments in the laboratory cannot be always ensured in practice on a large scale. With whatever chances of failure, however, the scheme was a bold one, conceived in a practical spirit, and now arises the question, "What is to be done?" The Thames Conservators must perforce require the riparian districts to comply with the terms of the Act. No less than twenty-one parishes combined in the Joint Board's scheme have to provide for the purification or else the diversion of their sewage. Some of them, as, for instance, Heston and Isleworth, are already prepared to proceed without delay with a practicable and well-considered scheme, the cost of which, it was stated in evidence, will amount to little more than one-half of that which an alliance with the Joint Board would have entailed. It is believed that the clearness with which the learned counsel for those two districts, Mr. Creswell, was able to prove his client's case, added to the fact that the Select Committee found they had no power to eliminate them from the operations of the Provisional Order, helped to the final overthrow of the Bill. The remaining districts could not do better now than follow out Colonel Cox's recommendation, and group themselves, together according to their obvious geographical limits, for they would then be formed into manageable units, while the principal difficulty which has hitherto attended most of the schemes, that of obtaining land for dealing with the purification of sewage will then, by being minimised as to quantity, be more easily overcome. The ratepayers of those districts may well imitate the example of Heston and Isleworth; for where there are but small interests to satisfy there will be probably but few objections to overcome, and matters which it was found impossible to arrange by such a cumbersome and discordant element as that of which the Joint Board appears to have been composed, may probably be more easily solved by a body whose interests, instead of being conflicting, are identical. It will still, however, be necessary for the ratepayers in every case to be careful

that, after the works have been executed, the persons in the employ of their respective Local Boards faithfully attend to their duties, otherwise they may at any time by carelessness find that their effluent is below the standard of the Thames Conservators, and so they may become liable to a heavy penalty, which they will not be able, and perhaps, in the interests of the general community, ought not to escape.

In regard to the state of the Thames itself, on which we touched in our "Notes" last week, the Conservators appear to consider that by widening and deepening the channel, and by facing the Middlesex bank with stone, to prevent its further degradation, the current would be diminished and a wide sheet of water would thereby be always maintained between Teddington and Isleworth. Another correspondent suggested the construction of two "half-tidal locks," at Isleworth and Putney respectively. The causes of the existing low state of the Thames was correctly ascribed, in a letter by Mr. Labouchere, which appeared simultaneously with our own remarks, to the deepening of the lower reaches in the neighbourhood of the Enhancement, by which the ebb-tide is enabled to flow off more quickly, and to the abstraction of over one-seventh of the fresh-water flow above Teddington by the Metropolitan water companies. But neither of the remedies suggested is such as will effectually correct the evil. The construction of weirs and locks at Isleworth and Putney would tend to shut out *pro tanto* the tidal volume which now flows past those places, and in every tidal river a diminution of the tidal reservoir means so much less demand, and a corresponding diminution of volume at the entrance, which in time must produce a deteriorating effect on the embouchure. So far as the proposed deepening and widening of the river's bed means increasing the tidal sectional area, the proposals of the Thames Conservators will be effective in causing a greater volume of tide to flow up; but it is not likely to produce any raising of the river surface at low water,—rather the contrary; while as regards the existing fresh-water volume, the increased sectional area will cause it to flow off faster than at present. The increase to the *tidal* volume is to be encouraged by all means, and therefore works like locks and weirs, which would diminish both the volume and the duration of flow, are to be deprecated; for, though they might maintain a broader sheet of water at first, yet it would be found ere long that the bed of the river above the weirs would gradually rise, and the shoals again reappear, while evil effects would soon be made apparent lower down in the deterioration of the tidal channel in consequence of the diminished quantity which would be entering twice in each twenty-four hours.

How far the further abstraction of water by the metropolitan water companies is to be carried it is impossible to foresee, but it is quite certain that some limit must be assigned, and that soon, if the navigation of the river is to be maintained. There is but one remedy for this, and that is storage; and if the Conservators are not provided with sufficient funds to carry out such works themselves, then the companies should not be allowed to draw any further volume from the river, until they have provided for the same by the construction of reservoirs on the various feeders of the Thames, so as to restore to the river during its low state an equal volume to that which they abstract. But if the Conservators receive, as is stated by Mr. Labouchere, large sums for the sale of their water, they ought to have the means wherewith to construct the necessary storage works; and if they could only be induced to follow out the process to its logical conclusion, they would find that by the construction of a series of reservoirs judiciously planned, and carefully managed, they will have not only enough water to maintain an adequate perennial flow in the river, but they will likewise help to diminish the disastrous effects of floods, and at the same time add materially to their funds by the sale of the surplus supply to the metropolitan and other water companies now, or hereafter to be established along the banks of the Thames.

## NOTES.

T appears from later information that the shelving of the Mortlake Sewage scheme by the Select Committee was due not so much to disapproval of the proposed system in itself and on principle, as to a conviction that the districts concerned could apply a similar system more economically and efficiently each for itself; and, moreover, that "the oxidising power of the Thames water on the purified effluent would be most effective when the effluent was delivered at different parts of the river." There is logic in the latter statement, certainly; the former surprises us, as we should certainly have thought that economy and general efficiency in the application of the system would have been secured by combination. The Committee, however, have some regard to the importance of the centralisation of authority, at all events, as they consider that the proper solution of the problem will not be reached "until the sewerage, from its production in the dwelling-house till it is delivered purified in the Thames, is under the control of the same authority, and, until the districts for house drainage are grouped so as to be identical in area with those for purification."

By the courtesy of the First Commissioner of Works, we have been enabled to inspect the interesting series of drawings by Mr. Pearson for the illustration of his scheme for treating the west side of Westminster Hall, which by this time will probably have been deposited in the Library of the House of Commons, as was promised on Monday evening. Mr. Pearson's report, which, in connexion with the careful and minute drawing of the ancient work as at present existing, forms a historical document of some interest, we propose to consider more in detail in another number,—the matter gone into being of too much intricacy and importance to be disposed of summarily and after only a necessarily brief study of the plans. It will be sufficient to observe here that Mr. Pearson urges the re-covering of the exposed wall with new building as soon as possible, with a view to its preservation, and that his proposal is to build a two-storied cloister, in accordance more or less with indications in the existing wall and documentary evidence; the lower cloister open, with the arches filled in with iron gilles, the upper closed and glazed, making a gallery extending the whole length of the Hall. The reconstruction of the great hutresses of Richard II., which will form part of the scheme, "is justified on the strongest grounds, those of stability;" they are at present in a dangerous state. The scheme also includes the raising of the towers at the north end of the Hall one stage, and the treatment of them so as to render them in some degree a connecting link between the severer work of the Hall and the more elaborate architecture of Sir C. Barry. It must be remembered that no part of the stonework which covers the existing front is in reality earlier than 1820. There is, therefore, nothing authoritative about it, and its alteration interferes with no ancient work; an argument which future builders will probably apply when they feel inclined to pull down in turn the restored work of our day. The design will unquestionably be an improvement on the existing north elevation of the Hall, and that Mr. Pearson's cloisters are designed in the true spirit of Medieval architecture, as far as that can be realised by any one in the present day, is what those who know his work will expect. Whether such a work can really be called "restoring" what was there before, or whether in any case that is what modern architecture should aim at, are, no doubt, questions to be asked.

A CIRCULAR has been sent round to the members of the Institute of Architects, intimating that it is the feeling of many members that the Institute should not any longer be without a portrait of the late Mr. Street, who had only just commenced at the time of

his death what would undoubtedly have been a brilliant term of Presidency of the Institute. It is proposed that the portrait should be a bust, and that Mr. Armistead should be asked to execute it. Mr. A. W. Blomfield is acting as Honorary Secretary in connexion with the scheme, which we entirely approve, more especially as we have no doubt of Mr. Armistead producing a work that will be, from an artistic point of view, an acquisition to the Institute.

WE extract the following from the summary of the annual address of the Sanitary Institute of Great Britain, delivered last week by Professor Bartlett:—"The Select Committee of the House of Commons have overwhelming evidence of the pollution of the rivers in the neighbourhood of the intakes of some of our metropolitan water companies, and if cholera should occur in those districts, it must be distributed far and wide. No dependence can be placed in the purifying power of the ordinary filters, as I find not one in ten sufficiently well made or fitted to prevent the finer particles of charcoal from penetrating through with the mis-called filtered water. Such filters are worse than useless, and the public can use a little very fine charcoal powder as a rough test to see if the filter is in working order when new. In the course of some important experiments this simple fact was discovered, namely, that the finest particles of charcoal which pass freely through most filters before they are clogged up with deposits from the water, when used in sufficient quantity form the very best of all filtering media. Not only are suspended matters filtered out mechanically, but most, if not all of the pollutions in solution are oxidised and rendered harmless."

PITHY things were said by architects and others at the conference last week. Architects, of course, need not be distanced by specialists if they keep on taking pains. The burden of the song as to drainage is always,—get good work done, and get somebody to keep it in order. And this is expanded to all lengths,—or put briefly as,—lay your drains on good lines, to good falls; ventilate them thoroughly; cut off your sink-pipes from your drains by air-spaces, let them deliver on the gratings of gulleys or into hopper-heads; cut off the house-drains from the sewers by ventilating-traps, with gratings over them. An employer is supposed to listen to such counsels with a very cheerful mind. He is supposed to be welcoming the golden age. Croakers hint, however, that architects must preach a little while longer yet, and go cautiously, besides, lest they leave their pupils,—that is their employers,—too far behind them. A year or two ago a system of drainage was laid down on the most modern and approved principles. After a proper interval the client threatened the architect with legal proceedings. He complained that on one occasion there was a disagreeable smell at the disconnecting trap; that the foul water ran from the sink-pipes full in sight; that there were hopper-heads negligently and ignorantly put to some pipes, and that the leaves lodged in the autumn in the gratings of the traps!

IT is of extreme importance that daily gaugings should be taken for the next few weeks of the actual flow of water over Teddington Weir. Measurements of the volumetric flow of the Thames are at present contradictory. The escape down the channel of 16½ metric tons per second is the lowest estimate generally known; and it may be gravely doubted whether the June and July flow of this year has been as much as that moderate figure. There are so many public bodies deeply interested in the matter,—to say nothing of the riverain proprietors, and of the navigators and frequenters of the river,—that it will be a perfect scandal if they are content to remain in ignorance of the facts. Neither the Conservators of the Thames, the Metropolitan Board of Works, nor the Local Government Board are in a position to fulfil all their duties without a knowledge of this minimum flow. It would, no

doubt, be somewhat of a fresh start, but it would conduce very much to the high public estimation of the Institution of Civil Engineers if they would allot a small portion of their noble revenue to the determination of scientific facts of public importance, in the same way that the British Association has done. In France and in Italy, as well as in other Continental States, the hydrometry of all the rivers of the country is ascertained by the Government engineers, and the details are made as generally accessible as can be desired. Is it creditable to us as a practical people that questions which can be at once answered as to the levels, fall, average flow, floods, and droughts of every French or Italian river are as yet unanswerable for the rivers of the British Islands?

THE terrible railway disaster near Penistone, the report of which has shocked us in Thursday's papers, seems to have been one of those events which can more truly be called "accidents" than railway disasters often can. The sudden breakage of the engine axle illustrates indeed the occasionally treacherous nature of iron when subject to continued stress and vibration at high speeds; and though we can never hope to eliminate entirely this element of danger, it will be very desirable if the history of that axle can be traced.

THE important decision in the case of a suit of a customer against the New River Water Company, in the Clerkenwell Police-court, last Wednesday, should be noted. The plaintiff sued the Company for overcharges during past years, pursuant to the decision in Dobbs's case. The Company, through Mr. Poland, stated that they had taken no proceedings for under-charges since Dobbs's case, and if these proceedings were allowed they might have 50,000 claims against them. The plaintiff was non-suited, on the ground that he must be considered as having acquiesced in the charges at the time they were made.

THE case of Snow v. Whitehead, heard before Mr. Justice Kay on Monday last, raised a curious and important question as to what constitutes a house of a specified value on an estate. The defendants were assignees of a piece of land in regard to which they had entered into a covenant with the plaintiff to build no house of less value than 400l. The defendants had built two houses which were of less value severally than 400l., and made a communication between them on the ground floor, claiming that they were thus one house of higher value than had been stipulated. The learned judge decided against them, holding that for the purposes of the covenant they were two houses. There can be no question that the law, as laid down in this case, represents the common sense of the matter (which law does not always represent). The object of a covenant of that kind in regard to building land is to ensure the erection of buildings of a certain standard in regard to appearance and value, and to permit the erection of smaller tenements arbitrarily connected together after they were built would be to invalidate the practical object of the covenant.

THE programme of the International Competition for the proposed new Exchange at Amsterdam, for which designs are to be sent in by the 1st of November, offers a remarkable contrast to some competitions nearer home. The whole of the drawings sent in are to be publicly exhibited; the best ten plans are to receive premiums of 1,000 francs each, and five of the authors of these ten plans are to be invited to enter into a final competition, in which they are to receive respectively premiums varying from 10,000 francs to 3,000 francs. A committee of judges has been formed, including eminent architects from various countries. Among them are the well-known names of Herr Cypers (Amsterdam), M. Paul Sédille (Paris), and Professor Kerr, to represent the interests of English architects. When our own authorities see how these things are done abroad they will perhaps not feel

quite so certain that they have done everything they ought to do for the architects in some of our own competitions.

IT is said that Lord Carrington's house in Whitehall is shortly to be removed,—probably next month indeed, and almost certainly not later than October. It is one of the very few houses built in London by Sir William Chambers, and remains almost exactly as it left his hand. The interior is marked by all his delicacy of design and treatment, and the detail throughout is worth study, and much of it is worthy of record. This is a hint for students who may not be able to spend their holiday out of town this year. We shall give two views of the interior shortly.

THE advantages of being, as people say, "connected with the Press," are probably hardly appreciated or realised by the outside world. Here is one example, for instance, of the paths of pleasantness in which one may be invited to walk, even in what might be thought the dull and prosaic study of sanitation. (N.B. The spelling as in the original document):—

"DEAR SIR,—We have erected a house in the Grounds at the Health Exhibition, where we show our system of ventilation." [System described.] "We are thinking of inaugurating the opening in the form of a lunch to a select number of the Press. Our modus operandi will be lunch at the Restaurant, then adjourn to the house for inspection. Explanation and discuss its Merits over a little champagne and cigars. Shall we be able to rely on your favouring us with your presence?"

Evidently the writers think, like Prince Bismarck at his recent "Früh-schoppen," that morning cups predispose us to "a more moderate and favourable view of men and things." We shall be happy, however, to "discuss" their system of ventilation in a kindly though, perhaps, a more cool and impartial spirit than the suggested "modus operandi" would be likely to induce.

A CONFERENCE was held at the Social Science Association on Wednesday, presided over by Mr. Samuel Morley, M.P., "for the purpose of considering the best means of promoting the formation of village communities, where manufactures and 'home industries' can be combined with the cultivation of cottage or co-operative farms, as a remedy for overcrowding in great cities, and want of employment in agricultural districts." The Chairman, followed by the Rev. H. Solly, strongly urged the importance and practicability of forming such communities, and carrying on various industries there, while at the same time relieving the congestion of towns. We have more than once expressed the opinion that a reaction must begin sooner or later against the enormous and almost suicidal crowding into London which has hitherto kept continually increasing; and we hope this is the thin end of the wedge.

#### CAMPS, CASTLES, FORTIFICATIONS, AND EARTHWORKS OF WARWICKSHIRE.\*

HOM HILL EARTHWORKS, KENILWORTH, &c.

DUGDALE, speaking of this place, says,— "Before the Conquest it was a member of Stoneleigh, being ancient demesne of the Crown, and had within its precincts a castle situate upon the bank of Avon, in the woods opposite to Stoneleigh Abbey, which castle stood upon a place called Hom Hill, but was demolished in those turbulent times of King Edmund and Canutus the Dane." The position of this small Saxon fort is at the junction of the parishes of Ashow, Stoneleigh, and Kenilworth, and the boundary-line of the two last is the ancient road within the outer fortification towards the river. This road came from Warwick and Blacklow Hill to Stoneleigh and Coventry. The situation agrees with Dugdale's description, and the place is still known to the oldest inhabitant as Hom Hill, although its name was changed to "The Crew" 150 years ago. The word Hom is said by the Rev. J. Skeat to be the

same as Holm,—flat land near a river encompassed by little brooks,—but is probably the same as bam or bome, a bamlet being a cluster of dwellings in the same way as the Charters of Evesham (Harl. MSS. 376, fol. 60), speaks of Evesham as *Ætbam*. Dugdale, in his "Antiquities," under "Newton," says Holm "is such grounds as are upon the whole encompassed by water."

The top of the hill (see plan on next page) is flat and oval in shape, about 200 ft. by 100 ft., formed to a surface, but there are no traces of earthen banks around it; probably a stone wall or wooden palisades encompassed the Saxon dwellings destroyed by the Danes in the year 1016. The oval is encompassed by a square-shaped outer rampart which is from 3 ft. to 15 ft. high, and its top s from 20 ft. to 40 ft. above the latter. The side of this rampart towards the river is perfect, and of a slight curve, and has the old road before mentioned running at its foot, whilst towards the Avon on the same side is an outer line of defensive bank and ditch, extending out beyond both ends of the fortifications; the road is 40 ft. above the river. The defensive works are stronger in the centre. The rampart is perfect on the south-west, but has been destroyed on the two remaining sides, partly by the construction of a new road about eighty years ago. At this point of the river old maps indicate that a ford existed at an early period. Ancient enclosures on the banks are called "Wayford Meadow," "Wayford Furlong," and "Garbridge Meadow." This road crossed the river at this point, coming direct from Kenilworth by the Hom to Starton; it was evidently in use in Norman times before the monks built their abbey at Stoneleigh. The names of villages, woods, and fields hereabouts are ancient, and show that the country was to a great extent covered with forest in Saxon times, whence lawless freebooters would issue to plunder travellers on the roads and people in the surrounding villages at will. The direct road from Warwick to Coventry was not made till the time of the Edwards, and communication between those towns was then as bad as it could be. To remedy the evil bill forts were therefore probably first constructed in still earlier Saxon times at Blacklow, Hom, and Stoneleigh, to guard the roads on the Royal demesnes and for the better protection of the villagers.

There is also an ancient earthwork in the Stoneleigh deer park, between the Coach and Stair bridges, occupying about two acres in extent, situated about forty yards from the river on its north-east bank, and 80 ft. above it, having a considerable look-out towards the upper valley of the Avon, but its surface is so much disturbed by ancient quarrying, that it is now impossible to state either its nature or use. It is said to have been a defensive work, and had a mill situated on an island near it. If so, it may have been a place of assembly for the Stoneleigh Manorial Court, as it is on the same hill, and only a short distance from the Mouslow mound, but overlooking another valley. Towards the river are the remains of an extensive terrace or rampart, along which an old road ran from Stanton to Chantry Heath, with similar arrangement to that at Hom. The form of the outer banks at several points favours the tradition that the place was an ancient fortified position.

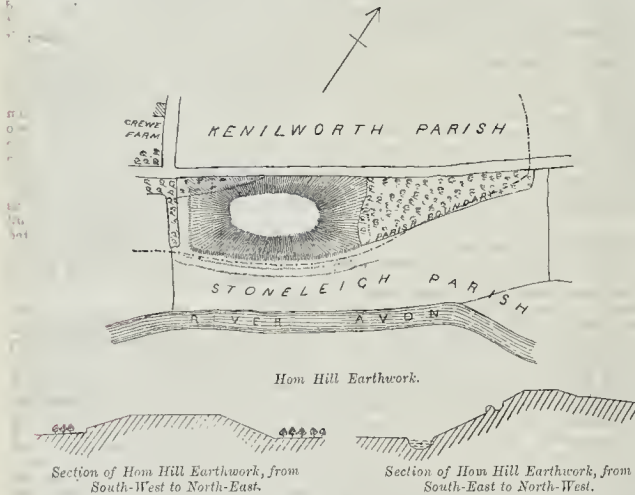

#### KNIGHTLOW TUMULUS.

Five miles and a half north-east of Coventry, on the old coach road from Birmingham to London, near the Roman Fosseway, within the parish boundary of Ryton-on-Dunsmore, and on the ridge of elevated flat land at the top of Knightlow Hill, stands what remains of an old wayside cross, resting upon a mound or tumulus of artificially-raised earth to the left on ascending the road, and from this mound the hill is said to derive its name. A new piece of road was made here in the early coaching-days to give easier ascent and descent to the hill; and from this high and elevated spot a good view is seen of the surrounding country, with the spires of Coventry in the distance. At this stone is still annually collected on Martinmas morning, at sunrise (November 11th), what is called "the wroth money," from various parishes in the Hundred of Knightlow. The tumulus upon which the cross was erected is about 30 ft. or 35 ft. square at the base, with sides running parallel to the road, having a large fir-tree growing at each angle, it being a tradition with the country people that the four

\* Continued from p. 37. The illustrations are all to a scale of 8 chains to an inch.

troops represent four knights who were killed and buried there. To trace the history and origin of the wroth money collected here, it is necessary to go back to early Saxon times, when the Midland counties of England were covered with dense woods and forests, which are stated to have extended at that period over more than a third of the land. Alfred the Great appears to have been the first king who endeavoured to reduce the Midland communities into districts, which he did by placing about one hundred villages together, under the ruling of some local thane, for the purpose of raising universal taxes equally upon the whole of the hundred, and for the regulation of other local matters. In the forest laws of King Canute we find mention of officers appointed by the Crown for the proper preservation of these forest districts. They had over them a verderer, or chief woodsman, who had power to act, as judge, and whose duties consisted of seeing that no encroachments were made or royal forest destroyed, to seize robbers frequenting the woods, the destruction of wild beasts, the stalling of beasts of venery, and to prevent cattle straying. He was empowered to hold courts every forty days, or as occasion required, in some convenient place in the district, with power to punish offenders, and of collecting fines imposed; and also to him appears to have been entrusted the gathering of the king's dues. One verderer was appointed

money," "rother," "wrother," "bryther," and "cattle money," and appears to have been paid by the inhabitants to the holders of different manors for some right of herbage, together with marking and guarding their cattle and swine, when browsing on the unenclosed lands within the township of the Hundreds. If originally collected for this purpose it would be a very useful tax in the dark ages from Rufus to Henry II., when animals were likely to be taken by the greater barons at any time, when might ruled against right, and very little security existed for the labour and goods of the thrifty husbandman, unless in some slight way protected by his lord. This fee has often been confounded with the collection of wroth money, which was a charge of payment in lieu of castle-guard. The Coventry Freeman to the present day pay a marking fee annually to the Finer, who is a person appointed by the Corporation, upon their cattle, which are allowed by right of charters granted by the Norman earls of Chester, and other lords of the manors, there to graze upon the herbage of the still unenclosed commons; and in other parts similar customs exist. At Coventry the fee appears to be exacted by the Corporation as lord of the manor, and on Martinmas morning the City Crier gives public notice that all cattle are to go to the proper office to be marked, and if found unmarked they will be impounded.

over the forest in a district. It is probable that at that early period this officer had control not only of the royal woods which then existed of the remaining portion of the ancient forest of Arden, in Warwickshire, but also of the then greater forest of Cannock, and other woodlands in the county of Stafford. At that time the open ground, which these woods and forests afforded here and there within them was mostly uninclosed, without any boundary, ditch, or division, the thanes and people living together in one community, with the cattle of which were left in the forests under the care of a swineherd, appointed by the Court of the Hundred, or local thane, to feed on the beech and oak mast, and the trees were then valued according to the number of swine that could be covered by their branches; thus, the commissioners appointed to take the Domesday state that the king's woods at Stoneley were four miles long and two broad, and formed pasture for 2,000 hogs. The people had many other privileges granted them, which they obtained in course of time as their rights, often paying acknowledgments to the king, or to their lord, either in labour or remuneration, in money or kind, and to these rights and charges are attributable "wroth money," "warth moneth," "hocktide moneth," "turfele moneth," and other old customs.

The payment of wroth money existed at the New Forest, in Hampshire, in 1670, where, in an abstract of forest claims, it is called "wrother

It is probable that the different amount of charges to the various parishes would be levied according to the number of cattle allowed to the inhabitants of each township. The office of verderer in this locality, at the time of the Conqueror's survey, appears to have been vested in Richard Chison, better known as Richard the Forester or Huntsman. He had eight manors in this county in the gift of the Conqueror, which he held by the service of keeping the forest of Cannock and other royal woods, and paying to the king ten marks annually. Thus the Conqueror, who is said to have loved the deer as if he had been his father, made good provision for his huntsman and attendants. This office, however, appears gradually hereabouts to have died out, and to have merged into that of the sheriff of the county. The square tumulus on Knightlow Hill is probably the grave of some Roman general, as it closely resembles the one at Cloudly Bush, and is near the Roman Fosseway. The stone on the tumulus, in the hollow of which the wroth money is now collected, is evidently of later date, and may have been part of the Stretton Market Cross, erected about the time of the Edwards. It appears of similar shape to those at Meriden and Dunchurch, and has on its side a mason's mark in the shape of a cross 6 in. long. Market crosses during the civil wars were much mutilated and uncared for, and the mile-stones of the country roads are, it is to be regretted, sharing the same fate now; whilst part of the Brinklow cross acts as a support to a lamp near the church in that village. The

early history of the Hundred of Knightlow is very obscure. The name is not mentioned in Domesday, but the parishes are there contained within the then Hundreds of Merston, Stanley, and Bromelaw. In the sixteenth year of Henry II. it is called Cnuchtelawa, twenty-first of Henry III. Knistelawe, fourth of Edward I. Knyhtelawe, second of Edward II. Knytelowe, ninth of Edward II. Knythlawe, and now Knightlow. According to Domesday, there were ten Hundreds at the Norman Conquest in Warwickshire. They were then reduced to six, and latterly to four. This reduction in number was not effected suddenly, but by degrees. Numerous rents and other feudal payments were made to the Crown, of which we find that in the second of Edward I. (1233) it was found by inquisition that this Hundred was yearly worth 26l. 17s. In the ninth of Edward II. (1315) upon inquisition it was found to be then in the king's hands, and in the fourth of Edward III. the king granted the baileywick of this Hundred to his well-beloved esquire, Edmund Shireford, for his life, he paying the ancient farm-rent thereof to the sheriff, after whose death it appears to have returned to the Crown, being governed by the sheriff, who accounted for it in the Exchequer. The towns within its precincts which did suit to this court up to the year 1656, were "Wolston, Lillington, Leamington Hastings, Bardingbury, Princethorpe, Hopsford, Ladbrooke, Bubbenhall, Shilton, Barnacle, Naption, Stretton-super-Dunsmore, Radford-Semeley, Bourton, Draycote, Bramcote, Church-over, and Walton in the parish of Monk's Kirby," and they pretty nearly agree with the list of places liable to pay wroth money. But, by some strange arrangement, Hyton on Dunsmore, within which parish the Knightlow Hill stands, is not in the list. In the reign of Charles I. we find this Hundred in the King's hands, who, in the seventh year of his reign, granted "to Francis Leigh, Knight and Baronet, his heirs and assigns for ever, all that his Hundred of Knightlow arising from certain manors, et cetera," therein mentioned, amounting altogether to 21s. 4d., also the rent of 37s. 8d. payable by the sheriff of the county. There are other matters granted, with a long list of appurtenances, among which occur the words "the wroth monies" and other small feudal pickings. This grant descended through his daughter Elizabeth, married to Thomas, Earl of Southampton, to the Montague and Scott families. It must be shorn of much of its ancient profits, if any indeed, remains, as all such feudal rights and impositions were abolished on the return of Charles II. to this kingdom. The court-leet of the Hundred is still held annually at Dunchurch, and proper officers appointed, although their services are no longer required, whilst the collection of wroth money takes place yearly at Knightlow Hill on Martinmas morning before sunrise, when the steward invites the party to stand round the stone (the original custom was to walk three times round it), proceeds to read the "Charter of Assembly," which opens thus—"Wroth silver collected annually at Knightlow Cross by the Duke of Buccleuch, as Lord of the Manor of the Hundred of Knightlow." The next proceeding is calling over the names of the parishes liable to the fee and the amount due from each, when each parish, by its representative, casts the required sum into the hollow of the stone, and payments are made as follows:—

Astley, Arley, Burbury, Shilton, Little S.	5
Walton, Barnacle, and Wolfcote (1d. each parish)	0 7
Whitley, Radford-Semeley, Bourton, Bramcote, Naption, and Draycote (1½d. each parish)	0 9
Princethorpe, Stretton-on-Dunsmore, Weston, Bubbenhall, Waverley, Church-over, and Ladbrook (2d. each parish)	1 2

The fine for non-payment in olden time was 1l. for every 1d. not forthcoming, or else the forfeiture of a white hill with red nose and ears of the same colour, but the fine has not been paid within man's memory.

The payments have been collected from time immemorial, excepting for a few years about the beginning of this present century, but the Scott family subsequently revived them or kept up "the charter," as it is locally called, but the

persons who pay the wroth money now are neither the lords of the several manors mentioned nor the churchwardens of the parishes, but gratuitous payments are made by the spectators in prospect of the comfortable breakfast given by the Duke of Buccleuch at Stretton afterwards. W.

Country.

ISTHMUS OF CORINTH CANAL.

EVIDENCE is not wanting that in ancient times an attempt was more than once seriously made to pierce the Isthmus of Corinth. For the credit of antiquity it is satisfactory to find that they chose the right point for their attempt. All traces of the old works must shortly disappear entirely when the new canal is completed. M. Gerster, the superintendent engineer, deserves our thanks for remembering the old while he inaugurates the new. He publishes, in the *Bulletin de Correspondance Hellénique*, a plan, with elevations and full engineering details, of the remains he has discovered while superintending the modern works. These remains must belong to the canal of Nero. But his attempt was not the first. Periander, Tyrant of Corinth, projected a scheme, but whether his project ever took effect we are not told. The engineer of those times had some curious scruples to contend with. What the gods had made was good, let man withdraw his impious hand, nor do violence to the sacred earth. "Fence not the isthmus with towers, neither pierce it with a trench, for had Zeus desired an island himself would have made it." Such was the answer that came from the Pythian shrine to the Cnidians when they desired to pierce their isthmus, and the like response must again and again have come to ambitious Corinthians. What machinations of commercial jealousy lay behind these Pythian oracles we can easily guess. In later and later days, when these pious scruples ceased, difficulties scarcely less curious were raised. When Demetrius Poliorcetes planned a canal, it was objected that the level of the Gulf of Corinth was higher than that of the Gulf of Egina, and that, were the canal effected, the water would rush down and flood the lower islands. So great was the fear, that, Strabo tells us the project was laid aside. But science advanced. Roman emperors were less credulous than Macedonian conquerors. Caesar planned the canal afresh, and would probably have carried it into execution, but death overtook him. Caligula sent a centurion to survey the ground. At last, Nero not only projected but began the work. In September, A.D. 67, Vespasian sent him from Galilee 6,000 Jewish prisoners for workmen. For some months the work was actively pushed. It ceased only when Nero was recalled to Italy to repress the insurrection of Vindex. After Nero the idea was taken up, indeed, by Herodes Atticus, but never carried further. M. Gerster calculates that the remains he has found justify the supposition that five or six thousand workmen were at work for three or four months. The line of excavation falls into three parts; on either shore a sandy plain with alluvial deposits, between them a rocky somewhat mountainous tract. At each extremity, through these two plains, Nero had dug a trench, the joint length amounting to about half the breadth of the isthmus. In the more difficult centre part he had sunk wells. The new canal will follow the same lines.

INTERNATIONAL

FORESTRY EXHIBITION, EDINBURGH.

SECOND NOTICE.

PASSING along the central avenue we notice the silver axe recently presented to Mr. Gladstone by "a few admiring friends," beside which are some chips of an ash-tree at Hawarden which was felled by the Premier. The axe is fitted with a polished black handle, and is provided with an enclosing case. There are also several examples of the tools used by the woodman in the royal forests; but some of these are not considered up to the mark by Scottish foresters.

To the right we observe two bays devoted to the display of South African products. These courts are very tastefully got up, the walls being hung with maroon drapery, decorated with horns of the gemsbach and koodoo, a wreath of native wild flowers, and a telling picture of a flock of ostriches. There is a model of a forest wagon laden with several

varieties of wood, and on the tables are seen Zulu assegais, ostrich eggs, hats made of reeds, Kafir necklaces, and bracelets made of melon seeds. There are numerous sections of the different trees indigenous to the colony, and a stand showing the various woods, polished so as to display their markings. These include the yellow wood (*Podocarpus Thunbergii*), which is well suited for making wagons and flooring. The stinkwood, which has a fine texture, and takes a good polish, displaying a rich colour similar to walnut, and is used in the manufacture of furniture. The sneeswood is of great specific gravity, and, owing to its capacity for withstanding the attacks of borers, is of great value for marine purposes. The stone pine, now extensively planted in this country, grows freely in South Africa, and is found useful in the construction of railways, and there are other woods more or less useful, but none of these are exported from the colony owing to the difficulty of transit, except to a trifling extent. There are no large rivers to float the timber to the sea, and there are few creeks at which vessels could load. The means hitherto adopted is to use bullock teams, but the process of transit is slow and difficult owing to the nature of the ground, but tracks are being gradually formed, and the attention of the colonial authorities is now directed to the conservation of the forest, and a superintendent has been appointed with a sufficient staff of rangers to guard the forest from the indiscriminate destruction of woods which was going on, and which in some places threatened to denude the country of growing timber. The Kaysna, or great forest, situated between Table Bay and Algoa Bay, still contains magnificent remains of the primeval woodlands. It extends for upwards of a hundred miles along the coast, with an average breadth of twenty miles, and here are found large game, as the elephant, the buffalo, and the antelope; but the Aborigines, a Hottentot tribe, the Outeniquas, have nearly disappeared. In the King Williamstown district there are also small Crown forests covering about eighteen square miles. These forests are now in process of being surveyed, so that they may be worked on a principle of rotation, and precautions are taken to prevent the scourge of forest fires. Plantations are being formed by Government on the Cape flats, and nurseries have been established, from which gaps are filled up in the Crown forests and trees, sold at a cheap rate to private planters.

THE LION OF ST. MARK ON THE COLUMN OF THE PIAZZETTA, VENICE.

A VALUABLE pamphlet on the above subject, by Signor Boni, of the Ducal Palace, has lately been published in Venice.

There are probably few monuments of past ages of which the existence and outward aspect are better known, yet just in proportion as this is the case, does its real history seem vague. There seems to be no satisfactory documentary evidence to determine it, and I am aware of no attempt having been made, before the one here referred to, to decipher its history and the manner of its construction from a close examination of the animal itself, this, no doubt, arising from the difficulty of obtaining access to the top of the column which supports it. I venture to think, therefore, that the appended translation, which I am able by the author's permission to communicate, will not be read without interest and instruction in this country:—

"On the morning of the 18th of September, 1883, as the grass was to be removed from the top of the columns of the Piazzetta, two long ladders were tied together, so as to reach the capital, whose height is more than fifteen metres.

I ascended by these, and as I placed my foot upon the capital, which is three metres square, I felt quite small, so colossal did the lion, whose wings are once and a half the height of an ordinary man, appear to me.\*

To accustom myself to the proportions of the lion I walked all round it.

It is made of many pieces held together by iron cramps, the square-headed rivets of which have in rusting loosened or quite separated their respective plates. Two fragments of bronze, which have been broken by the corrosion of the iron, or have fallen from the under-

side of the body of the lion, show that the rivet is more or less a centimètre in circumference.

The pieces which form the lion were made at different periods; fortunately the greater number are of the older period, from the time when the Doge Ziani erected the column (1176); we have then later renovations and restorations of Napoleon's time, or of that style which is recognisable by the classic modelling.\* Some of these pieces seem the work of clever hands.

The right forepaw and half of the left, half of the right hind paw, and the whole of the left, are not original, and, therefore, not worth the trouble of describing. It is a pity that none of the original claws remain, because the present ones have the character of no special period; they are indifferent and academical. The tuft on the head of the lion is replaced; the gospel which he holds under his foot has been renewed in lead. Both the wings are not only detached from the other parts of the lion, but evidently belong to a recent period. Nevertheless, there were wings at first, and of these there remain traces, which we will presently examine. The tail has also been restored.

All the rest,—that is to say, the head, with the mane and the body of the lion,—is original; the modelling of some parts where the old Venetian metal-worker thought fit to preserve it, is truly perfect: to convince ourselves of it, it would be sufficient to consider the muscles, tendons, and veins of the paw not entirely restored; here there is no ostentation of the doctrine of anatomy, that only is given which contributes to the majesty of a symbolical animal.

Holding on to the jaws and looking into the lion's mouth, I perceived that all the inside is hollow. The jaws are furnished with canine and molar teeth, of fairly accurate workmanship. The skin is wrinkled and hairy at the sides of the mouth, which, seen closely, altogether loses its grotesque sneer; its two monstachios (*buffi*), chased to represent hairs, but of one single piece, represent the long bristles of the feline species; the eyes are strongly accentuated, the eyelids muscular and rounded. The eyeballs appear to be of a glassy, white, and translucent substance, triangularly cut; that of the right eye reflects a reddish tint from below. They have been restored, and are probably, as they say, of rock crystal, although not transparent.

The old guides do not mention their former colour; certainly they were not white, for they would have given a strange expression to the lion's head, or, like the present ones, made him appear blind. The eyes of the feline race, like the crisolite in a poem of the twelfth century, 'dart flashes of fire' ('spande fiamme di color di fuoco'), or, like the topaz, 'have the colour of golden and resplendent light' ('ha color d'auro e splendente lume').

If such gems were not formerly set in the lion's eyes there may have been either cornelians or chrysope, or other such *cat-like* crystal. The eyes may have been still more fiery, and yet not so as to take away from the effect of the bronze, if made of one or more red gems.

The tufts of the mane spring round the neck and round the ears, short and wavy, then developing into symmetrical locks, those below mingling with those above, descend down to the breast, and lose themselves half-way down the back. Each lock, formed of five or six little cords, half a centimètre in size, tapers off in spirals, and the last wave stands erect, so that the mane is all hissing with points. Other little tufts are to be found regularly disposed behind the paws and elsewhere. Where the mane descends along the shoulders of the lion it covers the feathers of the bases of the ancient wings, feathers which may be seen also on the right side. The feathers are rudely interrupted by the chace formed for fixing the new wings. The difference between the old feathers and those of the new wings is evident; whilst the first are concave, rounded, and entire, those of the restored wings are convex and carved more naturally. The old wings developed themselves at a less distance from one another, and nearer to the neck, because the original feathers are to be found where the mane descends and where the restored wings do not even com-

\* The lion was lying in pieces at the Arsenal in the condition in which it had been returned from Paris in the year 1815. It was put together again and restored by Bartolomeo Ferrari, and replaced upon the column, on the morning of April 17th, 1816.

\* See, in connexion with this article, the illustration of the lion which we give in this week's number.

mence. As to outline, the old wings must have participated in that severity which, inspired by the sublime, does not descend to mean details. The severe line which forms the head of the lion, with the mane and the back, may give some idea of this.

Mr. Ruskin (in 'St. Mark's Rest,' i., 22), with that perception which is peculiar to him, arrived at the conclusion that the old wings were longer than the present ones, and that they were cut off into their feeters.

The practice of cutting out the wings so that the light might be seen through the larger feather, was introduced by the Byzantines in their mosaics, and Giotto adopted it for angels' wings. He was imitated in the fourteenth century by those who painted lions of St. Mark, as Jacobello del Fiore and Donatus Venetus, who adhered to the symbolical form of wings.

With greater reason it might be supposed that the bronze lion had its wings divided into feather, so that they might more readily be distinguished against the sky. But a mosaic record of them remains to us in the wood-engraving of Breydenbach (1486). In the painting by Bassano in the hall of Il Maggior Consiglio, where the column on the Piazzetta is depicted to a large scale, the lion is to be seen with carved out wings, and although they have been treated by him as accessories and painted roughly, still he has not passed the fact unnoticed that the larger feathers were detached one from another. The lion was gilded; I found traces of gilding in the protected parts of the upper jaw.

Under the body there is a small door,—restored,—large enough to put one's head through, but it is locked, and I do not know for what intended. I could not find any inscription or mark relating to the ancient casting, nor any that refers to the restorations. There are several initials, but they are recent and of no importance. I left the two fragments of bronze where I found them fallen on the slab of the capital.

This lion of St. Mark is admirable in its expression of boldness and magnanimous strength. It is looking into the distance, and its claws grasp the book: it seems to send a roar of defiance to the East. Mr. Ruskin, from whom 'one of the most splendid productions of Medieval art' could not pass unnoticed, spoke of it as a work of the thirteenth century (*vide* 'Stones of Venice,' iii., 233).

There remains to us the name of an *Aurifer Venetus* of 1300 on a bronze gate of the basilica of St. Mark; and Vasari tells us that the gates of the baptistry of Florence, modelled by Andrea Pisano, were cast in bronze by Venetian masters.—'Molto esperti nel fondere i metalli.' But I believe that our bronze lion is anterior to these works, and also to the stone St. Theodor erected on the other column of the Piazzetta at the beginning of the thirteenth century (Saxovino).

Without pretending to say that it was placed on the column immediately after its erection by Doge Ziani, we must allow that in the twelfth century there existed 'Venetian masters' capable of undertaking such a work, if they were worthy of the fame which afterwards became theirs in Tuscany.

Since the publication of the above the author has found reason for supposing that the book under the fore paws of the lion is possibly not part of the original conception.

Signor Boni will be known to many artists who have visited Venice. To those who have had the good fortune to be welcomed by him,—as he welcomes all who care to see her treasures and to learn something about them,—I need say nothing of his authority to speak on her ancient monuments. For those who have not had this fortune I may say that the author is well known beyond as well as in Venice for his untiring efforts to preserve her treasures from destruction.

To his pen was due the memorial 'L'Avvenire dei Monumenti in Venezia' (noticed at the time in the columns of the *Times*) which the Venetian artists adopted and presented to the Commission which has charge of monuments, at that time when the restoration of St. Mark's was so burning a question.

His sound views upon the proper treatment of 'Restoration,' explained in this and many other pamphlets and articles on the same subject, would form a very profitable study for many of those who have care of ancient monuments in this country.

W. D. C.

#### SOME MORE NOTES ON SASH-HANGINGS AND FASTENINGS AT THE HEALTH EXHIBITION.

In our notice of wood-working machinery, exhibits in wood and sash-hanging, and fastening appliances in connexion, we gave particulars of some recently-introduced methods for the ready removal or taking out of sashes for cleaning and securing the same. Though admitting that in some instances commendable improvements had been effected, yet, generally speaking, we were obliged to point out the drawbacks attending the adoption of nearly all the sash contrivances (ingenious though several of them are) on account of their non-adaptability save under special circumstances. We would rather bestow praise than dispense blame if we could conscientiously do it, but all intelligent exhibitors must be aware, as well as ourselves, that meritorious inventions or improvements are not necessarily thoroughly efficient and successful ones. Scattered through the galleries of the Health Exhibition, as we have remarked already, are a number of illustrations of what are termed "improvements" in window-frame and sash-construction, more particularly in respect to the hanging of sashes and their fastenings. Truthfully speaking, some of these "new systems" are not new, but reproductions of late eighteenth and early nineteenth-century methods, modified and re-introduced. Several attempts have been made to hang sashes on the balance principle without weights, and by the reduction of the number of weights for a pair of sashes, from four to two. In Venetian or "Wyatt" windows, that is, where there are a pair of central lights and side lights, all of which it is required to hang, the system of making two weights answer for hanging a pair of sashes has been often adopted by the expedient of fastening either end of the one length of sash cord to each sash, the looped middle behind the pulley stiles having a small sheave or pulley attached, somewhat similar to that in connexion with the weights of an eight-day clock. One of the drawbacks in this method of hanging is that both sashes cannot be equally raised and lowered to occupy a like position for ventilation with that of the ordinarily hung pair of sashes, in other words, the top or bottom sash must be either up or down and not equally open together. Adopting this balance principle of hanging, but dispensing with weights, an exhibitor hangs both sashes by passing the looped cord through a small pulley fixed at the back of the pulley stile. As friction in this case, as well as in ordinary cases, will lead to the wear and tear of the cord and its breaking, special provision has to be made to obtain access for repair or mixing, and without specifying other drawbacks, it will be seen that the system though applicable under certain conditions, cannot be generally adopted with success to the ordinary run of dwellings. The same exhibitor shows a very meritorious and ingenious system of hanging, in which he uses the ordinary sash-lines, but in the fitting and adjustment of the sashes, and in the method which he adopts for taking them out for cleaning, he makes a new departure. Here there is really no internal wooden stop to keep the bottom sash in its place. The inside casing shows a metal or zinc beading flush with the stiles of sash, behind which beading runs a groove, into which two spring bolts affixed to the top and bottom of the stiles shoot, forming, as it were, a tonguing for keeping the bottom sash in its position, and allowing it to move up and down readily. The shooting back of these bolts allows the bottom sash to be taken out, with cords attached, and cleaned on either side. The top sash, however, is not removed on a similar system to the bottom, but must be pulled down like an ordinary light, and cleaned by both underhand and overhand action. The parting slip in this system of sash-frame construction presents a T-section tonguing or passing into the groove in both sashes. The parting slip, instead of being fixed in a groove in sash-frame, is screwed on, and being in two lengths, allows half to be removed to take out the pocket pieces, if it be required, to get at the weights. The sash-fasteners (two in this instance, for sake of uniformity) are screws fixed on either side, passing through the thickness of the stile of bottom sash into a brass receiver with thread, sunk in the abutting stile of top light. There are other details which it is not necessary to dilate upon. Meritorious,

however, as the system may be, and though applicable under certain conditions, it cannot be generally adopted for reasons that will occur to the experienced architect and builder. In some early nineteenth century private mansions in London and the country sash-frames will be found in which provision was made for the passing up of a portion of the bottom sash when raised, into the head, or above the head of frame. In these instances the bottom sash was made two-thirds the height of sash-frame, and the provision at top was intended for allowing sufficient head-room when lower sash was raised for a lady or gentleman or family party to walk out upon a balcony or on to a pleasure-ground or lawn. This principle of construction is being again introduced to allow for ventilation and cleaning purposes respectively,—for if the bottom sash be run up into the extent of the recess provided, into the head of sash-frame, and the top sash pulled down to its limit, an open space would be formed between both sashes, but we must for the purposes indicated. Heavy sashes have been, and are, hung by a chain system, but save when these are sashes of exceptional dimensions, and weight, the cord or line system is still almost universally used in these kingdoms, despite of obvious drawbacks. The chief conditions of efficient sash-hanging are good materials, sufficient scantling and good workmanship. Flimsily made sashes and flimsily made frames are unserviceable, and an annoyance from the beginning. Solid work and good fitting, accompanied by well manufactured appliances, affixed by competent workmen, will generally wear well and give satisfaction. The ambitious desire to introduce innovations is a characteristic of our age in the fields of building construction as well as in other fields. It is our province as well as duty to take cognisance of every new material or appliance likely to prove useful to the building community, but we must hesitate to commit ourselves to opinions which cannot be sustained. "Rome," says the old maxim, "was not built in a day." In sooth, no; and our best inventions, after all, are only blurred "first-proofs" susceptible of many revisions and improvements before the standard of comparative excellence can even be reached.

#### Large Sales of Property at the Auction Mart.

—There were several sales of valuable estates at the Auction Mart last week. Messrs. Farebrother, Ellis, Clark, & Co. submitted to competition a freehold estate, with residence, on Putney Heath, containing 14½ acres. There was a close and animated competition for the property, which was sold for 25,000*l.*, being at the rate of 2,000*l.* an acre. Messrs. Norton, Trist, & Wainey offered for sale the freehold property in the Grove, at Hamstead, known as Fenton House, with one acre of land attached, which realised the large sum of 8,050*l.* There were likewise a number of sales of valuable ground-rents and leasehold properties in Regent-street and Oxford-street. Mr. Robert Reid sold the leasehold properties, Nos. 8 and 185, King-street, Regent-street, the leases having thirty-five years to run, for 5,300*l.*; also No. 154, Regent-street, lease thirty-five years, for 4,500*l.* Mr. Reid at the same time sold the freehold properties Nos. 48 and 49 in Long-acre, for 5,450*l.* Messrs. Driver & Co. sold two improved ground-rents arising out of City leaseholds in Stratford-place, Oxford-street. One of these ground-rents, of 632*l.* 10*s.* per annum, with renewal fines every fourteen years, amounting to 351*l.*, was sold for 14,705*l.*, and the other realised 26,300*l.* Messrs. Fox & Bousfield, in addition to the above, offered for sale the Rose Hill Park Estate, situated at Sutton, in Surrey, a freehold building property of about 102 acres, described as having a long frontage to the high road from London to Epsom, fully ripe for the erection of good-class residences, and alike eligible for a public institution or a cemetery. The property was put up at 20,000*l.*, and 23,000*l.* having been reached with no advance, the auctioneer observed that there was not a piece of land in Surrey that could be purchased for less than 300*l.* or 400*l.* an acre, but in many parts of the county 600*l.* an acre was easily obtained. The property was ultimately withdrawn at 25,000*l.*

**Hatchett's Hotel.** — Messrs. Archibald Smith & Stevens have received the order for the whole of the lifts (six in number) for Hatchett's new hotel, Piccadilly.

PRAYER NICHE: EARLY ARABIC WORK

Illustrations.

WAREHOUSE, STAR-YARD.

**THIS** warehouse, which has just been rebuilt for Messrs. Stevens & Sons, 119, Chancery-lane, is of red brick and Box Ground stone, and in design and construction is of the character we see in the old warehouses of Bruges.

It is situated in Star-yard, Carey-street, just behind the Law Courts.

The contractors for the work are Messrs. Patman & Fotheringham, and the building has been carried out from the designs and under the superintendence of Mr. W. F. Unsworth, architect.

SECTIONS OF NEW CHURCH OF ST. MARY, PORTSEA.

We gave a fortnight since the perspective view of this fine church, which forms one of the most artistic designs in this year's architecture at the Academy. We have thought it worth while to give the sections also, as they contain several points of unusual treatment, which will probably be of interest, especially to our younger and student readers. The treatment of the sanctuary arch, shown in one of the cross-sections, is especially rich and effective.

CROSS IN CLOISTER, SAN JUAN DE LOS REYES, TOLEDO.

This interesting cross forms another of the illustrations to the forthcoming work on Ancient Sepulchral Monuments, by Messrs. W. Brindley and W. S. Weatherley, which we have mentioned previously (*Builder*, May 2). It is a work very peculiar in style, combining details very much resembling Tudor Gothic (see the square leaves on the chamfer-planes), with other foliage work in the centre, partaking a good deal of Renaissance character. This is probably the real explanation of the incongruity of detail; it is a piece of work in which the spirit of the Gothic decadence is mingled with that of the Renaissance, at the period of transition.

PRAYER-NICHE: ANCIENT ARABIC.

This illustration, together with some others which we shall be able to give in future numbers, represents one of the examples of Arabic art in the Museum of the Mosque El-Hakem at Cairo.

The latter institution is still in its infancy, being only four years old. In 1879-80, the Minister of Education instructed the chief architect, Franz Bey, to gather together from mosques and Arabic dwelling-houses such objects of art as might be obtained; also interesting details of architecture and fragments from numerous places of interest in the City of the Caliphs, to form the nucleus of a museum in the above-named place of worship.

Unfortunately, the decade just preceding 1879-80 was most detrimental to the prospects of the undertaking. During that period the highly interesting monuments of Arabic art have been grievously plundered and destroyed. Wherefore, considering the enormous wealth which once was contained in the mosques, the results of collecting for the new museum have been very scant.

Still, however modest the beginning seemed to the promoters, the collection last year attracted the attention of the distinguished Orientalist and art-critic, Mr. Stanley Lane Pool; and ever since it has enjoyed the care and protection of the authorities of the South Kensington Museum. For, notwithstanding the comparative smallness of the collection, it contains products of the artistic skill of all epochs of Islam, and specimens of most varied materials from the beginning of the Transition period up to the present time.

The illustration given this week represents a Kiblah (a niche for prayer) richly carved in wood. It belongs to the Transition period. The ornamentation is almost entirely Byzantine, and the inscription is made in the characters of the first period.

The technical execution of this piece shows high finish, and certainly of workmanship. Unhappily the original has greatly suffered from varnish and painting (on the surface).

This niche was found in the Mosque of Sitte Ro'ah, who was a granddaughter of the prophet.

We are indebted to H. E. Franz-Bey both for the description and for the photographs from which this and other illustrations have been taken.

THE INSTITUTE OF ARCHITECTS' CONFERENCES AT THE HEALTH EXHIBITION.

(Continued from our Supplement.)

HYGIENIC VALUE OF COLOUR IN THE DWELLING.

MR. WILLIAM WHITE, F.S.A., read a paper on this subject. In it he observed that it is a recognised pathological fact that colour of some sort is indispensable to the healthy condition of the eye, and that the condition of the brain, again, is greatly dependent upon the healthy action of the nerves thus affected. These nerves are affected in a way sensibly different by different colours; in other words, in obedience to, and in accordance with, the pace at which the pulsations of light reach the eye, and upon which depends the nature of the colour seen. This sensitiveness extends also to the brate creation. By red these nerves are excited. By green, in like manner, they may be soothed; or they may be rendered torpid by the presence of blue. Yellow, like light, is the colour which the most strongly attracts the eye to itself. We are affected by black and white in the same sort of way as by darkness and light. Light in moderation will produce alertness or wakefulness; in excess it may produce restlessness and languor by weakening or dissipating the powers of attention. Shade may induce a frame of mind favourable to attention, contemplation, and repose; in excess it may induce melancholy and depression.

It is undeniable that the human system is thus affected; and when, from want of proper colour, these nerves have not been duly exercised, red is the colour most acceptable to the eye, bringing into healthy action the organs that had become inert. Hence, again, it is, that after long and close application, especially within doors, the eye can repose with satisfaction upon the soft blue of the sky or of distant scenery. The change is really needed; by the colour alone the optical sense is relieved, and the eye is content to rest, in its extended focus, upon this cool and refreshing and, as it were, more distant colour.—this perfect mixture of black with white, of darkness with light. It may be of comparatively small moment to those who enjoy constant change of scene, occupation or action. But all who labour require recreation and refreshment. And it is surely difficult to understand how it is, that with all the popular outcry for light and cheerfulness in hospitals, unions, schools, homes for the poor, a similar outcry for even a moderate amount of well-disposed colour has been but rarely, if ever, heard. That the sick and the poor should necessarily be condemned to drag out their existence within whitened walls, and without a spot of colour to relieve the dulness, to cheat the cheerlessness of their monotonous life, shows that sanitation has not made the same advance in this as in other branches of the science. And herein Miss Florence Nightingale has much to answer for. In her excellent and popular notes on nurses and hospitals, she recommended the use of glazed pure white tiles for the lining of the wards, to the exclusion of buff and red, or other colours which might be more cheerful, less glaring, and less costly.

Colour may be called a plaything or luxury, but there are few persons, if any, who would be able to live for a long period in a light white-washed, or in a dark blackwashed, apartment, void of other colour, without deterioration. In the one case a tendency to idiocy might be induced, and to melancholy madness in the other. People have been blinded by the white glare of the desert sand, or of the mountain snow. They have become mad or imbecile through confinement in a dark cell. This must not be called an exaggerated illustration, dragged in as a mere sensational argument; for, as in other matters, it is mainly through the more fatal results that men can be brought to see the great danger of neglecting precautions which to them have appeared to be trifling, needless, and obscure. I have learned, by my own experiment, that in the blinding, burning snow of high altitudes the eyes and the skin may be effectually protected by a change apparently so very slight and trifling as that of wearing a brown gauze veil instead of a blue one. Special colours have

been used medically in shades and glasses for the protection or preservation of the sight. The fact of some blind persons being able to feel colour with the finger shows how wonderfully their perception is connected with the whole nervous system. I remember the case of a blind boy, who described the touch of a scarlet geranium as the sound of a trumpet. It is said that many of those who are called colour-blind are not insensible to the influence of colour, although they may not have the power of distinguishing between certain complementary colours. The optic nerve may perform its office, but there would seem to be some local condition of the retina or of the cornea which interferes with the reception of certain rays.

In order to be healthy and cheerful, colour should be æsthetic; that is, in true accord with right perceptive feeling; in accord with Nature from the study of which all our best colouring is derived. We need not, for daily use, gaudy and startling effects, nor yet a dull monotony, but colouring of such force and variety as shall be essentially cheerful and agreeable. Hence we see that the employment of colour is not a matter of mere option or of taste, but of healthful, cheerful, and wise enjoyment.

The preservative properties of preparations of lead and arsenic, when employed in decorative work, whether internal or external, arise no doubt to a considerable extent from their antagonism, as to all organic life, so also especially to this species of vitality. But this cannot justify the continued unwholesome use of lead and arsenic for the decoration of dwelling-rooms, though the house-painter will still insist that white-lead and oil-paint forms the most efficacious covering medium that has been discovered. The trade in it has been long established, and he has been educated in its use; he is disinclined to change, and he justly bites mere experiment. But in interior painting substances are now gradually taking the place of white lead, which have ceased to be open to the charge of being experimental. The scientific investigation of their respective merits can be carried on only by those who devote themselves for the time to the subject, and many of these things will be submitted to scientific test under the auspices of this Exhibition.

Paper-hangings, again, are now made washable at the small cost of one penny per yard. It is of the greatest consequence that their colouring-matter should be free from volatile mineral poisons; and that, whatever be its composition, it shall not rub off. Only a few years ago even a medical man, a tenant of mine, who had selected his own paper for the dining-room, was made seriously ill from the imperfectly-fixed colouring, of rich yellow and brown, made with orpiment of arsenic. Other members of his household suffered, as well as the men employed to remove it from the walls. It is a satisfaction to know that, except upon the score of unscrupulous trade competition, it is needless that such goods should be sold at all, as is shown by Mr. Henry Carr's Exhibit, No. 552. Messrs. Woollams, Jeffreys, Heywood, and others, exhibit an ample variety of all colours and shades in a guaranteed harmless quality. In admirable decorative material we have also Hindley's Japanese leather papers, Lincrusta Walton, Hall's Corovollum, and others, together with a variety of damp-proof paints for interior surfaces, of questionable value in this especial respect, seeing that damp should be kept from penetrating from the outside, and not be merely covered up from sight within.

As a wholesome decorative covering for walls, a panelling of pine or fir is said to be one of the best, on account of its resinous odour. But such panelling must not be allowed to become a harbour for damp stagnant air behind it. These with other woods of a harder nature have always been popular. And a beautiful variety has been introduced in Roberts's Foreign and Colonial importations.

But unprotected panelling becomes dangerous in case of fire. There are now, however, for woodwork invaluable safeguards against fire, such as the asbestos paint, and the cyanite paint, which ought to be made use of largely for wall panelling and floors. Calamitous fires have been already prevented by the employment of them. But we cannot, with all of them, quite so perfectly preserve the charming brightness and freshness of the natural grain of the wood beneath them, and, indeed, a painted surface is more commonly implied by their use, and they need, so to say,

a fixing. Nevertheless, these paints give a good grounding for subsequent applications, whether paint, polish, stain, or varnish.

In conclusion, I will only say that we may well congratulate ourselves that we live in an age when colour is more prevalent and more really appreciated for its own sake than it had been for a long time previously. And convinced as I am that it has been ordinarily regarded too much as a mere personal indulgence for those who can afford to spend their means upon their own amusement or gratification, I would express a hope that I have succeeded in asserting its claim to be considered one of the many requisites of a healthy home.

The discussion on this and Mr. Aitchison's paper was opened by Mr. T. W. Cutler, who considered that hard wood floors were most to be desired, and washable papers were the best to use. Bed-rooms should be made as airy as possible, and be cleared from all superfluous furniture. He suggested the use of hard polished woods for doors and panels.

Professor Kerr quoted Lord Palmerston's saying that "dirt was simply matter in the wrong place." The use of carpets, hangings, and upholstery of that kind, was a thing to be practically discouraged, and considerations of climate, comfort, and cleanliness should be of the first importance. The public did not like polished surfaces in this climate, but they should be used as far as possible. The ladies and their housemaids must be looked to as the great preventers of accumulations of dust. The people of this country were becoming more alive to the virtues of colour. Looking at the matter scientifically it appeared that colour had a direct influence, good or bad, on the nervous system, and it was the architect's duty to take this into account.

Mr. Ewan Christian spoke of the depressing effect caused by some streets of compe houses in the outskirts of London. It was better to use even extraordinary colours than to have none at all. At the same time he bore testimony to the distressing effect of a crimson wall-paper; and considered that the question of dust came into the common-sense use of a house.

Mr. Stannus said that mention had been made of want of ventilation causing dry-rot. In Manchester it was customary not to fasten the floor boards until the house was plastered. The consequence was that the draught through the joists did away with the chance of dry-rot. It had been said that a liking for magenta and mauve indicated colour-blindness, but he believed they would yet be able to harmonise these two colours. All colour, he believed, came under the law which Mr. Ruskin had laid down, that colour must be varied. Colour which was flat was objectionable, but when varied it was delightful.

The Chairman, in closing the discussion, said he was delighted with the decrease in the use of compe. White brick was only a little less abominable than cement, and the effect of the white brick used in Cambridge was dreadful in the extreme. With respect to floors, he advocated the use of parquet or mosaics. It was not enough to denounce brick, and hunt down housemaids; but he believed that with impermeable floors and tiled walls they might have a wholesome and beautiful aesthetic architecture of the future.

Professor Hayter Lewis then took the chair, when Mr. Thomas H. Watson read a paper on "The Collection, Storage, Management, and Distribution of Water for Domestic Purposes within the House." This we are obliged to defer until next week, being unwilling to curtail it too much.

**Water Supply Conference.**—A Conference on Water Supply, under the auspices of the Society of Arts, will be held at the Health Exhibition on the 24th and 25th inst. The Conference will meet each day at 11 a.m., and will sit till 1.30, then adjourn till 2, and sit again till 5 p.m. The proceedings will be opened on Thursday, at 11, by the chairman. The papers and discussions will be arranged under the following heads:—1. Sources of Supply. 2. Quality of Water; Filtration and Softening. 3. Methods of Distribution; Modes of giving Pressure; House Fittings; Discovery and Prevention of Waste, &c. The proceedings will be continued on Friday, and if necessary on Saturday.

#### NEW METHOD OF TESTING CEMENT.

In an article contributed to the *Tiöpler und Ziegler Zeitung*, Dr. Michaelis calls attention to certain inconveniences attending the existing modes of testing cement, and suggests practicable remedies. According to his remarks, all parts of a cement which have not been reduced during the operation of grinding to a great degree of fineness, do not exercise any action during hardening, but really act in the same manner as sand. In fact, the residue on a sieve of 5,000 meshes per square centimetre (15 square inch), and even a portion of what passes through, has no cementing force. It would be interesting to know the degree of maximum fineness which a grain of cement should have in order to set, but, unfortunately, it has not been found possible to construct sieves of more than 5,000 meshes per square centimetre, and other processes for arriving at the fineness of powders do not seem to have entered the domain of actual practice.

It may therefore be said that in testing a cement the operation is performed upon a mixture of cementing substance and of inert substance. On the other hand, it is known that it is not the finest cement which, in the form of blocks of pure cement, displays the greatest resistance, but a cement with 60 to 70 per cent. of residue when tested with a sieve of 900 meshes per square centimetre, while in mortar trials the resistance with the same cement is in proportion to the fineness. It is this divergence which has induced German, Austrian, Russian, and Swiss engineers, to adopt the mortar test as most nearly corresponding with practical constructive requirements. This form of trial is, however, attended with difficulties, resulting from the use of sand, which is expensive and difficult to prepare, and from the length of the period of trial, which should not be less than a month. Under those circumstances it is argued that the trial should only extend to the really active portion in the pure cement,—that is, to the portion which passes through a sieve of 5,000 meshes per square centimetre.

Dr. Michaelis proposes to keep portions of the trial blocks in boiling water so as to expedite the hardening, thus allowing of a judgment being more rapidly formed as to the final result. The test would take place as follows:—There are taken 100 parts by weight of cement, which has passed through a sieve of 5,000 meshes per square centimetre, and 20 to 25 parts of water are added. Every five minutes two small blocks are made which are pressed into the moulds in the same way as the mortar blocks of one part of cement to three of sand. In this manner twelve to twenty-four blocks are made (section  $\frac{7}{16}$  of a square inch) according to whether one or two series of trials are to be carried out. They are kept during the first day in an atmosphere saturated with steam, and at a temperature of about 59° Fahrenheit. After twenty-four hours six or twelve blocks are plunged into water of about the same temperature, while the rest are placed in a vessel kept at boiling-point. After twenty-three hours, part of the blocks are removed from the latter, and are plunged for an hour into water at 59°, after which the test by drawing is applied to them as well as to a certain number of the slabs kept in the water of moderate temperature. The latter would give an initial resistance after having set, while the former would have a resistance about equal to that of the same cement after seven days. Finally, the remaining blocks are kept in boiling water, and in ordinary water during six days, at the end of which they are tested by the drawing test. Those which have been six days in boiling water have a resistance which nearly approaches that of the final hardening.

The value of the cement would, therefore, be determined according to the fineness of the grinding and the tests for drawing, within less than a week. The hardening in boiling water could only be supported by cements without any defects, all those in which the mixture is not homogeneous falling into pieces after a few hours. On the other hand, those cements which have resisted this test may be employed without fear that any inconveniences may result from their use. In this way a new and valuable indication is arrived at of the value of cements, the principle being that none can be considered first-class products, except those which not only stand the test of boiling, but also become rapidly hardened during that

process. The blocks made with the most powdery portion of the cement being liable to be injured by the appliances used in the drawing test, it is suggested to place a small piece of leather or indiarubber between the cement and the metal.

The new system of tests is thus based upon two methods, which have not as yet been adopted:—1. The employment, for blocks to be tested, of only the active part of the cement,—that is, of the part which passes through a sieve with 5,000 meshes per square centimetre (15 square inch). 2. The obtaining of a rapid hardening by keeping the blocks in boiling water; the final resistance being thus ascertained at the end of a week.

In reproducing the above details, the *Journal du Céramiste et du Chauffeur* remarks that the first-named method will not probably meet with general concurrence and adoption, by reason of the somewhat arbitrary nature of its fundamental principle. The sieve referred to has been chosen because it is the finest to be found, and the radical division of the cement into two parts (cementing and inert) is not considered as being in accordance with reality, for, in considering grains of cement of greater and greater fineness, it is clear that the cementing force (which is at first nil) increases until a maximum is attained, without it being possible to exactly determine the transition. Besides, doubts are expressed as to whether the physical or chemical quality of the portion remaining on the sieve should be absolutely without any influence upon the resistance.

On the other hand, it is admitted as probable that the acceleration of hardening induced by the operation of boiling, and the new indications which this process affords as to the quality of cement, may prove of material utility where it is desirable to economise time in making trials.

#### FIRE PROTECTION OF MANSIONS.

We gladly avail ourselves of the opportunity which the publication of a little work with the above title\* furnishes us of calling attention to the necessity of protecting country mansions against a danger to which they are especially exposed. The time of year is approaching when the "family" will return to their ancestral homes for a short season, and the cleaning process will be gone through. The plumber will be there, and the usual risks will be run with the too frequent result. Every one must remember some charming old mansion,—the delight of his sketching days—which is now a heap of blackened ruins, or has a grim place to a modern substitute which has none of the charms of its predecessor. It is grievous to call to mind the long list of historic houses which have in recent years been wholly or partially destroyed by fire. Belvoir Castle, Wynnstay, Warwick Castle, Hatfield House, Fryston Hall, Duncombe Park, Ingestre Hall, Blenheim Palace, Clmher, Wrotham, Sperr, Liandydroc, and many others can be counted up, all of them more or less full of priceless art-treasures which can never be replaced. "Insurance" is no security against such losses as these, which are incalculable and irreparable. And our vexation is intensified by the reflection that all or nearly all might have been saved by ordinary care and precaution.

What the necessary precautions which will insure safety are, and how they should be employed, Mr. Merryweather explains clearly and succinctly in the work before us, the result of practical training and a long experience.

The prime necessity is, of course, the provision of an ample and accessible water-supply. The many uses to which this can ordinarily be turned reduces the expensiveness of the provision; for, "apart from ordinary domestic duties, it can work coal, luggage, or passenger lifts; turn the spit in the kitchen, the lathe in the workshop, and hlow the organ." Valuable calculations as to the quantity to be provided are given, and wise cautions against wasting the power of the fire-engine in overcoming unnecessary friction in the hose by drawing water from a distant source, instead of from a special reservoir at hand.

Instances are given of mansions where all that science can suggest has been done for their protection from fire, and one ominous case in which an undue delay in considering the matter resulted in the loss of the house and its contents. The new house of the Empress of

\* Fire Protection of Mansions, by James Compton Merryweather, M.I.M.E. London: Merritt & Hatcher.

the French is apparently a model in this respect; no precaution has been overlooked, and the author adds, with the touch of a true artist in his craft, "the fire-buckets are beautifully emblazoned with the Imperial crown." As the work was carried out under the advice of Mr. Merryweather, we may just ask why the rubber-lined canvas hose, which he does not recommend, and which will only last five or six years, was used in place of the leather hose, which he does recommend, and which will last twenty years? We hope the difference in cost was not spent in emblazoning the fire-buckets, which would, at a crisis, be a poor compensation for a leaky hose.

It is soothing to learn that Hampton Court Palace is now, humanly speaking, proof against an outbreak of fire; and we must leave the Office of Works to settle with the author for his statement that the handsome new fire-engine house is "more or less" in keeping with the old buildings.

The remarks on saving life in case of fire should be read by all, though we fear that in an emergency few would be likely to remember them. An outbreak of fire, the author truly says, is generally accompanied by an outbreak of temporary insanity, and it is rarely that the frightened inmates can be prevailed upon to be "calm and avoid confusion and noise." Still, what it were well to do under the circumstances may, if once learned, recur to the mind at the right moment, and few are so well qualified to advise as the writer of the book before us.

We commend it with a clear conscience to all whom it may concern, and in one way or another it concerns us all. It is a pleasure in this age of silly "high-falutin'" publications to meet with a plain account of a practical matter unaffectedly written by a man who really understands what he writes about; and such is Mr. Merryweather's "Fire Protection of Mansions." *Verbum sap.*

THE TURNERS' COMPANY.

The Worshipful Company of Turners propose to give this year their silver medal, with the Freedom of the Company, to any workman, whether master, journeyman, or apprentice in the trade, in the United Kingdom, who may send in the best specimen of hand turning in wood, pottery, and precious stones. The competition in wood includes turning in both hard and soft wood. The qualities which will be considered in awarding the prizes will be the following, viz.—1. Beauty of design, symmetry of shape, utility, and general excellence of workmanship. 2. Exact copying, so that two objects produced (such as two cups, vases, boxes, or other articles) may be facsimiles in every part, or exact measures of capacity. 3. Finess of the work and design for the purpose proposed (for instance, turned wood for portions of domestic or church furniture). 4. Ability to turn, whether circular or oval, in both classes of wood. 5. Novelty in application of turning, or in design. 6. Carving and polishing are admissible, and if skilfully done, any additional effect produced will be considered, but it must be subsidiary to the turning. The work must be all hand-turning, produced in the lathe without special rest or tool apparatus, and the carving must be the work of the exhibitor. The competition in pottery includes terra-cotta, stoneware, earthenware, and porcelain. In this competition a bronze medal will be given to the competitor second in merit in each class, also certificates of merit and money prizes will be awarded according to the discretion of the judges. In the competitions for works in precious stones, and for engraving in intaglio and cameo, specimens will be divided into classes as follows, according to the material and the character of the work. Class A. Ruby, sapphire, emerald, and spinel. Class B. Topaz, aquamarine, crysolite, jargon, amethyst, rock crystal, garnet, peridot. Class C. Cabochon work of all kinds in regular or fancy shapes, including coral cut for mounting carved garnets, turquoise, onyx, &c. Class D. Diamonds, brilliants, and roses. Class E. Intaglio and cameo. In each class a medal will be given if the specimens entered are considered worthy; the chief medal and freedom or medals will be adjudged to those candidates who, in the opinion of the judges, show the highest excellence of workmanship, combined with the most general ability in the other branches of their trade. In making their award, the qualities that will be chiefly considered by the judges will be (1)

symmetry of form and proportion, (2) brilliancy of polish, and accuracy in the finish of facets; (3) form and relative proportion of facets, perfectness of edge; (4) skill in overcoming difficulties inherent to the material; (5) judgment displayed in choice of style and arrangement of facets, so as to hide natural defects in the stone, and still produce its maximum beauty; (6) in Class C, particular attention will be paid to the design shown in shape and arrangement of series of stones to form particular ornaments. Further particulars may be had on application to Mr. Edgar Sydney, hon. sec. to the Competition Committee, 4, Hare-court, Temple.

CAN THE NEW GOVERNMENT OFFICES BE DURABLE?

Sir,—I have read with attention Mr. H. Travis's letter on this subject in the *Builder* of the 5th inst., p. 9, and would recommend to consideration the use of Belgian granite for the new Government Offices as referred to by Mr. Gough in the *Builder* of the 9th of February. This material can be delivered in London, ready worked, prepared for fixing at 70 to 75 per cent. cheaper than Aberdeen granite. The new Palace of Justice at Brussels will satisfy any one as to the good work which can be executed in Belgian granite, and it has been introduced into this country in the new premises for the Capital and Counties Bank at Bristol, where it was delivered ready for fixing at a price of only 15 per cent. above that of the Bath stone quarried in the neighbourhood.

I think this stone deserves the careful attention of those who may be called on to decide the question of the material to be used for the New Offices, as it possesses many qualities calculated to commend itself to their favourable consideration.

AD. TAGNON.

DUST-CARTS, HOGS'-WASH CARTS, &c.

Sir,—My walk to business is usually through some streets at the West End in which are many superior hotels and lodgings, besides business premises, and it is always possible to know when the country people are in town by the activity of these carts. Of course they attend in the morning from about eight or earlier till ten or later, and during these hours the visitors are not always awake or looking about, but they must surely be susceptible of smell, and perhaps they accept it as natural to London. These quarters ought to be the models of nicety, but any one who chuses to try it may soon find more than he would expect in so respectable a parish as St. George, Hanover-square. If the cholera should come, something better should be arranged for disposal of refuse long before it gets so foul.

H. C.

CHIMNEY CONSTRUCTION.

Sir,—Will you kindly allow me to ask if any of your readers can oblige with the names of works where the following tall stacks are erected, viz.; Warrington, 440 ft. high; Wigan, 420 ft. high; Manchester, 410 ft. high. R. M. BANGROFF.  
No. 3, Elm Park-road, Finchley, N.

SPITALFIELDS MARKET.

HORNER T. THE WHITECHAPEL BOARD OF WORKS.

THIS case, which is of considerable interest to public bodies, was tried in the Chancery Division, before Vice-Chancellor Sir James Bacon.

Sir H. Giffard, Q.C., M.P., Mr. Crossley, Q.C., and Mr. Vernon Smith, appeared for the plaintiff, who asked for an injunction to restrain the defendants from placing posts or other obstructions in the four roads, north, east, south, and west, leading into Spitalfields Market.

Mr. Henry Lovegrove, surveyor, produced plans of the property, and gave evidence for the plaintiff, while Mr. W. La Riviere, surveyor to the White-chapel Board, gave evidence of the intentions of the committee. Mr. Longmore prepared a model of the streets. Mr. Finlay, Q.C., conducted the defence.

The Vice-Chancellor ruled that the special rights of the plaintiff as lessee of the market exempted him from the operation of the various Acts relating to streets and pavements, and gave judgment for the plaintiff, with costs, granting the injunction prayed for.

**Obituary.**—We regret to announce the death of Mr. Charles Marriner, A.R.I.B.A., which took place on the 16th inst., at Francis-street, Bedford-square. Mr. Marriner was for some years the valued friend and managing assistant of Messrs. H. Saxon Snell & Son. He was twenty-six years of age.

CHURCH BUILDING NEWS.

**Manaccan (Cornwall).**—A special effort is about to be made to raise funds for the restoration of the interesting old church of Manaccan, and it is proposed to hold a bazaar for this purpose on the 25th inst. This ancient church, to which considerable interest attaches, is sadly in need of restoration. As its name, Manaccan or Minster, denotes, there was doubtless once a monastery or abbey here. Later on it was connected with Glasney College, Penryn. In the latter part of the last century Richard Polwhele, the historian of Cornwall, was the vicar. The south door of the church is one of the best specimens of Early Norman architecture in the county of Cornwall. The belfry and bells, like the rest of the sacred edifice, are in a wretched condition, and the whole requires thorough renovation, which it is thought will take about 1,200*l.* to complete.

**Brawdy (Pembrokeshire).**—The church here, which for a country parish is one of the largest in the county, and lies off the high road between Haverfordwest and St. David's, was re-opened on the 10th inst. by the Dean of St. David's after the first instalment of the restoration had been effected by Mr. E. Giles, of Carmarthen, under the supervision of the architect, Mr. E. H. Lingin Barker, of Hereford. The work consists of new windows, gable crosses, trenches round building, drainage and ventilation, open pitch-pine seats and stalls on wooden platforms, encaustic tile floors in chancel and sacristarium, with similar bordering to the stone flagging in passages, repairs to roofs and walls, and the provision of a vestry.

ROMAN CATHOLIC CHURCH-BUILDING NEWS.

**Windermere.**—The Roman Catholic Church of St. Hubert, built at Windermere, was opened on the 24th ult. The church is designed in an early type of Gothic architecture, having nave, 42 ft. by 21 ft., sanctuary, 21 ft. by 18 ft., with sacristy, &c., on the south side. A north transept is to be added as funds permit. The roof to nave is formed with dressed pitch-pine rafters, framed in a pentagonal form; that to the sanctuary is barrel-vaulted in wood. The floors of the aisles and sanctuary are laid with Walker's wood-paving. The church will be seated with chairs supplied by Messrs. Jones & Willis. The walls are built of the local slate, with freestone dressings from Hexham. The west end is lighted by a triplet window, the lights being of equal height; and an octagonal spirelet rises from the south-west angle of the building to a height of 70 ft. The entrance to the tower is from the north side, through a boldly-designed porch, and the east end of the sanctuary is lighted with a wheel window of a very pleasing outline. The whole of the windows are glazed with antique glass in lead quarries, from designs by the architect. The church is erected upon a beautiful site, overlooking the lake, and forms a very picturesque feature in the beautiful neighbourhood. It has been built by local contractors from the designs and under the superintendance of Mr. Robert Walker, architect and surveyor, Kendal and Windermere.

**South Teddington.**—A new school-church for the Roman Catholic body was opened on the 25th ult. The building (according to the *Tablet*) is situated at the junction of Fairfax and Bushey Park roads, between Teddington and Hampton Wick stations. It is a solid parallelogram (55 ft. by 30 ft.) erection of white brick, having a bold and imposing facade, with stone facings, surmounted by a pediment and cross, and a square belfry of simple Italian character. It consists of two stories, the upper one being the temporary church, and reached from the porch by a stone staircase. It is lighted by eight windows glazed with tinted glass; there is a small organ-gallery over the entrance. The altar, raised on four steps, is of imitation marble, with the sacred heart in the centre. It has a stained open roof of low pitch. The architect is Mr. W. C. Monro, and the builder Mr. G. Constable.

**Salford.**—The Chapel of the Blessed Sacrament forms the south transept of the Roman Catholic cathedral at Salford. The decoration forms a special feature in this chapel: the roof is treated in white and vermilion, with medallions emblematic of the Blessed Sacrament, and golden coloured stars between. The decoration has been executed by Mr. J. Pippet, of the firm

of Messrs. Hardman & Co. All the marble and alabaster work by Mr. R. L. Boulton, of Cheltenham. Messrs. Southern & Son, of Salford, were the contractors for the woodwork. The wrought-iron work has been executed by Messrs. Hardman, Powell, & Co., of Birmingham. The whole has been designed and carried out under the direction of the architects, Messrs. Pugin & Pugin, of Westminster.

### Books.

"Bibliothèque de l'Enseignement des Beaux-Arts."  
Paris: A. Quantin, 7, Rue S. Benoit.

THIS series of elementary handbooks is issued under the patronage of the "Administration des Beaux-Arts," and has been crowned by the French Academy; to point out, therefore, the utility of its purpose and the excellence of its execution is almost superfluous. Since the appearance of the first volumes in 1853, a whole edition has already been exhausted; it is in the hopes that the series may circulate widely in England as in France that we note shortly the general outlines of the scheme. French educationalists have felt that, though the eight years of a course in a lycée may be devoted to the "humanities," on the subject of art education has been dumb. In every department of artistic and archaeological investigation French savants have been eagerly at work, but the result of their labours has been to the multitude, even to the educated many, a sealed book. In such department of study there was wanted a treatise, brief, clear, sound, simple, and above all cheap. It is in answer to this demand that the "Bibliothèque" before us is planned. When complete the series will comprise—1. Certain general volumes on the principles of art, e.g., "Aesthetics and the History of Art." Painting, sculpture, architecture, engraving, ornamentation, music. 2. Special volumes devoted to the history of particular branches and special periods, e.g., "Mythology in Art," Oriental archaeology, Egyptian archaeology, Byzantine art, numismatics, manuscripts, and miniatures, artistic anatomy, perspective, and a host of other kindred subjects. 3. A series of dictionaries of artists and art terms, guides to collectors, biographies of artists. 4. A series devoted to the discussion of special handicrafts bordering on arts such as ebonising, look-making, carriage-making. In fact, glancing down the prospectus of the series it is difficult to recall any subject of interest connected even remotely with art or handicrafts to which a volume is not devoted. The series will appeal as much to the intelligent workman as to the artist, the beginner in archaeology, and the general art-student.

Each volume is confided to a specialist of note. Such names as those of M. Chipiez, M. Collignon, M. Maspero, M. Marthia, M. Rayet, are sufficient guarantee of the quality of the work. Each volume is abundantly illustrated. In a series issued at the price of 3 francs per volume the illustrations are necessarily a weak point, but we may say at once that they are no worse than those current in books issued at five times the price. Fourteen of the series appeared in 1883, including "Archéologie Grecque," "Gravure," "Tapisserie," "Mosaïque," "Peinture Flamande." For 1884 are promised nineteen volumes, among them "L'Architecture," by M. Chipiez; "Bijoux et Joyaux," by M. Falize; "La Céramique," by M. Henri Havard; "L'Archéologie Etrusque et Romaine," by M. Marthia. This volume, the first to appear in 1884, now lies before us. In a series embracing so wide a field the execution of each individual volume must necessarily vary much. The volume before us is an excellent specimen of clear, popular, and, so far as is possible in an incomplete subject, complete treatment. To most of us the Etruscans are a people of vague, mysterious association. We have been, perhaps, to Bologna, and seen some odd bronze *reposed* work; to Volterra, and wandered through a museum of architects; to Florence, and, possibly, picked up some fragments of "*bucohera nova*," with queer Assyrian designs; to Corneto, and gone down deep into the earth, risking the perils of malaria to see terrible, painted demons on the walls of tombs that we know to be Etruscan. We carry away a general impression of grotesqueness, of coarse realism, but few of us would care to be questioned closely as to dates or processes. Some of us, who might know better, still talk of

the beautiful pottery that Greece has left us as "Etruscan" vases. The small volume before us will save us from much uncomfortable ignorance in future wanderings, and give us in outline all that is certainly known of "Lars Posreuna of Clusium" and his ancestors and his art tendencies. It tells us of the contents of "Terramare," those curious pre-historic mounds abounding in the basin of the Po; of the influence of Phœnicia and the early immigrants from Corinth; of the wonderful polygonal walls, the gates, and stone façades, many of which still remain to be the marvel of tourists. The Etruscans never seem to have advanced beyond the merest rudiments in sculpture in stone; terra-cotta and bronze were the materials they loved best, no doubt, because these materials most readily lent themselves to a certain photographic realism which always beset Etruscan art. The art of portraiture in bronze, the Etruscans probably taught to the Romans, an art eagerly affiliated by a people whose historical instinct was strong. The more ideal art of sculptured stone they must borrow later from the Greeks. All this interesting story of the fusion of art elements in Italy M. Marthia sets clearly before us, and then passes to the more familiar topic of the sculpture and architecture of Rome, carefully separating in each the indigenous from the foreign elements.

It is in such volumes as the present one on Etruria and Rome that the peculiar merit of the series is seen. Where the subject is obscure and such facts as are ascertained are recorded only in the monographs of the learned, the necessity for the middle man,—the populariser,—is doubled. If, as is the case with M. Marthia, he is both *savant* and populariser, his merit and the merit of the work is enhanced. Such a series is much needed in England, but in a country which trusts its art education much to private endeavour, little to State organisation, it can scarcely as yet be looked for. When it comes, we can only hope it may rival in excellence the existing volumes of the French issue.

*Handbook of Sanitary Information.* By ROGER S. TRACY, M.D. London: Trübner. This is a compilation, but it is a compilation by one who understands the subject dealt with, and which cannot fail to be useful to all into whose hands it may chance to fall.

Drainage matters are never safely conducted without the advice of experts, and the householder who should attempt to put his house in order under guidance of the wisest of handbooks only would probably do almost as much harm as good. But there are circumstances in which professional advice cannot be had, and then this little book would be a friend indeed. The chapter on disinfectants and their employment concerns every householder, and just now more than ordinarily. The chapter on foods is comforting, if its statement that the adulterations of trade are rarely deleterious may be relied upon. The book, as a whole, is clear and concise, and there is but little in it which is debatable. Exception may perhaps be taken by some to the statement that fresh air should enter a room at the ceiling, and the foul air leave it at the floor level; but if we can only persuade the fresh air to come in and the foul air to go out, we are not disposed to inquire too curiously into the "order of its going."

The handbook is an evidence of the increased attention which the Americans are giving to sanitary questions; not before it is time if other writers are to be believed.

*Drainage and Sewerage of Dwellings.* By WM. PAUL GERHARD. London: Trübner & Co. This is an American work, we are happy to say, and that it is of American and not of English houses that the author speaks when asserting that "Bath-rooms and water-closets are frequently located in the centre of a house with no other light but that from a window opening into the staircase hall." If, as the author says, it is not unusual to find water-closets and urinals in dark closets lighted only by a gas flame, with no outlet except into the hall or a bed-room, all we can say is that the appropriateness of his admirable treatise is beyond question. If the above be true, we can well believe that the "most remote, ill-lighted, and closely confined corner of the basement or cellar is selected for the servants' water-closet," and that it often proves the *post* of the house.

To awaken an apathetic public to the serious risks they run unnecessarily by their neglect of the securities of modern sanitary science, and

to enlighten them as to the easiest and most effectual remedies for the defects of American houses, is the object of the author. His book is avowedly a compilation from the works of other labourers in the same field; but it is compiled with judgment, brought down to the latest date, and copiously and clearly illustrated. We are glad to note the recommendation to dispense with the ordinary joinery about baths, sinks, and water-closet apparatus, limiting the wood-work about the latter to the seat; and we cordially endorse the extract he gives from "The House that Jill Built." "I don't believe," she says, "that there would be half the trouble with plumbing, either in the way of danger to health or from dishonest or ignorant work, if it had not been the custom to keep it as much as possible out of sight."

The book, like most American books, is well written, and the Americanisms which occur in it are piquant and expressive.

The labours of Dr. Simon and others, and the inventions of the late Mr. George Jennings, Mr. Hellyer, and other Englishmen are used and acknowledged by the writer, whose work on an increasingly important subject may be consulted with profit by all engaged in sanitary matters.

### The Student's Column.

HINTS FOR THE STUDY OF THE HISTORY OF ARCHITECTURE.—III.

HAVING disposed of the insulated styles of architecture, we now approach those recognised sources from which all the other styles throughout the known world are said to be derived. Before following the threads from the beginning onwards through the web, and treating the subject *synthetically*, it may be well to reverse the process and treat it *analytically*, in order to know what we are going to talk about.

Thus, the architecture of the present day, taken as a whole, is a general jumble of all the styles that have existed, the threads having sometimes got into an inextricable knot, owing perhaps to the use of various architectural sewing machines, purchased for the purpose of saving honest hand and brain work, but betraying their users into unexpected complications. Here and there, honest efforts are being made to lay in fresh threads, starting from some way back so as to derive strength from their neighbours, and with the full intention of leaving their individual mark on the web. But it is not so very long since dabs of colour, closely imitating those of certain former periods, were handily sewn down upon and proudly exhibited as part of the pattern. It will, therefore, save confusion to go back until we find the pattern running more evenly, let us say to the sixteenth century, in Europe. Here we shall find some of those elements generally known as "Classic" not unpleasantly mixed with others known as "Gothic." We shall observe that the Classic threads have joined the rest from a side direction starting ever so far back, while the Gothic threads have gradually acquired their colour and texture from Romanesque threads with perhaps a tinge from Byzantine ones. These two find their source, some in a straight line and others in a detour by the East, from Rome, and here we shall pick up that thread that added its colour to the sixteenth century. From Rome the threads may be traced back to Greece, and from Greece to Egypt and Assyria.

EGYPT AND ASSYRIA.

It is difficult to say Egypt from Assyria or Assyria from Egypt. It takes at least two threads to start a web (other than a spider's web), and the only question is, which is the older thread of the two? This is too serious a subject to tackle lightly, so we will take refuge behind Fergusson, and begin, as he does, with those West Asiatic styles which include Chaldean, Assyrian, Babylonian, and Persian architecture. We shall thus also be in harmony with the Bible record, which places the cradle of the human race in their locality, namely, in Mesopotamia, or the country,—as its name implies,—between the rivers Tigris and Euphrates. This is merely the central portion of an extensive area to which Fergusson, on page 161 of his Handbook, allots the architectural section which he calls Assyrian. He says that the three typical races of mankind, the Tartar, the Semitic, and the Aryan, are found living together in the Valley of the Euphrates, but

bat the architecture of Assyria was that of a Semitic people, and especially interesting as exhibiting actual examples of that style with which we have long been familiar from the descriptions in the Bible of the buildings of Solomon. Other references for study of this West Asiatic architecture are as follows:—Fergusson's "History of Architecture," vol. i. p. 130; Smith and Slater's "Classic Architecture," p. 43; Gwilt's "Encyclopædia," p. 15; Ramée's "Histoire Générale de l'Architecture," vol. i. p. 273; Rosengarten's "Handbook of Architectural Styles," p. 37; Viollet-le-Duc's "Habitations of Man in all Ages," p. 135; Viollet-le-Duc's "Lectures on Architecture," vol. ii. p. 173; Gaillhard's "Monuments Anciens et Modernes," vol. i., plates 43 et seq. There are valuable works, especially on this subject; notably Layard's "Nineveh," two vols. Svo., published in 1850, and Layard's "Nineveh and Babylon," one vol. Svo., published in 1853; and the Institute Library also contains the very fine work, Place's "Ninive et l'Assyrie," three vols. fol., published from 1867 to 1870. There is also an interesting article in the *Builder*, of Oct. 15th, 1881, on "The Recent Discoveries in Chaldaea."

But the subject can be studied in a more tangible form at the British Museum, which contains a large collection of the actual sculptures brought from Assyria, which were discovered by Layard, and are described in his works. These sculptures are all bas-reliefs carved on huge slabs of stone,—Fergusson, in one instance, calls them of alabaster,—which clothed the lower portions of the walls of certain magnificent palaces built on mounds overlooking the river. With the exception of these slabs, the structures appear to have been of a perishable nature, that is to say, that the upper story consisted of wooden posts supporting flat roofs of earth, made enormously thick to keep out the heat of the sun; that such posts were an easy prey to fire, and that the consequent fall of the roof would bury the sculptured slabs. Moreover, the walls behind the slabs were composed of mere sun-dried bricks, and being thus exposed, would soon crumble away again, so that in a very short time an enormous palace would become a grass-grown heap, and a tempting site for villages to be built on its breezy height.

This very concealment of the ruins has, however, led to their preservation in as perfect a state as at the time of their erection, about 2,000 years ago, or even more, the earliest described by Fergusson being from the north-west palace at Nimrod, about 900 B.C., of which he says the sculptures exceed in beauty those of the later palaces at Khorsabad and Koyunjik, built in the eighth century B.C. In Smith and Slater's "Classic Architecture," p. 43, will be found a complete plan of the palace at Khorsabad, from which the great winged bulls now in the British Museum were taken. The student will not fail to notice the *five* legs with which these bulls are provided. The Assyrians were accustomed to sculpture in relief, seen from one direction only, and not in the round, and therefore felt that both the front and side "elevation" of these animals should each appear with its proper number of legs. The bas-reliefs from the palace of Koyunjik, arranged in the basement at the British Museum, and representing lion-hunts, exhibit a very high order of art, and may be taken as models (as they were by the late William Burgess) for the proper treatment of sculpture in low relief. In Redford's "Manual of Sculpture," p. 105, it is remarked that "neither in Assyrian nor Persepolitan sculptures is the female figure to be found, and that thus we can readily see how it happened that the Assyrians never had any high ideal such as distinguishes the art of the Egyptians and Greeks." A statement nearly but not quite correct.

Botta, the French Consul at Mosul, is credited with the discovery of Assyrian sculpture, but his book on the subject is not in the Institute Library. Place's work, however, is to be found there, and is most interesting on account of the arrangement of the plates, namely, with an illustration of the actual state of the ruins at the bottom of the page, and above it, a conjectural restoration of its former state. Here the semi-circular arch is frequently shown, and its existence is borne out by some original bronze gates of Shalmaneser II., dated 859 B.C., to be found in the British Museum, on which a town gateway is represented with two semi-circular headed openings.

Before leaving the subject of Nineveh, it should be remarked that the Egyptians are said to have overrun Assyria from the nineteenth to the fourteenth century B.C., and Fergusson says they have left no monuments in the subject land. There are, however, some ivory carvings, in the Nimrod Gallery at the British Museum, from the north-west palace, which bear a strong resemblance to Egyptian work. On the destruction of Nineveh, says Fergusson, Babylon rose from its ruins with renewed splendour during the reign of Nebuchadnezzar, whose name is found impressed on every brick of the buildings, including the remarkable Birs Nimrod, a pyramidal structure surmounted by a temple, somewhat in the manner of the Mexican buildings, but square in plan, whereas they are oblong. "From Babylon we pass to Passargade, which was adorned by Cyrus and Cambyses between the years 560 and 523 B.C., and thence to the far more magnificent capitals of Darius and Xerxes, who have left on the platform of Persepolis remains of architectural magnificence unrivalled in the country, and which may be considered as the culminating form of the earlier architecture of the Assyrians and Babylonians."

Now, it is chiefly to Persopolis, in Persia, that we must look for the source of one of the features of Greek architecture, namely, the *voluted capital*. Here we find it in connexion with a column, which is also a feature not actually found in earlier Assyrian examples, though it is represented in their sculpture. In those sculptures the volute is laid horizontally, whereas on the actual Persian columns it is placed up on end. There has been more discussion about the origin of the volute than about almost any other decorative feature of columnar architecture. We have seen it in Indian stonework, evidently copied from wooden construction; and Viollet-le-Duc, in his "Habitations of Man in all Ages," considers it the natural way of ornamenting the ends of a wooden cross beam. The spiral is a form frequently found in nature, and anyone with a taste for lightness and grace would, almost involuntarily, trace such a curve on any object he wished to ornament. Look at the bas-relief of the little fishing pavilion from Khorsabad on p. 179 of Fergusson's Handbook, and the curling waves of the water, with which the voluted capitals harmonise; or look again at the wonderful curly locks of the Assyrian men and bulls at the British Museum. The fingers of their sculptors must have been always "on the curl."

Another origin of the volute is attributed by Skidmore to the spiral treatment of metal work.

Why, then, do we find no actual Assyrian stone columns with voluted capitals until we come to the date of Persepolis? Probably because the only columns used at Nineveh were, as above mentioned, of wood, for supporting the superstructure, and have, therefore, perished; while at Persepolis they are of stone, and have survived. These columns are closely fluted, and stand on a base,—two points which must be borne in mind when the Greek Ionic order is considered. Indeed, this word "Ionic," so far as it means Asian or Eastern, is more or less connected with Assyrian art. With which hint, and a passing allusion to the Lycian tombs in Asia Minor, closely imitated from wooden construction, and of which we have a splendid example in the British Museum, we must pass on to the other main source of Greek and subsequent architecture, namely, Egypt.

So far as the antiquity of existing buildings is concerned, Egyptian architecture is said to surpass all others. Egyptian chronology is too large a subject even for Fergusson to enter into, as he points out on p. 214 of his "Handbook of Architecture," that the actual differences between the best authorities, for the date of the Great Pyramid is no less than 2,400 years. All seem agreed, however, that the Pyramids of Gizeh, in the neighbourhood of Memphis, not far from the modern Cairo, and therefore near the mouth or lower part of the Nile, are the oldest buildings in Egypt. Moreover, these Pyramids, of which there are a great number, and all, apparently, royal sepulchres, are on the western or left bank of the Nile. The appearance of them is too well known to need description, but an idea of the size of the largest may be obtained by comparing its area with that of Lincoln's-inn Fields. They are entered from the north side by a passage sloping downwards, from which it may have been intended to watch

the polar star. But this is a mere speculation.

Besides the various handbooks that have been referred to, and in which Egyptian adjoins the chapter on Assyrian architecture, there are a great number of special books on Egyptian art. The library of the Institute possesses a copy of Lepsius, twelve huge folio volumes, some of which should certainly be studied, while the latter ones are more especially devoted to the painting, sculpture, and hieroglyphics of this wonderful nation (observe the difference between the latter and those of Mexico). Other works in the Institute Library are:—Lesuer's "Chronologie des Rois d'Egypte," 1 vol. quarto; Brugsch's "Egypt under the Pharaohs," (no architectural plates), 1873, 2 vols. Svo.; Belzoni's "Narrative of Operations," 1821; G. Long's "Egyptian Antiquities in the British Museum"; Col. Vyse's "Pyramids of Gizeh," 3 vols. royal quarto; Sir Gardiner Wilkinson's "Topography of Thebes," 1835, Svo.; Sir Gardiner Wilkinson's "Architecture of Ancient Egypt," 1850, text oct. and plates fol.; Sir Gardiner Wilkinson's "Egyptians under the Pharaohs," 1857, 1 vol. Svo. (This is a popular work, written as a guide to the Egyptian Court at the Crystal Palace. There is also Jones & Bonomi's "Guide to the Crystal Palace Courts.") Hoskin's "Travels in Ethiopia," 1835, 1 vol. quarto; Mariette Bey's "Monuments of Upper Egypt"; Wither's "Arts and Antiquities of Egypt," 1843, 1 vol. Svo.; Frith's "Egypt and Palestine," photographed and described, 1858, fol.; Arundel and Bonomi's "Gallery of Antiquities," treating of Iconography; Prisse d'Avenne's "Antiquités Égyptiennes du Musée Britannique," 1846; and there may be other works added since the above were consulted, so there is no lack of means to study the subject.

We have mentioned the Pyramids in reference to the antiquity of Egyptian buildings; there is not, however, much about them that can be called architecture, and we are more interested to arrive at some feature in which a source of Greek architecture can be recognised. Such examples occur in very early times, as far back as what is known as the Twelfth Dynasty, and in the form of columns supporting the entrances to a series of tombs cut out of the vertical face of the rock at Beni-Hassan. At first, such supports were square piers, then octagons, then sixteen-sided, and so on, as has been described in the case of columns in the Indian rock-cut temples, but with this difference, that whereas the Indian examples have all the changes of form exhibited in one column, the Egyptian ones are either square, octagonal, or sixteen-sided, &c., from bottom to top. Moreover, these sides (with the exception of one left for hieroglyphics) were sometimes hollowed or fluted, and in some instances the columns taper from bottom to top, and are surmounted by a flat slab of stone to help them in carrying the weight of the architrave over them. The result is a striking similarity to a Greek Doric column, but that there is a base which the Greek example lacks, and that the "cecinus" is lacking which the Greek examples always have. This is a cushion, as it were, interposed to soften the abrupt change of form between the circular column and the square surmounting slab or abacus.

In John Pennethorne's "Geometry and Optics of Ancient Architecture," which will be referred to in the next article, there is given, on page 113, illustrating the southern temple at Karnac, an Egyptian capital with the cecinus, and if this rare example actually was seen by a Greek, the origin of the Greek Doric column would be entirely settled.

The limits of this article permit no more than a passing allusion to the magnificent Egyptian temples (as distinguished from the Assyrian palaces), with their various orders of peculiarly Egyptian columns, their massive propylons with a roll up each of their sloping sides (which roll is by some thought to be derived from a bundle of reeds tied together, and which sloping sides are by Freeman referred to the natural slope of a rock), their obelisks, their colossal figures, their hieroglyphics, painting, and bas-relief sculpture showing the most wonderful power to conventionalise natural objects that the world has ever seen. We know from the Bible, Acts vii. 22, that "Moses was learned in all the wisdom of the Egyptians," and we may infer that there was a good deal for him to learn.

For actual examples of Egyptian architecture, the British Museum may be visited with much profit. There is a complete "lotus

buld" column, and there is a separate bell-shaped capital. There is also in a glass case an original model of an Egyptian house, which is especially interesting on account of the masonry joints being represented to sag from the four corners, bearing out a theory of Viollet-le-Duc's, in his "Habitations of Man," and corresponding with the masonry of the Japanese walls before mentioned.

#### BUILDING PATENT RECORD.\*

##### APPLICATIONS FOR LETTERS PATENT.

July 4, 1884.—9,744, T. Telford, Newcastle-on-Tyne, Chimney Tops.—9,747, W. Kennedy, Glasgow, Translucent Plates for use as a Substitute for Glass in Roof Lights, &c.—9,770, J. H. Johnson, London, Stop Attachment for limiting the Movement of Doors, &c. Com. by MM. Varielô & Cie and MM. F. Moulin, Paris.

July 5.—9,781, W. Pearenside, Liverpool, and R. Baynes, Liscard, Automatic Disinfecting and Deodorising Process.

July 7.—9,850, J. B. Coleman, London, Cooking Ranges.—9,857, F. Cuntz, Karlsbad, Austria, Intermittent Flushing Apparatus.

July 8.—9,877, A. Downing, Birmingham, Case-stay Fastening.—9,885, D. E. Langham, Wimbledon, Venetian Blinds.—9,886, T. W. Howell, Brighton, Fixing and Supporting Sheets of Glass for Covering Greenhouses, Railway Stations, &c.—9,887, H. M. Smith, London, Coating or Surfacing Bricks and Tiles.—9,888, L. E. A. E. D. de Liebhaber, London, Colouring Stones for Building purposes, &c.—9,894, E. Whitehouse, Birmingham, Blind-coat Pulley.—9,926, W. H. Lake, London, Bridge-piers, &c. Com. by A. Cottran, Naples.

July 9.—9,930, W. Finch, Burnham, Roofing Tiles.—9,954, A. B. Milne, Birmingham, Opening and Closing Fanlights, Skylights, Ventilators, &c.—9,955, C. H. Holmes, Derby, Manufacture of Houses.

July 10.—10,014, H. K. Bromhead, Glasgow, Wind-guard or Chimney-top.—10,018, H. Saunders, Brighton, Pavements or Coverings for Streets, Floors, &c., in Wooden Blocks.

##### SPECIFICATIONS ACCEPTED.†

July 8.—11, W. J. B. Graham, Charlton, Fire-resisting Compound.—5,014, A. J. Boulton, London, Venetian Blinds. Com. by J. Querre, Toulouse.—7,261, J. F. Wiles, Old Charlton, Fire-lighter.

July 11.—2,614, J. Donkin, Bournemouth, Combining Earth and Water Closets.—5,811, W. Devoll, Ercington, Double Siphons for flushing Water-closets.—6,727, G. Clutterbuck, London, Water-waste Preventer.—7,342, C. Toope, London, Protecting the Joists of Buildings from Fire.—7,672, J. W. Brown, Leamington, Cooking-ranges.—7,730, A. B. Brady, Maldon, Combined Sower Ventilator and Manhole Cover, &c.

##### ABRIDGMENTS OF SPECIFICATIONS

Published during the week ending July 12, 1884.

5,432, A. Hildesheimer, London, Fire-screens, &c. (Nov. 17, 1883, price 4d.)

A light frame is made in the form of an ezel, and across each side of the frame is stretched a sheet of galvanized or sheet-metal ornamented as required, and supports are placed across the frame where necessary, whereby a series of hollow chambers are formed inside the frame.

5,525, H. Hancock, London, Fastenings for Doors and Windows, &c. (Nov. 26, '83, 6d.)

The handle is placed in the centre of the door, and on the inner end of its spindle is a piston, which gears into racks on the rods of the bolts in such a manner that by turning the handle all the bolts are simultaneously shot out or retired into the edges of the door. These bolts are preferably placed on the top and bottom edges, and on the side edges of the door.

5,616, G. Hand-Smith, London, Production of Colours, Marks, or Designs in Marble, Wood, &c. (Dec. 3, '83, 8d.)

This is an improvement on the patent granted on the 29th of September, 1877, in subjecting the articles, which they have been marked or coloured as required to dry heat in a closed chamber first, and then afterwards admitting the vapour at a temperature of 200° Fahr. When the articles are treated sufficiently the heat is then gradually lowered.

5,621, G. W. von Nawrocki, Berlin, Wood Pavement. Com. by R. Albrecht, Tilsit, Germany. (Dec. 3, '83, 2d.)

To dispense with the usual concrete foundation, and yet to keep the blocks level notwithstanding the traffic thereon, strips of metal are passed through grooves made in the two adjacent side faces of the blocks whereby the several rows are locked together. (Pro. Pro.)

5,659, W. P. Thompson, Liverpool, Seal-traps for Wash-basins, &c. Com. by A. Edwards, Asbury Park, U.S.A. (Dec. 6, '83, 6d.)

These seal-traps are formed of iron, and the mercury by which the seal is effected is held in a small separate cap, which is screwed on over the trap. As the iron in which the mercury is held is in its plain state, the oxide of mercury is formed in the trap, which entirely prevents the growth of all vegetable organisms. The induction and seal-pipes above the mercury are coated with porcelain.

\* Compiled by Hart & Co., Patent Agents, 186, Fleet-street.

† Open to public inspection for two months from the dates named.

#### Miscellanea.

**Cast-Iron Columns as Principal Supports.**—The employment of cast-iron columns as main supports has, we understand, been greatly restricted at Berlin by a regulation issued recently from the architect's department of the police authorities of that city, causing great consternation amongst builders. The cause of the new order is said to have been a discovery in connexion with a fire last winter in the Allee-Jakobstrasse, when it was found that the hot cast-iron columns had been cracked by the effect of the cold water jet playing upon them, so that the upper stories of the houses were as near collapsing as they could possibly be. The state of the buildings in the Leipzigerstrasse and other localities where shop property abounds has also contributed towards the issue of the regulation. It happens almost uniformly that the whole ground story, and frequently also the first-floor, forms one open space, above which are inhabited floors, which have besides a plan quite different from those beneath them, when, of course, no account is taken of the old principle of "pillar upon pillar." The dividing walls of the upper floors rest uniformly upon cast-iron columns, and the safety of the family inhabiting those floors depends entirely upon the soundness of those iron supports, which, as has been pointed out above, have proved to be unreliable in case of fire. The Berlin police authorities insist upon it that, where partition walls rest upon columns, the latter are either to be bricked-in or covered with a patent plastering in such a manner that an air-space remains between the iron and the brick or plastering. In many cases a brick pier or granite pillar is prescribed.—Iron.

**Madame Tressaud's Exhibition of Waxworks** has just been removed from Baker-street (where it has been located for fifty years) to a new and extensive building specially erected for it in Marylebone-road. The new building was designed by Mr. F. W. Hunt, architect and surveyor to the Portman Estate, and built by Mr. H. W. Williams. It is in red brick, having six large glass domes. It has a frontage of nearly 400 ft. and an average of 60 ft. depth. The style is modern Italian, and the staircase originally stood in Baron Grant's mansion at Kensington. It is entirely of white marble, and supported by caryatides, modelled from those in the Louvre. The walls of the staircase have been lined with marble and alabaster by Messrs. Burke & Co., and otherwise decorated by them in the Venetian style. The new building also supplied the mosaic pavement. The new building is almost immediately adjoining the Baker-street Station of the Metropolitan Railway.

**Mr. Bailey Denton.**—There is no one whose name is better known in English agriculture, though his own experience might well induce him to suppose that he was better known in foreign countries than at home. We are very much interested in hearing of the distinction which has come to him from the French Government, who have conferred on him their cross for "Mérite Agricole." Mr. Bailey Denton has a large share in the history of the greatest agricultural improvement of modern times,—the power given to tenants-for-life to charge their estates for agricultural improvements. Not only in the original agency by which this great legal change was carried, but in the actual work of improvement effected under it, there is no one who holds a more prominent place in recent agricultural history. And it is satisfactory to find that this is recognised, if not by the authorities at home, at any rate by the Governments of other countries.—*Agricultural Gazette.*

**Sanitary Institute of Great Britain.**—At the anniversary meeting, held at the Royal Institution, Albemarle-street, on Thursday, July 10th, the Right Hon. Earl Fortescue, Vice-president of the Institute, in the chair, an address (as elsewhere mentioned) was delivered by Dr. H. C. Bartlett, F.C.S., on "Some of the Present Aspects of Practical Sanitation," and the medals and certificates were presented to the successful exhibitors at the Exhibition held at Glasgow in September, 1883. At the close of the address, the Chairman proposed a vote of thanks to Dr. Bartlett, which was seconded by Mr. R. B. Grantham, M. Inst. C.E., and a vote of thanks to the Right Hon. Earl Fortescue for presiding was moved by Dr. A. Carpenter, and seconded by Prof. F. de Chaumont, M.D., F.R.S.

**Birkbeck Building Society.**—The thirty-third annual meeting of the Birkbeck Building Society was held on the 10th inst. in the Theatre, 29 and 30, Southampton-buildings, Chancery-lane. The report, adopted unanimously by the meeting, states that the receipts during the year ending 31st of March last amounted to 6,815,812s., making a total from the commencement of the Society of 77,379,431s. The deposits from members and others were 6,107,851s., and the payments on shares were 180,543s. The gross profits on the year were 134,113s., of which 112,414s. have been appropriated to the payment of interest to shareholders and depositors, and defraying expenses of management, leaving a net profit of 21,699s., making, with the balance brought from last year a sum of 106,869s. to be appropriated at the next division of profits. In addition to this, the Society possesses a reserve fund of 60,000s., the whole of which is invested in Consols. The balance-sheet shows a sum of 2,713,960s. of surplus funds, which are temporarily invested in Consols and other securities. The total liabilities of the Society are 3,179,083s. and the assets 3,345,951s., leaving a surplus of 166,867s. The proportion of convertible securities and cash to liabilities to depositors is stated to be upwards of 94 per cent. There are 43,706 shareholders and depositors, and the number of shares in existence is 38,964.

**The Rating of Nutfield Priory, Surrey.**—On the 8th inst. Mr. Lumley Smith, Q.C., with Mr. Muir, appeared at the Surrey Sessions to support an order of the Ragiate Union Assessment Committee that the poor-rate assessment of this mansion should be fixed at 750l. (gross) per annum, the sum set thereon by their valuer, Mr. Charles F. Jones, F.S.I., of Temple-chambers, Fleet-street. Mr. Grantham, Q.C., and Mr. Ernest Baggallay were counsel for the appellant. The Bench affirmed the order of the committee, and dismissed the case with costs. The professional gentlemen engaged were, for the appellant, Messrs. Tewson, Clutton, & Pym, and for the Committee Messrs. J. W. Penfold, Frederick Venables, William Wood, of Crawley, and John Lees, of Reigate, together with Mr. Jones.

**Trade Festivities.**—The employees of the firm of Oldis Bros., builders, of Finsbury-pavement and Wilson-street, Finsbury, celebrated their annual holiday on the 5th inst., at Caterham. Among the toasts that of the "Firm" was very cordially received. On the same day the employees of Mr. John Smeaton, sanitary engineer of Brighton and Ludgate-croft, held their annual banquet at Brighton. Mr. Smeaton, in a lengthy speech, especially addressed himself to the younger men in his employ, and gave them, as an old plumber, a few words of kindly advice. Mr. J. D. Moylan, manager of the Brighton branch; Mr. Alexander McKay, foreman of the plumbers; Mr. Smith, foreman of the brass finishers; and Mr. Broadbridge, were among the other speakers.

**Ashton-under-Lyne.**—On the 28th ult. the foundation-stone was laid of extensive new schools for Holy Trinity Parish, Ashton-under-Lyne. The schools are being erected by the trustees of the late Mr. George Heginbottom, J.P., and will complete a scheme of church, parsonage, and schools, the realisation of which the deceased gentleman had greatly at heart. The school has been designed to harmonise with the church and vicarage, being Early English in style, in red brickwork with stone dressings, enriched in places with ornamental bricks. There will be numerous classrooms and a large room above, and accommodation will be provided for 650 children. The architects are Messrs. John Eaton & Sons, Ashton, and the contractors Messrs. Storrs, Stalybridge.

**The London and North-Western Railway Company: Costly Extensions.**—The London and North-Western Railway Company are about to carry out very extensive new works at some of their metropolitan stations, and also at no fewer than fifty-two stations and other points on their lines in the provinces, for which they have just obtained Parliamentary powers authorising an expenditure of 1,000,000l. The intended new works in London include the enlargement of the Broad-street Station for increased accommodation to the goods traffic. Under the legislative powers which have been granted, the Euston-square Station is to be enlarged, the work involving the purchase of some property on the south-west side of the Company's main line; also property situated in Cardington-street and in Hampstead-road.

**The American Petroleum Industry.**—A retrospect of the past condition of the American petroleum industry, compared with its present state, discloses some interesting facts. The first American petroleum was exported in 1852. Charles Lockhart, of Pittsburg, sent nearly 600,000 gallons to Europe in that year, and sold it for 2,000 dols. less than the cost of transport. In 1883 nearly 400,000,000 gallons were exported, for which 60,000,000 dols. was returned to America. At the present day there are 20,000 producing oil wells in Pennsylvania, yielding 60,000 barrels of oil a day. It requires 5,000 miles of pipe-line and 1,600 iron tanks of an average capacity of 25,000 barrels each to transport and store the oil and surplus stocks. There are now nearly 38,000,000 barrels stored in the oil region tanks. Besides the 5,000 miles of pipe line in use in that region, there are in operation 1,200 miles of trunk pipe lines connecting the region with Cleveland, Pittsburg, Buffalo, and New York, and lines building to Philadelphia and Baltimore. In the line between Ohio and New York 16,000 barrels of oil are transported daily. These are all the property of the Standard Oil Company, except one between Bradford and Williamsport, Pennsylvania. The Standard employs 100,000 men. The product of its refineries requires the

making of 25,000 oak barrels, of forty gallons each, and 100,000 tin cans holding five gallons each, every day. The money actually invested in petroleum production since 1860 is estimated to be more than \$25,000,000 dols., of which 200,000,000 dols. was capital from New York city. Since 1880 more than 12,000,000 dols. has been used in building iron tanks, and nearly as much in pipe lines, all by one corporation. The tanks cost on an average 8,000 dols. each.—*Iron.*

**Camberwell.**—On Tuesday last new parish rooms, &c., in connexion with St. Bartholomew's Mission, Camberwell, were opened by the Bishop of Rochester. These rooms, which are built in connexion with the Bishop of Rochester's Ten Churches Fund, and will be used for services until the church of the new parish is built, are placed in the midst of a large and increasing population. They consist of upper and lower parish rooms, with class-rooms, kitchen, &c., all substantially built, and so arranged (the site being limited) as to form part of a group of buildings of which the church will be the principal one. The work has been carried out by Messrs. Lawrance & Sons, of Wharf-road, City-road, London, under the direction of the architect, Mr. Ravenscroft, of Reading.

**The State of the River Lea.**—The condition of the river Lea is causing great anxiety to the London sanitary authorities whose eastern boundaries it defines. At the last meeting of the Hackney District Board of Works, Dr. Tripe, the medical officer of health, made a statement regarding the dangerously impure state of the river. Mr. Gane said that from Lea Bridge-road to Tottenham the river was simply a common sewer, the stench being so intolerable that it was almost impossible to walk along the towing-path. Mr. Rintz, the local representative of the Metropolitan Board of Works, said the Lea Conservancy Board had no power to disinfect the river, and if they spent money on such an object the auditor would most probably surcharge them. It was resolved that a petition should be addressed to the Home Office and the Local Government Board "to save the neighbourhood from the consequences of the pollution of the river Lea." In the Poplar district the sanitary officials report to the Local Board that the Lea Cut is in an extremely offensive state, more particularly between Bromley and Old Ford locks. The Poplar District Board resolved to serve the Lea Conservancy Board with a summary notice to remedy the evils complained of.

# Supplement to The Builder,

JULY 19, 1884.

## THE ROYAL INSTITUTE OF BRITISH ARCHITECTS: CONFERENCE AT THE INTERNATIONAL HEALTH EXHIBITION.

**T**HE first of a series of Conferences on the subject of "The Construction of Houses with regard to Sanitary Arrangements," organised by the Royal Institute of British Architects, was held on Thursday, the 10th inst. Mr. Ewan Christian, President of the Institute, was the chairman for the day, Mr. Charles Barry, F.S.A., being vice-chairman. There was a large attendance.

The Chairman, in opening the proceedings, referred to the great importance of the subject before the Conferences, and stated that the Institute did not, of course, hold itself responsible for the opinions of any individual speaker. The general question of house building was one of the most important questions of the day, and people should bear in mind Lord Bacon's wise aphorism,—"He that buildeth a house on an ill site committeth himself to prison." The same might be said of him that buildeth a house on an ill site.

### ON THE CONSTRUCTION OF HOUSES WITH REGARD TO SANITARY ARRANGEMENTS.

The introductory paper was on this subject, and was read by Professor T. Roger Smith, who commenced with a brief historical review of the history of the English habitation. He said:—"From the best preserved of the Mediaeval castles, such as Conway Castle, we may learn that the elementary principles of sanitation were understood, and pains and care taken to secure comfort and even luxury, so far as they can be enjoyed within the restricted boundaries of a fortified dwelling; while the semi-fortified houses, of which a few remain in tolerable preservation, such as Penhurst, Ighbam, Warwick Castle, and Haddon Hall, were many of them so complete that they continue habitable even by this fastidious generation.

Monastic buildings, from a time long before the Conquest down to the Reformation, afforded a series of admirably well-planned and well-built dwellings, for the residence in common of a large number of inmates, the general idea of which survives in the colleges of Oxford and Cambridge. The neighbouring detached but dependent buildings, such as the abbot's house, the mill, and the grange belonging to a monastery, were each and all of them good specimens of small dwelling-houses. They were, however, in all probability, far better than the houses which surrounded them, if we may credit a curious but by no means flattering account of the ordinary English dwelling-house at the close of the Middle Ages which has been lately made public in Brewer's "Henry VIII." It is from the pen of Erasmus, who, writing to Wolsey's physician on the dwelling-houses of England in the early years of the reign of Henry VIII., says:—"First of all, Englishmen never consider the aspect of their doors and windows; next, their chambers are built in such a way as to admit of no ventilation. Then a great part of the walls of the house is occupied with glass casements, which admit light, but exclude the air, and yet they let in the draught through holes and corners. The floors are in general laid with white clay, and are covered with rushes, occasionally removed, but so imperfectly that the bottom layer is left undisturbed sometimes for twenty years, harbouring abominations not to be mentioned. I am confident the island would be much more salubrious if the use of rushes were abandoned, and if the rooms were to be built in such a way as to be exposed to the sky on two or three sides; and all the windows so built as to be opened or closed at once, and so completely closed as not to admit the foul air through chinks, for as it is beneficial to health to admit the air, so is it equally beneficial at times to exclude it."

After the time of the confiscation of church property, under Henry VIII., a large amount of house-building on a great scale occurred. Of the vast Elizabethan and Jacobean mansions we are justly proud; and it is very doubtful whether the influence of Italian and French examples in the seventeenth and eighteenth centuries was not on the whole disadvantageous. Certainly some of the Palladian mansions of about a hundred years ago are less carefully disposed for health, decency, and comfort than the Elizabethan ones which preceded them.

If we try to form an estimate of our actual condition, it will soon become clear that, with our present habits of life, the influence of the dwelling on the health of its inmates is very great. I am inclined to believe that it is much greater than at any previous period. Indoor occupations, for men, are far more common than they used to be, and probably though women have to a large extent lived in the house for several centuries they now do so more than ever.

After enumerating briefly some of the most important points which have to be considered in house sanitation, such as adequate ventilation, sufficient means of warming, ample windows, sound construction, protection from noxious compounds in the paint or paperhangings used for the dwelling, complete systems of drainage and of ventilation for the drains, and an ample supply of pure water, hot and cold, the Professor said he proposed to conclude by a reference to the share which the architect may properly claim in the duty and privilege of promoting public health by improving the construction of dwellings:—

In other words, I propose to ask how far all this is an architect's question. It is not sufficiently known to the general public, but well known to ourselves, that the actual direct control possessed by architects over the majority of the dwelling houses built in England is extremely small. In ninety-nine cases out of a hundred the dweller in or near one of our towns, especially this metropolis, never dreams of building his own house, and looks out for one ready built by a speculator, and puts up with untold inconveniences and even dangers from its many defects. But notwithstanding all this, the opportunities which we possess of influencing the buildings of this country are very great; they are such as no other body of men enjoys. We can do a great deal to secure that the homes of England are healthy; and if we fail to do all that we can, we shall be failing in a great public duty.

In the first place, I think it may be safely affirmed that whatever may be the case in towns, the country house of a person of influence and importance is now never built without an architect. From parsonage houses upwards we have the designing and superintendence of all the houses of the clergy in their parishes, and the rich when they are living on the estates. These, then, we can make as fit to promote health and to avert disease as we are able, and they ought to be as healthy as any buildings can be. Collectively they provide for a vast number of residents, including a great proportion of the most important men and women of the country; and, in addition to this, they are conspicuous as models. The dwellings of the highly-placed should be perfect, not only for their own sake, but because such buildings are sure to be imitated, and their owners are most likely to promote sanitation when their own dwellings teach them what it means.

Next perhaps in importance from our present point of view are our countless residential institutions, if that term may be used to denote public buildings where persons live temporarily or otherwise. Every college, school, hospital, workhouse, &c., has its architect, and we have even seen military barracks erected by civil architects. The very purpose of these build-

ings renders attention to their sanitation one of the most positive duties of the architect.

At the other end of the scale the very numerous model dwellings erected in London and other cities for the urban labouring population, and not a few agricultural labourers' dwellings, are almost always put into the hands of architects, and are buildings in which sanitary excellence is often the only good quality that the architect has an opportunity to impart. Between these two extremes lie the numerous dwellings of the middle class, which, as has been said, are far less under an architect's control than the buildings above or below them; yet it must not be forgotten that from time to time an individual house is commissioned, and ought to become a model. I trust I have shown sufficient reasons for our recognising that this is pre-eminently an architect's question, and, if that be admitted to be the case, it will hardly be necessary for me to bespeak your best attention to those of our professional brethren who are to address us on some of the details of the subject, and ask you to contribute to its elucidation by joining with spirit in the discussions.

### THE SANITARY ARRANGEMENT OF HOUSES IN LONDON DURING THE LAST 120 YEARS.

Mr. Frederick W. Hunt read a paper on this subject. He said that in speaking of the sanitary arrangements of houses in London during the past 120 years, the points that present themselves for especial consideration are:—

1. Drainage, and the appliances in connexion with it.
2. Water-service, and its supply and arrangements.

And also the general arrangement of the houses during that period, and the use of the several parts and their ventilation.

Before the commencement of this century there was not any system of public or general drainage existing, the so-called sewers being provided for the purpose of carrying off surface water only, or for conducting fouled streams along their old courses. As new squares and streets were laid out and houses erected, sewers were formed under the new roadways; but these were still only for surface water, and it was illegal to conduct any focal matter into them. In the formation of these sewers, therefore, the questions of a proper fall, or construction with a view to proper cleansing, do not seem to have been considered essential by the engineer or builder. When, after 1815, it was allowed to carry the overflows from cesspools and other foul drains of houses into sewers, the existing sewers, constructed for the purposes before mentioned, were used, and some have continued in use until the present time, being sometimes only elongated cesspools with the onfall higher than the upper end.

When there were not any sewers for the reception of house drainage, each householder, large or small, had to provide for the reception and storage of all soil or refuse upon his own premises, until it could be removed with as little annoyance to himself or his neighbour as possible. The arrangements of houses, therefore, in the metropolis differed but little from those in the country, with the exception that those in town had not the space or accommodation the country afforded for the conveniences required.

Cesspools or cesspits were the means provided for the reception of all soil and sewage matter. These were usually constructed in the yards or gardens of the larger houses.

House-drains, similarly to sewers, were originally constructed to take the waste and surface water, and being for this purpose only, they were not very carefully laid, and were generally square in section, and frequently without any

paved bottom. These drains were connected with the sewer if one existed within reach, otherwise they had to go to a cesspool. In houses built after, or only immediately preceding, the commencement of this century, when the introduction of a water-closet into houses was becoming general, the drains were made of brick, circular in form, and such as are now called brick-barrel drains. These drains were constructed with mortar as a rule, though sometimes a portion of the bottom was laid in cement, and they still discharged into cesspools from which overflows were carried away. No doubt the overflow was frequently connected with the public sewer, but it was not until 1815 that the penalty against such connexion was removed. With means of overflow, and drainage allowing as it did of the use of a greater quantity of water, and at the same time obviating the necessity for emptying cesspools so frequently, water-closets, instead of privies, were generally provided for houses built at and after the commencement of this century, not only internally but externally. The difficulty that then presented itself to the builders was the keeping back of foul smells, which was provided against by traps in soil-pipes and dip-traps at the bottom of pipes, frequently so large that they might be called cesspools.

Previous, therefore, to this century, and for the first quarter of this century, we find a gradual suppression of privies, and the introduction into houses of water-closets, using the old flat bottom drains, or such drains as had been originally laid down, and these discharging into cesspools. It appears to have been considered that a drain would do for any purpose the needs of the occupier might require it to serve, and when all focal and offensive matter could be washed away out of sight, and traps were supplied to keep back offensive smells, it was sufficient to allow this refuse to find a lodgment in cesspools under the floors of the house, or for that matter on the surface of the ground under the floors. When one cesspool became no longer serviceable, rather than cleanse it a new one was made, and the drain directed to it. The site selected for the new cesspool was one that was convenient for the drain rather than for the health of the house.

Much has been done during the last few years in advancing sanitary knowledge, and I think I may summarise the principles gradually accepted, and now more generally acted upon as being,—increased fall to drains,—perfect water-tight joints,—the abolition of dip-traps,—keeping all drains outside the house,—disconnecting them from the main sewers,—the efficient cleansing of drains and the quick removal from them of all obnoxious matter,—the separation of surface water and sink and other wastes from soil drains,—and a continual free current of air through the drains from near their entrance to the sewers along them and up the soil-pipes.

One hundred and twenty years since, water-closets, as such, had scarcely been introduced. The form of such closet at first in use was no more than a receptacle capable of being washed out, from which a pipe was carried to the drain, having a plug to close the upper end, somewhat like a hopper-pan without a trap. This was fitted up in a cupboard or in a room, where convenient to the occupier, and provided with a seat.

Between 1770 and 1780 the first on record of several patents were taken out for an improved apparatus. The earliest were on the principle of a valve-closet, but the kind of apparatus known as the pan-closet, with a large container, came into use very generally at the commencement of this century.

The pipes from the apparatus to the drains have usually been made of lead. Other materials, such as earthenware pipes and iron pipes, have been used, but each of these were found to have faults greater than lead pipes. When it was found necessary to keep back foul smells, D-traps, and traps of various kinds, were introduced. These were formed in connexion with the pipes, and a dip-trap was built at the bottom of the descending pipe. As offensive smells were more and more objected to, the traps were increased in number and size, but the acceptance of the principles now acted upon, and referred to above, has gradually led to the abandonment of the dip-traps at the bottom of the pipe altogether, and to constructing one trap in connexion with the apparatus as small as possible.

After some remarks on wastes, sinks, and

baths, Mr. Hunt proceeded to the subject of water-supply, mentioning the dates of the formation of some of the leading water companies:—The Lambeth in 1785; the Vauxhall in 1835; the West Middlesex in 1806; the Kent in 1809; the Grand Junction in 1811.

The water-supply to houses was generally to one or more cisterns in the basement, according to the size of the house, one being placed in the front area; and when there was a second, it was placed at the back part of the house. At first, as the facility for a high service was very restricted, and the cost great, it was seldom used. A small cistern was afterwards placed over the water-closet, as such an addition was made to the house, and the water companies were able to give a higher service.

The service in the house was at first by a tap in the side of the cistern, but it was soon extended to the sinks for convenience. The waste from the cistern was generally by a trumpet-mouthed waste led direct to the drain, or to the trap under the water-closet apparatus, as the case might be, without any further trap or disconnection, and the supply was taken from the same cistern for all purposes.

The general position for the water-closet in the earliest days of its introduction was designedly in the centre of the house, near the best bedrooms, and where the descending pipes conveying the rain-water from the roof was available for use as a soil-pipe. Light and ventilation there was none, except by a fanlight or small window on to the staircase. Water-closets continued to be placed in this position until near 1850, and in large houses there were two or more so placed on the different floors of the house, and some that could have been as readily lighted and ventilated from the outside were not. The position of the water-closet for the use of the servants, and those in houses of the middle and lower classes, was frequently in the front vault, equally without light.

Houses formerly occupied by single families of the middle classes, but since becoming occupied by a family in each room, have remained without any improvement in this respect. They are still only provided with one water-closet, with a hopper basin and a defective supply of water, placed in a vault in perfect darkness, and where cleanliness is really a difficulty to attain.

**Ventilation.**—In houses built about 120 years since and later, the reception-rooms in large houses, and even generally, do not call for any special remark in this respect, but the offices and bedrooms were arranged rather to give the greatest accommodation than the best.

Borrowed light and borrowed ventilation was not considered to be undesirable, and the height and dimensions of the sleeping-rooms generally were of the smallest. The changes gradually adopted have been to make all sleeping-rooms higher, and give them all direct external light and ventilation, and to add other means of ventilation besides open windows.

As a concluding remark, I would say that the alterations in the sanitary arrangements of houses, during the period I have referred to, have been gradual, and until recently very reluctantly adopted. It has been, and still is, a difficult matter to persuade people of the necessity of making such alterations to their houses; and some prefer to ignore the fact that their houses are in an unsatisfactory state. There is a very prevalent idea that officers of health and inspectors of nuisances have had all objectionable arrangements done away with, and that no one would think of allowing any such to exist; whereas, I think it is rather a fact that those officers never interfere until the arrangements have become most defective, and are a serious nuisance felt by all in the neighbourhood, and that they seldom think of inspecting or interfering with the arrangement of houses of the middle and upper classes.

In the discussion which followed,

Professor Kerr remarked that it was not so very long since there were none of the appliances which had been referred to to be found inside our houses. The upshot was that there had been created underground an immense ramified world of filthy canals most favourable for the generation of poison. With this abominable underground world they had connected almost every room in their houses, admitting the poison which was generated there. As his contribution towards a solution

in part of the great difficulties with which they had to deal, he would state a few propositions which had been in his mind for many years. He would first lay down the following preliminary observations:—(1.) The atmospheric air has for perhaps its principal function, the universal work of cleansing. It performs this work automatically and indefinitely wherever it can force an entrance, but, wherever it is excluded, its work of cleansing cannot be performed. (2.) Decomposition in the open air is comparatively innocuous; but, when the air is excluded, it is poisonous. (3.) A house in this climate is a closed box, from which the cleansing air is apt to be excluded. (4.) Besides its own vitiated air, there ascend into the house foul vapours from the ground beneath. (5.) The house is also in communication with an underground world of sewers, in which the gases of decomposition are constantly being generated while the cleansing atmospheric air is primarily excluded. (6.) All communications from the house to this underground uncleanness are communications to the house therefrom. (7.) The cleansing atmospheric air will find its way into the house if it can; but the sewer air forces an entrance with still greater energy. Now there were three ways in which to meet the difficulties. One plan it was impossible to suggest, viz., the doing away with the appliances altogether. Another plan was to improve the appliances by increasing their complexity, which, he believed, was a mistake; and a third plan was to separate the appliances from the rest of the house, which was the scheme he had now to submit. He would, therefore, make the following proposals:—(1.) To form a separate vertical compartment or *annexe* at the rear of the house, extending from bottom to top, and thoroughly open to ventilation, to contain all water-closets, all sinks, all cisterns, the bath-room, the lavatory, the housemaid's closet, the scullery, and the butler's pantry in connexion. This *annexe* not to communicate with any of the living-rooms, but only with the staircase. All water-closets to have an intervening lobby well ventilated. (2.) To form in connexion with this *annexe* a vertical shaft, extending from bottom to top, and open at the top; to contain the water-supply and service pipes, the gas-supply and service pipes, the flow and return heating pipes, all waste-pipes, all soil-pipes, all ventilation-pipes from the rooms, and the ventilation-pipes from the drains. This shaft to be accessible at several stages, and to be large enough for a workman to ascend and descend by a wall ladder. (3.) To form in continuation of this shaft a subway under the basement floor extending from the front to the back, to contain the house drains, the water main pipe, and the gas main pipe. This subway to have a man-hole at each end in the open air. The disconnection of the house drain from the public sewer, and the provision of all requisite traps, &c., are taken for granted. The efficient ventilation of the public sewer by appliances of its own is taken for granted. (4.) All requisite branch pipes for water, gas, heating, waste, and ventilation to be capable of inspection and control from the shaft, and to extend therefrom to the shortest possible distances. (5.) Every apartment to be separately ventilated by means of tubes in the shaft, and every apartment in the house and in the *annexe* to be directly accessible to the open air by windows. The effectual sealing of the hed of the house against ground air is taken for granted.

Sir Henry Acland, bart., M.D., remarked that a great many of the subjects referred to were better understood 2,000 years ago than at the present time. Some of the works of the Romans in the neighbourhood of Rome and Carthage, and especially as regards their water supplies, were worthy the admiration of the engineers of the present day. Many great cities of antiquity, such as Nineveh and Sardis, he believed, were deserted, not from political causes, but by reason of the ground becoming so saturated with filth as to render them uninhabitable. It would, therefore, take all the care of the scientific men to prevent this in the case of this vast metropolis.

Mr. Lewis Angel, C.E., said that Professor Kerr had suggested a splendid scheme, but it would be a very costly one, and could be only regulated by State control. Almost the only sanitary dwellings fit to reside in at the present time were jails, workhouses, and asylums. He suggested that the Building Act should be applied to the whole country, a fee being paid to the

Local Authority on every new building, so as to provide for an inspecting staff.

Mr. Bourne, the Duke of Bedford's agent, said that a large section of the Bedford estate was built under the conditions referred to by Mr. Hunt. They had their closets outside the house, and cesspools, as there were no other method of getting rid of the drainage, at the time of their construction. Architects could only take things as they found them, and the letter part of London consisted of houses built some time ago, which had to be adapted to the present times. More legislation was required with regard to new buildings.

Mr. J. P. Seddon remarked that beauty was an important element in sanitary building. Architects should have more consideration for the work of their neighbours, and then they would not see the horrible messes which were made in London in the matter of façade.

The Chairman agreed with Sir Henry Acland's remarks on the Roman works. In the alleys of the thirteenth century the sanitary arrangements were as good as they could be, which showed the common-sense of the men of those days.

**DRAINAGE UNDER DWELLINGS.**

Mr. Charles Barry took the chair at the subsequent sitting, when

Mr. S. Flint Clarkson read a paper on this subject. He observed that however desirable it would be to avoid drains under dwellings altogether, back drainage was impossible very frequently for terrace houses,—those houses put close together which would always line the streets in the central portions of our towns. Anything which was desirable for other drains in less important situations might be considered absolutely necessary for those under dwellings, which should, of course, be as near perfection as possible.

1. *What to Avoid.*—By pointing out briefly the bad qualities of brick drains, such as used to carry away the refuse matter from dwellings, what are good qualities in drains generally may be perceived without an effort. New brick drains are rarely constructed nowadays, but plenty still exist under and round about houses, so that they are not as yet mere matters of antiquarian interest.

In brick drains (and in drains of rubble stone quality) the materials were porous, absorbing liquid foulness, and giving it out in foul air when stirred, half-dry or dry. The bottoms were too frequently of bricks laid flat in mortar; the bricks grew loose, and the bed of the channel became a row of little cesspits. In true barrel drains the round bottom was usually covered with cement, but it was applied with difficulty, and frequently not very smooth. With any slight disturbances the coating cracked, parts peeled off without anybody knowing where. Renewal was out of the question. There were thus always little pools above the porous bricks. Rats worked their way between flat covers and side walls, or enlarged any crack in a barrel. The bad air in the drain found its way into the building, and the rats, too. With bricks, barrels were not made less than 9 in. diameter, which we know is too large for an ordinary house-drain. Little streams of water turned through large flat-bottomed drains were shallow and slow; and in 9-in. barrels, with rough insides, there was but little improvement. The solid matter was left behind by the liquids; flushing applied with the most extreme rigour could not cleanse such drains. They were (1) of porous materials; (2) not smooth inside; (3) with joints too frequent, and soon becoming imperfect; (4) too large; (5) difficult to cleanse.

2. *Stoneware Drains.*—All the defects noted above may be avoided if good stoneware pipes are used as they should be. They are manufactured in many places in the United Kingdom, and are not expensive, not nearly so costly as brick drains cemented inside would be. Well-burnt, hard, glazed stoneware pipes absorb no moisture; the vitrified glaze renders them as non-porous (1) as an old-fashioned brown drinking-mug; they do not corrode; they are quite smooth inside (2); once well cleansed the surface is what it was at first.

The fewer the joints the more perfect the drain. If one could be put down all in one piece we should do well, but Nature has apparently not arranged for this. In the stoneware drains joints occur at every two feet, and if properly made they are very lasting (3). These numbers are those of the defects in the brick drains noted above; the contrast is thus pointed

out, and the way in which a defect is overcome.] The length of 2 ft. is convenient for making, firing, conveying, and handling; a length of 4-in. pipe weighs about 15 lb., and a length of 6-in. about 26 lb. In each batch of pipes there are failures which must be cast aside; they should never be sent out from the works. They may be of insufficient thickness, rough on their surfaces, too brittle, fired too much or too little, not cylindrical, or otherwise defective in form. The pipes are made thicker as the diameter is increased: a 4-in. pipe is  $\frac{3}{8}$  in. or  $\frac{1}{2}$  in. thick, a 6-in.  $\frac{1}{2}$  in., a 12-in. 1 in. If too thin or brittle, the broken pipes will saturate the soil around them with foul matter; if rough on the surface, obstructions will occur; in either case the drain will be blocked up. If they are not truly cylindrical in form (or not truly oval in the case of oval pipes), one pipe will stand above another at the joint and stop the flow. An ordinary pipe is constructed with a projecting rim or socket at one end,—a faucet into which the plain end of the next pipe fits as a spigot. The inside of the faucet and the outside of the spigot have parallel grooves to give a key to the material introduced to form the joint.

The lowest pipe is laid first, with the socket at the highest end. The plain end of the next pipe is placed in that socket, and the space between it and the socket is filled in with a mixture of cement and sand. Clay should not be used for drains under dwellings; there the joints should be as air and water-tight and as indestructible as possible. Before the cement has had time to harden the interior of the pipe is wiped out very carefully. *If this is not thoroughly done, a ridge or small lump of cement will stick up at the joint.* Long hairs, threads, pieces of cloth, or cotton stuff will attach themselves to such projections, soil will then cling, and a stoppage be managed sooner or later. To guard against such ridges or knots joints have been treated somewhat as in iron water-mains, that is to say, strands of gaskin have been put round the upper pipe, so as to make it fit tightly in the socket, and then cement packing, put to fill up the rest of the socket, cannot reach the interiors of the pipes. Some lodgment results, however, and consequent imperfect cleansing, if the whole space between the two pipes is not solidly filled up with something as hard, or nearly as hard, as the pipes themselves.

3. *Some Defects in Stoneware Drains.*—When pipes are ordered hurriedly and arrive too late,—there is sometimes a wish to use those which have come, and not to wait further for the special pipes which ought to have been ordered before. When the changes cannot be made at the junctions,—pipes of one diameter should always be joined to pipes of another diameter by diminishing pipes, and in no other way. Patched junctions are painful shows of inefficiency; obstruction comes sooner or later when the filling-up breaks down into the pipe. Right-angled junctions cause trouble; a branch should discharge through a junction at an angle approaching the line of flow of the drain which is entered. When bends are required, but have not been supplied, straight pipes will be used with apologies, "so as to get the work done," unless there is interference. If the curve is of short radius the spigot ends will actually leave the sockets on their outer sides. Speaking generally, very bad stoneware drains will be of porous pipes, rough in their insides, broken and pieced with cement; some joints gaping, others leaking; some badly made with bad cement, some with projections of the cement inside; not sealed over; laid to curved and irregular lines, with right-angled junctions; the curves made of straight pipes, without diminishing pieces at change of size, and occasionally with larger pipes inserted in the run of smaller ones; without inspection-chambers; put on new-made or yielding ground; parts running up-hill, and the rest laid to flat and irregular gradients.

4. *Iron Pipes and Subways.*—Some architects, in certain parts of their best work, use iron pipes with yare and lead joints, similar to those in water-mains, in preference to any stoneware drains. In Paris they are always used,—not buried in the ground, but exposed to view. In America they are common, and compulsory in some places for drains under dwellings. They are enamelled inside, or treated by the Bower-Barff (Rustless Iron) process. Mr. John J. Stevenson, the architect of the new mansions at Kensington-court, has taken great pains

there, and used all the most modern sanitary appliances. He has kindly lent me a drawing showing the system pursued. Heavy cast-iron pipes, 5 in. diameter, are laid in perfectly straight lines under the houses. They are lined with Dr. Angus Smith's composition, a preparation of tar, which gives a smooth and apparently indestructible surface. Joints occur at every 6 ft., and are thus one-third of the number in a stoneware drain; there are no difficulties with defective cement or the careless use of it. Being much more costly than stoneware pipes, the iron pipes are only used under the houses.

Similar iron pipes were put by Mr. E. C. Robins on wall brackets in a subway,—a kind of sub-basement,—in the Museum of Building Appliances, in Maddox-street, Regent-street.

5. *Lines and Levels.*—Long straight lines are always preferable. It is more easy to get the levels right, and to see that they are so; there are no checks to the flow, which is a very important point with water-horne solid matter; they can be more readily tested at first, and from time to time, and more readily unstopped. At the junction of the straight lengths of the pipe drains, and at any bends, small inspection chambers are put; at the bottom of these a length of half-pipe forms the channel. When the cover is off the character of the flow of the drain is seen at once.

Having determined the lines which the drains are to follow, it is then necessary to settle the inclinations at which they shall be laid, in order that they may convey all effete matter quickly to the sewers, and be self-cleansing. Of course if there was too much fall, and the slightest check, the solids would remain and the water-run away. But too much fall is the rarest thing; not being able to get enough is what we are wont to grumble about. The fall is strictly limited by the depth of the sewer below the lowest floor, and the necessity of keeping the drain well under the floor at the upper end; 2 ft. under the finished floor is considered desirable, though we have sometimes to make ourselves contented with less. The least fall approved for 6 in. drains is one in forty, that is, 3 in. fall in each 10 ft. of horizontal distance. More is valued if it can be managed, certainly. 4-in. drains should have more. It is desirable to have a flow of at least 150 ft. per minute, with a shallow stream of water. When drains are laid to flat gradients some special means of flushing them must be used daily.

If the pipes are laid upon yielding ground they will not keep level; some will tip one way and some another, the joints will snap, and sometimes the pipes also, resulting in hills and dales, leaking joints, and stoppages. A bed of cement concrete, carefully levelled on the top to the proper fall,—a bed of artificial rock in fact,—laid along the whole length, will give the pipes a fair chance. In this concrete grooves will be made to receive the lower parts of the pipe sockets, and the whole of the length of each pipe will then rest on an immovable bed.

Refilling the trench must be managed without disturbing the pipes. The hollows under them being very carefully filled up with concrete, it must also be put at the side of the pipes, with a thickness of 6 in. on each side, and then 6 in. over the top. Such a covering of cement concrete is usually stipulated for in by-laws for drains under dwellings, sealing up the pipes, altogether as an additional precaution against evil results from defective jointing. It also serves to protect the pipes from displacement by impact on the surfaces above them.

6. *Disconnection from sewer; ventilation; connexion with sewer.*—After the house drain has left the house, and before it reaches the sewer, a break is made, and the drain runs past an open space. On the side of this air-space next the sewer is a water-trap with a good seal, intended to prevent any bad air in the sewer from reaching the air space. If, however, this trap is neglected, or pressed upon, a good deal from the sewer, tainted air will not enter the house, but will find its way out of the air space. From the air space fresh air enters the drains under the house, and a current is kept constantly moving through them by arranging ventilating pipes at the higher ends, which shall run up to the top of the building.

Some disconnecting traps are large shaped pieces of stoneware, which shut off the sewer at one end, and receive the house drains at the other. A pipe carried up at the house end supplies the fresh air above the trap, when a grating at the surface of the pavement is

objected to. With other traps the construction of a manhole is contemplated. This is a little chamber built up under the pavement of an area, through which the drainage is carried in half-pipes of enamelled ware. The trap is a siphon or U trap put on the side of the manhole next the sewer. A grating at the surface is sometimes put when there is plenty of space; more usually a flue is constructed and filled in with a ventilator having small mica valves, which rise to admit air into the flue, but refuse to let the air come out. In time of storm there might be a set in the wrong direction,—the long upright pipe at the back of the building might carry a rush of air downwards, and it would find vent at the induct and cause annoyance. Protected by these mica valves, the flue is unobtrusive, and a moment of rest allows the pent-up air to go upwards according to its wont. The manhole makes inspection of the drains easy; an air-tight iron cover is often put over it.

The ventilating pipes, at the upper ends of the house drains, are of lead or of galvanised cast iron, well caulked at the joints, and all 4 in. in diameter, or as large as the branches they start from. The soil-pipe serving the water-closet is usually extended upwards; being joined at its foot to the house drains without any trap, a current of air passes steadily through drains and pipes. Long branches must have special ventilating pipes; short ones will be cleared of air by the discharges, and supplied with freshened air from the main drain. These upcast exhaust-pipes must not finish near windows or cisterns, nor be stopped at the eaves, so that they discharge under the open joints of slating; nor must they stop just above the tops of chimney flues, nor be carried into the flues themselves. If they are, bad air will reach the insides of rooms. Wires, or a perforated flue, must be put to keep out birds, or an approved cowl.

The drain should be connected with the sewer in the upper half, above the line of flow, at the haunch just above the springing. The custom at one time was to put the mouths of the house drains below the water-level in the sewers, but this is given up now; the intention was to prevent sewer air entering the drains. Connections must join the sewers obliquely in the direction of the line of flow of the sewer. The pipe sewer junction blocks invented by Mr. Cockrill, are a considerable improvement. Oblique junction blocks and bends are used for brick sewers. Flap-traps are railed at and still used. The hinged valve allows a passage out from the house-drain, but not into it; the flap closes by its own weight when the flow has passed through.

**7. Inspection, Flushing, and Cleansing.**—Other connexions with house-drains for sinks, baths, rain-water pipes, &c., the traps to them, and the ventilation of pipes and traps, form a branch of our subject not forgotten, but very extensive. The construction, maintenance, cleansing, and the efficient ventilation of sewers might seem another branch. Everybody is interested in it, architects specially so. It is well, however, for everybody to have his own province, and do the best he can in it; and architects are content with a province which extends, in large towns, as far as the walls of the sewers, but not beyond.

When the drains are completed, disconnected, connected, and ventilated, they must be examined keenly before they are used, so that if by chance there are defects, they may be remedied. If the lower end of the house-drain is plugged, and the pipes are filled with water, and left for a few hours, and the level of the water in the testing-bend has not sunk, it has been proved that pipes and joints are sound, that there are no vents for bad air, or cracks through which moisture will run away. The levels of straight drains can be tested by actual measurement, and the effectiveness of the gradient proved by floating down something in a good flush, and noting the time. At cast-iron terminals, with air-tight brass plugs placed in a back area at the upper end of a drain, various tests for soundness and level can easily be applied. With drains in use, water mixed with lime is poured in at the end. By the amount and character of the discoloration of the effluent water, before and after flushing, the condition of the insides of the pipes will be judged.

The beautiful arrangement shown by Mr. Hawksley (470, Class 22) for testing house drains and soil-pipes with a plumber's force-pump and gas pressure gauges, shows when

there is any leakage, and localises the leakage too. The traps act as plugs; the ventilating-pipes, and the end of the house-drain next the disconnecting trap, must be thoroughly plugged up. The smoke test calls attention to important defects; little holes many it is true, he plugged up by some chance at the moment, when the test is applied. Straw burned in the drain may send smoke all along it, or smoke may be generated in a vessel and forced in by a machine. These appeal mainly to the sight. The peppermint test,—a favourite one on account of the ease with which it is applied,—appeals to the sense of smell, as does sulphur burned in a shovel at the mouth of the disconnection chamber. Ether, oil of mint, and other strong smells have been suggested. The difficulty in actual life is in getting anybody to look for defects periodically.

In the discussion which followed, Mr. Thomas Worthington referred chiefly to the drainage in country districts. Mr. Hugh Lennox considered it a ticklish thing to lay down stoneware pipes which would remain thoroughly water-tight. If that were the case in new houses, what must it be in old ones? He had been long convinced that for drains under houses iron piping was the best thing to use. There was no difficulty in making an iron pipe water-tight, which would ensure people against the saturation of the under-part of their houses through leakage. Col. Prendergast referred to the confusion of mind which existed in the case of ordinary men as to whether iron or pottery piping should be employed. He had seen what was considered a most perfect iron arrangement put in, which had finally to be taken up and replaced by pottery pipes. In the iron piping they found a hole as large as one's fist, through corrosion. This statement brought Mr. Scott Moncrieff upon his legs, who said that before taking to the use of iron piping on a large scale he had made inquiries as to the experience of others, and at the present time there was a consensus of professional opinion in favour of iron piping. Sir Robert Rawlinson, he continued, had said that as, in London, it was necessary to drain under the house, iron piping should be employed. Even the best stoneware pipes were liable to leak at the joints. Where any doubt arose as to the possibility of corrosion, a subway would enable the user to detect this. He believed the whole question would eventually turn upon the preservation of the iron.

Mr. E. C. Robins, Mr. Edwin Hall, Mr. Dawson, Mr. Fowler, and Capt. Douglas Galton also spoke, the preponderance of feeling being in favour of iron piping.

The Conference resumed its sitting on Friday, when Mr. George Godwin, F.R.S., occupied the chair, Mr. Alfred Waterhouse, A.R.A., being the vice-chairman of the day.

Mr. Godwin made a few prefatory remarks upon the importance of the subject under discussion. In the solution of such questions no one had more interest than the architect, and the Council of the Institute had shown their appreciation of this by convening the present conference. The more fully the public were enlightened, the better it would be for architects and for the community at large. It was a difficult matter to turn the attention of the public to the subject of architecture, and they rarely gave it a thought unless they were building a house, or had some members of their family down with typhoid fever. Architects had paid less attention to the subjects under consideration than they might have done, but a great change had set in, and ventilation and other arrangements for the protection of health received the utmost attention at the hands of the profession, as well as that covering of heaty which they had always been expected to supply.

#### THE IMPERMEABLE CONSTRUCTION OF ROOFS, WALLS, AND BASEMENT FLOORS, WITH A REFERENCE TO VENTILATION AND WARMING INCIDENTAL THERETO.

Mr. Edward Cookworthy Robins, F.S.A., read a paper on this subject. He said that the enclosing walls of every house are an important factor in considering its sanitary condition; so also is the roof covering, which together with the walls, constitute its power of resistance to the winds and weather of our

inclement climate. Until late years, however, the site covered by the walls and roof of any building, has been thought to be sufficiently protected by them, and the existence of such a thing as "ground air" has been ignored in constructing the lowest ground or basement floors of buildings.

But what is ground air? It is the superincumbent pressure of the external atmosphere, which passes through the earth subjected to its pressure to find its escape in the direction of the least resistance, which direction is commonly that forming the site of a house.

When the earth is clean, and the house is pure, there may be no great harm in allowing this process to go on, but for one consideration, viz., the humidity of the air so passing during wet seasons. But in populous places where the earth is fouled by innumerable accumulations of refuse of all kinds, where defective drainage has rendered pestiferous the very soil upon which the house stands, it becomes a matter of enormous moment that the house itself shall not be made the safety-valve for the reception and accumulation of all these abominable impurities in the form of imperceptible "ground air."

**1. Impermeable Basement Floors.**—There are two ways of overcoming this evil. The one is by forming an impervious flooring as before mentioned, and the other is by constructing channels under the floor leading to the kitchen chimney-flue; these channels should be of porous materials, and should be 6 ft. apart, and by being carried to the kitchen chimney the ground air will be drawn off with the heated air and smoke of the chimney, and tend to increase the draught in the flue at one and the same time.

The ordinary materials for paving basement floors are all of a very porous character, but the experiments made on various materials show that hydraulic cement is almost impermeable, and a layer of cement concrete covered with pure cement, or an asphaltic surface, or concrete formed of Portland cement mixed with granite or slag chippings and finished with a smooth surface, will answer the purpose desired. But for the sake of comfort and warmth to the feet it is often desirable that wood should be the covering. This is equally well secured by the adoption of one or other of the many excellent wood block floorings exhibited in this great International Health Exhibition, to be laid on 6 in. of cement concrete. The blocks need not be more than 2 in. thick, and should not be less than 1½ in. thick and 6 in. long by 3 in. wide. They should be dovetail-grooved at the bottom, braced before using, and hopped in cement. Powdered cement should be brushed into the interstices after the laying is complete, and the surface well washed with pure water and left clean.

Deal, pine, pitch-pine, oak, walnut, teak, most kinds of wood, will do, which may be planed or polished, and laid in any variety of pattern, equivalent in beauty to a parquetry floor. Where there are no basements it would be better that all the rooms should be thus paved, the difference in the purpose of the rooms being expressed by the character of the design and the quality of the material used. Vitreous porcelain tiles are best for passages, being both impermeable and not slippery on the surface. But excellent tiles of every kind are now available for the purpose; and are most easily kept clean.

**2. Impermeable wall construction.**—In the second place, let us consider briefly the case of the enclosing walls of a building. Nothing but the observation of carefully-conducted experiments will enable you fully to realise the remarkable porosity of the ordinary building materials used for the external walls of dwelling-houses.

The impermeable qualities of terra-cotta give it a foremost place in decorative construction desirable in all buildings.

In the erection of buildings of the ordinary porous materials, however, precautions may be taken to achieve a similar result.

There are a variety of systems for forming hollow walls, the inner and outer casings being connected with strips of bent iron galvanised.

But hollow walls are not always efficient, and are rarely perfectly well done, and, of course, leave a space in which bad air can accumulate, and into which vermin may some day find their way, and being unable to get out, die, and thus fumigate the building. The system is

costly too, and covers a larger area than solid walls when the walls are less than two bricks thick.

There is another system which makes a wall at once air and water-proof so far as it extends, leaving nothing but the crevices in the ill-fitting of the joiners' work of doors and windows, which only good workmanship can eliminate.

It consists of an asphaltic bond between the inner and outer casing, applied in the following manner: Let us suppose a 14-in. wall, on one side 9 in. of brickwork, on the other 4½ in., with 1-in. division between, the opposite joints being left free of mortar for about three-quarters of an inch each. At every two or three courses the heated asphaltic is poured in, and the crevices all filled up with this impervious material, and the result is a wall much stronger than the ordinary wall, occupying no more space, and perfectly wind and weather-proof. Impermeable water-tanks may thus be constructed, an example of which may be seen in the Parkes Museum.

3. *Preserving Solutions.*—This was the subject of an interesting discussion at the Institute many years ago, under the presidency of the late Sir Wm. Tite, and in the Transactions of the Institute the whole matter was very carefully reported.

I invariably specify that the stone-work shall receive, when in a dry state, two coats of a solution, the effect of which is to render the surface of the stone comparatively impermeable, at all events, till such a time as the stone has had time to weather and form its own skin and natural protector from the weather. Wax and gum are dissolved in a spirit, and the solution is applied with a brush on dry stonework,—the spirit volatilises, and the congealing of the rest forms a skin as thick as the stone is impregnated; two coats are usually sufficient.

At Hanover Church, Regent-street, may be seen three different processes, none of which have, as yet, shown signs of failure.

The building had become perfectly black, but very few signs of decay had taken place, except in the towers, and I was desirous of removing the soot without taking away the weathered surface of the stone, and this I achieved by the use of the wet steam jet.

I also discovered that the portions which had been treated with linseed oil had not decayed to any extent, while the rest was so far gone that the greater part of the stones had to be replaced.

Of course a great deal of the defective stone we see arises from injudicious selection; there is good and bad stone of every kind, and unless pains are taken not only to select the quarry itself, but to mark the approved stones at the quarry, and then to see that they lie in the building on the same bed that they lay in the quarry, disappointment must ensue whatever the solution you employ; solutions should only be used to preserve good stone, not to make bad stones pass muster.

4. *The Roof.*—The ordinary horse-roof is a thing that forms a hat to a building; it may or may not have projecting eaves, or a brim to the hat, but is always presumed to rise above the greater part of the topmost rooms, and to form an air space protective of the inmates from the extremes of heat and cold. That this is but a presumption is, in many cases, only too true, and the cruelty of putting servants in slate, or even metal-covered attics, within a few inches of the outer air, is often forgotten, alike by the builder who sells, and the master who buys his family residence. A sufficient air space between the ceiling and the roof is indispensable for dryness and for the preservation of the timbers of the roof.

The ordinary speculative house-builder gets the thinnest slates, often absorbent of moisture and permeable by the sun and wind, and he fixes these with common nails to sappy battens, secured to light rafters at the least available gauge.

Zinc does not last above a dozen years in the English climate, as a rule; but, if used, it should be put on with laps, and without soldered seams or anything to hinder its free expansion or contraction, and should be put in much thicker than is customary—say No. 15 gauge.

Lead forms the best and most durable roof covering, properly laid, of sufficient thickness,—say 5 lb. weight for the square foot for ridges and flashings, 7 lb. for gutters and flats. But nothing is more effective than tiles, and nothing, when well done, warmer in winter or cooler in

summer. The Broseley tiles are admirable in colour and hardness.

5. *Ventilation.*—It is not my purpose to enter very deeply into the question of ventilating and warming, but it is obviously necessary to make suitable provision for ventilation, not only for the purposes of human respiration but for the sustenance of the healthful condition of the materials used in the construction of a house. Dry rot and other forms of premature decay being induced by the want of a free circulation of air about the places where it appears, the best proof of which is, that by the introduction of the air, the growth of the fungus is arrested.

As I have already remarked, the exclusion of the external air from the enclosing roofs, walls, and basement floors of dwellings, renders it necessary to provide ventilation of a simple kind.

If we have something to learn from foreigners of the scientific application of the principles of warming and ventilating great public buildings, as I have elsewhere shown, foreigners have much to learn from us of the domestic comfort derivable from the homely fireside of the English people. That it is wasteful of fuel is true; polluting to the outer atmosphere cannot be denied; nevertheless it is the best system of warming and ventilating ordinary living rooms. Every room in every home in England may be said to be provided with an extract shaft in its chimney-flue from the ever open fire-grate, carrying away in winter 200 ft. of air per minute. But few rooms have any corresponding inlets, and so to supply the omission, whizzing draughts come in through the key-hole and crevices of the doors and windows and floors, and even through the walls themselves.

A hundred years ago John Whitehurst, F.R.S., wrote a pamphlet on the ventilation of rooms by introducing fresh air from without to supply the want of it within, the full particulars of which were given by me to the Institute a few years ago in a paper "On the Relation of Sanitary Science to Civil Architecture." It consisted of tubes placed in the corners of the room, something less than half the height of the same, whose collected area was equal to or greater than the area of the chimney-flue; the air, entering these tubes through the walls below the floors, passed out at the open top with a current sufficient to carry the air to the upper part of the room, from whence it distributed itself without draught like the spray of a fountain, and fed the flue so that no pull was exerted upon the cracks and key-holes afore-mentioned, and the air was changed as many times in the hour as the size of it permitted its exhalation by the chimney-flue.

When there is no fire the aspiration by the chimney-flue is much diminished, but might be maintained throughout the summer by the use of a ring of gas-jets just over the mouth of the register.

The Hygastic School Board grates have recently been improved, and the fresh air (warmed in its entrance by passing under the iron hearth and fire-clay back) is brought in with a vertical current through the mantel-shelf instead of horizontally by the stove front, and rises to the ceiling and returns to feed the fire; by this means the cold air is warmed on its entrance, which is not the case in Dr. Whitehurst's plan.

Cowls may be useful to prevent down draught, but must not be relied on for creating upward currents. The best cure for smoky chimneys is Billing's throttle valve and terminal, designed by an architect, which is to be seen on one-half of Somerset House. Why the other half is not done to match it I can't tell you.

#### CHIMNEYS AND THEIR CONSTRUCTION.

This was the subject of the next paper, which was read by Mr. J. P. Seddon, who observed that chimneys, at present at any rate, are integral and important features of most buildings in England.

It may be that they can, and will be, ultimately dispensed with, and our towns made, by the progress of science and economy, to resemble those of the East, and they may become a mere collection of flat roofed boxes, fed with tempered fresh air and drained of foul air, by some parish pump and heating apparatus. If so they may be left to purely scientific men, to whom aesthetic considerations are questions of superfluity.

I have, however, now to speak as an archi-

tect addressing a sanitary conference upon chimneys as they exist, and I wish to show how they can, and should be, treated, so that they may be practically useful and ornamental as well.

They have been both, as witness the graceful chimney-shafts of Grosmont Castle, Southwell Priory, and those of Hampton Court, and a host of Elizabethan mansions, which are picturesque mainly by reason of these features. Alas! they seldom now are either the one or the other, as a glance at the skylines of our streets will reveal, since they are almost invariably disfigured by ugly cowls and tall-boys, which are but records of domestic misery and discomfort. Makers of such monstrosities eagerly compete for public patronage in this Health Exhibition itself, recommending them as palliatives for a disease which they assume to be universal and inevitable. I maintain that it is not the latter, and need not be the former, and that such costly and ugly excrescences may be altogether dispensed with, if proper attention be given to the constructing properly those very necessary portions of our dwellings called chimneys.

Now, why do chimneys smoke? First, because air is not laid on to houses, as water is, but rather sedulously kept out. The more sanitariously impervious (that is to say air-tight) we make our houses the more necessary it is to provide for the admission of air to them, and, unless this be done, smoke cannot ascend the chimneys. Secondly, because fireplaces are ill-constructed and gathered over in such a manner as to leave a large vacant space immediately over them, which acts as a reservoir of stagnant cold air that chills the smoke and prevents its rising to the flue. Thirdly, because flues are made too large (the ordinary size being 1 ft. 2 in. by 9 in.), and because they have no specially expanded places in which down-draughts may expend themselves; and fourthly, because the tops of the chimney shafts are not provided with any guard against the wind, which might be done in a proper architectural manner, instead of it being left to chimney quacks to supplement afterwards with their miserable metal makeshifts,—fantastic excrescences which Dickens has, however, so immortalized that I need not attempt to describe them further. I will proceed at once to consider what the proper construction of chimneys and their appurtenances should be to enable such subsequent appliances to be dispensed with. Beginning at the bottom with the fireplace itself, leaving the grate for later consideration, the first thing to be done is to provide a good and sufficient supply of fresh air from outside the building to the fireplace. This may be drawn from above the roof by special air flues in the chimney jambs.

Fresh air being brought to this point may be tempered or warmed by contact with the grate before its admission to the apartment, and it can be admitted thence without causing a draught, which is sure to occur if cold air be brought to any other part of the room, as its course thence is direct to the fire, to the annoyance of those who may be in its way. How it may be warmed will be seen when we come to the grate.

The next thing to consider is the outlet of the smoke from the fireplace. This should be contracted to the normal size of the flue, at least, or perhaps made slightly smaller, immediately over the fireplace, in order to insure a quick draught. This object is not effected at all by the usual construction of this part of the chimney, which is to put an arch in front, over the opening, and to gather the opening itself to the flue gradually behind. Arch, chimney-bar, and gathering can be dispensed with, and may be so economically, by forming in Portland cement concrete *in situ* a mantel-block extending the full width of the wall, and 9 in. longer than the opening, and 9 in. deep, with three circular holes pierced in it, each 8 in. in diameter. The central one is the outlet for the smoke from the fireplace, and the commencement of the smoke flue; the side ones are for outlets from the spaces to be formed around the grate, for warming the fresh air brought to them, and are the commencement of flues to convey the warm air to gratings for its admission to the apartment which may be arranged in connexion with the chimney-piece, or carried up to just below the ceiling or the cornice.

The construction of the flues from above this mantel-block is the next point to be considered. These are ordinarily made 1 ft. 2 in. by 9 in.,

but this size is too large; they should not be larger than 9 in. square, and are better lined with freclay pipes, 8 in. in clear diameter; the inside surface of these pipes should not be smooth or glazed, as such are said to be found to retain soot only till rain falls, when it becomes loosened and drops suddenly, causing annoyance, whereas the ordinary terra-cotta surface is rough enough to retain the soot till the chimneys are swept.

Midway between the top of mantel-block and ceiling line of apartment, the flue should be expanded and formed in such a manner as to break the line of ascent of the smoke, and to provide a flat space immediately under the upper part of the smoke flue, in order to divert down-draughts of air impinging on it, and give them a rotary direction, first sideways and then upwards, within the expanded place provided for the purpose, without stopping the upward current of the smoke from below. When the flues are lined with freclay pipes, special expanded pipes, which are made for the purpose, can be introduced, and more than one in the height of the flues may advantageously be used.

The construction of the chimney-stacks containing the flues above the roofs should be such as to protect them from cold and damp to which they are exposed. It is well to build them in cement and to line them with pipes; but the tops need careful arrangement, because the exit of the smoke from them is liable to be disturbed and hindered by winds. There should be at the top of each flue an expanded vacuum space, within which down-draughts may rotate and expend their force, and there should be louvered openings directing gusts of wind upward so as to assist, instead of retarding, the exit of smoke. All this may and should be executed in proper architectural materials and form, as stone, brick, or terra-cotta (the last-named material is specially suitable and easily manipulated for the purpose).

So much for the construction of the several parts of a chimney, namely, the fireplace, flues, and terminals, which need consideration as a whole, without which it is hopeless to expect success by the use of any of the numerous special appliances for the separate parts alone. I plead earnestly for these principles, as a matter closely connected with the health and comfort of the community, and specially invite discussion as to them.

There is, however, another point, which is, perhaps, not less important, but as to which what I have to say is more tentative and experimental. It relates to the grate within the fireplace.

Burning coal as we do, the main point, I think, we have to seek is the consumption of its smoke, or as much of it as is possible within the grate itself, so that the office of the flue should be to convey away the gaseous products only, and not soot. It appears to me that this is attainable by diverting the smoke after it has issued from the top of the fire, so that it should be passed again through the body or flame of the fire before it ultimately reaches the flue.

Perfect combustion is, I think, of more importance than is called "slow combustion," and a fire should not be smothered in its own ashes.

The cheerful English open fire is not likely to be driven out of fashion by even Health Exhibitions, and I do not think that the health of the public would be improved by the substitution of the close stoves in apartments which obtain more generally on the Continent and in America. Nor do I think that any of the systems proposed for keeping up throughout a dwelling-house the same temperature, are likely long to curtail the liberty of the English subject to make the room he occupies of the temperature he pleases. I certainly should not advise the most ardent believer in such a system to expend capital in building houses at present without fireplaces, with their separate flues, or to dispense with chimneys and their construction.

The warming of the fresh air brought to the fireplace is to be effected sufficiently by its passage down the flue and round the fireplace, care being taken that no smoke can penetrate to these spaces. The object is rather to temper than to heat the air, and to direct its point of admission to the apartment, so as to obviate unpleasant draughts. The air so tempered around the kitchen fireplace would be most usefully employed by being brought to the hall of the house which supplies air to all the rooms,

with means of shutting it off when not wanted in summer.

The ventilating grate or stove is, then, an essential part of the combination of appliances I would suggest for chimneys and their construction. And there are many excellent contrivances of this class in the Health Exhibition which can be highly recommended.

The best method of curing chimneys of smoking would, however, obviously be by consuming the smoke in the grate itself, and allowing nothing to pass up the flues but the heated gaseous products that necessarily remain even when the soot has been consumed.

I cannot see that this has as yet been altogether effected by any of the appliances for the purpose exhibited, although many praiseworthy efforts to do so have been made. But this is, in my opinion, the direction in which we are to look for further improvement, and to perfect chimneys and their construction.

In the discussion which followed the reading of these papers,

Mr. Charles Forster Hayward, F.S.A. said the advantage,—not to say the importance,—of having such parts of dwelling-houses as floors, roofs, and walls constructed in a manner so that they may not be too open to the influences of atmospheric changes, might at first sight seem self-evident to every one; but this point was enforced in the first paper just read, connected, as it necessarily was, with the second paper, which referred more particularly to another detail of construction, so essential in this country and climate not only to comfort, but to the possibilities of ventilation, viz, chimneys. Their point, therefore, was to discuss the effect of permeable or impermeable, porous, impervious walls, floors, and roofs,—impermeable to (1) air, had and good, including heat and cold; (2) water, i.e., damp and rain. If time permitted, these two aspects of the question might well be separately considered, but merely hinting at the ideas expressed by Pettenkofer and others as to the extent to which walls were permeable to air, he might at once say that if we would ventilate at all scientifically, and in any but the most simple and elementary manner, we must have walls and floors impermeable to atmospheric effects. Thus, if any sudden changes of heat and cold could to any great extent affect the interior of a building to be ventilated, all special arrangements would be upset, and obviously the introduction of wet and damp through the walls would greatly militate against any artificial means employed to ventilate. Impermeable floors in the basement were best secured by asphalt in some form, either as a layer on concrete with a smooth surface, or as a bed for wood-block or other such flooring, such as small joists hedged in or on the asphalt, to which joists the flooring may be nailed. Other floors of a similar or inferior nature might be used, such as cement, &c. Impermeable floors above the basement were obtained by the use of rolled iron joists and concrete, with asphalt or cement covering, or perhaps with a wood-surface as before. But this touched on the question of fire-proof construction. So he would only refer to a modification of those impervious floors, such as wood joists filled in with concrete or pugging, and then a surface of cement or tiles, and this he had often used for school passages, where fire-resisting material was sufficient, in opposition to fire-proof construction. They might remind themselves here of the old plaster floors of Nottinghamshire and elsewhere. As regarded wood-block flooring, he would remark that in one case he used some wood blocks bedded in a substance like asphalt, in a very damp basement, which had stood perfectly twenty years, and a similar one,—a French patent,—had best borne the wear and tear of an outer entrance-door for as many as ten years already. Now it was obvious that in these floors one must give up all the contrivances for ventilation through the floor, and omit all calculation as to air finding its way into the room through the floor (charged sometimes with the dust of the carpets and other objectionable matter). Also all the need of air-brick ventilation for the floor itself to keep away dry-rot, &c. Yet these floors would be all the more suitable for laying on air in pipes bedded in the substance of the floor, this being more rigid than the ordinary wood-joint floor construction. Passing this, he came to the walls, which were obviously imperfect if built of porous material,

whether of brick or stone, or with imperfect joints, or without damp-courses, either vertically or horizontally, either in basement or chimneys, where necessary. Hollow walls were well known as expedients which required careful work and some experience to make effective. Even all the galvanised iron ties, twisted and bent upwards, and the patent brick bond, were not enough unless care be taken to prevent lodgment of lumps of mortar, &c. during construction, so that in building hollow walls a space for taking out these below is best left to the last. Then the jambs of windows were difficult to manage, and other points required attention; but it was certain that two walls half a brick thick are better than a 9-in. solid wall to resist the wet; and that an outer stone construction should generally have a lining of brick a slight distance from the inner stone face to secure a wall impermeable to wet. But the best of all was against wet, though not always as against wind and draught, was vertical external covering of tiles or slate. The former obtained in such districts as Surrey and the latter in Cornwall and elsewhere. The use of substances such as Hygienic Rock cement in place of mortar for joints or as a coating internally of hollow walls, to prevent access of damp and weather was to be commended, but of the substances advertised for coating walls externally, little advantage might be expected, and less for those often mentioned as being certain specifics against damp, &c., internally. Certainly he should not think of such as affording means for what we call "impermeable" walls. Roofs might be made impervious as floors, and when so made would obviously be flat or horizontal, not sloping. For ventilation purposes this was not an unimproved advantage, for we had to give up the space between ceiling and roof so often; but for access to chimneys and for many town purposes a flat roof was in various ways desirable. Now, to ventilate and warm,—we must in thinking how best to utilise our impervious constructions, remember that we have to feed the human lungs first, and, secondly, the fire. When warming was not required, only human beings had to be thought of; but the chimney might be of great use, or, at any rate, if it existed, could not be ignored in any system of ventilation. Ingress of air was best secured by such tubes as were well understood as Tobin's (a convenient though inaccurate name for them), because they could be regulated in height and size, and by small valves and doors; they also could be placed regularly around a room away from an outer hall, being supplied from the other side by tubes laid in the floor. The hollow channels formed in the walls, with ingress into the apartment at the cills where they were usually high above the floor, had been found best in some cases where he had had to solve the problem practically. The same arrangement of tubes laid in the floor could be adopted to feed the fire, either in the hearth or at the checks at the side jambs; and, of course, the air could be brought in the same way to the back of the grate or stove, if so prepared to receive it, and there be warmed and distributed. Additional access of air could often be obtained,—indeed, sometimes only so, by spaces over the door-head, filled in with louvres, or by special ventilators made for doors, cutting into the mid rail, and avoiding, at least, the necessity for opening the doors and preventing cold draughts to the feet. One of these systems he had applied to school-rooms, and opening on to a corridor; the other to work-rooms of milliners and others. For egress of vitiated air, the chimneys come into use, with tall valves and other ventilators, but specially-built flues were best, lined with circular or square flue piping, but with regulating valves, which were so seldom used. Either accidental or artificial heat, such as gas burning in the tubes, should be used to keep up the essential draught. If it were congenial to our notions of comfort, those Continental tile stoves with tall flues going right through the rooms to the roof might be made to afford, effective egress of vitiated air, being conducted by the heat either into some adjoining flue or other ejector. The sum and substance of all this was a strong recommendation to the householder to procure, and so, of course, be willing to pay for, what was necessary to provide good impervious walls, floors, and roofs, if he would have a preliminary to good ventilation, or even warmth and comfort, without draught. Mr. Ralph Nevill differed with Mr. Seddon

as to the size of the chimney-flues, bis experience being in quite an opposite direction.

Mr. Wm. White considered that the size of the flue was not of so much importance as its proper construction. With regard to walls, he had seen, in the case of a storm, on the inside of 9-in. brick, the water huddling through with the air. Felt had frequently to be removed on account of the mildew and dry-rot it created, and he was endeavouring to substitute the Willerden paper for it. At the same time, felt was one of the best non-conductors of heat and cold. To render a floor impermeable, Dr. Richardson had recommended the turning of arches over the whole of the space under the floor. He considered the wood-block flooring more durable than the Staffordshire common paving tiles.

Mr. Schmidt remarked that he had found that Tobin's system would keep rooms well ventilated.

Major Rowe, President of the Sydney Institute of Architects, said that in Australia they had greater difficulty than in this country in finding good materials. It was generally necessary there to coat the walls with cement externally to keep out the damp. The common clay brick was useless for keeping out the rainy weather, and cement was largely used for ordinary houses in Sydney, but even that was not always successful, on account of the inferior work. When not under the control of an architect the cement was only put on about three-eighths of an inch thick; but whenever it was faithfully mixed and fairly put on it resisted the weather. They could get glazed bricks, but then the cost was considerable. From experiments made by himself, he had found that the sandstone which was largely used for building in Sydney, after it had been some time exposed to the air, was more damp-resisting than any quality of bricks they produced. He had seen in the *Builder* diagrams of an impermeable mode of building, which he was strongly in favour of. He considered 9 in. by 14 in. the best size for flues.

Colonel Prendergast thought that each separate apartment in a house should be ventilated by itself. He doubted the advisability of excluding all ingress of air through the walls. The removal of the vitiated air from the top of the rooms, although it had not been touched upon, was a matter of the most vital importance. He thought architects ought, when designing new houses, to make provision by which, at some future time, the vitiated air would be drawn off by channels from the tops of the rooms.

Mr. Waterhouse, A.R.A., drew a sketch on the black-board of an idea for getting rid of the vitiated air from the upper part of a room by making use of the ordinary flue. This was simply by having an opening at the top of the room connected with the smoke-flue over the mantelpiece. The draught of the chimney drew the foul air from the top of the room, while he had never found the smoke enter the room through the opening. He was making a plan at the present time for a physician who insisted that there should be nothing but solidity between the ceiling and the floor above.

Mr. Ewan Christian having taken the chair, Mr. Horace Jones read a paper entitled  
**SUGGESTIONS RESPECTING DOORS AND FIRE-RESISTING CONSTRUCTION.**

He said.—A consideration of many of the unhappy occurrences during the terrible catastrophe of fire within my own memory has induced me to formulate "A Suggestion with regard to the Construction of Doors, so as to afford opportunity of Escape from Fire." I append a list of the more prominent cases in which, by the newspaper accounts, some 5,000 lives are alleged to have been lost. Supposing this is somewhat exaggerated, and there is only one-half or even a fifth of that amount, it will still be a horrible and terrible tale to record against the builders and designers of public buildings.\*

Such, then, are the reasons which prompted my "suggestion,"—a suggestion applicable to the large doors of churches, theatres, concert-rooms, or other public buildings, also the street or entrance doors of mansions, hotels, boarding-houses, or any other place where numerous inhabitants are likely to be in occupation; also

\* We omit the list, most of the particulars of which have been reported in our columns.

to the subsidiary doorways of public buildings, which are only to be in use either for egress under special circumstances, such as panic or accident, or for ordinary egress.

The diagram will almost explain itself. If the unfortunate victims crowding and blocking

the door with frenzied fear but not unnatural panic, found suddenly that this blocked door, opening inwards upon them, had a means of safety in itself, by simply opening outwards the folding wicket framed within the door, their chances of escape from almost certain destruction would be very much enhanced, and their thankfulness can be better imagined than described.

Of course if the height of the door admitted it, the upper panels would be framed solid, the wicket opening and shutting to and from the transom only.

I would here observe that the cost of the extra labour in forming doors with these wickets, as shown by the model, would not be very large, a very small percentage upon the cost of an ordinary door being sufficient; the principal expenditure, of course, would be in the additional hinges and fastening, although the latter could be of any kind, from an "espagnolette" bolt down to barrel bolts or bars. They would, of course, open only from the inside, and either by sealing or other methods ensure detection where they had been unnecessarily tampered with.

I admit that wickets are often applied to large doors or gates; these wickets are, however, very small, very inconvenient, and generally open the same way as the gates.

I will now proceed to call your attention to a form of construction, or rather an application of the different qualities of two of the best-known and most universally-used materials.

Some years ago I had occasion to visit an engineer's workshop or factory that had been then quite recently destroyed by fire,—indeed, the ruins were still smoking,—and these shops consisted principally of two or three rather lofty storeys. A curious circumstance immediately presented itself: the beams or girders were composed generally of three distinct kinds, viz., cast-iron, wrought-iron, and timber.

I found that all the cast-iron girders, of which there were several, on the ground, broken in pieces; the wrought-iron laying, or rather hanging, from the upper floors, twisted into various shapes; the wooden joists generally entirely consumed, nothing but some small remnants of charcoal indicated where they had been; but there were two wooden beams, which, for some special reason, had been cased on two, and perhaps in some parts on three sides with thin iron plates. These beams alone remained *in situ*; both were well laden, and supported heavy and massive articles.

I inferred from this that the application of the thin plates to the sides of the timber prevented the combustion of the timber, whether by preventing the atmosphere getting at the fibre of the wood, or from any other cause, is immaterial as long as the result is the same.

As a proof to myself and the engineer whose premises were burnt, he tried the following experiment, viz.:—Selecting two or three pieces of ordinary timber, about 6 ft. or 8 ft. long, and say 6 in. by 4 in. scantling, and covering half their length with thin iron, bolted through on two sides. He had them placed in the furnace

of a steam engine; in a short time the uncovered or unprotected wood was entirely consumed, the parts protected had the sides charred, of course, but the middle of the scantling, desiccated thoroughly, yet quite sufficiently firm and solid to carry nearly, if not quite, its original

load. Acting on this information, several floors were executed, for instance, in the Sovereign Life Office, corner of St. James-street and Piccadilly; the British and Magnetic Telegraph and Submarine Station, at the rear of the Exchange, Threadneedle-street,—one floor in each, dividing portions of the building separately occupied; in some warehouses also for the storage of valuable goods, &c.

Of course the progress of improvement would naturally adopt some of the many useful and ingenious modes of constructing fire-proof floors, such as using rolled iron joists quite covered or embedded in concrete; but there are times when a different mode of construction may be advisable and the application of a useful beam of wood rendered fire-proof by the thin covering of iron not be neglected. Of course the embedding in concrete of iron will also apply to wooden joists without the protecting iron case, and; if so, an economy will be the result. Few fireproof floors can be constructed under 67. or 71. per square. I am, however, informed of one in which the constructors claim they can construct it at 51. 16s. 9d. per square.

I have inquired of a respectable and well-known firm of surveyors their estimate of the cost of fireproof construction according to the section given them, and also the cost of ordinary flooring; and they find that the cost of this floor would be 47. 10s. 6d. per square, or about seven shillings per square less than the cost of ordinary flooring.

In the discussion which followed, Mr. Henry Dawson considered that no absolutely fireproof method of construction had yet been devised. The better term to use was "fire-resisting," and such substances as bricks and terra-cotta, which had been subjected to intense heat, were the best suited for this purpose. Unless protected externally with Portland cement, manufactured iron, although it had been subjected to intense heat, was unreliable. With regard to Mr. Jones's door, it should have an inscription on it stating that the bolt was to be drawn in case of panic. The want of the bottom rail, he considered, must interfere with its construction.

Mr. Jones replied that his first model had the bottom rail, but he was afraid it might prove a trap for people falling over. These doors cost 10 per cent. more than ordinary doors.

Mr. William White remarked that it was generally known that an Act of Parliament ordered that the doors in public buildings should open outwards. In the case of a concert-room, he had designed a door, divided into two parts, one opening inwards and the other outwards.

The last Conference of the series was held on Saturday, the 12th inst., when the Right Hon. A. J. B. Beresford-Hope, M.P., was chairman for the day, with Professor T. Huxley Lewis as vice-chairman.

The Chairman said.—It was a right and happy idea of the Institute to come forward and claim its own share in the Health Exhibition. What can be the good and the meaning of architecture

if it is not the science of contributing to health, happiness, and longevity in the most permanent of all circumstances of a man's life, viz., his clothes? His boots and hats wear out, his clothes get shabby, his food perishes in consuming, but his house ought to be a part of himself, and it may be the inheritance of his family. Therefore it is our duty as architects to make our houses not merely beautiful, nor simply luxurious, but healthy. And in proportion as sanitary science becomes more and more exact, and is less and less experimental, the heavier is the moral responsibility on us, to be with the physicians, the ministers of health. There is one feature in this Exhibition which I have very much enjoyed,—I mean Old London. No doubt this Exhibition is meant to be an Apostle preaching health, and this Old London has been reproduced in all its exquisite picturesqueness as a proof of how beautiful and delightful an insanitary city might be. I was almost tempted to say, "An enemy hath done this." When I go through its frowning gateway, and see its beautiful houses, I say, "What can this be for, except to show the humbug of health and the beauty of insanitation?" I think something else was wanted; some approach ought to have been made to one of the cunning framers of odours, in Bond-street, to have supplied the standard odour which the Medieval town would probably have yielded to the passer-by. Instead of that broad footway, should there not be gurgling down the street,—not a trout stream, but one of a good deep chocolate colour, such as filled the central roadway of our Medieval cities? And, instead of the hard path, should there not be that delicious yielding substance, composed of many materials, which was what the Medieval ladies and gentlemen had to pick their way through? If all these things had been provided our street of ancient London would have been far more correct in its appointments. As it is, the beauty is apparent, the insanitation remains to be guessed. A short time ago,—and I am glad to have this opportunity of pointing it out to you,—I was very much struck by a print which appeared in the *Builder*, from the pencil of one who is well known as an artist and an archaeologist,—I mean Mr. Brewer. It was exceedingly picturesque and exceedingly sad. It represented a Medieval town, all capitals and carvings, clustered round a minster of exquisite Gothic proportions; but not a human being was to be seen in the engraving. In the accompanying letter-press, Mr. Brewer explained that the idea was that of a city that had been desolated by plague, and which was then uninhabited. The buildings were mainly Gothic, with some Renaissance among them, and it seemed to be a deserted city, say 1508. And in the middle of it all there was a sluggish stream running, with some broken stems, down which the maidens had gone to get their drinking water. A little further on this stream lost itself by a low-browed archway under a house, and was, in fact, the common sewer and common conduit. I was very much struck by it; there was something so extremely pathetic about it; the great beauty of the whole, and yet the history it revealed of the sufferings and the agonies that had attended the long plague by which the city was ultimately desolated. I would say that that engraving, alike in its teaching and for its great artistic power, deserves to be perpetuated in a more permanent form than even in the current weekly numbers of the excellent journal in which it appeared. Mr. Beresford-Hope went on to say that it was important in sanitary matters to carry health into existing buildings. It was not merely the work of the "jerry" builder they had to deal with and put right, but many of the most stately and luxurious buildings. There were no more treacherous buildings than those of the last generation, when mechanical science had attained a high perfection, but when chemical investigation had not equally advanced. He then spoke of a certain house at the West End of London, which nearly fifty years ago was overhauled regardless of expense by a man enlightened according to the views of those days, and fitted with all the most charming appointments of high London life. Among other things with which it was provided was a service of hot-water to most of the bed-rooms. In a few years this house changed hands, and the hot-water apparatus was cut off. Years rolled on, but now and then strange smells were smelt,

and people felt strangely heavy and depressed in certain rooms. At length, not many years since, an investigation was made, and this disused hot-water service was found to be in reality a machine for diffusing, without trap or hindrance, sewer gas fresh and rich from the main sewer, all over the house. He advised all, therefore, whenever they bought, hired, or inherited a house, first of all to look for the lost and forgotten and hidden drains and cesspools. He believed the number of these was incoceivable, and that if they could be dealt with, it would have an important effect upon the death and disease-rate.

#### SANITARY ASPECTS OF INTERNAL FITTINGS, &c.

Mr. G. Aitchison, A.R.A., read a paper on this subject. After some general remarks on the conditions of a sanitary life, he said,—I am inclined to believe, in the present state of London air, that if every house could be properly built and properly ventilated, it should be hermetically sealed to the outer air; but I fear such perfection is hardly to be looked for in our time, and I therefore say that the things we have mainly to guard against are dirt, dust, and the fouling of the air. By dirt I mean, when speaking to an audience like the present, the street mud we bring in with us, consolidated external and internal soot and dust, and such soft matters that are occasionally dropped about, such as particles of food, and the like. Every crack in a floor gets filled with this, so it is of the utmost importance that this dirt, if not to be excluded, should at least not rest for ever with us, and be liable to putrefy when exposed to damp and warmth. Every open joint between the floor-boards and beneath the skirting is usually filled up flush with dirt. Besides the dust from the streets, we make our own dust inside our houses,—particles from shoes, from wood and stone, from our clothes, oil-cloth, mats and carpets, are constantly being worn off and carried for a time in the air, together with the scales of our constantly-renewing skin; and as soon as the moving air is overlaid or becomes comparatively still, everything is covered with light dust, and a great deal of this dust is what the doctors call septic, or putrefying dust. Mr. Brudenell Carter, the eminent oculist, in his letter to the *Times*, described how he had reduced this to a small amount, and that, in consequence, the health of his family had improved. As regards floors, constant wetting is not wholesome, and even scrubbing will not remove dirt far down in the crevices of boards. Nothing is better for preventing the permanent location of dirt than really good hard wood polished parquet, but if that be found too expensive, then let the joints of the boards be well scraped out, filled with wood when wide, and let all the joints be puttied. And let the whole floor be painted or varnished; dust is then more easily and completely swept up, and wet flannel cleans the floor; but with parquet perhaps a washing once a year is enough with clean sweeping, and the wholesome application of turpentine and bees-wax.

These remarks apply also to all open joints in woodwork, furniture, and plastering; they all get filled with dust, and should be puttied up, and the dust kept out. Smoothness of surface is also a great help to cleanliness, and certainly as few ledges and holes for dust as possible should be left where the parts cannot be daily dusted. This particularly refers to wall surfaces, and to undercut ornaments in cornices and the like; tall bookcases and cabinets always have their tops covered with thick dust.

As to woven things, whether of cotton, wool, or silk, the less there are of these about a room the better; and wholly carpeted bed-rooms are simply an abomination.

What is still worse than a carpet, which is usually beaten yearly, is tapestry or other woven hangings, which often remain in position until they are worn out. Blinds we must have, but they can be glazed, and they generally get a yearly washing; but we might altogether abolish door and window curtains, and woven mantle-shelf coverings, and such like follies. It would also be healthier if we covered our chairs, seats, and sofas with leather, instead of silk, velvet, or cotton. The gilt and enamelled leather we can get, if not quite so beautiful in point of sheen, may be of excellent design and harmonious colour.

Next to polished wood, tiles, marble, glass and marble mosaics, the best wall finish is oil paint; this can be made agreeable to the eye by simple flat tints of harmonious colour, or it can be ornamented with floral or arabesque ornament, or with the highest triumphs of the painter's art, and this last will not only mark the owner's real taste for art, but will prevent the accumulation of dust on the picture frames.

Flock papers should never be used, except when they are painted over, as they form a natural receptacle for dust, and seem to absorb the greatest quantity of foulness from the air, and when the flock is not dyed "in-grain" whenever they are touched some of the colouring matter comes off and is mixed with the air of the room.

I am greatly inclined to recommend the varnishing of all papers, they can then be cleaned with a sponge; but it is absolutely essential to varnish them in nurseries. Children will lick the papers, and neither lead, copper, nor arsenic can be good for them, and neither size nor whitening are substances you would give to children without medical advice.

Let me say here that you cannot have your windows cleaned too often. When they are dirty they not only exclude light and sunshine, but are covered with thickened human exhalations and dust. If you are wealthy enough to have a dressing-room, banish into it every superfluous article from the bedroom; half the bedrooms in London are encumbered with cupboards full of boots, and wardrobes of old clothes, with baskets for dirty linen, books, ornaments, curtains, carpets, and the like, not to speak of mouldy sponges, nail and tooth brushes; these things occupy some of the air space, and pollute the remaining air with their exhalations.

I have no doubt that beauty of form and colour have a very important effect upon our health. All of us can bear witness to the dullness of a room of one colour, in which we have to sit when we are without occupation, and the desire we then have for some beautiful and intricate pattern to relieve its monotony. When a room is adorned with pictures we have not merely occupation, but delight, and those higher emotions that are only excited by the fine arts. When we choose wall-papers, those that are more beautiful in form and colour are to be preferred. We should, however, satisfy ourselves that the patterns on the papers with which our rooms are hung have not a look of motion. Nothing is more distressing than to be in a room where the pattern of the paper seems always crawling like a bag of worms. It would be well if we could have all things about us beautiful in form, elegantly simple, and all the colours harmonious and restrained; these great qualities seem to impart to us the feelings of self-restraint, dignity, and repose.

[For further particulars of Saturday's Conference, see p. 99.]

#### The Sanitary Assurance Association.—

At the ordinary monthly meeting of the Council of the Sanitary Assurance Association on Monday last, Professor T. Roger Smith, in the chair, a paper on the sanitary exhibits at the International Health Exhibition was read by Mr. Mark H. Judge, by whom it had been prepared at the request of the Council. On the question of the disconnection of house-drains Mr. Judge said:—Arrangements for providing a free passage of air into drains on the house side of the outfall traps, to form an air-break or disconnection between sewers and house drains, are now admitted to be necessary by all sanitary authorities; indeed, the principle involved in their use is the cardinal principle of modern sanitary architecture. By means of the outfall syphon-trap, combined with air-disconnection and outlet-ventilation above the roof, a dwelling is thoroughly protected from the ingress of sewer-air. That it is important that the admission of sewer-air to our dwellings should be prevented is universally admitted, even when no infectious disease germs are present in the sewers; but it is often a matter of life and death. Who, indeed, would be bold enough to assert that the miles of London sewers into which every house is supposed to drain in this great metropolis, with its 4,000,000 of inhabitants, are ever free from infectious disease-germs? These sewers drain alike the palace and the worst tenement-dwelling in which poverty and ignorance breed disease and invite death.

### The Proposed Additions to Westminster Hall.

**DURING** the present week the drawings showing the scheme for the treatment of the west side of Westminster Hall, lately laid bare by the demolition of the old Law Courts, to which we referred briefly in our last issue, have been in the Library of the House of Commons for inspection by any members of the Legislature interested in such matters, though we must regret that the drawings have not been systematically arranged on screens in a regular progression, so that they could be easily compared, instead of being merely placed in the room at random. There is a great deal of matter for study in them, but non-professional men will not find it very easy to seize the main points in any case, and still less so when the drawings can only be taken up one by one in the order in which the last comer may have left them. Political men are not very prone to take interest in architecture, and should, at least, have every encouragement.

Mr. Pearson's report, which is printed as a Parliamentary paper, can be obtained by those interested in the matter through any bookseller for the sum of two pence, and a very good two-pennyworth it is. Hence we have not felt called upon to sacrifice other matter, which cannot be bought with copper coin, for the sake of printing over again a report of sixteen foolscap pages, which any one can easily get for himself. We will endeavour, however, to make generally clear what is proposed.

Probably few of the many who traverse Westminster Hall, which is now a great vestibule to the Houses of Parliament, and was for a long time a *salle des pas perdus* to the Law Courts, realise that it was originally the centre apartment or great hall for a palace, built first by William Rufus, but of which it is not clear how much more of the palatial building was realised.\* The Hall as now seen is mainly as transformed by Richard II., in whose time the celebrated hammer-beam roof was added (after raising the walls slightly), which is the chief glory of the Hall. It is necessary to bear in mind this original intention of the structure in order rightly to estimate what has been and

what is proposed to be done. The "Hall" of a palace or of a mansion is essentially a piece of internal architecture, not intended to present any imposing appearance externally, as it must necessarily be surrounded by other and lesser buildings, forming other portions of the residential architecture. It is improbable, therefore, that Westminster Hall was ever for any long period open to view as it is now; on the west side, any more than on the east. It was probably from an early date the centre of a congeries of lower buildings above which its roof would rise, but which would have hidden its walls for the most part from view. When in use as part of the palace, the north end of the hall would be the serving end, the screen would have been placed there, and probably the kitchens would have been adjacent on the north-west angle of the building. From the earliest date there have been considerable adjacent buildings at this point, and the remains of Early English foundations and masonry abutting on the Hall and extending westward are still to be seen. These Early English buildings extended southwards along two bays of the Norman Hall, the rest of the exterior of which displayed there the usual shallow Norman buttresses which are still to be seen. Possibly at that time the outer wall may have been altogether visible from the west, after getting clear of the Early English buildings referred to. We extract the following summary of the main incidents in the Medieval history of the Hall from the "Report":—

4. *Henry III.*: 1217, 1221, 1224.—Throughout Henry III.'s reign extensive works were proceeding at the palace. At the same time the choir, transepts, and Lady-chapel of the abbey were being built. Extensive decoration was also in progress.

1244, 1263.—Probable date of the Early English work at the north-west angle of the Hall, of which traces are now visible. See plans No. 1, 4 (f), 5 (a) (b). Fire at the palace.

5. *Edward III.*: 1297 or 1299.—Great fire, which reached as far as the Abbey. This indicates that the fire was on the west side of the palace, and, as a consequence, Parliament had to be held at the house of the Archbishop of York at Westminster.

Edward III. built, adjoining the Hall, a room for "The Hall of the Family in Parliament time," from which we gather that the great hall was used in his reign for the sittings of Parliament, and the fact that Parliament had to adjourn after the fire implies that the great hall suffered. In Edward III.'s reign, at the time of the building of St. Stephen's Chapel, reference is made to new work in connexion with the Hall.

6. *Richard II.*, 1394-97.—It seems from Thomas Walsingham that it was customary for Parliament to sit in the Hall in Richard II.'s reign. Whether

to repair the damage which may have been caused by the last fire, or to make the Hall more suitable as a Parliament House, Richard entirely transformed it to its present shape. The walls were raised 2 ft., and re-cased, and new windows were inserted. The existing roof was added; a new northern porch and towers, and the large buttresses lately uncovered were built. Also "divers lodgings" on the west side; these were mostly contained by a wall erected parallel to the Hall, and connecting together the new great buttresses. The two tiers of wall arches between the Norman buttresses were also erected at this period. See plans Nos. 1 and 6.

We had, therefore, at that time a Hall originally Norman, with a fourteenth-century hammer-beam roof on it, massive buttresses and flying buttresses of the same date added for security to the new roof, and between these buttresses a new wall built, parallel to the west wall of the Hall, inclosing the space between the buttresses. It is to the north-west buildings that Mr. Pearson seems to apply the expression "divers lodgings," though we strongly suspect that if the whole of the inclosed ground were excavated the foundations of other "divers lodgings," of one date or another, would be found between the Hall and the Abbey. Of these Early English buildings at the north-west angle the foundations and portions of the plinth may now be seen, with the new buttresses built over them; while southward of the second bay the plinth of the longitudinal walls ranges with the buttresses, showing that they were built at the same time.

We give Mr. Pearson's synopsis of the remaining stages in the alteration of the buildings:—

7. *Richard III.*: 1484.—Repairs by Richard III. No traces visible.

8. *Henry VIII.*: 1512.—Great fire, which destroyed a large portion of the Palace; never rebuilt, and in consequence of which Henry VIII. removed to Whitehall in 1529.

9. *Elizabeth I.*: 1570.—Large additions to the west side of the Hall. A large part of the work built at this date remained until 1822. See No. 1.

10. *Charles II.*: 1680.—Additions by Sir C. Wren. See No. 2.

11. *George II.*: 1732.—Courts of Common Pleas and dooryard on west side of Hall; also committee-rooms along St. Margaret's-lane; all by William Kent. See No. 1.

12. *George III.*: 1793.—Widening of St. Margaret's-lane, whereby part of Elizabeth's work was demolished. See No. 4 (d) (c).

13. *George IV.*: 1820.—Sir John Smeaton began work of demolition previously to the erection of his Law Courts.

14. *George IV.*: 1822.—Restoration of north end by Thomas Gwynne, mason to the Abbey of Westminster.

15. *William IV.*: 1834-35.—Re-casing of the walls of Great Hall by Sir Robert Smirke.

\* We may observe that *Harper's Magazine* for August contains an interesting popular article on "The Great Hall of William Rufus," which comes rather *apropos* at the present moment.

We have, now that Soane's Law Courts are removed, got back to the Hall, with all its adjacent "divers lodgings" removed; the interior re-cased by Smirke; the north end restored by Gayfer, but the west side left with great portion of Rufus's Norman wall, of Richard II.'s large buttresses, and the foundations of the longitudinal walls between the buttresses, and of some portions of the buildings which formerly projected at a right angle to the Hall at the north-west. What is proposed is to repair and restore the buttresses and rebuild the walls between them, and to place a building also at right angles to the north-west portion of the Hall, on ground which has always been occupied by subsidiary buildings of one kind or another. The alterations also include raising the towers and some altering of the façade at the north end; but this we may regard as a separate matter, unconnected with the treatment of the western face.

The exposed western face, of course, includes a great amount of modern alteration, greatly due to Soane; and the buttresses have been cut into, pared, filled in, and knocked about in all kinds of ways, so that it would not be safe to leave them long in their present unprotected state. But amid all the modern alterations, a great deal of archeological interest remains in the old wall, and it is partly on this account that Mr. Pearson, as we observed in our "Notes" last week, proposes the restoration of the buildings which formerly ran between the buttresses, as the Norman walls will not long survive exposure, and must be either cased or covered. Of what nature was the building which formerly connected the buttresses and covered the lower part of the Norman wall? Part of the evidence on this ground we may give in the words of the report:—

"Richard II. entirely transformed the external and internal aspect of the Hall. Unfortunately the removal of the work by Sir Robert Smirke was so complete that but few of the old stones exist in the interior. Outside we see the flying buttresses and the massive supports, which were, however, much injured by later additions. Between the Norman buttresses, with the purpose of carrying the floor and roof of the building, which he erected in continuance of the Early English work already referred to, he built arches, of which the upper tier remain, and sufficient of the lower tier to enable me to restore their exact shape. He seems to have done this in order to avoid weakening the wall, which had to carry his massive roof, by inserting corbels or timbers into it. He began his work probably in the two northernmost bays, where he cut out a shallow chaco in the existing stonework to insert the arches; but, whether he found that this injured the wall, or from whatever cause, in the other bays the arch is merely set against the Norman work. He built the wall which connected his new buttresses 10 in. thicker up to the height of the floor than above; this also, no doubt, in order to carry the roof, and this I have maintained in my restoration."

Mr. Pearson therefore takes the existing remains as evidence of a two-story building between the buttresses. We can perceive no absolute evidence anywhere of an upper floor,—no trace of it in actual marks of any kind; but the double tier of wall arches and the evidence of the thinning of the upper portion of the wall between the buttresses, referred to in the above quotation, may be accepted as sufficiently probable testimony, as no other consideration will so fully account for these facts. The proposed new design shows a cloister, the arches filled in with iron grilles, on the lower story, and a closed and glazed upper story; a battlemented parapet, the buttresses and flying buttresses carefully restored, and the buttresses finished with large and heavy crocketed pinnacles. For the open cloister there is no evidence, saving a certain inherent probability based on the habits of Medieval building. For the battlemented parapet there is probability, in the fact that the original parapet of the Hall is known to have been battlemented, and in the height of the returns of the parapet above the roof-line, which latter is marked by the chases for lead; also in a certain print by Hollar; but we have had reasons for thinking that the belief in Hollar's accuracy is a kind of popular fallacy of archeologists, and that he is by no means the authentic witness that he is currently supposed to be. However, the

battlements are intrinsically probable, no doubt, and the base of the parapet is distinctly visible on more than one buttress. The pinnacles coincide in general appearance with one which existed on a flying buttress on the east side of the Hall, which Sir C. Barry pulled down, but of which there is an engraving in Brayley and Britton's "Westminster." So much for the longitudinal building between the buttresses. At the northernmost end there is to be a new two-storied building with a high-pitched roof, at right-angles to the Hall, and occupying nearly the position which the Early English building at the north-west angle occupied.

Now, in the first place, as to the uses of these new structures; for architecture, as we all know, is based on utility,—at least, we have all been told so often enough. The lower story of the new north-west building is to be put to a very good use; it is to have an open arcade towards New Palace-yard, and to be used as a shelter for horses and carriages instead of the shed or pent-house at present provided. The lower story or cloister of the other portion is to be an elongated *porte-cochère*, reached by a drive from the corner of New Palace-yard down to the south end of the cloister, turning sharp round into it. Doors will be provided with steps up into Westminster Hall from the cloister. In regard to this part of the work we have to observe that the turn into the cloister is inconveniently sharp for carriages, that the width of the roadway is 14 ft., and the clear height to the main beams of the floor above 12 ft. 6 in.; that the first dimension is a tight fit for large carriages to pass each other, which may at times be necessary, and that the height is equally a tight fit for the largest dimensions of carriage with the most imposing order of coachman. As to the upper stories, no use is suggested for them at all; there is only the general feeling that they are sure to come in useful. They would, however, come in more usefully if it had been settled for what they were to be used, and if they had been planned for that use. The fact is, the Law Courts have been removed before there was any notion what was to be put in their place, and now something must be put, useful or not.

The real use of the cloister building, in fact, according to the statement of the Report, is to preserve the old wall, and to restore what was there before. As to the first point one may ask, are the old walls to be left (the original portions of them) in their present state above and below? If so, they will look very unsightly, and the architect will be doing work in a way which no Medieval architect would have been content with. We observe, by the way, that there is no indication in the plan of the upper floor as to what is to be done with Kent's odd-looking ogee-headed doorway, across which the new floor will cut. It is indicated below, but seems to have been forgotten above. Secondly, will the open cloister afford much better protection to the lower part of the wall than at present? We should say, not any protection worth the money to be expended (21,000*l.*), if that were the object. Then, architecturally speaking, what is the value of the idea that we are to have restored what was there before? We must entirely decline to admit any value to the proposed addition on that score. If a complete portion, a complete bay for instance, were left to go by, then the rebuilding of the rest to the same design would simply be completing a design which was incomplete. But it is not the case with this restoration. There is not a single existing bit of design for exact imitation. It is all inferential. It is a strong inference that *something of that sort* was there; that is all that can be said. It is absurd to say that we are restoring, even in design, what was there before. And therefore such so-called restoration is archeologically not of the slightest value, and to represent it as such is to "say the thing which is not." *Au reste*, Mr. Pearson's work is in true Gothic spirit, and looks solid and good. But it will not, as we are told it will, add anything to the architectural dignity of the exterior of the Hall. It hardly does so in the perspective

drawing; and it will not look even as well as it does there. The level of the cloister will be far below the level of the public roads; it will stand in a hole, and be approached downhill; and it will be further bidden behind the tall and elaborate railing of the precinct, which must be continued on the same design, both for appearance and protection, but which in the drawing is artfully reduced to a low railing that a boy can look over (or climb over). That and the appearance of the levels we regard as a little bit of draughtsman's jugglery, to beguile the unwary spectator. Our conclusion is that a great deal of money is going to be spent on building which, except the shelter towards New Palace Yard, will be of little practical use or convenience; which will only half fulfil its proposed duty of protecting the exposed surface of the old wall; which is *not* a restoration, in the true sense, of what previously existed, and which, in its relation to the whole, has no architectural value commensurate with its cost. Bearing in mind that the Hall is essentially a central hall, that it was never meant to be seen all round, and that it probably was in former times hidden by buildings to the westward of it, a far more truly sensible architectural scheme would be to make use of the vacant ground for building a large range of committee-rooms and other buildings up to the street, which would be of real use, leaving a courtyard between them and the Hall, and then repairing the buttresses and old work of the wall of the Hall in a purely practical manner, rebuilding the buttresses and flying buttresses. The present scheme appears to us to rest on the assumption that the design of the Richard II. period was essential to the architectural completeness of the Hall, and was intended to be seen; whereas, we believe it was mainly utilitarian, as far as the buildings between the buttresses were concerned, and was very probably not seen, except from an enclosed courtyard.

The other portion of the scheme, the addition to and alteration of the north front of the Hall, appears to us to be desirable and an improvement. It is true, as we have seen it already well observed in a daily paper, that a "Hall" of this type has really nothing to do with a western façade and towers; but then on the north side it must always now remain open to New Palace Yard, and therefore can never again have the character of a central hall as far as that aspect is concerned. It has been all re-faced already, and, as the Report says, has "a spurious aspect," as well as looking somewhat mean in connexion with the rich architecture of the new "palace." The raising of the towers will give greater dignity to the whole, and will serve the intended object of connecting the north front better with Barry's adjacent work; and this part of the scheme, therefore, we can sympathise with and recommend.

#### THE PENISTONE DISASTER.

WHAT are the lessons to be learned from the Penistone accident? The facts do not seem to be capable of much dispute. An ordinary express engine, with a four-wheeled bogie in front and four coupled wheels behind, is descending a gradient of 1 in 124, on a half-mile curve, and with a tolerably heavy train behind it. The speed is high,—something between forty and fifty miles an hour,—but not excessive. One of the cranks of the driving-axle breaks suddenly, right across the outside web. The connecting-rod flies round, digs into the ground, doubles up, and breaks off. The engine and tender are thrown into violent oscillation, lurching heavily, and the engine leaves the rails. The driver puts on his brake,—the ordinary vacuum,—and stops his engine in some 200 yards. The tender and a horse-box following it keep the rails, until the engine has nearly come to a standstill; but the violent lurching is, of course, communicated to the train and is intensified by the centrifugal force on the curve. Such an action would necessarily bring a heavy horizontal bending stress upon the heads of the draw-

bars connecting the carriages to each other. In this case the draw-bar between the horse-box and the first of the carriages yields to this stress, and is broken clean off close to the head-stock. The safety-chains fail to hold the train on the draw-bar breaking; the carriage separates from the horse-box, goes off the curve at a tangent, and takes the rest of the train with it. In a few seconds the whole is piled up in inextricable and hideous confusion at the bottom of an embankment, and a slaughter has taken place comparable to that of many combats recorded in the pages of history.

The first question to be asked is,—How came the crank to break, since this was undoubtedly the primary cause of the accident? This point also is quite clear. All the witnesses speak to the existence of a flaw in the web of the crank on the inside, extending some 2 in. into the metal. The surfaces were not rusty, showing that there was no opening to the outer air, and probably, therefore, no crack on the outside which could have been detected by the eye. The crank had, in fact, been properly examined but a short time before, and there seems no reason to suspect any neglect in the running shed. The axle, which had already run about 50,000 miles, was of "Best Yorkshire" wrought iron, supplied by Messrs. Taylor Bros., of Leeds, than whom no firm enjoy a higher reputation for this class of material. All engineers know that such flaws do occur, though rarely, in the very best wrought iron, and that no ordinary test or examination will necessarily detect their presence. Is the character of the metal itself in fault? Mr. Daniel Adamson, the chairman of the Manchester Ship Canal Company, who has written a lengthy letter to the *Times* on the subject, appears to consider that it is. He says, "The public mind should be disabused of the belief that proper security can be obtained with a very strong metal." We were not aware that the public mind had been abused by the introduction of any such belief, or, in fact, had formed any judgment whatever upon this point. But the criticism is itself a very curious one; for the metal in this case was the best and purest wrought iron, softer and more ductile than the "mild steel" with which Mr. Adamson would insist upon replacing it. Now, it is quite true that railway engineers, even in England, have very much come round of late to the expediency of employing mild steel for railway-axes. They admit that the treacherousness, the liability to hidden cavities, and sudden fracture, which were urged with much justice against ingot metal in former years, are no longer fairly chargeable to the mild steel made for such purposes as axles by our most eminent steel-makers. Still, it will be news to them that the metal is actually so far superior to the much more expensive material known as the best Yorkshire iron, that it should be in all cases substituted for it; and they are hardly likely to take a boiler-maker's dictum to that effect. In fact, the substitution of what is supposed to be a more uniform metal would be a matter of regret, if it were at all supposed to supersede the rigid system of inspection to which every axle is now subjected. What is really needed is some system,—could such be devised,—by which the occurrence of those hidden flaws which the very best metal made by the very best process will sometimes contain, should be rendered patent to the eye of an inspector. Is there any chance of such a system being devised? It is clear that chemical tests, on which Mr. Adamson would rely, are quite useless; they can tell nothing but the general composition of the metal. Electrical tests may possibly yet be used with effect. They were proposed some years ago, and have been revived lately by Professor Hughes, the inventor of the microphone. With his beautiful instrument, the "magnetic balance," he has proved that in wires or small pieces of iron, almost all peculiarities of the metal, including the existence of flaws, can be detected with ease and certainty. His invention has been freely given to the world, but hitherto the world (as usual) has been wholly indifferent to the gift. So far as we are aware no railway or marine engineer

has taken any steps with a view to ascertain whether a similar system might not be applied to pieces of large size, such as those required in actual work. Failing this, mechanical tests in a proper testing machine do not seem impossible. If the axle which broke at Penistone, before having been set to work, had been subjected to a sudden cross-breaking strain, similar to that which caused its destruction, but very much below what it should be able to support with safety, we cannot doubt that the resulting deflection or bending would have been far greater than if the axle had been sound. What we would suggest, therefore, is that all crank axles, or other pieces of metal called to fill equally important positions, should be tested by strains similar to those brought upon them in actual work, and that their deflection under those strains should be recorded. A few experiments would be sufficient to show clearly how great this deflection should be in the case of a sound and perfect axle; and if any specimen showed a deflection decidedly higher than the limit, it should be rejected as of doubtful quality. The expense of such a system would not be great when it once became a regular part of the manufacture of an axle; and it appears to us the only method by which a single faulty specimen can be weeded out from a batch of sound and satisfactory articles.

The question of the use of the crank in the locomotive seems to require investigation. It is obvious that occasions of imperfection must occur in the forging of so complex a piece of ironwork as a double cranked axle, which are avoided in the manufacture of plain axles. The Returns of the Board of Trade, if duly examined, will show, or ought to show, whether in point of fact there has been any difference in the proportion of fracture of straight and of cranked axles, confining the inquiry to driving axles alone. The question of inside or outside cylinders, which is determinative of the use or the avoidance of a crank in the axle itself, is one on which much difference of opinion exists among engineers. But it is highly desirable that some authoritative decision should, if possible, be obtained as to the effect on the public safety of using or of dispensing with the cranked axle.

Leaving here the question of the crank, let us go on to consider the parting of the train at the coupling between the horse-box and the carriage. This was, in fact, the second cause of the accident, since, if these couplings had held firm, the whole would probably have been brought to a standstill with no worse evil than a good deal of shaking. Now, in the first place, it seems clear that the draw-book was broken by a strain to which it is never supposed to be subjected. A draw-hook and draw-bar are made to resist a direct pull, such as is brought upon them in starting or running, and for this they may be amply strong. But there can be no doubt that the strain which broke the draw-bar at Penistone was a strain acting in a direction more or less perpendicular to the length of the train, and due to the violent horizontal lurching of the two vehicles connected by the draw-bar. Probably no engineer, in fixing the dimensions of his draw-gear, has ever taken account of this particular kind of strain; nor, in fact, would it be possible to say how great its amount may be. It is one of those cases which are altogether abnormal and exceptional, and, for that reason, all the more likely to be fatally disregarded. Secondly, it is well to note that a draw-bar having given way, the safety-chains should have come in to vindicate their name, and save the train from parting asunder. As a matter of fact, they failed to do so. Where they broke, and how and why, no witness seems to have thought it worth while to record. We have here a moral pointed for us which has been drawn over and over again,—the moral that safety-chains (which are well-nigh universal on the railways of the world) are in plain words "a snare and a delusion." It must be remembered that these chains are necessarily lung slack, and, therefore, whenever a strain does come upon them (which is, of course, very rarely), it is in the nature of a very violent shock. Such a shock seems almost always in practice to be sufficient either

to fracture a link, or to draw the bolt from its fastenings in the head-stock. It will be well if English engineers should be taught by this terrible disaster to take heart, and abolish safety-chains henceforward; throwing the metal thus saved,—or, at least, some part of it,—into the neck and hook of the draw-bar, with a special view of rendering it secure, not only against a direct pull, but also against any cross-breaking strain, such as seems here to have proved so fatal.

Other lessons have been drawn by other parties, and may be taken for what they are worth. Thus Mr. Adamson, whom we have mentioned before, would insist on increasing the depth of our wheel-flanges from 1½ in. to 2 in., forgetful of the enormous expense which such a change would involve. Another correspondent in the daily papers lays all the blame on the fact that the horse-box had presumably four wheels; but as this horse-box kept on the line while the six-wheeled carriages failed to do so, his conclusion scarcely seems to follow from his premises. More than one of our contemporaries has seized the occasion to proclaim once more the defects of the vacuum brake, and to imply that if the Westinghouse brake were in use on the Manchester, Sheffield, and Lincoln Railway, we should not have this disaster to deplore. We are by no means interested in the vacuum or any other brake, but considering that the draw-gear broke very shortly after the disturbance began, and that the carriages then went immediately over the embankment, we fail to see that any brake could have done much to mitigate the disaster. Other lessons will, no doubt, emerge from the details, when these are fully known and considered; but we are inclined to think that those we have touched upon will be found at least to be among the most important. They may be summed up as follows:—

First. Necessity for some method of testing, not a sample out of every lot of axles, but every axle which has to fill an important place, in such a way as will insure its freedom from serious defects. Secondly. The unconditional abolition of safety-chains, and an increase in the section of draw-bars, especially with a view to meeting cross-breaking strains no less than direct pulls.

SURVEY OF WESTERN PALESTINE.

THE literary and graphic record of the survey of Western Palestine is now completed by the publication of two quarto volumes of memoirs, and an atlas of fifty plates. The volumes in question deal, one with the fauna and flora of Palestine, illustrated by beautifully drawn and coloured plates; and the other with Jerusalem, containing upwards of eighty illustrations. The atlas, or rather portfolio, contains plans, elevations, and sections, showing the results of the excavations at Jerusalem executed from 1867 to 1870 by Captain (now Lieut.-Colonel Sir Charles) Warren, R.E.; and the amount of positive information that is thus brought before the world may be estimated by the fact that the first two sheets enclosed contain a plan showing the actual rock-contours of Jerusalem on a scale of 2500, or 2166 feet to the inch. Important as are all the records and descriptions of the ancient masonry, which are very clearly given in this series of plates, it is obvious that in the rock-contours we are presented with the very skeleton, so to speak, of ancient Jerusalem. The vast piles of rubbish, amounting in some cases to a depth of upwards of 70 ft., that have resulted from the successive overthrows and destructions of the city, have so far masked the original surface of the ground, that many points have been long and keenly disputed, the key to the right comprehension of which is at once given by the recovery of the ancient levels, which formed the starting-points of the early builders.

A special value attaches to the Jerusalem volume of the memoirs, from the fact that, while stating in the plainest manner the various points as to which such ardent controversy has so long raged, it does so without entering on the arena of dispute. Remarkable pains appear to have been taken to enable the

student to form his own conclusions from the rich mass of evidence now exhaustively brought before the world. The volume commences with a chronological synopsis of the history of Jerusalem, giving the chief events, from the date of the first recorded siege, or capture of the city by David, about B.C. 1044, to the execution of the Ordnance Survey, in 1864. As many as twenty sieges occurred during this period; that resulting in the capture of the city by Saladin, in 1187 A.D., being the twentieth. The last record of the walling of the city refers to the work of Soliman the Magnificent, in A.D. 1542; and the last record of destruction is that of the burning of the Holy Sepulchre Church in 1808.

The first chapter of the memoirs deals with the architectural history of Jerusalem, commencing with the remarkable scarps in the present British cemetery, which are thought to be a portion of the very earliest defences of the citadel. This chapter is exhaustive of the bibliography of this part of the subject; and is illustrated by a plate containing five plans of the Church of the Holy Sepulchre, referred to as,—1, Constantine, A.D. 335; 2, Modestus, A.D. 616; 3, Arculfus, A.D. 680; 4, Nicephorus, A.D. 1048; and 5, Baldwin, A.D. 1103.

The second chapter gives the history of Jerusalem exploration, citing the records that exist from the earliest Christian account of the city, given by the Bordeaux pilgrim in A.D. 333, down to the clearing out of the Muristan by the German Government (1872-74), and the exploration of the Zion scarp by Mr. Henry Maudslay, in 1874. This chapter is followed by a statement of the principal controversies, indicating the points relied on by the advocates of the different views. The ground is thus cleared for the historic description of "Explorations in Jerusalem," seven distinct chapters on which occupy the remainder of Part I.

Part II., on "The Environs of Jerusalem," commences with a key-map on the scale of 2 in. to a mile, showing the Arabic nomenclature, and new buildings, ninety-six indications being referred to in an accompanying table. This chapter opens by an account, illustrated by a tracing of a squeeze, of the very ancient Hebrew inscription discovered in a rock-cut tunnel in 1880. A short chapter gives copies or facsimile reproductions of the various ancient inscriptions as yet collected at Jerusalem; and Part II. concludes with a chapter on the Holy Sepulchre.

It is in this chapter, which has to be read together with that on the "Holy Sepulchre and Calvary" in Part I. (p. 112), that many persons will find the most intensely interesting result of the entire labours of the officers who have surveyed the Holy Land. With one important class of readers, to whom the weight of ecclesiastical tradition is conclusive, there is, of course, no question open. It is accepted by them almost as a matter of faith that the sites of the crucifixion and of the entombment were known to Constantine, and protected by that emperor by the church of which the successor yet stands. To those persons who do not take this view, two questions arise,—one is as to the site of the Church of Constantine, and the other is as to the reliability of the assertion that that church stood on the very site of the events which its erection commemorated. As to the first, no one but Mr. Fergusson, we are told, doubts that the basilica of Constantine stood on the site of the present Church of the Holy Sepulchre. Mr. Fergusson's view is founded on architectural considerations alone, and these are controverted by the Duc de Vogüé. It involves, among other difficulties, the rejection of all the statements of early writers on the subject, the assertion that the magnificent Kufic inscription round the Dome of the Rock is a forgery, and the theory of a change as to traditional identification of the spot somewhere about the eleventh century.

The question as to the accuracy of the indications given to, or by, Constantine, will to many people seem more perplexed than that of the real locality of the basilica reared by him. The writers on both sides are cited in the volume before us. But to those who regard Jerusalem as a military position, as well as

to those also who are aware of the extreme rigidity of the Jewish law as regards places defiled by the death of a Jew, the rock-entour levels above referred to conclusively show that the site of the Holy Sepulchre Church is within the ancient, as well as the modern, city, and could not, therefore, have been the locality either of a place of execution or of a tomb. The traditional site of the place of execution by lapidation has now been recovered. It is on a knoll without the city, at a height of 2,550 ft. above the sea, or 110 ft. above the Sûkrah rock in the Haram enclosure, and is surrounded by a sort of natural amphitheatre from which the entire population of the city could witness what took place. In 1881 a smaller knoll at about 200 yards distant from the former was found to contain a Jewish tomb,—of which a plan is given in the account, first published in 1881, which gives Captain Conder's reasons for suggesting that this may be the veritable site of the tomb of Joseph of Arimathea. All other proposed identifications shrink to nothing in their interest compared with that of the true Holy Sepulchre.

Plates 48 and 49 reproduce reconnaissances of the plain of Philistia, and of the Jordan valley, by Lieut. Warren, in 1867. Although superseded by more detailed work since, these sketches of the country have great historic interest, and show how, step by step, the Palestine Exploration Fund pushed forward to obtain that complete knowledge of Syria which is now before the world. Exploration east of the Jordan, as is but too well known, has been arrested by political events, but enough has been done in Moab to render clear certain points which had perplexed the officers of the survey in the Holy Land, such as the occurrence of certain hollows cut in the rocks at conspicuous stations. Such hollows have been found also east of Jordan, always associated with cronelechs, dolmens, or other megalithic remains; and the absence of the latter, but presence of the former, in east-Jordanic Palestine, is held to point to the cleansing of the Holy Land from the structures associated with the pagan worship that prevailed before the Exodus.

Colonel Warren's plans are clear and exhaustive, and bring at once before the eye the result of an incredible amount of patient toil. The sections, as well as the plans, are drawn with that accurate skill for which the Royal Engineers are deservedly famous, and the drawings of the prodigious masonry yet standing in part of the wall of the noble sanctuary, or Temple enclosure, are beautifully finished, and faithful.

An appendix contains an account of the plain of Philistia, illustration of plate xlviii., by Colonel Warren, which was published in the quarterly statements of 1871; and one of the expedition to the east of Jordan, in July and August, 1867, illustrative of plate xlix. There is also a short notice of the pottery and glass found in the excavations, several plates of drawings of which are in the portfolio. The accuracy of the work, the fidelity of the records and sketches, the exhaustive examination of the country, and the faithful attribution to each member of the successive exploration parties, of his own work, combine with the excellence of the work of the printer and of the engraver, to make this volume a worthy monument of an exploration that does honour to our country and our era.

The excellent volume on the fauna and flora of Palestine is unapparently deficient in having neither table of contents, index, nor list of illustrations. The latter include beautiful coloured plates of the *Hyrax Syriacus* (the coney of the authorised version); the Syrian Bedin or ibex (the wild goat of the authorised version); six species of *Acomys*, or field mouse, and kindred species; the mole rat (*Sipylax typhlus*); and the quaint little jerboa (*Dipus Hirtipes*), among mammals.

The birds are illustrated by the white-throated robin (*Erithacus gutturalis*); the lovely Palestine sun bird (*Synæris oser*); cock, hen, nest, and young; Tristram's scree (*Scrivus canonicus*), and the Moabitic sparrow (*Passer moabiticus*); the Desert rock sparrow

(*Petronia brachydactyla*), a rare bird; the orange-winged blackbird, or Tristram's grackle, a species peculiar, as far as is known, to the immediate neighbourhood of the Dead Sea; a night-jar of peculiar colouring (the *Caprimulgus tamaricis*); and a curious and admirably-drawn species of darter (the *Plotus Levaillantii*), which hants and fishes in the Lake of Antioch. Three plates of reptiles and four of fishes, uncoloured, complete the illustrations of the volume, which is from the pen of Canon H. B. Tristram.

## NOTES.

**T**HE Committee appointed to consider the laying-out of Hyde Park Corner have stated that they are now in a position to invite subscriptions for three specified objects:—1. The laying-out of the place architecturally with suitable decorations, including candelabra. 2. The completion of the arch in the manner originally designed by Decimus Burton, with bas-reliefs round the "pediment" (query—"podium"?) and the erection thereon of a quadriga in bronze carrying a figure of Victory. 3. The provision of a suitable pedestal for the existing statue, and its erection thereupon at Aldershot. As to the latter item, we have already said that we consider it the best proposition that has been made for dealing with the colossal statue. As to the second proposition, having for years repeatedly urged that Burton's design should be completed according to his original intention, we are glad that this should be carried out, although we may observe that the suitability of such a termination to the arch is greatly lessened now that it is removed from its position as part of a monumental approach to London, and reduced to a mere park entrance, connected with nothing, and grouped with nothing else on the site. As to the first point, the laying out of the site, it seems to us perfectly unreasonable for the Committee to expect any subscriptions until they publish a plan showing what they mean to do, and no plan can possibly be satisfactory which does not commence by starting afresh, and obliterating all the lines of the present so-called "laying out" of the place, which is simply an estate agent's plan of the most commonplace description.

**T**HE question put to the Chairman of the Metropolitan Board of Works by Mr. Gray, in the House of Commons, on Monday last, refers to what appears to be a serious defect in the law affecting the construction of large buildings in the metropolis. A large hotel is in course of erection in Northumberland-avenue, with a lofty curb roof containing two stories, and in parts three stories of rooms, these rooms being enclosed with wood covered externally with slates. Sir J. McGarel-Hogg, in reply to the question, informed Mr. Gray that the building was constructed in accordance with the Metropolitan Building Act, and that if any alteration in the law was required it could only be effected by special legislation. In America the disastrous fire in the city of Chicago called the attention of the authorities to the danger from fire resulting from the construction of several stories in roofs composed almost entirely of inflammable materials, and the employment of Mansard roofs was forbidden unless wholly constructed of fire-resisting materials. The use of this form of roof has been hitherto restricted in this country, but there appears to be a growing disposition to adopt it in the case of large buildings, and it is well that attention should be called to the ease with which fire may be communicated from one building to another by this means.

**T**HE "Sanitary and Insanitary Houses" at the Health Exhibition will be open to the public next week, and on the method on which they have been arranged, will probably prove the most really instructive item in the whole exhibition, if visitors take advantage of the opportunities of instruction afforded them. The houses are arranged so that visitors enter

at the ground floor of the Insanitary House, and, after passing through its various attractions up to the top floor, they cross over to the Sanitary House, and descend through it. Every item in each house will have a label attached to it, and a small handbook is in preparation bearing the corresponding labels as marginal headings, accompanied by a short paragraph, giving, in plain language, the reasons why each arrangement is good or bad. The sub-committee for getting up the houses, consisting of Captain Galton, Professor Rogers Field, Professor Corfield, Mr. H. H. Collins, and Mr. Ernest Turner, have had an uphill fight to get the site and the money for erecting the houses; and great credit is due to them for the result, and for the manner in which it has been worked out.

THE current number of the *Quarterly Review* contains a readable article on Mr. Ferguson's "Parthenon" and "Temple of Diana," generally supporting his views, especially in regard to his very ingenious explanation as to the number of columns in the Temple of Diana, and the means of providing for the number specified by Pliny, to which we referred in reviewing Mr. Ferguson's work a little while since. The Reviewer calls this suggestion of the nine-columned back elevation of the temple, as supplying the uneven number (127) in the text of Pliny, "a stroke of real genius," and the expression is just. The article suggests nothing new in archaeological criticism. The writer has made a very absurd slip in representing Bacon as saying that some ancient monuments were to be "chewed and digested." Bacon never used a simile which, in relation to a temple, would seem so absurdly far-fetched. He used it of the contents of books, "some of which were to be tasted, some swallowed," &c.

ACCORDING to Mr. Bailey Denton, the minimum flow of water at Teddington is 450 million gallons daily; but it is doubtful if even that quantity has been available during the last two months. Mr. Phillips Eevan, whose pamphlet was reviewed lately in the *Builder*, states the average daily supply taken in January last for the supply of the metropolis by the several companies from the Thames to be nearly seventy-one million gallons; so that Mr. Labouchere's estimate of one-seventh is below the mark; while that assumed by Mr. Thrupp,—viz., two-thirds,—is altogether beyond it. That there should be some central authority for controlling the river Thames we are quite prepared to admit; but that a dictatorship should be accorded to Sir C. Dilke for that purpose, as suggested by Mr. Labouchere, is not quite apparent. As we have already more than once advocated, the real remedy for dealing with the water question for this country is the constitution of a Government Central Authority, to whom the regulation of the entire water interests of the kingdom should be entrusted, and to whom all questions of supply, drainage, floods, or transit should be submitted. The piecemeal legislation which has hitherto characterised our proceedings in those questions has been at the root of all our difficulties, and until this has been remedied by taking up the subject of water regulation as a whole, there seems but little prospect of their being satisfactorily solved.

THE indifference of the Government to the appearance of our public buildings is already sufficiently illustrated by the additions to the National Gallery and the Old General Post-office, where the sky-line has been destroyed by mean and incongruous excrescences; but if an additional proof were wanting of the disregard of art by public bodies, it is furnished by the recent erection of an iron shed on the inclosed space in front of the east wing of the National Gallery. The so-called "finest site in Europe" has been disfigured from time to time, first by a preposterous monumental column placed in its midst, then by the addition of commonplace statues on pedestals of different heights and sizes, then by the erection of a gigantic hotel overshadowing and dwarfing everything; but the crowning abomination is the erection of this iron shed. The trustees of

the National Gallery are men of culture; they are not unmindful of the appearance of the interior of the building in which the national pictures are kept; but they exhibit very little concern for the symmetry of its exterior.

THE Treasury have agreed to give the sum of 5,000*l.* towards the purchase of a site in Edinburgh for the New Museum of Antiquities and National Portrait Gallery of Scotland. The design for the new building (the cost of which, amounting to 20,000*l.*, was, as formerly stated by us, contributed by an anonymous donor), has been entrusted to Dr. Rowand Anderson. The loan exhibition of national portraits, in the rooms of the Royal Scottish Academy, continues to excite public interest. The works of Raeburn gain in public estimation both on account of their technical excellence and the truthfulness and force with which the characters of the sitters are brought out. Sir John Watson Gordon is equally happy in the latter respect, but is far behind his predecessor as regards dexterity of handling and brilliancy of colour.

THE fifth Congress of Italian Engineers and Architects will be held at Turin, from the 22nd to the 29th of September next. Foreign architects or engineers will be admitted on making application conformably to certain regulations, which may be obtained from the Secretary of the Società d'Ingegneri, &c., at Turin. Free entry into the rooms of the latter society will be accorded, during the period of the Congress, to any architect who brings a letter of recommendation signed by the President of the Architects' Society to which he belongs. Although Turin is not one of the special seats of early Italian architecture, there will be doubtless much to learn during the Congress, by any English architect who may find his way thither at the end of September, by which time we may hope that all fear of cholera will have disappeared.

ACCORDING to a well-informed correspondent, the show of sculpture in competition for the Wallace Memorial at Aberdeen, the designs for which were exhibited last week, was of a very inferior description, confirming what seems to be pretty nearly an accepted fact, that sculptors of eminence decline entering into such open competitions, where they have little chance of gaining either honour or more solid recompense. A limited competition to a certain number of eminent artists, by invitation, and with a fee to each competitor, would possibly have produced a very different result.

A DEPUTATION from the Society for the Protection of Ancient Buildings inspected, on Monday last, by permission of H.M.'s First Commissioner of Works, the drawings prepared by Mr. J. L. Pearson for the restoration of the west side of Westminster Hall, which are deposited in the library of the House of Commons, and afterwards made a minute examination of the buttresses and the exposed portions of the west wall of the building, accompanied by Mr. Taylor, of the Office of Works. The Society have it in contemplation to prepare a memorial to the Government with regard to the proposed additions to the hall and the treatment of the western wall, the greater portion of which is the work of Rufus, the original surface and the mason's marks remaining intact. If we read aright Mr. Pearson's report, however, the preservation of the original state of the wall is precisely one of his objects.

EVEN in these days of general dispersion of heirlooms it is not often that a genuine Mediaeval castle finds its way into the market. But at the present time there are two properties of, at any rate, feudal importance offered to public competition. One of these includes the extensive ruins of Middleham Castle,—a fortress peculiarly rich in historic memories. The Norman keep, built by Robert Fitz Ranulph soon after the Conquest, is almost the only part of the original structure that has survived, and is a grand specimen of massive masonry. Its dignity, however, is somewhat impaired by

the great height of the buildings by which it is enclosed, and which were erected,—chiefly in the fifteenth century,—to suit the sumptuous tastes and larger requirements of the Nevilles. The castle was often the residence of royalty. Richard Neville, Earl of Warwick,—the great "king-maker,"—entertained within its walls the ill-fated Edward IV., whose brother, the Duke of Gloucester, afterwards Richard III., made it his frequent abode. It will be remembered that he married Warwick's daughter and heiress, and it is said that their only son, Prince Edward, drew his first and last breath in Middleham Castle. After this period the building seems to have fallen into decay, and its ruin was completed in 1646 by the Parliamentary troops who did their work of destruction with characteristic thoroughness. To make the castle again fit for residential purposes is, of course, now out of the question, but there is much to be said in favour of its being acquired by the nation and placed under suitable custody. Independent of its claims to preservation, as the sometime residence of the last of the royal Plantagenets, it has an interest as having been the home of "the Last of the Barons," and, therefore, in a double sense, classic ground.

THE other property, better known to artists than to historians, is Boscastle (*i.e.* Botreaux Castle), on the north coast of Cornwall. The ruins are in themselves insignificant, and the memory of their founder is almost extinct, but the name still preserves some faint reminiscence of the baronial family of Botreaux, which was settled in Cornwall as early as the reign of Henry II., and sent one of its members as a Baron to the Parliaments of Edward III. The site is wonderfully beautiful and romantic, not far from Tintagel and other spots familiar to lovers of the picturesque and students of Arthurian lore. It may be added that Goodrich Court, which the late Mr. Blore erected for Sir Samuel Meyrick, is also offered for sale. The architect was very fairly successful in his effort to reproduce an externally faithful copy of the castellated architecture of the Edwardian era. The internal arrangements are, of course, far from being Mediaeval, and the famous collection of armour is no longer a part of the treasures of the Court. Contiguous to it, but not within the limits of the estate, are the beautiful ruins of Goodrich Castle, which every tourist has seen.

#### THE CHÂTEAU OF CHANTILLY.—I.

THE complete reconstruction of the Castle of Chantilly marks a date in its history, and adds to the interest felt in it by those whose imaginations have been kindled by a visit to this famous residence of the Comtesse Anne de Montmorency and of the great Condé. Each of these two great commanders, at an interval of two centuries apart, took up his residence at Chantilly, and employed his leisure in improving and beautifying it. Natural conditions of the soil have given to the Castle of Chantilly a character surviving all changes of style, taste, and fashion, and have influenced even those modifications imposed by the habits and necessities of modern life. The same conditions having also necessarily dictated the architectural course which has been adopted, it will be indispensable to our present purpose to examine them, as a means of tracing the reason and origin of much that has been done.

About twenty-five miles north of Paris, and two miles and a half from Senlis, in what was formerly the Ile de France, and is now the Département of the Oise, Chantilly rises from a varied, gently undulating, park-like country, on the borders of extensive forests. A rapid stream, La Nouette, formerly flowed through the marshy tract in the midst of which there rose abruptly an irregular mass of limestone rock, doubly protected by its height and by the stream surrounding it. These favourable conditions caused the spot to be chosen as the seat of a habitation as far back as the tenth century. Without carrying our researches to so early a period, and confining ourselves to feudal times, we find proof in various charters that in 1263 the fortified castle on the rock was a dependence of the

family of the Bouthilliers, who held office under the Counts de Senlis, their feudal lords.

Through William IV. de Bouthilliers, the castle descended to Jean de Clermont, Chancellor of France, who was killed at the battle of Poitiers; and by his will it passed to Guy de Laval (1356). From Guy de Laval it came to Pierre d'Orgemont, Chancellor of France and President of the Parliament; it was in his time that the Burgundians took possession of Senlis (1422), and when the English forced their way to the Isle de France (1425) Chantilly resisted and fell, being included in the list of fortified castles which were to be occupied by an English garrison. In 1429, when Charles VIII. reconquered Compiègne, Chantilly was restored to the d'Orgemonts.

Four years after these *travo vicissitudes*, Pierre d'Orgemont, third of the name, dying without issue, bequeathed the estate to Jean II. de Montmorency, grand chamberlain of France; and this is the origin of the possession of the fief by the Montmorency family (1429). Jean II. was succeeded by his son Guillaume, and Guillaume by Anne, who was born at Chantilly in 1493, and who was destined to become in course of time Grand Constable of France, the builder of the Chantilly of the Renaissance.

It was the end of the period of the Middle Ages,—that troublous time when part of the soil of France was still occupied by the invader,—and before the grandson of Jean II. had come to man's estate, France was in the full current of the Renaissance, Ravenna, Pavia, and Marignan had been fought, and Charles VIII., Louis XII., and Francis I. had made those famous expeditions into Italy which were to exercise so important an influence on the progress of French art.

There is every reason to believe that from the d'Orgemonts to the Montmorencys Chantilly retained its original aspect. It was in 1538, at a time when he was estranged from the Court, that Anne de Montmorency conceived the project of rebuilding the castle. The invention of artillery had rendered the means of defence proper to the Middle Ages practically useless; the greater or less elevation of a position no longer influenced its safety, nor was the depth of its trenches of the same consequence as heretofore. Notwithstanding the religions and civil wars which desolated France up to the close of the sixteenth century, the age had become more secure; the feudal system was overthrown, and the attitude of the nobles was no longer that of defence against a more powerful neighbour; the spirit of individualism and of adventure was, in fact, extinct. Architecture, the faithful mirror of the manners of the age, reflected alike in the planning and in the construction of buildings the changes which had come over the social conditions of the country.

This is not the place for sketching the rough, soldier-like features of the Constable Anne de Montmorency. Indeflexible alike to himself and to others, incorruptibly faithful to his country and his sovereign, Anne is the last man of the Middle Ages, the first "Grand Seigneur" of the Renaissance; the transition between the two periods is faithfully represented by the union in his character of brutality, violence, and egotism with high aims and strong feelings of duty and personal dignity. Rising to the highest political and military honours of the state, and possessed of an immense fortune, he resolved to transform the fortress in which his youth had been passed, and whose bare, stern walls were still pained with the blows of the Burgundians and the English, into a castle worthy of his wealth and grandeur, bearing the impress of that taste for the fine arts which he had acquired during his campaigns in Italy.

In the time of the Bouthilliers, of the Clermonts, and of the Orgemonts, Chantilly Castle rose from a triangular-shaped rock, surrounded on all sides by the river, whose course was accurately followed by the lines of the buildings. These were built round an interior courtyard, and abutted at the three corners against huge towers of defence. Beneath the ground-floor, which was on a level with the flattened summit of the rock, vast subterranean chambers were hollowed out, forming a complicated network of passages, hiding-places, covered communications, and rooms for domestic purposes, and for the use of the Corps de Garde. This part of the castle was lighted from the trenches, which were steep, and it formed a solid and majestic base for the massive erection above. The limestone rock upon which the

castle was built communicated with the plain below by a natural incline of very gradual ascent, which gave easy access to the east front. On the north side the slope ceased abruptly, and was replaced by huge steps cut in the steep rock. Whether natural or artificial, this terrace still exists, and is known as "Le Connétable." It gives access now, as formerly, to the principal front of the castle, which was isolated by means of a wide moat, and connected, both in the building of the Middle Ages and in that of the Renaissance, by a drawbridge between two towers, whose massive buttresses can still be traced.

Andronet Ducerceau, in his celebrated work published in 1579, "Les plus excellents Basti-

lower level than the castle, of course) upon which to erect an annex. This is the "Châtelet," the upper story of which corresponds with the ground floor of the old castle. The subterranean buildings were brought into the plan, and being enlarged by continuing the excavations in the rock, were made use of for all the household, civil and military offices. We may date from this time the truly exceptional importance of these vast subterranean chambers, so spacious and comfortable, as to remind the visitor of the similar structures at the Palais de Justice.

The plans preserved in Du Cerceau's work give us the Chantilly of the Renaissance as it was, and relieve us from the necessity of studying the edifice of Joan Ballant in detail.

Plan: Chantilly in the Sixteenth Century.—From Du Cerceau.

ments de France," has preserved the plans and elevations of the building with which the Constable Anne de Montmorency replaced that of the Middle Ages. He summoned the aid of a young man named Jean Ballant, who had lately returned from studying the monuments of antiquity in Italy, and was already reckoned among the distinguished architects of the day. Jean Ballant was associated with Philibert Delorme in the building of the Tuileries, and he it was to whom Catherine de Medicis entrusted the erection of her famous "Hôtel de Soissons" in Paris, of which one tower, intended for astronomical observations is still standing close by the "Halle aux blés." He added to his fame by two great works undertaken for the Constable, at Chantilly and at Ecouen.

Obligated by the nature of the ground to retain the triangular enclosure, and desirous of profiting by the labours of the engineers of the Middle Ages who had excavated the subterranean buildings, Jean Ballant contented himself with introducing the richer style of the architecture of the Renaissance into the façades opening upon the interior courtyard, and kept the massive towers of the exterior, which gave the castle its character as a fortified building. The Constable had a large family, a numerous retinue, a military establishment, and a body of troops, for whom accommodation had to be provided; the architect, therefore, came beyond the walls, threw a bridge over the moat, and selected a site on the south-west (at a much

One point, however, we must take note of, viz., the means of communication between the subterranean chambers and the terrace called "Le Connétable."

An agreement with the builders, bearing date 1538, proves that Jean Ballant, by equalising the steps of the terrace, underpinning the retaining walls upon the trenches, decorating them with gurgoyles to carry off the rain, and probably also by re-arranging the subterranean passages and chambers, gave to that part of the building the massive aspect it has ever since retained; it was he who christened it "Le Connétable."

Anne de Montmorency, dying in 1567, left his castle to his children, and it was in possession of his grandson, Henri II., Governor of Languedoc, Maréchal de Montmorency, when he was made prisoner at Toulouse in rebellion against the king; he was beheaded in 1632. This Montmorency married an Orsini, who, having been educated in Italy, had brought with her the architectural ideas of her country. It was she who directed the construction of the grand staircase on the north side of the castle, leading to "Le Connétable," and thence to the galleries and the ornamental water. The great allegorical groups of statuary peopling the niches, the huge vases, the heavy columns adorning this majestic staircase, remind us of the Florentine artist Ammannati, and of the gardens of the Pitti Palace, and other Italian villas. The staircase itself served as a colossal pedestal for the equestrian statue of the Con-

stable, which was overthrown during the Revolution. The rebellion and execution of the Maréchal de Montmorency led to the confiscation of his property; but Louis XIII. restored Chantilly to Charlotte de Montmorency, sister of the Maréchal, and she brought it as her dowry to her husband, Henri de Bourbon, Prince of Condé, father to the conqueror of Rocroy.

The great Condé (1621—1682) wrought a complete transformation in the architectural aspect of Chantilly, and this he accomplished under much the same political circumstances as those which had influenced his famous ancestor, the Constable Anne. He, like the Constable, was at the time living in retirement on his estate, suspected by the Court, and holding aloof from public affairs. At the commencement of the seventeenth century Chantilly still represented the refined age of the Renaissance, with a reminiscence of the Middle Ages; the great Condé succeeded in making it a striking example of the new architectural period that has received the name of the reign which witnessed its birth in France, and the grandeur, the magnificence, and the theatrical ostentation of which it so faithfully reflects. We must not neglect to note one circumstance of some importance in the history of French architecture. Chantilly Castle and gardens are of earlier date than Versailles, and, great as may be the disproportion between the two, it is, nevertheless, certain that it was after his famous visit to the conqueror of Rocroy at Chantilly that Louis XIV. determined upon employing Lenôtre to lay out the gardens of Versailles.

Condé rebuilt the whole castle with the exception of the Châtelet, the exterior of which was left untouched, while the interior was decorated according to the taste of the age. It was no more possible for Lenôtre than for Jean Bullant to ignore the conditions imposed upon him by the nature of the ground and the successive works of his predecessors in the solid rock. The triangular inclosure remained; even the corner towers were left standing, contrary as this was to the prevailing taste; those which broke the principal façade, right and left of the only entrance by the "Comptable" were razed to the height of the drawbridge, which was done away with and replaced by a front, resembling in its main features the porch of the Invalides.

Magnificent as were the proportions of the new building, its lines were of an extreme simplicity; the central design was crowned by a high-pitched roof with trophies at the two corners; the façade to the right and left consisting of a ground floor, an upper story, and a "Mansard" story, in the style of that at the Invalides, was pierced by windows (without architraves), with a balcony extending the whole length of the front. The building abutted at its northern and southern extremities upon the two corner towers, which were surmounted by observatories.

The plan of the Louis XIV. building was extensive and of magnificent proportions. Air was admitted to the subterranean chambers, the passages were widened, the military offices swept away, to make room for that exclusive attention to the "service of the table" which was required in order to provide, at any given moment, for those sumptuous banquets described by Madame de Sévigné which the tragic death of the "great" Vatel has rendered famous in history.

The principal staircase to the upper stories, placed in the southern angle of the court, was of enormous proportions; so also were the rooms, which all, from the antechambers to the galleries and the cabinets, bore the name of the King.

As we have already said, the Châtelet alone preserved its architectural character, the great Condé making it his personal habitation. The vast hall which looked upon the "Félonie" (the race-course) was magnificently decorated in the taste of the time, and entered from the famous "Salon des Singes," a unique example of a witty idea rendered by a skilful pencil. The Prince caused the warlike achievements of his father to be depicted on the walls of the great hall, leaving space for his successor to add the representation of the battles which had been won by his own valour.

Our space, too limited for its proper purpose, will not allow us to describe the gardens laid out by Lenôtre; it is only possible to do justice to their magnificence by examining the series of engravings of the seventeenth century, which

illustrates the royal visits to Chantilly. Anne de Montmorency had the genius of construction; and the Condés, by tradition, loved gardens and the chase; nor can it be denied that they loved show also, and sometimes mistook size for grandeur. This was notably the case with Louis Jules Henri de Bourbon, who, between 1719-1735, built the famous Chantilly stables of such unreasonable size that they ran the risk of spoiling the effect of the main building, had it not fortunately been preserved from so great a disaster by the distance of the stables, and the diminishing effect of the perspective. This pompous Bourbon had acquired enormous wealth by the timely sale of his shares in Law's famous bank, which had taken up its quarters in his own hotel in the Rue d'Arvoys, "L'Hôtel de Montmorency," called for the nonce "L'Hôtel de la Banque du Mississippi." The Château d'Enghien, built in 1772 in the space of four months, on the occasion of the birth of a Duc d'Enghien, lies to the east of the great castle towards which it turns its regular and finely-proportioned front.

At the time of the French Revolution Chantilly Castle, notwithstanding some alterations in detail, presented the same general appearance as in the time of the great Condé. An engraving of the 9th of August, 1789, representing the Revolutionary troops coming to take the cannons from Chantilly to arm the population of Paris, shows the castle as it existed on the eve of the great overthrow which was to leave no stone of it standing upon another.

The Reign of Terror came. The Condés emigrated; the Chantilly estate was sequestered, together with the majority of princely residences in France; the collections were dispersed, the statues destroyed; that of the Constable, represented as a hero of antiquity, his naked sword in his hand, which was placed on the "Comptable," was broken up; so were those of Henry IV., of Louis XII., and of the great Condé himself, the work of the sculptor Coyssier. The Museum of Artillery, which was said to contain a precious relic, the armour of Jeanne d'Arc, was dispersed; its principal contents, recovered at a later date, now form part of the Museum of the Invalides. The castle was converted into a prison under the Terror, and 1,100 prisoners were incarcerated there; then the "black hand" took possession of it, and dismantled it; finally, it was destroyed stone by stone, and the Châtelet was on the point of disappearing in its turn, when it was discovered that the possessors had not observed the terms of the bargain made with the State. The Ministry of War thereupon claimed the building for the use of the army, and a troop of cavalry was installed there; thus the great stables, the Château d'Enghien, and the Châtelet were saved.

Then came the Restoration (1815). Prince Joseph de Bourbon returned to France, and revisited Chantilly. The great castle was razed to the ground, and the cleared space levelled and enclosed by railings. In 1820 the last of the Condés, grand master of the hounds, who was fond of Chantilly, restored the Châtelet. It was then that a change was made of considerable importance in the history of building. From 1538 to 1820 the Châtelet was cut off from the upper castle by wide trenches and a drawbridge. These trenches were now filled up, and the two islands, upper and lower, were made into one. Other works were carried out of little interest from an architectural point of view, and the prince, who had hitherto resided at St. Len Taverny, had determined to take up his abode at Chantilly when his sudden death put an end to his intention. By a will, dated August 30th, 1829, the last of the Condés appointed as sole legatee his great-nephew and godson Henri Eugène Philippe Louis d'Orléans, Duc d'Anjou. The same will directed that the castle of Ecouen, Jean Bullant's *chef-d'œuvre* (also built by the Constable Anne de Montmorency) should be converted into a charitable institution. As such it is now in the hands of the administrative council of the order of the Legion of Honour. The final reconstruction of the castle of Chantilly was the work of the Duc d'Anjou.\*

**The Alexandra Palace.**—It is stated that the London Financial Association, as owners of the Palace and grounds, have let the Palace and the south portion of the park (exclusive of the racecourse) for exhibition purposes.

\* To be continued.

THE INTERNATIONAL FORESTRY EXHIBITION, EDINBURGH.

THIRD NOTICE.

AFTER passing the South African exhibits we come upon the Indian collection, which occupies the remaining bays of the central avenue to the right until the central transept is reached, of which it also occupies the whole south wing. It has been admirably arranged under the directions of Colonel Michael, C.S.I., who is considered the founder of practical forestry in India. The collection is the largest exhibited, and contains some splendid specimens of wood, every article being specially labelled, a practice which might have been generally followed with advantage. The "Index Collection," which has been sent from Calcutta, comprises about 800 specimens of trees from the various portions of India which have been alphabetically arranged and the geographical locality marked on each. From Bombay there is sent a fine collection of woods, which are cut so as to show the grainings and texture of the timber, both in its rough state and when varnished. There are important contributions from British Burma, and amongst these are beautiful specimens of teak contributed by the Bombay Burmah Trading Company. In preparing teak (*Tectona grandis*) for export the logs are sawn into squares. A market has to be found for such scantlings as can be cut from the slabs. The larger scantlings thus obtained are easily disposed of, and a fair price is obtained, although considerably below what the cost would be if cut of equal quality from the squares which form the bulk of the shipments. For any small sizes, however, say 6 x 1, the supply is considerably in excess of the demand, and such material can always be had in the principal markets of India at less than half the cost that would produce them cut from the square.

The logs shown are as imported to the European markets, but especially dressed and polished for exhibition. One is remarkable for its extreme length, the difficulty of bringing such very long logs from the forests being very great. Teak planks are principally taken off the sides of the logs during the process of conversion from the rough state into merchantable squares, and are much cheaper than if taken from the squares, while the quality is, if anything, superior, as the best wood is that nearest the outside. Teak is exclusively used for making wheel blocks, for the filling in of Mansel's patent railway carriage-wheel, which has for many years been considered the best for passenger carriages, as it is the only wood which will stand the tear and wear to which the wheel is exposed. The blocks are shown in their rough state as imported, and also in segments ready for use. A complete Mansel wheel is also shown. Teak railway keys are rapidly coming into use throughout Great Britain, the peculiar characteristics of this wood rendering it extremely useful and economical for this purpose, it being unaffected by heat, dryness, or moisture, while it is the only wood that can be used in close contact with iron without injury to either. The patterns shown are those used by three Scotch railways, and it will be noticed that two of those patterns are slightly tapered, the advantage of this form being that, while the keys can be more easily and firmly fixed into the chair, the wood retains all its elasticity. In the process of compressing and black-leading, which is generally a necessary feature in the manufacture of parallel keys (the form hitherto used in Great Britain), the valuable elasticity is greatly destroyed. From the small and refuse material are made step-ladders, and easels (the "Hatherly" patent), which from the lightness and rigidity of the wood are highly commendable. Two specimens of Robb's patent flooring are shown; one pattern is a sample of flooring for outside work, halls, &c., where considerable strength and great durability are the essentials; the other exhibits the patent as applied to flooring for public rooms.

The manner in which this wood can be employed in the most delicate work is shown in carved panels, cabinets, mantel-pieces, and articles of furniture. The Black-wood is another valuable tree largely used in the manufacture of artistic furniture, admirable examples of which are exhibited by Messrs. Peacock & Co., of Oxford-street. The Sissoo is another useful tree for wheel-work, it being related that the wheels of gun carriages which went through the tear and wear of the Afghanistan campaign

came back to India without a break-down having been recorded.

Amongst the specimens from the Andaman and Nicobar Islands is a slab, of great size, of the Poon (*Calophyllum inophyllum*), having a colour similar to that of light polished mahogany. Another tree, of which there are beautiful logs, is the Padook (*Pterocarpus indicus*) varying greatly in colour, some resembling cedar, others dark mahogany, and others having a dark scarlet tinge. Amongst the indigenous trees of these islands is the marble-wood (*Diospyros Kurzii*) with streaked markings of black and grey, which is used for cabinet-work. Fine specimens of chony come from Travancore, which display the black heart-wood surrounded by the lighter coloured sapwood. The luxuriance of vegetation in the Indian peninsula is exemplified by the bamboos exhibited, some of which exceed 80 ft. in length. Other interesting products derived from the Indian woods are medicinal barks, gums, resins, oils, perfumery, and dyes. The collection would be incomplete without examples of the native carved work, interesting specimens of which are lent by Sir Philip Owen and by the authorities at South Kensington Museum. Her Majesty and the Prince of Wales lend heads of forest animals, and His Royal Highness and suite are shown taking part in a tiger hunt, in a picture which gives a graphic idea of the situation, the odds against the wild beast appearing tremendous.

In an interesting preface to the catalogue of the Indian exhibits, Sir George Birdwood, C.S.I., gives to Edinburgh botanists the credit of having first called attention to the necessity for forest conservancy in our great Eastern Empire. About thirty years ago the Department of Forestry was originated by the East India Company, an impetus having been given to this important movement by the report of a committee on tropical forests, which was appointed at the Edinburgh meeting of the British Association in 1850. The grand primal forests were up till that time subjected to wasteful clearing, a process which would in time have subjected large districts to a state of barrenness, as has been done in Afghanistan through the disforesting of the uplands of that once fertile country. The Indian Forestry Department is now a great State institution, giving employment to thousands of natives, whose work is exerting an ameliorative influence on the climate and physical conditions of the country. As a result of tree-planting along the frontier towards Afghanistan and Beloochistan, it is interesting to learn that within the last ten years there is a gradually increasing annual rainfall in the Punjab and in southern Afghanistan, northern Beloochistan, and Scinde. Not only has this result followed, but it also appears that the Forestry Department has proved a financial success. Before 1848, we are told, the forest revenue was trifling. In 1881-2 it exceeded £74,000, the expenditure being 557,000, leaving a surplus of no less than 317,000, and by the development of the vast resources of the country this source of revenue may be greatly increased. The area of the reserved forests of India is 40,000 square miles, that of the unreserved has not yet been ascertained. The surveying of the Indian forests is being rapidly pushed forward under the directorship of Major Bailey, R.E. During the past year 361 square miles were plan-tabled on a scale of 4 in. to the mile, and 83 square miles triangulated; and the result of these labours may be seen on the walls of the Indian Court, in the shape of over 100 excellent maps.

#### THE NEW "MADAME TUSSAUD'S."

There is nothing to detain the mere student of architecture in the new building which now gives shelter to the famous wax-work show. It is not Gothic, nor, indeed, of any other assignable style, yet it illustrates one principle of Gothic design,—it is eminently constructional. Within is a long room; without, a long box. The whole building is admirably suited to its purpose. It is lighted, as it should be, from the top; the effect of its glass domes is not displeasing, and some art has been shown in relieving the monotony of the long expanse of the south wall. The gorgeous staircase from Baron Grant's ill-fated mansion in South Kensington is probably as well housed here as it could be anywhere. Thereby we approach, at an easy gradient, to a gallery of works the chief interest of which is not artistic. Lawrence's

portrait of William IV., which excited Hayden's wrath, presides proudly over the entrance-hall. The principal *salon* is a fine room, covered, suitably enough for its purpose, with a deep damask paper. To those unaccustomed to the splendour of courts, who regard statesmen with distrust, and pin not their faith upon princes, it suggests irresistibly how splendid a hall-room it would make, if this heterogeneous assemblage of rank and notoriety should take wings to itself and fly. We have one complaint against the show. The "Chamber of Horrors" is a mean apartment. De Quincey would have craved for these artists in murder a richer environment. Trade instinct, we should have supposed, would have suggested to Mr. Tussaud the propriety of giving to these favourites of the people a habitation at once richer and more awe-inspiring. They want some local colour; some more of the "trappings and snits of woe." They stand, huddled together, in a shabby, unfurnished chamber, altogether beneath their deserts. We are not that "shallow critic," decried by the great organs of the people, who "wonders at the public interest in great crimes, and finds fault with it." On the contrary, we do not wonder at all. We think, with De Quincey again, that a great murderer, like a great poet, must create the taste by which he is to be judged. But this he cannot do unless Mr. Tussaud will place him so that the full effect of his personality may make itself felt. As the room is at present arranged we may receive, indeed, a momentary shock: as from the awful resemblance between Charlotte Winsor and a collogue "bedmaker" of our early days; but we are not actually haunted by her memory. Finally, we must repeat that the arrangements for the reception of the "profession" are wholly inadequate whether we consider their own adventurous lives, or the number and high character of their admirers.

The life of Madame Tussaud herself is well worth study, and the works from her hands are infinitely the finest, as well as the fullest of interest in the exhibition. Her "Memoirs," published in 1838, twelve years before her death, contain most interesting records of the most terrible days of the Revolution. It requires no holdness of criticism to assert that there was genius as well as courage in the woman who produced those models of the murdered Marat, of the guillotined heads of Louis XVI. and Marie Antoinette, of Robespierre and the infamous Tiville. They are not pleasant sights, but they have a terrible historical interest. All these, and some more, were taken immediately after death by Madame Tussaud. She knew Voltaire, and, when no more than eighteen, took a model of him from life, which is, probably, the best work in the Exhibition.

#### NEW HALL OF THE BUTCHERS' COMPANY.

THE ancient hall of the Worshipful the Butchers' Company, formerly situate in Eastcheap, was pulled down to allow of the completion of the Inner Circle Railway, and the widening of Eastcheap.

The design of Mr. Alexander Peebles, F.R.I.B.A., F.S.I., for the new hall in course of erection in Bartholomew-close, in the City, was selected by the Court of Assistants from those submitted in a limited competition.

The chief entrance, in the centre of the façade, leads to the lobby, which will be enclosed with a handsome oak screen with double doors, all glazed with coloured glass in lead pantries, and thence into the hall, from which will ascend a handsome stone staircase. The committee-rooms, clerks' offices, waiting-room, lavatories, dressing and coat rooms will be upon the ground story, and the court-room, ladies' drawing and retiring rooms, upon the first story, whilst the large hall will be upon the second story, this arrangement being necessitated by the limited area of the site. Upon one side of the hall will be a musicians' gallery.

The kitchens and other domestic apartments, and those for the housekeeper's use, are upon the third story, approached from the street by a second and separate service staircase. Upon the basement story, at the foot of the service stairs, there will be a kitchen porter's office, fitted with a goods lift to the kitchens; and the

waiters' room and other necessary offices will also be upon the basement story.

The walls of the hall and court rooms will be finished with wainscot panelled dados, and most of the joiners' work will be of the same material. The stairs are to be of stone, and the corridors, landings, &c., paved with mosaic. Sanitation has received due consideration at the hands of the architect,—the drains being disconnected from the public sewer, and thoroughly ventilated upon Banner's system; whilst ventilation which is so important in a building of this character, has also received due consideration, and each apartment will be supplied with foul-air extractors, and fresh-air inlets through which cool air in summer and warm air in winter will be supplied by the appliances of the Eolus Water Spray Company.

#### THE NOTTINGHAM PORCH, ST. MARY'S, BURY ST. EDMUNDS.

THIS, which forms the north porch of the large and interesting late church of St. Mary, at Bury St. Edmunds, has been measured and drawn by Mr. G. G. Wallace, whose drawings, as previously mentioned, received special commendation when submitted in competition for the Architectural Association Travelling Studentship. The moldings, which Mr. Wallace has carefully and conscientiously given, exhibit the characteristic weakness of the style in this class of detail, but the general treatment of the front is picturesque and original. The porch is—or was when we knew it—connected with the porch of the opposite church of St. James by an avenue of trees, forming a happy mixture of natural and artificial architectural effect. The illustration may have special interest for some of our readers just now, as the church is included in the list of buildings to be visited in the course of the forthcoming Architectural Association excursion.

#### NURSES' HOME, ST. MARYLEBONE INFIRMARY.

THE Nurses' Home at Notting-hill, opened by H.R.H. Princess Christian this week, has been erected by the St. Marylebone Guardians as an adjunct to their infirmary at Ladbroke Grove-road, Notting-hill. The establishment is intended as a training school for nurses, and is interesting as being the first of its kind attached to a poor law infirmary. The architects, Messrs. H. Savon Snell & Son, have designed the building three stories in height, and the accommodation on the various floors consists of forty rooms, each 14 ft. long and 10 ft. wide, but one of them on the first floor is fitted up as a kitchen, which will be found useful in cases of sickness. At the ends of the corridors, giving access to the various rooms, bath-rooms are provided, and water-closets and slop-sinks are placed in the corner towers, but they are cut off from connexion with the building by means of cross-ventilated lobbies. Immediately fronting the entrance to the building, and leading out of the vestibule, is a class-room, 33 ft. long and 23 ft. wide, and on either side are the apartments of the superintendent.

Each of the nurses' rooms has a fireplace, and, in addition, the corridors can be warmed by hot-water pipes, which run along one of the side walls.

The builders, Messrs. Wall Bros., entered into a contract to erect the building for the sum of £8,903, inclusive of all engineering works and fittings. The heating works have been executed by Messrs. Fraser & Co.; the cold-water pipes and fire-mains by Messrs. Potter & Sons; the gas-mains and fittings by Messrs. Berry & Sons; and the electric-bells by Mr. F. Brown.

#### SCULPTURE AT THE ROYAL ACADEMY. NOS. VII. AND VIII. BY H.S.H. COUNT GLEICHEN.

A GOOD many visitors in going round the Lecture-room will probably have noticed the very pleasing and dignified portrait-bust of a lady, by Count Gleichen, to which a certain additional individuality is given by the addition of the wings from between which it seems to rise; a pretty fancy, which gives a touch of poetic feeling to the portrait.

The studies of children given on the other plate represent a class of subject on which Count Gleichen has often been engaged. The boy with the toy engine is not, perhaps, a strictly "sculpturesque" subject, but the figure is very bright and characteristic in manner and expression.

SCULPTURE AT THE ROYAL ACADEMY.  
No. 8.—STUDIES OF CHILDREN. BY H.S.H. COUNT GLEICHEN.

THE INSTITUTE OF ARCHITECTS' CONFERENCES AT THE HEALTH EXHIBITION. WATER SUPPLY.

THE paper on this subject by Mr. T. H. Watson, which was the concluding contribution to the Institute Conference at the Health Exhibition last week, we were compelled, as before mentioned, to hold over for want of space.

After having enumerated the various possible sources of water supply, from springs, lakes, and rivers, wells in the chalk, and rain-water, and regretting that the idea of storage of the latter on a large scale was still neglected, Mr. Watson continued—

The management of the water, after we have collected it and have got it delivered to our house, is the special subject of this paper.

In the metropolis there are at present two systems of delivery,—the constant and the intermittent. The latter is being gradually superseded. Much information on this and many other matters connected with the subject is published in the reports of Colonel Sir F. Bolton, the official water examiner appointed under the Metropolis Water Act, 1871. I do not understand that any effectual power is given by Parliament to compel the companies to deliver pure water. What is wanted is not a "standard of filtration" on which the companies may agree, but a "standard of purity and softness" on which the public may rely, and also we want "requirements," not exclusively with the object of saving water, but made also in the interests of the consumers, to facilitate the proper management of it within the house, and to insure the proper cleaning of all cisterns and tanks periodically. The periodical examination of cisterns as to their cleanliness, proper surroundings, and fittings, should be made the work of an independent public officer, acting under the direction of the sanitary authority entirely in the interest of the consumers, whether occupiers of private houses, chambers, clubs, hotels, or lodgings.

The great objection to the intermittent service is the much greater storage required in each house and consequent multiplication of cisterns and tanks, and the inconvenience of having to receive at a particular time the whole supply for twenty-four hours.

The constant service, however, requires fittings much improved on those which have been allowed to be used under the old system. The great hindrance to the introduction of this service is the expense and trouble involved in making the necessary alterations to the fittings to limit the waste of water.

The waste of water that may take place when the fittings are imperfect and the pressure is great, has led to the introduction of a throttle or ferrule into the communication-pipe, lessening the diameter of the water-way to such an extent that, when the pressure is reduced, the water may flow too slowly to be of effectual service. Some storage and a moderate pressure are, therefore, desirable. The constant system, to work effectually and economically, depends upon mutual fair dealing between the Water Companies and the consumers, but it is not easy to adjust things on this basis, and many persons advocate a mixed system. It is, therefore, important to consider the whole subject of cisterns and tanks.

**Materials.**—Stone, brick, or tile lined with cement, and puddled on the outside with clay, where the ground is porous, are found to be the best materials for tanks of large capacity. Soft water dissolves lime, but cement is not acted upon by any water. It may be trowelled smooth, and kept clean.

For house-cisterns, stone, slate, iron, lead, zinc, and other materials are used. Of these, perhaps slate is best, but it requires to be most carefully fitted and put together with slate cement and metal cramps. Iron rusts badly when alternately wet and dry; enamelled iron is expensive and uncertain, galvanised iron having a mere coating of zinc, which is dissolved by soft water, cannot be relied upon. Lead, of very ancient use, and its modern rival zinc, are also considered objectionable, and should not be used where anything better can be had. I think that stoneware is the best material for the house-cistern, and as the constant supply requires only a limited storage, say 100 to 200 gallons, there should be no difficulty in the general adoption of cisterns of this material, provided they are made and fitted in a way that will admit of their proper use.

Reservoirs for spring-water require to be fitted with means to aerate the water at the inlet. Large tanks must be thoroughly ventilated; all, without exception, require to be fitted with means to run the water off to the very bottom,—this is called "the wash-out," without which they cannot be effectually cleaned. A flap-valve and chain is the proper contrivance for this purpose. Tanks are usually constructed underground; it is sufficient, however, if they be half sunk in situations where the earth that results from the excavation can be heaped around and over them in a mound of sufficient thickness to protect the contents from changes of temperature.

The house-cistern requires to be close covered to keep out light, dust, and vermin, and no foul air should by any possibility find access to it. On lifting the cover (which should be kept clean) the whole interior of the cistern should be well lighted and in full view.

Most people would be shocked could they but look in the cistern of their house, but cisterns unfortunately are not usually placed where they can be looked into: the neglect of this is simply amazing.

The best system is to form a separate cistern room in a cool, light, and well-ventilated place in the upper part of the house; here the cistern stands just so much above the floor as will admit of the connexion of pipes, and give access to it all round. The cistern itself is close covered.

The arrangement I make is this,—standing in front of it with the cover removed, you see the service-cock near the back right-hand corner, a solid tin trumpet waste to take the overflow and form a wash-out, rises from the bottom of the left front corner; the cistern is fixed a little out of level,—the left front corner about an inch lower than the right back corner,—to drain the contents away completely when the waste is out. The proper cleaning and rinsing out of a cistern thus arranged is the work of a few minutes. It is to be done every three or four months. No supply-pipe is taken from the bottom. At about an inch from the bottom the supply to the hot-water system is taken; 3 in. above this level the cold-water supply is taken in a pipe sufficient bore to serve all the lesser branch-pipes. The object of this is to let the cold supply fail first in the event of any interruption of the service; there are then 3 in. in the depth of the cistern reserved for the hot-water system until the service is renewed.

The under-waste should be syphoned below the cistern to form a trap; the pipe should be carried to some convenient place in the open air, where the end of it can be readily seen by the company's inspector; this forms an efficient "warning pipe." At the same time it must discharge in such a way as not to deluge the house when the contents of the cistern are being run off for cleaning.

The regulations issued by the Water Companies are rather misleading. They suggest that every waste-pipe must be converted into what is called an "overflow-pipe"; that is, a pipe taken out of the side of the cistern near the top, and this so arranged as to act as a warning-pipe. A cistern thus fitted cannot be properly cleaned out except by such an expenditure of time and trouble as is likely to cause it to be neglected altogether. In my opinion this form of waste-pipe should never be admitted. The "wash-out" and "waste," when properly fitted, answer every requirement as an overflow, and the end of this, equally with the other, is an efficient warning-pipe when properly placed in view.

The plumber has been so accustomed to perforate the cistern when in position,—considering only how he can best accommodate his work without regard to its subsequent cleaning out,—that prejudice is likely to arise against the use of the stoneware cistern. I think the plumber should give way in this, and cisterns might then be kept in stock sizes, and perforated as follows, viz:—

Stock size 3 ft. x 2 ft. x 3 ft. = 100 gallons effective capacity.  
 4 ft. x 3 ft. x 3 ft. = 200 " "  
 " " " " " " " "  
 " " " " " " " "  
 Angles rounded in bottom and sides,—glazed brown, yellow, or white inside,—provision for service-pipe and waste-pipe as before described and for two supplies on the right side, near to, but not in the front,—the lower one to take connexion of 1 in. pipe, the upper one 1 1/4 in.

For drinking-water a separate cistern is recommended. It is not sufficient that this should differ from other cisterns only in being smaller and of a glazed material. Special arrangements must be made in its construction; these

must be determined by a careful consideration of its special use and the means by which it may be kept in order.

My idea is that it should be smooth and white inside, so that no dirt could rest in it undetected; glazed and rounded, that it might be readily cleaned; no larger than is necessary, and so shaped that it might be completely emptied and set in order every day; deep, rather than shallow, with a close-fitting cover going over the top rim no larger than could be safely handled with one hand.

The water required for drinking purposes as water, and in beverages as tea, coffee, &c., is estimated at two pints a day for each person; we may double this during hot weather, and double it again, as we need not be sparing where there is such abundance. I should say that one gallon a day for each person would be ample for such a cistern, or say 1 cubic foot for each multiple of five persons in a family, starting at 2 cubic feet as a useful size for a family of ten persons.

This cistern should be fitted up in the pantry, still-room, or any clean cool place in the house; its front edge should stand on a hard wood drainer, such as is found by the side of the pantry sink. Let the cistern be in full light, accessible in every part of it, and resting on a projecting bracket, which may also serve as a shelf for glasses.

The bottom of the cistern should be rounded and sloping towards the front, where a ground-in porcelain plug should be fitted so as to enable it to be completely emptied. A porcelain tap, the parts simply and easily cleaned, should be immediately over the plug, and should not draw the water quite to the bottom. The overflow should be provided for by a slight depression in the front of the rim, so that any waste may be observed as it flows down in a channel in the front of the cistern to the drainer.

A glass ball-valve, supplied direct from the main, and not from any other cistern, completes the apparatus. This tap may be small, the metal nickel-plated, and the ball and arm must be capable of being turned up out of the way.

With a preliminary swirl round and emptying, the plug is inserted, the ball turned down, and the cover put on,—the cistern is then charged. Every day, immediately before or during the intermittent supply, it is to be washed out with the remains of the last day's supply, rinsed out with the first of the fresh water, emptied again, and then set in order for the day. This would not take more than two minutes, and for that day, at least, the drinking-water would not be perceptibly worse than that which the Company supplies, while the addition of a pound of washed ice in summer time would give it just that degree of coolness that would render it use the more agreeable.

Of the other cisterns in the house I need speak but briefly. The hot-water tank should not be placed, as it frequently is, near to the cold water to affect its coolness. It is a mere accumulator or reservoir on the hot water circulation, and needs no special fitting beyond a manhole for occasional cleaning. It is best placed in the bath-room, where some of its heat may be utilised in a drying-closet.

Water-closets, urinals, &c., require waste-preventer cisterns. All those in use need improvement. The principal objections are that the incoming of the water is attended with noise: this may be obviated by taking the delivery nozzle down nearly to the bottom of the cistern; also the noise and want of force in the flushing of the closet. The valve should be contrived near to the pan, so that a column of water is standing above the valve ready to act the moment the valve is opened.

Where there is an open boiler a feed cistern is required. It has been the practice to put this in a dark cupboard, generally near the kitchen range. For this there is no necessity. It may be placed in any open light place where it can be got at all round; it only needs to be on the level of the boiler. It must have a close-fitting cover, and be kept quite clean. Stoneware is the best material for this purpose.

Too great a pressure upon pipes and fittings causes waste of water. It is advisable, in determining the place for the cistern, to arrange that the pressure does not exceed that which is due to about 25 ft. to 30 ft. head of water. In houses of many stories, with the hot-water system, this difficulty cannot be met, and a great want is a really efficient hot-water high-pressure tap.

In regard to the management of hot-water there are two or three points to be observed. The flow-pipes should always be fitted to a flange-joint on the top of the boiler and of the accumulator, the inner surface of which should be smoothly rimmed to prevent the formation of an air-trap,—the cause of the thumping and vibration often experienced. The flow-pipe should be of larger bore for a short part of its length immediately over the boiler, especially when the water is hard and much deposit is formed at the mouth of the flow-pipe. All supplies should be taken from the flow above the accumulator so as to draw the hottest water. Very short branch pipes should be admitted to binder the dead water becoming cold and causing waste. The return should take the shortest course to the lower part of the boiler; the feed-pipe should be entered into the return so as to deliver the cold water direct to the boiler and not reduce the temperature of the whole volume stored in the accumulator. The feed should have an elbow or dip at its connexion with the return so as to hinder the hot-water ascending into the cold-water cistern.

**Stop-cocks.**—There should be a stop-cock on the "communication" pipe to enable the service to be shut off entirely. There should be a stop-cock in a convenient place on every supply taken from a cistern, to enable the workmen to shut off the supply without interfering with the other service of the house, or emptying the cistern when alterations in any of the fittings have to be made.

**Distribution.**—The conduits for distribution of water now in use are exclusively of iron when of large capacity, coated in various ways to hinder the action of the water in direct contact with the pipes, from rusting the metal away. For soft water the pipes are coated by Dr. Angus Smith's process, with a varnish of coal-tar, or by a coating of cement or lime, paid over the interior metal surface of the pipes. The joints which used formerly to be made with tow yarn and lead caulked in, are now, where the capacity of the pipe admits of it, made on the inside with cement, to hinder the increase of organic matter observed in water that was allowed to come in direct contact with the yarn. Hard water has little action upon iron pipes, a coating is formed by the earthy salts on the insides of the pipes, and contact with the metal is thereby hindered.

For the smaller pipes within the house, on the whole iron tubes are considered best. Various processes have been introduced for protecting the metal from contact with the water; where, however, the water is at all hard, the inconvenience of direct contact is soon overcome by the deposit formed on the inside of the tubes. For soft and hot water the protective processes of Barding and galvanising are frequently used, but tubings thus treated do not admit of being worked up, or bent, without injury to the coating, and the only effectual way of employing either process is by taking down the whole of the work after it has been fitted, sending it away to be treated, and refixing the work without any alteration whatever: this becomes an expensive matter as the cost of labour far exceeds the value of the tubes. Wrought iron may be artificially coated with a deposit of lime after fixing, and when kept well painted on the outside, tubes of this material are, perhaps, the best and most economical for hot-water work.

In the discussion which followed,

Sir Joseph Fyler gave some interesting information about the water-supplies in India.

Mr. Crantham, C.E., considered that hot-water pipes were a source of great trouble in a house, and referred to an instance in which galvanised pipes, so used, got entirely stopped after a few years.

Mr. Schmidt, of Eastbourne, said that in that town they claimed to have a pure supply of water, owing to the liberality of the Duke of Devonshire. They had also a special Act requiring every new building to be carefully inspected. The death-rate there only averaged 13 per 1,000, and the water showed 9 degrees of hardness.

Mr. Ewan Christian, speaking of the action of water upon lead, stated that in the case of one old cistern he had found no deterioration. He was present some years ago at Canterbury when the ancient leaden pipes in the Close were being taken up, and he found they were as perfect internally as when they were laid down. As a contrary experience, he had put up a

milled lead cistern in Lancashire, not knowing the quality of the water, which was entirely destroyed within a year. He had found the same thing occur in Surrey, and in the neighbourhood of Alcot or water-pipes.

In the course of some remarks at the close of the meeting,

Professor T. Hayter Lewis said:—I have now to declare that this week's Conference is about to close, and as it has been conducted under the auspices of the Royal Institute of Architects, it may be well that I should offer a few remarks respecting the part which the Institute and its various members have taken, from time to time, towards assisting in and bringing forward, prominently, the various questions of sanitary science, and the better housing of the poor and rich alike. The history of the movement which has resulted in the present Health Exhibition is briefly this. Some forty years ago Mr. Edwin Chadwick published his report on the sanitary condition of the labouring classes, and this was soon followed by the establishment of the society for improving their condition. In 1847, for the first time, householders were compelled to drain into the sewers. Shortly before this time the Institute came into a vigorous life, thanks mainly to our dear friend, Professor Donaldson. In 1839-42 its first volume of Transactions was published, and amongst its articles are some on sewers, damp in foundations, hollow walls, warming and ventilation, filtering water, and artesian wells. All these were, of course, in addition to the valuable papers by Professor Willis and others on fine art and construction, and it furnishes, I think, a convincing proof of the interest taken by us in sanitary matters, at that time, no doubt, imperfectly studied.

It would be simply wearisome to give a lengthened list of the papers which have, since then, appeared in our Transactions, but I may be allowed to mention a few which have appeared in them and in other places by our members. In 1850, Mr. Roberts read a paper on the dwellings of the labouring classes, which has since been expanded into his well-known book on that subject. In 1851, we had the important subject of smoke-consuming, brought forward by Mr. Stevens. In 1852, Messrs. Aspiel & Whichcord produced a valuable paper on baths and wash-houses, and in the same year the arrangement of houses in flats,—a mode of building which is now, at last, coming into use, and which was investigated, at a much later period, with great care by the present secretary of the Institute of Architects, Mr. White. In 1854, Mr. George Godwin published his well-known "London Shadows," a work which did much to rouse public attention to the housing of the poor. In 1854 there was read by Mr. Boninno a paper on drainage, the discussion of which extended over three evenings, and will always be consulted as giving a clear account of the state of knowledge on the subject at that time. In the same year, Mr. E. C. Robins, one of the honorary secretaries of this Conference, who was then honorary secretary to a Local Board of Health, published his "Practical View of the Sanitary Question," a work which had a good practical result in many ways.

Amongst other subjects relating to health we have had the following treated at considerable length, taking them in the order of date:—Hospital construction, abattoirs, artisans' dwellings, house construction, heating and ventilation, public health, theatres, water supply, and model by-laws; and I conclude my list with a paper read a few sessions back, by Mr. E. C. Robins, on sanitary science in its relation to civil architecture, the discussion upon which, carried on by some of the most eminent men in various professions, occupied three evenings. For in all discussions at the Institute we invite the freest comments, not only from our own members, but from any visitors who can throw light upon the subject, whether their views are in accordance with ours or not.

We thoroughly acknowledge the great service done for the work by eminent men in other professions; we gladly accept their most valuable help, and we feel bound to keep well abreast with them in their scientific work, and to bring the results of their labours into a tangible form. And to bring them in the most practical way before our younger brethren, we have made it compulsory now for each associate before he is admitted into our ranks to pass an examination in which the leading principles of sanitation form a prominent feature. And it will serve as

an encouragement to them in the pursuit of this knowledge to know that our past vice-president, Mr. George Godwin, has recently had presented to him by Her Majesty, at our recommendation, her gold medal, for his long, zealous, and able advocacy of the work in which we are all now engaged.

Before I conclude, I must call your attention for a few minutes to a fact which is constantly overlooked, and the omission of which is often made to bear somewhat hardly upon our architects, although, in reality, it ought to weigh more heavily on the speculating builders, viz., that whilst sanitation has been erected into a science within a comparatively short time, most of the houses in which we live have been erected a comparatively long time, and though the sanitary details of the best houses erected even a few years since may now appear to be, and often are, very defective, as judged by our present state of knowledge; they were, when put up, very probably up to the state of knowledge at that time possessed. To give a clear example of what I mean, I will take the case of typhoid fever, whose special properties were not known forty years ago, and whose origin in foul air is a still later discovery. But foul air was, nevertheless, always sufficiently offensive, and a thing to be fought against, and, a few years back only, it was the belief (I might almost say the universal belief) that a well-constructed water-trap was an effectual preventive to its entry into the house. Now it is known that foul gases will pass this water.

The progress of knowledge, and the difficulty of keeping pace with it, is curiously illustrated by Professor Corfield in his "Common Defects in the Sanitary Arrangement of Houses." He says (to give a short abstract) the form of trap which was used first in connexion with water-closets was the siphon, which was afterwards discarded, but which we now praise, and the trap which supplanted it was the D-trap, which we are now condemning, and taking out whenever we can. It is by no means unlikely that, in a few years, another discovery,—viz., that of Pettenkofer,—may effect a very considerable modification of both the external and internal finishing of our dwellings. His theory of the filtering of air through our walls and floors has not yet been thoroughly worked out, but it evidently has a very important and quite unexpected bearing on their construction.

#### INTERESTING DISCOVERY UNDER PETERBOROUGH CATHEDRAL.

In connexion with the operations attending the rebuilding of the great central tower of Peterborough Cathedral, which operations were described at some length in the *Builder* of the 17th of May, a very interesting additional discovery has recently been made. It will be remembered that in excavating for the foundations of the new piers of the restored tower some hurried masonry was exposed to view, affording indications of the strongest kind that herein had been come upon the remains of the ancient Saxon church, which, along with the bulk of the other erections forming the stronghold of the monastic colony, fell a prey to the Northmen. This discovery showed that the more modern and much grander chancel occupied the same site in part as that originally chosen in the seventh century, and it led to further speculation, on the part of those immediately interested, with reference more particularly to a traditional crypt or vault alleged to have existed under the flooring of the church. Following the rather vague indications afforded by one of the old historians of the cathedral and monastery, a fresh opening was made in the flooring of the building, at a spot in close proximity to the northern flank of the tower now being restored, and hardening the southern termination of the north transept. The success which attended the exploration seemed to be complete and immediate, and was held as showing the calculation, thus based upon the historic mention alluded to, to have been a very accurate one. Directly beneath the existing flooring of the church at this point the workmen of Mr. Thompson, the contractor, came upon a small underground chamber, packed to the brim with a very curious assortment of unconsidered trifes. The chamber was quickly cleared of its contents, when it was immediately apparent to the Clerk of the Works and other adequate authorities present that here had been stowed away part of the *débris*

remaining after the sacking of the building by the Parliamentarians in the year 1643. The very fine choir-reef, at that time pulled to the ground with ropes on suspicion of strong leanings to Popery in the style of its ornamentation, had, it seems, been partly bestowed,—in fragmentary form of course,—within this hiding-place, and these fragments are now useful as showing the quality of a piece of art-work which, in the old times, was the object of so much admiration on the part of historians and others. Mixed with these were pieces of broken swords and other weapons of both iron and steel, also shreds of some kind of leather-work of the sheath order, fragments of stained glass, and some bones and half-burned bits of wood. The bones are judged to be those of the sheep chiefly, and it did not appear that any of them were of the human species. The underground chamber itself was found to be of no great size, being barely 7 ft. in length by about 3 ft. 6 in. wide and 6 ft. deep. It is furnished with two separate flights of steps descending to the basement, and was at one time approached, apparently, only by concealed traps in the floor of the minister, these traps in each case resting over the topmost steps. The walls of the underground chamber are of stone and lime, and the floor is of stone flags, which still bear signs of violent upheaval at some epoch of disturbance,—these most likely the handiwork of Cromwell's soldiers while in unscrupulous search of still more secretly contrived conveniences for the hiding away of valuables. The roof of the artificial cavity seems always to have been simply the floor of the church itself, which floor, as is well known, has at various times been slightly raised in level. If this is the crypt or vault mentioned in the old records of the building,—a theory which would bear some additional strengthening, perhaps,—its use in ancient times was in all probability that of a regularly contrived hiding-place for valuables. Its situation would be that most likely of any within the abbey walls to safeguard from sacrilegious attempts whatever treasure it might for the time contain. Its comparatively trifling dimensions rather militate against the supposition, however; for while the chamber thus discovered is not much more roomy than many a larger-sized grave,—though it is, in point of fact, not at all of the tomb order,—the language of the old historian seems to point to a receptacle of some considerable capacity. The two flights of steps form the most striking feature, and have led the Dean to the theory that it was rather a place where means existed of obtaining water from certain large pipes, discovered at a considerable depth below the church, and extending up to its entrance. Other authorities on the spot, however, do not hesitate to identify this curious chamber with the actual "strong-box" of the old abbots.

NATIONAL ART-STUDENTS' COMPETITION.

The drawings and other works sent in competition for the prizes given by "the Department" have been, as usual, open to public inspection this year in the Indian Courts in the main building. The authorities have separated the Gold, Silver, and Bronze Medal works from the rest on this occasion, so that they are not so difficult to find as formerly. In the main, decorative design seems up to the usual mark,—it is generally about the best portion of the work,—sculpture not quite so good as usual; life study much as usual, except one admirable drawing above the average mark. The Gold Medalists are Carl Amquist (West London School), holder of the Mence Travelling Scholarship, who has a good collection of coloured studies of Renaissance detail; F. Shelle (Hanley), designs for majolica ware, very good; C. B. Aylward (South Kensington), designs for textiles; F. Poole (Southampton), still life in water-colour, broader in style than usual in this class of the work submitted; A. G. C. John (two omitted to note the school), made study in chalk, admirable; Ernest O. Cooke (Nottingham), still life in oil; Sidney G. Mawson (Manchester), decorative designs based on floral forms, elegant and refined, but a little too naturalistic; Constantine Procopides (Manchester), designs for printed calicos, very good; A. G. Weatherstone (West London), decorative schemes of semi-architectural character, clever but rather gaudy; Tonelli Dominico, sculpture in the round; Harold Forrester (Hanley), vase with figures in low relief; and—Willdigg, modelled terra

cotta dish. We cannot go through the crowd of other awards, which, as we have often said, seem to be sown broadcast. We may observe that architectural work seems poorer than ever, and the things in this way, for which silver and bronze medals are given, are, as the Americans say, "a caution."

ELECTION OF TWO DISTRICT SURVEYORS.

TWENTY-SIX candidates presented themselves for the two vacancies caused by the death of the late Mr. Edwin Nash and by the Metropolitan Board of Works having decided to divide the hitherto single district of Penge and Lower Norwood into two separate districts named in accordance with the respective localities. The election took place at the meeting of the Board on the 18th inst.

The following is a list of the candidates, with the number of votes recorded for each in the preliminary voting for each appointment:—

Name.	Lower Norwood.	Penge.
Ashbridge, A.	27	23
Batterbury, T.	29	15
Belldigby, H. H.	13	12
Broads, C. W.	7	8
Cheston, H.	9	8
Clarkson, S. F.	14	17
Edmeston, J. E.	13	15
Elkington, G.	29	23
Grellier, W.	5	6
Hazellurst, E.	5	1
Hunter, P.	32	3
Inskip, G.	3	3
Jackson, G.	6	6
Lean, G. A.	3	6
Lean, W. H.	3	16
MacLellan, H.	11	8
Marsland, E.	23	27
Mundy, P. E.	14	13
Murray, R. G. C.	1	1
Nash, W. H.	3	3
Scrymgeour, W. H.	13	8
Smallpeice, W.	10	10
Spiers, W. E.	10	14
Stevens, W. H.	14	19
Stock, H. W.	19	17
Street, E.	18	19

The subsequent voting was as follows:—

	Lower Norwood.				
	Second Vote.	Third Vote.	Fourth Vote.	Fifth Vote.	Final Vote.
Ashbridge	16	9	—	—	—
Batterbury	12	11	10	—	—
Elkington	21	23	21	14	10
Hunter	30	27	28	27	30
Marsland	19	13	16	10	—
Stock	19	—	—	—	—

	Penge.				
	Second Vote.	Third Vote.	Fourth Vote.	Fifth Vote.	Final Vote.
Ashbridge	20	20	8	—	—
Clarkson	13	10	—	—	—
Elkington	28	25	23	25	23
Marsland	23	20	21	19	11
Stock	10	—	—	—	—
Street	23	12	16	13	—

Mr. Hunter was, therefore, the successful candidate for this district.

Mr. Elkington was thus successful in obtaining this district.

Both appointments were made subject to the usual conditions imposed by the Board.

SWIMMING-BATH FOR WHITECHAPEL.

We gladly give further publicity to the following on behalf of an object which should commend itself to all sanitarians:—

"Eleven years ago baths and washhouses were opened in Whitechapel. They have been a godsend to thousands to whom cleanliness had been an impossible luxury. It is now proposed to add a large swimming-bath, which shall be available all the year round, at a small charge. The Vestry has undertaken the expense of maintaining the bath, but justly shrinks from throwing the whole cost of construction on the ratepayers of a parish in which a penny rate produces only 600*l.* A thousand pounds is wanted to complete the sum necessary for the building of the bath. In a locality where the streets are so crowded that hoidly exercise can rarely be a pleasure, where cleanliness is expensive and difficult, and where most of the families occupy single rooms, a swimming-bath will give to many greater length of days, and more joy in living.

Contributions towards this sum will be received by

- F. D. MOCATTA, 9, Connaught-place, W.
- S. A. BARNETT, St. Jude's Vicarage, Whitechapel."

About 600*l.* of the sum required is, we understand, already promised or subscribed. We hope some of our readers may be able to assist in making the remainder. There could hardly be a more useful or truly humanitarian expenditure of money.

FIRE-EXTINGUISHING.

SOME simple but crucial experiments in fire-extinction were carried out on Thursday last with the "Harden Hand Grenade" on a vacant plot of land near the Farringdon-street station, of which record may be usefully made. Fires under various conditions were lighted, with the result that they were extinguished in a few seconds by the application of the grenade, which consists of a small glass bottle containing one pint of a fluid which, on exposure to the air or to heat, generates a considerable volume of carbonic acid gas.

Supposing a fire to have been discovered in a house or elsewhere, a grenade is broken by being struck by a second one, or it is thrown against the surroundings of the fire with sufficient force to break it and disperse the contents.

One experiment made on Thursday was very telling, and illustrated a very common and useful application of the invention. A wooden chimney, 14 feet in height, and about a foot square in section, had a fire of wood, petroleum, and kerosene lighted in its lower portion. The flames rose quickly high above the top. But on a single grenade, containing a pint of the fluid, being broken over the fire at its base, the flames from the whole interior (which had been painted with oil and pitch) were most speedily subdued. This experiment illustrated the rapidity with which ordinary chimneys when on fire could be extinguished. For the invention, nothing more than its capability of dealing with incipient fires is claimed. It is not intended to supplant the fire-extinguishers and hand-engines, still less the fire-brigades; and, consequently, the real point of value is its inexpensiveness, its handiness and readiness, and its efficiency for extinguishing fires in their incipient condition.

BUILDERS' BENEVOLENT INSTITUTION.

THE thirty-seventh annual meeting of this Institution was held at Willis's Rooms, King-street, St. James's, on Thursday last, Mr. Geo. Plucknett, J.P., treasurer, in the chair. The annual report, read by the Secretary, Major Bruton, states that during the past year seven pensioners (six men and one woman) have died, and nine new ones have been elected (seven men and two women), making an addition of four pensioners. Two widows of deceased pensioners have also been admitted to the benefits of the Institution. The Committee have yielded to the urgent necessities of applicants, and have added to the numbers of the pensioners in the firm belief that it would meet with the general approval of the subscribers; especially as there are several more applicants of advanced age hopefully seeking to be elected. There are now fifty-eight pensioners on the funds of the Institution, and to support them the Committee earnestly appeal to all who read this report to become subscribers, if they are not so already, and thereby help to sustain the charity. Very valuable aid, which is greatly appreciated, was given by the president of the year, Mr. Henry G. Smith, to the Institution, and the thanks of the subscribers are due to the gentlemen who kindly and successfully superintended the arrangements for the annual dinner and ball. The committee regret the loss by death, year after year, of the friends of the charity. In the past year two of the late patrons have considerably remembered the Institution in their wills. The late Mr. Charles Heck bequeathed a legacy of 250*l.*, and the late Mr. Henry Couchman 200*l.* These sums will be invested in accordance with the rules.

The balance-sheet shows total receipts from all sources during the year amounting to 5,266*l.* 2*s.* 3*d.*, the total expenditure being 2,273*l.* 10*s.* 5*d.*, leaving a balance in hand of 2,992*l.* 12*s.* 4*d.* The report and balance-sheet were adopted, on the motion of the chairman, seconded by Mr. Bussell.

Votes of thanks were given to the president for the past year (Mr. H. G. Smith), to the vice-presidents, to the trustees (Mr. George Plucknett, J.P., Sir S. Morton Peto, Ald. Sir J. C. Lawrence, bart., M.P., and Mr. C. T. Lucas), to the treasurer (Mr. George Plucknett, who was re-elected), to the auditors (Messrs. J. H. Hunter, J. Crutenden, and R. J. Ward), and to the committee, the retiring members being re-elected, and Mr. G. N. Watts was elected a new member of the committee.

On the motion of the chairman, seconded by Mr. Thomas Stirling, Mr. Stanley George Bird was elected president for the ensuing year; and it was announced that the annual dinner will be held at the Freemasons' Tavern on Nov. 6th.

After some discussion, in which the chairman, Mr. Stirling, Mr. F. J. Dove, Mr. Bussell, Mr. Foxley, Mr. T. F. Rider, Mr. W. Mitchell, and Mr. Hall took part, it was unanimously resolved to alter Rule 3, so that any future male candidate for the

benefits of the Institution must have been established in business for at least ten years, in lieu of five years, the limit hitherto fixed.

#### SOCIAL SCIENCE ASSOCIATION.

The annual business meeting of the members of this Association was held at the offices of the Association in Adam-street on Tuesday last. A report from the Council, detailing the action taken by the Association during the twelve months ending June, was presented, and ordered to be received and circulated. The report dealt with several subjects of interest in regard to which special action had been taken, and among these may be mentioned the Fine Art Copyright Bill, promoted by a Committee of the Association; their Bill to amend the law as to the administration and devolution of the estates of deceased persons; the conveyance of land by the system popularly known as one for the registration of titles as opposed to a registration of deeds; the marriage laws; stolen goods; instruction in workshops; milk supply; loss of life at sea; the Hospitals Association, which was the outcome of the Conference on Hospital Administration held last year under the auspices and management of a special Committee of the Council; the International Health Exhibition. The following appointments in the Association for the ensuing year, 1884-5, were then made:—President, the Right Hon. G. J. Shaw-Lefevre, M.P.; Presidents of Departments: I. Jurisprudence, Mr. John Westlake, Q.C., LL.D.; II. Education, Mr. Oscar Brown, Q.C., LL.D.; III. Health, Dr. Norman Chavers, G.I.E., F.R.C.S., Eng.; V. Art, the Right Hon. A. J. B. Balfour, M.P.; Chairman of the Repression of Crime Section, Mr. J. S. Dugdale, Q.C., Recorder of Birmingham. Sir Richard Temple was appointed President of the Council. Mr. Westlake, Q.C., LL.D., and Mr. Joseph Brown, Q.C., were appointed as Foreign Secretaries, G.I.E., F.R.C.S., Eng.; Mr. Andrew Dunn and Mr. Andrew Edgar, LL.D., were re-elected Auditors. The following were appointed Hon. Secretaries of Departments:—I. Jurisprudence, Mr. H. N. Mozley, M.A., Mr. Mayson White, M.A., Mr. Herbert A. Safford; II. Education, Mr. Rowland Hamilton; III. Health, Mr. H. H. Collins and Dr. Edward Sexton; IV. Economy and Trade, Rev. S. A. Steinthal and Mr. Edward J. Watherston; V. Art, Mr. Philip H. Rathbone and Mr. Arthur H. Mackmurdo, A.R.I.B.A.

It was reported that the arrangements for the Annual Congress, which is to be held at Birmingham from the 17th to the 24th of September, were in a very forward state.

#### SALES OF PROPERTY.

**Building Sites at Clacton-on-Sea.**—On Monday last Messrs. Baker & Sons conducted a large sale of building sites at Clacton-on-Sea. The sale took place by direction of the Marine and General Land, Building, and Investment Company, and comprised 100 plots of freehold building land, having frontages to the Marine Parade, Clacton-road, Pier-avenue, and other roads. The several lots offered varied in area from 18 ft. frontage and 80 ft. in depth, to 35 ft. frontage and 125 ft. in depth, the conditions providing that as to the smaller plots no houses of less value than from 180l. to 300l. were to be erected, and that as regards the larger plots, the outlay on each house was to range from 500l. to 1,000l., according to situation and area. On the various lots being submitted, there was an active competition, and ultimately sixty of the plots were sold at prices ranging from 200l. to 300l. each, the total proceeds of the day's sale amounting to 3,250l.

**Freehold Property in Highbury.**—During two days last week Messrs. Norton, Trist, Watney, & Co. were engaged at the Auction Mart in disposing of a quantity of valuable freehold property at Highbury. The property consisted of thirty-six houses in Highbury-place, which were sold for 52,900l., or an average of about 1,500l. each. Amongst the other property disposed of were five freehold houses in Highbury-terrace, which realised 7,180l.; two freehold houses in Highbury Park, sold for 2,660l.; and freehold ground-rents of 43l. per annum, which produced 1,860l. of the total proceeds of the sale amounting to 64,690l.

**Freehold Ground Rents at Clapham.**—An exceptionally heavy sale of property in Clapham took place at the Auction Mart last week, the sale being conducted by Messrs. Harris, Vaughan, & Jenkinson. The property consisted of freehold ground-rents and other freehold rentals amounting to 1,040l. per annum, with rack-rents in reversion amounting to 3,200l. per annum. The sale was by the direction of the trustees of what is known as the Bowyer estate, and comprised the ground-rents on 155 houses, shops, and other premises in High-street, Manor-street, Little Manor-street, Cross-street, and other streets and roads in the locality. The property was divided into fifty-one lots, which realised prices ranging from 400l. to 3,900l. each. The highest sums obtained were for the several properties in High-street. Amongst these was a ground-rent of 60l. per annum, secured upon two houses and three shops in High-street (per annum) in 1884. This lot was sold for 3,900l. The ground-

rent of 40l. per annum (increasing from 1890 to 125l. per annum), secured upon other premises in High-street, realised 3,500l. The reversion to this lot, the rack-rent of which is estimated at 450l. per annum, will take place in 1958. Three other ground-rents, of 80l. and 65l. per annum, upon properties in High-street, with reversions in seventy-four years, were sold for 3,040l., 2,700l., and 2,750l. respectively. The entire proceeds of the fifty-one lots amounted to 51,939l., being an average at the rate of fifty years' purchase; but in some cases the leases had only about fifteen years to run before the purchasers came into possession of the reversion. Where the leases had seventy-four years to run, the prices realised amounted to from twenty-five to thirty years' purchase.

#### WAR-OFFICE COMPETITION.

Sir,—According to rumour, the finish in this race is likely to be a very close thing indeed.

The judges have only selected nine, instead of ten, candidates for the final struggle, and thus save 600l. It would be a gracious and a popular act, and help to mitigate the disappointment of those who were so very near winning the great prize, if this spare 600l. were divided amongst, say, the second and third in order of merit.

H. P.

#### CAN THE NEW GOVERNMENT OFFICES BE DURABLE?

Sir,—In his notice of a proposal of mine on the above subject in the *Builder* of the 5th inst. [p. 9], M. Tagnon's recommendation of Belgian granite as a suitable material is altogether unpersuaded by evidence of its durability in our abnormal London atmosphere, with its destructive hydrochloric, sulphuric, and other gases.

So far as we may judge by his letter [p. 10], cheapness is its only value. But even upon this point he does not make out a very strong comparative case; for he tells us that it costs 15 per cent. more in this country than in France. This compares badly with the 3 per cent. extra for the English granites referred to in my proposal.

In making these remarks I have no wish to depreciate Belgian granite, for I am entirely unacquainted with its qualities; but English architects know well that stone which has lasted for centuries without decay elsewhere utterly fails when used in London. The new buildings referred to by M. Tagnon at Bristol and Brussels are not evidence on this point, nor did Mr. Gough's letter supply much practical information as to Belgian granite. The absolute durability in London of the materials I recommended is proved by existing structures, which are from 20 to nearly 100 years old, and are as perfect now as when left by their builders. I am, therefore, at present unable to see that there would be advantage in the British Government going to Belgium for a new and comparatively unknown material when there are such durable, economical, and splendid resources in this country as those I referred to in the proposal you were good enough to print.

J. L. TRAVIS.

#### STREET PAVING.

Sir,—At the present season, when the imperative necessity of immediately removing anything that may contaminate the atmosphere, or serve as a medium for the dissemination of the germs of disease, is fully recognised, is it not much to be desired that our streets, and especially our back streets and slums, should be more generally paved with some material, such as asphalt, which, being non-absorbent and impervious, cannot retain any liquid impurity; while its perfectly smooth and level surface is not only washed down by every shower of rain, but, offering no obstruction to the free action of the broom, is kept perfectly clean with the greatest ease, preserving the atmosphere in a sweet and wholesome condition?

SANITAS.

#### HENLEY-ON-THAMES.

Sir,—It may interest some of your readers to know that the town of Henley-on-Thames is to be sewered on the "Shone" system, and Mr. Shone, the inventor, and Mr. J. Sturgeon, of Westminster-chambers, are engaged as engineers.

The town not being sewered before, Shone's system will be carried out in its entirety, and the inventor will have a good opportunity of proving the efficacy of his system, for the sewage will be lifted above 120 ft. to the outfall works, which will be situated about a mile from the town.

It is hoped the work will be completed by Midsummer next.

FREDERICK BALL, Town Councillor.

#### CAREFUL.

Sir,—In your review of a work by M. A. Wazon on the "Sanitation of Towns and Villages" in your issue of the 12th inst., it is stated, respecting filtering material, that "careful is very costly." This statement, appearing in so eminent a journal as yours, is, we are afraid, unless corrected, likely to seriously affect us as the agents for Major Cassell's Careful, and we beg of you to allow us this opportunity of publicly stating that careful, if used according to our direction, is a very cheap filtering medium. This, together with the fact of its being so eminently efficient, as proved by the series of trials it was subjected to at the Army Medical School, Netley, under the superintendence of Dr. de Chaumont, Professor of Hygiene, is the reason of its being so largely used by Government and other large bodies.

J. & C. CHRISTIE (late "Gardners"),  
Sanitary Engineer, Charing-cross.

#### The Student's Column.

#### HINTS FOR THE STUDY OF THE HISTORY OF ARCHITECTURE.—IV. GREEK.

IT is one thing to perceive the sources from which Greek architecture was derived; but quite another thing to point out the exact channels by which they reached their destination. It is difficult to say whether it was fettered or brought. We shall have been prepared, by the last article, for two elements, one of a graceful kind from Asia, with which the term "Ionic" will be connected, and the other of a stern kind from Egypt, with which the term "Doric" will be connected, and these elements, after passing through the refining crucible of Greek art, have influenced the architecture of all the nations of Western Europe (see Smith & Slater's "Classic Architecture," p. 80). "We cannot put a finger upon any features of Egyptian, Assyrian, or Persian architecture, the influence of which has survived to the present day, except such as were adopted by the Greeks. On the other hand, there is no feature, no ornament, nor even any principle of design which the Greek architects employed that can be said to have now become obsolete."

If we turn to the aboriginal inhabitants of Greece in order to see how far they are responsible for the invention of Greek architecture, we shall find the various accounts of them somewhat conflicting. However, they may be found in "Fergusson's Handbook," p. 255; "Ramée," vol. 1, p. 373; "Rosengarten," p. 57; Gwilt's "Encyclopædia," p. 61; "Smith & Slater," p. 81; and Viollet-le-Duc's "Habitations of Man," p. 195. These, and all other authors, describe the Pelasgians, according to Fergusson, were by no means confined to Greece alone, but spread over Etruria (in Italy) and Asia Minor, and he adds that their power became extinct in Greece in the eleventh century B.C. The buildings attributed to them certainly testify to the Eastern influence that they would have encountered in Asia Minor, as may be seen by the scroll or voluted ornaments carved on a pillar in front of the Treasury of Atreus at Mycenæ, illustrated in all the handbooks at or about the pages just mentioned. At Mycenæ also is the famous Gate of Lions, so called from the pair of lions,—supporting something like part of inverted column, base upwards. This, at least, is the explanation of this feature by Professor Hayer Lewis after a recent visit to the spot.

The Treasury itself is a circular chamber of the form of a pointed arch in section, the arch being formed not of radiating courses, but of stone overlapping until they meet in a point. The internal surface was probably plated with brass, as indicated in the large internal view of it in Gall's "Itinerary of Greece," showing the attachment of such plates.

Their wall masonry was of the kind known as Cyclopean, like the Peruvian walls; and Dr. Phéné, in a paper read at the Institute (see "Loan Collection of Transactions," vol. i., page 138), has an ingenious theory that the polygonal outline of these huge stones is simply that of their natural fracture, in which form they were rebuilt, being raised into position on inclined planes, otherwise the labour of cutting and adjusting them would have been enormous.

So much for the Pelasgi, who appear to have combined massive building with graceful ornament, and who have been mentioned first because of the early buildings left by them.

The other, or Dorian race, says Ferguson, may have existed in Greece from the earliest ages, but only superseded the Pelasgi politically about ten centuries before Christ; but their civilisation took no new artistic form for at least three centuries afterwards, at which time what we know as the true Grecian form of art first made its appearance. It is in this Doric form that the Egyptian source of inspiration asserts itself; the tomb fronts at Beni Hassan, described in the last article, will have prepared us for the result so far as the columns are concerned; the small Egyptian temples called Mammisi (see Ferguson, page 240) may have suggested the general arrangement; but it is a remarkable fact that the earliest Greek Doric building, the temple at Corinth, is as completely and distinctively Greek, as if it were the result of a long series of gradual developments. It is perhaps more remarkable that the little temple at Siamus, which has all the appearance of an early step in such a series, comes quite late in the chronological list (see Smith and Slater, page 101).

Regarding, however, the forms of Greek temples ranging from extreme simplicity to completion in all their parts, we may say that the simplest was a mere rectangular cell, that the side walls were sometimes continued to form a porch, that a couple of columns were introduced between these prolonged walls or *antæ*, producing the arrangement known as "two column" or *distyle in antis*, or that, instead of the *antæ*, two other columns were used, making "four column" or *tetrapstyle*; that, if this were at one end only, it is called "front" or *prostyle*, and if repeated at the other end it is called "both front" or *amphi-prostyle*; that if the sides as well as the ends are then further enveloped in columns we have a temple with columns "around" it, or *peripteral*, the enveloping columns adding, at the ends, two to the four above mentioned, making "six" or *hexastyle*, front and back.

It is in this particular form, *hexastyle peripteral*, that the temple at Corinth bursts upon us in the seventh century B.C.—simple, solid, and stern in style, but leaving nothing to be added to its complete arrangement as a temple. This would seem to indicate that this arrangement had been laid down in the form of instructions to the architect by some one who knew exactly what he wanted, probably the priest,—a process much to be desired in the present day, instead of the clergy screening themselves behind the knowledge of Mr. So-and-So, the eminent architect.

Ramée, whose chapter on Greek architecture will be found in vol. i, p. 373, says that, first of all, the sacred element must be entirely separated from all that is profane or public; hence the custom of building the chief temple of a town upon an elevated rock or *acropolis*, which also insured a stable foundation. In connexion also with the respect for sacred things are the three steps surrounding the entire temple; so that, beginning to ascend with the right foot, one lands also on the right foot. Next, the Divinity (represented by a statue) must be inclosed with solid walls in the space called the *naos* or *cella*, turned towards the east, in front of which is the *pronaos*, and then the *porticus*. The other end of the building is occupied by the *opisthodomos* or treasury, and then the *posticum*. The whole was covered with a span roof of flat pitch, the end gables or pediments forming convenient spaces for sculpture.

The columns, as has been said, have no bases, whereupon arises a difference of opinion, one author saying that the idea was taken from posts struck in the ground, while other authors claim a stone original for these Doric columns and their capitals, although they claim a wooden origin for the entablature, or surrounding portion above the columns. There will always be some healthy fighting on this point; Viollet le Duc, in his "Lectures on Architecture," supporting the stone theory and illustrating it with his accustomed clearness. Moreover, in his "Habitations of Man," when speaking of the Ionic column, he says that the fact of its having a base is a proof that it was derived from a wooden original, such base being necessary to prevent the damp of the ground from rising and injuring the wood.

There is a great deal to be said about the beauties of Greek temples of the Doric "order," one of which, the Parthenon at Athens, built in 438 B.C. under Ictinus Architect and completed with sculpture by Phidias, is universally admitted to be the most beautiful building

the world has ever seen. Illustrations of it will be found in all the Handbooks, and it is now time to mention the special works on Greek architecture to be found in the Library of the Institute.

First of all are the magnificent series of folio volumes published by the Dilettanti Society, and first of these for completeness and accuracy is Penrose's "Principles of Athenian Architecture," 1851. In this will be found wonderful measured drawings of the Parthenon. Wilkins' "Magna Græcia" and a second copy containing the original drawings for it, dated 1807, are a good example for study in these days of "flicked-in Q. A. Perspectives." The "Antiquities of Ionia," in four parts, dating from 1821, three having been published about that time and the fourth part in 1881. And there is Cockerell's "The Temple of Jupiter Panhellenius at Ægina and of Apollo Epicurius at Bassæ, near Phigallia in Arcadia." Besides the above there are other important folio works. Stuart and Revett's "Athens"; John Pennethorne's "The Geometry and Optics of Ancient Architecture, illustrated by examples from Thebes, Athens, and Rome," 1878; Sir Charles Fellowes's "Asia Minor," containing landscapes in which temples are shown to a small scale; Norman's "Parallels," that is to say, comparative plates of the Greek and Roman orders; Gell's "Itinerary of Greece" 1810; Ferguson's "The Parthenon, an Essay on the Mode in which Light was introduced into Greek and Roman Temples," 1883, one vol. quarto.

Besides these are the various papers at the Institute read and bound together as one volume of the Loan Collection of the Transactions, in which will be found "The Report of the Committee as to Colours on the Elgin Marbles," 1837; Tite on "The Mausoleum at Halicarnassus," 1855; Texier on the same, 1863; J. W. Papworth on "The Roof of Temples called Hypæthrum at Ægina and Bassæ," 1866; Wood on "The Temple of Diana at Ephesus and Hypæthrum of the Greeks," 1877; Penrose on "Optical Refinements of Greek Architecture" 1877; Schliemann on "The Architecture of Troy," 1877, followed by a learned discussion, 1877; Phéné on "The Architecture of Troy and Mycenæ"; Lysandros Kaftangogloghin on "The Chreonean Lion" and on "Recent Discoveries at Mycenæ"; and Ferguson on "Wood's Temple of Diana at Ephesus," 1883.

The student will soon become acquainted, in reading up the subject, with the difference between the simple Doric order, and the lighter and more graceful Ionic order, which is said to have succeeded it in point of date, as applied to an entire building. There are, however, buildings of the Doric order which contain some Ionic columns, such as the Propylæa, or entrance to the Acropolis, at Athens, which is dated 436-431 B.C. in Smith and Slater. There is another curious but well-known building on the same Acropolis called the Erechtheion, which contains not only two temples joined together of the Ionic order, but a third tacked on to them, in which the office of the columns is performed by female figures called Caryatides, a copy of which may be seen in the church of St. Pancras in the Euston-road. The Temple at Bassæ, so beautifully illustrated by Cockerell in his work above named, contains not only Doric and Ionic columns, but Corinthian as well. This is an order with a foliated bell capital and slender proportions, which is not often found in Greek architecture, though the Greeks invented it, with a hint perhaps from Egypt.

In all these temples there is room for considerable difference of opinion as to the method by which daylight was admitted into them, or into such parts as were not hypæthral, that is "under,—or open to,—the sky." Cockerell illustrates simple openings left in the roof, but Ferguson continues to maintain that a sort of clearstory arrangement was adopted, which will be best understood by a visit to St. Peter's, Eaton-square, where M. Blomfield has ingeniously constructed such a clearstory into a church that is not unlike a Greek temple.

The choragic monument of Lycietes, surrounded by Corinthian columns, may be seen copied on St. Philip's Church in Regent-street. The front of the British Museum, with its sculptured pediment will, if the return colonnades be concealed, convey a notion of a Greek Ionic temple; but "walk in, walk in," and see the actual examples of ancient Greek work in that splendid collection!

## Miscellaneous.

### New Buildings in Gracechurch-street.

A new block of buildings has just been erected on the west side of Gracechurch-street, opposite one of the entrances to Leadenhall Market. The building has three frontages. The principal elevation is that in Gracechurch-street, which is 70 ft. in length, and upwards of 60 ft. in height, containing four stories above the ground floor. The lower portion of the façade is of red Aberdeen polished granite, with arched entrances to the upper floors at the north and south ends of the elevation. The facing of the upper portion of the frontage is in Portland stone, with a free introduction of carving. The frontage is ornamented, between the windows of the several floors, with fluted columns, the lower parts of the columns being in polished granite. At the north and south angles of the frontage there are pilasters of a rusticated and panelled character, the capitals being enriched by the introduction of sculptured figure-heads in the centre. The elevation terminates by an ornamental central pediment beneath which is inscribed "Woolpack-buildings," the name which has been given to the structure. Overlooking St. Peter's Churchyard, and approached from Gracechurch-street along a passage, is the north frontage, about 60 ft. in height. The other frontage is on the south side, in Corbett-court. The lower portions of this frontage are faced with Portland stone and polished granite, the materials of the upper parts of the elevation being red brick. The buildings have been erected from the designs of Mr. Thomas Dudley, and Mr. J. Bangs is the contractor.

**The Thames.**—It was felt while the Royal Commission on Metropolitan Sewage Discharge was sitting that some of the evidence given was exaggerated, and that the pessimist view taken of the matter by the medical officer of health for the port was scarcely justified by the facts. Unfortunately, however, the decision arrived at by the Commission has, during the recent hot weather, been far more than justified. It is no exaggeration to say that the whole river from Greenwich to Greenhithe has been full of sewage. The colour of the water is black and the odour intolerable. Such a state of things has naturally caused much anxiety. The Port of London Sanitary authority, alive to the danger, has addressed the Local Government Board, pointing out the necessity for immediate action. As a consequence pressure has been brought to bear upon the Metropolitan Board of Works, who have tardily agreed to the deodorisation of the sewage before it reaches the outfall. This, however, can merely be a palliative measure, the only real remedy being to remove the outfalls many miles further down.—*Lancet*.

**Railway Crossing Gates.**—Under the title of "Works in Iron," Messrs. Young & Co. issue a very useful and illustrative catalogue of practical ironwork, including some special descriptions of their opening and closing gates for railway level crossings, and the opening and closing apparatus which is worked from the signal-box, but with greater convenience than is possible with wooden gates. These gates are opened and shut by means of rods and chains working on wheels connected with the haek stile of the gate. These wheels are covered in with cast iron "wells" or boxes. Part of the top of these "wells" is movable, permitting free and easy access to the underground workings. The rods are protected by underground channels, which can be of wood, brick, or iron. Easy access can be had to these at any time by removing part of the cover. The speciality of this system of underground workings for the gates consists in the fact that whether in opening or shutting them it is always accomplished by drawing the rods. In other systems the gates are drawn one way and pushed the reverse way. The advantage of a constant draw over alternate pulling and drawing is obvious.

**Electric Gate Openers for Level Crossings.**—A French paper says that the railway companies are about to try an electric gate-opener. The method to be tried is briefly as follows:—A catch connected with an electromagnet keeps the gate closed. An approaching train closes the circuit at a certain distance from the gates, the catch is released and the gates open. When the last carriage has passed the circuit is broken again and the gates close. A bell is also rung as the train approaches.—*Electrician*.

**Stanley's Patent Plastering Process.**—The special feature of this process consists in substituting for the usual lathing key for plaster a fine woven wire with an open mesh, and which is corrugated equal to the usual centre to centre spacing of joists. The wire is fixed with the concave side of the corrugations upwards, each ridge of the corrugation being fixed by staples into the soffit of a joist. The plaster, in laying, is forced right through the meshes of the wire, thus ensuring a very firm key besides placing a sufficient amount of plaster between each joint, behind the wire, to cut off all draught from one jointing space to another, and thus further check the liability to rapid combustion in case of fire, which the plaster itself, on a wire key, will, in first instance, offer considerable resistance to. The liability to the cracking of the plaster from shrinkage of the ground is also much diminished. The process, which is American in its origin, is one of the best substitutes for the antiquated and flimsy lathing system that we have noticed.

**Smoke Abatement.**—On this subject Mr. Ernest Hart delivered a lecture last Monday, at the Health Exhibition. He cited statistics proving the enormous amount of waste which is at present going on in regard to the consumption of coal. The result of the trials made by the Smoke Abatement Committee proved that on an average in London 42 per cent. of the total heat generated in domestic grates passed away without in any degree being utilised in warming the rooms of the houses. The thick pall of smoke which frequently hung over the metropolis was productive of very baneful results to health, the mortality during some weeks when fog had prevailed being equalled only by that caused by a heavy cholera epidemic. We may observe, however, that this involves the assumption that smoke plays a larger part in the composition of "London Fog" than has by any means been proved to be the case.

**An Extraction Ventilator.**—Mr. W. H. Chapman, who has had many years' experience in practical matters as a clerk of works, has patented an ingenious and what appears likely to be an efficient mechanical extractor for exhausting gas from sewers, and foul air from large buildings or from railway tunnels. The principle consists in propelling air through a pipe carried up to near the top of an exhaust chimney, and then turned into and around the circumference of the chimney, so as to produce a continual vortex at its mouth, causing a powerful suction up the chimney. Mechanical power, such as a gas-engine, is required to propel the blast up the pipe; but for ventilation or extraction on a large scale it seems likely to be an efficient and by no means expensive system.

**Wrought-iron Watertight Casements.**—We have received from Messrs. Burt & Potts, of York-street, Westminster, a revised prospectus and price-list of their well-known wrought-iron watertight casements and frames, which have been largely used for many years past, and are likely to continue in demand, for they are strong (though light in appearance), and well adapted to resist the entrance of water, even in situations exposed to the most driving rains. The illustrative sections which are given will be found very useful for reference. Messrs. Burt & Potts, we may add, have just completed their contract for casements for the new building for St. Paul's School, Hammersmith, of which Mr. Alfred Waterhouse, A.R.A., is the architect.

**Honour to an Architect.**—The *London Gazette* of the 18th inst. contains the following announcement:—"The Queen has been pleased to give and grant unto Josiah Conder, esq., her Royal licence and authority that he may accept and wear the insignia of the Fourth Class of the Order of the Rising Sun, which his Imperial Majesty the Emperor of Japan has been pleased to confer upon him, in recognition of his services while actually and entirely employed by his Imperial Majesty beyond her Majesty's dominions." Mr. Conder, who is an Associate of the Royal Institute of British Architects, acted for some time as Architect to the Japanese Government.

**Theatres.**—Sir Henry A. Hunt has been appointed arbitrator in the matter of the appeal against the notice served by the Metropolitan Board of Works on the owners of the St. James's and Sadler's Wells Theatres, under the Metropolitan Management and Building Act Amendment Act, 1878.

**Tenders for Surveyor's Work.**—One of the persons tendering sends us the following list of tenders for the completion of Survey and District Map, Burgess-hill, Sussex, for the Burgess-hill Local Board:—

Arthur Leader .....	£125 0 0
C. O. Blaber .....	95 0 0
Charles R. Gritton .....	90 0 0
Frederick W. Hyde .....	63 0 0
E. J. Hamilton .....	55 0 0
H. C. Card .....	50 0 0
Samuel Denman .....	48 0 0
W. H. Nash .....	44 2 0
Thomas Hunter (accepted) .....	39 0 0

We are surprised to find that so many as nine tenders were sent in, for we hold that the practice of tendering for professional work is one strongly to be deprecated. It would appear from the list that surveyors can be as much wide of each other in their "tenders" for a given piece of work as builders themselves are sometimes found to be.

**New Flour Mills at Battersea.**—A description is given in a recent number of *Engineering* of the mechanical contrivances in the large flour-mills just erected at Battersea for Messrs. Marriage, Neave, & Co. It may be noted that the owners have apparently

desired to consider the architectural as well as mechanical side of the subject, having employed an architect, Mr. F. Bath, to design the mills "in the Queen Anne style." We should not have thought that stylo was specially suited for the architectural expression proper to a building of the class; but the intention to study architectural effect is at least to be commended.

**Leeds.**—In a competition instituted by Messrs. Milling & partners, Leeds, for the conversion of the old Corporation Gas-offices in Boar-lane, with an hotel, restaurant, and bodega, the designs of Mr. Nelson, architect, Leeds, have been awarded the first, and those of Mr. Jas. Ledingham, architect, Bradford, the second premiums. Mr. Watson, architect, Leeds, was the referee.

**Leith.**—The foundation-stone of a new Established Church at Lorn-street, Leith, was laid on Saturday, the 19th inst. The plans have been prepared by Mr. James Fairley, architect, Edinburgh, after the Gothic manner. There will be accommodation on the ground floor for 500 persons, and in the gallery for 955. The estimated cost is about 4,000*l.*

COMPETITIONS AND CONTRACTS.

TENDERS.

For the erection of artisans' dwellings, Gibson's Buildings, Stoke Newington. Messrs. Davis & Emanuel, No. 2, Finsbury-circus, E.C., architects. Quantities supplied by Mr. Frederick Downing, No. 7a, Whitehall-yard, S.W.:

Holiday & Greenwood .....	£12,108 0 0
Macey & Sons .....	12,063 0 0
G. S. S. Williams & Son .....	11,983 0 0
Edward Conder .....	11,730 0 0
John Mowlem & Co. ....	11,619 0 0
Chas. & Sons .....	11,947 0 0
William Brass .....	11,483 0 0
John Woodward .....	11,399 0 0
E. Lawrence & Son .....	11,124 0 0
John Grover (accepted) .....	10,913 0 0

For the erection of the first portion of proposed new buildings at St. Mary's College, Woolhampton, near Reading, Berks. Mr. Frederick A. Walters, architect, 4, Great Queen-street, Westminster:—

Norris .....	£5,884 0 0
Parmentier .....	5,590 0 0
Kemp .....	5,399 0 0
Kimberley .....	5,110 0 0
Claridge .....	5,071 0 0
Buckle & Wheeler (accepted) .....	4,350 0 0

For rebuilding Congregational Church, Robertson-street, Hastings. Mr. H. Ward, architect, Hastings:—

Dobson .....	7,240 0 0
Moon & Co. ....	8,200 0 0
Hughes .....	8,200 0 0
Rodda .....	8,100 0 0
Vidler .....	7,854 0 0
Petera .....	7,737 0 0
Jones & Co. ....	7,734 0 0
Twyler Bros. ....	7,595 0 0
Walker .....	7,500 0 0
Woods .....	7,500 0 0
Jenkins .....	7,450 0 0
Wright .....	7,380 0 0
Bingham .....	7,300 0 0
F. Crutenden .....	7,290 0 0
E. Foster .....	7,142 0 0
Higgs .....	7,120 0 0
Elbridge & Crutenden .....	7,100 0 0
Howell & Son .....	7,0 0 0
S. Clarke .....	6,526 0 0

For heating the Presbyterian Church, Chester, with keir "small-tube" hot-water apparatus:—  
John King, Limited, Liverpool ..... £104 0 0

For heating the New Wesleyan Schools, Morley, with their "small-tube" hot-water apparatus:—  
John King, Limited, Liverpool ..... £208 0 0

For completing eight houses on the Oldmill Hall Estate, Forest-gate, for the Land Investment Company, Limited, Messrs. Whitmore & Reeves, surveyors, Devonshire-square, Bishopsgate:—

Table listing contractors and amounts for the Oldmill Hall Estate. Contractors include Barke, Plainlow; Rice, Peckham; Pollard, Forest-gate; Mar in Stratford; R. & W. Foster, Canton-House; Brickell, Manor Park; Beale, Cambridge Heath; Sayer, Leyton; Richardson, Stratford; Perry, Goswell-road; Ditto, ditto (reduced and accepted).

For alterations at the Poplar Union Workhouse, Mr. G. Morris, architect:—

Table listing contractors and amounts for the Poplar Union Workhouse. Contractors include Smith; Sherwood; Howell & Son; Alexander; Denton; Stephenson; D. D. & A. Brown; Robson; Altridge & Jenvey; Mr. Walker; Johnson; Evans; Harper; Curran; Hunt; Harris & Wardrop.

For additions to the offices of the Hornsey Local Board at Southwood-lane, Highgate, Mr. T. de Courcy Meade, engineer and surveyor:—

Table listing contractors and amounts for the Hornsey Local Board. Contractors include Kerry & Son, Highgate; Haber, Highgate; Houghton, King's-cross; Keasley, Kensington; Greenwood, Herndon; Willmott & Co., Lambeth; McCornack & Son, Canonbury; Tall, Chelsea; Tongue, Plumstead; Latham & Son, Wandersland, City-road (accepted).

For the erection of warehouse, offices, &c., at Millwall, E., for Mr. J. T. Morton, under the superintendence of Mr. Wilks & Co., architect, 19, Union-court, Old Broad-street, E.C.:—

Table listing contractors and amounts for the warehouse at Millwall. Contractors include Perry; Brown; Holland; Heiser; Lion; Salt; Higgs & Co.; Downs; Harris & Wardrop, Walwood-street, Limehouse (accepted).

For new building on the site of Mageridge's Oranaries, Queen Victoria-street, E.C. Mr. Wimple, architect:—

Table listing contractors and amounts for the building at Queen Victoria-street. Contractors include Lawrence & Sons; Howe & Co.; Hall, Beddall, & Co.; Ashby & Horner; Colls & Co.; Morter & Co.; Scrivenor & Co.; Brass.

For alterations and additions to Messrs. A. Boske & Co.'s Chemical Works, Stratford, Mr. Richard H. Hill, architect, No. 9, Clement's-lane, Lombard-street:—

Table listing contractors and amounts for the chemical works. Contractors include Morter; Higgs & Co.; Allen & Sons; Greagar; Holland; Howe & Co.; Martin Wells & Co.; Norton & Sons; Harris & Wardrop.

For the erection of Liberal Club at Great Grimby, Mr. Charles Bell, F.R.I.B.A., architect, London and Grimby:—

Table listing contractors and amounts for the Liberal Club at Great Grimby. Contractors include T. Summerson; A. Haywood; J. G. Smith; N. Kirk; Willows & Boehnk; Nightingale & Danby; Tollant Chapman; Riggall & Henries (accepted).

For the erection of a Wesleyan Chapel, Grays, Essex, Mr. Chas. Bell, architect, Quantities by Mr. Henry Lovock, 26, Bridge-road, E.C.:—

Table listing contractors and amounts for the Wesleyan Chapel at Grays. Contractors include Lawrence & Co.; H. J. Carter; J. Anley; J. Brown; J. Baxter; Thompson & Son; Everett & Son; Geo. Green; W. H. Archer; W. Wood; Brickell.

For the erection of bailiff's cottage and farm buildings on the Corporation Farm at Hampton Park, Hereford, for the Hereford Town Council. Mr. J. Parker, city surveyor:—

Table listing contractors and amounts for the farm buildings at Hampton Park. Contractors include Edward Powell, Hereford; George Hudson, Hereford; Wm. Collis, Hereford; H. Webb, Hereford; Jas. Davies, Hereford; Jas. Watkins, Hereford; Gardner & Co., Hereford; A. J. Colley, Hereford; Jas. Collier, Hereford (accepted); [Surveyor's estimate, £380].

For the erection of new stabling, kitchen garden, and terrace walls, &c., at Sandhurst, for Lieut.-Col. Harvey, Mr. W. Ravenscroft, architect, Reading. Quantities by Messrs. Cooper & Sons, Reading:—

Table listing contractors and amounts for the stabling at Sandhurst. Contractors include Grover, Reading; Lawrence & Sons, Wharf-road, N.; Margetta, Reading; Smallwood & Co., Birmingham; Thos. Higgs, Goswell; Rider & Son, 181, Union-street, Southwark; H. Higgs, Reading; E. Hovoes; Bottrill, Reading (accepted).

For the erection of a house in the North Common-road, Ealing, for Mr. J. Lee Thomas, Mr. Robert Willey, architect, 68, Ludgate-hill, E.C.:—

Table listing contractors and amounts for the house at North Common-road. Contractors include Green, Clapton; Lathby Bros, Battersea; Peony & Co., Ealing; Waters, Ealing; Macey & Sons, Strand, W.C.; Nye, Ealing (accepted).

For the erection of a house at Harlesden for Mr. E. Powell, Mr. Robert Willey, architect, 68, Ludgate-hill:—

Table listing contractors and amounts for the house at Harlesden. Contractors include Standen, Harlesden; Tennant, Willesden; Waters, Ealing; Nye, Ealing; Bailey, Ealing; Peony & Co., Ealing.

For the erection of warehouse, &c., Theatre Plain, Great Yarmouth, for Mr. W. G. Knappes, Messrs. Bottle & Olley, architects, Great Yarmouth:—

Table listing contractors and amounts for the warehouse at Theatre Plain. Contractors include M. Barnard; Rana & Cooper; R. Davy; F. Hovoes; J. Leggett; T. Hovoes; J. W. Bray; Cork & Beech; J. S. Cooper (accepted).

For the erection of first portion of a curate's house to the St. Paul's Mission Church, for the Rev. Canon G. Venables, vicar, Great Yarmouth, Messrs. Bottle & Olley, architects:—

Table listing contractors and amounts for the curate's house at St. Paul's Mission Church. Contractors include Cornhill & Gaymer; Cork & Beech; T. Hovoes; J. Leggett; G. Nickerson; E. Hovoes (accepted).

For the erection of a class-room for the Cobbold Island Board School for the Great Yarmouth School Board, Messrs. Bottle & Olley, architects:—

Table listing contractors and amounts for the class-room at Cobbold Island. Contractors include B. Springall; J. W. Bray; J. Leggett; Cork & Beech (accepted).

For the erection of a class-room, &c., to the St. James's Church Schools, Great Yarmouth, Messrs. Bottle & Olley, architects:—

Table listing contractors and amounts for the class-room at St. James's Church. Contractors include M. Barnard; J. W. Bray; Hall, Beddall, & Co.; Cork & Beech; B. Springall (accepted).

For the erection of a class-room, &c., to the St. John's Church Schools, Great Yarmouth, Messrs. Bottle & Olley, architects:—

Table listing contractors and amounts for the class-room at St. John's Church. Contractors include J. Leggett.

For the erection and completion of new hay stores at the Foreign Gate Market, Deptford, for the Corporation of the City of London, Mr. Horace Jones, architect, Quantities by Messrs. William Reddall & Son:—

Table listing contractors and amounts for the hay stores at Foreign Gate Market. Contractors include Hubble & Trott; Hobbs; Staines & Son; Dickinson; Gentry; Howell & Son; Greenwood; Dickes'n; Nightingale; Morter; Mowlem & Co.; Richardson.

A.—All walls in brickwork. B.—Internal walls in concrete. C.—"Imperial" or "no" paving instead of York stone.

For the alteration and adaptation of the old Monastery Buildings to form new Gut Stores at the Foreign Cattle Market, Deptford, for the Corporation of the City of London, Mr. Horace Jones, architect, Quantities by Messrs. William Reddall & Son:—

Table listing contractors and amounts for the gut stores at Foreign Cattle Market. Contractors include Hubble & Trott; Hobbs; Howell & Son; Staines & Son; Dickinson; Richardson; Greenwood; Nightingale; Gentry; Dickes'n; Morter; Mowlem & Co.; Richardson (Accepted).

A.—If with York stone paving. B.—If with "Imperial stone" paving.

Accepted for five cottages at New-road, Holy Well Brook, near Halthax. Mr. T. L. Patchett, architect, Halthax:—

Excavator and Mason's Work. Thomas Walker, Stamford. Carpenter and Joiner's Work. Collins & Hirst, Sowdon. [Total amount, £345.]

For pulling down and rebuilding 56, Cheapside, for Messrs. Walce & McChulloch, Mr. B. Taberner, architect. Quantities by Messrs. Franklin & Andrews:—

Table listing contractors and amounts for the rebuilding at 56 Cheapside. Contractors include F. Mark; R. Conder; W. Stubbis; Downs; Patman & Fotheringham; Baylis.

For pulling down and rebuilding 57, Cheapside, for Mr. Thos. Cookesey, Mr. R. Cane, architect, Quantities by the architect:—

Table listing contractors and amounts for the rebuilding at 57 Cheapside. Contractors include Lawrence & Son; Downs; R. Conder; W. Stubbis; F. Mark; Baylis.

For repairs, painting, and additions to offices of St. Matthew, Bethnal-green Board of Guardians, Messrs. T. & W. Stone, architects, 2, Great Winchester-street, E.C.:—

Table listing contractors and amounts for the repairs at St. Matthew. Contractors include Needham & Disfore; Cohen; Peers; Thompson & Tread; Sharp; Hawkes; Richards; Oldie Bros; Wood; Beale; Thompson; Hobbs; Collis; Chillingworth; Wilcox; Deacon; Collins.

For rebuilding 77, High street, Ashford, for the Trustees of the late Mr. T. E. Scott, Mr. H. R. King, architect Ashford:—

Table listing contractors and amounts for the rebuilding at 77 High street. Contractors include Giles, Burdon, & Giles, Ashford; J. Wood, Ashford; W. Brooks, Folkestone; J. Huggan, Ashford; W. Baker, Ashford; Deane & Son, Deal; J. Bingham, Headcorn; Howland Bros., Ashford; Tournay & Son (architect's estimate, £630).

For new Mission-house, at Lennox-road, Finsbury Park, Messrs. Searle & Hayes, architects:—

Table listing contractors and amounts for the Mission-house at Lennox-road. Contractors include Maittick Bros.; Goodman; Cordell; Wilson & Exton.

For the erection of a villa at Lee-on-the-Solent, Fareham, Hants, for Mr. J. C. Robinson, Mr. J. E. Clifton, Swanage, architect:—

Table listing contractors and amounts for the villa at Lee-on-the-Solent. Contractors include Gamblin; Polford; Plummer (accepted).

For forming and completing a road at Lee-on-the-Solent, for Mr. J. C. Robinson, Mr. J. E. Clifton, surveyor:—

Table listing contractors and amounts for the road at Lee-on-the-Solent. Contractors include Benton; Hayer; Plummer (accepted); Butt.

For the construction of new staircase, &c., to Read's Restaurant, 94 and 95, Cheapside, E.C. Messrs. T. & W. Stone, architects, 2, Great Winchester-street, E.C.:—

Table listing contractors and amounts for the staircase at Read's Restaurant. Contractors include Building, Fitting, & Furnishing Co. (limited (accepted)).

For the renovation and resetting of the Birch Meadow Chapel, Broseley, Mr. S. K. Blund, Ipswich, architect:—

Table listing contractors and amounts for the chapel at Birch Meadow. Contractors include R. & J. Millington, Ockengat; W. & T. Bailey, Ironbridge; C. T. Smith, Broseley (accepted).

For the erection of boiler-room, coal-store, &c., and excavating for basement and subway to the proposed Jones Memorial Block, at the Royal National Hospital for Consumption, Ventnor, I.W. Mr. T. Helyer, architect, Hyde, Isle of Wight. Quantities supplied by Mr. H. P. Foster, 5, John street, Adelphi, W.C.:—

Table listing contractors and amounts for the boiler-room at Royal National Hospital. Contractors include Isaac Barton; Ingram & Sons (accepted).

For the re-erection of factory premises, 53, Parker's-road, Dockhead, S.E., for Messrs. T. & J. Hoaking, Mr. E. Crose, architect, 32, Brandon-square, S.E.:—

Table listing contractors and amounts for the factory premises at Parker's-road. Contractors include C. Clark; J. Ballers; F. Higgs; A. White & Co. (accepted).

For the erection of "Salvation Army Barracks" Redemptor, near Bristol, Mr. E. J. Sherwood, architect, No. 104, Queen Victoria-street, London. Quantities by architect:—

Table listing contractors and amounts for the barracks at Redemptor. Contractors include Francis King, Normanton-road; Bristol; Brock & Brown, St. Phillip's, Bristol; R. J. Crocker, Bedminster, Bristol; H. J. Hossiter, Edgewater-road, Bedminster, Bristol; H. Rossiter, Allings-road, Bristol; Edward King, Stapleton-road, Bristol; C. A. Hayes, 7, Redcliff-hill, Bristol; F. J. Coakal, Leytonstone, Essex; J. James, Stapleton-road, Bristol.

For the erection of Mission Chapel, Northfleet, Essex, Mr. Chas. Bell, architect:—

Table listing contractors and amounts for the mission chapel at Northfleet. Contractors include J. Gould; Mitchell; Wallace; Hopkins; Tuffe (accepted); Martin; Dering.

For the erection of the first part of Kensington Academy for Girls, Addison road, W. Mr. Hugh McLachlan, architect. Quantities by Messrs. McLachlan & Carson—  
 Laing & Son ..... £5,797 0 0  
 E. Stafford ..... 5,769 0 0  
 Snares & Son ..... 5,555 0 0  
 Scharian & Williams ..... 5,327 0 0  
 D. D. & A. Brown ..... 5,463 0 0  
 E. C. Howell & Son ..... 5,350 0 0  
 R. & E. Evans ..... 5,283 0 0

Special Notice.—Lists of tenders frequently reach us too late for insertion. They should be delivered at our office, 46, Catherine-street, Strand, W.C., not later than four p.m. on Thursdays.

TO CORRESPONDENTS.  
 J. M.—T. H. L.—C. L. T.—E. T. H. (next week)—C. B. A.—U. & Co.—A. L. F.—P. J. D. (next week)—J. C. M. (the principle may be called an old one in England now, and the special notice grants no advantage except where flat roofs are the rule)—H. G. & Son.  
 All communications regarding literary and artistic matters should be addressed to THE EDITOR; all communications relating to advertisements and other exclusively business matters should be addressed to THE PUBLISHERS, and not to the Editor.  
 All statements of facts, lists of tenders, &c. must be accompanied by the name and address of the sender, not necessarily for publication.  
 We are compelled to decline pointing out books and giving addresses.  
 Note.—The responsibility of signed articles, and papers read at public meetings, rests of course, with the authors.  
 We cannot undertake to return rejected communications.  
 Letters or communications (beyond mere news items) which have been duplicated for other journals, are NOT DESIRED.

PUBLISHER'S NOTICES.  
 THE INDEX and TITLE PAGE for Volume XLVI. (January to June, 1884) were given as a Supplement with the Number of July 12.  
 A COLOURED TITLE PAGE may be had, gratis, on personal application at the Office.  
 CLOTH CASES for Binding the Numbers are now ready, price 2s. 6d. each; also  
 READING-CASES (Cloth), with Strings, to hold a Month's Numbers, price 2s. each, also  
 THE FORTY-SIXTH VOLUME of "The Builder" (bound), price Twelve shillings and Sixpence.  
 SUBSCRIBERS' VOLUMES, on being sent to the Office, will be bound at a cost of 3s. 6d. each.

CHARGES FOR ADVERTISEMENTS.  
 SITUATIONS VACANT, PARTNERSHIPS, APPRENTICESHIPS, TRADES, AND GENERAL ADVERTISEMENTS.  
 Six Lines (about fifty words) or under ..... 6s. 6d.  
 Each additional line (about ten words) ..... 4s. 6d.  
 Terms for Series of Trade Advertisements, also for Special Advertisements on front page, Competitions, Contracts, Sales by Auction, &c. may be obtained on application to the Publisher.

SITUATIONS WANTED.  
 FOUR Lines (about THIRTY words) or under ..... 2s. 6d.  
 Each additional line (about ten words) ..... 6s. 6d.  
 PREPAYMENT IS ABSOLUTELY NECESSARY.  
 \* \* \* Stamps must not be sent, but all small sums should be remitted by Cash in Registered Letters or by Money Order, payable at the Post-office, Covent garden, W.C. to  
 DOUGLAS FOURDRINER, Publisher.  
 Advertisements for the current week's issue must reach the Office before THREE o'clock p.m. on THURSDAY.  
 The Publisher cannot be responsible for DRAWINGS, TESTIMONIALS, &c. left at the Office in reply to Advertisements, and strongly recommends that of the latter COPIES ONLY should be sent.

TERMS OF SUBSCRIPTION.  
 "THE BUILDER" is supplied gratis from the Office to residents in any part of the United Kingdom at the rate of 12s. per annum, FREE OF CHARGE. To countries within the Postal Union, 20s. per annum. Remittances payable to DOUGLAS FOURDRINER, Publisher, No. 46, Catherine-street, W.C.

SPECIAL.—ALTERATIONS IN STANDING ADVERTISEMENTS OR ORDERS TO DISCONTINUE same, must reach the Office before TEN o'clock on WEDNESDAY MORNINGS.

PERSONS Advertising in "The Builder," may have Replies addressed to the Office, 46, Catherine-street, Covent-garden, W.C., free of charge. Letters will be forwarded if addressed envelopes are sent, together with sufficient stamps to cover the postage.

Best Bath Stone.  
 WESTWOOD GROUND,  
 Box Ground, Combe Down,  
 Corsham Down,  
 And Farleigh Down.  
 RANDELL, SAUNDERS, & CO., Limited,  
 Corsham, Wilts. [Adv't.]

Box Ground Stone  
 Is the Best for Use in all Exposed Positions, being a well-known and tried Weather Stone.  
 50,000 feet cube in stock.  
 PICTOR & SONS, BOX, WILTS. [Adv't.]

Doubling Free Stone and Ham Hill Stone  
 of best quality, in blocks, or prepared ready for fixing. An inspection of the Doubling Quarries is respectfully solicited; and Architects and others are CAUTIONED against inferior stone. Prices, delivered to any part of the United Kingdom, given on application to CHARLES TRASK, Norton-sub-Hamdon, Ilminster, Somerset.—Agent, Mr. E. WILLIAMS, 73, Charlotte-street, Portland-place, W. [Adv't.]

Doubling Free Stone For prices, &c., address S. J. & P.,  
 HAM HILL STONE, Quarry Owners, Stone  
 BLUE LIAS LIME and Lime Merchants,  
 Stoke - under - Ham,  
 (Ground or Lump), Ilminster. [Adv't.]

Asphalte.—The Scyssel and Metallic Lava Asphalte Company (Mr. H. Glenn), Office, 38, Poultry, E.C.—The best and cheapest materials for damp courses, railway arches, warehouses, floors, flat roofs, stables, cow-sheds and milk-rooms, granaries, tun-rooms, and terraces. [Adv't.]

Asphalte.  
 Scyssel, Patent Metallic Lava, and White Asphaltes.  
 M. S T O D A R T & C O.  
 Office:  
 No. 90 Cannon-street, E.C. [Adv't.]

### Society of Arts Conference on Water Supply.

HE Society of Arts held a Conference at the Health Exhibition last week, on the important subject of Water Supply. H.R.H. the Prince of Wales had originally signified his intention of presiding, but circumstances having necessitated the postponement of the Conference,—which was to have been held soon after the opening of the Exhibition,—the chairmanship devolved on Sir Frederick Abel.

The Papers, which numbered seventeen in all, were divided under three heads:—

1. Source of Supply.
2. Quality of Water,—Filtration and Softening.
3. Methods of Distribution in detail.

The papers were, for the most part, short and condensed, as the time allowed for their delivery was limited to twenty-five minutes, and the speakers in the discussion were restricted to ten minutes. The topics discussed were very varied, and some of them were so important that it was scarcely possible to treat them exhaustively in the limited time available. One paper especially, that by Professor Sorby (which we print in another column), propounded so novel and startling a view as to the purifying action of minute animals and plants as to deserve almost a separate meeting for its discussion, while the paper which followed it, by Professor Odling, was of itself sufficient to occupy the attention of the Conference for an entire day; but the discussion was, of course, for want of time, brought to a premature close. Three out of the four papers first read referred exclusively to the "Underground Supply"; that by Mr. Whitaker, F.G.S., was illustrated by a series of very interesting maps, on which were depicted the entire chalk formation and the various permeable and impermeable beds by which it is overlaid. As the object sought by Mr. Whitaker in the construction of his maps was "Contrast and Conspicuousness," the colouring adopted by him differed from that ordinarily used in strictly geological maps, but to the engineer or to hymen not well versed in geological lore, the simplicity of Mr. Whitaker's maps depicts very clearly the area of the chalk formation which is accessible to surface water. The result arrived at somewhat reduces the excessive estimates which have been

hitherto current of the chalk area available for the absorption of rain, but at the same time confirms the fact that it is the chief water-bearing bed in the South of England. The second paper by Mr. Topley was interesting in indicating how the water supply always in past times influenced the distribution of the population; but under the present altered circumstances of England, the local supply has become rather a source of danger, so that all large cities and towns now prefer seeking for their water from a distant source.

Mr. de Rance's paper bore on the possible increase of the underground supply, which, he stated, might be accomplished by the sinking of "dumb-wells" through the overlying strata, and so carrying off into the water-bearing rocks much of those surface floods which now only run to waste after having mischievously inundated large tracts of land bordering their courses. Mr. de Rance estimates the area in England and Wales occupied by porous rocks at 26,600 square miles, while the tertiary, gault, weald, oolite, liassic clays, the triassic and permian marls, and the shales of the carboniferous period occupy a further 19,000 miles, in nearly the whole of which occur "pervious rocks" which might be further utilised by means of dumb-wells as underground reservoirs.

Mr. Lucas dwelt on certain particular areas of the chalk formation which he had recently surveyed, and drew attention to a notable exception which he had discovered in the green-sand formation of some springs remarkably situated on the high watershed ridge on which stands the town of Warminster, and which lies between the English and Bristol Channels.

These papers and the discussions which followed seemed to point to the conclusion that though there is undoubtedly a very large area from which an underground supply of water may be drawn, yet that, as far as inquiries have at present extended, the knowledge as to its capacity is not yet definite enough to frame an estimate of the sufficiency of its supply, especially as it is the minimum and not the maximum quantity available that should form the basis of such estimate, seeing that the storage in the chalk is always largest at the end of the year. The probability, therefore, is that it must be supplemented by leading to it some of the surplus water which now escapes by floods, and that, as far as experience at present extends, it seems certain that abstraction of water at definite points is impossible without injuriously affecting existing rights. Moreover, though, theoretically, water drawn from

the chalk is purer than that taken from river sources, yet, owing to the defective state of the law (as instanced in a late judgment), any one seems to be at liberty to pour any filth down a disused well without regard to the consequence of polluting the supply on which his neighbours are dependent. Until, then, this has been remedied, the superior purity of water drawn from chalk or other wells must always be doubtful, and such hidden dangers are more to be dreaded than those which are apparent on the surface, and are, therefore, better and more easily guarded against.

It is matter of regret that Professor Symons was unable to contribute a longer paper, as everything coming from him is so valuable and suggestive. In explaining the great difference in the rainfall over the United Kingdom, he instanced two places,—the Stye in Cumberland, and Clacton-on-Sea in Essex,—where the rainfall in 1883 measured 190.28 in. and 18.71 in. respectively, or ten times more in one place than in the other. It is well known that the population is almost always in an inverse ratio to the rainfall, and therefore there can be little question as to what the proper public policy should be, viz., to lead the water from the region in which it is most abundant to those places in which the population is greatest. As long, however, as our legislation stands as at present, there is the danger of its proving exceedingly damaging to the interests of the country generally, by conferring water rights which may hereafter become so valuable as to render it almost impossible to acquire them when the need arrives for a re-arrangement or a redistribution of the supply. Professor Symons pertinently asks, "Would it be possible to safeguard our successors, by insisting that special water-rights, if now asked to be created, shall be subject to revision, without compensation, after the lapse of 100 years?" It would be well if our Legislature could be induced to lay this point to heart, and adopt the suggestion ere it be too late for any fresh schemes that may be projected. Some efficient hydraulic organisation, however, must be created before it will be possible to solve the water problem satisfactorily, and before such organisation could be effectively worked it is essential that a knowledge of the laws of rainfall distribution must be better ascertained than they are at present. Professor Symons epigrammatically states the fallacy of the current popular assertion that there are few things so uncertain as the rain. He observed that it is both true and false,—true as regards our ignorance of the future, false as regards our knowledge of the limits within which the quantity of rain will be

found to vary. The following proportion he gives as being within 7 per cent. of the truth:—

Wettest year, 35 per cent. more than the average.  
 Driest year, 33 per cent. less than the average.  
 Driest two consecutive years, 26 per cent. less than the average.  
 Driest three consecutive years, 21 per cent. less than the average.

The subject of Mr. Bailey Denton's paper was the supply to villages and rural districts, the general defective state of which he ascribed to the unwillingness of local authorities to perform the duties devolving upon them. In explaining that the scarcity of water in the present year was due to a dry winter followed by an unusually hot summer, he observed that the deficit would have made itself more severely felt had it not been counterbalanced by the excess of rain which fell from 1876 to 1883, and which gave, on the whole, a considerable balance to carry over. It is doubtful whether that assertion is borne out, for one of the speakers in the discussion remarked that rain in a previous year gives no balance for the succeeding one; for that the summer supply depends entirely on the rainfall of the preceding months is borne out by observations of the reductions of temperature in well-water, owing to the melting of the snows after the month of February. As an inexpensive but efficacious mode of supply for rural districts whose population varies between 400 and 1,000, Mr. Denton advocated the employment of tube wells, and he likewise instanced the cases of Ahingdon and Warwick as towns in which water has been supplied to a population of 6,000 by means of syphons for the last four years without a hitch or difficulty of any kind. This last is a method which, whenever it can be made applicable, obviously commends itself on the score of simplicity and economy, but has to first cost and in subsequent working.

The scope of Mr. Easton's paper was confined to drawing attention to well-recognised principles, which he observed are too often forgotten or neglected. One of the points alluded to by him was that, though water of the purest kind may be delivered in mains, the position and condition of the cisterns to which it may be led too often rendered it utterly unfit for human consumption; and thence he argued that a constant supply should be substituted, wherever practicable, for the intermittent system, but that it should, of course, be under proper regulation, so as to guard against undue consumption and waste, as otherwise the cost to the consumer will be greatly enhanced.

The first division of the Conference was concluded by a contribution from Mr. Mansergh, who advocated a supply of pure "soft" water as being on the whole preferable to a pure "hard" water, and gave briefly a few typical examples of the utilisation of the different sources of supply, enumerating the towns of Lancaster, Glasgow, and Manchester as being supplied from elevated moorland springs, lakes, and artificial reservoirs on the gravitation system, while London furnished the type of water raised partly from rivers and filtered before delivery into the mains, and partly from underground springs. On the whole Mr. Mansergh seems to be in favour of the underground supply, which, he considers, combines the greatest number of advantages with the fewest disadvantages.

A perusal of these several papers leaves the unsatisfactory impression that as there is so much diversity of opinion as to the best sources of supply, it will be hopeless to look for any solution of the problem so long as it is left to the individual opinion of the various parties consulted in each particular case. This difficulty is recognised by some of the most eminent of the several lecturers, some of whom pointed out the necessity for the creation of a Central Government Hydraulic Department. This is a view which has been consistently advocated in the columns of the *Builder*, and which we consider should not be limited to the simple question of water supply, but should be extended so as to exercise a control over the entire water system of the kingdom; for, if one thing has been made clearer

than another by the various discussions which have taken place, not only lately, but on previous occasions, it is the intimate connexion that exists between the various branches of the water question, and how impossible it is to deal with supply, unless the drainage be simultaneously regulated; while the storage of the surplus which falls from the heavens obviously presents the only source from which either surface or underground reservoirs can be fed, or the all-important arterial system of even the existing lines of water-carriage can be maintained. The Protection from Floods Bill still remains unsettled; and it would be well if the Legislature could be persuaded to deal with the whole subject comprehensively, and go to the root of the matter, following the example of the Continental Powers, and creating a Water Department charged with the control and comprehensive treatment of the entire water system of the United Kingdom.

Passing on to the second division of the Conference, the quality of water, the two papers read by Professors Sorby and Odling call for special notice. As before observed, the former puts forward some novel and startling facts, on the truth of which hangs the solution of some, if not all, of the objections which are generally supposed to be ineradicable in connexion with a supply drawn from rivers, and yet, when calmly considered, Professor Sorby's conclusions are only a scientific elucidation of facts which have already been popularly exhibited by means of the solar microscope. When, by means of that instrument, the busy crowds that inhabit a drop of dirty water were first revealed to the human eye, the impression conveyed was a dread of what might not befall the unwary individual who incautiously swallowed such terrible objects. But Professor Sorby's investigations have removed all ground for fear, for they tend to show that those wonderfully minute plants and animal organisms are in reality our friends, and not our enemies. He views them as an atomic army of sanitarians, cleansing rather than polluting the water. His discoveries show them to be living and thriving on what would be death to us, and multiplying to an incredible extent in water sufficiently foul to require large numbers of them for its purification. Professor Sorby even throws out the hint that they may be able to make short work of disease germs, and that in this way an immense amount of infectious disease that otherwise would have to be drunk in with our waters will be disposed of. These disease germs and bacilli of sorts were a source of terror when they were first revealed; but now, when *microcosmi* and *bacilli* are known to people earth, air, and water in myriads, and their infinite variety rivals the number of the sands of the sea or the stars in the firmament, they have ceased to be regarded with horror. Thanks to Dr. Sorby, they may now be contemplated with comparative indifference, when it comes to be proved that they constitute the legitimate food of millions of *entomostraca*,—of how many millions who would venture an estimate, when as, in one season, it is stated, one single female cyclops may give rise to four thousand millions of young. The number of "free swimming" animals in fairly pure river water is not more than one per gallon; in muddy ponds 200 per gallon; in water into which sewage has been discharged, twenty-seven per gallon. The number of microscopic plants in the mud deposited from water is also truly astonishing. In that from pure rivers their number is comparatively small; but in the district of the Thames where sewage is discharged it mounts up to figures not easily comprehended by the ordinary mind. Thus in summer in one grain of mud at half-ebb tide there were found no less than 400,000, which would give 5,000,000 per gallon of water.

Under such circumstances, Dr. Sorby's idea that these minute organisms may be regarded as sanitary allies, and not as a relentless army of disease-mongers, that live only that man may die, should prove a most welcome source of consolation to the nervously disposed who constitute so great a part of the population. To learn that the *bacillus* has so many enemies

is an apt illustration of the well-known couplet,—

"So naturalists observe, a flea  
 Has smaller fleas that on him prey;  
 And these have smaller still to bite 'em,  
 And so proceed ad infinitum."

an extension of the truth of which Jonathan Swift was unconscious when he indited his rhapsody.

Another deduction from Dr. Sorby's investigation is that in microcosmic population the number in a given area bear a distinct proportion to the food supply. Hence by counting that population in a gallon of water it is possible to estimate with sufficient exactness the amount of sewage contamination that has been allowed to flow into it.

Professor Odling's paper most opportunely followed that of Professor Sorby. He commenced by observing that the views he was about to propound were not those which were most popular,—a fact which was made evident by his opponents in the discussion; nevertheless, to those whose judgment is not already biased by professional technicalities, Dr. Odling's arguments convey the common-sense view of the question, and in the opinion of many are likewise unanswerable from the scientific side. He explained how the chemist's definition of "purity" differed from the ordinary acceptance of that term, being used by them not in the sense of the opposite to nasty, but, as is often commonly used, to express the exclusion from one thing of anything else, whether better or worse; as, for instance, the expression of pure rubbish is as familiarly used as pure gold, or, as he humorously observed, "we speak of pure nonsense as readily as we speak of pure truth, irrespective of the circumstances that the nonsense would be benefited, though to the prejudice of its chemical purity, by its contamination with a few grains of sense." Pure water, as conceived by the chemist, he pointed out, had never yet been produced, and may be regarded as an ideal rather than as a real chemical substance. He likewise explained that air from which the minor constituents have been carefully abstracted is sometimes spoken of as purified air, but such air is absolutely incapable in relation alike to animal and vegetable life of fulfilling the functions of our atmosphere. It is exactly the same with water, some of whose minor constituents are known to be essential, while others, there is reason to think, are advantageous to the fulfilment of its functions in nature. Hence, "bearing in mind the interaction everywhere of life and the means of living, it is scarcely to be doubted that the actual mixed substance water is better suited to supply the daily wants of life than the ideal unmixed substance would be." He, therefore, deprecated the practice of using terms in their chemical sense to the general public, who are unacquainted with their particular significance. Dr. Odling then proceeded to show that just as there are different qualities of saline matter in water, so there are different varieties of organic matter in potable water, but that there is a vast difference in their relative proportions, and that while saline matter occurs in appreciable quantities of  $\frac{1}{10}$  to  $\frac{1}{2}$  per cent., the dissolved organic matter never amounts to more than an exceedingly minute proportion, say from  $\frac{1}{10000}$  to  $\frac{1}{1000}$  per cent., and that hitherto the nature of its constituents is almost if not wholly unknown. At the same time, however, the quantity of organic carbon existing in different waters can be definitely determined, and that it is found in its least proportion in uncontaminated spring or well water; that it is not easy to assign the order of seriation in general lake and river sources, but that on the whole it is probable river water must take precedence of lake water in respect to the smallness of its proportion of dissolved organic matter. After stating the result of the analysis of the water furnished by the five Thames waterworks companies, Dr. Odling summarised his remarks by thus describing in a popular way the proportion of organic impurity contained in that water. "If we suppose for an instant that the Thames Companies' water, instead of containing only three-tenths of a grain contained seven-tenths of organic

matter per gallon, a maximum which has occasionally been met with, even this exceptional proportion would but correspond to the presence in the water of exactly the thousandth part of one per cent. of the organic matter." And he concluded that, so far as organic matter is concerned, the water supplied to London from the Thames and Lea takes, on the whole, precedence of the highly and deservedly reputed water furnished to Glasgow, as it doubtless will do also to that about to be furnished to Manchester. Assurances such as these coming from so distinguished an authority as Professor Odling may well comfort the somewhat disturbed serenity of Londoners, and coupled with the previous remarks of Dr. Sorby, bear out the common-sense view of the case which cannot but commend itself to the unprejudiced understanding, that with so low a death-rate as that obtaining in a great city comprising nearly five millions of inhabitants the quality of the water supplied thereto must, on the whole, be exceedingly good; and though the River Thames above the companies' intakes is not yet wholly freed from the drainage of the towns on its banks, yet that it must practically have been reduced to an innocuous proportion.

It has never yet been determined how many of the minor constituents of ordinary water are not absolutely essential to the functions of human life, but there seems to be a danger, if chemists are to have their own way, of water becoming so chemically purified as to deprive it of its vivifying properties, and of mortality being actually increased rather than diminished when the chemist's idea of a pure potable water has been reached.

Space will not allow of the remaining lectures being noticed, but there is one point which we cannot help observing seems to have escaped the observation of both writers and speakers at this Conference when discussing the question of sources of supply. That point is the apparent anomaly of leading waters, which have fallen from the heavens on its surface, into the bowels of the earth, and then devising every possible expedient for economising the trouble and cost of raising it again, instead of adopting the simple plan of storing it in convenient and suitable sites, from which it may, in nine cases out of ten, be delivered by gravitation. The objections hitherto usually urged against storage evidently fall to the ground if the arguments of Professors Sorby and Odling are of any value, but of that value it is for our readers individually to satisfy themselves.

#### THE WAR OFFICES COMPETITION.

**T**HE five judges in the competition which was instituted for the new War and Admiralty Offices (Messrs. Childers, W. H. Smith, Ewan Christian, Hardwick, and the First Commissioner of Works), have completed their examination of the designs of the nine architects invited to join in the final competition, and have reported in favour of the one by Messrs. Leeming & Leeming, of Halifax. It may be convenient to repeat here again the names of the nine architects or architectural "firms" (reluctantly to use a phrase which suggests commercial participation in art) who were competitors in the final struggle, viz. :—

Messrs. Glover & Salter, London; Messrs. H. Hall & W. H. Powell, London; Messrs. Leeming & Leeming, Halifax; Messrs. Maxwell & Tuke, Manchester; Mr. Thomas Porter, Norwood; Messrs. Spalding & Auld, London; Messrs. Stark & Lindsay, Glasgow; Messrs. Verity & Hunt, London; Messrs. A. Webb & E. I. Bell, London.

By the conditions of the competition the judges were to select not more than ten out of the first anonymous competition, which selected ones were to compete again with fuller and more detailed drawings. The provision that not more than ten were to be selected was read, we imagine, by most of the competitors as implying the proposition "not less than ten," and some dissatisfaction has been expressed publicly, and much more privately, that the committee did not at least make up the ten, a dissatisfaction which was mingled

with some astonishment when it became known that some of the most eminent architects of the day had been among the rejected ones, and that no name that could properly claim to be among the most eminent was among the accepted. That people of the reputation of Mr. — and Mr. — should have sent in designs which were not even considered to stand, any of them, as a possible one out of ten, seemed inexplicable and unheard of, and it was hastily assumed by various persons, both within and without the ranks of the competitors, that so unlooked-for a result was due to favouritism. No conclusion, as a matter of fact, could be more illogical. It is always the eminent and successful architect whose name is before the world, who can command the most influence if private motives once come into play, and whose name has in itself the most effect on a committee.

Besides this, the choice of eminent men generally meets with the suffrage of public opinion, and so far it was the interest of the judges, if there was any interest in the matter, to smooth the way for the acceptance of their decision by such a choice, especially in the case of a public building of so much importance as this. The accusation of favouritism, therefore, was absurd in itself; but, beyond that, we wish to add that, from what we have seen and heard about the matter, we do not believe any competition has been or could have been decided with more absolute and *bona-fide* intention of perfect fairness to all than this one has been. Whether the result has been the selection of the best and most suitable design out of the whole number originally submitted is, of course, another matter. We may have absolute faith in the *bona fides* of the Committee, but not equal faith in their judgment. We should certainly have been disposed to think that the two professional members of the Committee, Mr. Ewan Christian and Mr. P. C. Hardwick, were exceptionally qualified to form an impartial and reliable judgment in such a matter. We were disposed to think, with one or two of our correspondents, that the selection of the nine designs out of 128 was accomplished in rather a short time; but it is very easily to be believed that among those 128 were a considerable proportion which it was not worth while to analyse, and which might safely be put on one side at once. But on the other hand, when we look at one or two that are among the chosen nine, we find it very hard, — nearly impossible, in fact, — to believe that some of the architects who we know were among the competitors could have sent in anything which was not superior to these. On this account we hold that the authorities would have done still more fairly by all concerned if they had organised an exhibition of the whole of the designs originally sent in. They would then have given the unsuccessful men the benefit of publicity, at least, for their work, and they would have shown emphatically that they did not shrink from public criticism as to the selection. They may call together such an exhibition still, and if they do not, the unsuccessful competitors themselves may organise one. But it would come with a far better grace from the Office of Works.

In regard to the final competition, and the process of selection, we may quote the words of the judges' report :—

"The judges, after a careful examination of these designs, selected three as possessing special merit, — namely, those of Messrs. Leeming & Leeming, Halifax; Messrs. Verity & Hunt, Regent-street, London; Messrs. A. Webb & E. I. Bell, Queen Anne's-gate, London.

After further consideration of the relative merits of these three designs, the judges are unanimously of opinion that, taking the plans and elevation together, and having regard to the conditions of the competition, Messrs. Leeming & Leeming have produced the best design, and they accordingly recommend to her Majesty's Government that, subject to the approval of Parliament, Messrs. Leeming & Leeming be employed as architects of the new building for the Admiralty and War Office."

The nine designs are now at No. 18, Spring Gardens, where they have been open during the last three days of this week to the inspection of members of Parliament and of members of the Institute of Architects and the Archi-

tectural Association; and for one month from Monday next they will be open to the general public for inspection, from eleven till four on each day.

We do not propose to attempt an analytical criticism of the designs after the short examination of them conjointly, for which alone there has been time this week. To attempt to form a judgment in one afternoon of the relative merits of plans which have occupied weeks or (taken altogether) months in consideration and preparation, would appear to us equal in justice to the authors and to ourselves. We propose to give a careful and detailed analysis of the whole set when we have had more time to consider them fully in reference to the requirements of the Office of Works. In regard to the general architectural merits of the designs it is possible, of course, to see more at a glance than can be accomplished in regard to plan. That the design selected is not the best architecturally, as far as style and picturesque effect are concerned, can be seen at a glance. It does great credit, however, to its authors in respect of the care and finish which has been bestowed upon every portion of the drawings, and is, in fact, one of the most admirable pieces of purely architectural draughtsmanship which we remember to have seen. That it has, even unconsciously to the minds of the judges, owed its position in some degree to this quality we should be disposed to believe. As to design, the features are Classic, grouped in a very odd fashion in some respects, and with apparently a great uncertainty on the part of the authors as to which portions, both of the whole and of details, they really wished to accentuate, and a still greater uncertainty as to scale. Details of one story appear to belong to a building of quite a different scale from those which another story suggests, and the whole design appears to need revision in this respect: it consists of a number of details which have no relation to each other or to any "common denominator." The one emphatic point in the design is where it should not be, in the shape of a high tower "over-crowning," as Dugald Dalgetty would have said, the Horse Guards. This is not only objectionable in itself, but at variance with the suggestion of the authorities, that an attempt should be made to lead down to the Horse Guards, and combine it with the new building; which would certainly have been possible and would have been an interesting little problem in design. Messrs. Bell & Webb's design, which is of the French Chateau order, is a far more picturesque building, and more of a united whole, than what must, we suppose, be regarded as the selected one. Whether the latter presents points of superiority in plan sufficient to atone for its inferiority in architectural treatment we shall be able to conclude when we have examined the plans more carefully. Messrs. Verity & Hunt's design is a powerful and massive-looking building, employing a large Classic "order" at the salient points of the design, and richly decorated with sculpture; it is much better grouped as a whole than the selected design, but not so elegant or finished in detail.

We have arranged, by permission of the Office of Works, who are now the owners of the drawings, for the publication of the whole nine designs, giving sufficient drawings of each to form a complete record in our pages of the materials of the competition; but the preparation of these will occupy a week or two, as we have preferred to wait till the designs were collected and exhibited under Government authority before taking any steps for their publication.

#### Birmingham Architectural Association.

On Saturday afternoon last the members of this association made an excursion to the Wolverhampton Fine Art Exhibition. Amongst those present were Messrs. Franklin Cross, O. Essex, H. H. McConnell, C. E. Bateman, F. W. F. Newton, and Victor Scruton, hon. sec. After visiting the industrial and archaeological sections the party proceeded to the department of Fine Art. They then visited St. Peter's Church and several other buildings in the town, returning home thoroughly gratified with their excursion.

THE CATHEDRAL OF OUR SAVIOUR  
AT MOSCOW.

(WITH ILLUSTRATION.)

**T**HE foundation stone of the present Khram Spassitel, Cathedral of Our Saviour, at Moscow, was laid by the Emperor Nicholas, the grandfather of the reigning Tsar, in 1839; and the remarkable edifice which bears that name was not completed till the year 1880. In some respects it is new, in others it belongs to ancient history; for though the present building was not commenced till 1839 the history of the cathedral dates back to much earlier times. Ever since the disastrous campaign of 1812 it had been the intention of the pious Alexander I. to raise a temple to God in gratitude for the deliverance of his country and in commemoration of the confusion of the French. This worthy idea did not find a fit and artistic expression until 1816, when a certain Witberg sent in a scheme that called forth universal admiration for its magnificence and grandeur. The emperor himself exclaimed, "You have divined my thoughts, my wishes for this temple, which I have kept secret in my bosom, never hoping to find an architect to satisfy me. You have made the stones to speak!" The extraordinary part of the matter was that Witberg was not professionally an architect, but had been seized with the idea that it was his mission to carry out this great work. He voluntarily devoted two years to the study of the principles of architecture and to travels in foreign countries that he might return with matured judgment, capable as well as willing to fulfil his mission. His plan was, indeed, sublimely fantastic and mystical. The cathedral was to be erected on the Vorobyovia Gory,—the Sparrow Hills, from whence Napoleon had first looked down on the ancient capital of Holy Russia. It was to represent a man, for the spirit of God is in each of us, and consequently it was to consist of three parts: one to represent the body, and dedicated to the Nativity; another to represent the soul, dedicated to the Transfiguration; the third to represent the spirit, and dedicated to the Ascension. The first and lowest church was to be placed at the foot of the Sparrow Hills, and built in the shape of a coffin,—it was to be dark, and only to admit the light from one side. The second church was to be on the side of the hill, and should represent a cross; whilst the third, which it was proposed to erect on the summit, was to be circular in shape to represent eternity. This too symbolic design was, however, not destined to be carried out. In 1825 a commission was appointed to inquire into the progress of the work, and the result was that the site was condemned as unsuitable, owing to the clayey nature of the soil. The foundations, the committee discovered, would sink into the ground, and the work requisite to make them secure would involve an enormous increase of expenditure. The most unfortunate part of the matter, however, was that the Commission discovered many serious malpractices, and proved that the moneys of the State and the building materials were embezzled most shamefully. The result of the whole inquiry was that Witberg was exiled to Viatka, in 1828; and the remarkable church on the Sparrow Hills was never heard of. It should be remembered that the strong hand and sharp common-sense of Nicholas is traceable in the appointment of this Commission and the summary punishment of the amateur architect, whose only vocation, it appears, was to embezzle; for Alexander had died long before 1825. The ruling powers of Russia now found themselves again face to face with the problem of erecting a fitting monument to remind future generations of the great mercy which Providence had shown to the Russian people, and to exhort them to piety and gratitude. The question was at last settled in favour of the present cathedral. This has been built entirely of Russian materials, not the least interesting among which is the Russian marble from the Kolomensky district of the Government of Moscow. The cathedral is faced with white stone; it is flanked by four towers, each surmounted by a golden cupola,

and the body of the building is covered by an enormous gilded dome, in which the whole of Moscow can be seen reflected. The relief work is in marble. The cathedral, from its base to its highest cross, stands 336 ft. 6 in.; it covers an area of 10,500 square feet, the centre dome is 98 ft. in diameter, this is gilt externally. A congregation of 7,200 persons can find easy accommodation in the body of the church. The northern and southern entrances are 300 ft. apart. The cathedral contains 726,530 cubic feet of air; it is lighted by sixty windows, and it has fourteen bells in its four belfries. It is difficult to identify the building with any particular order or school of architecture. Russians say it is built in the Græco-Byzantine style, which is so far near the truth that it seems like the work of a Byzantine architect tinkering a little with some reminiscences of Classic detail. The cathedral is situate some little distance from the Kremlin, fronting the Pretchistensky Boulevard, with the river at its back. It lies high, and is surrounded by a large open space. A handsome embankment, lighted by electricity, keeps the river in its bed. The golden dome of this national memorial can be seen from almost any part of Moscow, and is a most important feature in the beautiful panorama that unfolds itself before the spectator's eyes as he looks down on the white-spired city of the Tsars from the summit of the Sparrow Hills, the river gliding beneath him, and the gorgeous churches and innumerable ponds reflecting the rays of the sun in the distance. Its situation near the Kremlin, which is built on a bill, would have dwarfed it but for its enormous size. The interior is very richly decorated, columns of malachite with gilded capitals, and pictures of saints with gilded frames give it a gorgeousness which throws even the ritual into the shade. The Emperor Nicholas expressed the wish, when the question of decorating the cathedral had to be considered, that the pictures should illustrate the principal mercies of the Almighty towards Russia during the last nine centuries. The chief task, therefore, of the building committee became the choice of suitable sacred subjects for decorating the domes and walls in harmony with the Emperor's idea, and the assignment of a fit symbolical meaning to each portion of the interior. All decorations for the centre are descriptive of the earthly life of the Saviour, and illustrations of all such events as were calculated to corroborate His Divinity, and point to the fact that the destiny of the world is in the hands of Divine Providence. The other sacred pictures bear reference to all such events as were of any special importance to the spiritual and worldly development of the Russian Empire. They are distributed in various parts of the building, and correspond to its great significance as a national historical monument and a place of public worship. It was originally the intention of the Emperor to have all these paintings executed in the ancient ecclesiastical Byzantine style; but on secondary considerations this original intention was not carried out, and there are at present but few such pictures in the cathedral. The majority of the paintings has been executed by Russian artists of the modern academical school, and in harmony with contemporary conceptions of art. And here a difficulty at once arose. Unfortunately, contemporary Russian artists are but little familiar with the conventional types of the principal saints, and are not unfrequently guilty of the gravest archaeological blunders in their delineations. To avoid any possibility of error in this direction, copies of the celebrated holy pictures at the various monasteries and churches, illustrative of such subjects as it was desirous to depict, were carefully taken by monks accustomed to this sort of work, and these copies were made the basis of the pictures for the cathedral. In the principal and central dome, having a diameter of 91 ft., is representation of the God of Sabaoth of the Old Testament, with the Son of God sitting on His right hand, in the shape of a child, with the inscription "Logos," and on His finger the Holy Ghost in the form of a dove. He is surrounded by angels, and on the border

of the cupola are represented,—The Saviour, the Virgin Mary, the Archangels Michael and Gabriel, the Patriarchs, King David, the Prophets, the Apostles, the first martyr Stephen, the Emperor Constantine, the Grand Duke St. Vladimir, and the Grand Duke St. Alexander Nevsky. The four smaller cupolas have painted in them,—(1) on the eastern wing, the Holy Ghost in the form of a dove; (2) on the western wing (opposite the altar), the Saviour as a child, surrounded by angels; (4) on the northern wing, God Almighty, with a sceptre in one hand, and the Book of Judgment in the other. The respective cost of these six works of art were as follows:—The central dome, 100,000 roubles (about 10,000*l.*); the border, 100,732 roubles; the smaller cupolas, 43,000 roubles. There are 177 marble tablets in the walls of the cathedral, with inscriptions relating to historical events.

NOTES.

**S**OME months ago we gave an account of the projected expedition of exploration to be undertaken by Mr. Flinders Petrie, on behalf of the Egyptian Exploration Fund. Mr. Petrie has just returned to England, having completed his first campaign amid the extensive ruins of the ancient city of Zoan or Tanis. The vast mounds of debris which mark the site of the ancient capital of the Delta provinces were so extensive that the works had to take the form rather of prospecting than a thorough and systematic clearance of the site. The results obtained from a series of shafts and trenches sunk and excavated in the great temple area and of the greatest importance, as the antiquities discovered show that from the early days of the fourth dynasty until the time of the Ptolemies, the shrine was a favoured one. The earliest inscribed record is the inscription of Pepi, of the sixth dynasty, which was found built into the wall of a later edifice. One of the most curious results of the work here has been the revelation of the practical tendencies of some of the greatest Pharaohs. Rameses II. (Sesostris) seems to have been a great offender in this way. Requiring a statue of his mother, he took one of a princess of the twelfth dynasty, altered it by having the dress and hair elaborated in a Ramesseid fashion, in place of the antique simplicity; trimmed away the sides of the lower part of the thumbs, as they were thought too heavy, and then put on a bold inscription appropriating it; while the face was left fairly untouched. Above the whole vast edifice of the Temple towered a vast figure of Rameses himself, the building only reaching the waist. From fragments of arms, feet, and legs which remain, it is estimated that this colossal must have been at least 100 ft. high, and probably the heaviest statue known. Mr. Petrie brings with him a number of photographs and plans, and his report will be a valuable addition to Egyptian archeology.

**B**y the death of the Rev. Mark Pattison, late Rector of Lincoln College, Oxford, we have lost one of those rare and widely cultured intellects whose absence will be felt and regretted among all classes of educated men. His name was most prominently associated with the higher class of literary study and literary work, but nothing came amiss to his shrewd and observant mind; questions such as those of electric lighting, of natural history, of art criticism, all aroused his interest; and none who ever "talked architecture" with him, and noted his quiet yet trenchant criticism, and his faculty of immediately going to the root of the logical meaning of the art, will consider that a word in *memoriam* of him is out of place in an architectural journal.

**T**HE opinion we have already expressed in regard to the possible extra risk of such fractures as that which caused the dreadful accident at Penistone, arising in the case of crank axles as distinguished from continuous axles, is also adopted, we observe, in an able letter to the *Times* of Thursday last by Mr. G. F.

Armstrong, who, while stating that from his own personal knowledge the firm who make those axles spare no precaution that human skill and foresight can suggest in their manufacture, adds:—

“The real fault is in the design of axes of this character, not in their manufacture. Of all the mechanical elements which go to form the modern locomotive the cracked axle is mechanically the weakest, and a moment's consideration will show this to be the case. Suppose one of these axles were placed in an upright position, as a column, and employed to support a load placed on its summit, or, what is more to the point, and would also be far more trying to it, as a structure, to resist a series of downward blows, delivered in direction of its length, its inherent unfitness for such a purpose would at once be apparent. Nevertheless, this is precisely one of the functions which, in the locomotive, it is called upon to perform, but with this difference,—that the blows are then delivered, not axially, as would be the case in a column, but on the outer rim of the wheel, which in mechanical effect is the same as if the blows were delivered upon the axle, through the intervention of a lever equal in length to the radius of the wheel. The effect of this kind of usage may easily be conjectured. The material of which axles thus circumstanced are made, even when perfectly sound, and without flaw of any description, becomes in the paralytic short time fatigued, and would, were the structure not renewed, give way just as the one at Farnstone did.”

By the “blows on the rim of the wheel” Mr. Armstrong, of course, means those which arise from the “charge” of the flange against the rail in ordinary oscillation, or in going round a curve. This view of the matter alone explains why such a breakage should be more probable in going round a curve than on the straight; and it forms also, we may observe, the best answer to the ignorant and unpractical suggestions which writers in the daily papers have made as to the increased safety by deeper flanges. On Mr. Armstrong's theory, which we believe is quite correct, the blow of the flange against the rail will rather fracture the axle than lead the flange over the rail. Could more be said for the safety of the present flange?

ABOUT the same time that our remarks on the proposed alterations at Westminster Hall were going to press last week, we observe that Sir G. Campbell addressed a question to the First Commissioner in much the same sense as that which we have been advocating, inquiring “whether, since the report on Westminster Hall (just presented) showed that, from the time it was built and ‘divers lodgings’ were attached on the west side till the Law Courts were demolished the other day, the space on the west side of the Hall always had been occupied by useful buildings, he would fully consider the growing wants of Parliament, and provide for them?” The First Commissioner replied that Sir C. Barry had intended to erect an additional wing to “this building,” running from St. Stephen's porch, and meeting another coming from the clock tower. This extension, however, was abandoned some years ago, and he could hold out no prospect of its being revived, on which Sir G. Campbell intimated that, considering the strong opinion expressed by the Prime Minister in regard to the delegation of the duties of the House, he should take an early opportunity of asking him whether he will use his influence with the First Commissioner of Works not to make such delegation physically impossible by devoting the only available space to a piece of sham ancient architecture. We venture to hope that some other members of the House will show themselves alive to the fact that sham Mediaeval work is of very questionable value, and that the suggestions of Sir C. Barry, who was a practical man as well as an artist, may be worth consideration.

AMONG the special questions to be considered at the approaching Congress of the Social Science Association, those which more particularly deal with the class of subjects interesting to our readers are the questions in the Health Department on the “Best means of dealing with town sewage,” and on the “Best means, legislative or other, of securing those improvements in the dwellings of the poor which are essential to the welfare of the

community.” The Health Department have set themselves a tolerable task in those two questions, and if they can elicit a satisfactory answer to them they will deserve well of their country. In the Art Section, the really practical questions are “Should elementary instruction in drawing be made a part of national education?” and “What is the value to the ear, the mind, the health, and the disposition of the young, of class instruction in music?” Of the former we would only remark that to our mind the affirmative goes without saying; instruction in drawing means instruction in the meaning of the objects we see around us, and the cultivation of the power of seeing. We are convinced that the difference between the two boys in the story of “Eyes and No Eyes” was, that “Eyes” had been taught to draw. As to the musical question, we hope it will be discussed by those who understand what teaching music means, and not, as we heard it at the Manchester Congress, by a meeting composed of doctrinaire schoolmasters imbued with mistaken convictions about a supposed royal road to reading music. The third question in the Art Department, “How can a love and appreciation of art be best developed among the masses of the people?” is one of those questions out of “Cuckoo-Clondland” which have a way of turning up at social science congresses, and have about as much practical bearing as the question, “How may the general good of mankind be best attained?” We will suggest that as a departmental question for the next Congress.

WE fear the statue of Burns in the Embankment Gardens cannot be added to the very brief list of our successes in out-door monumental sculptures. It is, as is generally known, a reproduction of that by Sir John Steell at Dundee. The poet is represented seated, and with a pen in his outstretched hand, in a more conscious and theatrical attitude than we can at all associate with the idea of Burns. The face is shorter and rounder than the accepted portraits of Burns give us the notion of. It must be admitted that Burns is a difficult subject for the sculptor, inasmuch as the finest point in his face, his expressive dark eyes, with which all who knew him were struck, is exactly what sculpture cannot convey. But it might have been possible to catch somewhat more of the air of rustic dignity which one can imagine to have characterised Burns, instead of draping him and putting him into “an attitude” at variance with all our ideas of that simple unaffected man of genius. The pedestal, supplied by Messrs. A. Macdonald & Co., of Aberdeen, is a fine block of the native granite, but too large and obtrusive in its polished mass. The work, in short, is pretentious, which is, above all things, what a monument to Burns should not be. We cannot allude to the unveiling of the statue without a word of admiration for Lord Rosebery's speech on the occasion; as true in critical appreciation of his great countryman as it was eloquent in wording. In fact, the speech was the only wholly satisfactory part of the affair.

THE elevation of the new office for the Bank of Scotland in George-street, Edinburgh, is completed. It presents a stately and dignified aspect, is correct and harmonious in its parts, but is somewhat cold and uninteresting. The style adopted by the architects, Messrs. Kinnear & Peddie, is the familiar variety of Italian introduced by Sir Charles Barry, of which the Reform Club in Pall Mall is a well-known example.

A GRAND opportunity for architectural effect has been missed by the architect of the Waverley Hotel, which occupies one of the finest sites in Princes-street, in the same city, adjoining the Scott Monument. It is true he was hampered by a mistaken economy on the part of the proprietor, who has elected to build the new hotel in two sections, so that the new portion when completed might be used along with the old portion left standing. This necessitated the retention of the original low

ceilings, but no effort has been made to group any of the stories together so as to avoid the piled-up effect of flat above flat. The new premises consist of six floors, with two in the Mansard roof, and the elevation is profusely decorated with carving and polished red granite shafts at the division of the window lights. The ornamentation is crude and unsatisfactory, and some of it, after execution, has been cut off.

THE “Society for the Protection of Ancient Buildings” are appealing for funds to preserve from further decay the interesting little chapel of Llandanwg, near Harlech. From the sketches circulated with their letter, it appears that the church is a small building about 50 ft. in length, on the sea-shore, about two miles from Harlech, of which it was anciently the parish church.

“The nave and chancel were continuous, forming one chamber without a chancel arch, though the timbers of the two roofs were differently treated, and there was a chancel-screen of oak. Of the existing fabric the chancel is the best preserved. It was lighted by three windows, one north and south and one east. . . . The repairs recommended by the Society are, that the tops of the walls should be made good, the fallen timbers of the nave, as far as possible, replaced, new rafters, &c., provided, and the roof of the whole building covered with local slates bedded in mortar. Beyond this, shutters will be provided to the windows and iron ties placed across the building where required to prevent the walls from being thrust outwards; and it is distinctly to be understood that the subscriptions made in consequence of this appeal are made on the understanding that nothing beyond what has been recommended by the Society will be done.”

A sum of 80l. is wanted to accomplish this preservative work. We cannot always support the procedure of the Society, but are glad to be able to do so in this case.

MR. LABOUCHERE quoted in “The House” last week some of the strong expressions used in the report of the principal dockmaster to the East and West India Dock Company as to the state of the Thames at Blackwall and the neighbourhood. The minute of the Board was that “The condition of the water is such as tends to the enervation of the staff, and would be a factor in inducing cholera. The matter should be pressed upon the notice of the Board of Works and the Government, with a view to the river being dealt with, not only in the interest of the docks, but of the citizens at large.” There is, however, obviously, no possibility of any immediate change in this state of things. The distance to which sewage contamination, in visible and palpable form, finds its way up, is painfully evident from Putney Bridge at the flood, where the water comes up with thick curls and scrolls of brown matter just beneath the surface. Above Chiswick the mixture gets thinner, though even here the banks at low water show ample evidence of what has been brought up. Above weir we consider that the asserted pollution has been greatly and sensationally exaggerated. But the state of the tidal Thames is most serious, and calls for the earliest possible adoption of measures, which must be on a large and costly scale, for getting the sewage far enough out to elude being brought up wholesale with every flood tide.

“TO remain in Gallery No. 2 is impossible, the smell of cookery is quite too awful.” Numerous visitors at the Royal Academy Exhibition in the recent weeks would have been ready to repeat this lady's words; or to invent something more forcible, as they recollect that Gallery No. 2 had, in fact, no exclusive monopoly. The concentrated quality of the smells as the afternoon advances has been remarked upon by connoisseurs in evil odours; they have even gone so far as to suggest that the cooks must be in fault, for that the smell of good cookery, though it obtrudes at the wrong time, has always some redeeming points. In respect of this, the most universally appreciated of the fine arts, the importance of the instruction, *culara artem*, does not commonly need an expostor. Perhaps, when next year brings to us so many elegant surprises at the Academy,—such, for instance, as

a gallery in which architecture will "sit alone," and find there admirers fit, though few,—it will be made possible for delicate people to attempt to do justice, even to the second gallery, and no one will be wearied of the idea of refreshment by its fearfully pertinacious appeals.

#### THE CHÂTEAU OF CHANTILLY.—II.

We learn from that chapter of the work dedicated by the philosopher Cousin to Madame de Longueville which relates to the Prince de Condé and the splendours of Chantilly that as early as 1845, the Duc d'Aumale, then commanding the French army in Africa, entertained the idea of rebuilding the castle demolished during the Revolution, and of associating his name with it after the example of Anne de Montmorency and the great Condé. We find proof of this resolution in the various preliminary works then executed, and in the preparation of a scheme for the entire reconstruction of the castle dated before the Revolution of 1848. Thirty years, however, passed away before the Duc d'Aumale found himself in a position to realise what had never ceased to be his prevailing idea, and from 1848 to 1875 Chantilly remained uninhabited except during the time when Lord Cowley, British Ambassador to the Emperor Napoleon III, made a summer residence of the Captainerie or Châtelet, the only part of the building left untouched by the Revolution.

In 1875 the Duc d'Aumale summoned M. Henri Daumet, an architect trained in the École Française at Rome, and entrusted him with the difficult task of rebuilding the castle from entirely new designs. Added to the inevitable conditions imposed upon him in common with all previous restorers, M. Daumet had to follow certain definite instructions of a peculiar nature founded upon circumstances upon which it will be necessary here to lay some stress.

The successive calamities which had overtaken the latest owner of Chantilly had deprived him of any occasion for providing for the accommodation of a family. The Duchesse d'Aumale had died during his exile in England, and his last surviving children, the Prince de Condé and the Duc de Guise, had also been taken from him. The supplementary Château d'Enghien, built in the eighteenth century, was spacious and comfortable enough to accommodate at need the brothers and nephews of the duke. The new plan, therefore, had only to reserve a small portion of the castle for private apartments, and Chantilly was to become a palatial museum of art, in which the prince might collect the art-treasures amassed by himself and those that had belonged to Écouen and old Chantilly; the restored castle was thus to recall the memories at once of the Constable Anne de Montmorency and of the great Condé. The famous two-storied subterranean buildings were to be restored and rearranged. One wing only, called "Le Logis," was to be converted into living-rooms. In the remainder were to be placed the pictures, and collections of antiquities, of engravings, and of gems. The celebrated series of painted glass windows brought from the castle of Écouen had also to be displayed, and for this purpose a gallery must be prepared, the number of its windows corresponding with that of the specimens.

The Duc d'Aumale had carried the greater part of his treasures with him into exile, and those who have visited Twickenham will find at Chantilly many similar arrangements, resulting from similar needs. A magnificent series of tapestry hangings, representing hunting scenes after cartoons by Van Orley, dictated the measurements of the gallery dedicated to St. Hubert. Then, again, a new chapel had to be built, to contain the beautiful stained-glass windows lately discovered in the store-rooms of the castle, packed in the cases in which they had been brought from the castle of Écouen. They represented the Constable surrounded by his children (dated 1545), and had been carefully taken to pieces and preserved by Alexandre Lenoir. By him they were deposited in the Musée des Petits Augustins, and upon its suppression they were restored to their original owner the Prince de Condé.

The chapel was also to be fitted up with old wooden carvings from Écouen, a *chef-d'œuvre* of the art of the Renaissance, and with the beauti-

ful high altar in marble designed by Jean Bullant, which had escaped destruction. Finally, the same sanctuary was to receive the funeral monument of one of the Princes de Condé from the Church of St. Paul in Paris, consisting of groups and bas-reliefs in bronze, from the hand of the sculptor Sarrazin; and the urn containing the hearts of the Princes de Bourbon, found by a countryman in the ditches round the cemetery at Chantilly which had been outraged during the Revolution.

Such were the preliminary conditions for the rebuilding of the great castle. As for the Châtelet, it was to remain almost unaltered architecturally, all that was necessary being to restore and repair it for the reception of the Prince's library, which is well known to be a valuable one, and to replace in its original condition the "Galerie des Actions de M. le Prince," executed by order of the great Condé. In the place of honour in the centre of this gallery were arranged the banners of Rocroy, the weapons and bust of the hero, relics which the Duc d'Aumale had carried with him into exile as his most precious possessions.

It will be plain to our architectural readers that though such a programme as this might have its disadvantages, it would nevertheless be useful to the architect by giving definite points to work from and by dictating certain forms as inevitable. But it must further be borne in mind that the architect was absolutely confined within certain limits of interference (we allude to the necessity for adhering to the irregular ground-plan of the subterranean buildings), and that an exceptional amount of skill would be required in order to surmount so many combined obstacles.

The immediate result of the statement laid before M. Daumet was to suggest to him a plan for the upper stories in no respect conforming to the plan of the subterranean buildings. I believe that this is, perhaps, a solitary example of such an arrangement in a building of so great importance. A single instance will serve to show the nature of the alterations effected, and the preliminary works which must of necessity be carried out underground. In the Louis XIV. plan the chapel occupied the central part of one of the façades looking upon the triangular courtyard; now it projects from one of the extremities of the triangle (see the plan in this week's issue, and the perspective view published last week). Another improvement was the establishment of a communication between the underground buildings and the Châtelet such as had not before existed, affording a noble and dignified entrance from the grand staircase connecting the upper and the lower buildings into the great castle. This was effected by means of excavations in the solid rock, and that large portion of the subterranean buildings (which are so lofty and capacious that on one occasion a theatre was erected in them) on a level with the "Parterre de la Vallière" has been turned into offices for the transaction of business and for the preservation of archives, abundantly light and airy, and pleasant for habitation.

We shall now rapidly pass in review the main points of the edifice, endeavouring to give an idea of the way in which M. Daumet has solved the problem proposed to him by the Duc d'Aumale, and showing how far he has been able to reconcile utilitarian conditions with artistic requirements and architectural beauty.

Following the general plan, we shall enter the castle by the steps of the terrace called "Le Connétable." The equestrian statue of Anne de Montmorency, overthrown at the time of the Revolution, is shortly to be re-erected here; it is to be placed upon a lofty pedestal, in the style of that of Colonne at Venice. Crossing the moat to the former eastern, we shall see to the right and left of us the lower part of the two towers of the Middle Ages levelled with the top of the "Connétable," and find ourselves opposite the principal front of the castle (see illustration of the "Principal Entrance"). In the buildings of the Middle Ages, of the Renaissance, and of Louis XIV. this front showed lofty stories of living-rooms abutting on to the corner towers. It is now nothing but a covered passage, uniting the two main parts of the building, and consists of four arches on each side, with a central design reminding us of the Baptistery of Louis XIII. in the Castle of Fontainebleau. It is clear that the architect's idea in turning this front into an open gallery was to give air to the triangular courtyard inside. We would draw attention to the skill with

which M. Daumet has overcome the difficulties caused by the irregular shape of the courtyard, and has contrived to find the axes of construction indispensable to every good architectural composition. In the Cour d'Honneur, which we have just entered, in the axis at once of the portico, and of the north corner tower, we find the first vestibule which forms the entrance to the inner castle; this is a lantern, crowned by a dome, projecting into the courtyard, and leading into a second and larger vestibule.

We now find ourselves opposite the Châtelet, whose upper story is on the same level as ourselves. To our right we have the "Galerie des Cerfs"; to our left, a magnificent staircase in the form of an elongated horse-shoe, of which the wrought-iron balusters are a *chef-d'œuvre* of modern French smith's work. This leads us to the chapel, with its bell-tower rising above the corner of the principal façade. Turning to the right and ascending some steps, we come to the "Galerie des Cerfs" (see illustration); there M. Daumet has hung Van Orley's superb tapestries, to which the Count of Toulouse has added borders of his own armorial bearings. Above the entrance to this hall is the musician's gallery, corbelled out in the style of the Renaissance. The huge fireplace at the other end has a decorative panel,—a St. Hubert,—painted by Paul Baudry, decorator of the foyer of the Opera House. A door on the right, at the extreme end of the hall, leads to the picture-gallery, where we find the duke's collection of the different schools which form the plan the interior base of the triangle, and abuts on to the second tower of the north front, which opens into the gallery and forms a continuation of it on a somewhat higher level. The spaces between the ribs of this circular vaulted recess are ornamented with charming designs by Paul Baudry; here the Prince has arranged his collection of sketches by masters of every school.

Turning our back to the door of the "Galerie des Cerfs," and looking down the centre of the picture gallery to gain a general effect, we see that the projection of the corner tower which opens into the gallery has afforded the architect an opportunity for some very ingenious architectural decoration effected by carving the white stone of which it is composed. Still looking down the central line to ascertain our relative position, we shall see a door at the end of the picture-gallery on the right; this leads to the *logis*, or private apartments of the prince, occupying two stories of the whole of the north wing between the corner tower of the principal façade and that where the sketches are exhibited. It will be observed with what accuracy, exactly at the intersection of the triangle formed by the interior courtyard, the architect has drawn a straight line dividing his great triangle into two equal triangles. This line has made the axis of the chapel, of the terrace adjoining it, and of the courtyard, thus concealing the irregularity of the site to which he was bound to adhere. We need not examine the interior of the *logis*, only observing that it is approached by an external gallery facing the courtyard, exactly as the picture-gallery and "Galerie des Cerfs" are approached by the "Galerie des Offices," which renders them available for habitation. There are three doors on the left of the picture-gallery: the first leads to the "Tribune," the second to the "Cabinet des Chartes," while the third (corresponding to the door leading to the *logis*) opens into a long gallery called the "Galerie de Psyché," extending from the tower where the sketches are to the tower "De Trésor," which forms the west corner of the castle. This gallery, specially constructed to contain the beautiful series of stained-glass windows from Écouen representing the fable of Psyché, thus forms the north-west front of the castle. Entering from the picture-gallery we shall have on our left the windows containing these lovely designs, executed in *grisaille*, probably by Bernard de Palissy himself. The wall on the left is covered with an interesting collection of portraits and sketches. The north-west tower, opening from this gallery as the north tower opens from the picture-gallery, contains the "Trésor," that is to say, the antiques, bronzes, gems, jewels, and other valuable curiosities.

We must now retrace our steps into the "Galerie de Psyché" in order to leave it by the door on the right leading into the "Tribune." This is a perfect sanctuary of art, a hexagonal chamber with a vaulted roof richly

decorated in the taste of Nicolo del Abbate by carvings framing views of the various residences whose memory is dear to the owner of Chantilly. The Tribune contains the cream of the collection, the paintings by Filippo Lippi, by Sandro Botticelli, the masterpieces of the Italian school, Raffaello's Virgin "des Orléans," the Burgundian paintings of the fifteenth century, and a few examples of the modern French school by Ingres, Delacroix, Décamp, &c.

We may now return to the picture-gallery, again pass through the "Galerie des Cerfs" into the vestibule, and leaving the oval staircase in front of us pass from the ground-floor of the great castle into the first floor of the Château, which is on the same level. Outside, this charming little building designed by Jean Bullant about 1540, and forming a rectangle with the south-west front of the castle, affords a perfect type of the architecture of the French Renaissance. Inside, the decoration and furniture of the rooms give a good example of the wealth of the age of Louis XIV. The library and a suite of rooms, the Salon des Chasses, Salon d'Europe, Chambre de M. le Prince, and Cabinet de M. le Prince occupy the main body of the building, fronting on one side the "Parterre de la Voilérie," on the other the courtyard of the Château. The Salon des Singes and the long "Galerie des Actions de M. le Prince" occupy that part fronting the lake. The smaller façade at right angles looking on to the "Conservatoire," contains the Salons de Mnsique and Jean Bullant's rooms. Between the chapel and this part of the façade the old drawbridge is still preserved, and gives the character to this charming façade.

We might now descend from this upper story to the ground-floor and the courtyard of the Château, and so find ourselves on a level with the chapel, but we shall have a better idea of the architectural effect if we retrace our steps into the "Galerie des Actions de M. le Prince," and through the apartments as far as that larger vestibule by which we first had access into the castle. Turning now to our right, we descend the magnificent horse-shoe staircase, which, by the grandeur of its treatment, masks the difference in level between the rock on which the barons of the Middle Ages constructed their fortress, and the Château, the work of a later age.

The importance of the chapel as a portion of the design is greater in the present building than in any previous ones. The chapels of the Middle Ages and of the Renaissance (as far as can be judged from Ducercean's sketches), projected close to the entrance by the great staircase. The great Condé's was apsidal in plan, and occupied the site of the present vestibule. M. Daumet has made the chapel an important feature in his design. His circular apse has the advantage of abutting on the principal façade, and corresponds on the south-west with the corner tower on the north.

We have already spoken of the magnificent windows from Ecouen, which form the principal ornament of the interior of the chapel. The wood carvings from the same chapel have also been noticed, as well as the high altar with its bas-reliefs of the age of the Renaissance, representing the sacrifice of Abraham. M. Daumet has displayed special ingenuity in his arrangement of the fine bronze statues and bas-reliefs of Pierre Sarrazin, upon a circular plan, for which they were not intended when they were erected in the Church of St. Paul in Paris, upon the tomb of a Prince de Condé. He has placed them in a kind of sanctuary in the apse behind the high altar. In the centre is the funeral urn, the receptacle of the hearts of the Princes de Condé.

We have now completed our round of the Castle of Chantilly. Our description, although necessarily superficial, has, we hope, been graphic and practical. We must express our opinion, in conclusion, that M. Daumet has given proof of singular ability in surmounting the obstacles which beset him, chief among them being the extraordinary irregularity of the ground-plan. The only objection we have to make is that the north-west portion of the building, the front façade of the "Galerie de Psyché," does not correspond in height with the underground buildings which descend to the river level. Upon this side the statue is not in proportion with its base.

It is the duty of every architect who undertakes, not a mere restoration, but the complete reconstruction of a building, to stamp it with the character of his time for transmission to

future ages. In this case the work was a compromise between restoration and reconstruction. What style would be the necessary result of such a union? Hampered by the neighbourhood of the Château (in the pure style of the French Renaissance), and by the subterranean buildings with their escarpments on the trenches, how could the architect sound a distinct note, giving to the archaeologists of the future a key to the secrets of his own age? M. Daumet has been able to solve this problem without weakening the character of his work, for the excellent reason that the programme submitted to him by the Prince being at the same time archaeological and modern, lent itself to the joint conception. Following this, the architect could not fail to reflect the ideas which had dictated it. The re-builder of Chantilly, an historian with a seat in the French Academy, was inspired with the idea of rivalling the Constable Anne de Montmorency and the great Condé. He desired also to do honour to some noteworthy examples of the art of the Renaissance and of the age of Louis XIV. Naturally, too, he took account of those individual requirements which were peculiar to himself. Finally, since *noblesse oblige*, he wished to show himself as a prince of modern days, recognising the necessities of his time and rank. The new Castle of Chantilly thus forms at the same time a national monument of past ages, a museum of art, and the private residence of an historian of royal race, the heir of Montmorency and of Condé. This is the philosophical and æsthetic significance of the new Castle of Chantilly.

RAILWAY RETURNS FOR 1883.

THE railway Returns for 1883 show a considerable increase in the earnings per mile; and that to an extent which, had it not been counteracted by other causes, would have told materially upon dividend. But against a gain of 8 per cent. in gross mileage receipts has to be set an increase of 10 per cent. on capital cost per mile, and an increase of nearly 1·2 per cent. in working expenses. The result is that the proportion of net income to capital, which is the true test of prosperity, is almost identical. The main figures for 1882 and 1883 are as under:—

	1882.	1883.	Increase.
Length in miles .....	18,474	18,681	207
Cost per mile .....	£41,605	£42,017	£412
Gross Income per mile .....	£3,512	£3,808	£297
Working expenses per cent. ....	32	32·6	0·6
Net measure per cent. ....	£1,683	£1,803	£117
Profit on capital per cent. ....	4·27	4·3	0·03

The feature most to be regretted in the above table is the steady increase in the capital cost per mile. While only 207 miles of new line have been added to our railway system in 1883, the sum of 412½ has been added to the cost of every existing mile of line. The contrast that is thus presented to the management, and, we may add, to the prosperity, of the French railways is most striking in this respect. In 1867 every mile of railway in France (taking the main hulls of the railway property comprised in the six great systems) had cost 28,592½. In 1882 the cost of each such mile was 28,500½. The cost in England in 1867 was 35,254½, which had grown, as before stated, to 42,017½ in 1883. The working costs were, in France, 46·7 per cent. of gross income in 1867, and 49·2 per cent. in 1882; but the rates of fares and freights were 11·15 per cent. lower on the Continental than on our own lines. Working costs, in England, consumed 50 per cent. of income in 1867, and 52·6 per cent. in 1883; but, in 1842, the income of the London and Birmingham Railway, which had not then undertaken an immense mineral traffic at low rates of freight, amounted to 6,850½ per mile, out of which the working costs only came to 30 per cent. In 1848 the working costs on the Great Western Railway amounted to 40·6 per cent. of the gross income. At the present time, taking into account the lower freights and fares as well as the lower proportionate working costs in France, the rate of working expenditure in that country is nearly 11 per cent. lower than in England. It is on evidence before the Select Committee on Canals (252, 1883, p. 250) that "the proportionate cost of the engineering expenses (locomotion, maintenance, and repairs) on those railways of which the returns have been analysed, rises in a ratio of about half per cent. of gross revenue for every 1 per cent. of gross revenue which is derived

from mineral traffic." This computation, taken from English lines, is in remarkable accordance with the fact that the latter derive a little more than 22 per cent. of their revenue from their non-remunerative mineral traffic, which the French lines refuse to carry, and that the working expenses are 11 per cent. above those of the French lines.

Thus from 1854 to the present time, while the net earning on the capital of the English railways has been substantially stationary, rising a little at one time and falling at another, but maintaining no advance, the net earnings on capital of the six great French lines have increased by 78 per cent., rising from 3·11 to 5·56 per cent. That English shareholders should be content to receive so much less by way of dividend than would be divisible if the sound principle of only carrying at remunerative prices were adopted, is one of those things which can only be understood on the strength of the proverb that what is everybody's business is nobody's business. The non-remunerative traffic tells against dividend in two ways. One is the proportionate diminution which it causes on net, as compared to gross, revenue. The other is the loss of carrying capacity of the lines, due to the difference of speed in the trains; to which the difference of cost between the 28,500½ per mile of the French lines and the 42,017½ per mile of the English lines, is mainly due. For the difference in gross revenue per mile between 2,994 in France and 3,512 in England in the same year, is almost exactly the sum received for the carriage of minerals.

If the Board of Trade, instead of bringing forward a Bill which collapsed under the disapproval of all parties interested, had taken the advice long since given by their own officers, and insisted that the English Railway Companies should publish accounts as distinct as those of the French, German, and Italian lines, and our own Indian and Colonial railways, the plain facts would have been so unmistakably brought home to the English railway shareholders that they would have been likely to combine for the purpose of ensuring the 8 per cent. dividend which might be earned at less risk to the public than the present average net return of only 4·3 per cent. on their capital of 785,000,000.

FRANCE AT THE HEALTH EXHIBITION.

THERE are many points of similarity between France and Belgium exhibited here; not only in general principle, but also in regard to detail, so much so that it becomes difficult to draw a comparison or to clearly determine if any preference could be accorded to either nation for any innovation or improvement. The "object teaching" system is shown in much the usual way,—the manufacture of cotton, paper, &c., being traced through the various stages; and also the use to which plants can be put for coloring purposes or making fibrous material. As might be expected, the art of dress-making receives attention; and part of the children's education is directed in this channel, as cutting-out and making-up their own small garments forms a useful preliminary to the more business-like view which is eventually taken of that happy condition of being well-dressed, which with a Frenchwoman is usually supposed to confer more peace of mind than it is in the power of religion to bestow. China-painting, metallurgy, and wood-working on a small scale are taught in their technical schools, of which some good photographs of both exterior and interior arrangements are shown in working order, apparently carried out very systematically. The idea of specially ventilating the workshops is also recognised; although in this instance the height of the building containing a blast furnace would probably enable the ventilation to be effected without extraneous aid. A drawing of an apparatus for disinfecting clothing and hedding is shown, where the material to be cleaned is passed into a chamber surrounded by hot-air pipes and presumably some disinfectant, and, being subjected to the heat, passes out clean and once more wholesome. The general drawings, of which there are very many in this section, seem to attach more importance to the warming and ventilation of the buildings than to the sanitary arrangements as regards the drainage; for, as though the sobemes for warming are in some cases elabo-

ately shown, the drainage is not detailed to the same extent, but where examples are given they more or less show the ventilation of traps and soil-pipes. Vivisectionists and their opponents may find a good study in M. Pasteur's display of chemical and scientific apparatus, for M. Pasteur does not confine his attention to the animal world, but the prosaic fluids and solids of every-day life are also subject to searching scrutiny.

The ever-recurring question of workmen's dwellings is illustrated in many cases, although we look in vain for the six or seven-storied buildings which we have become accustomed to look upon as inseparable from this movement. M. Lombart, of chocolate renown, has built a small city for his employes, two stories and a basement, however, being the extent; and some blocks of buildings, containing three and four sets of rooms, are likewise given, but no special sanitary feature disclosed; but, on the contrary, the few indications that exist would lead one to think that the arrangements in this respect were anything but perfect. One point which strikes us is the absence of the military spirit of education which has hitherto prevailed throughout the kingdom; but, to judge by the illustrations here, the Republic trusts its educational tendencies more towards gymnastic and handicraft energy, the secret hope of the soldier under the old régime to become the head of the nation has given way to ambitions of a less ephemeral nature. Among the charitable institutions illustrated is the Maternal Charity Society which affords material help to the mother when the child is born and for the first few months afterwards. This society is no respecter of persons, making no distinction of country or religion, but vaccination is insisted upon. Founded in 1784, it was by Louis XVI. in 1788 placed under the protection of Marie Antoinette, and a large subvention granted. In 1810 the First Napoleon decreed that this institution should be founded in forty of the principal towns, and, in 1871, when the Republic was declared, and during the Presidency of M. Thiers, Marshal MacMahon and M. Grévy, until the end of 1882 the subvention of 40,000 francs was inscribed on the budget of the Home Secretary. The Society for the Protection of Infant Life and the "Société des Crèches," founded in 1869, are doing good work,—much needed on account of infant mortality assuming so serious an aspect, and particulars and details are given which will be of interest to those who have given attention to the subject as carried out in this country. The remaining exhibits are mostly of the regulation type, such as school furniture (which appears somewhat unsubstantial after visiting that in the Albert Hall) and drawings from the east and models from the antique, in which we know the French have always excelled. A few specimens of parquet flooring are added, and where the work is kept quiet it is fairly good, but where they have attempted anything unusual, such as coloured bordering, the effect is meretricious, as the ornament is harsh and angular and badly chosen. In ironwork there are a few well-finished castings and general fittings as well as small pieces of machinery which are creditable. There are also a few miscellaneous drawings of school buildings, large and small, varying much in merit, some of which are very pleasing, but many are of a nature that require no comment, more especially as they illustrate nothing in particular.

**The Footpath Preservation Society.**—This is the name of a society proposed to be formed for the preservation of foot and bridle paths; also for the protection of all rights of way and vacant spaces, such as village greens, &c. A Commons Preservation Society has been established, and doubtless is doing much good; but (say the promoters of the proposed new society), "Footpaths are of equal, or rather of greater, importance than commons,—these latter are comparatively few and far between. It is not every parish that possesses a common, but all localities throughout the length and breadth of the land have numerous footpaths. It may be remarked that, had such a society been established fifty years ago, a considerable number of footpaths would have been saved to the public." It is proposed to form local societies in connexion with the central body. Suggestions on the subject may be forwarded to Mr. Henry Allnutt, *Estates Gazette Office*, 6, Fetter-lane, London.

#### WHAT IS ART?

"What is truth?" said jesting Pilate, and did not wait for an answer; "what is art?" says Mr. James Stanley Little,\* and does not furnish us with a reply; for it is no reply to say that art is worship, is poetry, is religion, is truth, is the apotheosis of the ethereal, &c. This etymological dance ends where it began and leaves us no wiser. Art, it appears, is pain and anguish; it is also true religion, and true religion is the spirit of theology, so that art is the spirit of theology as well as the apotheosis of the ethereal, and all the rest. If it were worth while a few posing questions might, we think, be called from this pompous treatise. If art is poetry, how can "poetry be the forerunner of art" (p. 16), or "art and poetry be so nearly allied as to be almost indistinguishable." The fact is, the book is without coherence or consistency, and the author uses the same word in fifty different senses. "His work is," he says, "from beginning to end an outcry against oppression and prejudice." Who are the suffering and oppressed?—the victims of prejudice? The author says, in one place, that the writer and artist of merit has no chance unless he has gold or influence to buy his way; that the better his work the greater his chances of failure; and, with delightful complacency, he says a few pages further on that he is "free to admit that there was never a time when merit had so good a chance of being recognised as at present, for it is more possible now than heretofore to break down the barriers of prejudice and misfortune." One instance of oppression or prejudice is given at second hand. A young artist had striven for years to gain admission to the Academy schools, and failed at last because he drew, with the cast, which was to form his probationary test, the dust upon it. We should require proofs more relevant than this, and especially when we appreciate the generally aggressive temper of the author.

There is an old story, which is pat to our purpose, of an emigrant who, landing at New York in the heat of a political contest, was pounced upon by a horde of electioneering agents clamouring for his vote. "Pat's a democrat, Pat's a republican. What are you, Pat?" "Pat, gentlemen, I know nothing about your politics at all. But I'm agin the Government, any way."

And this is exactly the attitude of Mr. James Stanley Little. He expresses himself without reserve upon the subject. "I, for one, strongly believe that the inverse method to the one generally accepted" (whatever that may be, understood) "is the soundest method."

Drawing of at least an elementary character, is generally held to rightly precede exercises in colour and composition; and so, of course, our author would "evolve a picture in an inverse order:—(1) Composition; (2) Tone; (3) Colour; (4) Form; (5) Drawing. Can," he triumphantly asks, "my heresy go further than this?"

Unfortunately, Mr. Little is not only at war with acknowledged methods of art-teaching; he is opposed to the whole of our social ethics. The marriage-tie is an affair of priest and ring, frivolous at best, and sometimes positively unhalloed and pernicious. This is almost as good as the son calling his parents "interlopers." There is much more of this sort of stuff, into which we will not follow the author. His book is an ill-tempered attack upon things in general, and does not in any way answer to its title. Architects have little to thank him for, their art being excluded from his scheme, or named only to be reproached. The most lovely building in the world adds nothing, in the eyes of a poet, to nature's face, but ugly frowns and hideous contortions (? Melrose); and Decimus Burton's entrance to Hyde Park is a "lean and senseless deformity, meaningless, and positively offensive;" while St. Paul's, the "much vaunted," is "heavy!"

We will not waste more time on this curious and inconsequent essay. There is no satisfactory answer to be given to the question raised by the writer of it. In the present Academy exhibition there are two pictures with an identical title. In each there are husbandmen and horses, trees and sky. Their technical merits are about equal. The one produces no impression whatever upon the beholder; the spirit of the other falls upon him as with a holy calm. The one work is by a painter, the other

by an artist, and the quality which differentiates them is art. But who shall further describe it? All essences are inexplicable. Is there a satisfactory definition of the much lower form of art, wit? Art is like electricity,—a power which can be felt, but not explained. No man can explain how he accomplishes feats in art more than the electrician who employs and directs the tremendous energies of nature can explain their quality. The gifts of art and the discoveries of science are beneficent or malevolent as they are wisely or unwisely used, and we may be sure that indiscriminate railing will not advance the cause of either.

With all the flatulence and cocombry of the treatise under notice, there is some compensating amusement provided in the self-sufficiency of the writer, who talks of his "argument," and of having "proved" his contentions, as though he had really written upon some system. He is an admirer of Thackeray. Does he remember who "clinched an argument" with the recondite quotation, "Dulce et decorum est pro patria mori"?

#### ARCHITECTURAL SKETCHING.

The real object and value of architectural sketching appears to be either very little understood or very much disregarded. It is essentially a training, and that, too, of a close and rigorous kind; a means and not an end; one of several necessary courses of study which, if rightly pursued, is calculated to make a successful architect, and if wrongly pursued, to make a very indifferent artist. The volumes of "Leaves from an Architect's Sketch-book" which yearly fall from the press are for the most part collections of very imperfect renderings of the effect of ancient buildings intended to be attractive to a clever sketcher, and nothing more,—fly-leaves cast upon the waters to catch clients. Such sketches have rarely or never the charm of true artistic excellence, because their authors have not had the artist's severe training. To the architect they have little or no practical value.

The motives which actuate the artist and architect are widely separated. The former endeavours to fix upon paper or canvas a sympathetic record of the appearance of things, and to impart something of the sentiment which they raise in sensitive natures. The true business of the latter lies in the analysis of the means by which certain effects in architecture are produced, with a view to future syntheses to be attended by like satisfactory results. To him the effect of a beautiful building might for all practical purposes be noted down in words; but it is of the utmost importance that the means by which the effect is produced should be examined and delineated with care and completeness. This is, however, a long, tedious, and troublesome process; and ladders, tapes, rules, and lead ribbons are very prosaic things. Moreover, sheets of such studies,—more or less weather-stained and dirty as they must necessarily be,—do not make up a portfolio calculated to elicit the raptures of non-professional friends. Whilst, on the other hand, nothing is easier than to secure their applause by a few hasty scratches, and dots and flicks of shadow, which give with a sense of power and freedom in the sketcher a sufficiently accurate suggestion of the subject of his sketch to satisfy the lay mind. And thus it happens that the student for want of caution and guidance enters in at the broad gate, and fills his sketch-book with what will never be of any real use to any human being.

The Institute and Association prizes for measured drawings of old work do something towards correcting this defect; but the cure will never be wrought until the student himself sees clearly how comparatively useless is the system now followed, and how much more he might learn from the patient and systematic delineation of one noble building than from the hasty and casual misrepresentation of a dozen. The volume\* before us which has prompted these remarks is an evidence of the great and praiseworthy industry of its author, who has sketched right and left with varying success, and with, we fear, no corresponding advantage, owing to a mistaken course of procedure. The majority of the subjects chosen by him have but little merit as architecture, the minority deserve a

\* What is Art? By James Stanley Little. London: W. Swan Sonnenschein & Co.

\* An Architect's Sketch-book at Home and Abroad. By W. H. Thorp. Leeds; Jackson, London; Batsford.

more deliberate and careful treatment than has been accorded to them by a sketcher whose impartial pencil has dealt with good and bad indifferently. We see no evidence of care in the selection of the examples and no proportion in the respective treatment of them, the general views are often slight and coarse representations of commonplace buildings, and where details are given there is as a rule nothing worth the trouble of exhibiting at large. We would gladly exchange the whole for half the number of plates devoted to the close and complete illustration of a selected tenth part of the buildings portrayed. But then the book would have been addressed to architects and not to clients *in posse*, and one object of its publication would have been defeated. There is still room for a model architectural sketch-book,—Nesfield, Norman Shaw, and Burgess notwithstanding.

**A RELIC FROM DOLLY'S CHOP-HOUSE.**

"Farewell: and on Tuesday next expect me in London among the booksellers."—*Milton to Gill.*

AMONGST his forthcoming reprints, Mr. Elliot Stock announces an early issue from Paternoster-row of the first editions, in facsimile, of "Russelas" and "The Vicar of Wakefield." The *admonitio loci* will be revived by the binding of some copies in wood preserved from the panels of the dining-room at Dolly's,—a haunt, it is asserted, of Goldsmith, Garrick, and Johnson. That they frequented this tavern is by no means improbable; for it formed one of the four or five coffee-houses in a district which the hook-sellers have made peculiarly their own for more than a century past. The hook-sellers, indeed, especially favoured the Chapter in their street, where collected also a large company of University men, country parsons, and college dons. Goldsmith we know constantly visited the Chapter. "I am quite familiar," writes Chatterton to his Bristol home, "at the Chapter house, and know all the geniuses there: a character is now unnecessary; an author carries his character in his pocket." Again, writing from the King's Bench, May 14th, 1770 (three months before his death), he mentions that a friend had undertaken to introduce him to the Duke of Northumberland\* with view to a foreign tour; "but, alas!" he adds, "I spake no tongue but my own." A City club at the Queen's Arms, comprising Clutterbuck a mercer, Patterson a solicitor, Samuel Sharpe a surgeon, and Draper a book-dealer, constituted Garrick's standing committee in all matters of theatrical management. At that house, too, Dr. Johnson met his City Club, renewing fellowship with a few survivors of his club in Ivy-lane of some thirty years previously. This was the club from which he stipulated that patriots should be excluded, thus aiming a shaft at Wilkes, and consistently with his definition of a patriot as a factious disturber of his country's government, of patriotism as the last refuge of a scoundrel. Turning for the present from Queen Anne's clergy, Dr. Mead and the Fellows of the Royal Society, together with Addison and his "honest country gentleman" † at Child's; as well as from the trade meetings, the Wet Paper Club and the "Witeagomert" at the Chapter, we come to those who may with certainty be identified with the better fortunes of Dolly's. Amongst its patrons are reckoned canonists and doctors of the civil law from the Commons; Wilkes, Dr. Gower, Dr. Buchan, and Dr. Fordyce. These are followed in less remoter times by Brougham, Orsini, Denman, and Charles Sumner, the American statesman. Bonnell Thornton celebrates in rapture the grill-ale and beefsteaks to be had at Dolly's.

Dolly's stood in Queen's Head-passage, on the western side, a thoroughfare leading from Newgate-street into Paternoster-row. A coffee-house was opened here, hard by the supposed site of Tarleton's ordinary, the Castle, many generations ago; it escaped the Great Fire which played such havoc in the immediate neighbourhood. But at Queen Anne's accession the house became famous. She established here one of her favourite servants, Dorothy, a kitchen-maid, on the latter's marriage. The story further runs that Anne herself visited her old servant at a

house which thereupon had taken the Queen's Head for its sign and Dolly's for a name. The royal patronage gave celebrity to the tavern, which speedily found high favour with the *beaux esprits* of that reign. The house itself had been more substantially built; and covered an extensive cellarage, ranged on two floors. Amongst its more notable features were the handsome staircase, an oaken wainscoted parlor, conspicuous besides for two curious fireplaces and their mantel-shelves; and a posthumous painting of Dorothy, in Kneller's manner, variously ascribed to Opie or Gainsborough. The original building was demolished about thirty months ago, for the extension of a warehouse in Newgate-street. The new premises are in course of re-erection, having suffered severely in the fire which broke out last April in Lovell's-court, on the northern side of Paternoster-row.

**THE INTERNATIONAL FORESTRY EXHIBITION, EDINBURGH.**

FOURTH NOTICE.

FROM the province of New Brunswick appear forty different specimens of the woods indigenous to the country. There is hung on the walls of the Court allotted to this province a map upon a large scale, prepared by Dr. Bayley, showing the forests and unsettled land of New Brunswick and the geological nature of the various localities. There is also a map of the Dominion of Canada taken from the Geological Survey. In the northern portion, up to the sixty-fifth degree, are found the spruce, the larch, and the balsam-poplar; whilst to the southward, the bird's-eye maple, ash, and birch are common; whilst the hemlock tree (*Abies Canadensis*) abounds. This latter tree is chiefly valuable on account of the tannin extracted from its bark, which is exported in a liquid state. The wood was, until lately, considered of no commercial value, and was left to rot on the ground; it is now, however, worked up into interior fittings. Where the soil is poor, especially in the central and eastern districts, the forests consist principally of spruce and pine, which are formed into deals and transmitted to England. Along the St. John and its tributaries, where the soil lies on the upper alluvial formations and is very fertile, there are splendid forests composed chiefly of black-birch, beech, ash, elm, and maple. These hard woods remain almost untouched, and afford a large reserve supply for future use. They frequently suffer from fire and blow-downs; but when they are placed under proper supervision, of which there is none as yet, these casualties may be greatly mitigated. Many of the aboriginal Indians have settled down on reserve lands specially designed for them, whilst others are employed as lumbermen. They consist of two tribes, the Mic Macs and the Melicetes, and are, along with the early French settlers, with whom they are interspersed, members of the Church of Rome. The timber is generally floated down the small streams into the Miramichi and St. John in early spring when the freshets come on, where it is formed into rafts for transport down these rivers. The newly-formed railway which runs parallel to the St. John is also called into requisition for the transport of the timber. The value of the wood exported is about 800,000*l.* a year, and is likely to increase considerably as the resources of the country are opened up. The total acreage of the colony is 17,393,410, that portion of it along the banks of the St. John being fertile, but along the coast it is bare and uninteresting; and the same may be said of a great central tract estimated at 10,000 square miles, where, however, excellent coal abounds, which may yet form an important item in the products of the colony. According to the census of 1880-81 the population numbers 321,233, of whom one-fifth are descendants of the original French settlers, and who adhere tenaciously to the use of the French language.

The small island of St. Vincent (forty miles by ten miles; population in 1831, 27,122), enters a very creditable appearance. This island, which was ceded to Great Britain at the peace of 1763; taken by the French in 1799; and restored to Britain in 1783, is generally mountainous and rugged. The intermediate valleys, however, are fertile in a high degree, the soil consisting chiefly of a fine mould, composed of sand and clay. In 1812 St. Vincent was almost desolated by an eruption of the Souffrier mountain, which had remained quiet for nearly

a century before, but from which a torrent of lava and clouds of ashes issued which nearly covered this island. The chief products used to be sugar, rum, and molasses, but the cacao, from which chocolate is made, is now becoming more extensively cultivated than the sugar-cane, and it is more easily reared,—specimens of the fruit are exhibited, as are also specimens of the root of the lilaceous plant, from which arrow-root is obtained, an article which forms an important item in the commerce of the island. Seeds of various plants used as beads, calabashes as water-bottles, and woods from which dyes are produced, appear on the table. There is also a display of long tough fibres used in rope-making, a peculiar-looking seaweed, designated "Old Man's Beard," used for stuffing seats; a model of a woodman's hut (constructed of bamboo, and thatched with grass) such as is run up for temporary use; models of native boats, hats, and baskets formed of grass.

Sierra Leone is not of great commercial value to this country, but, as it consists of one vast and almost impracticable forest with only occasional spots cleared and cultivated, it is well that attention should be directed to it. Founded as the colony was from motives of philanthropy rather than from any political or commercial advantage, cultivation has made very slender progress, except so far as it has been introduced by Europeans. Little has been done towards utilising the wood which grows on the banks of the Gamhia, although labour is cheap and the means of export easy. The wood is not, perhaps, of the best quality as regards grain or texture, but, when a useful wood can be supplied at 2*d.* per cubic foot, there seems no reason why a market cannot be found for it. Thirty-two specimens of the wood of native trees are exhibited. One of the hardest of these woods is the koorobongo, which resembles oak in texture, and is mostly used for stockades. There are also inferior varieties of mahogany and rosewood, which might be turned to advantage in the manufacture of cheap articles of furniture, &c., as well as in the building of canoes, to which work they now appear to be confined. Several of the trees of Sierra Leone are said to be possessed of good medicinal qualities, the bark of one of them, the Singocko, being used as an aperient, and a decoction of the leaves as a cure for toothache. From the Tanne-coombah fruit oil is obtained, and the native soap is made from the refuse. From the fruit of the Ilwera the natives manufacture a red wine, and from the Tallumhoro poison is extracted, which is used for ordal purposes. The manufactured articles exhibited are made in design, but appear substantial and display considerable ingenuity in their construction. Sofas and chairs, ranging in price from 2*s.* to 6*s.*, of very creditable workmanship, are manufactured in Combo and largely exported to Senegal. Several specimens of rubber are shown, both in the crude and the pure form; these are obtained from the rubber taul, which grows on the banks of the Gamhia and reaches a height of from 30 ft. to 40 ft. The trade in this article is yet in its infancy, having only been established two years ago, and may yet, with care and attention, be developed. Another plant indigenous to the country is the indigo, which has been little cultivated hitherto but is now attracting attention; specimens of the dye are exhibited. Other products of the colony exhibited are samples of wax, gum, brimstone, logwood, palm-oil, rice, &c.

The chief deterrent to the development of the colony is the malarious nature of the climate, which unfits it as a residence for Europeans, who might supplement the want of mechanical skill possessed by the natives, and reduce their labour to a state of discipline. In 1820 the population stood at 12,000, whilst in 1839 it had increased to 42,000. This rapid increase was chiefly owing to the great number of slaves rescued by British cruisers and settled in this place of refuge.

The Maharajah of Johore has shown an enlightened spirit in sending for exhibition a large number of specimens of timber grown in the country over which he holds sway, as well as samples of its finest produce. The timber trees of Malacca are numerous, and of these 350 varieties are shown. Amongst the products are gun, camphor (*camphor officinalis*), gum dammar, used for varnish, gutta-percha, caouchouc, gambier, varieties of incense, pepper, &c. The first gutta-percha known to commerce came from Johore, and it continues to be an important article of export. A set of

\* Sir Hugh Smithson, bart., created Earl Percy and Duke of Northumberland 22nd of October, 1766,—the nobleman to whom Goldsmith pleaded not for himself, but for his brother Henry, in Ireland.  
† The Spectator, Nos. 1 and 606.

the tools used by the Malays in cutting timber and building houses and boats is produced. Samples of ratan canes, barks for making native houses, and ropes are shown; a model of a raft, with photographs illustrating its descent to the sawmills, as also views of the saw-mills which belong to a younger brother of the Maharajah and a gentleman who is a native of Edinburgh. The walls of the court are gracefully draped, and a portrait of the Maharajah, which conveys a pleasing impression of this ruler, occupies the place of honour. The collection is, at the close of the Exhibition, to be presented to the Edinburgh Museum of Science and Art.

#### SEWAGE CONTAMINATION OF WATER.

Under the title, "The Detection of Sewage Contamination by the Use of the Microscope and of the Purifying Action of Minute Animals and Plants," the following paper was read at the Society of Arts Conference on water supply last week, by Mr. H. C. Sorby:—

"By studying with the microscope the solid matters deposited from the water of a river, the previous contamination with the sewage can usually be detected without any considerable difficulty. If the amount be serious, the characteristic particles of human excrement can easily be seen; and even if it be small, and has been carried a long way by the current, it can usually be recognised by means of the hairs of rats derived mainly from the droppings of horses, which resist decomposition for a long time, and are not consumed as food by minute animals. I, however, do not propose to enter into detail in connexion with this part of my subject, but specially desire to call attention to the connexion between the number of minute animals and plants, and the character of the water in which they live, and also to their influence in removing organic impurities.

The chief animals met with in fresh water are various entomostraca, rotifera, and the worm-like larvæ of insects. I find that the number per gallon and per-centage relationships of these mark, in a most clear manner, changed conditions in the water, the discharge of a certain amount of sewage being indicated by an increase in the total number per gallon, or by an alteration in the relative numbers of the different kinds, or by both. All my remarks apply to the warm part of the year, and not to winter.

It is known that entomostraca will eat dead animal matter, though probably not entirely dependent on it. I have myself proved that they may be kept alive for many months by feeding them on human excrement, though they soon died without it. If the amount of food in any water is small, not many of such animals can obtain sufficient; but, if it be abundant, they may multiply rapidly, since it is asserted that in one season a single female cyclops may give rise to no less than four thousand millions of young. In stagnant muddy ponds, where food abounds, I have found an average of 200 per gallon. In the case of fairly pure rivers the total number of free-swimming animals is not more than one per gallon. I, however, found that where what may be called sewage was discharged into such water the number per gallon rose to twenty-seven, and the percentage relationships between the different groups of entomostraca were greatly changed. In the Thames at Crossness, at low water, the number was about six per gallon, which fell to three or four at Erith, and was reduced to less than one at Greenhithe.

There is, however, a very decided limit to the increase of entomostraca when the water of a river is rendered very impure by the discharge of too much sewage, probably because oxygen is deficient, and free sulphide of hydrogen present. Such water is often characterised by the great number of worm-like larvæ of insects. Thus, in the Don, below Sheffield, in summer, I found the number per gallon, of entomostraca only about one-third of what it is in pure waters; whilst, on the contrary, the number of worm-like larvæ was more than one per gallon.

Now if the minute free-swimming animals thus increase when a certain amount of sewage supplies them with ample food, it is quite obvious that they must have a most important influence in removing objectionable impurities. The number of the excrements of entomostraca in the recent mud of such rivers as the Thames

is most surprising. In one specimen, from Hammersmith, I found that there were more than 20,000 per grain; and the average number at Erith, in August, 1882, was above 7,000, which is equivalent to about 200,000 per gallon of water at half ebb, from the surface to the bottom. This enormous number must represent a very large amount of sewage material consumed as food; and though, as in the case of larger animals, a considerable part of their excrements, no doubt, consist of organic matter capable of putrefaction, yet there can be no less doubt that the amount entirely consumed in the life processes of the animals is also great.

As named above, I kept cyclops alive for many months by feeding them on human excrement. It is thus easy to understand why, when they abound in the Thames, the relative amount of human excrement is very considerably less than in the winter, when their number must be much smaller.

We thus appear to be led to the conclusion that when the amount of sewage discharged into a river is not too great it furnishes food for a vast number of animals which perform a most important part in removing it. On the contrary, if the discharge be too great, it may be injurious to them, and this process of purification may cease. Possibly this explains why in certain cases a river which is usually unobjectionable may occasionally become offensive. It also seems to make it clear that the discharge of rather too much sewage may produce relatively very great and objectionable results.

Though such comparatively large animals as entomostraca may remove much putrefiable matter from a river, we cannot suppose that, except incidentally, they remove such very minute objects as disease germs, but it would be a subject well worthy of investigation to ascertain whether the more minute infusoria can and do consume such germs as a portion of their food. If so, we should be able to understand how living bodies, which could resist any purely chemical action likely to be met with in a river, could be destroyed by the digestive process of minute animals. Hitherto I have had no opportunity for examining this question critically, but have been able to learn certain facts which, at all events, show that it is well worthy of further examination. It is only during the last month that I have paid special attention to the number of the larger infusoria, and various other animals of similar type, met with per gallon in the water of rivers and the sea, which can be seen and counted by means of a low magnifying power. At low water in the Medway above Chatham, in the first half of June, the average number per gallon has been about 7,000, but sometimes as many as 16,000. Their average size was about  $\frac{1}{1000}$  inch. Possibly the number of still more minute forms may be equally great; but, even if we confine our attention to those observed, we cannot but conclude that their effect in removing organic matter must be very considerable; and judging from what occurs in the case of larger animals, those  $\frac{1}{1000}$  of an inch in diameter may well be supposed to consume as food particles of the size of germs. Up to the present time, I have, however, collected so few facts bearing on this question that it must be regarded merely as a suggestion for future inquiry.

So far, I have referred exclusively to the effect of animal life. Minute plants play an important part in another way. The number per gallon of suspended diatoms, desmids, and confervoid alga is, in some cases, most astonishing, and they must often produce much more effect than the larger plants. As far as I have been able to ascertain, their number is, to some extent, related to the amount of material in the water suitable for their assimilation and growth. In the mud deposited from pure rivers their number is relatively small, but in the district of the Thames, where the sewage is discharged, I found that in summer their number per grain of mud at half-ebb tide was about 400,000, which is equivalent to above 5,000,000 per gallon of water. This is two or three times as many as higher up or lower down the river, and, out of all proportion, more than in the case of fairly pure rivers like the Medway. Their effect in oxygenating the water must be very important, since, when exposed to the light, they would decompose carbonic acid, and give off oxygen, under circumstances most favourable for supplying the needs of

animal life, and counteracting the putrefactive decomposition so soon set up by minute fungi when oxygen is absent.

Taking, then, all the above facts into consideration, it appears to me that the removal of impurities from rivers is more a biological than a chemical question; and that in all discussions of the subject, it is most important to consider the action of minute animals and plants, which may be looked upon as being indirectly most powerful chemical reagents."

#### Illustrations.

##### THE BRITISH CHAPEL, MOSCOW.

THE new building will, it is expected, be opened for service during the present month (August). It takes the place of the old chapel which had been in use since 1825.

The British Colony at Moscow dates from about 1555, when the Russia Company obtained their first charter, but from 1714 when the court and principal foreign factories were removed to St. Petersburg to 1825 they seem to have been unable to maintain a separate place of worship. In raising the requisite funds for the new building local efforts have been largely aided by the Russia Company and by liberal subscriptions from England and elsewhere.

The nave is 41 ft. 6 in. wide, with apsidal chancel at east end, and large cloak-room at the west separated from the nave by a traceried stone screen with swing doors, and over this room are placed in the gallery the organ and choir, caretaker's bonac; vestry, committee-room, and library are placed on the south side. The lower story of the tower is formed into the porch; above this are fire-proof, safe, and munition rooms, specially made for the use of the British residents. The roof is in one span, with inner boarded ceiling, coved and vaulted over the windows, the central part being wagon-shaped, the principals wrought and filled in with tracery; this treatment is carried into the apse without any chancel arch, the space between this ceiling and the roof being filled in with earth to equalise the temperature. The walls are of brick, with terra-cotta tracery and dressings. The internal fittings are of oak and pine, the floors of asphalt and marble mosaic, of Russian manufacture.

All the windows are fitted with movable interior frames of oak, and glazed with lead lights. The accommodation is for 300 persons. Mr. R. K. Freeman, F.R.I.B.A., of Bolton-le-Moors, is the architect, the greater portion of the ornamental woodwork, &c., having been executed in England, the other parts being carried out by Russian tradesmen.

##### SCULPTURE AT THE ROYAL ACADEMY.

NO. IX., "ISAAC AND ESAU."  
BY MR. E. ROSCOE MULLINS.

THIS group, which in the Academy catalogue bears for a title the pathetic appeal of Esau to his father, "Bless me, even me also, O my father," is a life-size composition in terra-cotta which, in this year's exhibition has occupied a conspicuous position in the Central Hall, opposite the entrance. The work has given its author a more prominent position among the sculpture contributors than he has previously held, and deservedly, for it is unquestionably the best thing he has produced, and marks a decided step in advance. The two heads are very expressive in themselves, and the hands also of Isaac; and the two group into a fine and truly sculpturesque outline.

### THE THAMES AND THE PUBLIC HEALTH.

UNDER this title Mr. G. Phillips Bevan read a paper at the "Balloon Society's" meeting last week. Going briefly into the history of the London water supply and the extent to which it was now depending on the Thames, and pointing out that the water demand had increased at an even greater ratio than the increase of population, he said:—

Directly, then, at least 72 million gallons a day are taken from the river at Hampton and Thames Ditton, and the question even now is simply this:—Can the Thames afford to be tapped daily to such an extent? But, if we project ourselves into futurity for even ten or twenty years, bearing in mind the almost incredible rate at which London is growing, and chiefly too in the directions of north-west, west, and south-west, which altogether depend upon the river companies, we shall not, I think be deemed immoderate in our calculations if we estimate the demand to be at least 85 or 90 millions by 1894, 110 millions by 2004 (if the world lasts so long). Adding this river supply to that of the other Companies we shall, probably, require 210 million gallons a day in twenty years time. That the Companies are aware of the increasing inability of the river to meet the demands upon it seems evident by the endeavours that they make to extend their gathering grounds; but even this must have its limits, and, in itself, is not free from contamination dangers. I see it frequently remarked that the flow of water cannot be seriously interfered with below Kingston, inasmuch as there is a daily quantity of 400 million gallons going over Teddington Weir, but this I believe to be mere guesswork or the result of a measurement taken a considerable period ago and not in the least to be relied upon now. Indeed, it is on evidence that for as much as twelve days together in the years 1858, '59 and '64 the daily flow at Hampton has not exceeded 350 million gallons, and the well-known engineer, Mr. Bateman, put it as low as 308,720,000 gallons per day for a considerable period. At any rate, the question would be easily answered by taking daily gauges of the flow at Teddington for the next few weeks, and it is a matter of extreme importance that this should be done, as one of the standpoints of our knowledge of the hydrometry of the Thames, which appears at present to be extremely limited.

Having now arrived at the tolerably patent fact that the river flow is greatly diminished,—it may be from one or all of the causes that I have mentioned,—we ask the question, where are we to find the remedy? And the answer groups itself into two distinct modes,—1. That of husbanding the existing Thames supplies; 2. The obtaining an existing new and independent supply. Under the first heading, the favourite proposal seems to be the construction of one or more half-tidal locks. Mr. Labouchere, who has excellent opportunities for studying the condition of the Thames at Twickenham, suggests that the river-banks between Battersea Bridge and Teddington be faced with stone, and that there be a half-tidal lock at Isleworth and another at Putney. Just above the lock weirs a certain amount of dredging would be needed, while from the Putney lock to Teddington there would be a wide sheet of water available for boating purposes, and covering all the mud banks. This sounds very nice, but judging from the opposition that was given to the Richmond proposal some little time ago, to make a lock at Isleworth, there is evidently a strong feeling that the inhabitants above these locks will be benefited at the expense of those below them, and that the large river trade will be seriously injured thereby. Every one naturally thinks of his own interests first, but in dealing with such a vast question, we cannot afford to entertain any proposal which will not benefit the whole river. Others consider, and I believe amongst them is the worthy President of this Society, Mr. Le Fevre, that a series of locks should be placed at intervals, but extending far below the upper river reaches, and coming as low down as Gravesend.

It must, of course, be assumed that, whatever the means adopted, the river companies should be precluded from tapping a single gallon of water more than they are already doing. They already abstract two-thirds of the daily flow, and we see what are the consequences. The question of flood-water seems a very important and neglected one, and surely our engineering

authorities can devise some storage schemes which will insure us a large additional supply without any extra call on the river.

The second heading, that of more extended supplies, is a very wide subject, and has been fruitful in the bringing forth of many schemes, of more or less value. They must be classed under the two first divisions,—1. Schemes affecting the Thames basin; 2. Schemes entirely independent of it, and involving the obtaining of water from other sources and by other means. A vast number of persons appear to be under the impression that the water difficulty is quite a recent feature, and would perhaps be surprised to learn that it is a very old one—a difficulty, indeed, which impressed the scientific men of ten and twenty years ago much more forcibly than the present generation seems inclined to appreciate.

A brief sketch of these various schemes was then given, and the lecturer proceeded to touch upon "the fearful shortcomings of our drainage system." From Henley to Gravesend comes the same cry, that our noble river is nothing but a sewer, and a sewer of extremely filthy and dangerous nature. Of all the many fearful muddles and failures of systems with which we have become so familiar within the last few years, that of the Thames drainage stands out in gigantic prominence, and it is hard to say whether the Lower or Upper Thames has come the worst off, although from different causes. Below bridges, we have expended millions in constructing what appeared to be the most perfect drainage system in the world,—and after the experience of a few years' working, we find that we have succeeded in paying the bed of the Thames with a new and fictitious bed of excremental matter; that, instead of getting rid of our sewage far out to sea, as was hoped and intended, it is, like the poor, always with us, churned backwards and forwards with the tide, and each day presenting a more threatening aspect to the public health. Above bridges, millions have certainly not been spent, but thousands have, not in perfecting a system of drainage, but in most ingeniously contriving to prevent any system at all being made. Let us for a moment glance at the facts which characterise both sections of the river at the present time. The London area of drainage north of the Thames is 53 square miles, the sewage of which is collected in reservoirs of 94 acres at Barking, the capacity of these being 35 million gallons, or 5,600,000 cubic feet. The drainage south of the Thames is 66 square miles, the sewage being collected at Crossness in reservoirs of 6½ acres, and in capacity of 25 million gallons, or 4 million cubic feet. The average daily discharge of sewage into the Thames is 164 million gallons, the Lower Thames receiving about 60,000,000,000 gallons in the course of a year, the amount of suspended matter being estimated by Professor Frankland, as long ago as 1879, at 1,354,000 tons. Of course, it is a matter of gigantic difficulty to deal with this mass of filth, and up to the point at which it is received at the outfalls, no fault can be found with the system. But here the mistakes appear to begin. At the time of high water, all that is done is to open the sluice-gates of the reservoirs for four hours during the ebb, and let the sewage pass into the tide way. As a matter of course, some will go out to sea, but the bulk only travels a short distance down the river to be brought up by the next tide, while a certain proportion is deposited, and, in point of fact, the volume of the river is physically unable to carry it away. Two questions naturally strike one here. 1. Why is not the public health better protected? 2. Why are no endeavours made to utilise the sewage and reduce the expenses? Here we are met with the old bugbear of expense, as if the health of the people was a matter to be regulated by pounds, shillings, and pence, and was not paramount over all such faulty considerations. If we are too poor to devote a few millions to this end, let us do away with the luxury of an annual war in our foreign possessions for a few years,—let us cut down some of the extravagant expenses of the School Board,—anything, indeed, to ensure the primary duties of a Government towards the population. To begin with, at any cost this mass of pestilence-breeding sewage should be deodorised or rendered innocuous, if nothing else is done; but that is not enough,—it should also be taken out of sight and out of smell of London city, and not be let go until it is cast fairly into the sea. We are told that to extend the outfall

works to Tilbury, fifteen miles lower down the river, would cost nearly three millions sterling, and that the pumping would represent another million. Very good, so far. But why stop at Tilbury? It is only partially lessening the evil, besides ruining the navigation of the river below Gravesend. I say that the only plan, and the cheapest in the end, is to convey the sewage of London straight across the Essex marshes to Foulness Island, a little to the north of Shoeburyness, and there, if possible, cast it into the German ocean, from whence there is not much chance of its returning. And why I say emphatically that this plan will be the cheapest in the end is because you will have here all the elements of a successful locality to deal with the sewage from a manufacturing point of view. Surely, unless our boasted scientific knowledge is all a sham and a delusion, some one of the many projects for converting sewage into a practical manure, and therefore of financial value, may be, after due consideration and further experiments, adopted with success. Space is of no object in Foulness or Wallasea Islands, and I see no reason why a busy manufacturing district should not arise here, and a brisk trade in artificial manure carried on from a harbour on the river Crouch, to which ships from all parts might resort; inland also, by means of railway extension. Even in the case of failure we should, at all events, secure a fair amount of immunity from epidemics and pestilence, which, even at a money computation, would be invaluable.

After speaking of the recent collapse of the Thames Valley sewerage scheme, on which we have already commented, Mr. Bevan concluded:—My belief is (whatever it may be worth) that an automatic power is needed to deal with the whole subject *ab initio*, so that the drainage of the Thames, from Windsor to Gravesend, should be under one strong hand, and should be made part and parcel of one scheme. I believe also that that one scheme should be the transportation of all this sewage to some place like Foulness Island, there to be dealt with commercially by the most approved form of treatment, and that at the same time, while not interfering unduly with the vested rights of the existing water companies, I believe that an additional and independent supply of the very best water possible should be procured and brought to London.

After the lecture and some discussion, the following tolerably tough "resolution" was proposed:—"That in the opinion of this meeting the system adopted by the people of Kingston, Richmond, and the adjoining districts, of drinking the water into which they put their sewage, is filthy, foul, abominable, and barbarous in the extreme, and calls loudly for an immediate remedy; and the disgraceful grossness of the river Thames at Barking and Crossness by the Metropolitan Board of Works ought to be at once stopped by the use of some such purifying process as that at Aylesbury, and also by a law compelling those inhabitants who have sufficient gardens to use earth closets, or some other equally efficient remedy." The above resolution was moved by Mr. W. H. Le Fevre, C.E., and seconded by Mr. J. J. Yonge, C.E., and carried unanimously.

**Lead Works in the Auction Market.**—The well-known lead works of Messrs. Walkers, Parker, & Co., were last week offered for sale at the Auction Mart, by Messrs. Fuller, Horsey, & Co., under an order made by Mr. Justice Chitty in the Chancery suit of Walker v. Walker. The property, which is said to comprise the most extensive lead works in the country, was described in the printed particulars as situated in different parts of England and Wales, including the London lead works and shot tower in the Belvedere-road, Lambeth; the lead works and shot towers at Elswick, Newcastle-on-Tyne, and Chester; the lead works at Dee Bank, on the Flintshire side of the river Dee; the Bagillt works, in Flintshire; and the lead works in Glasgow and Liverpool. The estimated aggregate value of the several properties was put at upwards of 300,000l., the value of the stock-in-trade of the works on the banks of the river Dee alone being set down at 90,000l. The property was offered in eight lots, but the highest prices bid for the several lots was limited to prices ranging from 15,000l. to about 30,000l., and 40,000l., which the auctioneer observed were very much below the reserve sums fixed by the Court, and all the lots were consequently withdrawn.

## NEW SCHOOLS FOR EDMONTON UNION.

The two foundation-stones (one at the corner of the boys' block and one at the corner of the girls' block) of the new schools erecting at Enfield for the Guardians of the Edmonton Union, were laid by the chairman, Mr. M. Latham, and the vice-chairman, Mr. Joseph Clark, on the 19th ult. The schools will ultimately accommodate from 500 to 600 children, the administration being designed for that number. The general scheme may be described as follows:—Entrance-lodge next road; some distance in from road, right and left of the ground, two receiving-wards; in rear, main building, divided into several groups, so that floors or blocks may be isolated in cases of epidemics or fire, extension made with ease, and the character of a public school imparted, the children meeting for instruction and recreation, and then filing off to different blocks or separate houses. The centre of the group contains master's and matron's quarters, committee-room, and bedrooms for servants, with stores, bakery, kitchen, dining-hall, lavatories, bath, laundries, engineer's shop, boiler-house, and workshops, with boys' and girls' and infants' schools grouped round and connected by corridors. These departments overlook large playgrounds open to the sun and not overshadowed by buildings. Beyond is a broad road running transversely to the estate, along the sides of which will be cottage homes, each home to have thirty-one children and two foster parents; the man, being a mechanic, will teach the boys his trade and the woman will instruct the girls in domestic work. In a distant part of the site is an infirmary made up of pavilions, and more distant still are farm buildings. Spade husbandry and gardening will form part of the industrial training. The infants' department has school mistresses' and nurses' quarters in centre; the boys and girls have chaperon and mistress and sub-mistress and mistresses at either end. The estate is 42 acres in extent. The architect of the buildings is Mr. T. E. Knightley; and the builder is Mr. Charles Wall. The contract amount is 54,000*l.*

## SURREY ARCHÆOLOGICAL SOCIETY.

The recent excursion of this Society to Leatherhead, Mickleham, Eppingham, and Fetcham was attended by upwards of eighty members and visitors. The first meeting was at Leatherhead Church, where a paper, written by Mr. R. H. Carpenter, was read by Mr. Thomas Milbourn, who said the writer was unable to be present. Mr. Carpenter in his paper said that the church was dedicated to SS. Mary and Nicholas. The plan of the church now consisted of nave and chancel, north and south transepts, north and south aisles, north porch, and western tower. There was evidence that the Norman and Early English church had a central tower at the intersection of the arms of the cross. In 1344 Queen Isabella obtained the living of Leatherhead for the Convent of Leeds about the time when the tower collapsed. The windows were very charming, and the church had recently been restored, yet there was much to be done. The plinth of the church could now be seen, and gave evidence of what the rest was before it was covered with plaster in 1733. This covering was put on in consequence of the decay of the soft Reigate stone, which was also used and had perished at Westminster Abbey. The company then drove off in carriages to Mickleham, where Mr. Ralph Nevill, F.S.A., read a paper, in which he stated that in 1823 the church was restored by Mr. Robinson, who showed unusual enlightenment as a restorer, considering the period. The church was erected in the reign of Edward I. on the site of an old one. The windows were put in in 1840, and the font was very ancient.

The excursionists having proceeded to Eppingham, Major Heales, F.S.A., read a paper on the church and its history. He said this was one of the few old churches of Surrey not mentioned in Domesday. The oldest document he could find referring to the church was of the fourteenth century, and this document referred to the oldest part of the church as being of the twelfth century. The walls were of extraordinary thickness, some of them being upwards of 3 ft. thick. The bench-ends were good, and the font was of the fifteenth century.

Mr. Granville Leveson-Gower, F.S.A., next

read a paper on the "Howards of Eppingham," after which the excursionists proceeded to Fetcham Church, where the architecture of the church was described by Mr. Chas. Forster Hayward, F.S.A. Mr. Hayward said the church was of very early date; there were Roman bricks used in the walls, and the columns were good examples of Norman work. The original form of the church was, like that of all Norman churches, cruciform. This church was restored by Mr. Joseph Clarke, F.S.A.,—the chancel in 1872 and the nave in 1877. Another paper was afterwards read by the Rev. W. H. F. Edge, M.A., on the "Parochial Records." The company were next invited to inspect the mansion of Mr. Hanky, J.P. (adjoining the church), and here some paintings, particularly one in the centre of the drawing-room ceiling by Sir James Thornhill, were much admired. The whole party then returned in their carriages to the Swan Hotel, Leatherhead, to dinner. Major Heales, F.S.A., presided. After the usual loyal toasts, the Chairman proposed "Success to the Surrey Archæological Society," and said they had now been established over a quarter of a century. Mr. T. Milbourn, hon. sec., responded, and said they now numbered 420 members. Other toasts followed, and several new members were proposed, and the company soon afterwards dispersed.

The annual general meeting of the Society took place on the 23rd of July, at 8, Danes' Inn, Strand. Major Heales, F.S.A., presided, and the report of the council and balance-sheet for the past year were unanimously adopted. Mr. T. H. Mandley, C.E., moved the re-election of the retiring members of the council, which was adopted. The auditors, Messrs. J. T. Lacey and W. F. Potter, and the hon. sec., Mr. Thos. Milbourn, were also re-elected.

## ROYAL ACADEMY.

The following is the list of admissions to the Architectural School of the Royal Academy in July of this year.

## Upper School.

Fell, R. D.  
Fox, Frank  
Simpson, F.  
Thomson, J.

## Lower School.

Hall, S.  
Mitchell, A. B.  
Newberry, J. E.  
Sedding, E. H.  
Selly, E. H.  
Troup, F. W.

## Probationers.

Anderson, P.  
Allen, N. W.  
Ayling, R. S.  
Boney, W. H.  
Burr, W. A.  
Buxton, W. L.  
Cresswell, J. J.  
Day, F. M.  
Dennis, L.  
Downing, H.P.B.  
Druery, H.

Ford, L. R.  
Gill, C.  
Harvey, G.  
Hitchin, T. H.  
Howie, W. H.  
Hutchings, H.  
Jemmitt, A. R.  
Lancaster, G. J.  
Leck, W.  
Manning, H. C.  
Marks, F. W.

Masey, F.  
Meedway, C. L.  
Newton, W.  
North, R. O'B.  
Schultz, W. H.  
Steinthal, A.  
Sykes, A.  
Taylor, A. S.  
Thorp, J. B.  
Webb, F. J.  
Wetherell, T. G.

## VALUE OF PROPERTY AT THE EAST END.

*Large Sale of Leaseholds at Stepney.*—Last week, Messrs. Fox & Dousfield offered for sale at the Auction Mart a large amount of leasehold property at Stepney. The property, consisting of 132 houses, included the whole of Albert-square, together with several shops in the Commercial road, and nearly the whole of Havering-street and Bower-street, producing altogether an annual rental of 3,927*l.* The property was stated to be held on three leases, of which forty years are unexpired, at ground-rents amounting to 352*l.* per annum. The property was offered in three lots, for all of which there was a severe competition amongst the numerous company present. The first lot submitted comprised ninety-three houses, producing a rental of 2,257*l.* per annum. It was put up at 10,000*l.* The third lot consisted of the houses on the south side of Albert-square, extending in the rear to the London and Blackwall Railway. This property produces an annual rental of 361*l.*, and amongst the competitors for it was a representative of the railway company, and several other parties, the competition being very close, and the bidings following each other in rapid succession. It was ultimately sold to the railway company for 7,250*l.*, and it was afterwards stated in the room that the company have purchased it in view of widening the line in the locality of Stepney Junction. The total proceeds of the day's sale amounted to 45,350*l.*, representing about 7½ per

cent on the rentals, after deducting the amounts of the ground-rents.

*Freehold Property in Whitechapel.*—Messrs. Weatherall & Green submitted for sale several freehold houses in Whitechapel. Amongst them were eight houses in Fieldgate-street, the rentals of which were stated to be between 400*l.* and 500*l.* per annum. They were sold for 8,000*l.* Seventeen houses in Greenfield-street, producing an annual rental of upwards of 400*l.*, were next offered. After some spirited bidings, they were knocked down at 9,000*l.* The King's Arms public-house, in Fieldgate-street, with a warehouse in the rear, was sold for 1,520*l.*, the aggregate sum realised by the sale being 18,520*l.*

## OUR PUBLIC BUILDINGS.

SIR,—May I be permitted space in your columns to direct attention to the works which are now being carried out in the Royal Exchange? Entering the building a few days ago I was astonished to find a number of workmen engaged in the erection of a ponderous roof of the artistic railway station type. We have not many fine buildings in the City, and among these we have hitherto numbered the Royal Exchange of Sir William Tite, and the City. An edifice such as the Exchange, with its fine Palladian court, was certainly intended to be hyphæthral, and a roof would be as incongruous as on the temples of Greece or Asia Minor. The exigencies of our insular climate, however, render it necessary that a roof should be added. In the construction of a roof to carry a second Exchange, and there the main features of the ironwork framing should be harmonious in proportion and style with those of the building, and, at the same time, of such slender construction as to exclude as small a proportion of light as possible; one of the chief requirements of such a building being a free and uninterrupted sky-line, to be carried out in a most cursory inspection, that these requirements are not met by the work in progress erections.

The girders are of the massive railway-bridge type, and there is not throughout the whole work a single line, curve, or moulding in harmony with the Classic features of the building. The work is sufficiently strong to carry a second Exchange, and there results consequently an exclusion of over 50 per cent. of light, while a series of heavy shadows are produced, which hide some of the finest details of the building. That such an artistic treatment is a necessity is fully contradicted by the designs which have been submitted in previous competitions. In the first competition in 1861, when the project of roofing the Exchange was first mooted, several leading architects competed. On the exhibition of the drawings, Sir William Tite, the architect of the building, withdrew his design in favour of that of Mr. F. Sang, who had been employed in the mural decorations of the Exchange, he considered it exhibited a treatment of iron and glass fulfilling all the above-stated requirements. In this design the framing of the roof was extremely light, the necessary support being obtained by an external framework to which the glass roof was tied. To this design the first prize was awarded. The competition, as is so often the case, proved a failure, and in this case a comedy in two acts, for a second competition was also abortive, and the designs sent in were shelved. The objections raised by some to the original design of Mr. Sang, that it was too artistic to admit of construction, and only a picture design, was met by the preparation of a complete series of working drawings, which proved to the satisfaction of both engineers and architects the practicability of the work. Notwithstanding this claim the design was neglected, and the present architect has failed to invest his structure with artistic merit. But a greater and more serious objection is to be found in order to carry the massive framing the fine balustrade on the parapet has been cut away, and in order to bed the heavy girders, the templates of several columns have been removed. If this work is allowed to go on and the roof erected, a few years' accumulation of London soot and dirt will render the meeting-place of City merchants as dark as an Egyptian tomb.

In conclusion, I should add that my knowledge of Mr. Sang's drawings and the result of the previous competition has been derived from an inspection of the original design, which is now exhibited near the Exchange, and from the correspondence which took place at the time. W. STR. C. BOSCAWEN.

British Museum.

## "TENDERS FOR SURVEYORS' WORK."

SIR,—Allow me to disclaim any connexion with the Mr. W. H. Nash whose name appeared in your last issue [p. 143], as tendering for surveyors' work in respect of a new district map for the Burgess Hill Local Board, and allow me at the same time to state that the remarks you made as to its being a practice which is strongly to be deprecated.

W. HILTON NASH, A.R.I.B.A.

**Erratum.**—In a mention of "New Buildings in Gracechurch-street" (p. 147, ante) the name of the contractor was erroneously given as Mr. Bangs; it should have been Messrs. W. Bangs & Co.

THE EARTHWORKS OF WARWICKSHIRE.

SIR,—It is always a source of gratification to an antiquary to see the studies he has pursued taken up by younger men with zeal, and I, in common with others, looked forward with pleasurable anticipation to the completion of your excellent "W." Though much has been done in late years to explore and survey the comparatively little-known earthworks in central England, there is much yet to do. much that is intensely interesting to those who trace unwritten history on the face of the earth and in the mounds and tumuli, which the "fathers of the land" have left us to mark alike their dwelling-places and their graves. From some cause or other "W." has not availed himself of the best information published on the subject; and hence, whilst describing the well-known earthworks of Brinklow and Chesterton on the Fosse, he has propagated a wilderness of errors, some of omission and others of commission. As these papers have been freely extracted in the Warwickshire newspapers, I have repeatedly asked, in some cases, and somewhat pertinently in others, what I think of these old-new revelations, particularly as I have been recently led into a controversy about the proper name of Roman Leicester, *Rata*, which "W." uses in the ablativ, *Ratis*, an error which Dr. Guest and Mr. T. Wright (both high authorities) long ago pointed out. That is not of so much importance as the incorrect manner in which the "perfect chain of fortresses" is handled about and mixed up in admirable geographical confusion. Berrow Hill (near Daventry), Edgeshill, Brinklow, Breerton Hill (which is in Worcestershire, many miles to the westward), Corley (which is north-east of Brinklow), back again to Brownsover, and then to Oldbury on the ridge above Maudeslum (Manchester). Here are the ancient camps and positions which every observer has ascribed to two distinct tribes, the Dobuni, whose frontier fortresses were undoubtedly occupied by Ostorius, and the Cornavii, or the Coritani (Mr. M. H. Bloxam thinks the latter), on whose boundary the Roman general passed. A glimpse of the country will show the reason of this. Between the two lines of fortresses lie the great midland plain watered by the Avon, the Leam, the Welland, and the Soar, or, as it is surmised, the Leir, which gave Leicester its distinctive name. On the west of this line, lying like an island in the sea, is Breton Hill, and this was probably one of the outposts of Ostorius. A recent writer, in allusion to Knebworth, or Nebworth, on the Rimington Hills, appears to think the small quadrangular entrenchment visible on the summit could hardly have been held by even a cohort; but I have before me a complete plan of the encampment made many years ago which shows entrenchments of great extent, which have been removed by modern improvements. In advance of this is the great oppidum of Meon Hill, more than thirty acres in extent, and which, from the small Roman encampment on its side, appears to have been taken by assault. The hill at Brailes is also a British post of importance outside the recognised line of posts presumably alluded to by Tacitus in the oft-debated and well-known quotation, and which stretched away to the eastward as far as Peterborough. Your contributor alludes to some slight opposition to Ostorius met with from the natives, and thus ignores the more than twenty years' war with Caractacus, Venisius, the great military chief of the Cornavii, who, with the Siliures, inflicted a disastrous defeat on the Roman legions. To him may be fairly ascribed the line of forts which yet remain intact, in Warwickshire, from Brownsover to the Ridgeway and into the Severn Vale. These are the most careful researches into the remains and graves which belong to that period show conclusively that it was the Angles, and the Angles alone, who penetrated by the Fosseway from the north into Mid-England; and except the raid of Ceawlin and Cutha into the Severn Valley (A.D. 584), we have no record or remains of the Jutes north of the Anglo-Saxon frontier. The graves there mark the boundary of the Anglo-Saxons.

With respect to Brinklow, which has been so often described, and which has been the subject of an exhaustive paper by Mr. G. T. Clark, F.S.A., in the *Journal of the Royal Archaeological Institute*, "W." has the credit of being the first to suggest that it was utilised by the Romans as a station on the Fosse. That it had a pre-Roman origin there is no doubt. The covered ways adjoining, and the relics which have been found and preserved, are evidences of this, but the actual Roman station remains in the neighbourhood, of which, notwithstanding their extent and importance, your contributor makes no mention, but passes them to describe and reproduce the well-known plan of Chesterton Camp.

He tells us, however, that the Saxons, Jutes, and Angles, between the years 450 and 550 "destroyed much of the Roman defences in the Midlands." The most careful researches into the remains and graves which belong to that period show conclusively that it was the Angles, and the Angles alone, who penetrated by the Fosseway from the north into Mid-England; and except the raid of Ceawlin and Cutha into the Severn Valley (A.D. 584), we have no record or remains of the Jutes north of the Anglo-Saxon frontier. The graves there mark the boundary of the Anglo-Saxons.

With respect to the type of earthwork, of which Brinklow is a fine example, and which Mr. G. T. Clark terms a "Saxon woth," these mounds defended by ramparts are common in Warwickshire,

without going to Loughton-en-le-Morthen for example, and without mentioning Tamworth and Warwick. There is an historical specimen at Seckington, another at Kineton (King John's Castle), near which early British pottery has been found. There is a small one at Kenilworth, hitherto unsurveyed. There is another at Allesley, adapted to a more recent times to a Medieval fortress, and in addition to these there are nearly two hundred moated areas existing.

Chesterton Camp was one of the regular stations (*massiones*) on the Roman road. In Warwickshire there is one at Manetter, and another, now partially removed, at High Cross (Benocs or Venonis), and some others less known. I wish, however, to point out that though Highdown Hill is a conspicuous feature in the landscape to the north of Chesterton, not the slightest sign of early occupation can be discerned on its wooded summit. On the contrary, Chesterton Hill is full of remains of an early settlement. The famous windmill, designed by Inigo Jones, is built on a mound which, in position and distance, is in a line with the signal-posts which stretch from the south-east to the north-west diagonally with the lines of fortification and the Fosseway. The square fortification at Lodge Coppice is more the enclosure of the keeper's lodge, a square stone building of singular appearance now removed, a sketch of which is now before me. That some ancient dwelling existed near the Royal Oak House, the black ground testifies, and the remains found prove, but the Roman station at Chesterton was to the west of Windmill Hill, where coins and spoils of the Roman period are constantly found to the present day, together with Saxon coins and those of the Conqueror, whose soldiers apparently rested here after ravaging Harbury, and on their return from Scotland, as coins of the Scottish contemporary kings have been found mingled with them. It is strange that "W." does not allude to this significant fact.

Space will not permit me now to pursue the subject farther, but perhaps you will permit me to point out that the site of Holm, or Hom Castle, has been so cut about by the landscape-gardeners that its original contour is lost, and whilst giving us again the interesting story of the "wroth rural site assigned for the place of assembly of the Stoneleigh Manorial Court, when Daydale tells us that it took place at Moteslow Hill, overlooking the village of Stoneleigh, and gives us the mode of procedure therat in full.

I have only alluded to a few salient points, which are beyond the reach of controversy, and in a few days I shall be prepared to show my readers more of Warwickshire Antiquities of the pre-Domesday Book period to any one who cares about the subject. On this map every known earthwork and historic site is laid down, and their connexion with those in the neighbouring counties, as well as those places where pre-Norman remains have been found. This map is intended to illustrate in detail my long-promised work on "Ancient Warwickshire," now approaching completion.

J. TOM BURGESS, F.S.A.

London, July 23, 1884.

PROPOSED PLUMBERS' CONGRESS.

SIR,—I am thoroughly of opinion that if the London and Provincial plumbers were to hold a congress some time early in the coming autumn, and before the National Health Exhibition closes, one would very much benefit the other by the interchange of ideas respecting sanitary work generally, and with a view of establishing a union whereby we could form ourselves into a company for the fostering and encouraging of good plumbing; for the establishing a code of rules on good plumbing; and for the protection of the trade generally from being murdered by the alarming growth of quack sanitarians who are dabbling in the plumbing trade to the great detriment of substantial work; and also to see if we could not establish some kind of regulation whereby we could petition Parliament to enforce a code of rules or laws whereby all sanitary work should be examined after being done, which test would prevent unqualified persons doing sanitary work, to wit, such as ironmongers, gasfitters, zincworkers, and such like, who are not capable of carrying such work out, and to inflict penalties upon all established and recognised plumbers who are found doing slop-work, and which would be likely to prove in any way detrimental to health. For my part I am willing to assist in getting such a congress, and I have every reason to believe that we could get many well-known provincial plumbers; such, for instance, as Mr. W. P. Buchan and other well-known sanitary authorities. I should like to see the Master of the Plumbers' Company, Mr. George Shaw, head the list.

Perhaps some of your readers would give me their views upon the subject, and send in their names as persons who would join in the affair. I can at any time command a very large hall in Kensington, which would be within a few minutes' walk of the Exhibition.

P. J. DAVIES.  
75, Earl's Court-road, Kensington, W.,  
23rd July, 1884.

IMPERMEABLE FLOORS AND ECONOMICAL FIREPROOF CONSTRUCTION.

SIR,—The papers read on the 11th inst. at the Health Exhibition Conference on the above subjects are of considerable interest, and with your permission I should like to make a few observations thereon.

One of the speakers drew attention to the usual practice in so-called fireproof (or more accurately fire-resisting) floors, above those on the ground level, to construct over the concrete a complete wood floor of the old type, i.e., with small joists and boards, so that there is a series of horizontal fillets supplied with fresh air through the perforated bricks inserted to prevent dry rot of those joists, which air feeds the flames arising in the room over the wooden floor, and attention was drawn to Messrs. Clarke & Co.'s new "patent," by which the joists are abolished and floor-boards are laid on a bed of mastic directly on the concrete. But in this patent there are fillets of wood bedded in the concrete, which I venture to think are unnecessary and a source of weakness. For it is evident that being put into a liquid bed of concrete the wood swells, and when it becomes dry it shrinks and remains loose in the material. Now, sir, I have often constructed floors which are exactly like Messrs. Clarke's, minus the fillets and mastic. My concrete I make of coke or pan breeze floated to a level surface, and when this is quite dry I lay dry boards on it and nail them to the concrete just as ordinary boards are nailed to wood joists. It is impossible to draw the nails; indeed, I have seen boards forced up, leaving every nail standing. The boards may be laid in tar or other bituminous material, as block floors are laid on the ground.

There can be no question that a floor so laid avoids the evil of the usual practice, and from the point of view of health it is vastly superior; it is drier, warmer, and there are no spaces for vermin, disease germs, dust, or filth to accumulate.

It was properly pointed out that in fire-resisting floors large iron girders, where necessary owing to the span, should be cased in fireclay to shield them from the direct action of the fire, but a very necessary further precaution is to leave the ends of the girders loose on their bearings and with a cavity at the back, because, though the fire does not directly attack the iron girders, it heats them and they expand. If bound at the ends they will burst out the walls.

Nothing was said of an evil which frequently, I believe, causes the complete destruction of warehouse buildings, having the most approved "fire-proof" floors, and that is the ordinary lift-shaft. A fire breaks out between two such floors, the windows break and supply the requisite air, and the story thus becomes, from the very impermeable character of its floors, like the furnace of a Cornish boiler, the lift-shaft furnishing the requisite draught like a tall chimney.

To avoid this, I have adopted the following method. The enclosure to the lift is abolished. All openings in the floor, and during the absence of the employés (when most fires occur) this opening is closed by means of hatches of tongued oak. Remember the object is not to resist direct action of the fire, but to stop draught. In fact, the hatches are dampers. They may be of concrete, if required, on wheels like trolleys. When the lift is in use the concrete platform will be docket flush with the floor. When not in use, small iron rails can be inserted in sockets and the platform rolled out.

We must all thank Mr. Horace Jones for his instructive suggestions on the casing of wood by iron plates. The samples he showed after their exposure to fierce heat were very interesting, and it is probable that the oak hatches sheeted with iron would be absolutely fire-resisting.

Lastly, Stress was laid by many speakers on the desirability of abolishing wood laths to ordinary wood ceilings, but no reference was made to a system largely adopted in London,—at least, which does this, and at the same time is sufficient to resist the fire arising from the destruction of the furniture of an ordinary room. This consists of nailing near the bottom of an ordinary joist an angle fillet, erecting a temporary cast platform (of the nature of ordinary centring for an arch) say 1½ in. below the joists, and then filling in with concrete, averaging some 2½ in. thickness (as sketch). When dry, the centring is removed, and the ceiling rendered. I have used this in a thousand or more squares. It takes the place of pugging, and saves the ceiling from the stain of any small quantity of water that may be spilled overhead.

EDWIN T. HALL, A.R.I.B.A.  
57, Moorgate street.

Mossley—The fine five-light east window of Mossley Church, near Manchester, has just been filled with Munich stained glass to the memory of the late Mr. J. M. Kershaw, J.P., of Ashton-under-Lyne. The subject introduced is the Ascension. The artists are Messrs. Mayer & Co.

## THE CONSTRUCTION OF SILOS.

SIR,—So many are now erecting silos that we think it desirable to call attention to the fact that we have proved most conclusively that there is little or no lateral pressure from silage, and that consequently there can be no occasion to erect very thick walls unless as retaining walls against the thrust of the ground outside.

We had erected on the Royal Show Ground at Shrewsbury three of our circular portable wooden silos, the largest of which holds 50 tons of silage. In this we put about 16 tons of grass, and applied our patent mechanical pressure, equal to 16 tons of dead weight, and thus reduced the bulk from 3 ft. in height to 3 ft., and, in order to afford the public an opportunity of seeing the whole process, we had placed a  $\frac{1}{2}$  in. plate-glass door, 30 in. high and 20 in. wide, which was flush with the interior of the staves, which are only  $\frac{1}{4}$  in. in thickness, and notwithstanding the great pressure, this glass door did not break, and neither did any of the staves bulge. The silage was cut out, after having been in the silo barely a week, in perfect condition.

We think this is so important a fact that it ought to be generally known, as the thicker the walls are constructed the greater the expense of silo-building will be.

We would also suggest to those who still prefer using dead weight as mechanical pressure, that in our opinion loose sand forms a most undesirable method of weighting. If used at all, it should most certainly be confined in boxes or bags: as, if otherwise, it mixes with the silage, and we are quite sure will not be appreciated by the cattle for whom the silage is intended.

F. W. REYNOLDS & Co.

Edward-street, Blackfriars-road.

## "STANLEY'S PATENT PLASTERING."

SIR,—My attention has been directed to a notice in your last week's issue [p. 148] referring to Stanley's patent plastering process. The directors request me to call your attention to the fact that this is practically an infringement of the process adopted by this company, a process which some few years ago you had the opportunity of investigating when the public test on the Embankment took place, when you kindly reported favourably of the merits of the same under date the 3rd of May, 1883.

The system adopted by Mr. Hitchens was only perfected after many and various trials. The material now in course of manufacture by this company has, I am happy to state, met with the cordial approval of the leading metropolitan and provincial architects, and is being largely specified by them.

Hitchens's system will only possess the qualifications stated in your paragraph, but is likewise a fire-resisting and sanitary material.

The Company is just completing the works at the Stock Exchange under Mr. Cole, and is about commencing the restoration of a very large block of buildings recently destroyed by fire at Messrs. Whiteley's, whilst nearly the whole of the buildings that were destroyed in Wood-street have had their interior finishings formed of this material.

I may also mention that the Sanitary and Insanitary Houses in the grounds of the Health Exhibition have been covered with Hitchens's material, the advertisements for which have now appeared in your columns for some time past.

R. E. EMSON,  
Secretary Hitchens's Fireproof  
Plastering Company.

## A LEAKY SLATE CISTERN.

SIR,—I erected a slate cistern on the top of my house some months ago, and although it was filled repeatedly without showing any leakage, it commenced leaking a fortnight ago, and on examination we found a slight shelving or vein on the floor, and close to the centre where it "tongued." The cistern,  $\frac{1}{2}$  in. thick, is well jointed, and we applied some kind of substance with varnish over the crack. To our surprise the tank leaked as badly, or even worse, than ever. Can any of your readers answer the following queries:—

1. Does alteration of heat and cold cause slate tanks to contract and expand when empty, notwithstanding their being (as in my case) but between two solid walls,—in fact, with three walls around, and covered with a heavy timber lid?

2. Would a piece of slate, 5 ft. 6 in. by 3 ft. 6 in. (size of floor),  $\frac{1}{2}$  in. thick, and bedded on  $\frac{1}{2}$  in. of Portland, cure the leakage, if properly cemented all round?

I have applied red lead, but fear it will not answer.

BOMBALZEN.

**Callington Public Rooms.**—The directors of the Callington Public Rooms recently offered a premium of £50 for the best set of plans and specifications submitted for building public rooms, with stable and carriage accommodation in connexion with its coffee tavern. The competitors were seven in number, and the design of Mr. C. D. Cooke, of Frankfort-street, Plymouth, who gave as his motto, "Cups and Saucers," was ultimately selected.

## Books.

*Outlines of Historic Ornament.* Translated from the German. Edited by GILBERT R. REDGRAVE. London: Chapman & Hall.

This is a useful treatise in the catechetical form of question and answer,—which certainly favours conciseness, and is so far commendable. The part played by the editor is not very clearly stated, and a few foot notes in amplification of the original, attested by the editor's initials, would have been welcome. For example, at p. 66 the especial characteristics of the Byzantine capital are given without touching upon its peculiar variation from the Classic type in the lateral increase of the mass above the abacus beyond the diameter of the column,—as in the Gothic styles. This feature more than any other differentiates the Byzantine or mixed from the pure Classic styles. Another characteristic of Byzantine art,—which we do not see referred to, but which we may have overlooked,—is the relation of the diameter of the column to its structural function, and not merely to its height.

Some of the answers are not quite conclusive, e.g., "Of what importance are figures in Gothic decoration?"

"Of very great importance; for in the larger buildings they are used in all prominent situations." (1)

Considering its German origin there is surprisingly little in the book about the architecture of the Fatherland; but what there is no doubt trustworthy. The illustrations are very numerous, and some of them are very good, and altogether it is a handy little volume which students may do well to possess.

*Concerning Carpets and Art Decoration of Floors.*

London: Waterlow & Sons.

This advertisement in masquerade is evidently the work of two or more authors, and it may be that the entire strength of Maple & Co. were engaged in its production. The first or historical portion is short but learned, all the sages of antiquity being brought upon the tapis, their testimony noted, and their opinions recorded. The second portion of the work is an ingenious variation of the assurance that Messrs. Maple & Co. are up,—or rather down,—to everything in the carpet and floor covering line and "will be happy on the receipt of particulars to advise," &c. The name of this eminent firm occurs on an average three times on each page,—say two hundred times in all,—and is not likely to be forgotten by the patient and conscientious reader; and so the end of the book will have been attained if only readers enough can be found. The scribe has acquitted himself fairly well of his very thankless task, and with such gratuitous cautions as that against choosing carpets with large patterns for small rooms, has mingled much that is both sound and suggestive. He has set his sails to catch the prevailing wind, and what can we wish but success to his enterprise?

## CHURCH BUILDING NEWS.

**Shirwell (near Barnstaple).**—St. Peter's church is about to undergo complete restoration at the hands of Mr. William White, F.S.A. Very little work of interest is now to be found, as the church was "beautified and restored" in 1704 by the then correct process of sweeping away all that was good and beautiful in the church. The nave oak roof has entirely disappeared, and plaster ceilings, "boxed" deal pews, hideous windows, and a stucco tower, are the main features of the eighteenth-century "restoration." New roofs of oak will be placed in the south aisle and chancel, and portions of the dilapidated walls will be rebuilt, and fourteen new windows of Ham Hill stone will be inserted to replace the present ones. The stucco will be cleared off the tower, and new copings and crosses put to the five gables. The interior will be fitted with pitch-pine seating, with wood block and tile floors. Carved oaken stalls will be placed in the chancel. Some very interesting fragments of carved bench-ends have been discovered by the workmen stowed away under the deal seats. Mr. Wm. Dart, of Crediton, is the contractor, and Mr. W. J. Dart is foreman of works.

**Manchester.**—The corner-stone of the Church of St. Agnes, Slade-lane, Longsight, was laid by the Bishop of the diocese on the 19th ult. The site is on the higher ground in the lane, and the

plot devoted to the sites of the church and parsonage is triangular, the church standing at the base, or northern side, Slade-lane on the easterly side, and St. John's-road, a continuation of the street which passes Longsight Church, on the westerly side. The parsonage will therefore stand on the south side of the church, with a southern aspect for the garden. The church, as now being built, will seat rather more than 500 adults, but the scheme provides for an addition of 100 or more. The plan comprises a broad nave of four bays, another narrower bay marked off from the wider portion by the pointed arch of two "orders" of mouldings. On the south side, at the south-west corner of the nave, is a spacious porch, gabled to the south. At the centre of the west end is a semi-octagonal baptistery, with a tall pointed arch opening into the church, and tall pointed windows piercing three of its sides. At the east end of the nave are a wide central pointed arch and two narrow ones. The left-hand archway leads to the organ-chamber, and to the choir and clergy vestries. A cluster of four arches, springing from a central stone pillar, marks a transeptal projection at the south-east corner of the church. The chancel, semi-hexagonal in shape at its eastern end, is raised seven steps in all up to the Lord's Table. It has around the four easterly sides twelve arches, eight of them pierced with long pointed windows, with stone cusped heads, and four with panels only, with cusped and pierced circles above them. These window-cills are kept well up, and the space below them is panelled or arcaded in brick. On the south side there will be sedilla and a credence. The roofs are to be open-timbered, and boarded. There is no plaster about the church. The walls inside will be lined to about window-cill height with brown glazed brick; above this with yellowish bricks from Rnabon. The windows are framed, as it were, in red brick. The cornices and arches generally are of the same material. But the chancel arch has stone voussoirs alternating with the brick. The walls generally are to be of grey brick, with red for the framing-in of the windows and for quoins and other parts. The strings, labels, and moulded parts are of terra-cotta. Though there will be stone in pillars, capitals, and bases, and in cills and cusps, heads of windows, and elsewhere, the church is a brick one. It is designed by the architects (Messrs. Medland and Henry Taylor) in brick, and would not be suitable for erection in any other material. The foundations have cost under £500. The superstructure, as above described, has been let for £2,700, with £125 for additional cost of a wood-block floor.

## The Student's Column.

HINTS FOR THE STUDY OF THE HISTORY OF ARCHITECTURE.—V. ROMAN.

THE general idea of Greek and Roman architecture, as conveyed to a superficial observer by their "orders," might be that they were much alike; moreover, there are instances of Roman architecture in Greece, such as the huge temple of Jupiter Olympus at Athens, which, Ferguson says, ("Handbook," p. 274), belongs strictly to the Roman school, and the sequel will show that the Greeks had a great deal to do with the introduction of the "orders" into Rome. There are, however, unmistakable distinctions between Greek and Roman architecture resulting from the usual causes of all architectural distinctions, namely, those of race, character, requirements to be fulfilled, and the means at hand for fulfilling them.

As to race, the architecture of Rome is traced back to the early inhabitants of the neighbouring district of Etruria, the modern Tuscan, who, according to Ferguson (p. 285) were an Asiatic people, who, twelve or thirteen centuries before the Christian era, emigrated from Lydia and settled themselves between the fertile valleys of the Tiber and the Arno, where they founded twelve cities, and established a federal union of twelve states, which is the peculiar institution of the race. He adds that they kept up a constant communication of commerce and arts with the cognate Pelagic races of Greece and other parts, whose art we have already described.

Here, then, we get a clue to the artistic merit of Etruscan work, which is famous throughout

the world, especially in regard of the Goldsmiths' craft. Of their architecture, the oldest remains consist of town walls and gateways. Here again we meet with the polygonal or cyclopean masonry, and the openings tapering upwards, such as we saw in the curiously similar work in Peru, and with the same progress towards refinement in the use of carefully-hewn squared stones. In Rosengarten's Handbook, on p. 103, will be found an Etruscan gate at Perugia. Here may be noticed a band of masonry, ornamented in a manner suggestive of the triglyphs and metopes of a Greek temple, in connexion with arches, which the Greeks from choice never used, but which we saw were used by the Assyrians. Thus we see that different races are like the subjects of the song, "some like coffee, some like tea," and, as pointed out in a former article, the national character or temper of a people,—in other words, their ethnology,—is no mean factor in the study of their architecture.

There are no Etruscan temples preserved, and the representation of them on tombs, says Rosengarten, are not calculated to lead to any conclusive idea. We are therefore left to a description of them drawn up by Vitruvius ("Marcus Vitruvius Pollio, a celebrated writer on architecture who flourished in the reigns of Julius Cæsar and Augustus"). He had laid down the proportions for a prostyle form of temple which has given rise to any amount of discussion amongst archaeologists and architects. The result given by Ramó (vol. ii., p. 591) seems the most likely-looking one, and is borne out by some slight existing remains. It should be compared with the very different result given by Fergusson on p. 287. From such temples is derived what is known as the "Tuscan" order, a shade simpler than the simplest Doric.

Etruria was long contemporary with Rome, in her early times her equal, and sometimes her mistress; therefore many characteristics of early Roman architecture are really Etruscan, and their influence survived after the Romans threw off the Etruscan yoke. The Etruscans were great tomb builders, and seem to have taken the most lively interest in their defunct relations. They provided them with all the furniture necessary for sitting (not forgetting the footstools), reclining to eat, and otherwise leading a happy existence, in spite of the lack of the important item, breath. Such tombs were cut in the rock; others were built in form of circular conical mounds, surmounting a cylindrical base or drum, illustrated by Fergusson on p. 291.

A valuable book to study on this subject is Denis' "Cities and Cemeteries of Etruria," 1843, 2 vols., octavo. The circular form of building remained a favourite one with the Romans, and was applied by them to their temples; while they also retained the passion for visiting the remains of their dead, more compactly disposed, however, in cinerary urns of portable size, and placed in recesses so like pigeon-holes that the buildings containing them were called "columbaria."

The examples of Etruscan masonry in Rome may be recognised by the regularity in the shape of the stones, which are the double cube of 2 ancient Roman feet, viz., 1 ft. 11 in. x 1 ft. 11 in. x 3 ft. 10 in. The buildings of this time are described by Taylor in a paper read at the Institute (Loan Collection of Transactions, vol. i.). Of this period, also, is the Cloaca Maxima, or great sewer, of Rome,—big enough, says Gwilt, for a cart loaded with hay to pass through it. Without a visit to the spot, it is rather difficult to describe the exact form of the bottom of it. On p. 253 of Fergusson's Handbook it is shown to have upright sides and a flat bottom, but the portion below the springing-line is concealed by the water in other illustrations of it.

In 145 B.C. Greece was subjugated by Rome, and the result was a great change in Roman architecture. Grecian forms were freely adopted, rather for the sake of adding ornament to the Roman constructions than anything else (see "Rosengarten," p. 110). "It is important to understand clearly that hereby is meant no structural and organic combination of the arch with the Greek columnar construction, for the latter must be considered merely as an imposing decorative system, originating just as little as the other from the structure of the building, and, therefore, without any structural importance. Viewed independently, the columnar construction forms only the outside covering of the building completed in the

rough, which might be at pleasure removed and replaced by another; whereas the removal of the decorative parts in Grecian architecture would have rendered the whole structure an impossibility."

Roman constructions, with the "decorative system" of the Greek orders applied to them, increased in number and magnificence, until Cæsar Augustus, who reigned at the time of the birth of Christ, boasted that he had found Rome of brick and left her of marble. Let us see on what class of buildings this magnificence was displayed. The Greeks have left us chiefly temples, some tombs and some theatres, consisting of an auditorium, rather more than semicircular, facing a stage, whereas Rome teemed with a far greater variety of buildings. Temples of course; tombs, in which the circle formed an important element of the plan; amphitheatres, in which the auditorium entirely surrounded the arena, as distinguished from the Greek stage; basilicas, or halls of justice; baths, which included several departments for recreation and study; circuses for chariot and horse races; forums for the public transaction of business; rostrums or bustings for public speaking; and arches for the triumphal entry of conquering Emperors or Generals. Besides all these, there were the wonderful engineering works, consisting of streets, viaducts, aqueducts, and bridges. Nor were these buildings confined to Rome,—she was the mistress of the world, and has left her mark in subject countries and colonies, far and wide. A few shillings spent on a return-ticket to Lincoln will enable the student to measure up a Roman archway, to say nothing of the ground floors of buildings that are constantly being unearthed around us.

Perhaps the best idea of ancient Rome may be obtained by asking at the Institute Library for Ashpitel's two views of it, as it was and as it is, and also for the key to them. The recently excavated Forum will throw additional light on it. A shilling or two spent on some of the numerous excellent photographs of the neighbourhood will make one feel almost at home in the place.

In order to obtain a more detailed acquaintance with the buildings, Canina's folio works should be examined. They are "Gli Edifici di Roma Antica," in 6 vols.; "Architettura Antica," in 2 vols.; "Pianta" (maps), in 1 vol. There is also his "Voci" in 1 vol. The maps of Rome show the city so crowded with enormous public buildings, that one wonders where the people lived. Piranesi's "Architettura de' Romani" is another folio work, which is useful on account of the Roman "orders" given on plate 6, *et seq.*, in vol. i. A more practical work is Taylor and Cressy's "Architectural Antiquities of Rome," 2 vols., quarto, containing general drawings and details to a large scale. It also contains a most useful frontispiece with all the principal Roman buildings drawn to the same scale and many of them in their relative positions to each other. Of course, Norman's "Parallels" is as useful in the study of Roman as of Grecian architecture. The late Mr. J. H. Parker spent much of his life in Rome, making notes of the excavations, and has published a series of octavo volumes, illustrated by photographs. It will be found that he differs from other authors in the names that he assigns to certain ruins. The amusement of restoring ancient buildings on paper (at which point it should usually stop) is demonstrated in an old book by Cameron, 1775, called "Baths of the Romans, with Restorations by Palladio." A work by Carloni, on the "Baths of Titus," is devoted to the coloured decorations of that building.

The Roman "orders" will be easily distinguished from the Greek ones. The Doric especially, which has a base, no flutings, and an utterly different capital and arrangement of the triglyphs next the angles. The Ionic differs somewhat less, but is sometimes found without flutings, as is also the Corinthian order, which became a greater favourite than it had been with the Greeks. It was, however, not rich enough for the sumptuous taste of the Romans, so they mixed it up with the Ionic and produced the Composite order.

The portico of the Pantheon at Rome is very similar in size and number of columns to the Parthenon at Athens, and they may be fairly compared as good examples of their respective orders (see Taylor and Cressy).

The Pantheon brings us to the consideration of a great distinction between Roman and Greek architecture, namely, the use of the arch and dome. This building consists,—besides the

portico, which Fergusson considers the oldest part, see p. 311 of his "Handbook,"—of a vast circular chamber, 145 ft. 6 in. in diameter, covered with a hemispherical dome, 147 ft. high to the top, which is pierced with an enormous "eye" 27 ft. in diameter, through which a flood of light illumines the whole interior. This building is more fully illustrated in Smith and Slater's "Classic Architecture" (p. 166 *et seq.*) than in the other handbooks, and there is a discrepancy between the drawings of the front elevation as given by Fergusson and by others.

There is also a circular Temple of Vesta at Tivoli, near Rome (the "order" of which is copied at the Bank of England), and several circular tombs in which the dome is, or has been, used as a covering; but the Romans also used the barrel and groined vault, as in the Basilica of Maxentius (or of Constantine), which is fully illustrated by Fergusson on page 320. Labour and material being of no object, they could afford to build huge vaultments, to restrain the thrust of these vaults. Viollet-le-Duc's "Lectures on Architecture," vol. ii., contain excellent illustrations of this method of construction, as shown, for instance, in the Baths of Caracalla. The portion illustrated looks vast, but it only represents about one-sixtieth part of the entire area of this huge establishment.

A greater sense of vastness must be conveyed by the Flavian amphitheatre, known as the Colosseum, of an elliptical plan, 620 ft. along its greatest diameter, and 513 ft. broad, and capable of seating 80,000 spectators. Compare this with the Albert Hall, which seats an audience of nearly 7,000.

Of decorative sculpture that has come down to us, the triumphal arches exhibit the richest examples. The arch of Titus is well known on account of the has-relief representing the carrying off of the seven-branched candlestick from Jerusalem, in the year 70 A.D. The column of Trajan is another rich example of decorative sculpture. There is a full-sized cast of it in the Architectural Court of the South Kensington Museum.

We know a good deal about the private houses of the Romans from the remains that have been so fortunately preserved for us at Pompeii,—though the circumstance of their preservation by an eruption of Mount Vesuvius was unfortunate for the inhabitants themselves. There was much Greek influence about Pompeian work, so that we may learn a double lesson from these ruins. Viollet-le-Duc, however, points out, in his "Habitations of Man," several distinctions between the Greek and the Roman manner of living and of planning their houses. The painted decorations at Pompeii have served as a model for many a building of our own day. It is, indeed, difficult to surpass them in treatment, though one would like to see them more modern in subject.

The arch, dome, and vault having now appeared on the scene as characteristic features of Roman architecture, we can pass on to the next thread in our web.

Sewage Gas.—10,270, W. Harrison, Sheffield, Spindles for Door-handles.—10,277, J. Gate, Plymouth, Water heaters for Bells, &c.—  
 July 18.—10,287, D. Rain, Over Darwen, Smoko and Hot-air Conductor.—10,293, W. R. Pullen, London, Embossing Leather Paper, &c.—10,294, W. R. Pullen, London, Wall-paper, &c.—10,295, W. R. Pullen, London, Stained-glass Work, &c.—10,296, A. G. Rumley, Bristol, Ventilating Drains and Sewers.—10,301, G. Skutter, London, Supplying Disinfectants to Water-closets, Urinals, and Drains.—10,311, R. Hodges and J. J. Gaunt, Birmingham, Roller-hilnd Furniture.  
 July 19.—10,328, W. Ereck, Dublin, Stoves for Domestic purposes.—10,332, D. P. Low, Glasgow, Cesspool and Filtering Deposit Removal Pan.—10,336, R. W. Brownhill, Handsworth, Self-acting Revolving Cooking Stove.  
 July 21.—10,378, D. Plumley, Newport, Rack Pulleys for Window-blinds, &c.—10,381, S. Turner, Barrow Haven, Clapper for Forming Kidges, Finials, &c.—10,393, C. Lawrence and T. F. Wintow, London, Ventilating Apparatus.—10,394, C. Lawrence, London, Ventilating Greenhouses, &c.  
 July 22.—10,431, G. F. Busbridge and J. H. Tervey, East Malling, Manufacture of Cement.—10,434, G. H. Brown and A. Brown, London, Domestic Fire-places.—10,442, B. Haich, London, Disinfecting and Deodorising Closets, Urinals, &c.—10,454, H. Frott, London, Ball Valve for High and Low Pressure Water.—10,460, E. Newton, Hitchin, Trap for Water-closets, &c.  
 July 23.—10,471, R. Chattwood, Bury, Ventilators.—10,480, C. O. Sortie, Christiania, Window-blinds.—10,503, W. P. Buchan, Glasgow, Water and Earth Closets.  
 July 24.—10,532, W. S. Rogers, London, Brick-work Facing.—10,540, J. E. Filling, London, Suspending Curtains over Doors, &c.—10,547, A. G. Brookes, London, Pavement. Com. by G. F. Zeigler, New York, U.S.A.—10,557, W. Hayward and W. Eckstein, London, Window-sashes.

SPECIFICATIONS ACCEPTED.\*

July 15.—2,851, J. H. Yeo, Brixham, Sewer-gas Preventer and Sewage Collector.—6,127, T. Durran, London, Connecting Water-closets, &c., with Ventilated Soil-pipes.—8,844, S. H. Rowley, Swadincote, Water-closet Basins.  
 July 18.—3,725, G. Crapper, London, Ventilation of House drains, &c.  
 July 22.—523, R. Pollock and T. H. Herberson, London, Ventilators.—801, T. P. Bache and G. Salter, West Bromwich, Door-springs.—2,379, S. Willett, London, Window-fastener.—7,203, W. J. Hopkies, Worcester, Expanding and Contracting Grate.—7,838, H. Steven and J. Walker, Glasgow, Cast-iron Skylight Frames.  
 July 25.—1,744, V. Skinner and H. C. Board, Bristol, Ventilation of Horticultural Houses and Buildings.—4,459, J. C. Garrod, Fulkestone, Safety Lock or Latch.—6,037, T. Grimbley and H. Grimbley, Barrow-upon-Humber, Lock-wing Roofing Tiles.

ABRIDGMENTS OF SPECIFICATIONS

Published during the week ending July 19, 1884.

5,650, R. Hall & C. C. Woodcock, Leicester, Wood Paving (Dec. 5, 1883, p. 44.)  
 The blocks have grooves or recesses formed in their upper surfaces into which concrete or other cement is poured.

5,734, H. H. Lake, London, Door Handles. Com. by C. E. Lacey, Calais. (Dec. 13, '83, 2d.)

The loose handle has a spring in its tube which the handle is pushed on the spindle, engages one of a set of ratchet-teeth thereon, and prevents the handle being taken off. A pin is passed through a hole in the knob to lift the spring and disengage it from the teeth when required to remove the handle. (Pp. 170.)

5,849, C. D. Abel, London, Manufacture of Moulded Ornamental Articles in Imitation of Wood and other Carvings. Com. by C. W. Radeke, Berlin. (Dec. 27, '83, 4d.)

This is an improvement on Patent No. 2,914, of 1881, in using sawdust, powdered resin, and slaked lime, which are reduced to a fine powder, and then, when quite dry, are fed into heated moulds and are subjected to great pressure therein.

Published during the week ending July 26, 1884.

5,796, A. Lorrain, Richmond, Producing Fluid Currents available for Ventilation. (Dec. 18, '83, 6d.)

A sail or flexible sheet has one end fixed to a bar while the other end is attached to a crank-pin which is made to revolve. The centre of gravity of the crank is so placed that when the pin is in its upper position the sail is stretched tight from the bar, while in its lower position the pin passes just under the bar. The sail is thus consecutively stretched and collapsed, and by its revolutions the current of air is produced.

5,821, G. M. Morgan, London, Working of Marble and other Stone, &c. (Dec. 20, '83, 6d.)

The marble, &c., is fixed on a travelling table which traverses backwards and forwards under a tool-rest wherein are fixed a number of tools—first roughing and then finishing tools.

5,855, C. D. Abel, London, Impregnation of Wood, &c., with Preservative Substances. Com.

\* Open to public inspection for two months from the dates named.

by J. A. Koch, Galveston, U.S.A., and W. Herre, Berlin. (Dec. 24, '83, 4d.)

The wood is first placed in a closed vessel containing water, and is heated therein up to from 126 to 248° Fahr., when sulphate of iron, common salt, and alum are added, and afterwards the vessel is allowed gradually to cool down.

Miscellaneous.

**Eye Hospital, Birmingham.**—The new premises of the Birmingham and Midland Eye Hospital were opened on the 24th ult. by Lady Leigh. The Rev. B. Jones Bateman, chairman of the Committee, in opening the proceedings gave a short sketch of the history of the Institution, which was founded in 1823. Lady Leigh having declared the Hospital open, Lord Leigh, in thanking the Committee on behalf of her ladyship, congratulated the Governors and Committee on the long list of subscriptions, especially the munificent gift of 5,000*l.* from Mrs. Barrs, of Dudley. The hospital is a brick building with stone dressings, embellished with a small amount of carving. It stands upon 1,080 square yards of land, and has three frontages, namely to Church-street, Edmund-street, and Warwick-street. It consists of four floors and a basement, the kitchen department being in the top story. There are two stone staircases leading from the main entrance to the top of the building, one passing through the side set apart for the male patients and the other that of the female patients, and a third stone staircase leading from the basement to the top story. The outpatient department is entirely isolated from the rest of the building; the large waiting-room occupying the internal space on the ground floor is under its own roof, thus forming a large internal area to assist the lighting and ventilating of the upper floors. This waiting-hall is arranged to accommodate about 250 patients daily. The hospital is arranged to accommodate beds for seventy patients, with ample cubical space per bed. The building has been erected by Mr. William Robinson, builder, under the superintendence of Messrs. Payne & Talbot, architects.

**Public Halls at Brixton.**—Brixton Hall, situate in Acre-lane, is at present undergoing very considerable enlargement. The works in progress include the extension of the present hall by increasing its length to the extent of 20 ft., and erecting a spacious gallery at the south end. The platform orchestra at the north end is likewise being reconstructed and enlarged. In addition to the extension of the large hall a second hall, with several apartments in connexion, is in course of erection. Messrs. Fowler & Hill, of Sergeant's Inn, Fleet-street, are the architects, and Mr. W. Downs, of Hampton-street, Walworth, is the contractor. Mr. E. Smith is the clerk of the works. The estimated cost of the works is between 4,000*l.* and 5,000*l.*—Gresham Hall (formerly known as the Angel Town Institution), in Gresham-road, having been destroyed by fire a few months since, is now in course of rebuilding and enlargement. Mr. T. Goodchild, of Duke-street, Adelphi, is the architect, and Messrs. Fish, Prestige, & Co., of Piccadilly, are the contractors. Mr. Roberts is the clerk of the works. The cost of the works will be about 3,000*l.*

**700 Per Cent. Increase of Value in a Century and a Quarter.**—The freehold house, No. 63, Lincoln's Inn-fields, with large fore-court and premises at rear extending to Queen's Head-yard, and covering an area of 11,350 square feet, was purchased in the year 1758 for the sum of 1,721*l.*, by Mr. Norton, a barrister, who afterwards became Speaker to the House of Commons, and subsequently the first Baron Grosvenor. It was put up to auction on Wednesday last by Messrs. Driver & Co., of Whitehall, and realised the sum of 13,000*l.*, thus showing more than 700 per cent. increase upon the price paid for the same property in 1758.

The National Association of Master Builders of Great Britain held their thirteenth half-yearly meeting at the rooms of the Central Association of Master Builders of London on Tuesday, the 29th ult., Mr. Stanley G. Bird, the president, in the chair. The meeting was largely attended by representatives from the provincial and local associations. After the routine business had been disposed of, several matters affecting the trade were discussed, more particularly the question of quantities. The next meeting will be held at Lincoln.

**Old and New Melbourne.**—The *Australasian Sketcher* for June 2 contains some interesting sketches of Old Melbourne,—not, indeed, that Melbourne is of any great antiquity, for many people now living have witnessed the growth of the city from babyhood to its present vigorous condition. Many of the earliest buildings erected on the site of the city have been removed to make way for modern improvements, and the few that remain are likely soon to disappear. The *Sketcher*, while doing its part in perpetuating the memory of the past, is not backward in recording the facts of the present, and in the same number gives a view of the new City of Melbourne Bank, at the corner of Collins and Elizabeth streets, on the site of the Clarence Hotel, one of the bits of "old" Melbourne included in the sketches referred to. It is stated that the "rookeries" on the adjoining blocks are being replaced by buildings worthy of the site and the city. The City of Melbourne Bank is in the style of the Italian Renaissance. It has frontages of 49 ft. to Collins-street, and 88 ft. to Elizabeth-street side. The chief features in the façades are large Corinthian columns, each about 30 ft. in height, which extend upwards to the summit of the first story. These rest upon bases of huestone, each 7 ft. high, and when complete this will probably be the largest colonnade of the kind in the city. The doorway, which is at the corner, will be recessed, thus forming a portico. The doorway opens in the base of a tower. The architects of the new building are Messrs. Terry & Oakden.

**Lifts at the Great Eastern Hotel, Liverpool-street.**—The whole of the lifts at this building are almost completed. They have been erected by Messrs. Archibald Smith & Stevens, of Janus Works, Queen's-road, Battersea, and consist of one Stevens and Major's hydraulic balance passenger lift, 82 ft. travel; one hydraulic luggage lift, same travel (these receive passengers and luggage on the platform of the station and carry them to all floors in the hotel); one hydraulic stores lift, about 70 ft. travel; one direct-acting wine-cellar lift; one hydraulic continuous lift for kitchen purposes; two hydraulic kitchen lifts with jigger cylinders. The whole of these lifts are driven by water from a large accumulator supplied by a set of treble-harrel force-pumps, in turn actuated by a 6-h.p. Crossley "Otto" gas-engine. There are, in addition, several hand lifts. The whole of the contract has been carried out under the supervision of Mr. T. W. Worsdell, Locomotive Engineer of the Company.

**The Manchester Ship Canal.**—At the sitting of the House of Commons Committee on the Manchester Ship Canal on Wednesday, the opposition evidence of the Liverpool Corporation was continued. Sir W. Forwood made an offer that if the promoters would be content this year with their canal down to Runcorn, and would next year produce a scheme for carrying the low-water channel along either the north or south bank of the estuary, no opposition would be offered by Liverpool. The case for the London and North-Western Railway, the last of the petitioners, was opened, Mr. Findlay, general manager, being examined.

TENDERS.

For additions to the Britannia Hotel, Sheerness-on-Sea.

Messrs. Jeffrey & Skiller, architects, Hastings	£1,400 0 0
England, Sheerness	1,400 0 0
Mower, Hackney	1,400 0 0
Stephenson, Ramstead	1,485 0 0
Schriener & Williams, South Kensington	1,468 0 0
Cephas Pond, Whitstable	1,454 0 0
G. White, Shepherd's Bush	1,350 0 0
Houghton, London	1,346 0 0
H. Wood & Co., Merton	1,331 0 0

For alterations and repairs to 121 Tottenham-court-road, and 33 and 33, Grafton-street, W., for Mr. B. Elzenberger. Messrs. J. Saville & Son, architects, 1, Arley-square, W.C. Quantities by Mr. Arthur W. Saville, 99, Strand, W.C.

Thomas	£1,098 0 0
Ward & Lambie	1,073 0 0
W. Smith	983 0 0
Spencer & Co.	989 0 0
Perkins	973 0 0
Anley	947 0 0
Royal	839 0 0
Jackson & Todd	895 0 0
S. Lambie (accepted)	879 0 0

For the erection of a new channel, &c., at Christ Church, Stone, Staffordshire. Mr. W. Hawley Lloyd, architect, 79, Colmore-row, Birmingham—

R. Bradbury, Stoneham-Trent	£1,399 0 0
H. & R. Inskip, London	1,398 0 0
W. Trow & Sons, Wednesbury	1,320 0 0
W. Collis, London	1,258 0 0
J. Gulliver, Newcastle	1,165 0 0

COMPETITIONS, CONTRACTS, & PUBLIC APPOINTMENTS.

Epitome of Advertisements in this Number.

COMPETITIONS.

Table with 5 columns: Nature of Work, By whom required, Premium, Designs to be delivered, Page. Includes entries for Public Baths and Winter Garden.

CONTRACTS.

Table with 5 columns: Nature of Work, By whom required, Architect, Surveyor, or Engineer, Tenders to be delivered, Page. Includes entries for iron Galleries, Infirmaries, and various paving and sewerage works.

PUBLIC APPOINTMENTS.

Table with 5 columns: Nature of Appointment, By whom Advertised, Applications to be in, Salary, Page. Includes entries for Clerk of Works and Surveyor.

For alterations, &c., at the Holy Well, Shoreditch. Messrs. Howden, Heath, & Berridge, surveyors:— W. Shurmer 1,619 0 0

For alterations, &c. at the King's Arms, Old Kent-road. Messrs. Wilson, Son, & Aldwinckle, architects:— J. A. Lark 1,619 0 0

For repairs to the School Board Schools, Barnes. Mr. Frank E. Thicke, architect:— Hunt 2154 0 0

For works to the Mews, Compton-street, Eastbourne. Messrs. William Reddall & Son, South-street, Finsbury, E.C., and Terminus-road, Eastbourne, architects and surveyors:— Bainbridge 2512 10 0

For internal painting and decoration at Freemason's Hall, Great Queen-street, from the designs and under the direction of the Grand Superintendent of Works. Quantities by Messrs. William Reddall & Son:— 21,121 13 7

For the erection of residence and studios at Chelsea. Messrs. Bailey Denton, Son, & North, architects. Quantities by Mr. A. J. Bolton:— T. Richards 23,789 0 0

For cleaning out docks, for the Brentford Local Board. Mr. J. W. Lacey, surveyor:— Thomas & Cardus (accepted) 2,300 0 0

For the erection of a new hall and offices for the Meat Worshipful the Butcher's Company, in Barton-cum-cloase, City. Mr. Alexander Peebles, architect. Quantities supplied by Mr. W. E. Stoner, Becklesbury:—

Table with 4 columns: £, s. d., Alternative works, Total. Lists various contractors and their estimated costs for the Meat Butcher's Company project.

\* Not estimated.

For the erection of shops and offices in Eastcheap, for the Agrated Bread Company. Mr. George Edwards, architect. Quantities by Mr. H. Lovegrove:— Scharian & Williams 28,704 0 0

For alterations to 91 and 93, Westbourne-grove, for Mr. R. Beardall. Mr. George Edwards, architect:— Sanders 2,338 0 0

For four semi-detached villas, for Mr. Lester, in the Gratton-road, Milland-road, Bedford. Mr. F. T. Morcer, architect:— Waits & Lester (accepted) 21,400 0 0

For alterations and additions to the Union Workhouse, High-street, Poplar, for the Guardians of the Poplar Union. Mr. George Morris, architect, Oriental-street, Poplar:—

Table with 2 columns: Name, Amount. Lists contractors for the Poplar Union workhouse alterations.

For making roads at Chatham, for the Rook Freehold Land Society (Limited):—

Table with 2 columns: Name, Amount. Lists contractors for road-making at Chatham.

For the erection of a class-room to St. Peter's Church Schools, Great Yarmouth. Messrs. Buttle & Olley, architects:—

Table with 2 columns: Name, Amount. Lists contractors for St. Peter's Church schools.

For Wesleyan Chapel, Halden, Kent. Mr. James Weir, architect. Quantities by Mr. C. G. Maynard:—

Table with 2 columns: Name, Amount. Lists contractors for Wesleyan Chapel, Halden.

For Park-street Bridge, Hertford. Mr. Urban A. Smith, county surveyor:—

Table with 2 columns: Name, Amount. Lists contractors for Park-street Bridge, Hertford.

For Hitchin Lockup. Mr. Urban A. Smith, county surveyor, architect:—

Table with 2 columns: Name, Amount. Lists contractors for Hitchin Lockup.

For making up and improving the Vemar-road, Byre-road, Wyverton-road, Fenge, for the Beckenham Local Board. Mr. Geo. B. Carlton, surveyor:—

Table with 2 columns: Name, Amount. Lists contractors for Vemar-road improvement.

For addition of infant school and offices to present School Chapel, Temple Cowley, Oxford. Mr. A. Marton Mowbray, architect, Eastbourne. Quantities supplied:—

Table with 2 columns: Name, Amount. Lists contractors for Temple Cowley school addition.

For alterations and repairs, S. South-hill Park-road, Hampstead Heath, for Mr. H. M. Clark. Mr. Thomas Milbourn, architect:—

Table with 2 columns: Name, Amount. Lists contractors for Hampstead Heath alterations.

For alterations to the Cook and Woodpack, Finch-lane, E.C., for Mr. C. Deakin. Mr. Arthur W. Saville, architect, 91, Strand, W.C.:—

Table with 2 columns: Name, Amount. Lists contractors for Finch-lane alterations.

For new Wesleyan Chapel, Tenterden, Kent. Mr. Jas. Weir, architect, 5, Victoria-chambers, Westminster, S.W. Quantities by Mr. C. G. Maynard, 21, King William-street, Strand, W.C.:—

Table with 2 columns: Name, Amount. Lists contractors for Wesleyan Chapel, Tenterden.

### The War Office and Admiralty Competition Designs.

**T**HE more careful and detailed examination of the nine designs now exhibiting at No. 18, Spring-gardens, which we have had time to make since last week, only confirms our first impression, and that of the profession generally, that the results can scarcely be deemed satisfactory so far as architectural design is concerned; and if the statement be true, as announced in the *Times* of July 31st, that the elevations and sections of Messrs. Leeming & Leeming's design were all drawn by one of the brothers (and they certainly seem to be all by the same hand), the reason is not far to seek. It would be quite impossible to expect that in the short period given (eleven weeks) for the working out of the second set of drawings, there would be time for both study of design and draughtsmanship. Of the latter we have only to speak in the highest terms of praise: both in the first set of sketch designs and in the final development of the draughtsmanship is as fine and delicate as we have ever seen; but there is a woeful absence of any attempt to study the relative proportions of the various details of the elevations, the result being, as we have already observed, that as many as three or four different scales are to be found in the same drawing. Taking Messrs. Leeming & Leeming's detail, for instance, the same design for the balustrade is employed for the arcading, for under the windows of the several floors, and as a crowning feature to the building, and there are as many as four different scales to them, and that not proportionately to their relative heights, for the area balustrade is larger than those in the floors above, the top-most one being double the size of any. Again, the subordinate orders of the windows reproduce on a very small scale all the features of the larger order which rises through the first and second floors, even to the curved "Queen Anne" frieze; a feature, by the way, quite out of place on a large scale, in serious Classic architecture. These are some of the defects which strike us at first in our examination of the drawings; to others we may have to refer later on. They are all capable of reconsideration before the detail drawings for execution are worked out; and we are of opinion that if Messrs. Leeming & Leeming had indicated the stone joints

(which they say they had intentionally left out) the want of scale of the several parts might have been observed. We would recommend them, as young men, to study carefully Sir Charles Barry's works, and notably the Treasury Buildings, in which they will find the same relative proportions between the mouldings of the windows and the principal order. We consider also that they will find in that building the utmost projection it is safe to give to a columnar order rising through two floors, and also to the rusticated piers supporting it. The projections which they have given, both on the Whitehall and St. James's Park fronts, would not only seriously interfere with the light admitted to the windows between, but would mar the breadth of their elevation and create a want of repose. Looking now to the plans of the nine competitors generally, they seem to reproduce, more or less exactly, to a larger scale, those first sent in, and we are anxious, therefore, to ascertain the principle on which the selection was made. It is evident, on looking at some of them, that architectural design was not much considered, and this may account for the fact that of the 128 who sent in (many of whom were well known for their skill in architectural composition), so few known names figured among the fortunate nine. We understand that at first six only were chosen, but it having been suggested that a sort of promise was made to nominate ten, three others were added to the list. It was quite impossible, however, to find a tenth, which proves that, either prior to the drawings for the first competition being sent in, or on a consideration of them afterwards, some distinct principle of plan was adopted for selection, entirely different from that which has hitherto obtained in Government buildings, and notably so from the plan published in illustration of an article by Mr. Shaw Lefevre, which appeared in the *Nineteenth Century* of November, 1882. The block-plan there distinctly shows on the west and north fronts, and in the central blocks at right angles to one another, the principle of a central corridor, with rooms on each side; it being recognised that this scheme of plan concentrates the offices of one department together, rendering intercommunication easier; though it has the serious defect of making the corridor very dark, unless special means are taken to obviate this defect. Now, every one of the plans selected departs more or less from this principle, by the adoption of a double corridor with courts between to light the corridor direct; and this, it seems to us, has guided the judges in their decision. It has added con-

siderably to the cubical contents of the building and has necessitated the introduction of a supplemental plan (as in Messrs. Verity & Hunt's design), or a mezzanine or extra floor (as in Messrs. Webb & Bell's design), to provide for the required accommodation; but, except in less important departments of some of the designs, this scheme of plan has provided for direct light and ventilation of the corridors. It has also enabled most of the competitors to arrange for those private corridors which were deemed desirable in some of the departments (notably that of the First Lord of the Admiralty), though no doubt this was provided for in some of the unsuccessful designs.

In order to explain more clearly the working of such a principle in the setting-out of the plan and to compare it with the single corridor system as employed in the Foreign Office, we note that the depth of the blocks of the north and south fronts in this latter building averages about 70 ft., being about 30 ft. for offices on each side of the corridor, including walls and projections, and 10 ft. to 12 ft. for the corridor. With the double corridor system a court from 20 ft. to 30 ft. wide must be added, and a second corridor, making the total depth about 105 ft. Now, applying this system in its integrity and taking Messrs. Verity & Hunt's plan as the simplest solution of the problem, it will be seen that it dispenses with all secondary courts, and provides for one large central court and a number of corridor courts. One double corridor block runs across the Whitehall front, and three others from the south, west, and north fronts, leaving a narrow slip at the end of the *cul-de-sac* in Spring-gardens (which Messrs. Verity & Hunt have utilised as their exit gateway with a corridor over on the first floor). This scheme rendered it necessary to decentralise the entrance gateway from Whitehall, which is treated as a subordinate feature, the central feature containing a foot entrance only to the War Office.

Messrs. Leeming & Leeming adopt a similar principle, except that on the north side they carry their double-corridor block through from front to back (leaving what seems to us to be too narrow a central court, only 80 ft. wide by 219 ft. long). On the remainder of the site (110 ft. deep) they project two double-corridor wings, leaving a 30-ft. space between; their main carriage entrance (also decentralised in the Whitehall front) enters in the centre of the long court and takes its exit between the two wings.

Messrs. Hall & Powell employ a similar principle, except that instead of two wings on

the north side they enclose a secondary court, and they make their carriage exit into the *cul-de-sac* before spoken of.

Messrs. Spalding & Auld adopt the double-corridor system round a court on the back of the site, and provide a second court on the block facing Whitehall, but with one corridor and offices on one side only of the same. They provide for two carriage entrances in Whitehall, a third leading from the first court to the second court, and a fourth taking its exit into Spring-gardens,—an arrangement which, on the ground-floor, has the disadvantage of interfering too much with the intercommunication of the departments.

Messrs. Glover & Salter adopt the double-corridor block for the rear of the site in St. James's Park, enclosing a large court, and provide three secondary courts on the Whitehall side (the central one not inclosed on the Whitehall side); they provide four carriage entrances, one down the central secondary court into their main court, one out of the latter into the *cul-de-sac*, and two through the blocks of the north secondary court; these latter might have been dispensed with.

Mr. Porter places a double corridor block round a large central court in the rear of the site, and another at right angles to it running into Whitehall. On the left hand side of the Whitehall front he provides a secondary court with offices on one side of corridor only, and a central secondary court open to Whitehall, which is, perhaps, the best feature of the plan, through which he takes his carriage entrance into his great court, with an exit through the centre of the north front.

Messrs. Stark & Lindsay adopt the double corridor block for the St. James's Park front only, providing three secondary courts on the Whitehall side, and a wing to the great court through which carriages enter, the exit being into Spring-gardens.

Messrs. Maxwell & Tuke (whose plan is in some respects the best submitted) provide a large central court, 113 ft. wide, and four surrounding courts. This plan is somewhat similar to that of Messrs. Hall & Powell, except that what we have described as corridor courts in the latter become secondary courts in consequence of their greater width. They provide two carriage-ways, one leading to the central court and an exit thence into the *cul-de-sac* of Spring-gardens.

Messrs. Aston Webb & Ingress Bell's plan we have reserved to the last, because it presents features totally different from any of the others. It is by far the most picturesque plan of the whole series, but the sacrifice they have made of the area of site in order to obtain their two courts, has necessitated an addition to the number of floors, so that their building towers above all the others. Messrs. Webb & Bell commence their design by setting back the main front of the building in Whitehall, retaining only two end wings. This is an excellent idea, and would, at all events, make the building to be seen fairly well from what is almost the narrowest part of Whitehall. At the back they provide a large court in the shape of a Maltese cross on plan; in three of the angles of the blocks surrounding it they provide corridor courts covered with glass roofs,—in the fourth angle the *cul-de-sac* of Spring-gardens comes in. There is a carriage-way from Whitehall to the centre of the great court, and an exit on the right into Spring-gardens. It may also be noted here that they have suggested a scheme for laying out the vacant space in Spring-gardens in which they utilise the screen now existing in front of the Admiralty buildings.

Looking generally at all the plans, we cannot help regretting that the requirements scheduled for the two offices left no margin whatever for courts and areas of proper size, and it is well known that a great number of intending competitors, many of them of eminence in the profession, relinquished at an early stage what seemed to them to be the hopeless task of providing the accommodation required with due regard to the lighting of the corridors and to the supply of courts of a proper size for light and air. This is painfully evident in the accepted design

of Messrs. Leeming & Leeming, who, we may presume, have just succeeded in meeting all the requirements of the schedule. A court 219 ft. long by 80 ft. broad is not a favourable proportion, and yet it has only left them a width of 25 ft. for the corridor court; this court on the Spring-gardens side is only 30 ft. wide, and will form a long dark hole. This is, however, not the most serious defect in the plan. The areas which were given for the rooms of the principal officers were all multiples of twenty, which seemed to suggest that 20 ft. was considered to be as great a depth of room as would be desirable; 300 ft., 350 ft., 340 ft., 360 ft. superficial areas therefore gave 15 ft., 16 ft., 17 ft., and 18 ft. as the width of the several rooms. Now, the average depth of the offices provided by Messrs. Leeming & Leeming is 25 ft., and in some cases the rooms are actually only 12 ft. wide, clear evidence that the competitors must have been at their wits' ends to comply with the demands and yet provide rooms of natural proportions. The general tendency of all public buildings is towards increased demand for space as the scheme becomes developed, and we recollect that in the India Office, waiting and interview rooms had to be utilised as office rooms,—other rooms devoted to purposes for which they were not originally intended, and open corridors enclosed in order to provide increased accommodation. It is much to be regretted, therefore, that at the first start an area so limited in space should have been decided on for requirements of so extensive a character. It has left little opportunity for a display of architectural effect; and, what is more important, has resulted in the curtailing of the proper width of the office rooms, and in an insufficiency of light and air in the areas and courts.

Having said thus much on the general scheme of the plans, we propose, before entering into detail, to glance at the general character of the architectural elevations, comparing them with one another as regards the grouping of the various projecting blocks, the sky-line, the relative treatment of the several floors, and the fenestration. Messrs. Leeming & Leeming, in the St. James's Park fronts, place square towers at the angles, which rise some 40 ft. above the crowning balustrade of the building, and are surmounted with circular towers and cupolas. The line of front between, on the west and south sides, is broken by two projecting blocks, about 45 ft. wide, each crowned with corner turrets rising above the balustrade, which they couple together by throwing an arch across; exception has been taken to this feature, which, however, appears to us to be novel and pleasing. It unites the turrets with more elegance than if a solid wall had been carried up, and needs only one thing, a group of sculpture to give a *raison d'être* for the arch, which would then take the character of a large niche for its protection. This would mask the sloping sides of the roof at the back, the effect of which is unpleasant. The intervening portions of wall are broken up by the Corinthian columns running through the first and second floors and their bases, to the extravagant projection of which we have already taken exception; if between the two projecting blocks three-quarter columns were introduced, and omitted altogether between the towers and the blocks, the design would gain in repose and breadth. The same omission might be made in that portion of the west elevation which runs in the same line as the Horse Guards front (except in the centre projecting block of the same), so that its character might be more assimilated to the simpler design of the Horse Guards. The corner tower adjoining the latter might be rusticated up to the level of the Corinthian order cornice, and the stone work above, including the tower and octagonal turret, omitted, so as to lead down gradually to the level of the Horse Guards front. This, in fact, was suggested in the admirable article before referred to by Mr. Shaw-Lefevre, and apparently not issued in the instructions, or Messrs. Leeming & Leeming would have thought twice before they reduced the present Horse Guards to absolute insignificance by the design for a lofty tower close up to it on the Whitehall front.

No perspective is shown of the Whitehall front, which appears to us to be incoherent in design. It is not symmetrical, it is not grouped, and it contradicts the blocks of buildings which lie behind it. In their treatment of the several stories, Messrs. Leeming & Leeming seem to us to have adopted the only principle which gives architectural grandeur and support, such as should be the characteristic of a public building. The ground-floor, and such portion of the basement as appears above ground, are treated as a podium to carry the Corinthian order, which rises through the first and second floors, the third floor being treated as an attic to the same. One exception, however, we have to take to the actual working out of the ground-floor story. The rustication ought to have been continued between the piers or pedestals carrying the columns instead of the panelling round the windows, which is suggestive of plaster or wood construction; it would further have the advantage of detaching less the piers or pedestals which now count as part of the Corinthian columns and interfere with their due proportion. The adoption of an order running through two floors has this one disadvantage, that it increases the dimensions from centre to centre of window when only one window is provided, which is the usual and only pure Classic treatment. Messrs. Leeming & Leeming have felt this, and have introduced two circular-headed windows coupled together on the second floor, and a group of three windows (one large and two small) on the first floor, and by so doing have destroyed the otherwise pure Classic character of the design, and reduced it to that of a warehouse type. Whether the requirements of light will hereafter necessitate their adhering to this treatment we know not, but the architectural character of their design would gain immensely if single square-headed windows, with 3 ft. to 5 ft. 6 in. opening, were employed instead.

Messrs. Verity & Hunt, in their St. James's Park fronts, have failed to group their elevations satisfactorily, in our opinion, owing, first, to the enormous width of their projecting blocks, which on the side facing the Horse Guards Parade are larger than the intermediate wall-space; secondly, because they mask this wall-space by projecting columns; thirdly, by the introduction of a bow-window on the St. James's Park front, which partially destroys the breadth of the wall-space; and fourthly, because they have not attempted to break the sky-line of the roofs by towers or other features rising above the main balustrade. They may have thought that such features were useless, and served no immediate practical purpose; but square columns, and cornices, and window mouldings, and to adopt the one and refuse to accept the other seems to us to be unnatural. In the Whitehall elevation, however, they do venture on a central dome and two square turrets at the angles of the building rising above the roofs. They might be higher, but, either way, they are a positive advantage to the architectural effect. This elevation is in other respects superior to the St. James's Park front, in that between the central and two side blocks which they have broken up the front they omit the Doric order which, in their design, run through the first and second stories. In their relative architectural treatment of the several stories Messrs. Verity & Hunt adopt the same principle as Messrs. Leeming & Leeming, viz a rusticated podium for ground-floor and basement, and an order (Doric) rising through first and second floors and an attic. Their windows are single ones, and square-headed, in which respect their design is superior to that of the successful competitor. Their ground-floor is rusticated throughout. In the Whitehall front the centre block is emphasised in the principal foot-passage entrance to the War Office. The great court lies on the right of this carriage-entrance is placed in the centre of a wing, between the centre and right-hand block. There is, however, no similar feature to provide it on the opposite side, and it is unfortunate that they should have emphasised the carriage-entrance in so marked a manner by figure sculpture, and on so large a scale;

that respect they seem also to have vulgarised their archway exit into the *cul-de-sac* of Spring-gardens, as shown in the large perspective of the interior court. Otherwise, we consider the architectural treatment of this design to be purer and more Classic in character than that of Messrs. Leeming & Leeming.

Messrs. Stark & Lindsay adopt to some extent the suggestion made by Mr. Shaw-Lefevre before alluded to, viz., to keep the block of buildings on the south corner of the site lower, so as not to dwarf the Horse Guards, and, in addition to this, they round off the angle overlooking the same. The remaining length of front, about 270 ft., they break up by two wide projecting blocks, which rise above the roof. By thus shifting the main features of their elevation towards the north, they are enabled to place in the centre between the projecting blocks the carriage-way to their courtyard. In the St. James's Park front they have lofty corner towers rising above the main roof, and crowned with features resembling those of the western towers of St. Paul's Cathedral, and too large in scale. The centre portion of the remainder of the front is relieved again by a projecting block with corner towers, and crowned by lofty French roofs; similar treatment is employed on the two other fronts. The lower stories, basement, and ground-floor are richly rusticated; the first and second floor enriched with three-quarter detached columns, and the circular-headed windows between with archivolts carried on smaller columns or shafts, a treatment derived from the Pesaro Palace at Venice, and which was employed for the Army and Navy Club, in Pall Mall. The attic above is kept plain. This is the only elevation which, treating each story by itself, and not running the order through two floors, has, nevertheless, obtained a certain palatial effect, and we attribute it to the fact that the two stories (first and second floor) are equally enriched, so that they count in the mass as one. Their richness is emphasised by the rusticated ground-floor and the plain attic, and the completeness of the design is carried out by the elaborate leadwork of the lofty roofs, and the rich corbelled cornice.

Messrs. Hall & Powell treat the left-hand block in Whitehall in a similar way to Messrs. Stark & Lindsay, that is, by keeping it one story lower. The centre portion of the 270 ft. remaining they set back 25 ft., its width being equal to that of their central court. The projecting blocks, therefore, represent the double corridor blocks behind. They are relieved again by corner projections crowned with mansard roofs. The carriage entrance is placed in the centre of the front, set back, and a portion of this is emphasised by a pediment. The St. James's Park front shows similar treatment. Considering the skill in the grouping of the projections which agrees in all cases with the actual buildings behind, one is surprised at what must be called the monotonous and commonplace effect of the whole building, which seems to us to be deficient in similarly good grouping in the stories. The ground-floor is rusticated, the first floor divided up by an order; then it would seem that the resources began to fail, and the two stories above are left quite plain and bare; in fact, it would seem as if another architect had been called in to complete above the first floor. The buildings also are all carried up the same height. If between the centre and side blocks of the St. James's Park front the upper portion of attic had been omitted a much better skyline would have been obtained. The figure-sculpture is beautifully designed and drawn in this set of drawings. We should note that Messrs. Hall & Powell place a low building next the Horse Guards in the Parade Elevation. Messrs. Stark & Lindsay the contrary.\*

"Preparations for Meeting the Cholera" will be the subject of a lecture to the members of the Association of Public Sanitary Inspectors, at 1, Adam-street, Adelphi, on Monday next, by the President, Mr. Edwin Chadwick, C.B. Chair to be taken at seven o'clock.

\* To be continued.

RAILWAY GOODS RATES.

THE Bill introduced by Mr. Chamberlain to amend the Railway Regulation Acts has brought this subject into prominence, and much has been said and written about it. There is one phase of it, however, which has received but little attention, and that is the charges imposed upon small consignments. This is probably due more to the want of information as to how this class of traffic is dealt with than to any lack of appreciation of its importance. It is pretty generally known that the tonnage rates are not applicable to small consignments. In fact, a consignment must weigh 500 lb. or over or it is technically known as a "small," and is subject to an additional charge beyond the amount arrived at by calculating at the rate per ton. For instance, while 5 cwt. of goods chargeable at 30s. per ton would be charged 7s. 6d., the sum of 4s. 2d. would be demanded for 2½ cwt. at the same rate. This is in accordance with a scale of charges agreed upon by all the English railway companies in 1877, and as the former scale of "smalls" only extended to 1 cwt., the change must have increased their receipts very appreciably. Many a railway account contains scores of items ranging up to 500 lb., upon all of which this additional charge is imposed. The weights are in groups, advancing upwards from 1 qr. by 14 lb. at a time, and the method will be best explained by the following extract from the scale:—

Weight not exceeding.	Above 38s 4d. and not exceeding 40s. per ton.	Above 40s. 4d. and not exceeding 43s. 4d.	Above 43s 4d. and not exceeding 46s. 8d.	Above 46s. 8d. and not exceeding 50s.
	s. d.	s. d.	s. d.	s. d.
0 1 0	1 0	1 2	1 3	1 3
0 1 14	1 3	1 5	1 6	1 6
0 2 0	1 6	1 8	1 9	1 9
3 2 14	7 9	8 5	9 0	9 7
3 3 0	8 0	8 5	9 3	9 11
3 3 14	8 3	8 11	9 7	10 3
4 0 0	8 6	9 2	9 10	10 6

In the smaller weights the additions are, of course, very considerable (as the product at the rate per ton would be far too small to allow of any profit), and the percentage added decreases as the weights advance, so that upon the higher weights shown in the extract it only amounts to some five to ten per cent. The remark just applied to the small weights as to the insufficiency of the tonnage-charge to yield any profit is alleged by the companies to be applicable to all weights up to 500 lb., though, of course, they will only bear additions decreasing *pro ratio*, as above explained. In the case already given, the extra charge is about ten per cent., which is a little below the average, and it is frequently much more than this on account of the grouping system by which goods are advanced both in weight and rate for charging purposes. Thus, a consignment weighing 2 cwt. 1 qr. 16 lb. is treated as weighing 2 cwt. 2 qrs., and if rated at 29s. 2d. per ton would come under the 30s. per ton group. It would therefore be charged 4s. 2d., precisely the same as the example first quoted, but in this case the extra amount would be 8d., or nearly twenty per cent. on the actual product at 29s. 2d. per ton. The additional charge is still further increased if the goods are of several different descriptions, and come under more than one of the five classes into which general merchandise is divided. For example, a person may have a consignment weighing, in the aggregate, 5 or 6 cwt., but consisting of articles in different classes in the railway books. Each portion will be charged in accordance with the scale. The following extract from a railway bill will serve to illustrate this:—

cwt. qr. lb.	Rate.		Amount.
	s. d.	(as per scale)	
2 0 18	45 4	6 2	
0 2 22	38 4	1 11	
2 1 2	65 0	8 7	

These goods were all for one firm, would be carted all together at both the sending and receiving stations, yet it will be seen that there is an additional charge of 2s. 10d., or fully 20 per cent. The regulation for charging goods of this mixed description allows of the aggregate weight of the consignment being

charged at the highest rate to which any of the articles belong, if such amount is less than if the charges were in accordance with the scale. Thus, if in the example just given, the charge on the aggregate weight (5 cwt. 0 qr. 14 lb.) at the highest rate (65s.), had been less than 16s. 8d., the scale would not have been brought into requisition; but at the same time the consignment must have been subjected to a considerable addition, through some of the articles being treated as belonging to a higher class than the one they really stood in. On the other hand, another regulation provides that when parcels and packages consigned as if to be delivered in one lot, are afterwards found to involve separate deliveries in portions weighing each 500 lb. or under, an additional charge is to be made for each such separate delivery.

The foregoing scheme has been adopted by all the English railways, and also applies to traffic passing between England and Ireland. Scotland still holds aloof and keeps to the old system, only recognising three "smalls," viz., not exceeding 1 qr., 2 qrs., and 1 cwt. respectively. It is not to be expected that the system we have attempted to describe has been acquiesced in by the public without protest, but no action that has been taken has effected any modification of the scheme. It is doubtful if the railway companies would consider that Mr. Chamberlain's demand for revised classifications of rates affected them in this respect. Some of them actually possess Parliamentary authority for charging what they please for weights not exceeding 500 lb., and the classification which the new Bill requires them to submit refers more to the basis upon which the rates per ton are fixed, the proportion claimed for various services performed, &c., than to any minor matters of this sort. If, as seems extremely probable, the Bill should fall to the ground through opposition and pressure of other business, it is to be hoped that this question will not be overlooked in any future measure, for it may be regarded as certain that the companies exceed the powers intended to be conferred upon them in this matter. In cases, for instance, where the aggregate weight of a consignment is over 500 lb., it seems unfair to single out a portion to be subjected to the "scale." It is quite possible under this rule to have portions of a consignment weighing quite a ton in the aggregate thus "excessed," and it is very improbable that Parliament would have intentionally legalised such a practice. In fact, many of the Parliamentary powers enjoyed by the railway companies were conferred when the system was in its infancy, and do not meet the requirements of the present time when it has grown out of all proportion to anything then anticipated or provided for. The companies have of late, under pressure in some cases, and voluntarily in others, made various concessions in favour of the public, but in this matter of "smalls" they press very heavily upon several trades, and as it is very necessary in these days to "look after the pence" it is a sore point with many. In fact, it was found to be absolutely necessary in some cases to alter terms of delivery through the increased freight expenses, caused by the introduction of this scale, and it is very unlikely that the companies would lose much by making some modification in the system, as an increase in traffic would probably follow such a step.

NOTES.

IN the course of a brief conversation in the House at the close of last week, in regard to the new proposals for dealing with Westminster Hall, the First Commissioner said, in answer to a question from Mr. Peddle, that no doubt two architectural journals had written against the scheme, but "he had observed that they were not unfrequently critical of such proposals." Now, supposing that is so, will not some people think it a fair conclusion that, inasmuch as architectural journals at all events are likely to understand architecture better than other journals, the cause of such frequent

adverse criticism is that architectural matters are generally wrongly managed by the official authorities of Government? But, waiving that, certainly our own criticism was in no hostile spirit, but a fair consideration of both sides of the question. We opposed one part of the scheme, and supported another, on grounds of pure architectural criticism, which do not seem to be understood. We showed that the cloister would be inadequate for its proposed practical use, and would not have the effect shown in the views placed in the House of Commons; and we protested, as we always have protested and always will, against the idea that architecture is a matter of archaeological sentiment. Architecture, whenever it has been a living art, has been a practical one dealing with contemporary buildings according to the necessities of the day; and Barry, the architect of the Houses of Parliament, was the last great English architect who worked in this spirit. The proposed cloister is an archaeological toy, and we oppose the expenditure of money on it. The proposed raising of the towers is for purely architectural reasons, such as we hold to be sound, and we therefore support it. That is the philosophy of the matter.

PARLIAMENTARY Committees seem bent on giving us shocks of surprise at present; and shortly following the unexpected murder of the Lower Thames valley drainage scheme comes the announcement of the rejection of the Manchester Canal Bill, which its promoters had begun, not unreasonably, to regard as safe. Whatever the ultimate result may be, the Parliamentary history of the Bill demonstrates anew the unfitness of the present Parliamentary arrangements for the authorisation of public works. Bearing in mind the evidence given that it now costs more to convey raw and manufactured cotton backwards and forwards between Liverpool and Manchester than it did before the construction of railways, the public interest demanded the action of an impartial and competent tribunal, which should not only be able to hear and weigh the evidence adduced on both sides, and to originate any inquiry of its own motion, but further to suggest and to sanction such modification of the original plan as might commend itself to the court, when fully informed. Instead of this, the promoters of this important measure have had to run the gauntlet before four several committees. In 1883, after an enormous expenditure of time and money, the Commons Committee, admitting the principle of the measure, so truncated it (not without considerable excuse) that the Lords Committee threw it over. In the present year, with hardly less effort and hardly less expenditure, the Bill was carried through the House of Lords, only to be thrown over at the last hour by the four members of the Select Committee of the Commons. That this further waste of time and of money is little short of a public scandal, will be very generally felt. It has been held by many persons conversant with the subject that the inauguration of the scheme as a bone of contention between Liverpool and Manchester was a mistake. The navigability of the Mersey is a national question. The first enemy of the Manchester manufacturer, as well as of the Liverpool merchant, is the bar of the Mersey; and if Lancashire will resolve, in the first instance, to make the Mersey as accessible as the Thames, the common action thus set up will not cease until Manchester possesses the cheapest mode of communication with the sea.

THE collection of antique casts at the South Kensington Museum, which has been arranged under the able direction of Mr. W. C. Perry, is now complete, and the private view took place on Thursday last. The room is a fine and well-lighted one, and the collection is a very large and typical representation of sculpture of the archaic Greek, Greek, and Roman schools. The general arrangement is chronological, the archaic work commencing on the wall on the left of the spectator on entering, and continuing round till the Greco-

Roman school is reached on the opposite wall. The floor is occupied with a number of the larger works which require to be seen all round, and here, of course, the chronological grouping has necessarily given way to considerations of space and effective arrangement, which considerations have also partially interrupted the chronological arrangement round the walls. But the whole collection is admirably disposed for study; and, with the aid of the very full and excellent annotated guide prepared by Mr. Perry, the educational value of the whole is as excellent as its general effect. We have the greatest pleasure in announcing the completion of the collection, which we shall consider more in detail on another occasion.

THE most recent step in the Thames Commutations Question has been the resolution of the Common Council to build a low-level bridge with swing openings below London Bridge. We fear this will be found to be a mistake, as it has been found to be elsewhere. To have one swing bridge is not so unpractical, certainly, as the idea of the double or "duplex" bridge, between the arms of which vessels were expected to stand quietly in a strong tide-way, like horses and carriages pulled up on a roadway, while one arm of the bridge was closed behind them and the other opened in front of them. But even the single-swing bridge, with piers in the stream, will probably be found to be a great obstacle in the way of shipping. It will either have to be open too long for convenience to the land traffic, or the opening must be left till the vessel is dangerously near. It is a great pity that specially-constructed ferry-boats are not tried first. It has been objected that they would equally be in the way of traffic up and down stream, but few people seem to be alive to the fact that when two objects are both free to move on the water the danger from the current is, at least, got rid of, as it acts on both of them equally, while the difficulty of avoiding collision is much greater when one object (the bridge) is fixed and the other moving with the current as well as with its own motion. But the fact is, scarcely any of the people who talk about the matter have any correct notion of the behaviour of ships on water.

THE French archeological schools at Rome and Athens do admirable work, not only by the issue of their "Bulletin" containing the account of the most recent discoveries, but also by the publication, from time to time, of a treatise devoted to some special topic. The "Bibliothèque" thus formed already numbers thirty-six volumes, on such diverse topics as "Monuments relating to the Myth of Psyche," "Christian Painting and Sculpture in the East," "The Dialect of Cyprus," &c. The volume to which we would call special attention is a treatise by E. Pottier, on "White Athenian Lekythoi with Funeral Representations." These white lekythoi are a class to themselves; their authenticity is certain, their date almost equally so. On artistic grounds their importance is, therefore, for the history of art, very great. M. Pottier devotes the second part of his treatise to the consideration of questions of technique; he reserves the first part for the consideration of the religious and social meaning of the designs painted on them. These have reference to,—1, funeral ceremonies. M. Pottier collects nine vases, which depict the "exposition" of the dead man, five which show his "deposition" in the tomb. The intermediate ceremony of the funeral procession never appears. 2. An allegorical scene from the descent into Hades, on seventeen vases; the dead man is led to Charon's boat by Hermes Psychopompos. 3. Offerings made at the tomb. This scene appears on no less than 500 lekythoi, of which 102 are described for the first time by M. Pottier. The composition is always conceived after one and the same definite type: a stele in the centre with acanthus ornament, and decorated with ribands; this stele stands sometimes on steps, sometimes is simply raised on a mound. Women and, less frequently, men, approach in attitudes of

grief, but not in mourning garments; they bear offerings in their hands. Sometimes the dead man himself is seated below the stele, sometimes a tiny winged figure (an eidolon) flutters about the tomb. Four plates accompany the treatise, giving the most interesting specimen of each scene,—the exposition, the deposition, the passage to Hades, and the offerings at the tomb.

THE Committee of the House of Commons appointed to inquire into the question of the steps necessary to secure the enjoyment of the river as a place of recreation, and into the legislation affecting the use of the Thames, issued their report on the 4th. The main points of the report are clearly in favour of the public, and against the selfish eccentricities of "riparian owners." The Committee recommended that the towing-path along the river-side be continuous, and be made a public path from end to end, and maintain that "the river is open from bank to bank wherever the Thames water runs." The latter decision, if sustained, will put an end to the fencing up of backwaters. They propose that the Conservancy should have large powers to deal with all persons guilty of rough and disorderly conduct, and that police supervision should be increased and systematised.

THE state of the Thames seems likely to furnish matter for lively correspondence for some time to come. We may suggest that those who study such correspondence in the daily papers will do well to consider the relative weight of impartial scientific evidence, as compared with the suggestions of those who are not scientific and who live on this or that site on the banks of the Thames. Scientific men, for instance, disapprove of any more locks on the Thames, for logical reasons which they have given, some of them in our columns. A gentleman who is not scientific, but who has a house at Twickenham, says the scientific men are all wrong, and there should be a weir at Richmond, which will keep the water deep and clear before his lawn. Which is most likely to understand the subject or to give an impartial judgment? For personal reasons we should be very glad to see a lock just below Putney, but it has not occurred to us on that account to recommend this course on public grounds.

WE record with great regret the sudden death, from apoplexy, on the 2nd of this month, of the eminent French architect, M. Paul Abadie, whose reception of the members of the Conference of French Architects at his own great building, the Church of the Sacré Cœur, was mentioned in our columns very recently. M. Abadie was a member of the Institute of France, and an Honorary and Corresponding Member of the Institute of British Architects. He was Inspecteur-Général des Edifices diocésains, and an officer of the Legion of Honour.

THE name of Mr. Charles Manby, who died on the 31st ult., has been closely associated with the advance made, during the present century, by the engineering profession in England. Born on February 4, 1804, he was apprenticed at an early age to a practical mechanic, and taught to earn his bread by daily toil. He was engaged as a youth on his father's contracts on the East and West India Docks, and was entrusted with the construction of the first pair of marine engines with oscillating cylinders, and with the building of the *Aaron Manby*, the first iron steamer that ever made a sea voyage; steaming from London to Paris in 1821. In 1839 he was appointed secretary to the Institution of Civil Engineers. The number of members at that time is not stated in the report for the year, but in 1837 it was 252, comprising all grades. In 1858, when a timepiece and candelabra, and a cheque for 2,000l., were presented to Mr. Manby in recognition of his services to the Institution, the number stood at 797, and the receipts had risen from 1,410l. in 1838, to 2,016l. in 1856. The testimonial in question was presented on the retirement of Mr. Manby from the post of

secretary, in which he was succeeded by Mr. James Forrest, who had been connected with the Institution since the year 1842, and who entered on the post of assistant secretary in June, 1856. In November, 1876, a second piece of plate, accompanied by a purse of 4,088*l.*, was presented to Mr. Manby by the President of the Institution, in recognition of the services he had rendered as honorary secretary. Mr. Forrest's name first appears as "secretary" in the Report of the Council for the session 1859-1860, but the name of Mr. Manby has been retained as "honorary secretary" down to the last report.

THE Home Secretary and the Lord Chamberlain have intimated to the Metropolitan Board of Works that in their opinion it would be advisable that the Board should introduce into their Various Powers Bill next Session a clause making it compulsory for places of amusement to have a certificate from the Board as to the security of the buildings for the public, before applications are made for licences. The effect of this clause would be to transfer the responsibility with regard to the safety of the public in places of amusement from the Lord Chamberlain and the magistrates to the Metropolitan Board of Works. Such an alteration in the law may be desirable, but it should certainly be accomplished in some more comprehensive manner than by the introduction of a clause into an Omnibus Bill. The Metropolitan Board will probably have something to say on the subject, and are not likely to accept the responsibility of answering for the construction of these buildings, and to leave the Lord Chamberlain his privileges and emoluments.

THE trustees of the National Gallery appear to have become conscious of the ugliness of the shed they have caused to be erected in front of that building, and have sought to relieve the plainness of the structure by the exhibition of advertisements relating to iron buildings in a manner with which we have become familiar through the iron sheds erected at the Health Exhibition at South Kensington. This is a step in the right direction, and it is to be hoped that the trustees will see what a capital field the front of the National Gallery presents for the display of advertisements, and will utilise it accordingly. The proprietors of some of the soups and cigarettes which are now widely advertised would no doubt gladly avail themselves of this opportunity of bringing their wares more prominently before the public, if it were offered them.

WE have received a very pretty got-up circular, illustrated with various sketches, from the management of the Female School of Art, at 43, Queen-square, stating the importance of enlarging the premises by new buildings in the rear, which would enable the Committee to provide adequately for branches of study for which there is at present not sufficient room. The school was founded in 1842 at Somerset House, has continued to grow in numbers and success ever since, and "has taken a high place among the institutions designed for enabling women to earn their own livelihood." It is on this latter ground especially that we desire to say a word in its support. As we have before observed, we doubt the advisability, from an artistic point of view, of women setting up any separate standard of their own in art; and the female artists of real genius, in fact, mostly decline to occupy that position, and prefer to be judged along with men. But a school in which the needs of women wishing to develop the means of supporting themselves are specially considered, is a valuable institution, and should not be allowed to flag for want of funds.

A CORRESPONDENT sends us a note as to the proceedings that have recently been taken in regard to the celebrated spire at Grantham, which was struck by lightning a year ago. In putting up the new lightning conductor (which is of Liège manufacture, all of one piece, and carried to a deep well dug for it in the churchyard), the workmen re-

ported the stonework much damaged. Mr. J. Oldrid Scott was consulted in the matter, and after a study of the spire through a powerful telescope, decreed that the upper portion should be taken down and rebuilt. Apparently the ladders up the face of the spire were too much for the nerves of any but workmen, who ought to have more credit than they always get for the matter-of-fact way in which they quietly face considerable danger of this kind in the pursuit of their calling. The upper 16 ft. of the spire has accordingly been taken down, the stones numbered, and built up inside the church. The country-folk who came to the agricultural show, a week or two since, thought the spire had been drawn inside out, like a stocking. The men are now working at the repairs, sitting on boards slung from the cap of the scaffolding which has been erected over the apex. The prayers of the congregation for their safety are asked daily in the church far below them. The crockets of the spire, our correspondent adds, are worked on a separate rib of stone butt-jointed in a chase up the angle of the spire, with no bond into the work; not a scientific way of doing it. There is living in Grantham an old woman who, when a girl of eighteen, climbed to the top of the spire by the crockets, for no better reason than that a young man had promised to marry her if she would. She did an even more dangerous thing than she was aware of, considering the construction of the masonry, and unhappily without the desired result, as the prudent "young man" afterwards declined to marry any woman who was foolish enough to do such a thing,—a decision more creditable to his head than his heart.

OUR esteemed contemporary, *La Semaine de Constructeurs*, to which we have occasionally been indebted for interesting facts in regard to building work across the Channel, fairly puzzled us in its last number of Aug. 2. Under the heading, "Décor intérieur des Halitations," is an article dealing mainly with the delights of that peculiarly English invention, "le bowindow," and an illustration labelled "une intérieure d'un bowindow-foyer,—architecte, M. Robert." It struck us that we had "heard this learning before," the illustration was not new to us; and, sure enough, on investigation, we discovered that the view was from an interior by Mr. Edis, published by us in the early part of the present year, and that "M. Robert" was the form in which the name of Mr. Robert W. Edis presented itself to the French mind. The absolute inability of our neighbours to get an English name right is really phenomenal. In this case half the name appears to have been accepted as equivalent to the whole; but then what *did* the French editor think that the words "W. Edis" stood for? Did he confuse it with the "fecit" or "delt," which often stands after the draughtsman's name? Let it not be supposed, however, that our contemporary over the water borrowed from us without acknowledgment. On the contrary, there was due and complimentary reference to "le journal si répandu, *le Builder*, autrement dit 'le Constructeur.'" The art of "conveying" architectural drawings from other people without permission or acknowledgment, brought to such perfection in some quarters in London, does not seem to have been similarly developed in Paris.

**Improved Industrial Dwelling Company.** From the half-yearly report of the Improved Industrial Dwellings Company, Limited, presented to the meeting just held, it appears that the company now possesses thirty-four estates in various parts of the metropolis, on which 4,314 dwellings have been erected, and are in occupation, and 656 are in course of erection, making a total of 4,970 tenements. When these are completed the number of persons residing in the Company's dwellings will be about 25,000. The expenditure on capital account has reached 866,281*l.* The usual dividend of 5 per cent. was declared for payment, after carrying 500*l.* to the reserve fund for equalisation of dividends, which now amount to 56,000*l.*

THE BAKERIES AT THE HEALTH EXHIBITION.

Food is the most important constituent of health, and bread, in temperate climates at least, is the chief element of food supply. For this reason, the bakeries have rightly had assigned to them important sites in the Health Exhibition.

It seems almost an anachronism to speak of the introduction of bread into these Isles, yet there appears to be little doubt that the baker's craft came to us by way of Greece and Rome from the East. In classic days the Athenian bread was celebrated for its high quality, and, indeed, Athens appears to have been the prototype of the Vienna of the present day, inasmuch as it was the metropolis of bakers.

Wheat is of all cereals the best suited for bread-making, and of this grain there are over 150 named varieties known to the scientific world. To the miller, however, these fine distinctions possess no practical interest; but still the characteristics of different descriptions are of great importance. White and red wheats are the two broad distinctions. The former is a harder and smaller grain than the latter, and is said to afford a higher percentage of nutrient principles; thus, a soft white grain may only contain 8 to 10 per cent. of flesh-forming principles as compared to the 18 to 20 per cent. of albuminoids found in some of the hardest varieties. The balance of material in the softer descriptions is made up by starch granules, which afford the chief force-producing element of bread food. The fibrin which forms the principal part of the albuminoids in wheat is more largely contained in the outer parts of the grain, and these are mostly separated from the flour during the various processes of milling, as will be more fully explained when we come to speak of the distinctions between white and whole-meal bread.

The particular adaptability of wheaten flour for bread-making lies in the property possessed by it of preventing the too ready escape of carbonic acid gas which is evolved in the process of fermentation. This action is owing to the great tenacity of the gluten of wheaten flour, which forms, when moistened, a close viscid mass. The carbonic acid gas is dried out in the process of baking, but before it escapes it forms innumerable small holes which render the bread light and digestible. In times of great scarcity, rye, barley, oats, beans, peas, and even acorns have been mixed with wheaten flour for making into bread; but a good "sponge" can never be obtained excepting from a flour almost wholly made from wheat.

The principal exhibits at the Health Exhibition give a fair idea of the internal economy of high-class bakeries, all the operations of making and baking bread being carried on in practical style, and indeed on a somewhat extensive scale. Each of the four principal establishments is fitted with an oven differing in essential features from those shown on the other stands, so that four distinct principles of baking are illustrated. The first exhibit that is met with on entering the east corridor is that of Mr. J. Marshall, of the Strand. The oven shown on this model establishment is one of great interest not only to bakers, but to the general public also, if only on account of the total abolition of smoke that undoubtedly attends its use. At the Smoke Abatement Exhibition Mr. Boer, the inventor, exhibited the first oven of this class, which took a gold medal. That now shown differs from the original in many respects, and is the result of the experience gained in actual work. The new arrangement has been patented by Messrs. Gilsen & Boer, of 180, Union-street, Southwark. The oven is similar in all respects to an ordinary baker's oven, with one important exception. In place of the usual coal fire there are a number of gas jets, which heat the brick-work in the same way that the flame from the coal does. The gas, however, creates no smoke, air being mixed with it previous to ignition, as in the Bunsen burner, and perfect combustion is thus produced. The arrangement of burners is such that the heat is distributed under the crown of the oven; the flame, starting from the front angle on the right, passes towards the rear, and then back to the remaining angle or register corner. The advantages claimed by the inventor for his system are numerous, and most of them will be apparent from the description given. For instance, there can be manifestly no smoke, that most fruitful source of trouble

and anxiety to all bakers working in the ordinary way. It will also be evident that the space usually taken up by the storage of coal will be set free, probably to be occupied by another oven. The absence of the ash-pit is a greater advantage than at first sight might appear. In smaller and ill-regulated establishments, which are far more numerous than could be desired, the ash-heap becomes a receptacle for refuse of all kinds, and frequently of matters of the most offensive description. When these are allowed to accumulate they give forth unpleasant odours, which are absorbed by the ferment or by the "sponge," which is a mixture of the ferment and flour. Although the condition of London bakehouses has greatly improved of late, much remains to be done in this direction; and, indeed, until a better class of journeymen can be trained, no possible amount of inspection will prevent dirty habits from being practised, which have become ingrained by years of usage. Another point of advantage claimed by the advocates of this system, is the uniform temperature at which the oven can be brought at each operation. About 500° Fahr. is the best heat of oven for bread-baking. If higher than this the oven will be "rash," and if lower it will be "slack." With the ordinary coal fire it is necessary to heat the oven a good deal above the temperature required for baking, as the process of "scuffling" or clearing away the soot and dirt cools the brickwork considerably. For this reason, even supposing exactly the required heat to have been obtained at first, it is a matter of guess-work how far the temperature will be lowered by the scuffling. With gas the conditions are always the same, so long as the pressure in the mains and the quality of the gas remains constant; and it having once been ascertained how long it is necessary to keep the flame alight to get the required heat, it is easy to guard against undue ranges of temperature, and of course there is no scuffling. Probably the most promising feature in this invention is that it can be applied to the ordinary baker's oven at a comparatively small cost, and in the great majority of cases without interfering seriously with the ordinary routine of business. A short time ago Messrs. Gilson & Boer converted one of Messrs. Bertram & Roberts' ordinary ovens at the Crystal Palace into a gas oven in the space of twenty hours. The oven shown on Mr. Marshall's stand will hold ten bushels, equal to 320 half-quartern loaves. In London there are about 6,000 ovens such as this, excepting, of course, that they are worked with coal fire in place of gas. If all these were fitted on the principle we have described, it is estimated that they would burn 6,000,000 ft. of gas per day. The great advantage to the community that would arise through the freedom from smoke will be manifest. Although the Smoke Nuisance Act is occasionally put in force against bakers, its provisions are practically inoperative so far as abolishing the evils attendant on the use of coal in the ordinary baker's oven is concerned. Wood is the best fuel that can be used for baking, as it produces little smoke, and the products of combustion given off by it are not of an objectionable nature. In Continental cities wood is mainly used, but it is long since the London bakers gave up the cleaner and more wholesome fuel for coal. To Henry Sibthorpe belongs the credit, such as it is, of having introduced the roasting coal ovens of the London bakers. In 1835 he was granted a patent for "The art & skill of erecting and making of ovens in such sort as that the said bakers, baking cookies, and other persons, may heat the same ovens with sea coales digged out of the earth, and therewith may bake assone & as fayre & for lesse charge than they nowe dooeth with wood, and with much more safety." Sibthorpe appears, however, to have had considerable difficulty in persuading the "bakers and baking cookies" to adopt his plan. The more extensive use of sea-coal as fuel appears, however, to have been engaging the attention of the advanced spirits of that age, for the public records show that a large number of patents were granted about this time for different stoves and ovens in which coal was to be burned. Whether the reign of smoke, so far as bakeries are concerned, will be brought to an end after fasting for 250 years by such inventions as those of Mr. Boer and others we are about to describe, remains to be seen. For the present by far the great majority of bakers use the ordinary smoky coal oven. Messrs. Marshall also

same building by Messrs. Bynon & Cox, of Torquay. This oven is self-contained, requiring no brickwork setting. It is said to be remarkably economical, and seems especially well adapted for hotels, asylums, and other large establishments.

On Messrs. Marshall's stand is shown a Melvin's patent doughing machine. This is one amongst other classes of apparatus which have been introduced of late years, and is designed for the purpose of superseding the uneconomical and uncleanly manual processes of treating dough; processes which are yet, unfortunately, the general practice in ordinary bakeries. The machine consists of a long wrought-iron trough mounted on dwarf standards. Within this, and extending for the full length, is a series of mixing blades made of Siemens' rolled steel and mounted on three horizontal steel shafts. These are actuated by suitable spur-gearing at each end. The disposition of the blades is made with a view to cutting, pressing together, and turning over the dough in the most effective manner. The blades are arranged so that they do not act simultaneously, and no unequal strains are, therefore, thrown on the gearing. The machine is emptied by tilting the trough, the movement of the blades discharging the dough.

Adjoining this stand is the bakery of Messrs. W. Hill & Son, of Bishopsgate-street, who are perhaps best known to the public as the purveyors of whole-meal bread. This is a very different article to the brown bread of ordinary bakers, which is simply white bread with a certain quantity of pollard or bran mixed in with it. The meal obtained by milling wheat is divided into different products. The chief of these is flour which is made from the white inner part of the grain, and is the richest in heat-giving principles, as it contains nearly the whole of the starch. Next in the scale comes which are known in the trade as "tailings" which are composed of the inner coating immediately enclosing the starch cells. Outside this are other layers or envelopes which, when ground and separated by sifting, form respectively "middlings," "sharps," "pollard," and "bran." Now, as the flour produced from the inner part of the grain consists chiefly of starch, a carbo-hydrate or heat-giving principle which may be converted into work done, so the products of the outer coatings contain the greater amount of nitrogenous substances that supply the flesh-forming principles required to build up the human body. In addition to this, certain mineral substances, necessary for the formation of the bone structures of our frame, are contained in the three exterior envelopes. Premature decay of teeth is a trouble that appears to be of constantly increasing seriousness, and the theory has been advanced that this is due to the almost universal use of white bread. If we were to depend on chemical analysis alone there is no doubt that whole meal affords a more valuable food product than can be obtained from fine white flour. But the physiologist has to go further than the chemist, and he tells us that a large proportion of the flesh-forming substances in the whole meal passes through the system unassimilated. On this account the use of whole meal has been a good deal objected to by many authorities on these subjects. The reason that a great part of the nutritive principles in whole-meal bread is excreted, is that the rough particles of the outer coatings so stimulate the intestines that the food does not remain sufficiently long for complete absorption of all the nourishing principles to be effected. Although it is undesirable that any large amount of food should be taken into the stomach which would not become assimilated, yet the loss of a part of the nourishing constituents of the grain, in the case in point, may be well submitted to if a gain is made in other directions. Stimulation of the intestines is exactly the action which is so much required by an increasing class in the present day, in which sedentary occupations are constantly multiplied as the use of machinery displaces the need of manual labour. In addition to this a system of artificial locomotion has become so ramified that the natural walking exercise taken by an ordinary citizen is too often insufficient for the purposes of health. On the stand occupied by Messrs. Hill & Son several machines used in baking are exhibited. The most noticeable of these are Pfeiderer's mixing and kneading machines, of which several examples are shown both at work and unattached. This machine

consists of a mixing-trough mounted on a suitable framing, in which a pair of blades are caused to rotate by gearing. These blades are made of such a shape that the paths of rotation can bisect each other, although the blades travel at different speeds. A very ingenious arrangement is applied for reversing the motion of the blades. A couple of loose pulleys are placed on the main driving shaft, one having an open and the other a crossed belt, so that they run in opposite directions. By means of a hand wheel and sleeve attachment, a friction-clutch placed between the two pulleys will engage either one or the other, and so cause the blades to turn in either direction as may be required; or the clutch can be kept central, in which case neither pulley is engaged. The trough can be emptied by power if required. A leading screw stands vertically at the back of the machine, and engages in a sleeve attached to the lower part of the trough. In this way the latter can be turned over on the trunnions upon which it is supported, the action of the blades helping to discharge the dough. It is said that with this machine bread dough can be thoroughly mixed, kneaded, and discharged in 40 to 50 seconds. Another clever machine shown on this stand is an improved dough-dividing apparatus, which will produce fifty rolls or buns from one mass by a single operation. The dough is placed on a circular steel table, and a cap or hollowed lid is pressed over it. The table is divided in such a way that it allows of a number of steel partitions to rise up from below, which will divide the space between the table and the lid into fifty exactly equal parts. The partitions are sharpened at their upper edges, and act as knives dividing up any substance that may be contained in the machines. Messrs. Hill & Son use Messrs. patent hot-air ovens, of which they have two on their stand, one a two-decker oven, and the other a single with travelling bottom, which can be withdrawn bodily, running out on wheels on a framing with rails provided for the purpose. In this way the whole batch can be set or withdrawn at once. On this stand is shown a 3 ft. grist mill by Messrs. Hughes & Sons, of Great Dover-street. It is especially designed for provincial or foreign use in parts where corn may be grown, but transport is difficult. A small crane is attached for lifting the stones, and pulleys are fitted so that the ordinary portable engine may be used as a motor.

Messrs. T. Watt & Sons of 6, Clewlow-terrace, S.W., occupy the next stand, and are chiefly engaged in producing what are known as angel cakes, a dainty compound, of which an enormous quantity must have been sold since the Exhibition opened. Indeed, the business done by those exhibitors who retail their wares, has exceeded the expectations of even the most sanguine, and many in many cases have afforded a handsome return on the outlay. It is said that the sixpenny dinner of the Vegetarian Society are affording a profit of 30% per week, whilst the returns from the shilling portions of strawberries and cream retailed by the dairy companies will form no inconsiderable item when these exhibitors make up their balance-sheets. Messrs. Watt bake their angel-cakes in Perkins's steam oven, which is heated by means of a number of wrought-iron tubes, the ends of which are welded up, a small quantity of water having been placed in each tube. The tubes are slightly inclined from the horizontal, the lower ends being placed in the furnace which lies at the back of the oven. In this way steam is formed in the pipes, by the heat from which the baking is effected. The Perkins' system is well known, but two adaptations of it shown in the Exhibition will, perhaps, be more novel to the majority of visitors. These are a ship's oven and a military field-oven mounted on wheels. The ship's oven is shown in operation.

Messrs. J. Baker & Sons, of 58, City-road, E.C., have a most complete display of baker's appliances in full operation. Their ovens are the only ones shown in the exhibition that work on the ordinary principle of allowing the products of combustion from the furnace to pass into the space where the bread is placed. There are two ovens on this stand, the one of greatest interest being known as the "Bailey & Baker Patent Continuous Oven." The furnace doors are placed under the oven door, and there are four flues leading into the oven at each corner. A hollow space lies between the sole of the oven and the crown of the furnace. A single flue of special construction carries off

the products of combustion, and the whole of the flues are arranged in such a manner that, it is said, the fumes of the furnace never come in contact with the bread, but remain in the roof of the oven until they escape by the outlet flue. Messrs. Baker exhibit "Thompson's Double-action Dough-mixing and Kneading Machine." By means of suitable mechanism the mixers can be made to revolve in the trough at high or low speeds, and either in opposite or the same directions as required. In this way a quick action may be obtained for breaking and stirring the sponges, and for mixing the dough in the earlier stages, whilst the slower and more powerful motion is useful for kneading when the dough becomes stiff. By the differential speed action of the mixers the blades always pass each other at different points of their orbits. By alteration in the speeds and direction of motion of the mixers, the machine can also be easily adapted for working different grades of flour. A strong flour will bear more vigorous usage than a softer variety, which would give a dead dough if too roughly handled. A sifting and mixing machine shown in operation on the upper floor of this establishment is an ingenious apparatus. The effect of emptying a sack of flour into the hopper and then starting the machine is curious, the white mass seeming to melt away much as one might imagine a heap of snow would disappear in a blast furnace. The wire bottom of the sieve is made semi-circular, and on the arcs thus formed a scraper or agitator is caused to oscillate rapidly, and so keep the particles of flour in motion. We are told that this machine will pass a sack of flour (280 lb.) in three-quarters of a minute when power-driven. A machine for cleaning currants is ingenious, the fruit being freed from stalks and dirt, without being broken, by series of oscillating arms working in a receptacle with a wire-sieve bottom. A large number of other machines used in bread and cake-making are shown on this stand, a biscuit-baking machine being the most noticeable. It would, however, be impossible to describe this without the aid of illustrations which our want of space alone would prevent us publishing.

In the gallery containing the Bakeries there are several exhibits of various machines and apparatus, that of the Globe Mill Company, Limited, of Chiswick-street, who exhibit Thompson's centrifugal pulvriser being perhaps the most interesting. In this mill the grain is crushed by the centrifugal action of an iron ball pressing against the casing of the machine. The method is said to be very effective.

CHINESE ARCHITECTURE, AND WHAT IT TEACHES.

So much has been said on the many and so diverse architectural styles and modes of building that have obtained in past times, and in various countries all the world over, that it would seem somewhat difficult to select out of them any one that has not been well looked at and into, and thoroughly analysed; but without pausing to go into details, it may be fairly said that there is at least one of them which yet needs to be further and more carefully studied by the student of architecture as one of the world's primitive outcomes, viz., the architecture of China. It is a subject just now of somewhat more than commonplace interest, from the fact of the great show at South Kensington, containing, as one of its primary attractions, a Chinese Court, or section, full of objects specially suited, in many ways, to illustrate the fine art and the architecture of the strange and far-off land of which so much has been dreamed, and even said, but of which so little, so very little, in accurate detail, is really known. It may be of interest, therefore, to call attention to it, as here in part seen, and, in some aspects of it, for the first time, in so genuine a way, and with so little in it comparatively of foreign influences.

It may be well just to bear in mind the exceptional character of this so distant and so large—for it is some eighteen times the size of Great Britain,—portion of the world. It holds 360 millions of people, whose homogeneity is complete. It has a "history" of longer duration than any other community, past or present, and had existence long before either antique Greece or imperial Rome had even their world-renowned "beginnings." It has nearly 7,000 miles of

boundary line, including land and water, and has two of the longest and most notable rivers in the world. It has also its world-famous Great Wall,—an architectural work with which few building feats will compare. It is well called the "myriad-mile" wall. It is no less than some 25 ft. thick at the base and 20 ft. high, and it forms the imposing boundary line of one side of the vast country,—the Pacific ocean forming the other and opposite one. Much more might be said here in detail which would account for the unique character of the art and architecture of China, but space forbids, there being so much of detail to be looked at and into. We would now only call attention to the contents of this Chinese Court, and more especially to the architecture to be seen in it, though in the shape only of models.

We thus point to some of the more exceptional and singular characteristics of China for the purpose of drawing attention to the contents of the Chinese Court or Division at the International Show, as it fortunately contains among so many objects of interest some few that are altogether unique. There are some models, most carefully executed, of those very unique and picturesque architectural constructions the many-storied towers or pagodas, which, in this strange land, takes the place of the Dagoba or relic shrine of the Buddhists in India. There are several of these in glass cases ingeniously modelled; one of ten stories; and a model gives a far better and more picturesque idea of such structures than any drawing, however correct or elaborate, can possibly do. As a work of architectural art it is most surely infinitely to be preferred to such misapplications of architectural forms as the single and isolated column from the front or side of a temple, as seen in Wren's monument, imposing as that may be, or the Nelson Monument in Trafalgar-square, or even to the more appropriate example of the use of such a form as at Westminster. One of them has eleven stories or galleries, and is, we are told, some 200 ft. in height, with others less than this, but fully as quaint and characteristic. In these we see, though perhaps dimly, a little of the indigenous art of China.

We note these curious buildings so typical of the country, and apparently so in harmony with its other buildings and scenery, in the hope that some effort will be made to retain them for one or the other of our national museums, either for the South Kensington Museum or the British Museum. As examples of the picturesque in architecture they can hardly be surpassed, and, as models, are equally noteworthy. We know so little of the architecture of China, familiar as the matter may seem, that it would be a sad oversight to let slip this opportunity of adding to our sources of information about it, the more especially as all here would appear to be "for sale," and both the "antique" and the quite new are really valuable and worth preserving and looking at twice, the simply common-place and worthless being passed by. Many other things here are noteworthy, but we should, perhaps, be travelling too far from our proper subject-matter to describe them, but we may add one other item architectural, which calls for it,—it is that of the Memorial Gateways, as they are termed. These models also are worked out of soap-stone, and are fully as characteristic as the pagodas. They are difficult to describe, and one of them, perhaps the best, is so broken by its having fallen to pieces in its glass case that it is all but impossible to restore it even to the mind's eye. Should this meet the eye of the Commissioner who has authority here, we would hope that this "broakage" may be put right,—but the work of a few minutes.

Much more might be said by going a little into detail, especially into that of its all but unnoticed house architecture, and cottage and temple building; but our main object here is to call special attention to the advantage and desirability of obtaining for our national museums some selected portions of this almost unique collection of Chinese fine art, and models of its architecture. The whole, or at least the major part of these illustrations of the architectural art of China, might well form a nucleus for a complete outline representation of Chinese architecture,—an art so isolated and complete in itself, and yet, at least in the interior, and away from the coast-line itself, so characteristic and national. It is a thing not a little to be desired, for, as we have already hinted, the architecture of China is unique, both in kind and in its history, for all the old architec-

tures have had their "decline and fall" long since. They have had to be revived by other races of men, and under quite new conditions, e.g., the Greek in England; but this strange style of architecture yet lives, not as a broken link merely from the chain of art, but as belonging to the past of it, and as yet a part of it. Indeed, in it do we not see the long past of art in the very and actual present? It must needs, therefore, be worth a little attentive study, if only to find out if possible how this can have been. Here, at least, it is.

WHITEHALL COURT.

"See under Ripley rises a new Whitehall,  
While Jones' and Beyle's united labours fall."  
Pope.

In our issue of the 19th of July last we announced that it had been decided to pull down, at no distant date, Lord Carrington's town residence at Whitehall. But this is not the only change which is about to pass over so time-honoured a quarter. The death-warrants are signed of a much older though less conspicuous building,—we mean the Almonry Royal at the further end of Middle Scotland-yard; together with the large building, formerly Lord Stuart de Rothesay's, which is occupied by the Royal United Service Institution. To the wide waste which lies adjacent to these several buildings has already been given the name of Whitehall-court, and here, given the mammoth height of the Hôtel Métropole, sets of chambers and offices will be constructed. By the levelling and excavation of the ground some interesting relics of the earlier Whitehall are brought to light. There are laid bare, for instance, portions of three massive stone walls running parallel almost due north and south, and even with the river's course. These walls clearly mark the successive reclamations from the foreshore which have been made at this spot. That which lies westwards, being the most remote from the waterside, forms part of a rampart along which a terrace ran from the Small Beer Buttery to the land-side head of the Palace public stairs. The Beer Buttery is still represented by the now deserted Almonry Royal and Queen's Treasury; an existing archway in the ground-floor of the latter gave access on to the terrace, that was made to prevent the inundations from which the Palace inmates constantly suffered. At the northern end of the terrace were the Great Bakehouse and Scotland Dock. At the end opposite was the bridge or stairs, for the ordinary traffic of boat passengers; this should not be confounded with the Privy Stairs a few yards higher up the stream. The causeway leading from the old court (now Whitehall-yard) to the public stairs may still be traced, though much of it has been removed within the few past months. The ground is dug away from its northern wall, also of stone, discovering the marks of the water level on either side, and a large opening is made through it to a garden beyond. The dimensions of this garden east and west should be carefully observed, since they indicate the width (75 ft.) of the ground, which for 200 ft. northwards from the causeway was taken from the river at the building of Fife House. The tradition which connects Great Scotland-yard with a home of the Scottish Kings when they came to our Parliaments received a singularly practical revival at the laying out of the new garden; for Lord Fife overlaid the ground with veritable soil carried hither from Scotland. This northern earth, however, disappears with the excavations, though these reveal the base of the second and later river wall, which again has given place to the Embankment wall, some 200 yards further southwards. That second wall, if fully laid bare, would be found to extend to the eastern corner of the new hotel. Fife House and Little Fife House were demolished just twenty years ago upon the laps of the crown lease. The staircase of the former,—the last home of Lord Melbourne,—was removed to South Kensington; and nothing is left of either *in situ* but the gateways and a heap of stones, mortar, and red brick, with some broken carvings scattered around. The Earl of Fife's house, in fact, stood over the "small beer cellar" of Hollar's print No. IV. The Almonry Royal and the Queen's Treasury, being one building, represent, as we have said, the Small Beer Buttery, which is clearly marked upon Fisher's ground-plan taken in 1680, and known by Vertue's en-

graving. We are not certain at what particular period the royal arms ceased to be distributed at the Palace Gate; but the southern half of this old building has long been known as the Almonry Royal, and was conspicuous for a good Tudor window in stone (which we notice is now taken away) in the ground-floor overlooking the river. The Almonry Office served for a term as the treasury of the Princess Dowager of Wales, and subsequently passed to the purposes of Queen Charlotte's comptroller and secretary. The Queen's Treasury,—the northern half containing the archway and buttery hatch,—was assigned to King George II.'s consort, and then to the queen of his successor on the throne.

Lord Carrington's house, No. 8, Whitehall-yard, occupies the position of the Wardrobe in Fisher's plan. Between the Wardrobe and Inigo Jones's Banqueting Hall stood the Palace Gate. Whitehall-yard corresponds with "The Court" beyond, down whose length still runs the pathway to the public stairs. Rather more than halfway southwards the pathway became a passage. This had to the south the Great Hall,—that is, the hall of Wolsey's time; the chapel and its two vestries, with offices against the river. On the other and northern side of the passage ranged the pantry, kitchen, privy larder, and some cellars. The Great Hall and chapel sites are those of the existing Army Medical Department (No. 6, Whitehall-yard) and its garden, the passage going through an archway beneath that office and skirting the garden. Lord Gage's house (No. 4, Whitehall-yard) and its garden show the positions respectively of the apartments which, in King Charles II.'s reign, were tenanted by the Countess of Falmouth and Lady Arlington. Viscount Gage's residence and the adjoining Board of Trade offices are separated the one from the other by a piece of original stone wall. Immediately south of Inigo Jones's famous structure, into which a less enlightened age fixed an incongruous northern entrance, were the Lord Keeper's rooms. Those have given way to Lady Clifden's stables. Gwydyr House projects into the once Privy Garden, though in the adjoining enclosure we can see the survival of that garden where Pepps, to his no little benefit and delight, saw my Lady Castlemaine's finest smocks and linen petticoats, richly loaded, hanging in the air. Her kitchen, where on a memorable evening the rising tide interfered with preparations for the King's supper, lay on the further side of "the street" by the Duke of Albemarle's lodgings, over against the Tilt-yard Parade in the Park.

#### THE OLD LONDON STREET AT THE HEALTH EXHIBITION.

A PLEASING, because not oppressively learned, little book\* is published by Messrs. Waterlow & Sons à propos of Old London in the International Health Exhibition. It contains a set of eleven views, or "gravings,"—for the most part excelsa embellished,—of the salient features of Mr. Birch's handiwork. Mr. T. St. Edmund Hake contributes the letterpress, or "historical sketch." It devotes a few opening sentences to the origin of London, though we could wish he had written even less. For his readers will naturally infer that the river Thames has always flowed within its now artificial channel beneath the shadow of St. Paul's, and that the *Civilis Trinobantum*, possibly the after site of *Verulamium*, is indubitably identical with the *Augusta* of a later day. Of Butcher-row, Mr. Hake reminds us that "in one of the houses in this row the Gunpowder Plot conspirators met." Winter's confession does not identify the actual house, in one room of which, he says, the conspirators took the oath of secrecy, and then in a room adjoining received the sacrament. Tradition, however, points to the dilapidated structure which, until the 30th of March, 1798, was standing at the south-eastern corner of the junction of Butcher-row and Clement's-lane. The singularly picturesque house, well known by Capon's print of 1799, with J. T. Smith's and W. Spiller's earlier views, at the south-western corner of Chancery-lane (and which was pulled down for the widening of that thoroughfare), is described as the certain home in Fleet-street of

\* The Historical Sketch of the Old London Street, Edited by T. St. Edmund Hake. London: Waterlow & Sons (Limited).

Izaak Walton. Walton did remove in 1624 to the northern side of Fleet-street, sharing a house there with one John Mason, bosier, next door to the Harrow inn. It is a question whether this was the house that gave way to Mr. Attenborough's late premises, or the house which, together with its neighbours, was pulled down rather more than three years ago, and, having a modernised front, formed Mr. George Kenning's Masonic dépôt. So again in describing the old house on Little Tower-hill,—a veritable relic of King Henry VIII.'s reign,—Mr. Hake speaks of its medallions as being those of the Roman emperors. As a matter of fact, it was then customary to reproduce in plaster on a house any coins that were discovered beneath it. Aid-Gate bore stone carvings copied from coins found in digging its foundations (1606). So we may account for the various figures on ancient house fronts of the cardinal virtues or similar emblematical devices. We write thus in no captious mind, but the rather to show how much care has still to be bestowed in dealing with the antecedents of these old dwellings which are thus suddenly restored to us.

Their realistic air has been enhanced by the introduction of groups of workmen who may be seen engaged upon the employments once peculiar to the different guilds. The conditions under which the street is open to public inspection perhaps render impossible its presentment under one or two aspects which seem to have escaped general notice. It would be highly instructive to see how such a thoroughfare was ordinarily lighted, paved, and drained. On the latter two points we will but make a passing reference to the works of Oldham and Swift, of Hogarth and Smollett. We cannot here stop to show how or when the moon's rays were first supplemented with the lantern's or cresset's feeble aid. Regulations *ad hoc* were frequently promulgated, to be no less commonly disregarded. The earliest legislative enactment appears to be that of 1708, when an Act passed "for the paving, cleaning, and lighting of the streets of London, Westminster, and Southwark." But Heming had already secured letters patent for an exclusive right to light the streets, engaging to maintain a lantern before every tenth door, between the hours of six and midnight on every moonless night, from Michaelmas to Lady-day. Oil-lamps came in, under John Verant's patent, with the last decade of the seventeenth century, having been first adopted to serve the Court between London and Kensington Palace. They have survived within our own memory along the Finchley-road beyond Swiss Cottage turnpike. Dean Clayton of Kildare and Watson made some futile experiments with coal-gas, leading the way to the thoroughly practical investigations of Murdock. Murdock built in 1798 the first gas-works of any size at Boulton & Watt's Soho works. Ten years later he received the Royal Society's Raunford Medal in reward of his enterprise. As far, though, as our own city is concerned the initiation of our existing system should be ascribed to the labours, commercially speaking, of Winsor, who began in 1803 with an illumination of the Lyceum Theatre, and of William Knight, who founded the gas-works that, until lately, stood in Whitefriars. By these, on Christmas night, 1814, a considerable part of the town was lighted. Accum's Treatise appeared in the year following. We now read with amusement how long had been popular prejudice against gas. Even Murdock opposed, probably on private grounds, Winsor's scheme for a National Light and Heat Company; Sir Humphry Davy had declared that it would be as easy to bring down a bit of the moon to light London as to succeed with the novel illuminant.

**Clocks.**—A large new clock has just been erected in Ombertsey Church, near Worcester, by Messrs. John Smith & Sons, Midland Clock Works, Derby. It strikes the hours upon a ton bell, chimes the Cambridge quarters upon four bells, and shows time on four dials, each 6 ft. across. The movement is fitted with all the latest improvements of the makers, and it has one of Sir Edmund Beckett's double three-legged gravity escapements, with a 2-cwt. pendulum. The same firm have just erected a similar clock in Enville Church, Staffordshire, as a memorial to the late Earl of Stamford and Warrington, and it is a large village clock at Woodford, Northamptonshire.

#### PATENTS.\*

THE modern "patent right" is simply the royal "monopoly" of immemorial usage under a new name, and the power to grant it to particular individuals resides as heretofore in the Crown alone. Its exercise has often been connected with gross injustice and hardship, and the irregularities of which it was the occasion culminated under the Stuarts, whose prerogatives in this as in other respects were at last restricted by law. The statutes of Elizabeth and James in this behalf were so wisely framed that they have remained without substantial alteration to the present time, and the Act of 1833, which became operative on the 1st of January this year, leaves the principle almost untouched, and deals mainly with the question of procedure: the only constitutional change consisting in the provision by sec. 27 that "a patent shall have to all intents and purposes the like effect as against Her Majesty the Queen, her heirs and successors, as it has against a subject."

By repealing and consolidating some two-and-twenty previous statutes, the "Patents, Designs, and Trade Marks Act, 1833," secures to an inventor, by a very simple and cheap process, the benefits accruing from his invention. Heretofore seven personal visits and four separate payments were required for the protection of a patentee. He may now secure protection of a patent, at an outlay of 2*l.*, and by the simple and ubiquitous aid of the Postmaster-General. All the inventor has to do is to fill up and address to the Comptroller of Patents a form of declaration, to be obtained at any post-office, and affix a 1*l.* stamp. With this he may send a provisional specification and drawings (compulsory under the new Act), and after an interval of nine months furnish a complete specification and drawings, bearing a 3*l.* stamp, or he may send the complete specification and drawings with his original application, and 4*l.* in all. The documents will be open for public inspection for two months, and if unopposed the patent will be sealed, and stand good for fourteen years, provided only the patentee sends at given intervals to the Comptroller further fees, amounting in all to 100*l.* In certain circumstances the patent can be renewed for a second term of fourteen years. As will be seen, these steps may all be taken without the intervention of an agent, or the outlay of any sums in excess of the above fixed fees. As, however, much still depends upon the character of the specification, and perils abound on every side, it may be as well for inventors to seek the advice of those whose special business it is to advise on the subject.

In the case of opposition to a patent, or the revocation of one already granted, such aid cannot be dispensed with. A novel point in the new Act is the extension of its provision to aliens, who can now take out patent rights in the United Kingdom and the Isle of Man direct without the intervention of an agent holding the right in trust. A clause is provided by which Government departments may use any patent in the service of the Crown on terms to be agreed upon with the patentee, or failing such agreement upon terms to be settled by the Treasury. We shall be surprised if this does not give rise to some contentions. An apparently arbitrary circular by the Postmaster-General forbids the Post-office employees to take out patents without his consent. This is surely too general in its terms, and should be limited to inventions bearing upon the public service.

The sections of the Act which deal with the registration of designs and trade-marks exhibit the same desire to simplify procedure and secure equity in the application of the statute. But, after all, the matter is necessarily a complicated one, and the legal commentators on the new Act foreshadow many points upon which a good deal of judicial acumen will doubtless be exercised. Of the two books before us one is by a lawyer and the other by a professional patent agent, and as each looks at the subject from his own side it is essential to a complete understanding of the Act, its facilities and its shortcomings, to consult both works, or others like them. It is evident that the authors have respectively striven hard to classify and elucidate the subject fully by notes and illustrations, and not without success.

Patents, Designs, and Trade-marks Act, Rules, &c. By J. B. Hunt. London: Waterlow & Sons.

## WATER SUPPLY.

The following are the main portions of the papers read by Mr. G. J. Symons and by Mr. E. Easton at the recent Conference of the Society of Arts on Water Supply at the Health Exhibition. Mr. Symons's subject, as mentioned in our last, was "The Origin of Water Supply." He said:—

All water supply comes from the clouds, and it is with the products of the clouds as rain (including therein snow and hail) that I have to deal.

Perhaps before describing the general features of rainfall distribution, it may be permissible to explain (for the use of those who have never done it) how the fall of rain is measured. If we imagine a flat dish—a tea-tray, for instance,—placed upon a lawn during rain, it is obvious that (subject to loss by splashing) that tray would at the end of the shower be covered by a layer of water of a depth approximately equal to that which fell upon all portions of the lawn, and the depth of the water on it (say  $\frac{1}{2}$  in.) would be the depth of the rain fallen. Obviously, besides the loss by splashing, the water on this tray would soon evaporate and be lost, besides which the depth could not easily be accurately measured. For these reasons, some form of funnel is always used, so that the rain may be, as it were, trapped, prevented from splashing out, and from evaporation. In the gauge before you (a very inexpensive one) all known sources of error are guarded against, and, as the water collected by a 5 in. funnel is measured in a jar only  $\frac{1}{16}$  in. in diameter, it will at once be seen that its vertical depth is multiplied nearly tenfold, and, therefore, even  $\frac{1}{16}$  of an inch is easily measured.

There are other patterns specially adapted for observation on mountain-tops, where they can only be visited once a month; others for observations during heavy thunderstorms, so as to obtain data needful for drainage questions; others in which every shower that falls writes down its history, the instant of its commencement, its intensity during every minute, and the time of its termination; but I must not stand between you and other papers with a discourse on the many interesting points which these gauges bring out.

During the last twenty-five years, I have done what I could towards establishing a complete system of recording the rainfall in this country. In early days the British Association for the Advancement of Science gave considerable help, but some ten years since they dropped it. Government have never given any help at all, and now the whole cost, or 99 per cent. of it, is borne by the observers themselves, a body which has now grown to the very large number of nearly 3,000. I do not know the precise number, but there are every year new stations beginning, old ones stopping, and others interrupted, yet for 1883, I have just had the pleasure of printing perfect records from 2,433 stations, every record having been previously carefully examined and verified.

I refrain from going into the subject in detail, desiring chiefly that you should realise the fact, that large tracts of country have twice and even three times as much rain as others. If we descend to single stations, the differences are of course greater, e.g., in 1883, the rainfall at The Stye, in Cumberland, was 100.28 in., and at Clacton-on-Sea, in Essex, it was only 18.71 in., that is to say, the one was more than ten times the other.

Here I should like to interpose a question as to public policy. There is often a great outcry if the water in one district is taken to another. Surely, while there is no relation whatever between the density of population and the quantity of rainfall, one early duty of a Government is to see that all parts are amply supplied with the first necessary of life. Englishmen have a dread of centralisation, but in many ways they pay a long price for their dread. At present, it is not very often that any town can even state before Parliament its views as to the effect upon it of what its next neighbour may be obtaining powers to do. Having suggested one semi-legal question, I may as well mention at once another. Up to the present time, there being no Hydraulic Office (as I hold that there should be) in this country, all the larger water questions come before Parliament as Private Bills, and provided that they get through Committee, they, as a matter of course, become law,—law for all time to come. No one can foresee what will be the total population of this

country a century hence. No one can tell where the bulk of the people will reside, nor what will be the need for water in various parts of the country. Water-rights are already very valuable, and they will, probably, become still more so. Would it be possible to safeguard our successors by insisting that special water-rights, if now asked to be created, shall be subject to revision without compensation after the lapse of 100 years.

However, to return to rainfall, and explain why I stated it to be the origin of water supply. All rain and melted snow must be disposed of, either by evaporation, percolation, or flow into streams and rivers. The first class, evaporation, is, of course, not a supply, and therefore we must not pursue it. Percolation is the source of all springs and of all well-water. Sometimes, as at Lancaster, the springs are so large that even a considerable town can be supplied by merely laying pipes to the sources whence they burst forth; sometimes they run down into the reservoirs of gravitation water-works; sometimes they pass, as in the chalk districts, for miles beneath impervious strata, finally being either pumped up from wells, or even, in rare cases, rising as true artesian wells above the surface of the ground; and sometimes they pass even deeper, as in red sandstone supplies pumped from extreme depths for Liverpool and other towns.

The water which runs off the surface is utilised either by throwing a bank across a stream, and thereby forming a reservoir behind it, as, for instance, in the new supply for Liverpool from the Vyrway, where the reservoir will form a lake larger than many of those in Cumberland. Sometimes the lakes themselves are utilised as reservoirs, as, for instance, Loch Katrine and the surrounding lakes, and sometimes, as at York and London, the rivers are drawn from by powerful pumping machinery.

Mr. Easton's paper dealt with the subject of "Water Supply" in its mechanical aspect. He commenced by observing that the three chief points which have to be considered in relation to this subject are:—

1. The source of the water.
2. Its distribution; and
3. The conditions under which it is used.

1. With regard to the source, it is evident that in designing waterworks the engineer has to provide that the water shall be adapted for the purposes for which they are intended to be used, both as regards quality and quantity. The question of quality will depend upon circumstances. It is essential, of course, that in every case the water shall be free from contamination by organic and other impurities; but the necessity of its being chemically free from other constituents will depend, to some extent, upon the purpose for which it will be used; for instance, in a manufacturing district, where the water is required for dyeing and such-like purposes, it must be free from certain mineral ingredients, whereas for the supply of drinking-water and for general purposes, this is a qualification which need not be insisted on.

Sources of water proper for use may be classed under two distinct heads. 1. Those which are afforded by nature in a state absolutely pure and fit for use, such as water drawn from wells and deep-seated springs. 2. Those derived from water courses or gathering grounds, which are open to the atmosphere, and which must necessarily be exposed to the risk of contamination from external agencies.

In the case of the former, no works for storage or purification are necessary, the stratum of rock or other material from which the water springs, forming a natural reservoir and filter.

In the second case, it is necessary (a) that all direct pollutions shall be prevented from coming into the source; and (b) that in almost every instance, efficient means of filtration should be provided. The filtration ought, wherever it is found impossible to altogether prevent the chance of contamination, to include the use of some deodorising agent, of which there exist more than one capable of practical application.

As instances may be mentioned the filtration at Wakefield, where, for many years, by the use of Spencer's magnetic carbide of iron, a water very much contaminated was rendered perfectly wholesome; and that at Antwerp, where Professor Bischoff's spongy iron is employed with an equally good result.

2. Essential as it is to ensure that the source

of supply is proper for the required purposes, it is equally essential that the mode of distribution shall be such as shall prevent its deterioration before being used.

To effect this, it is absolutely necessary that the reservoirs into which the water is collected for distribution should be covered, and that the mains and pipes should be perfectly airtight, and laid at a proper depth below the surface, so as to preserve the water in its original state of purity, and, as much as possible, at the same temperature, during its passage from the source to the consumer.

One great cause of the complaints of the quality of the water in most large towns, is the use of cisterns for storing it in the houses, which it is impossible to employ without the risk of some injurious effect upon the water.

It is scarcely credible that the favourite place for fixing the cistern from which the water for drinking and culinary purposes is drawn is immediately over the water-closet or next to the dust-hole, whilst even in the better class of houses, where the cisterns are fixed in the roofs, they are very rarely sufficiently covered, and are open to contamination from soot, dust, inroads of black beetles, and other abominations. The latest researches of scientific men show that there is no more fruitful source of disease than such a condition of things affords.

This consideration naturally leads up to the third division of the subject, viz., the conditions under which water should be used. And first it is essential that a constant supply should be given, without which it is difficult to avoid the deterioration of the water above alluded to.

Not only is it impossible to give an adequate supply by the intermittent system, without having storage cisterns in the houses, but there is also a serious danger of contamination by the possible admission of foul air or gas into the mains when the water is turned off. There have been several instances of a water supply being seriously affected from this cause.

But to give constant service it is absolutely necessary also that the supply should be under proper regulations, which shall ensure the prevention of undue consumption and misuse of the water.

Not only are the difficulties of providing the supply greatly increased where waste is allowed to prevail, but the cost to the community is augmented without the slightest corresponding benefit to health.

Nothing is more fallacious than the idea, prevalent among a large section of consumers of water, that the allowing of taps and water-closets to run to waste, assists in the flushing and cleansing of the sewers, and, therefore, conduces to health. These continuous dribblings of water can have no effect whatever in removing any obstructions or accumulations which may exist in the large drains. The only proper and effectual way of removing focal matter is so to regulate the use of water that it shall be proportionate to the work it has to do at the moment. Where this is done, by the use of properly-constructed water-closets, well-proportioned drains, and by keeping out from the system of sewers the rainfall on the streets and houses, the ordinary quantity supplied to a town is quite sufficient to perform this service without having recourse to extraordinary means.

For these reasons it is not desirable that the supply should be unlimited in quantity; on the contrary, every precaution should be taken to make that quantity commensurate with the real wants of the consumers.

It is quite certain that in almost every town a very large proportion of the water delivered through the mains runs needlessly to waste. The waste of water, whether it arises from leaky joints in the mains and service-pipes, or from defective fittings inside the houses, can only be injurious to health from the increased humidity which is thereby imparted to the atmosphere, and which, as is well known, contributes so much to the spread of infectious diseases and the establishment of epidemics.

At this moment, when we are suffering to a greater extent than usual from the contamination of the Thames, owing partly to the presence of a large quantity of sewage, but also to the abstraction of a large proportion of the summer flow of the river, it is manifest that the reduction by thirty-three per cent. of the amount drawn from and discharged into the river would

go far to ameliorate the condition of things now complained of.

It is needless to discuss the method and conditions of supply, if the sources of water are not to be preserved to us, and it is quite certain that with the immense growth of the population of this kingdom, it will not be long before this preservation becomes a pressing necessity.

In the report presented to Parliament by the Duke of Richmond's Select Committee on Conservancy Boards, in 1877, a very workable scheme was recommended by their lordships. The Committee say that:—

"In order to secure uniformity and completeness of action, each catchment-area should, as a general rule, be placed under a single body of Conservators, who should be responsible for maintaining the river, from its source to its outfall, in an efficient state. With regard, however, to tributary streams, the care of these might be entrusted to district committees, acting under the general directions of the conservators; but near the point of junction with the principal stream they should be under the direct management of the conservators of the main channel, who should be a representative body, constituted of residents and owners of property within the whole area of the watershed."

But although the question of improving the water supply, by preventing the pollution of the rivers, was incidentally mentioned by their lordships, it was evident that the main object of the report was the prevention of floods and not the conservancy of water for the supply of populations. Now, it may well be said that the one subject is at least as important as the other, and just as the recurrence of a number of wet seasons at that time brought the question of the floods prominently before the Duke of Richmond's Committee, it may safely be asserted that a corresponding succession of dry seasons will compel the serious attention of the Government to the other part of the subject.

When presiding over the Mechanical Section of the meeting of the British Association, at Dublin, in 1878, on which occasion the opportunity was taken to very fully discuss, from a variety of aspects, this question of rivers conservancy, I made a suggestion which, I believe, is worth repeating at the present time:—

"A new department should be created,—one not only endowed with powers analogous to those of the Local Government Board, but charged with the duty of collecting and digesting for use all the facts and knowledge necessary for a due comprehension and satisfactory dealing with every river-basin or watershed area in the United Kingdom,—a department which should be presided over, if not by a Cabinet Minister, at all events by a member of the Government who can be appealed to in Parliament."

It is earnestly to be hoped that no further time will be lost in passing an Act to deal with this subject, and that no considerations of a party or private nature will be allowed to prevent a scheme of so important and impartial a character being made as complete and comprehensive as possible.

#### PROPERTY SALES AT THE AUCTION MART.

**Whitechapel.**—Messrs. Weatherall & Green last week continued their large sale of freehold houses and shops in Whitechapel. The sale, which occupied three days, comprised upwards of seventy lots, including more than 100 houses and a number of valuable freehold ground-rents. In last week's *Builder* we gave particulars of the first day's sale, which realised 18,820*l.* The second day's sale consisted of property in Greenfield-street and Yalford-street, fifteen houses in the first-named street being sold for an aggregate sum of 8,860*l.*; and twenty-five houses in Yalford-street realising 5,160*l.* Freehold ground-rents of 53*l.* per annum, with early reversions, were sold for 2,350*l.* The last day's sale consisted of houses in Commercial-road, Coke-street, and Plumber's-row, together with a number of ground-rents. Six houses in Commercial-road realised 7,370*l.*; seventeen houses in Plumber's-row were sold for 5,740*l.*; and one house in Coke-street realised 560*l.* Freehold ground-rents, amounting to 170*l.* per annum, with early reversions, were sold for 2,390*l.* The total proceeds of the three days' sale amounted to 50,550*l.*

**Croydon.**—A freehold estate, known as Waddon House, near Croydon, was submitted for sale in several lots by Messrs. Blake, Haddock, & Carpenter. Waddon House and sixteen acres of freehold land were sold for 12,110*l.*; an adjoining residence and 10 acres of land realised 3,730*l.*; a plot of building land, containing between five and six acres, was sold for 3,480*l.*; another plot of building land, containing four acres and a half, fetched 1,710*l.*; and a mansion, known as the Priory, with eight plots of building land, was sold for 5,330*l.*, being a

total of 26,500*l.* In addition, three freehold residences on the estate were sold for 4,465*l.* *Ground-rents in Cheapside and at Islington.*—At a sale of ground-rents held by Messrs. Debenham, Tewson, & Co., the large sum of 11,600*l.* was obtained for a freehold ground-rent of 800*l.* per annum in Cheapside. The same auctioneers also sold freehold ground-rents in Islington, of 41*l.* per annum, with early reversions, the sum realised being 4,570*l.*

#### Illustrations.

##### THE OPERA CAFÉ ON THE OPERA-HOUSE PLATZ, FRANKFORT-ON-THE-MAINE.

**HIS** café was built in the years 1881-2 on the now Opernhaus Platz, from the designs of the architect, Herr Franz Jacob Schmitt, of Frankfort-on-the-Maine. It is carried out entirely in heavy stone, and all the structural parts are in Voges sandstone, veined and beautiful as marble, and of a whitish yellow colour, from the quarries of Deidesheim in the Rhenish Palatinate; the neutral wall surfaces are covered with white limestone from the quarries near Bar-lo-Duc, in Franco. The core of the wall-work consists of brick, but the collar and foundation-walls are of red quarry-stone, which comes in immense quantities into Frankfort, by water transport, from the very extensive sandstone quarries on the upper Main.

The two lower floors of the café, which are in rusticated masonry, comprehend the business portion of the building. On the first-floor a balcony with a grille of forged ironwork runs along the whole front of the building. Over the four rusticated columns rise on high bases eight Corinthian three-quarter pillars, extending through two floors, and carrying entablatures. The figures on the four sides of the façade timber work represent the four elements:—Earth, Air, Fire, and Water, by two female and two male figures, modelled by the sculptor Eckhardt, in Frankfort-on-the-Maine. The models of the two female caryatids, which off-frame the two windows on the third floor, come also from the hand of this gentleman.

In the design of the present building the architect was forced to take into consideration the façade of the opera-house in order to obtain a fitting and harmonious effect against the opera-house itself, which is designed in the Greek Renaissance style, and the dwelling-houses which border the Opernhaus Platz.

The new building at the corner of the Opernhaus Platz, a double house, was also built from the plans and details of the same architect. The three façades of this combined business and dwelling-house, in all 66 metres long and 19 metres high to the crest tile, were also built entirely in square sandstone, and equally richly decorated with sculptures from the models of the sculptor Herold, in Frankfort-on-the-Maine.

##### STAIRCASE AND DINING-ROOM, No. 8, WHITEHALL.

THESE elegant interiors, the work of Sir William Chambers, are within that square, plain-looking mansion opposite the Horse Guards, from which the Prince and Princess of Wales the other day witnessed the procession of the demonstrators to Hyde Park. The treatment of the dining-room is very simple and appropriate, saving only the rather too florid and naturalistic ceiling decoration, which has more of a drawing-room character, but is too much of the pie-crust order in any case. The staircase shows that extraordinary development of sliced-up architecture which modern criticism has taught us to condemn; but the whole has the merit of dignity and refinement proper to a house interior of the first-class. The illustrations, which are reproduced from photographs by Mr. Bedford Lemore, may be of some value as records of a London mansion which will soon be numbered with the things of the past. Some further particulars as to the site and its associations will be found in another column, under the heading, "Whitehall Court."

##### ST. GEORGE'S MISSION HOUSE.

THIS building is intended to serve as a centre for the parochial work of the parish of St. George-in-the-East,—an ecclesiastical workshop where the various branches of church-

work in an East-end parish have their centre of organisation. In the basement is a gymnasium for the boys, fitted up with the necessary apparatus, and having a wood block floor. Here are also the kitchen for preparing soup, and for brewing tea for tea-meetings; the heating apparatus for warming the Mission Hall above, and water-closets. On the ground-floor are two entrances, one to the upper floors of the house, the other specially for the Mission Hall at the back. Between these is a room for Infants' Sunday School. Behind is the hall, a large room intended for concerts, mission services, parochial entertainments, and Sunday school. There is an entrance from the churchyard by Sunday use. The gas pendants, specially made by Messrs. Slater, of Holborn, are hung with balance-weights, so that they can be turned up out of the way when a magic lantern is being shown. The floor is of wood blocks, and all the woodwork of deal, stained and varnished. Five of the lunettes have been filled with very excellent paintings, by members of the Kyrie Society, who have also given some charming panels of flowers painted on Willesden paper.

The first floor of the house is a large room for Sunday School, reading-room, &c. On the second floor are three rooms, one of which is used as a class-room, the others, and also the three rooms on the third floor, being living-rooms for caretakers, &c.

The work throughout is plain but substantial, and has been well carried out by Mr. Charles Cox, of St. George's Works, Hackney; the architect being Mr. Keith D. Young, of 17, Southampton-street, Bloomsbury, W.C.

The perspective view of the interior was drawn by Mr. W. H. Atkin Berry.

##### WEELEY CHURCH, ESSEX.

THIS little country church, situated on rising ground, surrounded by beautiful trees and a lake of water near, was rebuilt in the year 1880, by Mr. E. C. Robins, F.S.A.; that is to say, the whole is new but the western tower, which remains as it was. Such slight alterations as were originally proposed involved in the raising and re-erection of the roof and parapets, is indicated in the illustration which we present to our readers, but have not yet been realised.

The old church was a dilapidated barn-like structure, accommodating about 200 persons, concerning which the architect reported, "with the exception of the tower, there is really nothing of interest or value remaining, scarcely a moulding left. The church is very dilapidated, and owing to defective foundations has had to be buttressed up to prevent the walls giving way outwards, more particularly at the chancel arch; to enlarge it is out of the question. The fittings are simply hideous, and it is quite impossible to think of it as 'that holy and beautiful house where our fathers prayed Thee.'" It now consists of a nave and chancel, with north aisle and open porch, soon in our view. It accommodates 300 persons, and cost less than 3,000*l.*

##### COMPLETION OF ST. SAVIOUR'S, LAMBERT ROAD, BRIXTON.

THIS church, which was erected from the designs of Mr. E. C. Robins, F.S.A., and was consecrated in September, 1875, giving accommodation for about a thousand persons, without galleries, is now about to be completed by the execution of the upper part of the tower and spire.

The building is an example of the thirteenth-century French Gothic, and was originally intended to have a lofty spire reaching about 180 ft. in height; economical reasons have necessitated a simpler termination to the lofty tower, and we now give an illustration of the whole church as it will appear when Mr. Bangs has completed his contract.

The total cost, including both the former and the present contracts, will be below 9,000*l.*

**Surveyorship, Richmond Vestry.**—On the 1st inst. Mr. Walter Brooke, Assoc.-M. Inst. C.E., commenced his duties as Surveyor to the Richmond Vestry, Surrey. Mr. Brooke was three years and a half Assistant Engineer and Surveyor to the Hove Commissioners, Brighton, and previously four years assistant to the Borough Engineer, Brighton. He was elected out of ten selected candidates. There were 138 candidates for the appointment, which is worth 300*l.* per annum, with a horse and dog-cart.

HEALTH EXHIBITION LECTURES.

ANGLO-SAXON HOUSES.

On Saturday afternoon a lecture was delivered by Professor Hoggett, at the International Health Exhibition, on "Anglo-Saxon Dwellings." Dr. Zeiffi presided, and there was a good attendance.

The lecturer, in his opening remarks, said he wanted to tell his audience something about Early English houses. Those who were scholars of the true University stamp would turn up their English noses at English things, because they had been trained to admire only Greek and Roman antiquities. Such gentlemen would know all about the atrium, the compluvium, the basilica, and all other buildings, or parts of buildings, peculiar to the Greeks and Romans, but they would be almost indignant if they were asked how those lived who crushed the power of Rome and threw off the yoke of the arch-tyrant,—who called Freedom from the deep and founded her empire on the waves. It was contrary to history to suppose that the martial, poetic, and industrious race which overthrew Rome, and bore in it the germ of the new civilisation which now covers the face of the globe, was a race of rough, untutored savages. The remains of their arts, which have descended to us, their noble language, and still nobler literature, prove them to have been men of thought, skill, refinement, and enterprisa. The civilisation which they brought from Scandinavia was very different from that of the classical civilisation of Greece and Rome. The tastes of our ancestors were totally different from those of the classic nations of antiquity, and however excellent Greek and Roman models may have been, they clearly did not suit them.

In the cold, bleak north, man required warm houses and plenty of fuel, consequently Nature supplied him with enormous pine forests to build a house and brighten a hearth. Nor could better materials have been supplied for either purpose. No structure was so warm as a house of wood, and the glowing embers of a large wood fire were known to be the best adapted to the requirements of a household.\* The Anglo-Saxons were away in the summer on board their ships, and the house was, therefore, more calculated to keep the owners warm than to protect them from the heat. The houses which the Early English constructed in Scandinavia were more to their taste and better suited their requirements than any marble palaces beside the Tiber. And when they found such buildings in Britain, of the Romano-British stamp, they looked upon them with contempt, and pulled them down as they cut down the owners. Consequently, our own immediate ancestors built rather in the style of their forefathers than that of the nations they subdued. The Scandinavian was in the very nature of his love and life a warrior. His gods were gods of war, and his thoughts were those of a soldier. Even in peace he was a hunter, and the distinctions in his social existence were derived from warlike habits. One of the first principles of the Anglo-Saxon military education was that the soldier in war, whether on board ship or on the field, should have no protection from any kind of fortified work. The house was the dwelling-place in peace, and had for our remote ancestors no reference to war. Consequently it was described in such a manner as recalled to our minds the old-fashioned farm-house with its out-buildings, rather than the mansion of a later time. In the Older England, whence we came in the fifth century to Britain, there were grand structures in wood, giving our forefathers room to hold festive meetings in the winter, when cold and snow prevented their great assemblies in the open air. Such an apartment was the great hall of Herót, in our own grand national epic of Beowulf, the description of which afforded a ready clue to the architecture of the earliest English in Britain, as the other references to dress, arms, manners, and customs presented a vivid picture of English life in the fifth and sixth centuries. They were introduced in this glorious poem to a palace, which consisted, for the most part, of a large oblong building, used for the meeting-place of the warriors, forming the train of King Hrothgar, to whom the structure belonged. The internal arrangements were simple enough. There was the oblong room or hall, with its high bank on one side supporting the throne of the king, and below this, all round the walls, were

placed the benches for the warriors. The walls were hung with tapestry, the work of the Queen and her train of maidens. This was a necessary adornment, inasmuch as the joints between the logs, though carefully caulked and stopped up with tow, could not be hermetically sealed against the wintry blasts that cut their way through every crack and cranny. So the hangings on the walls were of immense use in keeping out the wind. Nor were the benches and settles without their bright and attractive coverings. Some of these coverings were as valuable as to render their mention in wills as bequests an important item. Besides the wall-hangings woven by the fair hands of tender women, there were other ornaments wrought by harder hands and less gentle fingers. The coat of linked mail, the splendid shield with its bronze or golden boss and circling ring or border of the same metal, the helmet ornamented with the wings of the sea eagle, the horns of the croch, the grim face of the boar or wolf, the sword, the boar-spear for the hunt, the gar for combat, and the lighter spears hurled as javelins at the more distant foe; such a group of splendid weapons marked each warrior's seat, as the escutcheons and coronets in another great house mark the seats of our earls and thames at the present day. There were but two windows, one at each end, and they were called wind-eyes, their object being ventilation rather than lighting the hall. The roof was of the gable form, rather pointed, and covered either with wooden shingles painted and gilt so as to glitter in the sun like gold, or else they were ordinary tiles highly glazed and of variegated colours. In the centre of the hall was the fireplace or hearth formed of burned clay, and surrounded by a low wall of fire-bricks from which the smoke rose in eddying columns to escape through an aperture in the roof left there for its passage. At each end of the long hall was a door, and during a feast both doors were open, and the poorest passer-by might enter and be certain of noble aims. The floor was of deal planks, but the hearth was a little cubical mound of earth surmounted by fire-bricks, tiles, &c. The external appearance of such a hall, judging from the description of Herót, must have been very imposing. The horizontal trunks were surmounted by the highly-pointed roof, gaily decked with shining shingles or brilliantly coloured tiles, bright and glowing in the sun. The effect was that of plates of gold used as tiles burnished and bright. At the gable ends the ornamental boards or planks that finished off the roof were, like the ends of the Swiss cottages and the modern Russian country houses, carved into fantastic forms. Those of the hall in question were carved into the resemblance of the antlers of a mighty stag or hart, and seen from a distance it must have conveyed the impression of a huge stag tossing its antlered brow aloft. When the winter set in and meetings in the open air were impossible, and the Viking expeditious equally so, such a grand hall must have been a bright scene indeed. The roaring fire in the centre, the splendid colours of the gorgeous tapestry shown up by cressets or iron lamps banging from the rafters; the four massy pines supporting the roof in the centre, in the stems of which some rude likeness of Thor and Odin Frigga and Freya were carved, painted and richly adorned with gold and gems, the brilliant arms glittering from the rich coloured ground of the tapestry, the gay dresses of the seated warriors, red, blue, and white, richly bordered with beautiful gold fringes. The harpers, with their harps and gay mantles, occupied the centres of the hall on each side of the fire, and around the blaze the busy cooks plied their art. Behind the seats of the joyous warriors golden-haired damsels poured liquor from such jugs as may be seen in the British Museum, into such horns as that rescued from the tumulus at Taplow, and also forming part of the national treasure in Bloomsbury. When the lady of the house, followed by her maidens and the other ladies who were present at the feast, withdrew, as is the custom of their descendants at the present day, they sought the bower, or women's apartments, built off from the great hall, and entered by a door at the side of the high seat or daïs. In these rooms the maidens of the household spun flax for the linen of which the fine under-clothing was made, or wove the web and worked the threads in the wool for the tapestry hangings of the hall and other rooms. Then there was the "Mithum House," or treasure

chamber, where rings and bracelets and money were stored. Next came the "Wæpen-hús," or armoury, with its store of helmets, byrnie (or coats of mail), white shields for the inferior warriors, spears of all kinds, bows and arrows, swords and axes. Again, beyond these places were the out-houses for the corlis, or free labourers, and the thralls or slaves. Then there was the *cyzene*, where certain preparations were made, and some portions of the cooking performed, that done in the hall being confined to the roasting on the spit, and to the boiling of the grand stew or soup in the gigantic cauldron swinging over the royal blaze in mid hall. All these buildings were to the rear of the great hall, and they were none of them higher than the ground-floor. There were also the *Buc-hús*, where various kinds of bread were made, the *breiw-hús*, a most important element in the comfort of an English house if all tales were true; the malt-house, where the malt was stored; the pantry, a building set apart for the preservation of the food of the household. Vegetables were preserved in the so-called *bed arn*, and the wine was kept in a cellar dug under the earth and called the *win arn*. The hors arn was the stables where the "fettered whirlwinds" were confined. For such corn as was consumed in the house there was the *gweorn* or handmill, but besides this there was the *mylen* or windmill that ground in larger quantities. The cows were confined in the *scyppen* or cowhouses. Then came the wash-house, where the linen of the household was washed, and, considering the scrupulous cleanliness of the Anglo-Saxons, this must have been no mean portion of the establishment, for they used table-cloths, towels, and napkins, which, besides the linen portion of their clothing, had to be kept white and clean. Those who had travelled in Sweden or Russia must have been struck by the number of bathing-houses for all classes of the people. Hot baths, vapour baths, and cold baths could be had at prices varying from 1d. to 6s. or 7s. of our money. The Russians visited the bath-house generally once a week, and certainly never less than once a fortnight. They said they acquired in such baths sufficient heat to keep them going another fortnight. Thus, when Tacitus speaks of the constant use of the warm bath by the northern nations they were led to understand why the Anglo-Saxons paid so much attention to the bath as to have a separate building provided for it in their great houses. Now all these places were buildings connected with the great hall of an Anglo-Saxon gentleman or person of distinction, and perhaps some would say that they were houses, not a house. His reply was that the original meaning of "house" was home rather than only one building, just as on a grand farm in some out-of-the-way place where "Threadneedle-street" was never heard of, if such a place were within the province of imagination, they would find the house itself not more than one story high, and all the various departments of the household, except the kitchen, carried on in out-buildings, as was the case in Russia. But the true English style of building was confined to one floor, and that was the ground-floor. By this means the fatigue of going up and down stairs was avoided, and the possibility offered of having all the dwelling-rooms of the same temperature, and of passing from one room to another without running the risk of chilling the whole body in the transit. In the Scandinavian houses of an early period there did not appear any trace of the unwholesome staircase, which emittened the lives of so many people in this country. Certainly they bad stairs, but they were the steps by which to mount the watch-tower built on a hill near the house, and used by the watchman to scan the whole neighbourhood to see if there were signs of intruders or visitors. The poorer classes, of course, lived in less pretentious dwellings; and, like the huts of the Russian peasants, their houses consisted of only one room, sometimes partitioned off into smaller apartments. But he was not by any means prepared to say that they were anything like so badly off as the poor were in this great metropolis. As long as they did their duty, civil and military, their lords were not unmindful of their wants. They were allowed wood enough for fuel and to spare, while the timber for their huts was supplied by the lord of the manor. In such poorer houses the hall was not wanted, and therefore the space which it would have occupied

\* The learned Professor's enthusiasm has certainly carried him a little too far here.—Ed.

## LEAKY SLATE CISTERN.

SIR,—In answer to your correspondent's questions, we have always found slate cisterns get leaky if they often run quite empty, and especially if allowed to get dry, however they may be fixed or built up.

We should much doubt the efficacy of covering the bottom as proposed, but if mastic, mixed with boiled oil, were used, instead of Portland, it might answer.

We should say,—judging, of course, from "Bombazens's" letter,—that his cistern has not been properly fixed, and we think it would pay him in the long run to have it taken to pieces, and refixed by a competent person.

J. & C. CHRISTIE.

## IMPERMEABLE CONSTRUCTION.

SIR,—The statement by Mr. E. C. Robins at the Conference of Architects (see *Builder*, July 19) that an application of linseed oil or of gum and wax dissolved in spirit will preserve external stonework in London is so entirely opposed to present opinion, and to the actual experience of the last thirty or forty years, that I apprehend there must be some mistake.

It is, as we know, always dangerous, in scientific matters, to base a general opinion on a single unsupported fact. We are told that stone in Regent-street which was coated with linseed oil fifty years ago is now undecayed. But there are several things to be considered before the oil can be credited with such an excellent, if not wonderful, quality. Even accepting the fact with as much confidence as Mr. Robins does, it must, I think, be taken as the exception that proves the rule; but if other-wise, it is one of the most valuable discoveries of the century. Nearly the whole of the present annual expenditure of 2,500*l.* for restoring decayed stone at the Houses of Parliament with new insertions,—a process finally adopted after the trial and failure of numerous chemical ingredients,—will at once be saved.

And as members of Parliament often trouble the First Commissioner of Works about reducing this vexatious impost, there can scarcely be a doubt that if Mr. Robins would, in the public interest, lay his discovery before him, it would be accepted if backed by adequate scientific evidence.

In the meantime, I, for one, must be excused for thinking, as I said before, that there is some mistake. Can it be possible that we have heard nothing before now of a discovery of such national importance, and which, years ago, eluded the search of such Nestors in science as Newton, Fuchs, Kuhlmann, Moreau, Serey, and our own rarely successful countryman,—Frederic Hansome? I find that as many as seventeen patents for stone preservation have been taken out in less than twenty years. Various kinds of vegetable, animal, and mineral substances were proposed,—amongst them oil, gum, wax, flour, bitumen, blood, and water-glass, were to be used in varying solutions. Many were allowed a test-trial by the Government, but they all failed. Not one has secured permanent adoption by the public. (Can Mr. Robins succeed with oil, or with wax and gum, when others fail?)

In the meantime, buildings constructed with soft, porous, freestones blacken and decay with more or less rapidity. It is as reasonable to expect oil and vinegar to unite as to believe that limestone or sandstone can exist in the presence of an ammonia, muriatic acid, and a dozen other natural or unnatural agencies floating unseen in the London air. As to better selection of stone, no quarry-owner would permit the best blocks to be picked out by one customer, unless, indeed, he was willing to pay the price of marble. Such a system would soon ruin the good name of the best quarry, and bring the owner or lessee into bankruptcy.

This state of things,—pending some further reliable evidence,—is exceedingly unsatisfactory, if not discreditable, and appears to me to demand from architects. If it be possible, the adoption of such a radical change in the external construction of our more important national buildings of the future, as shall enable them to resist the destructive effects of our abnormal atmosphere.

What this should be is a difficult but very interesting question; but I do not think that terracotta, though durable when well burned, would be tolerated for a great national edifice. As you are aware, Mr. Editor, I have my own idea on this subject, and you have allowed me to place its merits or demerits before your readers. It has at least one great advantage, namely, that the evidence in support of it is not only simple but local, and could therefore be easily tested.

I venture to trouble you with this letter, because I do not see that any notice was taken of the statement I refer to in the discussion which followed the reading of Mr. Robins's interesting paper.

II. T.

**The Rivers Pollution Act at Reddish.**—The Reddish Local Board having obtained an order from the Local Government Board suspending the Rivers Pollution Act, 1876, have given instructions to Mr. R. Vawser, C.E., Manchester, to prepare a plan for the complete sewerage of the district.

## CHURCH BUILDING NEWS.

**Lincoln.**—The foundation-stone of the tower of St. Swichin's Church, Lincoln, was laid on the 19th ult. by Mr. Alfred Shuttleworth. It is now many years since the church itself was erected, but owing to the fact that the parish funds were not forthcoming to warrant the immediate completion of the design. Under these circumstances the chancel and tower were left to be added at a future time. In March, 1879, the Vicar, the Churchwardens, and the parishioners had the satisfaction of seeing the corner-stone of the chancel laid by Mr. N. Clayton, the senior partner of the firm of Clayton & Shuttleworth, through whose generosity that portion of the edifice was principally erected. For the building of the tower the parishioners have to thank Mr. A. Shuttleworth, who will, it is understood, bear the whole cost of the work. The tower and spire, when completed, will form a very important object in the heart of the city, rising, as it will, to a height of 107 ft. above the floor of the church. It will be of three stages, flanked by massive buttresses. In the lower side of the western face there is to be a deep-recessed doorway, flanked by a blank arch on each side. Over this is to be a three-light window. The second stage is to be arched on three sides with loop-lights to the belfry. The upper story will have two windows on each face, well recessed and finished on the outside with crocketed pediments running up into the cornice, the spandrels thus formed being filled with diaper work. Above this the spire will rise to a height of 106 ft. This will have three bands of ornamental diaper work upon it at different heights, and at the corners terminating the buttresses are pinnacles, 32 ft. high, connected with the spire by flying buttresses. On each of the cardinal faces of the spire there will be a lucarne with gabled pediment. Seen from the interior of the church, the lower part of the tower will be enriched with arcade work on the north, west, and south sides, the eastern face being occupied by a noble arch opening into the nave. The material for the interior will be of Ancaster stone; the exterior will be of Lincoln stone with Ancaster dressings, the material from the old church being used in the new building. The plans for the church and spire were prepared by Mr. Jas. Fowler, of Louth, whose architectural efforts adorn so many parishes in the county of Lincoln and elsewhere. The building of the tower is entrusted to Mr. Baines, of Newark, who erected the chancel in 1879. The cost of the present work (5,700*l.*, exclusive of architect's fees) is to be defrayed by Mr. A. Shuttleworth, as before mentioned.

**Blyth-on-Tyne.**—On Tuesday afternoon the foundation stones of the new church of St. Cuthbert, at South Blyth, were laid. The site (given by the lord of the manor, Sir M. W. Ridley, Bart., M.P.) of the new church is west of the old building, and when completed the two buildings will be within one and the same enclosure. There is no record of the old church ever having been consecrated, consequently the vicar intends to devote it to secular purposes. Only part of the new site is at present being built upon, and the church now in course of erection, which will be stone and in the fourteenth century style of architecture, will, when completed, seat about 370 persons, and will cost 3,000*l.* Mr. W. S. Hicks, of Mosley-street, Newcastle, is the architect, and Messrs. E. & J. R. Taylor, of Benfieldside, the contractors for the main portion of the work.

**Littleham.**—On the 27th ult. a new reredos was unveiled at the recently-restored church of St. Margaret, at Littleham-on-Ummerthorpe, and stands upon a polished Devonshire marble super-altar, which has been prepared to receive it. The reredos itself is of dark oak, and has been made from a design of Mr. R. Medley Fulford, of Exeter, the architect under whom the general restoration of the venerable fane was carried out. The reredos is the work of Mr. Harry Hens. The main feature in the reredos is a figure of Our Lord as the Redeemer. The reredos consists in the main of seven compartments, three large and four smaller ones. All these contain sculpture. In the centre the gable is surmounted by a tall and handsome foliated cross. The four niches contain statues of the four Apostles. On the right hand side of Our Lord is a large panel in which, sculptured in high relief, is a representa-

tion of Christ bearing the cross. On the other side is shown in the same way the entombment.

## PROVINCIAL NEWS.

**Manchester.**—On the recommendation of Mr. Henry Sheldermire, architect, of Liverpool, the tender of Messrs. Robert Neill & Sons, of Manchester, has been accepted by the directors of the Lancashire and Yorkshire Railway Company for the new Exchange Station buildings, hotel, and offices, Tithebarn-street, Liverpool. The amount of the estimate is close upon 100,000*l.* and the work will be proceeded with at once.

**Bolton-le-Moors.**—In the year 1870 the sum of 30,000*l.* was left by the late Mr. Stephen Blair, of Bolton-le-Moors, to build and endow a convalescent hospital near that town, under the condition that if a site were not given or provided within a fixed time the gift would lapse, Mr. Blair not being able legally to leave money for the purchase of land, and the money would go to the family of the testator's brother Mr. Harrison Blair. The trustees are Mr. Harrison Blair, the Rev. Canon Powell, Mr. C. Wolfenden, Mr. Thomas Glaister, Mr. W. Hargreaves, and Mr. J. Hick. Mainly through the exertions of those who would have benefited had the site not been given, a suitable plot of five acres was found, just in time to prevent the legacy becoming void. Mr. Kuwles most generously gave the land, a plot pleasantly situated to the north of Bolton, and about half-way between Mr. Creg's house and Bromley-cross station. The land slopes towards the south and west, and the country round about is attractive. Since the year 1870 the money has been well invested, and has greatly increased in amount, so that a larger and more complete hospital, duly endowed, can be erected. The trustees have engaged the services of Messrs. Medland & Henry Taylor as architects. The building, as now designed, is divided into three departments, for men, women, and children, with a central administrative block. The preliminary works of levelling, foundations, and boundary walling have been already let to Messrs. W. Thornton & Sons, and are to be pushed on with as much speed as may be.

## The Student's Column.

## HINTS FOR THE STUDY OF THE HISTORY OF ARCHITECTURE.—VI.

## ROMANESQUE AND BYZANTINE.

**I**N the last article the birth of Christ was referred to, but nothing further was mentioned on the subject. But it was reserved for Christianity to give the distinctive colour to the next thread introduced into the web,—introduced, too, a long way back and alongside of the Roman thread before it openly affects the colour of the web; but, having once got a firm hold on the pattern, it has continued to suffuse the whole with its various shades.

For the first three centuries the Christians in Rome were so persecuted that they had to carry on the practice of their religion in catacombs, the subterranean vaults from which it is said the Romans had dug out pozzolana for their mortar; and, considering the quantity of mortar that had been required for the buildings described in the last article, it will be readily seen that these catacombs are very extensive. On their walls may be found numbers of those symbols expressive of the Christian faith, which are still used in our churches, such as the  $\chi\rho$  &c. (X and P are the first and second Greek letters in the name of Christ (ΧΡΙΣΤΟΣ)), and must not be confused with the Roman letters, as was done in a modern stained-glass window representing a Roman standard with the letters XPQR!

In the fourth century the Roman Emperor Constantine established Christianity as the state religion; and we get what Ferguson calls Christianised Roman, or Romanesque architecture; moreover, he transferred the empire from Rome to Byzantium,—thence called Constantinople after him,—which led to what we may call Easternised Roman, or Byzantine architecture. For this reason, these two styles are coupled as the subject of this article.

It now becomes more necessary to "keep one's weather eye open" in order to detect the

various shades that are attributable to Western, i.e., Roman, and Eastern, i.e., Byzantine, influences respectively. At Byzantium, Constantine touched what has been called "the edge of the world: the knot which links together East and West; the centre in which all extremes combine" (Smith & Slater, p. 210). Here he came under the influence of Oriental art (see Freeman's "History of Architecture" on this subject), the elements of which are utterly different from those which he brought with him from Rome. For a time it appears that he gave and left there an impression of Roman work derived from the Pagan temples amongst which he had lived; but within two centuries of his migration to the East, "the East" (or, as Ferguson suggests, on page 945 of his Handbook, the Sassanian style) had migrated into the conception and design of the Christian churches erected by these Roman emperors, of whom Justinian has left us the largest example, namely, the Church of Santa Sophia (or Holy Wisdom). This huge building is illustrated in all the handbooks. Ferguson, who prefers to place his chapter on Byzantine at the very end of his Handbook, p. 943, illustrates this church by a plan at two levels, and a longitudinal section drawn to his usual scale of 100 ft. and 50 ft. to the inch respectively. Smith & Slater's "Classic Architecture" gives a section on p. 212, and Rosegarten gives, in addition, on p. 180, a bird's-eye view illustrating the dome system.

It is in the construction of their domes that the Byzantines differ from the ancient Romans, who simply placed a circular dome on a circular wall, with the one exception pointed out by Ferguson, p. 345, of the Temple of Minerva Medica, where the dome rests on a decagon, or ten-sided, substructure; the change between the two forms being effected by means of *pendentives*. The Byzantines eclipsed this completely by raising a circular dome on a square, or four-sided, substructure; each side of the square being occupied by an arch.

This subject should be studied from Scott's Academy Lectures, in the excellent and clearly-illustrated chapters on domes and vaults. The student can, however, easily realise the shape of the dome of St. Sophia by peeling a hemisphere of an orange, and cutting four contiguous semicircles out of it. These will represent the four arches, the portion above their crowns will represent the dome, and the remaining triangular portions will represent the four pendentives. It should then be noticed that there is no substructure vertically under any part of the dome, so that Procopius, who witnessed the erection of the St. Sophia, described it "as if suspended by a chain from heaven."

Such a dome is very flat in section, and, both for constructive and æsthetic reasons, the domes were afterwards made steeper, and also raised on drums pierced with windows. Their situation on plan is at the centre of four equal arms, constituting the nave, choir, and transept, as distinguished from the *unequal* arms in the Western churches, where the nave is longer than the choir and transept.

There are in the Institute library two copies of Salzenburg's magnificent work, containing drawings of St. Sophia, one of which is in the loan collection, and will well repay the somewhat Herculean labour of carrying it home to study. There are also the following:—Couchand's "Eglises Byzantines en Grèce" (one vol. quarto); Lenoir's "Architecture Monastique" (two vols. quarto); Texier & Pullan's "Byzantine Architecture," 1854 (one vol. quarto); F. de Vermeilh's "Architecture Byzantine en France," 1854 (one vol. quarto); De Vogüé's "Syrie Centrale," 1865 (two vols. quarto); and vol. iii. of the loan collection of the Institute "Transactions," containing a paper by G. J. Wigley, on "Archæological Studies in Jerusalem," 1856; J. L. Potié's "Remarks on Byzantine Churches"; and C. C. Nelson's notes, in 1855, on Salzenburg's work above mentioned; "Early Christian Monuments of Constantinople, Fifth to Twelfth Century," published in 1854 (one vol. folio). There is also Wyatt & Waring's Guide to the Romanesque and Byzantine Court at the Crystal Palace.

The student will soon become familiar with the characteristics of Byzantine buildings, their mosaic decorations and the sharp foliage carving and subsequent surface treatment, which was gradually evolved from Roman work, as pointed out in a most interesting series of examples by Ferguson (see p. 952 of his Handbook).

Commerce carried Byzantine art westward, producing here and there such exceptional buildings as the Church of St. Mark, at Venice, and St. Vitale, at Ravenna (though Ferguson includes this church in his chapter on Romanesque), and further westward still, we find the result of a Venetian colony in France, as evidenced by the Church of St. Front, at Périgueux, almost a copy, in plan, of St. Mark's, at Venice. But the Byzantine influence is shown in many parts of Europe, more in details than in entire buildings, and perhaps more in textile fabrics,—which formed the staple of Eastern commerce,—than in architecture.

It has seemed best to glance at this Eastern branch of Christian architecture first of all, and thus leave the way clear for following the Western or Roman influence, being prepared with knowledge which will enable us to recognise the colour of the Eastern thread which, from time to time, puts in an appearance in many subsequent parts of the web. Sir Gilbert Scott notices what he calls the Greek or Byzantine character of Corinthian capitals, illustrated by the Choragic monument of Lysicrates (distinguished from the Roman capitals in the temple of Mars Ultor); by scroll-work at St. Denis, near Paris; by a cornice at St. Denis; by a capital at St. Mark's, at Venice; at St. John's, Constantinople; at St. Front, Périgueux; by the column of Marcion, Constantinople; by carving from St. Germain des Prés, Paris; by the north-west portal of Lincoln Cathedral; and by the enriched shafts of the west portal of Chartres Cathedral ("Academy Lectures," vol. i., p. 80).

When Constantine left Rome, the Christians had crept out of their catacombs, and had, in some cases, announced the fact by building a church over the entrance to their former hiding-place, or over the spot where they had buried a saint or martyr.

Rosegarten, on p. 169 of his Handbook, points to this custom as the origin of the subterranean chapels or crypts so often constructed under the principal altar of subsequent churches.

What form were these emerging Christians to adopt for their above-ground churches? Ferguson, on p. 481 of his Handbook, points out "the remarkable fact connected with the early history of the Christian religion, that neither its founder nor any of his more immediate successors left any specific directions either as to the liturgical forms of worship to be observed by his followers, nor laid down any rules to be observed in the government of the newly established church." This is a point upon which there may be difference of opinion, to judge from the many proofs of a precomposed liturgy given by Wheatley "on the Common Prayer."

Be that as it may, it is generally admitted that the Christians began on the principle of the hermit crab, who establishes himself in some one else's ready-made shell, of course on the understanding that some one else had no further use for it. Thus, the Halls of Justice, or *Basilicas* mentioned in the article on Roman architecture, were found to be very well suited to the requirements of a Christian church. See Ferguson, p. 482. The bishop naturally took the place in the apse previously occupied by the prator or quæstor, the presbyters those of the assessors. The altar in front of the apse was ready in position and only needed change of purpose, and with a few alterations brought about by the introduction of a choir, provided with two pulpits or *ambones*, and of screens or *cancelli* (from which the word "chancel" is derived), and of a transept which converted the plan into the shape of a *cross*, and sometimes a chancel arch, and generally a *narthex* and *atrium*, or forecourt, we get a series of basilican churches that Ferguson, on p. 485, enumerates as dating from the fourth to the fourteenth century. One of the most beautiful, that of St. Clemente (of which photographs can be easily purchased), exhibits the original choir and ambones and also an arrangement of piers and columns which form a pleasant relief to the usual innumerable arrays of columns (which were a glut in the market when there were so many Pagan buildings to "de-columnise") that one finds in most basilicas.

These buildings, then, are emphatically Romanesque, or Christianised Roman, and the term may be fairly carried on to describe all those buildings, not only in Rome or Italy, but in many other parts of Europe, in which the chief inspiration of the architecture was Roman, be the forms of

the buildings what they might,—and of course they would vary with all the different requirements that had to be fulfilled. A good general notion of the style may be obtained from Gally Knight's somewhat pictorial "Ecclesiastical Architecture in Italy from the time of Constantine to the Fifteenth Century," 1844, two vols., folio; or from Isabelle's "Édifices Circulaires"; or, going further westward to France, from Révoil's "Architecture Romane du Midi de la France," 1873, three vols., folio.

In the next article we shall meet with another element which suffused European architecture long before the Roman element died out, and as fresh threads multiply, the web becomes more and more broken in colour, and we have to look all the more keenly for the predominating tint here and there in order to assign the proper title to the architecture. One peculiarity, however, of the English translation of Rosegarten's "Handbook" should be guarded against, namely, the application of the term Romanesque to all the Christian architecture of Europe down to the Renaissance. In Italy, indeed, Romanesque architecture never died out, but survived in Florence and Pisa throughout the Middle Ages, eager to bloom afresh when the turn of Classic art should come round again. Other countries, however, so entirely threw off all vestige of Roman tradition, construction, ornament, and feeling, that the term Romanesque ceases to be applicable to their architecture.

It may be as well to mention also to beginners that the French word "Romane," applied to architecture, signifies Roman, and "Romane" signifies Romanesque, while "Romanesque" signifies Romantic.

Smith & Slater carry their illustrations of Romanesque architecture into France and England, giving examples which are also known under the local terms of Saxon and Norman; and Ferguson, on p. 522, remarks upon the very gradual nature of the change, in France, from Romanesque to Gothic, and reserves for his chapter upon "French" architecture, p. 593, the description and illustration of several most decidedly Romanesque buildings, such as the porch of Notre Dame des Doms at Avignon, and the angle of the apse at Alet. His woodcuts are chiefly taken from the following works:—Laborde's "Monumens de la France," Chapuy's "Moyen Age Monumentale," Taylor & Nodder's "Voyages dans l'Ancienne France," Renouvier's "Monumens de Bas Languedoc," and other works.

The features which distinguish the mixed Romanesque style from the purer Romanesque work built in Italy will be pointed out in the next article, which will treat of a thread that put in an appearance from quite a different direction.

Books.

Practical Guide to Photography. London: Marion & Co.

THIS is an amateur's practical guide, giving instruction in a concise form, and will prove very useful to the beginner. There are chapters on the dark-room, development, exposure, defects, optics, portraiture, printing, retouching, &c., as well as on the ferro-prussiate process, now being so much used by amateurs and engineers. The work is clearly written, but Messrs. Marion do not forget to mention their own goods. We totally disagree with their recommendation of certain instantaneous shutters fixed on the hood of the lens: this is not the proper place for a shutter; it should be either in a similar position to the diaphragm, or in front of the plate, as in Edwards's plan. We should have liked to see the chemical part of the subject treated of. The book contains over 200 pages, and we consider it one of the best handbooks for the novice which has yet appeared. It deals with many subjects which the beginner ought to have an elementary knowledge of, and which otherwise could only be got from more elaborate treatises on the particular subject. Attention is called to the value of photography to the engineer, builder, and architect, and it is stated that photographic reproductions of buildings must always be infinitely more faithful and useful than the most elaborate and laboriously-prepared sketches or drawings. This, we consider, has not yet come to pass; for a good sketch does not distort,—the lens does, and renders the near object larger, and dwarfs the distant; besides which, one sketch educates the mind and eye much more than a dozen photo-

graphs taken. The camera can, however, be made a very useful and pleasant adjunct to the sketch-book.

*The Fisheries of the Adriatic and the Fish thereof.*  
By G. L. FABER, H.M. Consul, Fiume.  
London: Bernard Quaritch. Wyman & Sons, Printers.

This is a sumptuous book, bearing the imprimatur of no less an authority than Mr. Albert Günther, which is better evidence of its value than any we could offer.

But we can hear testimony to the exhaustive character of the work, and the heauty of its numerous illustrations, and few could fail to be interested in the many diagrams in plan and elevation of the various picturesque fishing-craft used in the Adriatic, their nets and multitudinous appliances; while the *Cimarol*, or device for the mast-head, acting as a weather-cock, and figured at p. 105, is more wildly and quaintly beautiful than anything which the pencil of Mr. Norman Shaw has produced, and we have always considered vane and weather-cocks as amongst his strong points. Besides answering its purpose, the *Cimarol* is full of religious symbolism and versatile fancy. The hook is an eminently practical one, and not the least interesting parts of it are the chapters on the curing and cooking of the fish described, and the statistics of their capture. Once more we ask, when are we to have this wealth of the sea brought to our tables fresh, and at a reasonable price? The author predicates that the supply of fish will hereafter be as regular and as abundant in inland towns as the supply of meat. Perhaps. But will it ever be within the means of the poor man? The Fisheries Exhibition was to have done a great deal for us. What has it done to increase and cheapen our fish supply?

#### BUILDING PATENT RECORD.\*

##### APPLICATIONS FOR LETTERS PATENT.

July 25.—10,564, E. W. Brown, London, Spring Door-locks.—10,580, F. Locking, Liverpool, Heating the Rooms of Buildings, &c.—10,587, J. E. Tilling, London, Suspending and Working Window-curtains.—10,605, G. D. Feters, London, Spring-rollers for Window-blinds.

July 26.—10,621, R. J. Worrall, Liverpool, Brick Walls for all purposes, &c.—10,622, C. G. Tebbutt, Bluntisham, Bricks for Paving Stables and Stable-yards.—10,642, J. C. Cowell, Higher Tramere, Double-valve Flushing-box and Water-waste Preventer.

July 28.—10,662, C. Groombridge, London, Apparatus for Raising and Closing Window sashes, Shutters, &c.—10,664, T. Purdie, Glasgow, Water-closets.—10,667, W. Clark, Reading, Method of Glazing.—10,678, S. Johnson and R. Freeman, London, Flooring, &c.

July 29.—10,687, J. Shanks, Barnhead, Water-closets and Urinals.—10,708, W. B. Shorland, Manchester, Latches.—10,707, J. Wolstenholme, Manchester, Pipe-trench for building purposes.—10,712, E. J. Day, London, Travellers for supporting Window-curtains, &c.—10,717, W. J. Holmes, London, Instantly Syphonizing with great velocity for Flushing Closets, &c.—10,731, R. Weaver, London, Water-waste Preventers.—10,742, S. B. Goslin and J. J. Brown, London, Water-closet Apparatus.

July 30.—10,751, R. Ann, Handsworth, Automatic Spring Hinge.—10,754, E. W. Buller, Birmingham, Lock Spindles, and attaching them to Knobs and Handles.—10,759, J. C. Baker, Liverpool, Apparatus for Ventilating.

July 31.—10,801, H. T. Owens, Birmingham, Scouring Knobs to Spindles for Door Locks and Latches.—10,821, J. Honeyman and W. P. Buchan, Glasgow, Water and Dry Closets.

##### SPECIFICATIONS ACCEPTED.†

July 29.—8,245, J. A. Turner, Manchester, Wall Papers.

August 1.—5,845, E. S. Romilly, London, Chimney-pots.—7,507, T. Frost, Adelaide, Exhaust Ventilators.—9,647, H. H. Lake, London, Ventilating Cowl. Com. by H. L. Day, Minneapolis, U.S.A.

##### ABRIDGMENTS OF SPECIFICATIONS

Published during the week ending August 2, 1884.

5,527, J. H. Reynolds, Troy, U.S.A., Ventilators and Chimney Cows. Com. by A. J. Robinson, Boston, U.S.A. (Nov. 25, '83, price 6d.)

A dome-shaped plate is placed above the chimney, and another similar but inverted plate is placed below, and the pipe from the chimney rises through the centre of the latter. A shield is fitted round these plates bearing an annular space round their peripheries into the shield.

\* Compiled by Hart & Co., Patent Agents, 136, Fleet-street.

† Open to public inspection for two months from the dates named.

5,772, D. R. Clymer, Reading, U.S.A., Construction of Ceilings and Floors of Buildings for facilitating exit therefrom in case of Fire. (Dec. 18, '83, 6d.)

A hole is made in the flooring of each room, and a corresponding hole in the ceiling below, both being fitted with hinged doors, and rolled up between the two is a ladder by which access is granted to the room below.

5,905, E. Edwards, London, Detonating Alarm for Doors, Windows, &c. Com. by H. Gibout, Paris. (Dec. 28, '83, 2d.)

A hammer is pivoted on the door-post, and is held back by a catch on the door. When the door is opened the catch is released, and the hammer falls on the d-tonating cap of a cartridge placed in a recess in the door-post. (Pro. Pro.)

5,931, W. R. Lake, London, Portable Ladder Apparatus to serve as a Fire Escape. Com. by E. Canziani, Milan. (Dec. 29, '83, 2d.)

A series of ladders are arranged and fitted on a portable carriage, and the ladder is erected by joining the several parts together. (Pro. Pro.)

#### Miscellaneous.

**Arbitrations.**—A Bill has been introduced into the House of Lords by Lord Bramwell for consolidating the general law as to arbitration. It does not deal with special measures of arbitration, such as the Act of George IV. regarding disputes between masters and workmen, or with the special provisions for arbitration contained in many Acts of Parliament, as, for instance, in the Artisans' and Labourers' Dwellings Act or the Land Clauses Consolidation Act. The Bill proposes no change in the law; the utmost that it does is, when there are conflicting decisions, to state the law in accordance with what appears to be the correct view. It is intended, however, by those at whose instance the Bill has been prepared to propose certain changes in Committee. Among these are an abridgment of the power of revoking submissions to arbitration; the simplification of procedure in some respects; the laying down a common form of submission in accordance with the general understanding of men of business, which is to be implied in all references unless the contrary is expressed; the assimilation of the English and Scottish law of arbitration; the enabling an arbitrator to procure the attendance of witnesses out of the High Court's jurisdiction; the alteration of the law as to the liability of executors and administrators who refer; and the simplification of the law as to costs.—*Standard.*

**The Extensions at the Waterloo Railway Station.**—The South-Western Railway Company are vigorously carrying out the enlargement of their Waterloo Station, the works in connexion with which have been continuously going forward during the last four or five years. For some time past they have been the owners of a large block of property on the east side of York-road, and extending to the west boundary of the station. Upon this property stand several houses and shops, and other business premises, all of which are at present in course of demolition in order to clear the site for the erection of an extensive block of new offices having their frontage to York-road, the buildings being a continuation of those recently erected on the south side of the York-road approach to the station. They will have a frontage to York-road of upwards of 200 ft. in length. In addition to these buildings the roof of the enlarged station westward for giving increased accommodation for the Windsor traffic is at present in course of construction. The Iron Roof Construction Company are supplying the iron.

**New R. C. Church and Presbytery, Bootle.**—On the 20th ult. the foundation-stone of a new church for the Very Rev. Dean Kelly was blessed by Dr. O'Reilly, R.C. bishop of Liverpool. The presbytery has accommodation for four priests, and the church, which is of large proportions, is designed in the style of the Early Decorated period, and built of local red sandstone, the wall-facings being hammered. It has a spacious nave, aisles, and chancels, with carefully-arranged confessionals, and is 63 ft. wide internally and 152 ft. long. Messrs. Hadfield & Son, of Sheffield, are the architects, and Mr. W. Haworth is acting under them as clerk of the works. Messrs. G. Woods & Son, of Stanley-road, Bootle, are the contractors, their foreman being Mr. Bishop.

**Electrical Propulsion of Tramscars.**—We understand that the Ryde (Isle of Wight) Pier company are about to make experiments on the propulsion of their tramscars by electrical energy.—*Electrician.*

**Thames Communications.**—At the last meeting of the Court of Common Council, Mr. F. Green, chairman of the Bridge-house Estates Committee, reported on the reference of the 20th of December last, recommending that a low-level bridge with mechanical openings be erected at Ingonate-stairs, at the end of the street known as Little Tower-hill, by the Corporation, out of money to be raised on the credit of the Bridge-house Estates, and that it be referred back to the Committee to obtain and submit a design or designs for such a bridge together with an estimate of the expense, and for authority to make such inquiries, seek such practical information, and obtain such professional and other assistance as the Committee may think necessary to enable them to form a sound judgment upon the subject, in view of an application being made to Parliament during the present year. Mr. Deputy Fry moved, as an amendment, the omission of the words "with mechanical openings." Mr. Peebles seconded the amendment. After a long debate, the report of the committee was carried by eighty-three votes as against fifty-eight recorded for Mr. Deputy Fry's amendment. Mr. Peebles moved an addition to the report, instructing the committee to publicly advertise for designs and offer premiums, and that three empires be appointed,—the President of the Institution of Civil Engineers, the President of the Royal Institution of British Architects, and an engineer to be selected by the committee to award the premiums, and to advise the committee which design was most suitable for adoption. This amendment was defeated by 81 votes to 40, and, no further amendment being proposed, the report was put and carried. We are informed that in the division which took place upon Mr. Peebles's amendment five of the six architects who are members of the Court were present and took part, viz., Deputy Hamnack, Deputy Saunders, and Deputy Taylor, who voted with Mr. Peebles, and Mr. H. H. Bridgman against.

**The Statistical Works of Dr. Farr.**—It has long been the source of much regret amongst students of vital statistics, as well as among those practically interested in this branch of sanitary science, that the valuable statistical work of the late Dr. Farr is, from the form and manner of its publication, not generally available. The Sanitary Institute of Great Britain propose, in these circumstances, to publish a selection from Dr. Farr's official reports, papers, and addresses, and have confided the selection and editing of this memorial of his labours to the capable hands of Mr. Noel A. Humphreys, of the Registrar-General's Office. It is proposed that the volume should consist of not less than 450 pages 8vo., and that it be published at the price of 30s., or, to subscribers, one guinea, provided that the number of subscribers warrants the Institute in incurring the expense of publication. Intending subscribers are requested therefore, to send in their names without delay to the Secretary of the Institute, in order that the Council may be able to determine whether they will obtain sufficient support to justify them in publishing the book.

**Machinery at the Shrewsbury Agricultural Show.**—Referring to the recent show of the Royal Agricultural Society, held at Shrewsbury, Messrs. W. H. Bailey & Co., of the Albion Works, Salford, were exhibitors of a novelty in the shape of a modification of their well-known hot-air engine, of the vertical type, in which an ordinary gas-jet is employed for the purpose of generating the heat necessary for driving the engine, instead of using gas-coke or other fuel. This engine is described as a pumping-engine, and is intended to be employed for the purpose of pumping domestic water supplies. The advantage of this form of pump is that after it is once put into motion it can be left for hours, no stoking being required, whilst the amount of gas consumed varies from 15 ft. to 30 ft. per hour, according to its duty. Messrs. Bailey & Co. also exhibited their ordinary patterns of hot-air engines.

**The Island of Herm.**—We are informed that this property has been sold by private contract by Messrs. Debenham, Tewson, Farmer, & Bridgewater, for about 7,500l. The purchaser is a member of a firm of Scotch fish-curers, and it is understood that, in addition to the agricultural and other resources of the island, it is intended to make it a depot for the fish-curing business.

New Buildings in Wych-street and Holywell-street.—The demolition of several of the ancient houses in Wych-street and Holywell-street has been quickly followed by the erection of new buildings of modern character. The ground-floor of the Wych-street frontage contains five shops and the Holywell-street frontage six shops. The portions of the buildings are faced with polished Aberdeen granite piers resting on Portland stone bases. Above them are cornices in Bath stone, the upper portions of the frontages being in that material and yellow brick. They contain two floors, with an additional dormer floor set back some distance to the rear of the main cornice. The first and second floors have each ranges of six three-light mullion windows, the central part of the windows having arched heads. Between the windows the frontages are ornamented with fluted and panelled pilasters, carried up to the main cornice. The dormers have alternate

arched and pediment heads. The upper floors are intended to be let as offices, the entrance being in Holywell-street. Messrs. Francis & Sons, of Old Broad-street, are the architects, and Mr. Richard Condon, of Ball's Pond, the contractor. Mr. C. Chandler is foreman of the works.

The Re-Building of Garden-court.—The rebuilding of the chambers on the west side of Garden-court, in the Temple, which was recently taken down, and which included the apartments at one time occupied by Goldsmith, will very shortly be commenced. The necessary excavations preparatory to getting in the foundations, are now in progress, and the superstructure is expected to be proceeded with in about a month from the present time. The buildings will be erected from the designs of Mr. St. Aubyn, architect, to the Honourable Society of the Middle Temple, Messrs. Patman & Fotheringham being the contractors.

For the restoration of Highfield House, Catford Bridge-Kent, partially destroyed by fire, for Mr. Alderman Whitehead. Mr. Josiah Houle, F.R.I.B.A., architect, 71, Guildford-street, W.C. :—

Table listing contractors and amounts for Highfield House restoration: Jerrard (£3,164 0 0), Macey & Son (3,069 0 0), Kearley (2,558 0 0), Spencer & Co. (2,615 0 0).

For four houses and shop at Grassmoor, near Chesterfield (exclusive of bricks, which will be supplied by the proprietors), for the executors of the late Mr. C. Oaley. Mr. S. T. Rudge, architect, Hucknall, near Mansfield. Quantities supplied by Messrs. Rudge & Sharp :—

Table listing contractors and amounts for houses at Grassmoor: Farnsworth & Son (£610 0 0), Thos. Madin (608 13 0), Wheelodon Bros. (580 0 0), C. Marsden (538 17 0), D. Brown, Hasland (549 0 0), E. Heath, Hasland (536 18 4), D. Jowett, Grassmoor (517 17 0), R. Donald, Kirby Polly (514 0 0), C. Hays, Clay Cross (511 10 0), H. Shaw, Sutton-in-Ashfield (505 9 9), E. Tinkler, Clay Cross (498 19 0), Roe & Son, Alfreton (498 13 0), Wilson & Wain, Pilsley (469 15 0), Revill & Holmes, Grassmoor (433 2 0).

For new house, for Mr. W. H. Manser, Newmarket. Mr. John Flatman, architect, Newmarket :—

Table listing contractors and amounts for new house at Newmarket: Edwards (£1,645 0 0), Simpson & Sons (1,430 0 0), Hook & Tebbitt (1,383 0 0), Saint & Sons (1,360 0 0), Kerridge & Shaw (1,247 0 0), Densoe (accepted) (1,200 0 0).

For painting, &c., Settles-street Schools, for the School Board for London :—

Table listing contractors and amounts for painting schools: E. J. Coombe, St. George's (£257 0 0).

For painting, &c., Farmcombe-street Schools, Brompton :—

Table listing contractors and amounts for painting schools: E. J. Coombe (£259 0 0).

For stabling, &c., at The Vale, Sydenham, for Mr. T. B. Muggidge. Mr. Geo. Lon, architect :—

Table listing contractors and amounts for stabling: Eustace (£1,006 0 0), Jarrett (990 0 0), Holway (850 0 0), Oliver (835 0 0), Marriage (accepted) (878 0 0).

For additions to Brighton-road Schools, for the Croydon School Board. Mr. Robt. Ridge (Surveyor to the Board), architect :—

Table listing contractors and amounts for Brighton-road schools: Marriage, revised estimate (accepted) (£3,540 0 0).

For painting, &c., at the Workhouse Schools, Hornsey-road, for the Guardians of the Poor of St. Mary, Islington. Mr. William Smith, architect, 1, Gresham-buildings :—

Table listing contractors and amounts for painting schools: Grosvenor (£450 0 0), King (32 0 0), River Bros. (517 0 0), Austin (530 0 0), Pickford (453 10 0), Wood (432 0 0), Oldis Bros. (395 0 0), Larke & Son (374 0 0), Burgess (367 0 0), Kelly & Son (350 0 0), Travis & Son (349 0 0), Hewitt (349 0 0), Stevens Bros. (343 0 0), Woods (340 0 0), Talbrook (335 0 0), Harper (312 0 0), Richards (309 0 0), Sharp (290 0 0), Thompson (287 0 0), Crowne Bros. (285 10 0), Hobbs & Son (272 10 0), Collier (248 0 0).

For alterations and additions to 43, Green-street, Park-lane, for Mr. D. W. C. Hood, M.D. Mr. George A. Dunce, architect, Quantities by Mr. C. L. Cadbury, 57, Moorgate-street :—

Table listing contractors and amounts for alterations at 43 Green-street: Binder & Co. (£1,099 10 6), W. & H. Curtis (963 18 0), J. & P. Hermon (926 0 0).

For alterations and additions to shop, 206, Upper-street, Islington, for Mr. L. Siegelard. Mr. Geo. McDonnell, architect, 2, Arundel-square :—

Table listing contractors and amounts for alterations at 206 Upper-street: Chant (£730 0 0), Goldman (accepted) (700 0 0).

For laying down a 6-in. fire main and fitting up hydrants at the Workhouse Schools, Hornsey-road, for the Guardians of the Poor of St. Mary, Islington. Mr. William Smith, architect, 1, Gresham-buildings :—

Table listing contractors and amounts for laying down fire main: Jeakes (£212 5 0), Merryweather (330 0 0), Stiller (215 0 0), Shand, Mason, & Co. (135 0 0), Simpson (139 18 0).

For the erection of new school buildings, with master's house, in the Enborne-road, for the Governors of St. Bartholomew's Grammar School, Newbury. Mr. J. P. Power, architect, Basin-hall-street, London. Quantities by Messrs. Batstone Bros. :—

Table listing contractors and amounts for school buildings: B. E. Nightingale (£3,176 0 0), T. L. Green, London (7,795 0 0), E. James, Newbury (7,337 10 0), Harris & Wardrop, London (7,274 0 0), Silver, Sons, & Flewood, Maidenhead (7,215 0 0), S. Ellis, Newbury (7,170 0 0), J. Crook, Southampton (7,147 0 0), Stephens & Bastow, London (6,999 0 0), W. H. Simmonds, Reading (6,983 0 0), T. J. Sanders, Southampton (6,883 0 0), C. Claridge, Banbury (6,750 0 0), Ball, Sons, & Co. (Limited), Southampton (6,591 0 0).

Table with columns: Nature of Appointment, By whom advertised, Applications to be in, Salary, Page. Includes Curator, Art Museum; Surveyor; Clerk of Works.

TENDERS.

Table listing tenders for rebuilding the Ship and Turtle Taverns, Leadon-bail-street, for Messrs. C. & A. Falster. Includes T. Little (£21,290 0 0), J. J. Sargeant (21,290 0 0), etc.

Table listing tenders for rebuilding and alteration of premises, Little Park-street, for the Guardians of the Coventry Union. Includes T. W. Whitley (£410 0 0), T. Mayo & Son (410 0 0), etc.

Table listing tenders for completion of premises, Rective-buildings, Ducks-foot-lane, for Mr. E. H. Thompson. Includes J. Beale (£363 0 0).

Table listing tenders for rebuilding premises, Finsbury, for Finsbury Estates Company (Limited). Includes Hall, Beadall, & Co. (£13,930 0 0), W. Brass (15,750 0 0), etc.

Table listing tenders for erecting the internal fittings to the Green Man and Still public-house, Upper Whitecross-street, for Mr. E. Cain. Includes Howlett (£489 0 0), A. Thomas (269 0 0), etc.

Table listing tenders for alterations and additions to the Limes, Warwick-road, New Barnet, for Mr. G. Page. Includes W. James (£325 0 0), T. Butcher (302 0 0), G. J. Kieck (accepted) (256 0 0).

For the erection of new Town-hall, Gosport, for the Town-hall Committee acting on behalf of the Local Board, Guardians, Overseers, and the Thorough Trustees, Messrs. Davis & Emanuel, architects, 2, Finsbury-estate, City. Quantities supplied by Mr. H. P. Foster, 5, John-street, Adelphi :—

Table listing tenders for Town-hall at Gosport: W. Hill & Co. (£9,561 0 0), Foster & Dickson (9,555 0 0), G. Burbidge, Southsea (9,363 0 0), J. Barton, Ryde (9,070 0 0), W. R. & G. Light, Portsmouth (8,520 0 0), W. Lowe, Gosport (8,788 4 10), J. Crook, Southampton (8,327 12 4), D. W. Lewis, Southsea (accepted) (7,906 11 0).

For cottage residence at Teddington, for Mr. G. H. Harrison. Mr. George A. Dunage, architect, 5, John-street, Adelphi :—

Table listing tenders for cottage residence at Teddington: J. & P. Hermon (21, King-street, St. James's) (£1,727 0 0).

For the erection of new buildings, consisting of cart-shed, stores, walls, &c., at the parish yard, Wandsworth-road, Clapham:—

Stewart	£390 0 0
Carnick & Sons	785 0 0
Dickeson	785 0 0
Garraat & Son	770 0 0
Leylands Bros.	740 5 0
Tickley & Appleton	715 0 0
Victory	686 10 0
Priestley	665 0 0
Jewell	669 0 0
Cooke & Co.	635 0 0
Hunt	633 0 0
Aldridge & Jevey	630 0 0
Feltham Bros.	625 0 0
J. Holloway	595 0 0
Howard	594 6 0

[Surveyor's estimate, £637.]

For forming a new road between Cold Harbour and Bridge-road, Poplar, to be called Managers'-street, for the Metropolitan Asylums Board. Messrs. A. & C. Harston, architects, 15, Leadenhall-street, E.C. Quantities not supplied:—

Adams, Hackney	£185 0 0
Victoria Stone Company	471 0 0
Raffy, Bromley	440 0 0
Moxlem & Co.	434 0 0
Novell & Robson	425 0 0
Beadell Bros., Eritth (accepted)	358 0 0

For enlargement of lecture-hall, Market-street, Clay Cross:—

C. W. Hays	£168 15 6
E. Tickler (accepted)	151 0 0

For the erection of a block of three small cottages at Crouchfield, Hemel Hempstead, for Mr. Thos. Donit, jun. Mr. W. A. Fisher, architect and surveyor, Hemel Hempstead:—

Lent, Piccott's End	£610 0 0
Plant, Hemel Hempstead	574 19 6
Horn, Hemel Hempstead	525 10 0
Mox, Two Waters (accepted)	458 0 0

For new premises at Lavender-hill, Clapham, for Messrs. Arding & Hobbs. Messrs. Tolley & Son, architects:—

Marriage (accepted)	£9,000 0 0
---------------------	------------

For additions to Bella Vue, Sydenham hill, for Mr. W. A. Little. Messrs. Tolley & Son, architects:—

Marriage	£780 0 0
Falkner	675 0 0
Keupp	670 0 0
Roberts (accepted)	646 0 0

For engineers' work at the new dining-hall for the Guardians of Hackney Union. Messrs. Leo & Smith, architects. Quantities by Mr. Walter Barnett:—

Newton, Chambers & Co.	£12,000 0 0
Thos. Horn & Son	8,978 0 0
C. Jeaker & Co.	9,150 0 0
Wm. Beuhau	8,730 0 0
J. Richmond	7,880 0 0
J. & F. May	6,708 0 0
Fraser & Fraser (accepted)	6,590 0 0

For foundations and basement on the Winchester Estate, Old Broad-street. Mr. F. T. Pilkington, architect. Quantities by Mr. W. Barnett:—

T. Boyce	£5,500 0 0
C. Shaw	5,000 0 0
J. Grover	5,250 0 0
W. Shurnar	5,830 0 0
Reading	5,521 0 0
Higgs & Hill	5,980 0 0
J. Moxlem	5,569 0 0
J. Moutter	5,444 0 0
Simpson	5,240 0 0
W. Brass	5,373 0 0

For heating workshops, Manchester, with their "small tube" registered hot-water apparatus:—

John Ki. g (Limited), Liverpool	£983 0 0
---------------------------------	----------

\* Accepted.

For extension of premises at 128, Goswell-road, for Messrs. Carter, Paterson, & Co., under the superintendence of Mr. William Eve, 10, Union-court:—

Lawrence	£1,680 0 0
Dovns	4,534 0 0
Bangs	4,304 0 0
Mortier	4,405 0 0
Harris & Wadrop	4,440 0 0
Higgs	4,280 0 0
D. D. & A. Brown (accepted)	4,189 0 0
Perry & Co. (error, tender withdrawn)	4,735 0 0

For the construction of the requisite works in laying and completing about three miles and a half of Birmingham Corporation Tramways, in Parade, Sand Fitz, Summer-hill, Spring-hill, and Dudley-road, to the borough boundary:—

J. Biggs, 3, Villars-road, Handsworth (accepted), at schedule of prices.	
--	--

For alterations and additions to St. Paul's Church, Knowbury, Saleop. Mr. Edward Turner, architect, Bowking-green-street, Leicester. Quantities supplied:—

Thrall & Payne, Leicester	£1,766 0 0
J. Grosveour, Ludlow	1,890 0 0

For alterations and additions to premises, Nursery-road, Reading, for Mrs. Vener. Mr. Joseph Greenaway, architect, 19, Duke-street, Reading:—

Simpson	£164 0 0
Polley	161 0 0
Goodchild	149 6 0
Hawkins	135 0 0

For alterations, &c., to the George and Dragon public-house, Hackney-road, for Messrs. Francis & Co. Messrs. Bird & Walters, architects:—

Mower	£225 0 0
Shurman	222 0 0
Jackson & Todd	210 0 0
J. Anley	215 0 0

Alterations and additions at 13, Orington-square.—Messrs. Scharian & Williams's tender in this list should have been stated as amounting to 1,723*l.*, not 1,787*l.* We inserted the list as sent.

New Methodist Free Church, Fockham.—The lowest tender for this work was that of Messrs. J. Allen & Sons, and T. Allen, as printed last week. Correspondents should be more exact in giving particulars, and more distinct in their handwriting.

Special Notice.—Lists of tenders frequently reach us too late for insertion. They should be delivered at our offices, 46, Catherine-street, Strand, W.C., not later than four p.m. on Thursdays.

TO CORRESPONDENTS.

T. L. B.—H. H.—H. P.—R. A. B.—G. H. B.  
All communications regarding literary and artistic matters should be addressed to THE EDITOR; all communications relating to advertisements and other exclusively business matters should be addressed to THE PUBLISHER, and not to the Editor.  
All statements of facts, lists of tenders, &c., must be accompanied by the name and address of the sender, but necessarily for publication. We are compelled to decline pointing out books and giving addresses.  
NOTE.—The responsibility of signed articles, and papers read at public meetings, rests, of course, with the authors. We cannot undertake to return rejected communications.  
Letters or communications (beyond mere news-items) which have been duplicated for other journals, are NOT DESIRED.

PUBLISHER'S NOTICES.

THE INDEX and TITLE-PAGE for Volume XLIV. (January to June, 1884) were given as a Supplement with the Number for July 15.  
A COLOURED TITLE-PAGE may be had, gratis, on personal application at the Office.  
CLOTH CASES for Binding the Numbers are now ready, price 2*s.* 6*d.* each; also  
READING-CASES (Cloth), with Straps, to hold a Month's Numbers. Price 2*s.* each; also  
THE FORTY-SIXTH VOLUME of "The Builder" (bound), price Twelve shillings and Sixpence.  
SUBSCRIBERS' VOLUMES, on being sent to the Office, will be bound at a cost of 2*s.* 6*d.* each.

CHARGES FOR ADVERTISEMENTS.  
SITUATIONS VACANT, PARTNERSHIPS, APPRENTICESHIPS, TRADE, AND GENERAL ADVERTISEMENTS.  
Six lines (about ten words) under... 2*s.* 6*d.*  
Each additional line (about ten words) ..... 6*d.*  
Terms for Series of Trade Advertisements, also for Special Advertisements on Front and Back Coverings, Contracts, Sales by Auction, &c., may be obtained on application to the Publisher.

SITUATIONS WANTED.  
FOUR LINES (about thirty words) or under ..... 2*s.* 6*d.*  
Each additional line (about ten words) ..... 6*d.*  
PREPARATION IS ABSOLUTELY NECESSARY.

\* \* \* \* \*  
Stamps must not be sent, but all small sums should be remitted by Cash in Registered Letter or by Money Order, payable at the Post-office, Covent-garden, W.C. to  
DOUGLAS FOUDBREYER, Publisher,  
Addressed to No. 46, Catherine-street, W.C.  
Advertisements for the current week's issue must reach the Office before THREE O'CLOCK P.M. ON THURSDAY.  
The Publisher cannot be responsible for DRAWINGS, TESTS, MONIALS, &c. left at the Office in reply to advertisements, and strongly recommends that of the latter COPIES ONLY should be sent.

TERMS OF SUBSCRIPTION.

"THE BUILDER" is supplied direct from the Office to residents in any part of the United Kingdom at the rate of 1*s.* per annum, PREPAID. To countries within the Postal Union, 2*s.* per annum. Remittances payable to DOUGLAS FOUDBREYER, Publisher, No. 46, Catherine-street, W.C.

SPECIAL.—ALTERATIONS IN FOUNDING ADVERTISEMENTS or ORDERS TO DISCONTINUE same, must reach the Office before TEN O'CLOCK on WEDNESDAY MORNINGS.

PERSONS Advertising in "The Builder," may have Replies addressed to the Office, 46, Catherine-street, Covent-garden, W.C. Free of charge. Letters will be forwarded if addressed envelopes are sent, together with sufficient stamps to cover the postage.

**Best Bath Stone.**  
WESTWOOD GROUND,  
Box Ground, Combe Down,  
Corsham Down,  
And Farleigh Down.  
RANDELL, SAUNDERS, & CO., Limited,  
Corsham, Wilts. [ADVT.]

### The Main Drainage of the Metropolis.

It appears from the historical sketch prefixed to the report of the Royal Commission on Metropolitan Sewage Discharge, that the subject of the drainage of surface-water had attracted the attention of the British Legislature at an early period. As far back as the reign of Henry III., and subsequently, in the reigns of Henry VI., Henry VII., and Henry VIII., laws were made regulating the conditions under which works for this purpose were to be executed. These Acts were, however, of a local character, and the first general Act was the Bill of Sewers which was passed in 1531, in the 23rd year of the reign of Henry VIII. This Act was continued, amended, and explained from time to time.

At the present moment, when public attention is being afresh directed to this momentous question, it may be useful to summarise briefly the main points in the modern history of London drainage.

In the year 1732 the river Fleet, which had been a navigable stream, and which conveyed the surface drainage of a considerable area of London to the Thames, was covered in and converted into a main sewer below Holborn. About the same time the Ranelagh sewer and King's Scholars' pond, which were formerly open ditches, were also closed in.

At the commencement of the present century it was penal to discharge sewage or other offensive matter into the sewers which were intended for surface drainage only. The sewage of the metropolis was collected into cesspools, which were emptied from time to time, and their contents conveyed into the country for application to the land.

About the year 1810 water-closets were introduced, which originally discharged into cesspools, but eventually overflow drains from the cesspools were formed, delivering into the sewers, whence the sewage was discharged into the Thames. In the course of time this practice polluted the river to such a degree that it became evident that some remedy was imperatively required, and many schemes were suggested for the purpose. As early as the year 1834 Mr. John Martin, the painter of "Belshazzar's Vision," the "Plains of Heaven," and other extraordinary pictures, proposed a scheme for intercepting the sewage in combina-

tion with a grand scheme for the embankment of the Thames. This scheme was rejected at the time as being of too costly a character, but was eventually carried out, only about twenty years after it was first proposed, by the Metropolitan Board of Works.

Some ten years later, namely in 1845, Mr. Thomas Wickstead renewed Martin's proposal, but suggested carrying the sewage to Barking Creek, on the north side of the river, and to Greenwich Marshes on the south side of the river, with the additional provision of deodorising the sewage before its discharge by means of chemicals.

In 1846 a company was established by Act of Parliament for the purpose of collecting the sewage from some of the principal metropolitan sewers and utilising it by applying the sewage to agricultural land. The attempt was, however, unsuccessful, and the project was soon afterwards abandoned.

The drainage of the metropolis was at that time under the charge of eight separate authorities, or, as they were then called, Commissioners of Sewers, each exercising independent jurisdiction within its own district. These bodies were abolished in 1848, and a royal warrant issued appointing a fresh Commission, consisting of twelve members for London outside the walls, and five *ex-officio* members for the City proper. This body was superseded by a further Commission appointed in 1849. The new Commission determined that the sewage should be kept out of the river altogether, and instructed their consulting engineer to prepare a scheme by which the sewers were to be made to deliver into large tanks, whence the sewage could be pumped and conveyed to the land outside the metropolis. A rival plan was proposed for intercepting the sewage and discharging it into the river beyond the metropolitan boundary.

A public competition was advertised for the best plan of dealing with the sewage, and 116 designs were sent in. The Commission were unable to decide on the designs submitted, and eventually the Commissioners resigned, and were succeeded by a third Commission, who reported on the 8th of March, 1850, that none of the designs sent in could be recommended for execution. The Commissioners eventually instructed Mr. Frank Forster, who had been an assistant of Robert Stephenson, to prepare a scheme for the main drainage of the metropolis, taking advantage of the various plans which had been suggested for that purpose. Mr. Forster accordingly prepared designs for the main drainage of the south side, with the assistance of two other officers of the Com-

mission, one of whom, Mr. John Grant, is now Assistant Engineer of the Metropolitan Board, and the other, Mr. Cressy, was for some time in the receipt of a retiring allowance from the same body. By this scheme it was proposed to form one main intercepting sewer, with a pumping station on the banks of the Ravensbourne river, and a second station in Woolwich Marshes. The sewage was proposed to be discharged into the Thames at the upper end of Woolwich Reach.

Mr. Forster prepared a further report on the drainage of the northern part of London, in the preparation of which he was assisted by Mr. William Haywood, the engineer to the City Commissioners of Sewers. This report was dated the 30th of January, 1851, and proposed to intercept the sewage by two main conduits converging on the east bank of the River Lea, where a pumping-station was to be erected. Thence the sewage was to be conveyed to Galleon's Reach, and discharged at high tide. The estimated cost of this scheme was a million and a half, exclusive of the cost of the acquisition of the land and compensation.

The third Commission having no funds at command to carry out the schemes proposed, was in its turn superseded, and a fourth Commission was appointed in 1852, which renewed the consideration of Mr. Forster's plans. Mr. Forster's health gave way; he resigned his position, and soon afterwards died. This Commission was succeeded by a fifth, appointed in the latter part of the year 1852, which had for some time under consideration a plan promoted by a private company, which was rejected by the House of Commons in 1853. Immediately after the failure of this project, the engineer to the Commission, Mr. (now Sir Joseph) Bazalgette, was instructed to prepare, in conjunction with Mr. Haywood, a scheme for the drainage of the north side of the Thames, taking for a basis the scheme proposed by Mr. Forster. This was done, and their plans were submitted and approved by the Commissioners in the early part of 1854. A serious difference of opinion took place between the Home Secretary and the Commissioners, the Home Secretary advocating the separation of the surface-water from the sewage, in consequence of which the Commissioners resigned. In 1854 a fifth Commission was appointed, partly nominated by the Government and partly by election. They invited fresh plans, but little progress was made with the question. The condition of the river, in consequence of the abolition of cesspools, and the substitution of water carriage, became worse and worse, and

the Government, recognising the impotency of mere Commissions to cope with the evil, resolved to create a new representative body, to whom the task of purifying the river should be confided. A Bill was accordingly introduced into Parliament constituting the Metropolitan Board of Works, which received the Royal assent on the 16th of August, 1855, and came into operation on the 1st of January, 1856. The chief duty of the Board, as defined by the Act, is the construction of "such sewers and works as they may think necessary for preventing all or any part of the sewage within the metropolis from flowing or passing into the river Thames in or near the Metropolis." By the 136th Section any plan for the disposal of the sewage is to be approved by the Government Board of Works. In accordance with this proviso a plan, prepared by the Engineer to the Metropolitan Board, was submitted to Sir Benjamin Hall, the First Commissioner of Works, as early as the 3rd of June, 1856, or very nearly within six months of the date when the Act of Parliament came into operation. This plan was objected to by the First Commissioner of Works, and a second plan, showing the outfalls removed two or three miles lower down the river, was afterwards submitted for approval.

This plan was also vetoed, on the ground that the position of the proposed outfalls would allow the sewage to return into the metropolitan area. The two plans submitted by the Board were considered by the First Commissioner to be wholly at variance with the spirit and intent of the Act and the intention of the Legislature. In the meantime the First Commissioner consulted Captain Burstal as to the nearest point at which the sewage might be discharged into the river without the possibility of its flowing back into the metropolis. Captain Burstal advised that the nearest point at which the outfall should be formed was the upper part of Erith Reach, nearly opposite Rainham Creek, on the south side, and at Rainham Creek on the north side. The Board adopted this recommendation, and forwarded a third scheme embodying the alteration in the position of the outfalls suggested. The First Commissioner resolved about this time to appoint an independent Board of professional advisers to report upon the whole question of metropolitan drainage, including the means for utilising the sewage, a strong feeling having been expressed by some members of the Board that sewage might be made a source of profit.

The referees so appointed, consisting of Captain Douglas Galton, Mr. James Simpson, and Mr. T. E. Blackwell, having collected information from a variety of sources, and examined a number of schemes which were submitted to them, presented, in July, 1857, a report, in which they expressed a strong opinion that the plan proposed by the Board was insufficient, inasmuch as it did not provide for the removal of a sufficient quantity of sewage from the metropolitan district, including the prospective increase in the population of such district, and that the provision for the removal of storm-water during rain was not carried to the extent necessary to prevent the pollution of the river. Subsequent events have justified the apprehensions entertained by the referees, it having been recently found necessary to supplement the system of sewerage originally laid down by the Board at an estimated cost of about a million and a half.

As regards the disposal of the sewage the referees reported that they considered that the best mode of dealing with it would be to discharge it in such a manner that it will be rapidly and certainly mixed with large volumes of water and be finally carried to the sea. The points selected for the outfalls were one on the north side of the river very near Mucking Lighthouse in Sea Reach, and the other on the south side at Higham Creek near the Lower Hope. The referees proposed that the sewage should be carried to these points by a main channel on each side of the river, delivering at low water; that on the north side would have been about twenty miles long, and that on the south side about sixteen miles and a half long, measuring from the boundary of the metro-

polis. It was not at first proposed to cover these channels except where they passed through populous neighbourhoods, or where they were formed in tunnels underground.

The Metropolitan Board objected to the scheme suggested by the referees, the main grounds of objection being the locality of the outfalls and the length of the long outfall sewers leading thereto. A conference took place between the various parties interested at the office of the First Commissioner, in the course of which a question was asked, as to whether the Government would defray the cost of carrying the outfalls to Sea Reach; but to this there was no favourable reply. The vestries about this time, true to the eternal spirit of Vestrydom, urged the Board not to assent to any scheme for carrying the sewage beyond a point that would satisfy the requirements of the statute, and on the 16th of November the Board passed a resolution affirming the principle that it would be unjust to the rate-payers to extend the outfall to Sea Reach, and that to do so would be a contravention of the intention of the Legislature.

In November, 1857, the Metropolitan Board referred the various reports that had been submitted to their engineer, with whom were associated Mr. Hawksley and Mr. Bidder, with instructions to report as to the best means of carrying out the main drainage of the metropolis, with an estimate of carrying the sewage to Erith Reach and Sea Reach respectively. On the 6th of August, 1858, Mr. Bazalgette and his coadjutors made their report, which was of a very exhaustive character, and virtually settled the system which was ultimately carried out. The consideration of this report was delayed for some time, and in the meanwhile a change of Government took place, and Sir B. Hall was succeeded by Lord John Manners as First Commissioner of Works. Sir Benjamin Hall being in opposition, was able to take a more liberal view of the duties of the Government with regard to the drainage of London, and expressed an opinion that the time had come when the Government should take the matter into their own hands, the work being of too great a magnitude to be undertaken by the local authority. Stimulated by a prospect of Government interference, the Metropolitan Board passed a resolution approving of the main features of their Engineer's report, and appointed a deputation from their body to explain the scheme to the new First Commissioner, and to point out to him the difficulties with which the Board had to contend, from the fact that their designs were required to be approved by the Government. The representations of the Board were effectual, and a Bill was introduced to relieve the Board from the necessity of obtaining the sanction of the Government to their scheme for the drainage of the metropolis, which became law on the 2nd of August, 1858. The Board were further empowered to borrow money to the extent of three millions, and the time for executing the works was extended to the end of 1863. It appears from the debates upon the Bill that it was felt that the scheme proposed by the Board for the disposal of the sewage was not final, and that it might be necessary eventually to carry the sewage to the sea; but it was clearly seen that the construction of intercepting sewers was a necessary preliminary to the carrying out of any system of main drainage, and that the decision as to the distance of the outfalls from the metropolis might be postponed for a time.

Immediately after the passing of the Act the Metropolitan Board took the matter earnestly in hand; the drawings were speedily completed, and contracts entered into for the construction of the works, which by the year 1863 were sufficiently completed to allow of temporary arrangements being made for the discharge of a portion of the northern sewage at Barking. The northern and southern outfalls were completed in 1864. In 1865 the great drainage system was declared open by the Prince of Wales on the 4th of April in that year. The north low-level sewer was not completed until the year 1875, this portion of the work having been delayed by the con-

struction of the Thames Embankment, of which it formed part.

In 1881 it was found necessary to enlarge the drainage system by the addition of relief sewers in the low-lying districts, the estimated cost of the works being one million and a half. It was also resolved to increase the capacity of the reservoirs at Barking and Crossness outfalls, to about 50 per cent. beyond their original size, at an estimate of about 160,000*l.* These works are at present in progress.

The estimate of the cost of the works, as recommended in Sir Joseph Bazalgette's report of 1858, was 2,300,000*l.*, and the further cost of carrying the sewage to Erith was estimated at 350,000*l.*, making a total of two millions and three quarters, while the cost of extending the outfall to Sea Reach was estimated at 2,950,000*l.*, making a total of five millions and a quarter. The total amount expended by the Board on main drainage and main sewers, up to the end of 1883, was 5,939,056*l.*, or very nearly six millions of money.

Such is the story of "penny-wise, pound-foolish," for which we are now suffering payment, literally, through the nose, besides being threatened with "what worse remains behind."

#### THE WAR OFFICE AND ADMIRALTY COMPETITION DESIGNS.\*

**R**ESUMING our remarks on the selected designs, we observe that Messrs. Maxwell & Tuke take no notice of the Horse Guards building. They divide up the whole front, emphasising the centre with projecting blocks which mark the lines of building beyond, and which form lofty square towers crowned with octagon towers and roofs. Similar towers, smaller and of less height, form the end features of the front. The carriage-entrance not being in the centre of the building, but between the north and one of the central towers, they have endeavoured to mask it with a colonnade, but we doubt whether it was worth while doing so. The St. James's Park elevation is similarly treated to that in Whitehall, the corner towers, however, being of greater magnitude (53 ft. square). The arrangement of pediment and corner towers which decorate the centre block is weakly designed. In their treatment of the stories they rusticate both ground-floor and first floor, the latter with greater richness; in the towers and projected blocks a Corinthian order runs through two stories (second and third), and between them through one story only. This arrangement is not happy, as it gives too much importance to the second floor.

Messrs. Spalding & Auld's design would appear to have been chosen for plan only; their elevations are suggestive of a Crystal Palace bazaar, and their perspectives too terrible both in design and drawing to be described.

Mr. Porter's design also owes its chief merit to the lighting of the plan, and to the idea of setting back the centre portion of the building. He makes no attempt at grouping his stories, and reproduces features already well known at Burlington House.

Messrs. Aston Webb & Ingress Bell and Messrs. Glover & Salter both depart from the styles hitherto adopted in the Government buildings in Whitehall; the former reproducing a simple but effective version of the François Premier style, or early French Renaissance, and the latter, what is now known as Burges Gothic.

Messrs. Webb & Bell, recognising the impossibility of showing any important and lofty building well in the narrow part of Whitehall, have set back their front some 62 ft., bringing out the two ends as wings, a favourite old English method of treating principal elevations. The recessed front is relieved by a projecting block 125 ft. wide, the centre portion of which rises higher than the rest, forming a sort of tower. There is a similar feature in the centre of the St. James's Park front, as well as at each of

\* See p. 181, ante.

the ends, and the other two fronts are variations of the same. In the angle of the south and west elevations fronting the Horse Guards Parade is a lofty well-designed tower, rising about 200 ft., with an open loggia at the top and crowned by a pyramidal roof. There is a second tower at the north-east angle of the Spring-gardens front. No regard is paid to the low buildings of the Horse Guards, which sink into absolute insignificance by the side of Messrs. Webb & Bell's lofty mass. In their relative treatment of the several stories the lower story is rusticated with alternating quoins to the window dressings. The two next floors, or rather the second floor and mezzanine, are grouped together; that is to say, the window mouldings run one into another on the projecting blocks; between them they are enclosed in an arcade, which forms one of the prettiest features of the building. On the Whitehall side scarcely any projection is given to this arcade; on the St. James's Park, Spring-gardens, and Parade side (south front) it projects 6 ft., or rather the wall above and behind is recessed 6 ft., and on the west side facing the parade it forms a balcony 20 ft. deep, whence the evolutions in the Parade can be witnessed by the head officials and their friends. The rooms on the first floor, which rise the full 28 ft., have millioned and transomed windows, with small pediments over them. A band of ornament, in which the anchor, rose, and crown are conspicuous features, runs round the whole building above this double floor, marks its importance, and ties the building together. On the second-floor story the windows have architrave mouldings round and between the blocks, and above the arcade a further enrichment of flat pilasters, the same treatment being adopted for the third floor, which is crowned by cornice and balustrade. Lofty roofs terminate the building, with dormer windows of simple design, which are destined, even at 100 ft. from the ground, to light offices and other rooms for which Messrs. Webb & Bell have not been able to find room elsewhere. The general effect of their building is not palatial, however; it is most skilfully and artistically grouped; but, after all, it is more suggestive of magnificent residential flats than of a public monument. They send in a very fine drawing of the interior of one of the glazed courts before spoken of. Its effect would have been infinitely better if they had omitted the two upper stories, and the second and third floor corridors would have been better lighted.

Messrs. Glover & Salter have not done their Whitehall front justice by taking their point of view from an impossible position. As shown, it looks like a design for two separate buildings with variations of treatment. The right-hand block has the centre portion carried up to some sort of tower; the left-hand building, corner towers of different heights and a centre gable with corner turrets. If this gable had been omitted and the other towers had changed places, it seems to us the two buildings would have better balanced. The St. James's Park front is very much better, and is very palatial in its appearance. The ground-floor should have been left plain without window mouldings, and treated in the same way as the windows in the towers, and the general effect of the building would have gained, as the whole front is too equally enriched. Had the competition taken place in 1866, this design might have been the selected one, *mais nous avons changé tout cela*.

Before entering into a detailed account of the arrangements of the successful and other plans, it would be as well to note that prior to the first competition a very complete schedule of all the requirements was issued by the Board of Works Department. The programme defined the relative position to be occupied by the War Office and Admiralty on the site,—the requirements as regards carriage entrances to the principal courtyards (the plural of the latter word showing that the promoters of the competition were quite unable to foresee that there would be in most of the selected designs only one principal courtyard), intercommunication between the two departments on each floor, a complete list of every room required,

and of the position it should occupy relative to other rooms on the same and other floors, and a tabular statement of all the rooms, showing their area, number of clerks occupying each, and the approximate superficial area to be occupied by each department.

Notwithstanding the amount of information thus given, it was still necessary to read between the lines, and numberless questions were constantly being sent to the Board of Works, which they steadily refused to answer. In this we consider they were mistaken. The principal disadvantage of a competition is that the competitors are, as a rule, expressly forbidden to obtain any information from precisely those authorities (viz., the promoters) who are the only ones capable of giving it. It was rumoured that the Board of Works had prepared plans themselves, by which all others would be judged. We may safely say now that their plans were quite different in principle from those actually selected. Be that as it may, it would have been quite feasible for the Board of Works to have intimated to the competitors that any questions submitted to them before a certain epoch would receive their favourable consideration, and that those questions which were worth answering, together with the answers, would be published a week afterwards. The object of both promoters and competitors being to produce the best design, this undertaking would probably have saved an immense amount of wasted labour on the part of the unsuccessful competitors, and might have resulted in the production of a more useful series of plans than those which are now the property of the Government. As it was, those who had friends at court consulted them, and the competitor who got hold of the best man possibly had an advantage over his less successful rivals.

The problem, therefore, settled itself down into a gigantic puzzle, and those who were fortunate enough to have been able to shake the rooms down into their right places and to unite the same with a skilful arrangement in the lighting and ventilation of the corridors and grouping of departments were selected for the second competition.

The instructions issued for the second competition laid stress only on the importance of duly considering the sanitary problems in connexion with the building; the proper ventilation of closets; the advisability of having a carriage entrance into Spring-gardens (which most had given); and facilities for intercommunication with the Horse Guards.

The relative position of the principal rooms in the two departments having been more or less defined, the selection of the successful plan seems to have depended chiefly on the principle of lighting the corridor, skilful grouping of the offices of one department together, and providing that privacy in its arrangement and separation from other sub-departments which in some cases were desirable.

The plans of Messrs. Leeming & Leeming are admirably arranged in these particulars. The south-west block of their building, viz., Park, is devoted on first floor to the higher officials of the War Office Departments A and E, with a private staircase for their separate use. In like manner the north-west wing of the building is kept apart for the higher officials of the Admiralty, A, also with their special private stairs; and the block east of it for the Controller and the E department.

Messrs. Leeming place their principal entrance to the War Office under the loggia by the side of the carriage-entrance, not a very dignified entrance; in the arrangement of this and of the vestibule they show a want of knowledge of Classic planning. They provide an entrance in the middle of their long court, and they have private entrances from St. James's Park for the staff suite. The Secretary of State's room is placed in the angle of the south and west fronts, the Commander-in-Chief being on the Parade front, separated by an ante-room (through which, by the way, they must both pass to enter their rooms). The other rooms of the Secretary of State's department continue along the west front. The Commander-in-

Chief's department (E) continues along the south front facing the parade, and half of it overlooks the centre court. The principal rooms of the Accountant-General's department (D), on the first floor, is on the west front, overlooking the parade, and department B overlooks Whitehall. The defects of the arrangement seen to us to lie in the separation of the Financial Secretary from his department D, and the Surveyor of Ordnance from his department B. The placing of the War Office Library on the valuable space of the ground-floor when it might have been placed on the third seems also to us to be a great mistake. The principal entrance to the Admiralty is in Whitehall, on the other side of the loggia to that of the War Office, and with a similar vestibule, in which there seems to be a waste of space. There is also an entrance from the centre of the court, and private entrances for staff suite from Spring-gardens; besides these are four other entrances under the carriage-way exit into Spring-gardens, which we presume are intended only for the clerks of the department, and are necessitated by the cutting through of the building with a carriage-way. In this respect the plan is inferior to that of Messrs. Verity & Hunt, who, taking their carriage exit the shortest distance into the *cul-de-sac*, cut off only the Whitehall block, in which they place the department F, as on that floor it needs no intercommunication with the rest of the building. The Hydrographer and Director of Works in this department (Admiralty) are too far apart. There do not seem to be any special staircases, either, for messengers, which should have been in connexion with their lobbies. Looking at the sanitary and closet arrangements, they appear to us to be defective so far as the number of closets is concerned, there being apparently only six to each floor in each department, exclusive of one or two private ones; this is just about half the number which would be required, and has been provided for, in the other designs. The closets are defectively lighted, and are placed in the internal angle of two walls at right angles to one another,—the worst possible position. We have already referred to the narrowness of the central court, and to the bad proportion given to some of the rooms; in this specially directing attention to what appear to us to be defects in the plan, we are actuated not by the desire of finding fault, but of suggesting alterations and reconsideration whilst there is yet time. If the depth of the rooms facing the Parade and court were decreased to 20 ft., and less projection given to some of the blocks, 10 ft. or 12 ft. could be gained to add to the width of the central court, but this would not widen the court sufficiently to get rid of the objection on sanitary grounds to a court so narrow in proportion to its height, in which the evil which attaches to even the largest quadrangles, of the formation of strata of stagnant air in the angles,\* would extend itself nearly to the whole area of the court.

Messrs. Verity & Hunt provide their principal entrance to the War Office from Whitehall, making it the central feature of their principal elevation; they have another entrance from the centre of their court, and three private entrances from the Parade and St. James's Park. The Secretary of State and Commander-in-Chief are given rooms of equal importance in size and position (which shows greater wisdom than that laid down in the instructions); each also has his private staircase and own ante-room independent of the one common to and between both their rooms; each also has his closet, in which and in other respects Messrs. Verity & Hunt have arranged their plan better than Messrs. Leeming & Leeming. The Commander-in-Chief's room coming so low down on the south side, his

\* The present editor of this journal, in an article a few months since in the *Fortnightly Review* ("How our Public Works are carried out"), pointed out in strong terms beforehand, in reference to this building, the sanitary objections to closed quadrangles for what are practically residential buildings, and suggested that, if such a form of building must be adopted, it should be with partially open angle staircase or communication towers, which would both admit circulation of air, and form a source of special architectural effect; and the late editor of the *Builder*, Mr. G. Godwin, who has preached so much (often to sadly deaf ears) on the subject of sanitation, made a similar protest in a letter in the *Times* of Thursday last.

department E occupies the first floor rooms along the west front facing the Parade and across into the Whitehall front. The Secretary of State's department A runs round the remainder of the south and one-third of the west front. Department B occupies the first and second floor overlooking the court; and D, which it was suggested in the conditions might be placed in one block, is taken to the second floor over the Parade and St. James's Park. The principal entrance to the Admiralty is in the centre of the court, east side; and there is a second one opposite the War Office entrance, exclusive of the private entrance for the staff suite.

The First Lord is placed in the centre of the St. James's Park elevation, which accounts for the bow-window we have objected to externally. The other Naval Lords have their rooms also facing the park, and the remainder of the department over Spring-gardens. Messrs. Verity & Hunt retain the privacy of the official corridors, by making the inner or central court corridor the only public one, and it is impossible to pass from it into the other without crossing a messenger's lobby. They have also messengers' stairs round the lift in all their lobbies. The defects in their plan, compared with Messrs. Leeming & Leeming's, are that their staircases are not so well lighted (generally speaking, top light only), and that in their corridor courts, although they are 5 ft. wider, they are not so long as Messrs. Leeming & Leeming's, who, above the first floor, open them out to 110 ft. in length. The closets, sixteen on each floor to the War Office, and fourteen to the Admiralty, are well placed and ventilated, being placed across some of the corridor courts. We note that private closets have been supplied to the principal rooms in the Admiralty, not where they were required, but where they could be conveniently placed. Thus the Civil Lord is provided with one to himself, whilst the first, second, and third Naval Lords have none.

Messrs. Aston Webb & Ingress Bell attach so much importance to the ventilation of all their closets that they make both the Commander-in-Chief and Secretary of State walk down two corridors to reach theirs, an arrangement to which they would possibly demur; there are at first sight too few closets, but as, from the wasteful arrangement of plan, Messrs. Webb & Bell only place on the east floor two-thirds of the accommodation given by other competitors, probably in adding the extra floors they provide the same as in the other designs. Messrs. Webb & Bell provide one principal entrance from Whitehall for the War Office, and one from Spring-gardens for the Admiralty; to the latter there is also an entrance from under the carriage exit into Spring-gardens or a special one if this is omitted. Besides these and private entrances there is one common to both War Office and Admiralty in the centre of the court. There is a great waste of space in their designs; the entrances are too large; the centre one in the court, with council-room over, seems to have been introduced for artistic effect, and they provide refreshment-rooms on each floor, which were not asked for; some of the arrangements also are defective, as, for instance, when in three cases they separate the principal offices in the Commander-in-Chief's department from their confidential clerks'. They take credit to themselves for having provided much more accommodation than was asked for, but it has been done by increasing the number of floors and the height to which the clerks would have to ascend, and therefore at the expense of their convenience.

Messrs. Stark & Lindsay provide principal entrances for both departments from Whitehall, two provided with porches in their main court, and two minor ones, the staircase in each case being in close proximity. There are apparently no private staircases for the Commander-in-Chief and Secretary of State, and the arrangement of the closets in ante-rooms is clumsy. Sufficient space for the Secretary of State's department has not been left to give more than four rooms facing St. James's Park; the others being obliged to content themselves with the court prospect, which is a mistake. The Financial Secretary and Surveyor-General

of Ordnance are also separated from department A, contrary to the instructions.

Messrs. Hall & Powell place the principal entrances to the two departments within the principal court, and provide covered porches, which, however, are too long, considering that there will never be many people to set down at the same time, as ministerial receptions will never be held in these buildings. Their Secretary of State for War and Commander-in-Chief's rooms are arranged in the same way, and in the same position as Messrs. Verity & Hunt's; the private staircases, however, are not contiguous to their rooms, but have to be reached across a corridor. The arrangements in the Admiralty department are similar to those in Messrs. Leeming & Leeming's plan; the isolation of the two departments A and E is better provided for in the two-wing blocks of the latter. Some of the staircases are not well lighted, and the corridor courts are too small, being about 20 ft. by 25 ft., as against 30 ft. by 40 ft., in Messrs. Verity & Hunt's, and 25 ft. by 110 ft., in Messrs. Leeming & Leeming's design, above the first floor. The waiting and interview rooms are placed in the same position as these latter, viz., deriving their light from the small corridor courts; they are not likely, therefore, to be seized upon as offices by clerks discontented with upper floors.

Messrs. Spalding & Auld, in their double corridor blocks on the St. James's Park side, give undue importance to the stairs leading to the basement, and by covering their corridor courts over the ground-floor deprive the basement of light and ventilation. It is only on the first floor and above that they provide the double corridor, lighted through the courts; the width of the corridor on the ground-floor and basement being added to the rooms, making them 28 ft. to 33 ft. deep.

Messrs. Maxwell & Tuke's plan does not gain on careful examination. Courts covered over with glass are highly objectionable and unhealthy. They become intensely hot in summer, and the rooms looking out on them are deprived of both light and air. The departments are not grouped so well as in some of the other plans, and there is not the same supervision over admission to corridors, private or otherwise; some of the rooms in the Admiralty could be entered by any one coming from Whitehall through the central court without passing any messenger's lobby.

Messrs. Glover & Salter do not comply with the instructions as regards the proximity of the Secretary of State for War and the Commander-in-Chief's rooms. Instead of one ante-room there are four or five offices between. Not content with running a carriage-entrance through the small north court, where it is not required, they provide one into St. James's Park, where it was expressly forbidden. We presume that it was the style of their elevations which resulted in their design being chosen among the nine, for surely no one could for a moment accept the principle of lighting and ventilating two corridors and five or six floors of closets by a well-hole 10 ft. by 8 ft., that being the size of the corridor courts which they provide.

Mr. Porter's court, opening into Whitehall, and his extravagant allowance for entrance saloons elsewhere, provides for about two-thirds only of the accommodation required on the first floor, and, like Messrs. Webb & Bell, he has to make up for it by adding a mezzanine floor for repositories (which in most cases are not lighted at all) and an extra basement. The isolation of the south block in Whitehall from the remainder of the War Office Department would be a great inconvenience, especially for the Financial Secretary, who is quite cut off from the department he has to deal with. No light is provided to the side corridors in his plan. The staircases are insufficiently lighted by top lights only, and he makes no attempt to provide private entrances or staircases for the staff suite or private retiring-rooms for the heads of departments.

This terminates our general description of the designs; having carefully examined them all, we are of opinion that, on the whole, the best plan has been chosen, and as regards the

general effect of the St. James's Park view we think Messrs. Leeming & Leeming's design groups fairly well, and has a pleasing skyline. As it is now proposed to carry out this design, we venture to offer a few suggestions, and first to express the hope that a model will be prepared to a sufficiently large scale to enable one to judge of grouping and of detail. To think that the quarter-inch detail is actually going to be built as a portion of one of our public buildings is really uncomfortable to contemplate. We have already suggested that the ground-floor story should be rusticated between the piers; that the latter and the Corinthian order above should have their projections diminished, and that, if possible, the coupled windows on the second floor and the triplets on the first floor should be exchanged for single square-headed windows; if it be considered that more than one window is absolutely required, it will then be better to give up the Corinthian order going through the two floors, adopt an order for each (as in Messrs. Stark & Lindsay's design), and have triplet windows, as shown in their front elevation, on the left-hand side. The coupled windows, with the keystone and "the sweet little cherub that sits up aloft," which decorates the second floor, never will accord with the great Corinthian order. We have suggested certain modifications in the west front facing the Parade, viz.: the lowering of that portion of the elevation adjoining to and in line with the Horse Guards; to complete what we said about it before, it will be necessary to bring the lofty tower from Whitehall, and place it in the angle, as Messrs. Webb & Bell have done, between the two fronts facing the Parade, instead of the insignificant lantern there now. The tower will then form a centre of interest, group with the projecting blocks on the south and west elevations, and allow of a low block of buildings adjoining the Horse Guards. To place such a tower anywhere in Whitehall would obviously be absurd, and the design for the tower being good it seems to be a pity to lose it; in addition to this we consider that if the upper square portion of the corner towers of St. James's Park front (as much as rises above the roof) were diminished in height 10 ft. to 15 ft., the remainder of the building would gain in scale. The Whitehall front, as designed in the first competition, and modified in the second, is so hopeless that it will have to be remodelled. In doing this, one of two courses must be adopted; the carriage-entrance must either be placed in a centre between two projecting blocks, or it must be contrived in the middle of one projecting block. The first course would result in a treatment similar to that adopted by Messrs. Stark & Lindsay and by Messrs. Hall & Powell. The second will be a modification of their altered design as sent in. The central block, with entrance archway, should be retained, and one of the small projecting blocks now on the left-hand side of the front placed at the extreme corner on the right; this would leave space for six bays or five Corinthian columns between (six would have been better); repeating the same features on the other side of the central block would occupy about 270 ft. of the whole length; the remainder should be kept down one story and curved round as in Messrs. Stark & Lindsay's design, or lowered as in Messrs. Hall & Powell's design, so as to merge into the level of the Horse Guards. This would carry out the suggestions (before alluded to) of Mr. Shaw-Lefevre, and would prevent the Horse Guards, which is really a well-proportioned building, and refined in style, being spoilt. It should be understood that the chief fault in Messrs. Leeming & Leeming's present design is not that they carry their carriage-way through a projecting block, but that, having done so, they design another block to pair with it in which there could be no archway; worse than that, by adding two pediments carried on coupled columns on each side of the central gate they emphasise its irregularity and call attention to it. There is an inequality in the number of the columns between the blocks which is perplexing; the difference between three and four columns is not sufficient and is too much, besides which, strange to say, the inter-

columns of the great columns is not the same throughout the elevation. In the Great Court, without there being any absolute need for it, they have placed their entrances out of the centre, an arrangement most objectionable to any one with a true Classic feeling for design: there was no necessity for it, the vestibule and waiting-room might have changed places in the War Office, and the Admiralty subscription library might have been shifted to the other side of the waiting-room on the Admiralty side, and then the entrances could have been brought to the centre. It is precisely these little vagaries which make us afraid of what may happen in the execution of the work, when draughtsmanship will not count for much. The effect of the interior of this principal court would be much improved if an order to each story were adopted instead of the single order running through two floors, which tends to dwarf the court, and is not required there for palatial appearance. The same remark applies here to the single round-headed windows of the second floor, to which we have alluded when speaking of the quarter-inch detail; they are, and always will be, out of scale with the large order. We must say, in conclusion, that we consider it most unfortunate the judges did not advise the selection of one or two designs on the grounds of merit in architectural composition. We have already seen two whose architecture was quite equal, if not superior, to the best of those set in, and there are others who competed who could not have conceived anything so defective in scale and purity of design as the elevations of the successful competitors, though possibly the draughtsmanship might have been inferior.

THE NEW SCULPTURE COURT AT SOUTH KENSINGTON.

THE remarkable collection of casts in the new gallery at South Kensington, which is entered from the left of the architectural court, enables the visitor to see before him at a glance the progress of Greek sculpture, from the rude efforts and naive expression of its childhood, to the magnificent development under Pheidias of an art perfectly balanced, intellectually and physically, and representing the abstract ideal of humanity in the persons of heroes and anthropomorphic divinities. Thence he may note the intrusion of the individual and realistic feeling in sculpture, under the influence of which the productions of the art become more decisively the work of special artists employing each his own peculiar method, and the subjects and their treatment become less ideal and abstract, and partake of the character of *genre* or even of portrait representation. He may trace the further progress of the realistic and prosaic feeling in some of the works of the Roman period, in which the representation of personal expression is more marked than it ever was in the more abstract art of the Greeks, as in the sad and pathetic figure of Agrippina the younger (243 in the catalogue of the collection). The collection does not follow out the subject to the actual decadence of sculpture in the later Roman period, though the subject is touched upon sufficiently in the conclusion of the preface to the catalogue, in which Mr. Perry glances at the curious historic facts as to the influence of Christianity on art of this class. The utter degradation of plastic art, he observes, is shown in the magnificent porphyry sarcophagus of Constantia, the daughter of Constantine, which is now in the Vatican:—

"The subject, and the subject alone, reminds us of Greek art, for it is derived from the worship of Bacchus; but the representations are used to represent Christian ideas. In this case the imbecility of the artist, and the meanness and poverty of the work, are thrown into striking relief by the coarseness of the material, the elaborate care and infinite labour expended on the execution, and the rank and celebrity of the personage whose remains it enshrined. We see that the unhappy sculptor was not only devoid of all inventive and creative power, but incapable even of *imitating*, like his predecessors of the time of Hadrian, with skill and good judgment. Greek sculpture, the child of Greek religion,

the nursing of freedom, the companion of poetry, architecture, and painting, which had survived the fall of Greece and Macedonia, was buried beneath the ruins of the Roman Empire. The new and purer faith which succeeded to Greek and Roman Polytheism led to no revival of plastic art. The Christian inherited from the Jew the commandment of the Decalogue. 'Thou shalt not make to thyself any graven image.' The one God whom they worshipped in common was 'a spirit whom no eye hath seen or can see,' and the promised Messiah was 'a man of sorrows and acquainted with grief, who when we beheld Him has no beauty that we should desire Him.' And so Art sank to rise again like the pale ghost of its former self at the so-called Renaissance, with the revival of humanism, and the revolt of a luxurious and semi-heathen society against the abstract spirituality and the ascetic morality of one section of the Christian Church."

This consideration brings into high relief the ever-veiled question of the relation between morality (in the widest sense) and art. Sculpture, dealing with form rather than with expression,—for we are nearly all agreed that intensity of expression is hardly within the scope of sculpture, or, at least, is a hazardous experiment,—not unnaturally flourished most in times and among people with whom bodily form and the perfecting of the physical state of the body were matters of high interest; and it might even seem as if the most favourable atmosphere for sculpture was that in which, morally as well as physically, the natural man prevails over the spiritual man, and that times of licence and disregard for any restraining laws were favourable to the luxuriance of the art. This is the conclusion to which Mr. Perry's sentence, quoted above, would lead, and the conclusion which was substantially adopted by Winckelmann and echoed in the writings of such critics as Mr. Pater, whose early essay on Winckelmann and his views was about as pure a piece of paganism as ever was indited. But there are comparisons to be made in the Gallery at Kensington which may give us pause before adopting this conclusion. If we compare the "Apoxomenos" (173), the statue of a young man scraping himself with a strigil, with the nude heroes of the Parthenon, we cannot but see that the former, splendid as it is in execution and in its representation of the most perfectly shaped male form, represents a purely animal beauty; whereas in the Theseus and Hyllus, if the figures were in the same state of preservation, we should see equal perfection of form accompanied by that intellectual dignity and expression which gives the last and highest interest to sculpture, and which can hardly co-exist with a low state of moral feeling. The "Apoxomenos" is a realistic translation of natural form and action pure and simple. As Mr. Perry says,—"The style of this great work is perfectly free from all conventionality, and shows that the artist copied nature alone; the hair, especially, is here thrown about in the most easy and natural manner. The very nature of his occupation implies a constant change of posture, and we see from the position of his feet that the attitude is accidental and momentary, and one of a series of graceful movements. The face, which is simple and agreeable, shows the gentle satisfaction arising from successful labour. The Apoxomenos is a grand example of the *genre* style in its highest form."

This is perfectly true, and the work is all that is said; but it almost remains a question, was the result worth the consummate skill employed in producing it? and does not such a work, in intellectual value, rank below not only the Parthenon nude figures, but below such a draped figure as that grand portrait statue of Sophocles in the Lateran (224 at Kensington). The latter is an expression of the highest human dignity and intellectual character; the Apoxomenos is only a splendid specimen of the animal called "homo."

The collection commences with a cast of a portion of the bronze Balawat gates, followed by that of the famous lions and their column from Mykenæ (as we are now asked to write it). Mr. Perry denies the very early date of this monument, and says pointedly that "we have only to compare this work with the undoubted Assyrian sculptures to detect in it the Greek desire to be true to nature." The details,

as now brought before us in the cast, tend to bear out this remark, which must, however, be taken also to separate from the Greek art the grotesque metopes from Selinus, which may be taken as showing how practically distant then were places really so near each other as Sicily and Greece, when these rustic specimens of art could be produced on an important temple in Sicily at a period when Greek art had at least entered upon the discovery of something very different from these childlike attempts. Stiff as the Branchidae figures are, they are works of serious art as compared with the alto-reliefs of Selinus. One of the interesting fragments among the earlier works in the collection is a small bas-relief of a succession of dancers from Branchidae, of the end of the sixth century B.C., "important as one of the earliest examples of the stratified arrangement of figures, so that one figure is partially covered by another," as in the Parthenon frieze.

One of the strange facts which recent researches have brought out into new light, and which is largely illustrated in the Gallery of Casts, is the existence of a "pre-Raffaellite" movement in Greece and Rome under the Empire,—a fact of great importance in its bearing upon the real significance of the modern movements of the same tendency. We see, hence, that affectation of archaism is no new thing; that it is apparently a natural tendency in certain stages of highly cultivated society. One of the most notable examples is the "Athene Promachos" (58), in which, while the figure itself is stiff and archaic, the border of the garment is worked with small figures in bas-relief in a perfectly free style. The "Archaistic Pallas" from Herculaneum (59) is still more remarkable, and represents a feeling and treatment exactly analogous to that which has pervaded some of our modern stained glass designers. There is nothing new under the sun. We should suppose that the ancient pre-Raffaellite movement originated in Rome, and that the Greek artists of the day recognised the demand, and laid themselves out to supply it.

The immense progress and change which took place in the art of sculpture in Greece within two or three centuries, as brought into such prominent light by the juxtaposition of so many works in this gallery, form a remarkable testimony of the extraordinary artistic vitality of the period. Within that short period the whole range, from the stiff, artificial figures of the seventh century B.C., to the splendid work of the fifth, and the exquisitely finished naturalism and *genre* of the fourth, was run through. That there will ever be such a time for sculpture again can hardly be hoped, for never again in the history of the world is there likely to be a nation combining such intellectual force and energy and civilisation with so much freedom in regard to the display of the body and so much of open-air life. Modern civilisation has shut itself up in clothes, and in clothes for the most part of a peculiarly unsculpturesque type; and, say what we will, the masses of the people are out of harmony with such work as Greek sculpture, and can only be got to like or understand it by a kind of surgical operation. The tendency of such collections as that at South Kensington, of course, may be in time to familiarise and harmonise the mind of the people more with the antique ideal, and render it a less distant and *outré* thing to them. Whatever we may think as to the future possibilities of sculpture, however, it is a satisfaction to think that we have so many of the productions of the great age of the art left to us as an eternal possession, now reproduced and multiplied in so many ways that we need never fear their loss, and may consider at leisure in what way we can turn to account the lessons to be derived from them.

One lesson other than artistic may be suggested, perhaps, by the proximity of the Health Exhibition to the South Kensington Museum, that of the heathy of the physically healthy body when not cramped and spoiled by conventional habits and conventional garments. Look at that same Apoxomenos, for instance, which is the model of manly physical health; look at the Niobe or the Sophocles in their

grandly-folding robes, giving dignity without cramping the figure in any way; and then go over to "The Healtheries" and look at some of the cases into which the human figure has been forced, as exhibited both in the "historic dresses," and in some of those unhistoric ones that are moving about in the show, and see "what a deformed thief this fashion is." The collection of antique costumes has, in fact, far closer relation to the Health Exhibition than half the objects within its walls.

## NOTES.

**A**FTER a smart discussion, the House of Commons in Supply on Thursday, the 7th, induced the First Commissioner of Works to postpone the demand for the requisite funds to carry out the proposed alterations to Westminster Hall, and to ask for an *ad interim* vote of 3,000*l.* for repairing the buttresses, which was agreed to, and which is, of course, an immediately necessary operation, considering the state of the work. Perhaps even those most interested in carrying out the work will subsequently see that it was just as well not to spend so much money in a Medieval restoration without consideration, especially as that restoration will not carry out the practical objects put forth; a point to which we saw no reference made in the discussion. The open cloister will not do much to conserve the Norman wall, and its dimensions will be so cramped as to render it inconvenient as a carriage porch. These practical points seem to be left out of consideration in a scheme which is purely an affair of sentiment.

**I**T appears that the competition for the Dublin Science and Art Museum has resembled most other architectural competitions in its economical aspect. The cost of the designs has been found to be considerably above the architect's estimate. The Chancellor of the Exchequer, in reply to a "question," at the latter end of last week, said that "the Consultative Committee recommended a design by Messrs. Deane; but when the cost of this came to be worked out it was found to amount to 140,000*l.* (the competition having been invited for a building to cost 110,000*l.*) It then became necessary to ascertain whether any other design came within the prescribed limits as to cost. The Consultative Committee recommended a second and a third as admissible; but the cost of these has been estimated, and we have learned that each of them would be slightly in excess of 140,000*l.* We are thus reduced to the position of abandoning the designs altogether, or of consenting to accept Messrs. Deane's design, with a possibility of effecting some economies in its details, and although we cannot but deplore the excess above the limit in which the competitors indulged, it has been determined to accept Messrs. Deane's design." On the whole, Messrs. Deane may be said to be exceptionally fortunate competitors; but on the other hand, it must be said that to find the three leading architects in a large competition all exceeding the stipulated limit of cost by about 30,000*l.* is not a circumstance calculated to raise our ideas as to the value and efficacy of the competition system as a means of securing public interest in architectural matters. Probably all these gentlemen were betrayed into exceeding the limits of cost in the anxiety of each to produce the most attractive design; and if Messrs. Deane had been asked straight off to design a building to cost 110,000*l.*, they could have done so. In this instance, therefore, the competition system has brought forward no new talent, as Messrs. Deane had already made their reputation, and the announcement of instituting the competition has cost 30,000*l.*

**T**HE London and South-Western Railway Company have received a pretty sharp rebuke in the terms of Colonel Rich's report upon the causes of the late fatal accident between Downton and Breamore, and one which certainly does not come too soon.

Colonel Rich has no doubt that the accident was caused by the train having been run at too great speed over a weak road. The train having two engines and eight short vehicles with short wheel bases, was not calculated to run steadily at great speed over a line of such gradients and curves. He adds:—

"The London and South-Western Railway Company have had three cases of passenger-trains leaving the rails since September last. The first, which occurred near Portsmouth, was caused by the great oscillation of the last coach of the train. The oscillation made the springs of the coach turn over, and then it left the rails. This coach was of bad construction. The second, which occurred at Brockhurst, in January, was caused, like the present disaster, by a train, made up of inferior rolling stock, being run at express speed along an old and very light permanent way. The numerous complaints which have been made of the violent shaking which passengers experience when travelling on parts of the London and South-Western Railway leave no room to doubt that a great deal of reform in the management and improvement in the working of this railway is required. I believe the complaints are caused in a great measure by bad driving, using inferior stock, and by the coaches in the trains not being properly coupled up. I would strongly urge the Company to make a thorough examination of their system and stock, to classify the drivers, to classify their stock, to classify their several lines and parts of their system, and to classify their trains. It cannot be expected that the whole of a company's stock and railway shall be of the best description, but the public has a right to expect that old and inferior stock shall not be run over old, weak, and inferior parts of the railway, such a species to make it unpleasant and dangerous to all that use it."

The Board of Trade point out to the company the serious and grave responsibility they will incur if they do not take immediate steps to improve both road and rolling-stock. The peculiar idiosyncrasies of carriage action on the railway in question are familiar to all who travel on it in fast trains, though few passengers probably trouble their heads to think of the reasons for them. Now that these have been pointed out by Colonel Rich and emphasised by the Board of Trade, there will probably supervene a prudent desire on the part of the public to avoid the railway in question as much as possible, until it shall have certified itself reformed.

**T**HE announcement has been made from Cairo that if an expedition for the relief of General Gordon, for the preparations for which Parliament was lately asked to sanction a supplementary vote to the extent of 300,000*l.*, is finally determined on, the operations will be undertaken on the Nile itself *via* Dongola, and that the scheme of the Berber-Suakin Railway may be considered as abandoned. The railway plant which has been already landed at Suakin will be sent on to India, where it will, probably, be utilised on the frontier, and be of infinitely more importance than it could have been in the Soudan. Our readers will remember that we recently pointed out that the Nile was the real Highway of Egypt, and that it would be well for those concerned in the welfare of that country to set about removing or overcoming the existing impediments to its effective navigation. The Mudir of Dongola offers to place 1,000 men to haul steamers over the Second Cataract. If it is possible to effect this by human power, how much more easily and effectively could it be accomplished by the application of a little engineering knowledge? When penning our remarks on the Suakin-Berber Railway we little expected to see the suggestions then made so soon carried out.

**T**HE advocates of additional locks and weirs on the Thames below Richmond have been fittingly replied to by Mr. Redman in a letter to the *Times*, in which he points out "the necessity of watching with the greatest attention any attempt to obstruct circulation in the channel of our great commercial river lower down stream." The weirs would not be any obstruction to the flow of the flood waters, and the intermediate ponds created by them would, when once filled, require only the quantity taken off by evaporation to maintain them; but it is the obstruction to the free flow of *tidal* water which would prove so mischievous. What, then, is to be thought of

a proposal which was recently seriously suggested at the Balloon Society as one that must ultimately be adopted, to the effect that the whole river to Gravesend would have to be locked up, and that no satisfactory arrangement could ever be arrived at either for purposes of navigation or for the disposal of the sewage question until the river was thus manipulated! Every infringement on or curtailment in the dimensions of a tidal river produces a corresponding deteriorating effect on its *embouchure*; and the public, as we have before hinted, would do wisely to listen to such practical authorities as Mr. Redman rather than to the wild suggestions of people who make it their particular boast that they are "not scientific."

**W**E learn from the *American Architect* that the publication in our columns (March 15 of this year) of the names of architects who have engaged not to enter into any competitions unless the award is made with the aid of a professional adviser, has stimulated our American contemporary to offer to its readers the consideration of a somewhat similar proposition, bearing the signature of the Secretary of the American Institute of Architects, and inviting architects to pledge themselves not to compete unless the conditions of the competition are such as to insure to the competing architects the following conditions:—

1. To issue a programme prepared with the help of an architect, such architect or his partners to be debarré from competing.
2. To have at least one architect as member of the jury of award, such architect to have the casting-vote in event of a tie.
3. To assure to the architect securing the award of the jury the execution of his design (if the building is built) at the regular compensation of five per cent. on the entire cost of the work.
4. To make no use whatsoever of rejected designs, but to return all such to their authors without loss of time.
5. To pay to the successful architect, in case it is found necessary to abandon the project, the commission regularly charged for so much of the usual professional work as has actually been performed by him, such charge being the usual percentage computed on the estimated cost of the design which it is now found inadvisable to carry into execution.

The term "public building" is understood to include all national, State, county, and municipal edifices, but does not refer to buildings erected through the enterprise of private individuals. We are glad to find that the prominence given to the list in the *Builder* has been the means of suggesting an invitation to the members of the profession in America to adopt the same course, and we hope the appeal will be largely responded to.

**A**T the Educational Conference last week Dr. Jex Blake read a paper on School Museums of Science and Art, dwelling with emphasis on the value of a School Art Museum, an institution which, he believed, Rugby alone at present possessed. The idea was received, he said, with much laughter at first, and they were told they could neither get funds to build and equip such a museum, nor boys to enter it when built. They did, however, raise the funds, 9,000*l.*, needed to build the art museum and Temple reading-room, with curator's house, opened in 1879; they had been given objects to help to start it worth about 4,000*l.*; and they had, by a charge of 10*s.* 6*d.* a year on every master and on every boy who had voluntarily used the museum, bought during the last five years about 1,000*l.* worth of carefully-selected objects. Dr. Jex Blake went on to speak of the value of such a museum as subsidiary to school teaching:—

"It supplied the drawing-master with excellent examples, in both form and colour. It supplied the classical and historical teacher with the original of many a simile in the old poets; with the photograph of many a classical site, temple, or ruin; with the portrait, on coin or medallion, if not in life-size bust, of many an emperor, king, reigning favourite, general, or statesman; with the emblems of scores of cities in Italy, Greece, Asia Minor, and the Isles of the *Ægean*; with the whole scenes from the civic or religious life of Greece, as in the reproduction of the Panathenic Procession from the Elgin marbles; and to the student of the Middle Ages or the Renaissance was of more obvious value still. Indirectly, an art museum was a great instrument

or refining and elevating taste, and since they had had an art museum, a totally different and vastly better style of decoration had been adopted by the boys in their private rooms, called studies, at Rugby."

We hope both that the Art Museum at Rugby may continue to flourish and increase, and that other great schools will follow the example of Rugby. If an art museum, and periodical lectures in it, were part of the curriculum of our great schools, we should, perhaps, not hear such a proportion of nonsense spoken in our Legislative Assembly whenever such subjects come on the *tapis*.

**T**HE case of the Direct Spanish Telegraph Company v. Shepherd, which is published in the current numbers of the legal reports, decides an important point in connexion with the renting of buildings. The plaintiffs and the defendant were lessees and lessor, and there was a covenant in their lease that "the lessor will during the said term pay all rates and taxes payable in respect of the demised premises, except for gas consumed by the lessees." On the one hand the lessees said that this meant that the landlord would pay the water-rates; on the other the lessor said that water-rates did not fall within the covenant, since they were not properly rates at all, but only charges for goods supplied. It is unnecessary to discuss the argument at length, it is sufficient to say that the Court decided that the agreement in question included water-rates. The decision will, of course, govern all similar cases, and must be borne in mind in drawing up agreements.

**A** CASE for compensation, on account of the death of two children by the fall of the chimney at Bradford two years ago, which came before Mr. Justice Manisty at Leeds on Wednesday last, came to no result, through the inability of the jury to agree. They agreed in considering the chimney a dangerous structure when it was built, and "a very dangerous structure on and after the 20th of December, 1882," but could not agree as to fixing responsibility on any one. As judgment may be moved for in the Divisional Court, we refrain from any comment on the case; on the general question of the accident and the verdict of the coroner's jury we expressed ourselves strongly at the time.

**T**HE reply of Captain Gullett, R.N., in command of the training ship *Wasp*, to the statement that "the measures for the deodorisation of the London sewage had proved successful," should be studied by every one who takes an interest in the purity of the river, or in the safety of London. It should be compared with the conversation on the same subject in the House of Commons on the 8th current. The use of permanganate of potash at 130l. per ton for merely rendering the exhalations less offensive, has not, as may be readily understood, been carried on to any considerable extent. It would be interesting to know whether the experimental use of this costly oxygenator by any chance coincided with the visit of the deputation of the Metropolitan Board to Barking. But even the use of the comparatively cheap disinfectant, perchloride of lime, costing only 9l. per ton, at the rate of thirty tons per day, will form an item in the cost of concentration that London will not like to pay. Two hundred and seventy pounds a day comes to 97,59l. a year,—for palliation alone! No wonder that the Local Government Board "are not prepared to express an opinion as to the effect of the means adopted by the Metropolitan Board of Works." We venture to suggest that unless some one be prepared to express an opinion shortly and decisively, the public will be apt to form, and to express, a very decided opinion of its own.

**I**N reference to the recent accident on the steep portion of the Highgate Tramway, we have received an explanatory circular, which is not very clear in its language. The main paragraph is as follows:—

"The driver on the descending car, having confidence in the sufficiency of his wheel-brakes alone, neglected to make the slipper-brake connexion with

the car attached. In descending the hill the cable runs out of the gripper, and the car descends by gravitation to a point about 30 ft. below, when the cable is again taken up by the gripper, and the car then proceeds at the same rate of speed as that of the travelling cable. In this instance the absence of the powerful slipper-brake allowed the car to run past the usual point, and, gaining momentum in its progress, came into collision with the car at the bottom of the hill, thereby injuring one inside passenger and one outside passenger. When the driver found that the car was skidding only with the wheel-brakes he at once called upon the conductor, who was beside him collecting fares, to return to the car and apply the slipper-brake, but in jumping off to do this the conductor fell heavily upon some loose stones and was left behind. This was really the most unfortunate part of the occurrence, because the driver, not knowing the conductor had fallen, continued to stand by the wheel-brakes instead of returning to the car and applying the slipper-brake as he otherwise would have done."

It seems unquestionable that there was either ignorance or considerable carelessness on the part of the driver; but there seems no need for any repetition of such an accident with proper caution, and probably the incident will lead to greater care in future.

**T**OO much publicity cannot be given to the sad accident to which a surgeon of the Lewes Infirmary calls attention in the *Times*. Serious injuries were received by an unfortunate railway labourer on the London and Lewes line from a bottle thrown from a passing train, which struck the poor man in the face and caused fearful injuries. If the people who travel in fast trains are so stupid that they cannot realise that a bottle thrown out of a carriage window strikes any one who may be in the way with the full speed at which the train may be going, the act ought, in the protection of life and limb, to be made a criminal one, and the thoughtless perpetrators rendered subject to fine or imprisonment, as the only lesson they seem able to appreciate.

**W**E have received the prospectus of the proposed Exhibition of Inventions which is to be the attraction of Exhibition-road next year, in the place of "the Healtheries." The two main divisions, inventions and "music," seem rather oddly assorted. The first division is to include "apparatus, appliances, processes, and products, invented or brought into use since 1862" (what a medley it will be!), and the second division will include "examples of musical instruments of a date not earlier than the commencement of the present century," and machinery or appliances connected with their manufacture or use, and historic collections of musical instruments or of engravings or paintings representing musical subjects. It appears to us that this is an absolute plethora of objects of interest, which will be too large for any one to study. It would have been better to be content next year with "Inventions" (surely a large enough field), and leave music to follow in 1886.

#### THE SANITARY AND INSANITARY HOUSES AT THE HEALTH EXHIBITION.

The educational value of that popular place of resort familiarly known as "The Healtheries" has been greatly augmented by the opening of the Sanitary and Insanitary Houses, which have been erected under the supervision of a special committee consisting of Mr. H. H. Collins, F.R.I.B.A., Professor Corfield, Mr. Rogers Field, M.Inst.C.E., Captain Douglas Galton, and Mr. Ernest Turner, F.R.I.B.A., than whom no better representatives of the architectural, engineering, and medical professions could have been selected for the purpose. They have carried out their work on the whole in a very satisfactory manner, especially when it is borne in mind that they had very limited funds and space at their disposal. We speak altogether without reference to the façades of the houses, which are merely intended to represent those of typical commonplace dwellings of their size. A "Guide" to the two houses is in preparation, and we have been favoured with advance proof-slips of the same. In the preface the objects aimed at in the construction of the two houses are briefly stated, though it is hardly correct to speak of the

houses as two "full-sized models of houses." All the details shown are, it is true, of full-size, but several of the "rooms" in which they are shown are much smaller than would be the case in houses of the external appearance of those here represented, and in some cases they are mere strips or corridors, so that it would perhaps be more exact to speak of the collective exhibit as "two full-sized sections of houses," while an explanatory note or sentences should be added with the view of making it clear to non-technical visitors that the awkward shapes and limited cubical capacity of the rooms, even in the Sanitary House, are not in any way to be taken as models for imitation, except in regard to the means adopted for making them habitable,—for beyond doubt such rooms exist in vast numbers in actual buildings. Many and flagrant are the defects illustrated in the Insanitary House, there are one or two notorious sanitary shortcomings which are not illustrated by it. For instance, we noticed no "bedroom" built without a fireplace,—a means of ventilation the presence of which should always be insisted upon in the absence of other special appliances, for however comfortable and pleasant it may be in torrid weather like that now prevailing for people to sleep with their bedroom windows open, it is hardly possible to follow this course in the severe winter months, at any rate not with windows of ordinary construction. Tens of thousands of houses are to be found in London with at least one "bedroom" bereft of fireplace and all other means of ventilation except the window and such providential assistance as is afforded by chinks and cracks in scamped joiners' work. In hotels and boarding-houses not specially built for their purposes it is a very common thing to find what was originally one large room divided by partitions into three or four smaller rooms. The existing fireplace cannot be divided or distributed among the smaller rooms, so it remains (when it is not foolishly blocked up by a screen) for the benefit of one room out of the three or four. It never enters the mind of the "spirited proprietor" to provide any means of ventilation (other than that afforded by the windows) for the two or three rooms thus left without fireplaces. By dividing up a large house in this way it is easy to provide sleeping-rooms for a much greater number of people than it would otherwise accommodate. But when the number of people sleeping on a given number of floors in such establishments is largely increased, additional accommodation in the shape of water-closets is rendered necessary, and these have too often been placed in any dark and ill-ventilated corner that could be found for them, sometimes with their doors actually cheek-by-jowl with bedroom doors. And, in many instances, what closets they are! Either they will be of the now generally condemned (generally condemned, that is, by all sanitarians) pan-closet type, with their filthy iron "containers," or they will be old, badly-made, or worn-out valve-closets, which refuse to hold water in the basin, even when there is a proper flush available, which is not always the case. Now that people are "on the wing," and are crowding into seaside hotels and lodging-houses, we cannot urge them too strongly to look into some of these questions for themselves,—to mind where they sleep: if within measurable distance of a water-closet, to see what sort of condition it is in, and to inquire how far they may be prejudicially affected by it.

To return to the Sanitary and Insanitary houses at the Health Exhibition. The committee whose names we have already given claim,—and we think with justice,—not to have exaggerated defects in the Insanitary House. Although there are thousands of houses which do not contain all the sanitary defects here illustrated (simply because all houses are not provided with baths, housemaids' sinks, &c.,—not, of course, that such things are insanitary in themselves, but they are generally improperly fitted and connected with drains, and so bring sewer gas into the houses), we believe it to be impossible to find any house, however costly and luxuriously appointed (unless built or overhauled of late years under the direction of architects who have given attention to sanitation), in which there will not be found several of the most glaring defects which are now to be seen exposed at Kensington. Many of the shortcomings here "shown up" are almost universally to be found in our houses, and it is

to be hoped the public will really be induced to study what is now set before them, and to compare what they see at the Exhibition with what they have in their own homes. They may take it for granted that the things condemned are condemned for good reasons, and that the appliances and methods recommended for adoption fully meet the requirements of the best principles of sanitation, without calling for needless expenditure. The committee "wish it to be understood most distinctly that while they have of necessity selected for the purpose of illustration fittings made by particular manufacturers, they do not wish to give the idea that the fittings adopted are superior to those of similar types produced by other makers." In many cases, as they point out, there are several appliances equally efficient to those which are used, although limited space would not permit examples of all varieties of good appliances to be shown. This is very fairly put, and, in view of some correspondence on the point which we published a few months ago, we are bound to say that the committee's performance is in accordance with their words. Names of manufacturers whose appliances are used are not needlessly paraded, although they are recorded in the Guide. The Committee, indeed, have, as far as possible, chosen illustrative apparatus and appliances which do not bear their manufacturers' names. Possibly the labels describing the insanitary fittings are here and there somewhat too brief and too technical in their wording to be easily comprehended by the average visitor into whose hands the "Guide" may not fall. This shortcoming, as we conceive it to be, might be usefully met, we think, by displaying, adjoining the label, a clearly-drawn section, properly figured and lettered, showing the points which are commended or condemned; and it would be additionally instructive if, alongside the section of the good or had appliance, a section of its *opposite* were shown. Thus, in the Insanitary House, the drawing showing the dangerous appliance should be accompanied by a drawing showing the safe and healthy appliance; while in the Sanitary House the diagram of the sanitary fittings should be accompanied by one showing "How not to do it." The drawings or diagrams which we suggest should be similar to those given by Mr. Frégin Teale in a work published by him a few years ago on "Dangers to Health." We are led to make these observations in consequence of remarks which we heard fall from some of the visitors the other day. Referring to certain of the fittings in the Insanitary House, we heard more than one person say, in effect, "How can that be unhealthy? We have exactly the same kind of thing in our house, and that is not unhealthy!" Beyond doubt large numbers of people enjoy (or appear to enjoy) immunity from diseases likely to be engendered by the improper and defective sanitary fittings of their houses; but, on the other hand, perhaps equally large numbers suffer from apparently minor disorders and illnesses or physical disabilities which come upon them they know not how, but which sanitarians shrewdly suspect to be due to the absence of properly-devised, properly-constructed, and properly-fixed, sanitary fittings. It should not be forgotten, in these days of elaborate systems of sewerage, that the ignorance or cupidity of a builder or plumber (or their workmen) may result in sewer gas being effectually "laid-on" to a house without the supply being suspected or discovered for a long time.

For these reasons we are glad that visitors to the Health Exhibition may now easily (if they will spare an hour or two from pleasure for observation and thought) master the nature of the sanitary defects to be looked for (only too surely to be found) in their houses, and at the same time make themselves conversant with the sanitary principles necessary to be observed in the production and maintenance of a healthy house. "Something wrong with the drains" is a common explanation of illness in a house, but, as the Committee point out, the healthiness of a house depends on numerous conditions besides those of drainage and water supply, as,—to cite another instance within the control of the architect and builder,—in the matter of provision for ventilation and the removal of products of gas combustion. The Sanitary House illustrates some good and simple devices for ventilation, one of the most notable of which is very easily adaptable to every sash window, viz., the provision of a deep bend on the sill, so

as to allow of ventilation at the meeting-rails by slightly raising the lower sash. The means of draughtless ventilation thus to be obtained for a trifling sum paid to a carpenter for making the alteration is not by any means new; this particular method of obtaining ventilation has been before the public and the building trade for many years, but has not been adopted to any considerable extent. The same remark applies to other contrivances and their applications to be seen in the Insanitary House. We trust that this apathy as to things essential to a healthy dwelling may be greatly shaken by the lessons afforded by the Sanitary and Insanitary Houses at the Exhibition; but if this feature of the Exhibition is to be made the most of, the appliances requiring water for illustration should be more efficiently supplied with it than they were at the time of our visit.

The various defects and their remedies which are illustrated by the two houses form a long catalogue, there being upwards of one hundred items. Many of these are, of course, "doubles" or repetitions (in different situations) of identical points. But, even allowing for this, the number of details in which it is necessary to observe the recognised principles of sanitation is considerable in a house of any size, for they include water-supply fittings, baths, water-closets, lavatories, sinks, drains, and soil-pipes, and their proper and allowable connexion with each other, to say nothing of foundations, damp-courses, sanitary materials for construction, &c. We do not propose on the present occasion to enumerate all these details, but we shall return to the subject, merely premising that all the defects which are "shown up" in the Insanitary House have been condemned by us and by sanitarians generally for many years past, and that the means shown in the Sanitary House for obviating them have had our unremitting advocacy and encouragement.

#### THE LATE M. PAUL ABADIE.

OUR readers can recall the visit made on the 11th of June last by 300 French architects, assembled in congress, to the works in progress at the Church of the Sacred Heart at Paris. The master of the work, M. Paul Abadie, did the honours of his beautiful edifice; and in congratulating him his *confères* inscribed themselves to be invited by himself to the ceremony of inauguration. Since then, M. Abadie had assisted on the various juries of the competitions of the Académie des Beaux-Arts; and on Saturday, the 2nd of August, he met his colleagues of the Institut for the award of the Grand Prix d'Architecture. It was but a few hours after, on his return to Chateau, where he possessed a charming summer residence, that he fell struck by an apoplectic fit.

Notwithstanding the holidays and the almost general dispersion of the colleagues and friends of this eminent architect, numerous was the audience which, without official state, rendered to him the last honours on the following 5th of August, and listened at the cemetery to the speeches pronounced by M. Eug. Guillaume, of the Académie des Beaux-Arts; by M. Alfred Normand, of the Société Centrale des Architectes; by M. Henry Révoil, diocesan architect; and by Le P. Montazeau of the *cercle* of working masons and stonecutters; and all were thinking that the mortal remains of the master should repose, not in the village cemetery, but in the crypt of his own monument, in a vault at the Church of the Sacred Heart, beside the spot reserved for the prelate who initiated the work.

English architects in their French travels should not omit to visit the provinces of Angoumois, Périgord, and Bordeaux, where are to be found a number of interesting edifices, restored or built by M. Abadie (to whom Paris has not long owed his last work, the Church of the Sacred Heart), but we think that there is profit for all in reviewing briefly the beautiful works executed between 1814 and 1874 by M. Abadie in the centre and west of France, at Périgueux, at Angoulême, and at Bordeaux, and with these alone we can occupy ourselves here.

Grandson of a plasterer of Bordeaux, and son of Paul Abadie, architect of the Department of La Charente, M. Abadie, born at Paris in 1812, studied painting and architecture in the curriculum of the École des Beaux Arts, and was presented by his Professor, M. Achille Leclerc,

for the competition of the Grand Prix d'Architecture in 1839. He passed immediately after into the service of the Bâtimens civils, which he quitted in 1847 to take up the position of Inspecteur at the restoration works of Notre Dame, Paris, under the order of M. Lassus and M. Viollet-le-Duc. But in 1849 M. Abadie, attached in 1844 as architect to the Commission of Monuments Historiques, was nominated auditor to the Cultes and diocesan architect to the dioceses of Angoulême, Périgueux, and to a portion of that of Bordeaux, and to him we owe in this beautiful region of the Romano-Byzantine architecture of France, the construction or the restoration of more than thirty cathedrals, churches, chapels, or towers, and some civil edifices of genuine interest, all works upon which we have taken in former times, in the company of M. Abadie, numerous notes, which we abbreviate below, so as to mention the most important.

*Cathedral of Périgueux* (Dordogne).—Beyond the works of general consolidation, notably the renewal of the substructure of the pillars of the cupola of the crossing and of that of the south bay, M. Abadie had to reconstruct almost completely the cupolas with small bells of this cathedral and its apsidal chapel.

*Cathedral of Angoulême* (Charente).—The restoration of the principal façade of this church, which appears to-day as it was originally, the small steeples, and a crowning pediment placed on an arcade, as well as the reconstruction of the north steeple, are beautiful works of architecture and archaeology.

*Church of St. Michel d'Entraygues* (Charente). This church, to-day completely restored, date 1127, presents this curious particular of being a French edifice which, by its octagonal plan, enriched by a circular apse on each side, recalls the better Church of San Vitale at Ravenna.

*Church of St. Michael at Bordeaux* (Gironde). Remarkable work of total reconstruction with enlargement at the base. The spire alone, which is 75 metres in height, raises itself to a total height of 112 metres.

*Churches of St. Ausone and St. Martial at Angoulême*.—These two modern buildings, one First Pointed in style (*ogival primaire*), and the other in the Transitional Romanesque style, present a porch with clock-tower, and a nave and aisles behind, a transept with a square choir for the first, and a choir with a circular apse for the second.

*Church of Notre Dame at Bergerac* (Dordogne). A work of much importance, in the First Pointed style, presenting a porch with steeple of 80 metres, nave with aisles, transept and choir, with radiating chapels, the entire edifice having a length of 96 metres.

*Church of St. Ferdinand at Bordeaux*.—A work equally important and of the same style, but with square choir and two steeples.

*Church of St. Genès at Périgueux and Church of St. Bernard at Mussidan* (Dordogne).—Two buildings in the Pointed style, presenting porch and single nave, transept, choir with apse, and steeple.

*Hôtel de Ville, Angoulême*.—Perhaps the most remarkable edifice of all this branch of the work of M. Abadie, who essayed with boldness and success, in France, in the middle of the nineteenth century, the construction of an Hôtel de Ville, recalling the communal mansions, and the palaces of the consuls or *eschiers* of the Middle Ages. The principal façade of this Hôtel de Ville, with its architecture of transition from the Romanesque to the Pointed style, with its buttresses, its pointed arches, and its twin windows, with its belfry more than sixty metres in height, is invested with a beautiful dignity; but that opposite on the Rue de Plaisance, showing on its first story the great bays which indicate the Salle des Fêtes, and more remarkably still, the façades, as well as those to the court, the vestibules, and staircases, indicate sincere research and a profound feeling for the architecture of the Middle Ages, imitated in its principles and broad lines, but wisely M. Abadie has repudiated whimsicalities and capricious exaggerations. It is a brilliant brief in stone on behalf of an architectural epoch which our own has too often extolled or decried; but which few artists have, as M. Abadie did, studied with conscientiousness, and in dealing with which few have been inspired with so much success.

A FRENCH ARCHITECT,  
Hon. and Corresponding Member, R.I.B.A.  
August 9, 1884.

THE ARCHITECTURAL ASSOCIATION'S  
EXCURSION.

BURY ST. EDMUNDS, the head-quarters of this year's excursion of the Architectural Association, has a history extending back far beyond any period of English architecture which has ever interested the students who make these annual trips, even under the excellent influence of the late Mr. Sharpe. It was far away in the really dark ages of the earlier centuries of our era that the place first assumed a form as the home and dwelling of one Beodric, and became, in course of time, the seat of a monastery and church founded in honour of the Virgin. Beodrics Weorthe, as it was then called, might never have emerged from obscurity had it not been for the cruel slaughter by the Danes of Edmund, a local chieftain much beloved by his people. Such was the veneration in which this leader had been held, that after his death he was canonised, his body was brought to Beodrics Weorthe, and shed such a lustre of sanctity over the place that presently the small monastery grew into a large and powerful abbey,—one of the largest and proudest that England has ever seen,—and the town which grew round it was called the Burgh or Bury of St. Edmund. The monastery was freed from episcopal authority; the abbot was mitred, and exercised a jurisdiction such as had few parallels in the kingdom,—that of the Bishop of Durham being the only one quite comparable. The abbey itself was worthy of its lord. Its precincts embraced a vast area, and enclosed a great extent of building. The abbey church was one of the largest in the land; and, as handmaidens to it, there were, in close proximity, three others, two of which remain to the present day, eloquent witnesses of the former splendour of the foundation. Quaint old Fuller bears his testimony in his wondrous manner. There was formerly, he says, "so magnificent an abbey church in Bury, that the sun shined not on a fairer, with three lesser churches waiting thereon in the same chureyard. Of those, but two are extant at this day, and those right stately structures:—

"And if the servants we so much commend,

"What was the mistress whom they did attend?"

This enormous abbey church was built by the first abbot after the Conquest, and gradually extended itself until, in the course of time, and soon after the erection of the two churches which still remain, came that great blow to ecclesiastical architecture, the dissolution, and behold! the fabric crumbled to pieces, grass silently covered the floors, flowers bloomed over the roofless walls, trees vied in bulk with the columns of the steeple; and now, over the house where Abbot Hugo hurried himself out of sight and memory of his troubles, spreads a fair expanse of gardens, wherein the youth of St. Edmund's Bury delights to wander. Few are as the remnants of the monastic buildings, there still remain the two great gateways, some 150 yards apart: one raised in later years, the other the very gateway beneath which Monk Samson hurried after his companions with his frock skirts looped over his elbow, when they were bound on that important mission which ended in Samson's becoming the Lord Abbot.

But these are things at present only cursorily examined by the excursionists. Their work hitherto has lain farther afield.

Mildenhall was the first place visited. To reach it the road passes near several villages of historical interest. At Fornham St. Genevieve, for instance, a considerable battle was fought, late in the twelfth century, and a few years before monk Samson became abbot. The then Earl of Leicester, for some reason (and very little reason seems to have sufficed a baron in those days), rose against his king without success. He fled abroad, and presently returned with an army of Flemings, with whose help he hoped to take St. Edmund's Bury; but before he reached the town he was met by the Lord Chief Justice of the day, who had studied war to as good effect as law, and was smitten hip and thigh, and summarily committed,—Countess, Flemings, and all,—to the sluggish waters of the Lark. Relics of the battle have been found from time to time,—swords, skulls, and a ring, presumably the property of the Countess. But nothing of all this turmoil shows itself to the nineteenth century, and the Flemings sleep beneath the fields as quietly as in a graveyard, except that a bone now and then turns up to prove that they are not wholly a myth. All the country between Bury and Mildenhall has

remains of ancient civilisation,—of a kind. In the name Icklingham, another village passed *en route*, the memory of the Iceni, the first recorded inhabitants, is said to linger. Here also went a Roman road, the Ickfield Way, and just off it are the remains of a Roman villa. But when the guide-book says the pavement of the chancel of Icklingham All Saints is Roman, it misses the mark by a good many centuries. From Icklingham the road passes across open "plains" and near tumuli, and so at last to Mildenhall.

The church and the Manor House were down on the programme, but the former is by far the most interesting, and speaks of a prosperity somewhat diminished from the times when Mildenhall was the centre of a large timber trade, and was much resorted to for the purchase of fish. But that was before the draining of the fens, which has left the town rather stranded. Fuller says that the parochial churches of Suffolk are "no one of transcendent eminency"; but herein he does the county somewhat of an injustice; for Mildenhall, Lavenham, and Melford really reach his standard, not to mention others which are not included in the Association's programme. The chief glory of Mildenhall is its timber roofs, elaborately carved, with bold brackets, and great angels with outspread wings steadfastly gazing on the floor. These angels are quite the most striking part of the design, though the purist some few years back might have objected that they were too important for mere accessories. Outside, the principal interest lies in the north aisle and porch, a piece of beautiful design, late in date, but with greater chances of being well designed in consequence.

The Hall offers little attraction to the architect, much of its original seventeenth-century character having disappeared. There are fragments of panelling inside, and in a room hung with tapestry is a portrait of Catherine of Braganza, said to have been sent to Charles II. "for approbation of the person." If so, the sample seems to have given satisfaction, for she became queen. This portrait bears out Evelyn's criticisms which implied that greater beauty was to be found in the king's own realm; though we see nothing here of "her teeth wronging her mouth by sticking a little too far out."

From Mildenhall the way led back through the Icklinghams, where the unrestored Church of All Saints was visited. Unrestored indeed it is, for it has never been used for some four or five years, and is left to shift for itself; just enough being done to keep the weather out. The church is interesting, if only because it has never come under the restorer's hand, but it is interesting in a fragmentary way, and not as a complete design. There are a good many scraps of Decorated work, which is the prevailing style, though the presence of a Norman window shows that these head-quarters of the Iceni had not been neglected during the ten centuries which elapsed between them and the builders of the bulk of the church. A detour from the straight road back led to West Stow, where are the remains of a Saxon manor-house, recalling on a small scale East Barsham in Norfolk. The detrital has been much defaced; but enough is left to prove that at one time the house must have been very rich in appearance. Even now its shapely brick turrets crowned with figures, its crows' foot gables, and its delightful colour, raise high hopes, which, however, are destined to be somewhat damped on a closer inspection. The builder was a certain Sir John Crofts, who lived about 1540, and who had been attached to the household of Mary, Dowager Queen of France and Duchess of Suffolk. A pleasant reminiscence of his attachment is furnished by Sir John having put his mistress's arms over his main gateway. The royal lady thus commemorated was mother to that Duchess of Suffolk whose effigy lies on an interesting Early Renaissance tomb in Westminster Abbey, and who, in her turn was mother of the hapless Lady Jane Grey. On the wall of one of the rooms inside the gatehouse is a rough wall-painting, setting forth four aspects of life. One represents a youth hawking, and bears the legend, "Thus do I all the day." The next shows a young man whispering to a maiden; beneath, the inscription, "Thus do I while I may." At them gazes a middle-aged man, who says, "Thus did I while I might"; while the series is completed by a greybeard, who exclaims, "Good Lord, will this world last ever?"

From West Stow the drive is not long to

Hengrave Hall, one of the typical Tudor mansions of England. Its gateway, with the two flanking towers and detached stone pillars, and the elaborate oriel window over, are well known. This is the most notable feature outside; what there may be inside it was not vouchsafed to the excursionists to discover. The hall is built of white bricks with stone dressings, and, in consequence, its appearance is a little *triste*, and bodes ill for the future of many modern buildings of the same material, but which lack the spirit of Tudor work. Hengrave is extremely interesting from an historical point of view, inasmuch as it was one of the first unfortified dwellings which were erected, and because there went to its completion not only many ecclesiastical revenues but the actual stones and lead which had once formed part of certain monasteries in the neighbourhood. The blow which crumbled the church brought into existence another kind of architecture, not less interesting and quite as useful to the modern practitioner. The history of Hengrave has been written at large, as well as the doings of the Hengraves, the builder, "Kytson, the Merchant," and the Gages. Those who desire to pursue the subject can hardly do better than go to the fountain-head for their information.

The church, which is not a stone's throw from the house, has long served simply as a mausoleum to the mansion. It contains some seventeenth-century monuments as fine as anything outside Westminster Abbey; while of the structure itself, the arcade and the baby clearstory over it will afford some interest and amusement. The day's labour found an end at Fornham All Saints, where a short stay was made. The church has been carefully restored, but however eminent the restoring hand, much of the real flavour goes under the process.

Tuesday saw the party *en route* for Wetherden, an interesting church, but not one of the finest examples of Suffolk work. It has, however, some excellent roofs, and a sadly defaced monument to a Sir John Salyard. The arch-destroyer, Dowsing, worked his will upon this Papistical relic, and not only knocked off the arms and noses of the little sculptured figures of Sir John and his three wives, but did his best to erase the words "Argus animas propicietur Deus." Perhaps he objected to any mercy being shown to the soul of a Papist; but he might have reflected how few would read the petition, and that fewer still would echo its sense. The arms which profusely adorn the tomb are also to be seen scattered along the base of the south aisle outside, where they form part of a very handsome and characteristic series of flint and stone panels.

Woolpit, the next church visited, is in many respects finer than Wetherden. Its roofs are quite as good; there is more panel-work of flint and stone, and there is here a very remarkable south porch of two stories rising above the roof of the south aisle, and hiding much of the clearstory (from which it is detached). The design is vigorous and bold, but somewhat lacking in refinement. One need not come to Suffolk to see as good a porch, whereas one must do so to see such flint panelling as one meets here. The nave roof is a very elaborate double hammer-beamed roof, with angels at every possible possible coign of vantage. They nearly all bear some symbol or other, perhaps on a shield, perhaps not. Among these are included a key, a cross, a circle, a triangle, ladder, five wounds, anchor, chalice, money-bag, shell, crook, candlestick, and the letters L. X. J. S., besides others. The existing church is some centuries later than that to obtain which Abbot Samson, when yet a monk, made his perilous journey to Rome, passing for a pilgrim, and using as a talisman the enigmatic phrase, "Ride ride Rome, turne Cantarehri," whose meaning, if any one will satisfactorily explain, he will greatly oblige readers of "Past and Present."

The next church, that of Rattlesden, had also been much restored, and though rich in flint panel work, and containing a good Jacobean pulpit, it did not detain the party long. The last and longest stay was made at Rushbrooke Hall, a fine, quiet Elizabethan red-brick mansion, rising from a picturesque but insanitary moat. The courtyard and one side next the moat still retain much of their original character; but the other two sides and the interior have been entirely recast in later times. There is much wood panelling and plaster work of the very Classic era, but the

principal charm lies in the unpretentious dignified aspect of the whole place. External detail there is little or none; but, with such colour, one seems to miss it less. To fill such a house worthily, to live up to it, in fact, one feels that the inhabitant must be a worthy man. Of course there is a tale of horror connected with it, though, strange to say, no one knows of any ghost. A young lady was murdered in one of the rooms, and her body miserably cast into the moat beneath. The blood stains are still shown, and are said to be indelible. No one offered to prove the fact, or to prove the efficacy of any detergent, as the miserable man did to the blood stains of Rizzio at Holyrood in the introduction to one of Scott's novels. And, doubtless if any one had, the astonishment and wrath of the housekeeper would have been no less than that which agitated the guardian of the empty home of the Scottish kings.

The following remarks were made by Mr. Sodding at Wetherden in regard to the objects and value of excursions of this kind:—

"We are now doing architecture 'by picnic,' as my Lord Salisbury would say, and I am persuaded that it is only by picnics of this kind,—wholesome picnics organised by a caucus,—picnics extending over several consecutive days, and kept within the bounds of a given circuit,—that the architecture of our native land can be satisfactorily studied or the wealth and variety of its types be fairly explored. These systematic tours of ours should make systematic students of us all; they should not only extend our stock of examples, but quicken our instincts and make us keen and discriminating observers of the idiosyncracies of the district we pass through. To have learned the characteristics of a district is to possess the key that unlocks the meanings of things: you know then what to expect; you can interpret things idiomatically, as it were. And the knowledge is twice blest: it adds immensely to the delights of study, and endows every piece of design in a district with relative importance. Given an adequate sense of the local style of a district, and the humblest little church (provided it be unrestored) has value; as one of a group bearing the family likeness it takes its place along with the others. Herein, moreover, lies the great distinction between old art and new. The old bears the superscription of local origin, and each detail partakes of characteristics that have been slowly evolved by many generations of native craftsmen. It is idiomatic, hereditary, traditional, and full of characteristic traits. The new, on the other hand, has no local style, and no character, except that which is reflected from the personality of its nineteenth century architect. We parted last year in Somerset,—Somerset which is to me the architect's Utopia,—and this year our luck is to be in a county as different from that in architectural types as it is in physical surroundings. It is this fact that has led me to make these observations; and I think that perhaps it is a good thing that the flavour of the Suffolk work is so different to the other, inasmuch as under the compulsion of contrast we can learn more of the wealth and variety of English design. But if the contrasts between the two counties are so striking, the coincidences are none the less so, and both of them abound in specimens of that period of English art which, in my opinion, deserves most to be prized for its detail—the Perpendicular. As to the local style of the East Anglian churches, I venture to think that it not only stands in some respects apart from the ruck of English work, but that there is much in the architecture that is quite unique. I would say that while the main qualities of Suffolk work agree in the main with these found in the contemporary architecture of other countries, yet Suffolk is the last place I should name to a foreigner as containing typical English work. It is not English in the same sense as Northampton or Somerset work is. I don't mean simply that you have not the same strange, vast churches elsewhere as are found here, nor the same materials used in so singular a way; but that standing in the presence of this Suffolk work, there comes to me an ever-recurring sense of something foreign about it. Yes, and I have not with curious traceries and strange mouldings, and peculiar treatments of wood, and stone, and brickwork, which I can't match elsewhere, and which one can only ascribe to foreign influences. It is English in a sense, but not wholly so. I would

even hazard the opinion that the locality is indebted to Flemish and Dutch influence for its typical expansive churches—parochial churches of so vast a size that, as in the cases of St. Nicholas Yarmouth and York Minster, is actually outrivalled in width. This is but a personal theory of mine. I would, however, say in support of it, first, that Flemish town churches are very spacious things; second, these that vast churches are entirely confined to the Perpendicular period—just when the Flemish influence was at its height. In my opinion, then, the Lavenham, Melford, Mildenhall, and Southwold type of churches, with their maximum of area and of fenestration, and their minimum of wall-space, represent the ideal of the Fleming imparted to the South-folk builders.

#### DESIGN FOR PROPOSED NEW WAR OFFICES, BY MR. E. R. ROBSON.

WE give this week the design sent in to the First Competition for the War Office and Admiralty Buildings, by Mr. E. R. Robson, a design which shows a great deal of careful adaptation to the peculiarities of the site. Mr. Robson regards the Horse Guards not as a building to be crushed out by the new one, but as forming "the very centre and turning point of any new design," and this has led to a careful manipulation of plan and design having for its object the greater emphasis of the centre. The tower of the Horse Guards is not shown on these drawings, but enough of the Horse Guards buildings is given to show the scale and the connexion of the new building with the old one. The stone screen now forming the eastern entrance to the Admiralty is preserved in nearly its present position, and the semicircular sweep of the buildings within it would have had a fine effect. The Whitehall front is studied for street architecture; towards the Park windows are more freely recessed and balconies added. "Sculpture is not plastered everywhere, with no other meaning than a reference to the tax-paying powers of the British nation, but is studiously limited to proper positions, and confined to subjects symbolising the Queen, the Army, and the Navy."\*

"The object of the plan has been that all the rooms should be well warmed, lighted, and ventilated; that the whole plan should be simple, the corridors straight, well lighted, and easily accessible from entrances and staircases. The ends of Courts are always placed next corridors, for light.

The approach leads to a Principal Court, where the great entrance of the Admiralty is found at one end, and that of the War Office in a corresponding position at the other. Through this a carriage-way leads, by a slight incline, up to the state-doors of the chiefs, and the entrances for receptions, &c. On each side a decline gives access to the vans and carts going down to the minor courts.

The entire scheme is so framed that separate blocks can be built in such order as may be desired.

Between Cooks' Bank and the new buildings is interposed a passage 10 ft. wide, forming a public thoroughfare equal to that now leading into Spring-gardens from Whitehall, and affording valuable light, air, and isolation to the new buildings themselves.

The warming and ventilation were to be modelled on the principles observed in the Municipal Offices at Liverpool. Every corridor to be treated as a reservoir of warmed fresh air; every room to have a small open fire; every room-door to have over the architrave louvres sloping upwards for admission of air; every room to have a separate flue for extracting foul air, of size proportioned to wants.

Every set of latrines open into a small separate court. Some of the lighting is necessarily obtained from wells, forming also the lighting and ventilation to w.c.'s, lavatories, &c.; but it is to be noticed that in all these cases the windows towards corridors are for light only.

The rooms, we may observe, are not made too deep to be properly lighted from windows at one side or end, thus avoiding a serious defect to be found in some of the accepted plans. The arrangements for isolating one de-

partment from another, and the latrines from the offices and living-rooms, seem very complete, but it must be admitted that the site seems rather overbuilt. In giving Mr. Robson's views as to the architectural propriety of keeping the building low, and leaving the Horse Guards as a centre, we do not, of course, commit ourselves to that view; but it is a logical idea consistently carried out. The breadth of treatment in the elevations would give a building of solid, business-like character, and with an absence of anything like pretence, which seems suitable to an official edifice of whatever kind. Some people, perhaps, may think that a War Office should have more expression of "swagger" about it, but that impression belongs to the John Bull of the last rather than of the present generation.

#### LAVENHAM CHURCH, SUFFOLK.

THE Church of St. Peter and St. Paul, Lavenham, one of the grandest parish churches of the fifteenth century in the kingdom, formed one of the main objects of interest in the excursion of the Architectural Association this week. We give a view of it, reproduced from a photograph by Mr. Spanton, of Bury St. Edmunds, and will give next week a similar view of Long Melford Church, a few miles from it, and another of the notable churches of Suffolk.

Lavenham (also called Lanham or Laneham) Church, was founded at the expense partly of the De Vere family and partly of the Springs, wealthy clothiers in that part of the country, to the memory of one of whom a chapel in the church is dedicated. Externally the church is a splendid specimen of flint masonry, the massive tower, about 140 ft. in height, offering an almost unperished wall of irregular flints with their broken faces outwards, giving an exquisite variety and sparkle of colour. The parapet exhibits a succession of panels carved with highly conventional floral ornament of very bold and effective character, unusually so for such late work. Some of these details we have no doubt will have been carried away in the sketch-books of the Association party.

#### ANCIENT ARABIC TABLE.

This beautiful piece of work is another of the specimens of ancient Arabic art in the Museum of the Mosque Al-Hakem, at Cairo, photographs of which have been forwarded to us by Franz Bey, and one of which we published in the *Builder* for July 19th of this year. The present example is a small table (Kursi). The top, which is shown on a second plate, is in perforated brass, the inscription and other ornament being in silver plate. The inscription states that this piece of furniture was the property of Mabouhed ibn Kalaouin. The table on side view wants outline and form, like so much other furniture of Oriental type, though covered with delicate and beautiful detail. In the design of the top the main form is better, and the detail even finer than on the sides, and the decoration has the merit (not always found in Oriental work) of being admirably grouped and subordinated.

#### The College of Physicians and Cholera.

The College of Physicians, thinking that the public in England may fairly look to them for advice and guidance, have issued instructions. They, above all things, recommend sanitary measures, pure water, free ventilation, avoidance of overcooling, great cleanliness, and thorough drainage. They point out the danger of excess in eating and drinking. Milk and also drinking water should be boiled; vessels used for food should be cleansed with boiling water. Persons engaged about cholera patients are not, with proper precautions, more liable to the disease. Of these precautions extreme cleanliness and the use of disinfectants, such as carbolic acid, are the principal. House-to-house visitation should be organised and temporary hospitals established. These hospitals should be numerous rather than large. Any unusual looseness of the bowels ought to be promptly attended to. Medical advice should be sought, and meanwhile ordinary medicines, such as chalk mixture and cinnamon powder, may be taken. These instructions are perhaps mild and trite, but they are sensible; and, as the most of them apply to other diseases as well as cholera, they cannot be accepted too gratefully by the public.—*Lancet*.

ANCIENT ARABIC TABLE,  
FROM THE MUSEUM OF THE MOSQUE AL-HAKEM, CAIRO.  
(Plan of top.)

THE ROYAL ARCHAEOLOGICAL INSTITUTE AT NEWCASTLE.

We continue our notice\* of the proceedings of the Archaeological Congress just concluded at Newcastle-on-Tyne.

On Wednesday, the 6th inst., there were excursions to Warkworth and Alnwick. Arrived at Alnwick Castle, the excursionists were addressed by Mr. G. T. Clark, F.S.A., who observed that though Alnwick was less strong naturally than the frowning half-seagirt rock of Bamborough, less exposed to a surprise than the strongholds of Berwick and Norham, it was, nevertheless, for centuries the chief of the Border fortresses, and famous not only for its capacity and material strength, but still more famous for the great race of warrior heroes who so long inhaled and maintained it. Nevertheless, Alnwick was a very strong place. Its position, thirty miles from the Tweed, protected it against sudden and unforeseen attacks; Prudhoe and Newcastle were in its rear, Warkworth, Harbottle, Wark, Ford, and a score of smaller but still strong places, lay at convenient distances, and looked to Alnwick as their central point. Alnwick, moreover, had been fortunate in the fate that had befallen it. It had maintained its local rank and condition. Although much even of the purely military part of the castle had been under the hands of the restorer, so skilfully had this work been accomplished that they had now before them the castle of the De Vescies and the Percys as it presented itself to friend or foe in the fourteenth century. But Alnwick fortress had an earlier history, for its position was such as was often selected by the constructors of strong places in the ninth and tenth centuries. Judging from the disclosures of modern excavation and research, Alnwick was probably the seat of a considerable Saxon estate, for at the Conquest it was certainly a place of some importance. Algernon, who became duke in 1847, set himself to work to restore the seat of his fathers to more than its ancient splendour. Happily, he secured the aid of Mr. Salvin, who, more than any architect of his day, understood how to restore, to rebuild, and even to add, without in any degree departing from the lines of taste and symmetry.

The Architectural Section was opened at Newcastle in the evening, when the President, Canon Raime, delivered an interesting address, observing that it was out of the domain of history that he looked upon the handiwork of ancient builders. The dates which the historian discovered were the framework upon which the whole system of architectural science was laid down. It was history, likewise, which reproduced men and manners, the feats of armies, and the achievements of the gentle life, without which stones were stones, and wood and water, the forest and the moor, lost half their charm. And there was added to history in Northumberland the poetry of legend and tradition, which invested tower and stream in that wide district with its own inimitable grace. Domestic architecture in Northumberland from the very earliest times was the architecture of defence, as was the case, although to a less extent, upon the borders of Wales. At Hexham they would find the most interesting remains of Anglo-Saxon work in the county, and they might mark the influence of the place in the churches in the neighbourhood, beginning with Ovingham. At Holy Island and Farne,—still more sacred ground,—there was little of that date; there was next to nothing else at Tynemouth,—later building had obliterated or concealed it; but at Whittingham, Edlingham, Bolam, Whalton, Longhoughton, and other churches, they would find Saxon towers or masonry, whilst the interlacing sculpture met their eye in many of the churches and churchyards. He would ask them to contrast the condition in the last century with that of the present day. There had certainly been a most remarkable change. In the archdeaconry of Lindisfarne nearly every church had been either rebuilt or restored within the last thirty years,—not always wisely or well, but still assuredly,—not in the spirit of that Northumberland Yeoman whom he could name, who chiselled away the whole corbel gable formed of grotesque heads, as he thought his congregation looked too much upon them when they ought to have been looking upon him. In the archdeaconry of Northumberland there had been less done, but still a great deal. He was

unwilling to criticise. He remembered an old friend of his making the caustic remark that Medieval architects erected buildings which we were unable to restore. He did not agree with that; but he did think that in far too many cases ancient remains had not been sufficiently respected, and that modern practitioners had often entirely overlooked the feeling and the character of the architecture of the district in the work which they carried out. Every county,—nay, various parts of each county,—had architectural features peculiar to themselves with which an architect ought at least to make himself acquainted.

The Historical Section held a meeting at the Castle, when Mr. Bain read a paper on "The Percys in Scotland." Before the Antiquarian Section, the Rev. Joseph Hirst read an interesting paper on "The Mining Operations of the Romans in Britain."

On Thursday, the 7th, there was an excursion to Holy Island, where the Dean of Chester delivered a short *extempore* address on "St. Aidan and King Oswald of Northumbria."

Mr. J. T. Micklethwaite, F.S.A., described the Priory from an architectural point of view. The ruins, he said, were an exceedingly interesting study. What they showed was what all the Benedictine churches of the twelfth century showed. All Benedictine churches were built in the eleventh or twelfth centuries. They were altered as people got more room or more ambitious, till very often very little of the original work was left. Here it was not so. This work had not been free from alterations, but it retained its original character more than any other that he knew of in England. There was no tradition of an old cathedral there at all. It was an entirely fresh beginning in Norman times irrespective of anything that might have been on the site before. The old church, part of the Scottish manor, might not have been such a shabby thing as some of their friends thought. It certainly was a wooden erection, but it was probably of a fair size, because they could compare it with what they knew to have existed in other places. With that later building, however, they started entirely free from any previous structure. The apsidal end and other evidences seemed to indicate that the church had been built at two periods in the Norman time.

Mr. Hodges, Newcastle, differed from Mr. Micklethwaite in regard to the old Saxon Church. He had carefully examined the ruins in company with eminent local antiquaries, and they came to the conclusion that the architectural history of the church had been written wrong all through. They believed it was "all bosh" about a wooden church; and that the site was the site of the Saxon Church of Lindisfarne. He thought in the apsidal end they had the remains of a Saxon Church. He should tell them that the church was built about 1130, after the nave of Durham Cathedral was finished, or was still going on; and it was almost a copy on a small scale of that cathedral.

Mr. Micklethwaite said Mr. Hodges's theory was a very tempting one, but he could not accept it without further testimony.

On Friday, the 8th, there was an excursion to Bamborough Castle, which was described by Mr. G. T. Clark, who said that here, not the first fortress in Britain was founded, but the first Saxon work of which we happen to know the exact date. Ida landed here, and so completely struck terror in the Celtic people of the district, that his name descended to us as Ida, the plane bearer. Ida founded Bamborough, so calling it in compliment to his spouse, Bobba.

In the Architectural Section a paper on "The Peles of Northumberland" was read by Mr. C. J. Bates. In the Antiquarian Section, the Rev. G. F. Brown read a paper on "The Fragments of Sculptured Stones at Monkwearmouth and Jarrow." He described at length the sculptured fragments at both places, and said that as many of them were exposed to the weather some step should be taken to preserve them. As many of the sculptured fragments in the country were in the same condition, he thought that measures should be taken to get pictures of them, so that they might not be lost altogether to posterity. His university, Cambridge, he believed, was prepared to move in that matter and had submitted to him a number of questions, one of which was as to what assistance there could be obtained from the local archaeological societies. The reply of the

Newcastle Society was very cordial. It would do the whole of the work for its own district.

On Saturday, the 9th, there were excursions to Monkwearmouth, where the church was visited and discussed; and to Ravensworth Castle, where Mr. W. D. Longstaffe acted as *cicerone*. In the Antiquarian section, in the evening, Dr. Bruce gave a lecture on "The Northumberland Small Pipes." In the Architectural section, which held a meeting at the Old Castle, the Rev. J. R. Boyle read a paper on "The Saxon Churches of Northumberland and Durham," making special reference to Monkwearmouth and Jarrow. The Historical Section also had a meeting, when the paper read was on "The Constitutional Rights of the Houses of Parliament," by Mr. J. P. Harrison.

On Monday last there was an excursion to the Chesters (the Roman Sillurnum), and to the Roman wall. Dr. Bruce acted as *cicerone*. In the evening the Antiquarian Section held a meeting, when the Rev. G. R. Hall read a paper on "The British Remains in Northumberland." In the Architectural Section, Mr. C. J. Bates continued his paper on the Mediæval castles, towers, and castle-houses in Northumberland, and Mr. W. H. St. John Hope read a paper as to "Recent Excavations on the Site of Alnwick Abbey."

On Tuesday last there were excursions to Prudhoe, Ovingham, Bywell, Corbridge, and Aydon Castle, Prudhoe Castle being described by Mr. Clark.

On Wednesday the proceedings were brought to a close by a visit to Bracepeeth Church and Castle, and to Durham Cathedral and Castle.

THE ROYAL HISTORICAL AND ARCHAEOLOGICAL ASSOCIATION OF IRELAND.

At the August meetings held in Armagh, presided over by Lord Castlemont and by Dean Reeves, the following papers were read by Mr. James J. Phillips, architect, Belfast.

(1) "Notes on some old Wrought-iron Cyllic Work in the Vicinity of Armagh." I could not help observing when first I visited Armagh, some eighteen years ago, the frequency with which, in certain parts of the city, one met with excellent examples of a peculiar class of architectural wrought-iron work, which, on a return journey to the locality some years afterwards, I noticed was very sensibly diminished, owing, no doubt, to municipal exigencies, and the structural changes of residences into shops, &c. There is, however, sufficient of this work now remaining in the vicinity of the cathedral and elsewhere to show that at one time this was the *locale* of the labours of a blacksmith or family of blacksmiths, whose artistic power was very considerable, and for the merit of whose productions we must entertain the highest respect. Owing to civic changes just referred to we need not seek in the bustling and changeful streets of the city, or even under the shadow of the Abbey Minster, for the culminating work of this handicraftsman, but in the more remote suburbs where cluster the gables of the quaint old mansions (few and far between though they be) of the county families, and to which such artworks serve as the harmonious adjuncts. Accordingly, we find in the pastoral village of Richhill, about five miles distant from Armagh, a veritable trophy of the blacksmith's handicraft, in which design and execution go hand in hand; and we have preserved to us here, where the *requiescat in pace* of a monumental work of art is little likely to be disturbed, the most beautiful specimen of old wrought-iron grille work in the province of Ulster. It is of a period of art which we may call its *habitat* in such classic localities as the Inns of Court in London, at Gray's Inn, and the Inner Temple, or in Cheyne Walk, Chelsea; and it is quite a charming surprise to us to come on it here in this quiet out-of-the-way village in Ireland, and leads one to cast about in the vicinity for old red brick mansions, with braided brown-tiled roofs, or for that class of dormers and oriels, and such features, so greatly sought after by that school of architects who are partial to Free Classic treatments. In England such work has been variously termed late seventeenth-century work, and by some called Queen Anne work, although probably the majority of it was executed during the reigns of the two first Georges. Even the casual observer is struck with the dignity and

\* See p. 218, *supra*.

breadth of treatment of the grille and screen-work at Rich-hill, and with the clever manner in which each field of vertical bars is alternated with panels of characteristic scroll-work, the upper parts enriched with forgings, forming a sort of *cheveux-de-frise*, while the gates are crowned by convoluted and foliated forgings, which upheld the arms and crest of the owners, the details of which are manipulated with great taste and refinement. Sufficient effect is produced by simple treatments of the hammered bar without aping cut-stone mouldings or wooden carvings, or placing sheet iron festoons and garlands to rot in the humid atmosphere of this island, although we find many instances of this treatment in the contemporaneous art iron work in England and the Continent.

(2) "The Ancient Abbey of Armagh."—This paper bore upon "The Carol of the Prior Claustralis in Irish Abbeys."

#### BUCKINGHAMSHIRE ARCHÆOLOGICAL SOCIETY.

The annual meeting and excursion of the Architectural and Archæological Society for the County of Buckingham took place on Monday last, August 11th. The day was fine but extremely hot, and the programme occupied all its sunniest hours. The members left Aylesbury by special train at 11 a.m., and reaching Buckingham at noon, paid a visit to the parish church and the few other objects of interest which the town contains. The church possesses scarcely a single feature on which either architect or antiquary can look with pleasure, except it be the site. It stands upon a natural rock of some elevation, and known as the Castle Hill. No doubt in earlier times the spot was occupied by some sort of fortress, and massive foundations and a deep wall have been discovered. But the church itself dates only from the year 1750 and, until 1862, was a conspicuous example of the worst characteristics of the eighteenth century. The late Sir Gilbert Scott,—who was born at the parsonage house of Garscott, a district of Buckingham,—did his best to turn Crecian into Gothic, and certainly deserves much credit for what he was able to achieve. New windows, buttresses, and parapets were introduced, and a chancel of fine proportions was added. The pillars, alternately stone and marble, have, on the whole, a good effect, and the tower and spire, rising to a height of 150 ft., rescue the town from appearing absolutely insignificant. The manor house and the house occupied by Mr. Hearn, and said to have been King Charles the First's quarters in 1644, are worthy of notice, and still more so is the old Grammar School, part of which dates back to the fifteenth century. Leaving Buckingham, the excursionists ascended the hill on the north-east side of the town, and visited the church of Maids Moreton, which is said to have been built by two maiden sisters of the Lord Peover in the fifteenth century, and is rich in beautiful details of Perpendicular work.

The tower, by a peculiar arrangement of its buttresses, has the appearance of being octagonal, and the grouping of the western porch is unusually elegant. The same term may be applied to the sedilia, which have been restored with great care by Mr. St. Aubyn. The old chancel screen is of good design, and the pulpit, presented by the family of the Bishop of Winchester, is an admirable example of modern skill. From Maids Moreton to Lillingston Dayrell is a drive of some three miles through rather pretty country. The parish church was restored about fifteen years ago, and a north aisle added by Mr. G. E. Street. It is rich in sepulchral memorials of the Dayrell family, in whose possession the manor has continued from the reign of Henry III. to the present time. The excursion ended in a visit to Stowe House, where the Duke of Buckingham and Chandos (the President of the Society) entertained the members and their friends at luncheon. Although shorn of its former splendour, and wholly wanting in archæological interest, the mansion, with its noble portico, colonnades, and pavilion wings, forming a frontage 916 ft. in length, has a certain grandeur which compels admiration, and the gardens and pleasure-grounds are of unusual beauty. It may be doubted how far these excursions serve the cause of archæology, but there can be no question that when combined with dual hospitality they are inconveniently popular.

#### SUSSEX ARCHÆOLOGICAL SOCIETY.

The Sussex Archæological Society held its annual meeting on the 7th inst., at Brickwall, Northiam, the seat of Mr. E. Frewen. The *Sussex Advertiser* says that the meeting was a complete success. About 150 ladies and gentlemen took part, proceeding by special train from Brighton, Lewes, and other stations to Robertsbridge, where carriages were in waiting to convey the excursionists to Salehurst Church, a picturesque old building. Here a paper on that church was read by the Rev. J. W. Loosmore, vicar of the parish. The party next proceeded by carriage to Bodiam Castle (built in the reign of Richard III.), some members separating to walk round by Robertsbridge Abbey, the remains of which were inspected and explored. At Bodiam Mr. Lacy W. Ridge read an able paper, explaining the principal features of the building, chiefly from an architectural point of view. Thence the party drove to Brickwall Park, where the dinner-table stood pitched. Mr. Frewen took the chair. Archdeacon Hannah proposed the only toast drunk, viz., the Chairman. Dinner over, the visitors were conducted over Brickwall House, and shown the valuable oil paintings and other objects of interest stored there, including Queen Elizabeth's shoes. The party next visited the Queen's Oak, under which Queen Elizabeth had dinner on her journey from London to Kye. [The oak is shortly to be bricked up where decayed, for its better preservation.] The company also went over the church, part of which was supposed to be of Saxon origin, and the mausoleum of the Frewens, and then drove to Battle Station, where the special train was waiting to carry them home. The weather was all that could be wished, and the excursion proved most enjoyable.

#### CRYSTAL PALACE SCHOOL OF ENGINEERING.

ON Saturday last the thirty-fifth term closed in the usual manner, and Lieut.-Gen. Sir Gerald Graham, V.C., K.C.B., R.E., presented to the students the certificates awarded by the examiners, who, for this term, were Mr. W. H. Stanger, A.M.I.C.E. and Mr. John Brunlees, M.I.C.E.

The course of lectures for the term was on "Railways: their Construction and Appliances." The highest number of marks attainable was 278. Mr. H. Copeman was first with 221 marks; he also received a certificate of merit for work in the drawing-office. Forty students attended the lectures, thirty-six were eligible for examination, and twenty-three received certificates. Mr. G. A. Keene was first in the order of merit for work in the drawing-office, with 174 marks for lecture examination; twelve certificates were awarded to other students for work in the drawing-office. For work in the pattern-making and smith's shops twelve certificates were awarded. Mr. G. H. Sowray was first with 147 marks for lectures; in the fitting-shop eleven certificates were awarded. Mr. J. A. Taylor first with 140 marks for lectures.

For students in the Civil Engineering Section, taken in the second year's course, the honours awarded were,—first term, general surveying and preparation of plans for Parliament, five certificates. Mr. J. A. Marrot, first; second term, calculations, plans, and estimates for railway and dock, four certificates. Mr. L. O. Cooper-Coles, first; third term, design and construction of existing and other engineering works, eight certificates. Mr. W. Worsfold, first.

In the Colonial Section thirteen certificates were awarded, ten of the first, two of the second, and three of the third grades.

General Graham briefly addressed the students, saying that he had in his visit seen enough, in his examination of the students' work, to impress him deeply with a sense of the value and importance of the instruction and training given. The unoccupied field for engineering talent and enterprise was illimitable. Roads and railroads over and under land and sea were only a branch of the subject; others vastly important lay in the directions of electrical engineering and mechanical inventions, improvements, and adaptations. He regretted much that he had been unable to visit the camp of the students in the colonial section, and to overhaul their cooking, living, and sleeping arrangements and provisions, to have seen how they "rouged it," as well as to have inspected

the construction of their floating and spar bridges and other work. He considered the course in this section of great importance, in the trained intelligence with which it equipped intending colonists, a power that they would find much more effective and useful than money or letters of introduction without such training. It was not surprising that the school, which commenced nearly twelve years ago with fifteen students, should in the last term have had above eighty in attendance; that about 120 former students of the school should now be in the employment of well-known civil engineers, and about as many with mechanical engineering firms; and that others were occupying useful and honourable positions, for which they had received an important part of their qualification here.

Mr. Stanger, Examiner, on behalf of his colleague and himself, said that their duties had resulted in the greatest satisfaction with regard to both teachers and taught. He had no suggestions to offer as to the lines on which the examination should be conducted, but he would take leave to say that examination did not always secure the "steady slogger" the honours he had earned by conscientious hard work. Mr. Stanger commented on the work of a number of the students, and, among the cautions he offered were those against loading drawings heavily with colour and depending upon sand-paper rather than sharp tools in pattern-making. He also urged the students strongly to thoroughness in all their work.

Mr. Kimber moved a voto of thanks to General Graham for presiding, and Mr. J. W. Wilson, Principal of the School, gave some interesting particulars respecting former students.

#### PURCHASES BY THE ART-UNION OF LONDON.

The following works have been selected from recent exhibitions by the prizeholders of the Art-Union of London for the current year:—

*From the Royal Academy.*—Is Duelling Lawful? painted by S. W. Lee, 4*l.*; On the Cornish Coast, by T. S. Crossford, 40*l.*; A Zeller of the Sea, by Charles A. Smith, 40*l.*; The Mounts Mountains, by Walter F. Stocks, 31*l.*; 10*l.*; In the Woods, by Wm. F. Huik, 30*l.*; Making Friends, by Thomas Pyne, 20*l.*; Our Ironbound Shore, by T. Malcolm Stewart, 15*l.*; Sunny Days, by E. Glegg Wilkinson, 15*l.*; 10*l.*; and Twilight Grey, by W. Ayerst Ingram, 10*l.*; 10*l.*

*From the Society of British Artists.*—Sleep, painted by G. H. Barrable, 60*l.*; The Wandering Minstrel, by W. Holycroft, 50*l.*; The Gossip, by Wm. Bromley, 40*l.*; Who Killed Cook Robin? by Mary K. Benson, 35*l.*; A General's Farewell, by Edward Holmes, 35*l.*; Mabel Sibbold, North Wales, by Sidney R. Percy, 35*l.*; A Turn in the Lane, by J. Clayton Adams, 30*l.*; Near Tintagel, North Cornwall, by T. S. Crossford, 30*l.*; A Summer's Morning, by Gustave de Bryonville, 30*l.*; My Face is my Fortune, by Edwin Roberts, 30*l.*; Lechard, a Bright Day in Autumn, by J. J. Lannatyne, 25*l.*; 'Tis Sweet to visit the Old Wood, by Thomas King, 25*l.*; The Ruinet, by Aldw. Williams, 25*l.*; My Lord's Lounge, by R. S. James, 25*l.*; 2*l.*; The Thames at Wargrave, by Stuart Lloyd, 20*l.*; Summer Sea, by L. C. Nightingale, 15*l.*; 15*l.*; The First Fench, by A. C. Dodd, 15*l.*; The Farnstead, by J. E. Grace, 15*l.*; Autumn Morning, by Stuart Lloyd, 15*l.*; The Llugwy, North Wales, by James Peel, 15*l.*; A Bit Hard of Hearing, by Everett Salisbury, 15*l.*; and On the North-east Coast, by R. Hurling, 10*l.*; 10*l.*

*From the Grosvenor Gallery.*—In the Stillness of Autumn, painted by Thos. Ireland, 45*l.*; Harlequin through the dim woods dying, with a moon, faintly the winds are sighing, by J. Whipple, 40*l.*; October, by Miss Flora M. Reid, 30*l.*; An Old Bridge in Surrey, by J. E. Grace, 31*l.*; 10*l.*; and Phillips, by Lady Louisa Charteris, 15*l.*; 15*l.*

*From the Royal Institute of Painters in Water-Colours.*—General March of a Hero, painted by Wm. Wyllie, 100*l.*; A Wiltshire Village—Evening, by C. J. Lewis, 2*l.*; and King Harold's Bridge, Waltham Abbey, by Ald. Hutton, 12*l.*; 12*l.*

*From the Nineteenth-Century Art Society.*—Looking up the Muskege, Cairo, painted by R. M. Chevalier, 75*l.*; St. Peter's Port, Guernsey, by Chas. F. Draper, 20*l.*; A Wooded Pool, by Fred. Hines, 20*l.*; and Resting in a Wood, by Geo. D. Huxton, 10*l.*; 10*l.*

*From the City of London Society of Artists.*—Quiet Pools on a Highland River, painted by Wm. J. Ferguson, 20*l.*

*From the Society of Lady Artists.*—After the Rain, painted by Fanny Assenbaum, 15*l.*

*From the Crystal Palace Picture Gallery.*—At Antwerp in the old time, painted by H. Schaeffels, 60*l.*

"The Bakeries at the Health Exhibition."—Messrs. Harris & Co., of Upper George-street, Bryanston-square, write to say that whereas on p. 186 of our last issue we mentioned Messrs. Watt & Son as occupying the next stand to Messrs. Hill & Son, and working Messrs. Perkins's steam oven, they (Messrs. Harris & Co.) have, from the commencement of the Exhibition, occupied the position referred to, and are the patentees and sole manufacturers of the "Angels' Cake" to which reference was made.

IMPERMEABLE CONSTRUCTION.

Your correspondent, "H. T." (p. 210), whose initials I do not at present recognise, seems to have missed the point of my remarks on the preservation of the external faces of buildings. I do not profess to cure bad stone, or to render as good as new stone which has already decayed. But I have proved to my own satisfaction and from my own experience that it is quite possible to preserve from premature decay stones which, without the preventive measures I am accustomed to employ, would certainly not resist the effects of the atmosphere. "H. T." speaks of arresting decay after it has set in; I speak of what it is desirable to do to prevent decay before it has set in. I prefer to find the key before the horse is lost.

With regard to the preservation of new stonework by the application of linseed oil, Professor Cockerell adopted this wise course with reference to Hanover Chapel, with the result I had the opportunity of proving when I cleaned down the building with the steam jet.

I will take the opportunity of early inspecting the various buildings to which I have applied the Indestructible Paint Company's solution as the buildings were cleaned down, and will note the result. E. C. ROBINS.

WARWICKSHIRE EARTHWORKS, &c.

SIR,—Allow me briefly to reply to the letter of Mr. J. Tom Burgess, F.S.A., in your issue of August 2nd, wherein I am accused of propagating a wilderness of errors through not having trailed myself of the best published information on this subject. In answer, let me say many if not all authorities within reach were duly consulted, the several sites inspected, and much information obtained on the spots from old inhabitants personally. It was never my intention to thoroughly exhaust the subject under notice, and accordingly much information was rejected as superfluous, speculative, or unsuited for general information. If my views do not suit or coincide with any particular theory of Mr. Burgess, I cannot help it, but am pleased to say that Mr. M. H. Bloxam, F.S.A., and several other good authorities, have sent me flattering and congratulatory letters, as to the worth and success of the series of papers now publishing; and one of them goes so far as to hint that I "might well have expected Mr. Burgess's wrathful criticism, for does he not state that he is himself publishing a long-promised work on the subject, and by his letter draws the attention of the public to his book, thereby effecting a cheap advertisement of it?" It is not now my intention to open up a controversy in your pages on the points disputed, and I have no leisure time on my hands to do so; but I shall be pleased to see Mr. Burgess's map of early earthworks, and his sketch of the keeper's lodge and enclosure, Chesterton, at a suitable time hereafter. W.

LEAKY SLATE CISTERN.

SIR,—Thanks for kindly inserting my query (p. 176), and also Messrs. Christie's note in reply thereto (p. 210). The leak, which was stanch on Monday by my steward, after a Wicklow tradesman had tried it ineffectually, has not yet shown any symptoms of passing the water. The sole cause of leakage was a vein shelving towards the centre,—a simple flaw in the floor.

I will adopt Messrs. Christie's suggestion, and also keep the tank always filled. The cistern is flush with the lead of the house, and 4 ft. deep, protected on three sides by the thick walls of the dwelling. It seems impossible for any alternation of heat or cold to affect it, especially when covered on the top with timber 1½ in. thick, added to which sacks filled with straw could be placed over it.

BOMBAYEEN.

**Asphalte Work.**—The Brunswick Rock Asphalte Paving Company's tenders have been accepted for the following among other things—(1) For laying with asphalte 1-inch thick seven warehouscs in Royal Victoria Docks, for the London and St. Katharine Docks Company; (2) for laying footway of main line entrance to Liverpool-street Station, for the Great Eastern Railway Company; (3) for the whole of the asphalte work at the new Mansion House Station, for the Metropolitan District Railway Company; (4) for laying the floors of new buildings at Caterham Asylum, for the Metropolitan Asylums Board.

The Student's Column.

HINTS FOR THE STUDY OF THE HISTORY OF ARCHITECTURE.—VII. LOMBARD AND RHEINISH.

Now let us turn again to Keith Johnston's Physical Geography, and on the third of the small maps of the known world at consecutive periods, we shall see that, while the Roman Empire was in "full swing" about the year 300 A.D., there is a northern district appearing on the scene, coloured purple, and called Germania. It is kept well within bounds, while the yellow colour of the Roman Empire ranges from side to side of the map, spreading from Britannia at one extreme, round by Spain and North Africa, across the Red Sea, and over Syria, until it touches Persia. The next map tells a very different story. It is dated about 500 A.D., and all the north-western and western and south-western yellow colour has given way to the invading purple.

The text tells us that this is due to the Goths, both Ostrogoths and Visigoths, the Vandals, the Franks, and the Huns, sweeping down from various directions north of the Alps, and, after vicissitudes of victory and defeat, displacing the power of Rome in all but its eastern empire.

Of these invaders we have to notice Theodoric, king of the Ostrogoths, 493 to 525 A.D., who not only visited Rome, but went further, and built himself a palace at Ravenna, at which place his tomb remains, and will be found illustrated on page 518 of Fergusson's Handbook. It is chiefly remarkable for its circular roof formed of a single slab of stone 35 ft. in diameter, with handles left in the solid by which it was raised into position. The palace has excited the admiration of Freeman, who, in his "History of Architecture," page 163, revels in strong language in praise of a succession to the then effete Roman style, which he holds in contempt. He says, "In this first of Teutonic buildings, every mind, not warped by the pedantry of classicism, must at once recognise not only a wonderful change, but a wonderful improvement. The architect at once grasped the great law that the construction and the decoration must be derived from the same source."

We are told that the Goths were got rid of by Justinian, but that, soon after his death, another race of conquerors came down from the North to enjoy the fertile plains watered by the river Po. These were the Lombards whose name has stuck to that country ever since. They, too, are the people who developed a style of architecture which may be regarded as a reaction from the monotony of the Roman style, and which certainly took unnumbered liberties with the sacred "orders," of which we now take leave for many centuries. Fergusson says, on p. 350 of his Handbook, that, before the age of Charlemagne, viz.—768 A.D.—the transformation was complete as regards the valley of the Po being inhabited by the same races who occupied that of the Rhine. As a consequence, the change in the architecture is distinct and clear, and he illustrates the chapel at Primi, built in the eighth century, as an early and characteristic example of Lombard work, as may especially be seen in its groined stone vault.

In this form of roof lies one of the chief distinctions between the styles that we have now to consider, and the basilican churches which were, as a rule, covered with wooden roofs only. It will soon be noticed that the various portions of the superstructure which had to be supported, regulated the size and disposition of the piers that had to carry them, whereas the columns and arches in a basilica had simply to carry a flat wall, and there was an end of the matter.

This difference will soon be seen in glancing through any of the following works:—Osten's "Bauwerke in Lombardie," seventh to fourteenth century, one vol. folio; De Dartein's, "Étude sur l'Architecture Lombarde," 1805, parts 1 to 5, fol. [this book also illustrates the Basilican, Romanesque, and Byzantine styles referred to in the last article]; or Griner's "Terra-cotta Architecture of North Italy," with coloured plates by Lose, 1867 (one vol. large quarto). Hopps's "Essay on Architecture" now becomes an important work, while Ruskin has a good deal to say on the subject in the course of his "Stones of Venice,"—for example, on page 359 of vol. 1, on the "Northern Energy." In fact, there is very little sympathy

between the temper of these invaders of the sunny South and of the nations whom they supplanted, so that we shall find, as usual, the expression of their temper in their architecture; and as to their decorative sculpture, it shows, according to Ruskin, amongst other things, that the Lombard was strongly imbued with the love of a joke.

After contemplating the high degree of execution that the Romans had attained in sculpture, especially of the human figure, it seems rather a drain upon one's credulity to be asked to admire these Lombard bogeys. One must borrow a pair of spectacles from Ruskin or from Freeman in order to see them in their proper light. The former especially devotes a great many pages to "the grotesque" in art.

Most authors agree in pointing to the Church of St. Michele at Pavia as an exponent of all the peculiarities of the Lombard style; Fergusson going so far as to say (page 536 of his Handbook), that there is hardly any feature worth mentioning which was invented after the date of this church, which took its present form either at the end of the eleventh or the beginning of the twelfth century.

Let us then examine the design of this building, which is illustrated by drawings to a large scale in De Dartein's book. There is also a ground-plan of it in Rosengarten, page 232, and an internal view on page 235, while Fergusson gives a longitudinal section and an external view of the apse on page 557. The plan shows a choir, transept, and a short nave of four bays only, with side aisles; but even these four bays are broken into main groups by greater and lesser piers, and a glance at the internal view or section shows that certain portions of the piers extend higher than others, some having capitals to carry the arches dividing the nave from the aisles, and the vault over the aisles, others rising to the level of the triforium, or gallery above these aisles, while others pass by this level and ascend to the springing line of the vault over the nave. This vault, moreover, is not only groined, but is strengthened by transverse and diagonal ribs. The piers, besides having the above-named duties allotted to certain portions of them, have further subdivisions which, when traced up to their capitals, are found to carry corresponding subdivisions in the arches.

Such subdivisions were not known in the arches of the basilican churches described in the last article, wherein any relief or ornament that might be required would be obtained by panelling the soffit, as at St. Clemente, in Rome.

The vaulting of the nave and aisles has a further influence on the plan of St. Michele, by requiring external buttresses, which now become a recognised feature in the style.

Next we come to the cross, or crossing of the nave and choir, and the transept. Here is no such dome as we have described in the Byzantine churches, but one changed from the square to an octagonal plan, in which form it is continued up above the surrounding roofs. This polygonal form of central so-called dome continued to be a favourite feature with the Italians long after they had shaken off the Gothic style, as may be seen in Strack's "Central und Kuppelkirchen in Italien," 1882, two vols. folio, and in Laspeyres's "Kirchen du Renaissance in Mittel Italien," 1882, folio, which books illustrate buildings as late as the sixteenth century.

To return to St. Michele. The exterior of the apse has a row of narrow semi-circular-headed windows, just under the eaves, which were the forerunners of the characteristic galleries in a similar position in many subsequent churches, such galleries lighting the space between the hack of the vault and the outer wooden roof, and, as Fergusson points out on page 536, they are an admirable substitute for a cornice. These galleries came to be repeated on other parts of the buildings, the west front of St. Michele exhibiting them along the gable. This front has also semi-circular-headed doorways with several subdivisions in the jambs and arch, such as we noticed inside, while the opening itself is square-headed, the space between the lintel and the arch being devoted to sculpture. There are two ordinary features of Lombardy architecture which are lacking in this west front; one is the projecting porch with its columns carried on the backs of animals carved in stone, and the other is the usual wheel-window in the nave gable.

There are, however, both inside and out, several specimens of reed-like piers or pilasters

of slender proportion, which would have taken away the breath of any Roman architect; indeed, the tendency of the whole style is towards vertical lines. Before leaving the neighbourhood of the Alps, the early architecture of Switzerland should be noticed. There is an excellent work on the subject; Blavier's "Histoire de l'Architecture Sacrée du midi, au 10me. Siècle dans les anciens États de Genève, Lansanne, et Stion," 1855. It is in two volumes, one of which has illustrated text, octavo, and the other plates—abing folio. The playful liberties taken with Roman details will be found amusing. Fergusson has selected from it, on p. 550 of his Handbook, the plan and a view of the Church of Romain-Motier, consecrated in 753 A.D., which already shows a distinction from Lombard churches of an early date, being more in harmony with the next great group of buildings that we have to examine, and which constitute what is known as the Rhenish style, or German round-arched Gothic.

Of this Fergusson says, on p. 559, that there is none perhaps of the Mediæval styles so complete within itself and so easily traced; he also says that it begins absolutely with Charlemagne, —768 A.D.,—up to whose time Germany seems to have been in such a state of anarchy and confusion that no great buildings were or could be undertaken. There are two important hooks bearing specially on this subject. Moller's "Denkmaeler der Deutschen Bankunst," two vols., small folio, that is to say, the first volume, for the second one treats of the later pointed examples, which have ceased to be distinctively Rhenish. The other work is Patric's "Denkmaeler der Bankunst des Mittelalters in Sachsen," &c., 1836 to 1843, four vols. quarto. There is great need of rearrangement of, and a good index to, the plates of this work, which has been published in numbers from time to time.

There is one building which may be earlier than the date of Charlemagne, namely, the Porch of the Convent of Lorsch (Fergusson, page 560, and Moller, vol. 1, pl. 1), as it is made up of Roman orders, Corinthian and Ionic,—which are quite extinct in the Dom at Aix-la-Chapelle (or Aachen), built by Charlemagne, which, with the exception of the later choir, is a polygonal church consisting of an octagon surrounded by a sixteen-sided aisle, and is, historically, very important. Charlemagne is said to have been a great traveller and to have studied Byzantine and Lombard art, and to have copied this building from St. Vitale at Ravenna. There are other polygonal churches of this style illustrated in Fergusson; the typical form, however, of Rhenish churches is that of a long nave and aisles with a transept eastwards, and with the peculiarity that semi-circular apses are used to terminate nearly every limb of the building both eastward and westward. The churches at Cologne are very pronounced examples of this fashion, as will be seen from the illustrations of them in all the handbooks; indeed, the Cathedral of Mayence has a triple apse grouped around the westernmost bay. Western doors become conspicuous by their absence.

The eaves galleries of the Lombards were carried to great perfection in Rhenish churches, and in the form of the many towers to each building, variety was carried to a greater extent than in any other style. Moreover this style was carried on with the exclusive use of round arches long after the pointed arch had been established in other countries.

In taking leave of the Early Gothic style, the origin and development of the pointed arch must not be forgotten; but this will be treated of in connexion with the perfected thirteenth-century Gothic style. Gailhard's work, before mentioned, is illustrative of these as of other styles.

Meanwhile another distinct style, arising from the adoption of the Mahometan religion, has appeared on the scene and has darted about into so many parts of the world that the next article seems the fittest place for considering it.

**The Extensions at Waterloo Station.**—In our description of the extensive works here, it was stated that the Iron Roof Construction Company were doing the ironwork. We are asked to explain that all this ironwork is being manufactured by Messrs. M. T. Shaw & Co., at the London Constructive Iron and Bridge Works, Millwall, and that they are also the contractors for the erection of the same.

#### BUILDING PATENT RECORD.\*

##### APPLICATIONS FOR LETTERS PATENT.

Aug. 1.—10,835, G. Gowing, Ripon, Scraping and Cleansing Drains.—836, D. Cockshaw, Normanston, Joining Sanitary Pipes, &c.

Aug. 2.—10,875, F. L. Fear and P. Wilson, Birmingham, Door-springs.—10,876, J. Wilkinson, Birmingham, Ball-casters.

Aug. 5.—10,912, J. Green, Sheffield, Screening Closets.—10,931, A. C. Henderson, London, Alarm Latches.—Com. by O. Blanchot, Paris.—10,940, R. R. Parker, Dalmuir, Scouring Lock and Door Handles to their Spindles.

Aug. 6.—10,972, G. F. Newman, Birmingham, Spring Hinges for Closing Swing-doors.—10,977, G. Sanford and D. Hearnshaw, Birmingham, Holding the Corals of Window-blinds, &c.

Aug. 7.—11,021, A. Imber, Cologne, Retaining walls.—11,041, S. Lawrence, Glastonbury, Roofing Tiles.

##### SPECIFICATIONS ACCEPTED.†

Aug. 5.—1,112, T. S. Wilson and H. T. Johnson, Manchester, Ventilation of Soil-pipes, &c.—6,306, E. Page, Forest Gate, Grease-intercepting Gully-trap for Sinks.—9,657, J. J. Green, Halifax, Chimney-pots.—9,770, J. H. Johnson, London, Safety Bar for Limiting Movement of Doors, &c. Com. by MM. Varidel & Cie. and M. P. Moolin, Paris.

Aug. 8.—265, J. G. Ackroyd, Sowerby Bridge, Raising and Lowering Window-sashes.—711, G. Bisley, Rotherhithe, Fasteners for Window-sashes.—8,334, C. Dollin, London, Chimney-tops and Exit Ventilators.

##### ABRIDGMENTS OF SPECIFICATIONS

Published during the week ending August 9, 1884.

5,493, F. Leslie, Lond-n, Chimney Cowl and Ventilators. (Nov. 23, 1883, price 6d.)

A series of truncated conical shells are mounted one above another, the lowest being fixed as a collar round the top of the flue-pipe. On the top of the uppermost one is a horizontal annular metal plate, the opening in its centre being rather larger than that in the cone, and above this is another horizontal plate, which may have a diameter larger in diameter than the annular plate and cones to throw off the water.

5,940, H. Darby, London, Warming Air for Heating Apartments, &c. (Dec. 4, '83, 6d.)

Two vertical tubes form standards for supporting the stove, and they are connected together by several horizontal tubes, into the lowest of which the chimney of the lamp or the flue of the stove is led. A partition is here formed, so that half the heat, &c., passes to one side and half to the other, thence, along the other horizontal tubes, and down the hollow standards to the outlets, below which are receptacles for the condensed vapours.

5,925, J. S. Stevens and C. G. Major, London, Spring Hinges for Doors. (Dec. 29, '83, 6d.)

This is an improvement on Patent No. 5,281 of 1883, in fixing the piston to the piston-rod and attaching the outer end of the rod to the end or back of the box. The cylinder also has its closed end towards the pivot of the door, to the arms of which it is connected by rods, while it is entirely free to move in the box. Thus, when the door is opened the cylinder is moved on the piston, and not the piston in the cylinder.

#### Miscellanea.

**New Refrigerating Chambers at the Central Markets.**—During the last few months a massive and lofty chimney-shaft has been in course of erection at the west end of the Poultry Market. This structure is in connexion with refrigerating apparatus, which is being constructed by the New Zealand Frozen Meat Company for the purpose of storing and preserving the cargoes of raw meat which they import. The company have leased from the Corporation a large portion of the basement under the Poultry Market. Several of the arches in the basement have been converted into airtight chambers, and in these the meat will be stored. The refrigerating apparatus will be driven by powerful engines now in course of construction. The chimney-shaft is 10 ft. square at the base, and rises to a height of about 120 ft. It is faced with red brick, relieved by Portland stone and blue brick bands, the upper portion of the structure being in Portland stone upwards of 6 ft. in height. The four sides of the structure are in the form of panels. Communication with the meat chambers in the basement will be effected by lifts for lowering and raising the meat. Although the works have been carried out by the New Zealand Company primarily for their own special business, the apparatus will be available for use by the dealers generally in the markets. The air-tight chambers and other works, including the erection of the chimney-shaft, have been carried out by Messrs. Dove Bros.

\* Compiled by Hart & Co., Patent Agents, 186, Fleet-street.

† Open to public inspection for two months from the date named.

**The "New Town" of Earsfield and the South-Western Railway.**—The South-Western Railway Company are making large extensions at their new station at Earsfield for the accommodation of the traffic to and from that station (between Clapham Junction and Wimbleton), which since its opening a few months ago has considerably exceeded the company's expectations. They are at present engaged in the erection of waiting and refreshment rooms, together with other accommodation, on both sides of the station, the covered platforms of which are upwards of 600 ft. in length. This station promises to be one of the most profitable of the company's roadside suburban feeders, owing to the rapidity with which Earsfield and the locality are being developed. A large proportion of Earsfield is being erected on the Garrett Park estate, which is in the immediate locality of the station. The estate is upwards of 40 acres in extent, and a considerable part of this large area having already been laid out for building upon, between 200 and 300 houses have so far been erected, the houses and villas being let at rents ranging from about 30l. to 60l. per annum. Building on the estate is still going forward, more than 100 houses being now in course of erection, and it is intended shortly to lay out a further portion of the estate. The ultimate intention of the owners of the estate is to convert a portion of it into public recreation-grounds. The plans likewise include the conversion of the old Manor House into a suburban hotel for dining and pleasure parties. In the meantime two hotels are about to be erected in the locality, one on the estate, to be called the Garrett Park Hotel, and the other adjoining the railway station called the Station Hotel. In other directions in the immediate vicinity of the station, building is actively going forward, more than 200 houses having recently been erected in Earsfield-road, nearly one mile in length, which runs parallel with the railway, in the direction of Wandsworth-common. The increasing population of the locality has resulted in a line of omnibuses which commenced running on Monday last between Wandsworth, Earsfield, and Tooting.

**Precautions against Cholera.**—This was the subject of an able paper read by Mr. Edwin Chadwick, C.B., on Monday evening last, before the members of the Association of Public Sanitary Inspectors. The following are the main conclusions of the paper:—That our inquiries at the first general Board of Health have been affirmed by the latest and widest experience. That the Asiatic cholera is not spread by human intercourse, and that the practice of quarantine is useless and mischievous. That the most efficient preventives are the effectual cleansing of places and of persons; of persons by constant head-to-foot washing by tepid water. That the most effective treatment of cholera is in the earliest premonitory stages ascertained by house-to-house visitations, under competent instructions. That the fatality of pronounced attacks is aggravated by removal to large hospitals. That in the earliest detection and action of premonitory symptoms of all epidemics, officers of health should be appointed to make regular visits of examination to schools and workshops, followed by visits to examine the conditions of houses. That the power should be early exercised for the reduction of overcrowding. That for these purposes and the reduction of the expenses of preventible sickness, premature working disability, and excessive funerals, an augmentation of efficient sanitary service is required by the increase of the force of qualified sanitary officers. The discussion on the paper was adjourned.

**Parcels Post Accommodation at St. Martin's-le-Grand.**—When arrangements were in progress at the General Post-office for the accommodation of the Parcels Post Department, the space beneath the open area on the south side of the Post-office buildings, extending from St. Martin's-le-Grand to Foster-lane, was converted into a spacious apartment for the reception and despatch of parcels, the parcels being lowered into and raised from this apartment by lifts fixed along each side of the ground-level above, which was asphalted. For the protection of the horses and vans in waiting, and generally to facilitate the work of this department of the postal service, the area or space referred to has just been covered in to its entire length by a roof of iron and glass. The contractors for the work are the St. Pancras Iron Company.

**The Comedy Theatre, Manchester.**—The new theatre which is to be called "The Comedy," now erecting in Manchester for Mr. Edward Garcia, is situated in Peter-street, nearly opposite the Theatre Royal. The principal façade, 105 ft. in length, and main entrance, will be towards Peter-street, the gallery and stage entrances being in Bootle-street. The new theatre will be adjacent to Albert-square, immediately opposite the Central Station, and within a few minutes' walk of the Oxford-road Station. The building is arranged and divided longitudinally into three parts. The front portion contains the entrances and exits, the foyer, retiring and refreshment rooms; the centre portion is occupied by the auditorium, and the back part is devoted to the stage and its appliances; the adjacent property on the western boundary has been secured by Mr. Garcia, in which will be placed the dressing-rooms, property rooms, and the paint room, all of which will be approached directly from the street, but conveniently connected with the stage. The means of ingress and egress have, we are informed, had the most careful consideration of the architect, and have been arranged in consultation with the City Surveyor. All public staircases are 5 ft. wide, 12 in. tread, and 6½ in. rise; they are constructed of solid concrete resting on iron supports, and without "winders." The seating accommodation will be as near as possible as follows:—Stalls, 70 seats; pit, 667; dress circle, 200; upper circle, 264; gallery, 710; making a total of 1,920 seats, which, with standing accommodation, would realise an audience capacity of about 2,500 persons. The style adopted by the architect is "Venetian Gothic." The façade is faced with red brick, and strings, corbelling, oversails, and pointed arches are executed in terra-cotta from Mr. Edwards's works at Raahon, the labels, columns, balcony, &c., are executed in Halifax stone. The proscenium will be finished with a deeply-moulded architrave, forming a sort of frame to the stage pictures. Above the proscenium will be a recessed arcade. In the centre compartment will be seated figure typical of the Drama, those on the right and left being filled respectively with figures symbolic of Music and Painting. These figures will be flat and decorative in character, and in the style of the proscenium frieze executed for the Prince's Theatre by Mr. H. Stacy Marks, R.A. The building has been designed, the plans prepared by, and the whole of the works, including the decorations, are being carried out under the immediate superintendence of, the architect, Mr. Alfred Darlyshire, F.R.S.A., who for many years was associated with Mr. Culvert and Mr. Browne in the decorations and alterations at the Prince's Theatre, Manchester, and more recently with Mr. Irving, at the Lyceum, London. The contractors for the entire work are Messrs. R. Neill & Sons, of Manchester.

**An Ancient Lead Font.**—A correspondent writes:—There are so few ancient lead fonts remaining in England that any fresh discovery should be preserved. Very recently, in commencing the restoration of St. Margaret's Church, Wychling, under Mr. Joseph Clarke, F.S.A., the diocesan architect, the bowl of a circular lead font was discovered enclosed in a mass of brickwork, measuring 11½ in. deep and 1 ft. 5 in. in diameter. The lip is turned over with the rest on one side for the cover cast on, spreading and carried down as a band to the bottom of the bowl; but on the other side the rest seems to have been added after the font was cast. The ornament is curious; the circumference is divided into ten panels, and the lower parts of these panels are subdivided by a small semicircular band in the centre. The upper decagonal panels have each a stem terminating under lip by a band, with a beautiful floriated pattern. The semi-panels are quite plain. There is a fillet at the bottom of the bowl, all being cast in low relief. The lead is singularly thin, but these surface castings add strength. The usual hole for the drain-pipe remains, but has been mutilated. The date is probably late in the thirteenth century, or early of the fourteenth century. There are as well other interesting remains in this church, which is situated in one of the most secluded parts of Kent.

**North London Tramways.**—The tender of Messrs. Wilkes & Co., of 17, Devonshire-square, for altering the North London Tramways to make the line suitable for steam traction, has been accepted.

**Resignation of the Surveyor to the Vestry of Chelsea.**—We regret to hear of the resignation of Mr. George H. Stayton, C.E., the surveyor to the Vestry of Chelsea. The cause which has led Mr. Stayton to take this step is ill-health. During the time Mr. Stayton has held the appointment of surveyor to the Vestry (since Feb., 1875) important works have been carried out under his direction. Principally may be mentioned the establishment of the wharves and plant at an outlay of 26,000l.; the construction of several miles of new sewers and improvement of others in various parts of the parish at a cost of 32,000l.; the erection of the public offices at Kensal Town, which cost nearly 3,000l.; the laying down of three miles of wood pavement by the Vestry's own staff, at a cost of nearly 26,000l.; and the re-arrangement of the system of public street lighting at a saving of some hundreds of pounds a year. The formal acceptance of Mr. Stayton's resignation has been deferred by the Vestry till the first meeting after the recess. The members of the Vestry expressed great regret at Mr. Stayton's determination. Mr. Stayton purposes leaving England for Australia before the ensuing winter.

**Refuge Harbours and Ports of Shelter.** A meeting of noblemen, members of Parliament, harbour authorities, shipowners, and others,

will shortly be held at the Westminster Palace Hotel, over which Lord Warney has kindly consented to preside, to consider the details of a Bill and to make a concerted effort to give effect to recommendations of the Royal Commission and recent select Parliamentary Committee on Harbours and what is most desirable should be done to save the lives of our seafaring population. Also the best method of settling the question of sites for these harbours. Any particulars relative to the meeting alluded to will be gladly forwarded in reply to letters addressed to the Hon. Secretary, National Refuge Harbours Society, 17, Parliament-street, London.

**A Memorial Pulpit.**—A memorial to the late Rev. John Purton, for forty-nine years rector of the parish, has just been erected in Oldbury Church, near Bridgnorth. It consists of a carved oak pulpit in the Early English style, with clergy desks and seats. The whole has been executed by Messrs. Jones & Willis, of Birmingham and London.

**Mr. G. S. Aitken, F.S.A. Scot.**, an architect practising in Dundee, has in preparation an illustrated and descriptive work of the three Scottish Abbeys of Arbroath, Balmorino, and Lindores. Measured drawings and views will be given, and the work will cover a field not hitherto occupied.

**COMPETITIONS, CONTRACTS, & PUBLIC APPOINTMENTS.**  
*Epitome of Advertisements in this Number.*

**COMPETITIONS.**

Nature of Work.	By whom required.	Premium.	Designs to be delivered.	Page.
New School	Redruth School Board	25l.	Sept. 13th	ii.
Public Baths	Corporation of Stockport	£30, £30, £20	OCTOBER 1st	ii.
Municipal Hall and Offices, Bombay	Municipal Commissioners.	Rs. 5,000, 3,000, 2,000.	Nov. 6th	ii.

**CONTRACTS.**

Nature of Work, or Materials.	By whom required.	Architect, Surveyor, or Engineer.	Tenders to be delivered.	Page.
Troop Stable Barracks at Canterbury	War Department	Official	August 19th	ii.

**TENDERS.**

For the erection of new premises, for Messrs. Thupp & Maberly, Oxford-street. Messrs. Henry S. Legg, of Christ's Hospital, and Arthur Kinder, of Queen Victoria-street, joint architects:—

Wall Bros.	£14,997 0 0
Chappell	11,919 0 0
Jerrard	14,559 0 0
Kirk & Randall	14,175 0 0
Holland & Hannen	13,831 0 0
Perry & Co.	15,706 0 0
Hall, Beddall, & Co.	13,680 0 0
Brass (accepted)	12,973 0 0

For pulling down and rebuilding Nos. 1, 3, 5, and 7, Great Portland-street, 37 and 38, Great Castle-street, and premises in rear of Oxford-street, for Mr. J. P. Robinson:—

Holland & Hannen	£23,045 0 0
Lawrence & Sons	52,989 0 0
Hall, Beddall, & Co.	62,553 0 0
W. W. McGregor	50,600 0 0
C. Shaw	43,969 0 0
W. Brass	41,272 0 0
Perry & Co.	38,209 0 0
Higgs & Hill	37,740 0 0

For additions at 24, Park-lane, for Sir T. Brassey, K.C.B., M.P. Messrs. E. George & Feto, architects. Messrs. Stoner & Sons, surveyors:—

Hall, Beddall, & Co.	£16,840 0 0
Simpson & Sons	14,655 0 0
Brass	13,980 0 0
Colls & Sons	13,690 0 0
Peto Bros.	13,220 0 0
Manley	11,516 0 0

For the construction of brick and pipe sewers, precipitator-tanks, preparat on of land for filter-beds, &c., for the Willesden Local Board, being Contract No. 1, for the Brent District Main Drainage. Mr. O. Claude Robson, engineer to the Board:—

Williams, Son, & Wallington	£31,855 0 0
Bottoms Bros.	27,965 0 0
Oliver	26,660 0 0
Cooke & Co.	25,971 0 0
J. W. & J. Newve	25,840 0 0
Beadle Bros.	25,614 0 0
Rogers & Dickens	25,590 0 0
Newell & Robson	25,414 0 0
W. Beave & Son	24,938 0 0
C. Killingback	22,897 0 0
G. Felton	22,100 0 0

For additions to residence and erection of stabling, Chapter-road, Willenden Park, for Mr. Henry Dobbin, Mr. Walter Graves, architect. Quantities by Mr. H. E. Pollard:—

Table with 2 columns: Item description and quantity/cost. Includes William Oldrey, S. Melville, C. Cheshire, Cowley & Drake, Ward & Lambie, E. Toms, Ben T. Wood, W. Martin (accepted).

For the erection of detached residence, Willenden Park, for Mr. Henry Dobbin. Mr. Walter Graves, architect. Quantities by Mr. H. E. Pollard:—

Table with 2 columns: Item description and quantity/cost. Includes J. C. Tanner, W. Martin, E. Toms, S. Melville, Ben T. Wood, Ward & Lambie, Cowley & Drake.

For alterations, repairs, and decorations to 60, Brompton-square, for Mr. J. K. Stevens. Mr. Alfred Wright, architect. Belgrave House, 190, Brompton-road:—

Table with 2 columns: Item description and quantity/cost. Includes Craske, Jelly, Wilkins & Kent, W. Johnson (accepted).

For the erection of house and shop at King-street, Rungate, for Mr. H. Maull. Messrs. Hinds & Son, architects. No quantities:—

Table with 2 columns: Item description and quantity/cost. Includes Paramor & Son, Duckett, Martin, Smith, Bowman, Miller, Newby (accepted).

For paving Peppers-road as a new street, for the Greenwich Board of Works:—

Table with 2 columns: Item description and quantity/cost. Includes Mowlem & Co., Woodham & Fry. [Only two tenders received.]

For the Foundry Bridge, Norwich:—

Table with 2 columns: Item description and quantity/cost. Includes Horton & Sons, J. Barnes, Downing & Sons, B. Cooke & Co., Barnard, Bishop, & Barnard, Cleveland Bridge and Engineering Company, Jukes, Coulson, Stokes, & Co., R. Tidman & Sons, J. Butler, G. E. Hawes, H. Lacey, W. J. Botterill, Cook, Bennett, & Thew, T. H. Blyth, J. Holroyd.

For painting and decorating externally the several buildings of the Licensed Victuallers' Asylum, Old Kent-road, consisting of the chapel, chaplain's residence, Board-room, library, lodges, and 170 houses. Mr. W. F. Potter, architect. Quantities prepared by Mr. C. R. Griffiths:—

Table with 2 columns: Item description and quantity/cost. Includes Brazier & Son, F. & C. Hersee, B. Cook, E. F. Walsby, W. Wythe, W. Wells, S. Hayworth.

For internal repairs at the above Asylum:—

Table with 2 columns: Item description and quantity/cost. Includes E. F. Walsby, F. & C. Hersee, W. Wells, W. Wythe, S. Hayworth.

For new roads and sewers from Lordship-lane, on the Allen's College Estate, Westminster:—

Table with 2 columns: Item description and quantity/cost. Includes Mowlem & Co., Henry Hart, Wilkes & Co., G. Butter, Wheeler & Hindle, Eyles & Co., W. Harris, R. Mays, Eli Wilson.

For additions to Arundel-street Schools, Portsmouth, for the Borough of Portsmouth School Board. Mr. George Rake, architect, Portsmouth. Quantities by Mr. C. W. Bevis, of Southampton:—

Table with 2 columns: Item description and quantity/cost. Includes Earwaker, Biden, Evans, Roberts, White, Clark, Lewis, Tull, Quick, A. Light.

For painting and other repairs at Furnival's Inn, E.C., for Mr. H. Peio. Mr. R. Groom, architect, 171, Queen Victoria-street:—

Table with 2 columns: Item description and quantity/cost. Includes C. Wall, W. Nash, Goodwin, Gregory & Beuce, Oldis Bros, Kirk & Randall.

Accepted for building new premises and altering present premises at Mare-street, Haslemere. Mr. Mark W. King, architect:—

Table with 2 columns: Item description and quantity/cost. Includes Oldis Bros.

Accepted for shop front building and shop fitting, at No. 133, Fulham-road, Mr. W. Newton Dunn, architect:—

Table with 2 columns: Item description and quantity/cost. Includes Oldis Bros.

For alterations and additions to the Crown public-house, No. 43, Stanhope-street, Clare Market, for Mr. Thos. Finch, Mr. John T. Woodward, architect. Quantities not supplied:—

Table with 2 columns: Item description and quantity/cost. Includes Phelps & Bisler, F. Love, Beale.

For building a new bank at Canterbury, for the directors of the London and County Banking Company, Limited. Mr. J. G. Hall, architect, Canterbury:—

Table with 2 columns: Item description and quantity/cost. Includes Wiltshire, Gaskin, Paratony & Son, Denne & Son, Newlay & Son, Adcock, Doyr.

For the erection of new residence at Maidenhead Thicket, Berks, for Mr. A. Lawrence. Mr. Arthur Vernon, architect, 23, Great George-street, Westminster, and High Wycombe, Bucks:—

Table with 2 columns: Item description and quantity/cost. Includes Suel, Lovell, Martin, Taylor & Gribb, Cooper & Son, Hunt, Silver, Sons, & Filwood.

For pulling down and rebuilding the Horse and Groon, Upper Horseway, for Mr. W. H. Chapman, Messrs. Perry & Reed, architects, 8, John-street, Adelphi. Quantities supplied:—

Table with 2 columns: Item description and quantity/cost. Includes Clark & Bracey, Outhwaite, Patman & Fotheringham, Brass, Macey, J. Beale.

For new counter and alterations to Coffee House Tavern, Beals-street, Regent-street, for Mr. North. Mr. George Treacher, architect, 23, Carter-lane:—

Table with 2 columns: Item description and quantity/cost. Includes Langridge, Drew & Cadman, Howitt, J. Beale.

For London and County Bank, Kensington, Mr. A. Williams, architect; Messrs. Widnall & Trollope, surveyors:—

Table with 2 columns: Item description and quantity/cost. Includes Chamberlain, Chappell, Lovett, Holland & Hannen, Troughton & Sons, Aldin & Plattner, Perry & Co., Peto Bros., Rider & Sons.

For the erection of the first portion of the monastic buildings of Buckfast Abbey, Buckfastleigh, Devon, for Right Hon. Lord Clifford of Chudleigh. Mr. Frederick A. Walters, architect, 4, Great Queen-street, Westminster. Quantities supplied by Mr. W. H. Brayshaw:—

Table with 2 columns: Item description and quantity/cost. Includes Walsheban, Lethbridge, Moss & Son, Luscombe & Son, Pugh, Gibbard, Cowlin, Stephens.

For new Primitive Methodist chapel and lecture hall at Aldwick, Croydon. Mr. James Veir, architect, 9, Victoria-street, Westminster. Quantities supplied by Mr. C. G. Maylard:—

Table with 2 columns: Item description and quantity/cost. Includes Shapcott, Homewood, Hobbs & Son, Humphreys, Marriage, Holloway.

For warming, &c., above:—

Table with 2 columns: Item description and quantity/cost. Includes Shapcott, For alterations and additions to stable, coach-house, and dwelling, at 17, Pitt's Head-mews, Park-lane, for the Hon. A. de Tatton Egerton, M.P. Mr. E. Cross, architect, No. 32, Berners-street:—

Table with 2 columns: Item description and quantity/cost. Includes R. Elwin, W. Downs, W. A. Rhodes, J. & J. Greenwood, J. Hoare & Son, F. Higgs.

For wrought-iron galleries, for the Guardians of the Poor, of St. Leonard's, Shore-ditch. Mr. J. Wallace Peggs, engineer, Queen Anne-street, N.W.:—

Table with 2 columns: Item description and quantity/cost. Includes Macfarlans & Co., Joseph Stone, Turner & Co., Jukes, Coulson, Stokely & Co., Brunel & Co., Gardner & Co., St. Pancras Iron Works Co., B. Cook.

For making good certain repairs at houses known as Nos. 1 to 9, Providence-place, Verulam-street, Gray's Inn-road, for Mr. T. Parker. Mr. H. I. Newton, architect:—

Table with 2 columns: Item description and quantity/cost. Includes W. Read, B. Cook.

Special Notice.—Lists of tenders frequently reach us too late for insertion. They should be delivered at our office, 48, Catherine-street, Strand, W.C., not later than four p.m. on Thursdays.

TO CORRESPONDENTS.

G. M.—J. S. G.—A. C. (plan and letter received, shall appear as soon as practicable in 'The Builder' (general)—E. W. W.—E. J. K. (drawing received, send description)—W. F. S.—O. M. W. S.—G. R. D.—M. F. B.—H. H. B. (just week)—A. Verina (your story rather too long and incoherent for our crowded columns)—C. H. C. (below your marital)—A. D.—K.—& Co.—H.—S. All communications relating to advertising, and all artistic matters should be addressed to THE EDITOR; all communications relating to advertisements, and all business matters should be addressed to THE PUBLISHER; and not to the Editor. All statements of facts, lists of tenders, &c., must be accompanied by the names and addresses of the senders, but necessary for publication. Writers are compelled to decline pointing out books and giving addresses. NOTE.—The responsibility of signed articles, and papers read at public meetings, rests, of course, with the authors. We cannot undertake to return rejected communications. Letters or communications (beyond mere news-items) which have been duplicated for other journals, are NOT DESIRED.

PUBLISHER'S NOTICES.

CHARGES FOR ADVERTISEMENTS. SITUATIONS VACANT, PARTNERSHIPS, APRENTICESHIPS, TRADE, AND GENERAL ADVERTISEMENTS. Six lines (about fifty words) or under, ..... 5s. 6d. Each additional line (about ten words) ..... 6s. 6d. Terms for Series of Trade Advertisements, also for Special Advertisements on front page, Competition, Contracts, Sales by Auction, &c. may be obtained on application to the Publisher.

STATIONS WANTED. POSTS LISTS (about THIRTY words or under) ..... 2s. 6d. Each additional line (about ten words) ..... 6s. 6d. PREPARATION IS ABSOLUTELY NECESSARY. \* \* \* \* \* Stamps must not be sent, but all small sums should be remitted by Cash in Registered Letters, by Money Order, payable at the Post-office, Covent-garden, W.C. to DOUGLAS FOULDRINE, Publisher, Addressed to No. 48, Catherine-street, W.C.

Advertisements for the current week's issue must reach the Office before THURSDAY noon, on THURSDAY. The Publisher cannot be responsible for DRAWINGS, TESTIMONIALS, &c. left at the Office in reply to Advertisements, and strongly recommends COPIES ONLY should be sent.

TERMS OF SUBSCRIPTION. 'THE BUILDER' is supplied gratis from the Office to readers in any part of the United Kingdom at the rate of the per annum, PREPAID. To countries without the Postal Union, 25s. per annum. Remittances payable to DOUGLAS FOULDRINE, Publisher, No. 48, Catherine-street, W.C.

SPECIAL ADVERTISEMENTS IN STANDING ADVERTISEMENTS OR ORDERS TO DISCONTINUE, name, must reach the Office before TEN O'CLOCK ON WEDNESDAY morning.

PERSONS Advertising in 'The Builder,' may have Copies addressed to the Office, No. 48, Catherine-street, W.C. Letters will be forwarded if addressed in envelopes are sent, together with sufficient stamps to cover the postage.

Best Bath Stone. WESTWOOD GROUND, Box Ground, Oombe Down, Corsham Down, And Farleigh Down. BANDELL, SAUNDERS, & CO., Limited, Corsham, Wilts. [Advr.]

Box Ground Stone. Is the Best for Use in all Exposed Positions, being a well-known and tried Weather Stone. 50,000 feet cube in stock. PICTOR & SONS, BOX, WILTS. [Advr.]

Douling Freestone and Ham Hill Stone of best quality, in blocks, or prepared ready for fixing. An inspection of the Douling Quarries is respectfully solicited; and Architects and others are CAUTIONED against inferior stone. Prices, delivered to any part of the United Kingdom, given on application to CHARLES TRASK, Norton-sub-Randoin, Hants. Somerset.—Agent, Mr. E. WILLIAMS, 73, Charlotte-street, Portland-place, W. [Advr.]

Douling Free Stone. For prices, &c., address S. & J. STAPLE, Quarry Owners, Stone and Limo Merchants, Stoke-under-Ham, (Ground or Lump), Hants. [Advr.]

Asphalte.—The Seyssel and Metallic Lava Asphalte Company (Mr. H. Glenn), Office, 33, Poultry, E.C.—The best and cheapest materials for damp courses, railway carriages, warehouse floors, flat roofs, stables, cow-sheds and milk-rooms, granaries, tun-rooms, and terraces. [Advr.]

Asphalte. Seyssel, Patent Metallic Lava, and White Asphaltes. M. STODART & CO. Office: No. 90 Cannon-street, E.C. [Advr.]

J. L. BACON & CO., MANUFACTURERS OF IMPROVED STEAM AND HOT-WATER APPARATUS, FOR WARMING AND VENTILATING Private Houses, Churches, Schools, Hospitals, Manufactories, Greenhouses, &c. OFFICES AND SHOW-ROOMS: No. 34, UPPER GLOUCESTER PLACE, DORSET SQUARE, LONDON, N.W. And at DUBLIN, BELFAST, GLASGOW, and NEWCASTLE. Illustrated Pamphlet on "Heating" post free.

### On Structural Proportion in Nature and Art.

THE *Journal of Hellenic Studies* for October last contains an article by Professor Michaelis of Strasburg, who has already explored so assiduously the private collections of ancient art in England, upon a remarkable basso-relievo among the Arundel collection at Oxford. It is illustrated by an excellent plate, after a photograph, and is replete with proofs of the learning and the labour which the author has always at command for a worthy subject. The slab is in the form of a pediment, but with the narrow angles cut off by a vertical line, and bounded on all sides and horizontally by a narrow projecting border. The surface is occupied by the figure of a man, somewhat above life-size, in relief, with arms extended and open palms. The head, shown in profile, reaches to the central angle, and the figure is cut off a little below the line of the nipples by the horizontal cornice. The features are battered; but the arms, though in low relief, are boldly modelled, and exhibit distinguished mastery of outline. In the field, as it may be called, above the right arm, is the outline of the sole of a foot, formed by a shallow scraped line, which shows distinctly the contour of the toes. Fortunately this has not suffered so much, scratched and rubbed as it is, as to frustrate the recovery of its exact dimensions.

This sculpture is of interest from three points of view,—on all of which the Professor disserts with true German elaboration. As a specimen of ancient sculpture it invites consideration as to its period and its style; it then appears to supply authentic original evidence on matters metrological,—the standard foot of the sculptor's nation,—and lastly, what we are now chiefly concerned with, we appear to have before us a visible memorial of the modulus of the artist as applied to the proportions of the human figure.

Those who are acquainted with the present German school of archeological research and criticism will be quite prepared to find that little difficulty is made of assigning the work to a particular half-century by indications of style; and that a banking is even indicated for narrowing the limitation within a precise decennium. We may pass over this discussion, contenting ourselves with the remark that if there were no other reason for disallow-

ing an Attic origin for the monument, we should decline to give weight to the argument that "an Attic artist would certainly have raised from the ground all the outlines rather strongly with a sharp edge, and would have represented the muscles of the arms with more subdued modelling." This seems to be an inference from some characteristics of the frieze of the Parthenon,—a work executed for an exceptional position; but even there, if the critic will look again, he will find that not "all the outlines" were so treated, and a little further observation will reveal a reason for the variation of method.

Again, only a few sentences can be spared for the very acute and learned, but nevertheless slightly perplexing, metrological analysis.

The best measurement that can be made of the footsole gives it as 0.296 m., which coincides with the Roman *pes monetalis*, and differs by .012 m., or more than the eighth of an inch, from what has been the very generally accepted Attic foot, 0.308 m. But we are not allowed by the Professor to assume that we have before us a work executed in Greece when under Roman domination. We are called upon to accept 0.296 as the true measure of the Attic foot which became the model for the Roman. Be it so; but it is then pointed out that this foot is exactly one-seventh of the breadth given by the extended arms of the sculpture, from finger-tip to finger-tip, and an anomaly declares itself in consequence, which is frankly recognised. This extent is called a fathom; but the Attic foot which is represented by the sculpture, was reckoned by the current standard, the sixth of a fathom, not the seventh. The Egyptians, however, we are reminded, had two fathoms, of which the longer, the royal fathom, just meets the case: assume that it was this which Herodotus said coincided with the Samian fathom, and the difficulty may be surmounted by the further assumption that the monument is to be referred to Samos; we are then, it is true, face to face with the incongruity of the association of an Egyptian or Samian fathom with an incommensurate Attic foot; but the learned author is equal to the occasion, and meets this new difficulty, better or worse, by the conjecture that "possibly the conditions of international commerce at Samos were such as to require an indication of a double system," &c. "The addition of the Attic standard measure would then be far from startling. Possibly this addition was only made after Samos had passed entirely into the dominion of victorious Athens," and so forth.

But all this ingeniously-butressed superstructure rests precariously upon the assump-

tion that the full extent of the expanded arms of the sculptured figure must necessarily represent a definite measure of a fathom, the accepted equivalent of the height of a well-grown and developed man. But it is clear that the figure represents the proportions of the human figure upon, not a natural but an enhanced scale,—a scale which gives a stature of the excessive height of seven standard Greek feet.

The most certain fact in the case is an intention to exhibit the proportion of the length of foot of a well-made man to the extent of his expanded arms and hands, as one-seventh; and doubtless with reference to the common and notorious experience that this extent was equal to his full stature. But a pure exhibition of proportion is independent of the natural scale; the sculptor might have taken any stature at choice or at random. He chose to take, not the length of an actual human foot of a man 6 ft. high at the utmost, but the reputed foot,—the standard Attic foot measure as a modulus,—conceding, for argument sake, that the foot measure, 0.296 m. is the true Attic. This decision fixed him with a representative figure beyond the ordinary life-size; in fact, of an implied height of 2.070 m., instead of about 1.750 m.—that is, of 7 ft. instead of 6 ft., and consequently a breadth for the expanded arms of his monument which by the same difference exceeded that of the average or ordinary man. Had the sculptor adhered to Xenophon's definition of the fathom, the extent within reach of the extended arms of an ordinary man, he must have given up the Attic foot, whether .308 m. or .296 m., as a modulus, and engraved a shorter foot-sole,—a foot-sole not exceeding  $1.75 \div 7 = .250$  instead of .296.

Assuming, then, that the expanded arms are to be taken as index of stature, we find that the length of one-seventh of this given to the foot is in accordance with the rule laid down by Leonardo da Vinci, but not specified by Vitruvius in his well-known canon.

The Vitruvian rule of making the hand, measured from wrist to tip of middle finger, one-tenth of the stature, is borne out very closely by the marble; and so also is the rule of one-tenth for the face from the chin to the roots of the hair above the forehead.

The record of Vitruvius again gives the height of the head from the crown to the chin as one-eighth of the stature, and the monument approaches this as nearly as 0.255 in. to the required 0.250.

A number of other precisely-adjusted proportions may be detected in this interesting

effigy, but enough have been noted for the purpose at present in hand. It will be observed that in these proportions as derived and copied from Nature's own handiwork, the dimensions brought into comparison are not reducible to terms of a single uniform modulus. Dimensions which compare variously in terms of different prime numbers, 2, 3, 5, 7, &c., defy reduction to a common unit of moderate subdivision. It is this difficulty which occurs in tuning musical instruments of fixed notes, and which is met or modified by the contrivance of equal temperament. The equivalent of this in architecture is the regulation of dimensions by subdivisions of a fixed modulus; this is very largely favoured by Vitruvius, but it is observable that he still preserves traces of the more scientific system of regulation by direct proportion. Modern examination has gone far to prove that this system was practised exclusively in the best Athenian age.

Of course there is no record to inform us how early the Greeks, in their devoted admiration for the human figure, began to recognise exact numerical standards of proportion for its most perfect development; but that it was at a very early age can scarcely be doubted. The conditions of health, activity, and athletic vigour occupied their attention from the earliest times of which we have historical record; and incomplete and fragmentary as are the remains of their early sculpture, an art which was steadily progressive through centuries, they are sufficient to indicate a sustained endeavour to approach nearer and nearer to distinct typical forms of which the characters were directly dependent on proportion. That the arts of sculpture and architecture should have been in course of development and intimate connexion together, through a long series of years, without mutual reactions, is not to be supposed; it were vain to speculate which of the pair was under greater obligation to the other. It is quite possible that the sculptor owed first to the architect his confirmed conviction of the value for artistic expression of exact and appropriately adjusted numerical proportion. However this may be, it most certainly appears, upon study of the finest productions of either art, that they held in common by the principle that an harmonious whole was not to be built up out of varied combinations of one uniform elementary dimension, or fixed invariable unit, but by varied proportionate subdivisions freely based upon the simplest of the prime numbers, 2, 3, 5, 7, more especially.

A notice remains of the principle which one ancient writer adopted and worked out in a lost treatise on the proportions of the human figure, which in itself has much to recommend it; he set forth that the proportion of every member, from the least to the larger, was adjusted to that with which it is in immediate organic relation. The finger has dimensions proportionate to the hand, the hand to the forearm, the forearm to the upper arm, the arm to the body, and so onward by a series of deductions and comparisons, which would lead ultimately to the estimate of full bulk and stature. This scheme is virtually implied in the proverbial phrase, *ex pede Herculem*; the foot of Hercules being given, the proportions of the hero at large are given. That the given foot would determine stature, within certain limits, is unquestionable; and it is also to be conceded that it would, within certain limits again, decide the character of the figure,—would give assurance of a frame as contrasted as possible to that of a Ganymede or an Apollo. But still, apart from previous knowledge of the type, it would by no means suffice for the recovery of the sculptor's ideal. The tracery of a window, or even the fragment of a moulding, suffices for general conclusions as to the style and period of a ruined cathedral, but will go little way indeed towards enabling us to restore, with any completeness and precision, the lost glories of a vast original and complex structure. The creative impulse of true artistic design, as of natural organisation, enforces the subordination of parts to a whole, of the subsidiary as derived, to the superior as antecedent. In both cases what controls the number, the nature, the inter-

dependence of component members and their proportionate adjustments, is the equivalent to a primary characteristic idea; it is therefore from this idea that the processes of invention and imagination are most safely understood to start, and analytical study is only complete when this generative thought is recovered. The human foot is doubtless most admirably subservient to the purposes of the general organisation, but, taken by itself, it might be studied for ever, and no process of deduction would derive from it a knowledge of the marvellous mechanism of the human hand with which it is so intimately associated. Few triumphs of sagacity are more surprising than that of Professor Owen, who by minute scrutiny of a single fossil bone sent to him from Australia, announced the former existence of a bird of proportions that to the uninitiated seemed inconceivable, until confirmed by subsequent transmission of more of the skeleton. But the divination was effected by quickness of observation, sagacity and study, co-operating with stored knowledge of other complete organisms. The bone, taken by itself, would no more reveal even to an Owen, or necessitate all the details of the organism, than a moulding from Glastonbury would give up to an Australian Fergusson the plan and elevation of a cathedral. It is, no doubt, true that invention and imagination the most emancipated, when exercised upon an architectural problem, cannot emancipate itself from relation to material conditions, and will be largely controlled, if not governed, by them. It may be allowed to the imagination of the poet to give a local habitation and a name to "airy nothing," but an architect cannot escape from having to take into account the cohesion, resistance, and equilibrium of wood and marble, of bricks and mortar, and must, perforce, submit to limitations of proportionate parts, of voids and solids, of spans and scantlings accordingly. But this does not deliver over the mastery of his art to the material it is employed upon.

He works in this respect on parallel lines with the creative energies of nature. The foot of the camel has relation in size, strength, and elasticity, to a sandy desert, and the hoof of a horse to springy turf. But in both cases these particular material conditions are quite insufficient to decide the general habits and capacities of the animals. They are, as they have to be, regulated and subjugated in a manner and to an extent which gives them their place in a series of correlative adjustments. It is only so that they display their proper significance and become instrumental in conciliating a variety of secondary purposes in furtherance of main and important ends. It is only when this conciliation is perfected in the completed work, an ultimate harmony of admirably correlated functions and services, be it the organised animal or the architectural structure, that the idea which has governed the regulating and subjugating process all through becomes apparent and obtains its full expression. The material conditions in each case set limits to what can be done with them, but cannot determine what shall be or what must be done. Hence it is, that if we hope to discover the secret of those proportionate adjustments which in either case hold a complex of details and members together in unity, we must consider the main purposes, and, therefore, the largest relations first, and descend from those to the subordinate. By starting from the stature of the man we may more safely deduce not only foot and hand, but the limbs and general proportions; even as the proportions of nave and choir will guide us most satisfactorily to the appropriate dimensions of aisles or entrance-porch, or the predetermined scale of reception-rooms will impose and govern the nature and distribution of offices.

In dealing with any practical problem whatever, the primary requirement is a well-studied and distinct conception of the end proposed,—the chief purpose which renders it necessary or worth while to entertain the problem at all, and then of all the indispensable accessory aids and completions of that purpose. When we further proceed to realise the conception,

particular adjustments are necessarily influenced by the nature and limitations of the means and materials at command. But the managing and moulding power still resides in the intelligence, and intelligence works from the end in view to the means by which,—from the general to the particular,—from a purpose as a whole to the several secondary and inferior furtherances as parts. Such is the grand conception of Cuvier as it is of Aristotle, almost the first name of importance on such a subject, that we come to looking back through the centuries before Cuvier. It was propounded by Anaxagoras that man is the most intelligent of organised beings in consequence of having hands: nay, argues Aristotle, man has hands because he alone of animals is gifted with sufficient intelligence to make right and full use of them. To the like effect, when in his treatise on the Generation of Animals he disserts on the development of the embryo, he notices that nature manifests the most essential characteristics, first in decisive outline, and afterwards brings forward the subordinate completions, even as a painter, he says, first makes a general sketch, and settles the leading contours of his design to be completed afterwards by filling in details and finishing with colours.

It appears, then, that if we are to hope to attain to a thoroughly worthy and masterly conception of the principles of proportion in the human figure we must not be contented to rest in compiling a list of the proportions of particular members,—mere detached hints and notices which may have their use in keeping an artist clear of any very gross divergences from a normal standard: what is required is a comprehensive theory which shall embrace the entire system in a simple scheme, and a coherent unity from which subordinate proportions are developed in appropriate gradation. That a somewhat nearer approach to a solution of the problem than is provided by the systems most in vogue is not hopelessly unattainable, may be set forth in a future article. The theory of composition in all the arts is in closest relation to a theory of harmonious proportion, and if ever a clue to its true significance is to be grasped, it may be hoped for from the study of that work of nature of which Haulel is only echoing Aristotle's reverential awe and admiration when he exclaims,—“What a piece of work is man! In form and moving how express and admirable!”

#### THE METROPOLITAN BOARD OF WORKS AND LONDON THEATRES.

**S**TIMULATED to action by the destruction of the city of Chicago and the disastrous fire at the Brooklyn Theatre in 1876, a Select Committee of the House of Commons was appointed in the year 1877 to inquire into the constitution, efficiency, emoluments, and finances of the Metropolitan Fire Brigade, with a view to providing further security from loss of life and property from fire. This Committee, which was presided over by Sir Henry Selwin-Ibbetson, consisted of twenty-one members, and included Sir Andrew Lusk, Mr. Locke, and Mr. Ritchie as representing Metropolitan constituencies, and Sir James McGarel-Hogg, the chairman of the Metropolitan Board of Works.

The immediate object of the Committee was to inquire into the working of the Metropolitan Fire Brigade, but the scope of the inquiry was enlarged by an instruction, moved at the instance of Mr. Onslow, that the Committee should have power to take evidence and report, with special reference to better means of preventing loss of life and property from fire in theatres and other places of public amusement. This instruction led to the taking of a considerable amount of evidence with regard to the construction of theatres, the means then available for the extinction of fire and the preservation of life in theatres and music-halls, and resulted in an important amendment of the law as affecting these places.

The Committee received evidence as regards theatres, &c., from the then Lord Chamberlain

(the Marquis of Hertford), the permanent secretary of the Lord Chamberlain's department (Mr. S. Ponsonby-Fane), and the architect officially consulted by the Department (the late Mr. J. T. Robinson); Mr. J. F. Powall, the chairman of the Middlesex magistrates; Mr. George Vulliamy, the Architect to the Metropolitan Board of Works; Captain Shaw; Mr. Edwin Chadwick, C.B.; Mr. F. C. Penrose, the Surveyor to St. Paul's Cathedral; Mr. C. J. Phipps, the architect of several of the London theatres; the proprietors or lessees of the Court Theatre, the Criterion Theatre, the Folly Theatre (now Toole's Theatre), the East London Theatre, the Pavilion Theatre, and the Gaiety Theatre; the proprietor of the Canterbury Music-hall; Mr. Maberley, the architect to Exeter Hall; and Mr. Mitchell, one of the Committee of Management of the Sacred Harmonic Society.

One of the most important witnesses examined by the Committee was the Hon. Spencer Ponsonby-Fane, the controller or permanent secretary of the Lord Chamberlain's department, who, in the course of his evidence, admitted that the control of the Lord Chamberlain over theatres was inefficient, and suggested that there should be a Government department to superintend all public buildings as regards their construction; that the Lord Chamberlain's licence should be preserved, but that the issue of such licence should be dependent upon the production of a certificate from the department that the building to be licensed was in a satisfactory condition. The censorship of the Lord Chamberlain over pieces to be performed, Mr. Ponsonby-Fane suggested, might be retained.

Speaking of the Opera Comique Theatre, Mr. Ponsonby-Fane, in the course of his evidence, characterised it as being "one of the most fortunately placed theatres in London," and explained that the tunnel under the street was made after the theatre had been built and had been opened to the public, and that the tunnel had been added by the permission of the Lord Chamberlain. "I must point out to the Committee," he concluded, "probably anticipating objection, "that it is underground; that it is fire-proof; people might be drowned there, but certainly they could not be burned."

It was elicited from this witness that the Lord Chamberlain had no power to require structural alterations to be made to existing theatres, and that in fact the only means of reaching a manager who disregarded the Lord Chamberlain's recommendations was the withdrawal of his licence, and this, he considered, would be too great a punishment. "The Lord Chamberlain," he said, in reply to a question (No. 1,251), "has no staff of inspectors. I, as the permanent Secretary of the Department, look to it entirely, assisted by the Examiner of Plays, who is an officer of the department. We also employ from time to time the best surveyor we can find to accompany us in those inspections, but we cannot be always inspecting. The inspection takes place once a year, or at the request of any manager if he is going to make an alteration."

The Committee made a report, in which they stated that in their opinion the structural conditions and arrangements of places of public amusement requisite to meet the danger of fire or panic are mainly regulated by practical considerations, and can only be settled by experts. As a safeguard against fire from without, the Committee recommended that the building should be isolated, either by an intervening space or by a wall of proper strength and material. With regard to the interior, in addition to the necessity of substantial fireproof construction, four points appeared to the Committee especially to require attention, viz.:

- (1) Subdivision of risk, by separating from each other the various parts of the buildings, rooms, and passages by fireproof partitions;
- (2) distribution of rooms, with a view to minimise the chance of a fire breaking out; for instance, no room should be constructed above the stage, nor should the carpenters' shop be allowed to be placed above the lights of the gallery;
- (3) facility of egress. The outlets should be numerous and separate; passages should widen outwards, and be large enough

to contain a considerable proportion of the whole audience. In these passages no steps should be allowed, or other impediments likely, in case of pressure, to throw down persons or injure them. At the same time arrangements should be made to break the pressure by the interposition of barriers at intervals, or giving an angular direction to the passage; all doors should open outwards; (4) appliances for the extinction of fire. Hydrants in connexion with the mains, and provided with hose, should be placed round the building, and also carried within, capable of throwing a jet to any part of the interior.

The report, in conclusion, recommended that no new theatre or large music-hall in the metropolis should be finally licensed until it had been certified that in respect of position and structure, it satisfied all due requirements for the protection against danger from fire, and that the Metropolitan Board of Works should be the certifying authority.

The report also recommended that, with respect to existing theatres and halls, the Metropolitan Board should have power to call on the proprietor to remedy such structural defects as appear to the Board to be the cause of special danger, and to admit of being remedied by a moderate expenditure, option being allowed to the proprietor to refer the whole question to arbitration.

That, with a view to the prevention of danger from fire, the Lord Chamberlain and the justices should be authorised to make regulations as to the management of theatres and music-halls under their jurisdiction; that, for the purpose of ascertaining whether such regulations are complied with, provision should be made for the inspection of these buildings, and that any breach of the regulations should be punishable on summary prosecution.

It was further recommended that effect should be given by the Legislature to these recommendations.

In the session of 1877-8 a Bill was introduced into Parliament by the Metropolitan Board of Works, which became law as the Metropolitan Management and Building Acts Amendment Act, 1878 (41 & 42 Vict., ch. 32). By the 11th section of this Act the Board are empowered to require the proprietors of theatres and of certain music-halls in use at the time of the passing of the Act to remedy structural defects which may result in special danger to the public frequenting the same. The consent of the Lord Chamberlain in the case of theatres under his jurisdiction, and of the Home Secretary in the case of all other buildings, is necessary before any proceedings can be taken by the Board, and the defects must be such as can be remedied by a moderate expenditure. Music-halls containing a superficial area of less than 500 superficial feet for the accommodation of the public are exempt from the operation of the Act.

The penalty imposed by the Act for non-compliance with the Board's requirements is 50*l.*, and a further penalty of 5*l.* per day in case of the continuance of such default. Provision is made for an appeal, the matter in dispute being referred to an arbitrator appointed by the First Commissioner of Works.

The Board are further empowered by the 12th section to make regulations with regard to new theatres and such music-halls as are not exempted from the Act, with respect to the requirements necessary to protect the public from danger in the event of fire, and may alter or vary the same from time to time.

No new building can be opened or used as a place of public amusement; that is to say, for the public performance of stage plays, or for "dancing, music, or other entertainment of the like kind" (these words being the form used in the Act of Geo. II.,—25th Geo. II., cap. 36), without a certificate from the Board that the building was on its completion in accordance with the Regulations made by the Board, so far as the same are applicable, and to the conditions (if any) annexed thereto.

In accordance with the provisions of this Act the Board, on the 2nd of May, 1879, drew up a series of regulations for the construction of theatres and music-halls. These regulations provide that previously to any house or other

place of public resort being opened for public entertainment, notice shall be given to the Board, accompanied by drawings of the building, with a specification of the materials to be employed, and a statement as to the number of persons to be accommodated in the building. If the drawings are approved, a certificate is issued by the Board in respect of the building, on its completion in accordance with the drawings approved by the Board.

The regulations further require that every theatre shall have a proscenium wall of brick to separate the stage from the auditorium; that the staircases and the floors of the several passages, lobbies, corridors, and landings shall be constructed of fire-resisting materials; that the minimum width of all staircases and corridors shall be 4 ft. 6 in.; that a clear passage-way, not less than 3 ft. wide, shall be reserved round every part of the building appropriated to the audience; that all iron-work used in construction should be protected from the action of fire; that a separate exit should be provided from every tier or level, communicating directly with the street; that all doors be made to open outwards; that where the building is warmed artificially hot water only, at low pressure, shall be used; that the means of ventilation shall be explained on the drawings; that no rooms be formed over the auditorium or in the space under the same; that the scene-docks, property-rooms, and store-rooms be separated from the theatre or other buildings by fireproof construction; that provision be made for extinguishing fire; and that all gas-pipes be of iron.

The Metropolitan Management and Building Act Amendment Act, 1878, received the Royal assent on the 22nd of July, 1878, but very little was done under its provisions with regard to existing theatres and places of amusement until the occurrence of the disastrous fire at the Ring Theatre at Vienna in December, 1881, which again called public attention to the subject.

In 1882 an Act was passed to confer various powers on the Metropolitan Board of Works and to amend certain Acts relating to that Board: the 45th section of this Act,—the Metropolitan Board of Works (various powers) Act, 1882 (45 Vict., c. 56),—gives the Board power to regulate the times during which the exit doors of places of public entertainment shall be kept open; the conditions under which such doors may be closed, and the persons to be charged with the duty of closing and opening the same; the nature of the fastenings to such doors; and the notices to be posted in such house, room, or place of public resort, specifying the means of exit.

The penalty for non-compliance with the Board's requirements is 10*l.* for every day, and the Board are authorised to enter and inspect any place of public resort for the purpose of ascertaining that their requirements have been complied with at any time.

On the 18th of April, 1882, shortly after the Easter recess, Mr. Dixon-Hartland called attention in the House of Commons to fires in theatres, and moved for a Select Committee to investigate the state of the exits of the metropolitan theatres and the appliances existing for the prevention and extinction of fires in theatres and music halls. Sir Wm. Harcourt, the Home Secretary, thanked Mr. Dixon-Hartland for calling attention to the matter, but assured him that in his (the Home Secretary's) opinion the then existing machinery was perfectly effective if put in force, adding that he had instructed Captain Shaw to report upon the condition of the London theatres; that he had already received reports as regards eight theatres, and that he had communicated with the owners of the rest. On receiving this explanation Mr. Dixon-Hartland withdrew his motion.

On the 17th of July, 1882, Captain Shaw presented to the Metropolitan Board of Works a report upon the remaining thirty-three theatres in the metropolis, he having on the 21st of March reported upon eight others. These reports were made at the instance of the Home Secretary, moved thereto, it was reported, by an exalted personage; the reports were printed and were forwarded to the Home

Secretary, and by him communicated to the various owners, but they have not been made public for obvious reasons. Captain Shaw's reports are of an exhaustive nature, and deal with every branch of the subject, including recommendations with regard to the site, the number of persons to be accommodated in different parts of the House, the lighting, warming, and ventilation, the storage and protection of scenery and properties, watching, and appliances for the extinction of fire, all of which are matters beyond the control of the municipal authority. It is satisfactory to know that, as regards the watching and fire-appliances, in only ten instances are they condemned as bad, and that out of these ten theatres eight have been rebuilt, and in eight cases only the appliances were reported to be insufficient and to require supplementing chiefly by additional lengths of hose.

There are at present forty-three theatres in London and the suburbs, of which number nine have been recently rebuilt or remodelled, and six may be called new, having been erected since the passing of the Metropolitan Building and Local Management Amendment Act, 1878, upon sites not previously occupied by theatres.

The following is a complete list of the theatres kept open under the authority of Letters Patent or of a licence from the Lord Chamberlain or from the Justices of the Peace:—

Adelphi Theatre.	Hengler's Grand Cirque.
Alhambra.	Her Majesty's.
Astley's (now Sanger's Amphitheatre).	Imperial.
Avenue.	Lyceum.
Britannia.	Marylebone.
Comyngham (now Holborn).	Novelty.
Comedy.	Olympic.
Court.	Opera Comique.
Covent Garden.	Pavilion.
Criterion.	Philharmonic.
Crystal Palace.	Prince's.
Drury Lane.	Princess's.
Elephant and Castle.	Royalty.
Empire.	St. George's Hall.
Folly (now Toole's).	St. James's.
Gaiety.	Sadler's Wells.
Globa.	Standard.
Greenwich.	Strand.
Hackney or Clapton Park.	Surry.
Haymarket.	Savoy.
	Variety.
	Vaudeville.

The new theatres are the Avenue, Comedy, Empire, Novelty, Prince's, and the Savoy.

The total number of theatres licensed by the Lord Chamberlain in 1877 was forty-four, by the magistracy six, making, with the two patent theatres, Drury Lane and Covent Garden, a total of fifty-two, from which it would seem that the total number of theatres in London has decreased instead of having increased, as might be supposed from the numerous new theatres recently opened.

The course adopted by the Board with regard to old theatres is to make complete drawings to scale of every theatre, which include plans of the several tiers, elevations, and sections, so that any system of construction can be debated apart from the actual building, and the whole of the facts brought under the notice of the Board. The preparation of these drawings necessarily takes some time, weeks, and, in some instances, months being occupied in the admeasurement and drawing out of the plans, &c., of a single building. When the drawings of a theatre or other building are completed the premises are surveyed by the Superintending Architect of the Board, who reports as to the condition of the premises and suggests what alterations are, in his opinion, necessary to secure the safety of the public in the case of fire. The Architect's report is considered by a Committee specially appointed for the purpose, who inspect the building if they consider it advisable to do so, and report to the Board the result of their deliberations. The next step is to serve a draft notice upon the owner, and to invite the owner to confer with the Theatres and Music Halls Committee. The Board are not required by the Act of Parliament to confer with the owner, but they have adopted this course with a view to consult, as far as possible, the convenience of owners and managers, and in order to avoid making requisitions which may be found to be

impracticable. At this conference the Board's draft notice is discussed, and any modifications suggested by the owner are taken into consideration and accepted or rejected by the Committee as they may think fit. It sometimes happens that the whole, or nearly the whole, of the Board's requisitions are agreed to by the owner without material alteration.

The Board then proceeds to serve a sealed notice upon the owner, having first obtained the consent of the Lord Chamberlain, and this notice becomes binding unless appealed against within fourteen days from the service of such notice. In the event of the owner appealing, the appeal is heard by an arbitrator appointed by the First Commissioner of Works, who has power to confirm the same with or without modifications as he may see fit, or may refuse to confirm the same, and order the payment of the cost of proceedings at his discretion. In the case of an appeal the time specified by the Board for the completion of the works (which is generally six months) does not begin to run until the day after the appeal has been decided by the arbitrator.

The principle upon which the Metropolitan Board has acted with regard to existing theatres has been to endeavour, as far as possible, to bring them in harmony with the Board's regulations for the construction of new theatres, regard being had to the special circumstances of each case. It is, of course, impossible to deal with the question of site, the action of the Board being confined by Act of Parliament to the enforcement of such structural alterations as may be considered necessary in order to secure the safety of the public, and in the case of old theatres the site has been perforce accepted as satisfactory, although in some cases it is notorious that the site does not fulfil the conditions which would be required in the case of the erection of a new theatre.

We break off here, reserving some further remarks on the subject for a future article.

### CONCENTRATION.

**T**his is of daily increasing importance, both to men of science and to men of practice, to arrive at those clear and definite laws which regulate concentration. It is not by any means an academical question that this is chiefly necessary. Concentration, to a certain extent, is the work of nature herself. Intentionally or unintentionally, it is always going on, over vast districts of the surface of the earth, from the simple natural action of increase of population. For good or for evil, the process is unsleeping and irresistible, and it becomes all those who have to do with the housing, the feeding, or the medical and sanitary care of their fellow-men, to make themselves fully acquainted with the nature and the details of the process.

But it is not alone, or even principally, as a natural process that concentration has to be regarded. It may be considered as a central principle in a large class of human actions. The birth of civilisation is due to a certain amount of concentration; to that degree of association between individuals to which we owe the birth of families, of tribes, of municipalities, and of nations. The art of war has been described by one of its greatest masters as consisting in the concentration of overpowering force on definite obstacles, while at the same time maintaining such a distribution as to allow of the full service of necessary supplies to the attacking force. As in war, so in civil society, and so in mechanical or other physical operations. Rightly to balance the two energies of concentration and of distribution is the great outcome of practical wisdom.

In those appliances which, within the past fifty or sixty years, have placed the provision of the necessaries of life, for crowded masses of human beings, on a wholly novel basis, the importance of knowing how far it is advantageous to concentrate is cardinal. We do not, of course, imagine that the rate of increase of the seven millions of men, women, and children who now inhabit the valley of the Thames, and their tendency to agglomerate in one or other locality in that basin, is likely to be

affected by any study of the rules of concentration. But given the material facts of the growth and distribution of the population, there are many points connected with their welfare which will be well or ill carried out, according as the measures taken are, or are not, in accord (whether designedly or otherwise) with the laws of concentration and distribution.

It may almost be predicated that concentration, as a general rule, tends rather to mischief than the reverse. That first and simplest form of association to which we owe,—let us say,—the village community, can hardly be spoken of as concentration. Up to a certain point, as yet undecided, the increase of population on a given area is or may be attended with the increase of health, wealth, and comfort. But the time arrives when health is affected by density of population; and from that point (the position of which is determined by many conditions, of climate, of soil, of elevation, and of sanitary care), the death-rate rises with the increase of numbers. This is, perhaps, the simplest form in which it is possible to measure the effect of concentration.

Again, in cases where a destructive effect is intended, as in the procedures of war,—concentration pure and simple may defeat the object of those who have recourse to it. Mere aggregation of mass may have none but a disastrous result. The hosts of Xerxes, mass for mass, could have devoured the little band of Leonidas. At Crecy, at Agincourt, at Waterloo, mass was ever in favour of the French. But increase of rigidity, of hardness, of consistency, of temper of some kind, is an absolute necessary for the successful concentration of mass. An enormous hammer of lead, or even of iron, would tear itself to pieces on a small steel anvil. Concentration of mass may be simply mischievous unless attended by concentration of strength.

There is, however, one form of concentration to which we owe most of our material and scientific progress. That is what is usually known as the division of labour. By concentrating his thoughts on one study, or by continually directing his arm to one repeated operation, a man can, usually, do both more and better work than by any more dispersive direction of his powers. We do not speak of the educational effect on his character, but simply of the outcome of his work as a producer. And as it is with one workman, so it is with many. The idea of the factory is to facilitate that concentration of detailed energy which we call the division of labour. And thus we have seen of late, and seen with much regret, the monster manufacturer, merchant, or tradesman overshadow, stunt, and finally ruin those hundreds of smaller industrial workmen who are unable to compete with the organised power of concentration.

To this, however, there is a limit. It may be hard to say where the line is drawn. But of its existence there can be no doubt, and some light may, perhaps, be thrown on its whereabouts.

In the familiar case of the movement of an armed host, indeed, there is no doubt where the power of concentration finds its limit. It is in the genius of the general. Masses of men which Marlborough, Napoleon, Buonaparte, or Wellington could have moved with the ease and certitude of pawns on a chess-board, may be simply massed as victims for slaughter by such generals as led the armies of France at Sedan or at Metz. And so in civil or mechanical procedures a degree of magnitude may be attained under the rule and guidance of a man of genius, which will fall into hopeless confusion on his death or departure.

A striking instance of the self-imposed limits of concentration may be traced in our railway system. With the admirable coaching system which rose to its zenith from 1815 to 1835 the object proposed and attained by the traffic manager was to take his passengers to the very heart of the towns linked together by the four-in-hand vehicles. When the iron horse began to displace the well-bred team, Robert Stephenson, Brunel, and our other early engineers would fain have run their trains to the "White Horse Cellar" or the

"Saracen's Head." But a hostile interest intervened. All over the country mayors, aldermen, burgesses, and municipal authorities of all kinds barred the way. To stop at the outskirts of a town was all that was permitted, and even that grudgingly. Oxford and Cambridge bristled up against the Great Western and the Eastern Counties lines as if they had been the very fortresses of the Consistory of Rome; and Stephenson had to halt at Camden-town and Bruel at Paddington.

As the new mode of transport developed its powers people became conscious of the fault committed. Then, at tenfold cost, and often but imperfectly, central stations rose in Birmingham, Manchester, and elsewhere. London itself was bridged and tunnelled, and for a certain time the idea of a central station for the metropolis was entertained, and the creation of one heart for the regulation of all the great arteries of the railway systems was regarded as, if not probable, at any rate desirable.

Beyond that stage we may be said now to have grown. There can be little doubt, we apprehend, that if between 1835 and 1845 a central London station had been built, the enormous concentration of traffic would by this time have rendered it inadequate. Space would have failed, at any admissible cost, for exterior growth. Streets and roads would have been blocked by accumulated traffic. Subdivision would at such times become more important than centralisation, and a certain number of suburban main termini, linked together by through lines, would have been desired. In point of fact, something approaching our present arrangement, only provided with better intercommunication, would have been adopted from the first, if the wants of the future had been foreseen, and if we had been wise enough to provide for them.

This question of concentration assumes just now its most serious form with reference to the main drainage of London and of other districts. It comes to the fore in the lamentable series of events, detailed in a recent number, that have resulted in leaving the Thames Valley undrained. We ought to think ourselves fortunate if we are not tainted by pestilence that to concentrate the sewage of a vast province like London at one spot and then to throw it into the river was a mistake of the gravest kind. We are told now by the Metropolitan Board of Works that the sewage is "deodorised." But before the report of the Royal Commission this same Board told us that, as it then was, it was unobjectionable. The true mode of dealing with sewage has not yet been arrived at, thanks to the utter want of organisation in which the framers of the Health Bill of 1872 took delight. To concentrate on one spot a large amount of matter which was to be destroyed, without having arrived at any plan for effecting the destruction, is perhaps one of the most unfortunate instances of concentration which the world has yet seen.

One of the advantages proposed from concentration is the saving of cost of management. On this score some persons are very sanguine. To a certain extent they are justified. But it is only to an extent that may be very easily determined. When competing interests,—coaches, railways, docks, gas works, water-works, or what not, grow up, or rather are forced into existence in rivalry with each other, duplicate establishments are formed, and a more or less completely double cost is incurred. And, as contrasted with a similar enterprise which from the beginning had been in one able hand, it is possible that the waste may be great. How far, however, it may be reducible by a subsequent fusion of the formerly competing interests is generally very doubtful. But it is a matter which, in each case, admits of anticipatory solution. A certain normal cost of management is well known to be appropriate to each great industry. It may be increased, to any amount, by quarrelling. It can never be reduced below the normal minimum; and experts familiar with the subject can generally give a shrewd guess as to that normal rate.

The one industry as to which it is not easy

to fix a limit of profitable concentration is the manufacture of gas. That exception to the general rule is intelligible. In all cases of concentration,—take a coal station, for example,—three things have to be considered. The material for the industry has to be brought to the spot, to be treated on the spot, and to be conveyed from the spot. In the mineral traffic of railways the second operation appears at present to fix the limit of concentration. It is easy by the confluence of several lines of railway, to pour into a given terminus a stream of coal traffic such as it would prove impossible to sort or to arrange. Space fails; and the cost of shunting becomes enormous. Here, too, occurs a double difficulty in removal; for first the empty railway trucks have to be sent back by rail, and then the retail dealers' wagons have to be sent away by road. The station work at present limits the capacity of a coal station. Next to this, the wharfingers' or cartmen's work,—or removal by road,—would do so. The amount of mineral that could be concentrated in a given time would be prodigious, but then the block would be absolute.

In gas the removal of the chief product, the gas itself, is so simple and so easy that no limit can be readily imagined as to quantity, and the procedures are so simple and orderly that the increase in area of ground required for increased production can be foreseen. As to the removal of the subsidiary products there may be more difficulty, but the amount received for residuals per 1,000 cubic feet of gas sold differs so little (regard being had to the price of coal) over thirty-five different great gasworks in town and country, that it may be doubted whether the difficulty of removing them has begun to tell, and for the simple concentration of coal an enormous amount is manageable.

In this respect, however, we think gasworks stand alone. For mineral trade, for merchandise, even for passenger traffic, for drainage and sewage, and for water supply, either the possibility of concentration beyond a certain point, or, at all events, its feasibility, is more than doubtful. The subject is not one that should be approached, as has hitherto been too often the case, under cover of a cloud of platitudes. It is one that demands the careful investigation of the man of business, an investigation which can hardly fail to be attended with a considerable success.

Of the influence of concentration on architecture we have not now room to speak. Its most obvious results take the form either of increase in the relative height of buildings, as we now witness in London, or in the creation of a quasi-palatial street architecture (as in Paris, and even more conspicuously in Turin), in which the individuality of the house, as an architectural unit, disappears. We recently spoke of the effect of concentration in raising the cost of urban life, and were able to point out the very simple numeric law which appears to regulate that increase. It is possible that in this case the evils induced by concentration may bring with them their own remedy. Such, however, is not the case as to the concentration of sewage,—the effect of which, as at present carried on at Barking, was illustrated most forcibly the other day by the seizure of two members of a scientific deputation to the spot with diarrhoea. With all that, abroad and at home, now menaces health, it is hardly too much to say that, unless we find an adequate mode of destroying sewage,—that is to say, of oxidising all the effete organic matter that it contains, for the mineral matter has agricultural value,—accumulated sewage will, perhaps not destroy London, but grievously scourge the inhabitants of the Thames valley.

NOTES.

**W**E learn that considerably over one hundred portfolios of designs for churches were sent in by architects desirous to compete for the Liverpool Cathedral. These were pretty soon reduced to forty, and then came the tug of war to result in the survival of the fittest. Among the twelve architects selected were Mr. Pearson, Mr. Waterhouse, Mr. Bodley, Mr. Brooks, Messrs. Paley & Austin, Messrs.

Somers Clarke & Micklethwaite, Mr. Emerson, Mr. J. O. Scott, and Mr. Blomfield. It is rather odd that while in the case of the War Offices competition (in which Mr. Christian was a juror whose opinion probably had considerable weight) the selections were mostly from among architects who had not attained the highest position, in the Liverpool competition,—in which the same eminent architect is principal adviser,—the result seems to have been the selection of several of the best known church architects. Are we to look for the explanation in the fact that in the one case the designs to be judged of were mostly Classic, and in the other case probably all Gothic?

**A** PUBLIC MEETING was held last week at Woolwich which may possibly do more towards solving the problem of the best method of communication across the Thames below London Bridge than has been accomplished by the committees which have lately been engaged in discussing this question. The inhabitants of North and South Woolwich having waited so long in vain, have, it appears, determined to take the matter now into their own hands, and called a meeting to hear the particulars of a scheme for steam ferries, which has been designed by Mr. W. May, C.E., by means of which vans and carts with loads of any weight would be transported from one side of the river to the other without difficulty, and at a small cost. The main features of the scheme consist in an improved method of constructing the platforms and staging, so as to avoid any inclines for horses with heavy loads. At stations where the traffic will be the greatest there are to be one tidal and two travelling platforms, each of which is to run on a pair of rails securely fixed on the fore-shore. The tidal platform is to be manoeuvred by machinery as the tide rises and falls, so as to bring its deck on a level with the deck of the boat, and is to be worked automatically by means of electricity. The boats are to be fitted with double engines and twin screws, and lighted with the electric light. They are to ply three times in the hour between 5 a.m. and midnight, and the tariff is as follows:— Vehicles with load and one horse, 9d.; with two horses, 1s.; with three horses, 1s. 6d.; with four horses, 2s.; cab and driver, 6d.; pony-cart, donkey, &c., from 6d. to 3d.; passengers, 1d., with a discount of 25 per cent. on all return tickets, and of 50 per cent. on all workmen's tickets. The latter will thus be able to go to and from their work for a penny daily. There seems to be little doubt but that, if once fairly started, the scheme, which is in accordance with what we have repeatedly recommended, will prove abundantly remunerative, for the capital required to start it is estimated at 15,000l., a sum which will probably be forthcoming from the inhabitants of Woolwich, who it is to be hoped will thus lead the way in providing for their own accommodation, and so point the moral of the late proceedings of the Metropolitan Board of Works in proposing to lay out 750,000l. on a single bridge.

**I**N a foot-note in our last, attention was called to what is, no doubt, a serious defect in the selected design for the new Admiralty and War Office. The principal court is only 80 ft. wide, and is closed at both ends (there being, however, gateways on the north and east sides); one of the courts in the south wing is 35 ft. wide, and the other courts are each only 25 ft. wide. The buildings fronting on the principal court are about 90 ft. high, and those abutting on the minor courts are about 100 ft. high. It is not fair to blame the architects for the exigency of the means of internal lighting and ventilation; the fault lies rather with the Government, who, with ill-judged parsimony, persist in endeavouring to cram two large departments upon a site which is too small for the purpose. The question of the site has never been fairly discussed in Parliament, and it is not too late to appoint a Commission to consider the relative merits of the Great George-street site and the Spring-gardens site. The latter was selected by the First Commissioner on account of its comparative cheapness, most of the houses in

Spring-gardens being already occupied as Government offices, but we repeat what we have often urged before, that in the case of an important public building its economical erection should not be the only consideration, and that other questions should be taken into account, the foremost being the capability of the site as regards sanitation.

SOME of the competitors proposed to utilise the stone screen in front of the Admiralty in the new buildings, but there does not appear to be any provision to that effect in the selected design. We shall probably be told by the First Commissioner that he intends to preserve this screen, and its ultimate fate will in all likelihood be that it will be sent to join the Burlington House Colonnade, which is at present used as an impromptu gymnasium in Battersea Park.

THE prorogation of Parliament and the consequent scarcity of news has caused the recent fires that have taken place in the metropolis to be noticed more prominently than they would have been had they occurred during the session, and the newspapers are full of suggestions intended to guard against a similar loss of life to that which lately took place in Picnic. One of the most obvious precautions would be to make the upper floors of every house fire-resisting. This might be done by pugging between the joists with coke-breeze and Portland cement. The additional cost of this treatment of the floors of a three-story house of a rental of from 30*l.* to 35*l.* per annum would not exceed 5*l.* The Legislature recently required the site of every house to be covered with a layer of concrete to prevent the damp rising, and it would not be unreasonable to require this additional precaution to secure the safety of the tenants in the case of fire.

IT is impossible for us to read the accounts of the alarming fire which occurred on the morning of the 15th inst. in the rear of the Mansion House Railway Station without feeling serious misgivings as to the safety of large numbers of workpeople similarly situate to those who were with so much difficulty rescued from the burning building in question. Here is a case in which what is described in one account as the only available staircase to several floors occupied by male and female workers is set on fire and becomes impassable; and this, be it observed, during the working-hours of the day. How long will it be before the papers will have to chronicle an appalling sacrifice of life under such circumstances as these? And how much longer will it be tolerated that large establishments, occupying several floors, and employing, it may be, hundreds of hands, are "provided" (as are some that we know of) with only one staircase, and that of most combustible materials, thus making the workshop a veritable death-trap in case the staircase is on fire and no other means of escape are available? Lofly buildings of the workshop type should, under such conditions as those mentioned, be provided with at least two staircases, and it goes without saying that these staircases and their approaches should be as far as possible of incombustible materials, and so constructed as to resist the rapid spread of fire. In addition to these obvious precautions, other safeguards should be provided. Theatres have lately had their due meed of attention in this particular, and it behoves all concerned (whether as guardians of the public safety or as employers) to see that our workmen and workwomen are not cut off from all means of escape from fire while pursuing their occupation.

RAILWAY travellers passing through Rugby of late will have observed a new station rapidly rising. The poor and shabby station of the London and North-Western Railway has long been so familiar an object to the traveller to and from the North that he will almost experience a feeling of regret at seeing the new building about to supersede the old one. But in truth it was high time that Rugby had a larger and better station. We do sincerely hope, however,

that the great company to whom the line belongs will take care that some attempt is made to make the new station not only useful for its practical purposes, but a pleasing piece of architecture. A place like Rugby, the seat of an historic public school, ought not to be put off with a building hideous to the eye, as is the case with the majority of railway stations. Without attempting striking artistic effects, the architect of railway stations has admirable opportunities for doing work which shall be pleasing to the eye. It is a thousand pities that more attention has not been given to this aspect of the railway station question, so that the opportunity may be seized of doing something to improve the neighbourhood of railway stations from an artistic point of view. The actual cost of carrying out a pleasing design is but at the most a trifle more than that of carrying out one without artistic merit or ornamentation. Among roadside stations many will recall Box-hill, as an instance of a successful attempt to break away from the ordinary routine of station architecture. But large buildings, such as the new station at Rugby, should at any rate have some care bestowed on their external appearance as well as on their fitness for practical use.

THE letter from Mr. Charles Barry which was read at the last meeting of the Metropolitan Board of Works deserves a passing note, inasmuch as it announced the intention of the Governors of Dulwich College, who are large land-owners in the sylvan suburb, to allot seventy-six acres of land to the purposes of a public park. But it appears that the Governors cannot appropriate the land in question to such a purpose without the authority of a special Act of Parliament, and for specified reasons they are unable to take upon themselves the trouble and expense of this process. Accordingly they have asked the Board to promote a Bill in Parliament authorising the Governors to set apart the land for the purposes of a park, and to hand it over to the Metropolitan Board for custody and maintenance. The letter was referred to a Committee of the Board for consideration, and it is to be hoped that no technical difficulty will intervene to prevent the appropriation of the land to the purposes of a park. Railways and tramways, and the work of the house-builder, are rapidly altering the face of this still pleasant suburb. The picturesque aspect of Croxted-lane and other spots has been effaced, to the regret of many besides Mr. Ruskin.

IT is proposed to form a new society for the preservation of London antiquities. We should have thought that there are already sufficient societies for that purpose, and that to start a new society would only have the effect of crippling the resources of existing societies. What is the Topographical Society for London (which was established with the laudable object of preserving a record of Old London, now fast vanishing away) doing?

IF we may believe the account communicated to the daily papers, a French military engineer, Captain Renard, has solved the problem of propelling and steering balloons irrespective of the wind. The motive power is said to be electricity, served from a series of accumulators, providing a sufficiency of power for several hours. The balloon to which the machine was attached, was experimented with over Meudon, and brought round in a semi-circle against "a slight breeze";—so the *Times* correspondent of Wednesday last. We should hesitate to accept this vague account of the partial solution of the problem (for to travel a short distance against a slight breeze is not, after all, to accomplish much) as an indication of the commencement of a new era in locomotion; but we shall, at all events, look with interest for further and more exact particulars. It may be that aerial locomotion is only a question of time, but it is probable that a considerable period will elapse before all the difficulties connected with it are overcome.

ON Monday afternoon we attended, at the invitation of Mr. Parker-Rhodes, to see him "square the circle" by means of his "invention of a geometrical instrument for commercial and educational purposes, which discovery and invention he offers gratuitously to this and foreign countries." Briefly stated, the method which Mr. Parker-Rhodes adopts to obtain the square of a circle or of any irregular-shaped figure is to take two sheets of stout millboard, superposed. The upper sheet is perforated with the circle or the irregular-shaped figure to be squared, either full-sized (where practicable) or to scale. The lower piece of millboard is placed beneath the perforated piece, so as to form, as it were, the bottom of a shallow trough whose outline is formed by that of the perforation of the upper piece. Into the shallow trough so formed small shot is poured until the whole area contained within the lines of perforation is covered with shot (in one layer), as closely packed together as possible. The amount of shot thus enclosed is then poured on to a square slab, bounded on two of its sides by raised borders or ledges, ruled and figured; and by means of movable L-squares (varying in size according to the space occupied by the shot) the shot is "cornered" on the square slab, and the dimensions of the square covered by it seen at a glance. Mr. Parker-Rhodes thinks that his invention would be useful to the land surveyor in dealing with a piece of land of many angles and unequal sides, as he could, after obtaining the actual measurements of the sides of the land, make a drawing of its outline to scale, and then cut out this figure in millboard, see what quantity of shot would be required to fill the area of the perforation, and then ascertain the size of the square which the same quantity of shot would fill. Mr. Parker-Rhodes must have a delightful idea of the simplicity of surveyors.

IN the *Builder* for May 10th we printed a portion of a paper read at a meeting of the Balloon Society by Mr. H. Lefevre, on "The Study of Earthquakes," together with a letter from Mr. J. S. Green, of Yokohama, addressed presumably to the reader of the paper, and forwarded to us with his manuscript, as a kind of rider to it. From a copy of the *Japan Gazette*, which a correspondent has obligingly forwarded to us, it appears that Mr. Lefevre is accused of having taken much of his information unacknowledged from the proceedings of the Seismological Society of Japan, published in the *Japan Gazette*, and that a Mr. T. R. Green is also, for reasons we do not make out, very angry about it, and very anxious to state in the Japanese paper that he is not Mr. J. S. Green,—a proposition which appears self-evident. We need only observe that we printed Mr. Lefevre's paper, as we print any other paper read at a public meeting, on the responsibility of the author, and that it rests with him, and not with us, to answer the charges made against him from Japan, and to settle the claims of the two Mr. Greens of Yokohama.

#### THE ARCHITECTURAL ASSOCIATION'S EXCURSION.\* (WITH ILLUSTRATIONS.)

WEDNESDAY morning in last week saw the excursionists on their way through the pleasant Suffolk roads to Lavenham, which boasts the magnificent church illustrated in our last week's number. It is, indeed, a beautiful building, and is, in some respects, more easy of comparison with modern work than most Medieval churches, in that it is (except the earlier chancel) practically all of one style instead of having gradually grown up through different periods. Many of the smaller churches one loves for their very mixture of styles; they carry their history written on their front. Like many faces, they charm as much by their expression as by their features. Lavenham, however, is an acknowledged and conscious beauty. It is purely a bit of design, owing nothing to chance, but all to skill. It was the result of the

\* See p. 223, ante.

prosperity which successful trade induces. In the fifteenth century Suffolk and Norfolk were the seat of a large woollen industry, which has now migrated to Yorkshire, leaving many villages hampered with magnificent churches, far too large for the diminished population. Indeed, in some parts of Norfolk it is melancholy to go into church after church and find them too big to accommodate the entire parish, all told. Lavenham, however, is not in this sad condition, for, though the ancient glory of the place is dimmed, there is plenty of life left, and the church is treated with all befitting care. It is almost entirely Perpendicular in style, having been built by two wealthy and powerful families towards the end of the fifteenth century,—the noble De Veres and the commercial Springs, who were closely allied by marriage. After the fashion of the age, the arms of the founders play a conspicuous part in the decoration of the fabric, and help to form a particularly fine base all the way round, the five-pointed mullet of the De Veres serving the purpose very well. Those were days when heraldry was still a living art, and a man's arms gave legitimate scope for unaffected decoration. May not the nineteenth century sometimes ease its despairing envy a little by reflecting how very much circumstances were in favour of the Medieval architect? The buttresses are particularly good, and so is the parapet, except for the introduction of a large leaf out of all scale. Inside, the quiet, handsome roof strikes one as more dignified than the florid timber-work of Woolpit; but if florid work is desired, no better specimen could be found than the wonderful Spring pew, now in the north aisle. It is inclosed by a screen, the tracery of which presents an infinite variety of beautiful carving. It is true that the old Gothic forms are entirely superseded, but the delicacy of the carving, the vigour of its lines, and the exuberance of fancy displayed, must delight all whose sympathies are not very narrow. We hope to illustrate one or two scraps from this work, which probably owes its peculiar characteristics to Flemish influences. There are several other good screens, and some good brasses, in the church, while in the village are a few interesting houses and the Wool-hall.

Leaving Lavenham, a few miles' drive brought the party to Melford and the adjacent Hall of Kentwell. Here, again, it is not the detail which charms, but the general air of the place, its picturesqueness, and, above all, its colour. The red brick has toned down into an infinity of shades, the mortar has fallen out, and covered the surface with a network of delicate black lines, and brilliant lichens creep here and there, carrying all lovely hues, from orange to tender grey, wherever they go. Tall chimneys rear their insecure length in picturesque confusion; dormers peep out in unexpected places; a long length of timber and plaster overhangs the moat on its wooden joists; ivy clammers along the terrace walls and droops into the still waters of the moat; and the sketchers rise from their work like men who have feasted on bon-bons. Of solid food there is little: nothing to measure. But they find good, wholesome diet at Melford Church.

Like Lavenham, Melford Church is practically of one design throughout, although the pillars of the nave seem to be some decades earlier than the rest of the work, which ranges from 1450 to 1490. Here, as at Lavenham, the size and number of the windows recall "Hardwick Hall, more glass than wall." When the church was in its prime, before the first iconoclasts had left their mark upon it, it must, indeed, have been a wonderful sight. Every window glowed with rich glass; across the whole breadth of the church stretched the "fair roof-loft with the rood; Mary and John of every side, and with a fair pair of organs standing thereby."\* Beyond this, at the east end, stood the altar with the Crucifixion over it, and on each side "a goodly tilt tabernacle, reaching up to the roof of the chancel." At the end of the "Jesus lie" stood another altar with a fine reredos, and on each side "a fair tilt tabernacle," one with a figure of Our Lord, the other enshrining Our Lady of Pity. No church could have been richer in works of art or in its vestments and furniture. There were in the vestry, says old Roger Martyn, whose account we have been quoting, "many rich copes and suits of vestments," and a cope-press

with "devices to hang on all the copes, without folding or frumpling of them."

All this glory and splendour lasted barely a hundred years, for with the Dissolution of the Monasteries and the throwing off the Papal yoke, there arose a spirit of antagonism to much of the religious superstition hitherto prevalent; and ignorant zealots indulged their natural instinct for destruction by smashing or defacing as many of the superstitious paintings, coloured windows, and images as they could. It is at least charitable to suppose that their destructiveness, like Falstaff's cowardice, arose from "instinct." It would be, however, a mistake to suppose that the Puritans are responsible for all the mischief. No doubt they did much, and zealots like Dowling thought they were doing God's service in dishonouring the memorials of the "Scarlet Woman." But nearly a hundred years before the Commonwealth the tide of destruction had set in, and the churchwardens of Melford gave one man sixteen pence in 1562 for "ye scraping owt of the payntinges all ye lengthe of ye quire," and another man 2s. in 1579 for "defaceinge of ye sentences and imagerie in ye glasse wyndowes." And no doubt these are but isolated instances of the vandalism of the times when Shakspeare sighed to see,—

"Brass eternal slave to mortal rage."

Notwithstanding the liberality of the churchwardens of Melford towards their destroying agents, there is still some very fine glass left, although it is not in its original position.

Long Melford Church is remarkable in that the names of its founders and benefactors are given in long inscriptions that run the length of the parapets, desiring prayers for the souls of those mentioned, who repaired such and such arches, or covered the porch, or glazed certain windows. The inscription round the Lady-chapel, for instance, calls on the reader, in the orthography of the time, to "pray for the soul of John Hill, and for the soul of John Clopton, esquire, and pray for the soul of Richard Loveday, butler with John Clopton, of whose goods this chapel was embattled by his executors. Pray for the souls of William Clopton, and Margery and Margy his wives." The good man had two wives of the same name, and apparently, to avoid confusion, had recourse to calling one Margery and the other Margy. We are also requested to pray, not only for the soul of John Clopton, but also "for all the souls that the said John is bound to pray for." The inscription closes with calling Christ to witness that the builder did not place these names on record from vainglory, but that the souls might be remembered. When we recollect that within some half-century from the utterance of this devout prayer, all praying for departed souls was held to be superstitious, and is so held now by the frequenters of the very church where the impassioned prayer is inscribed, may we not reflect without horror that perchance our great-grandchildren will forego with equanimity some of the privileges we now hold most precious, and forsake without disaster the views we now most highly cherish?

Inside the church one of the most curious features is the Clopton Chapel, where on a wood cornice are painted a number of verses, said to be the production of Monk Lydgate, the poet. They have suffered much at the hands of many workmen, but a great deal may still be deciphered. They are in effect a long cry for mercy, many of the verses ending with the refrain,—

"Graunt or we dye shrifte hosell and repentance."

The Cloptons, who did so much towards the erection of the church, whose litany adorns their chapel, and who so ardently desired the prayers of the world for their souls, lived at Kentwell, but in an older and different house from that which now exists. They also built the remarkable Lady-chapel at the east end,—a work of excellent proportion outside, and of very curious plan. There are several interesting monuments and brasses in the church, the finest being a Renaissance monument to Sir Wm. Cordell, who died in 1580. This is a work of great refinement and delicacy; of course it is not Gothic, not,—as Pugin would have said,—not Christian; nevertheless, it is well conceived, well balanced, full of grace and freedom, and the mouldings are particularly refined. Indeed, as a matter of sheer design and display of imagination, the finer Renaissance monuments will bear comparison with anything of an earlier era.

With Long Melford the day's work ended; and a better day could not be spent in any county. But before the village was left the rector, the Rev. C. J. Martyn, who had done all he could to further the objects of the Association, sped his parting guests with a cup of afternoon tea, an attention much appreciated by the hot and weary sketchers.

On Thursday, the 14th, the first place visited was Hawstead, a church of various dates, but with a particularly elegant tower, built by the Sir R. Drury who lived at the demolished Hall or Place. There are some good brasses and monuments, among them a monument in the north wall of the chancel to a Fitz-Pustace, with a holly-carved floral pattern on the arch. There is also a delicate and charming Renaissance monument to Elizabeth Drury, who died in 1610. She was the only daughter of the last of the Hawstead Drurys, whose memory lives in Drury-lane. She is said, by a local tradition, to have died from a box on the ear administered by her father; but the only reason for this supposition is that her effigy is carved with her head leaning on her hand, a position which brings to mind the remarks of Bosola to the Duchess in John Webster's play of the "Duchess of Malfi" (1623). Bosola says, "Princes' images on their tombs do not lie, as they were wont, seeming to pray up to Heaven; but with their hands under their cheeks, as if they died of the toothache." Elizabeth Drury is just as likely to have died of the toothache as of a box on the ear. But, however she may have died, she was particularly well buried; and, to judge by the work, Italian artists may have been employed on her tomb.

Stanningfield Church only detained the party a quarter of an hour, which, however, gave time to sketch the pleasant little tower, and to look at the font and the Rookwood monumental slabs. Thence a short drive led to Coldham Hall, once the seat of the Rokewoods, and built in 1574 by Robert Rokewood. The details of the porch, as well as the mullions and labels, are of brick covered with stucco, as are most of the dressings of domestic buildings about here. The details are, architecturally speaking, extremely poor, but here, as at Rushbrooke and Kentwell and Pakenham, poverty in detail is atoned for by picturesque grouping and fine colour. The house is interesting historically from the fact that the son of the builder, Ambrose Rokewood, was concerned in the Gunpowder Plot, and suffered death at Tyburn in 1605. The unfortunate gentleman seems to have been more sinned against than sinning for, as he touchingly said at his trial, "he had been neither author nor actor," but only the depository of the terrible secret, which, out of love to his friend Catesby, "whom he loved above any worldly man," he would not divulge. It must have been true love that was content to prove itself at the cost of life.

Plumpton Hall came next on the list, where Mrs. Bevan entertained the whole party at luncheon, and afterwards read a short paper on the history of the place, from which the following is extracted:—"Lands in Whepsted were given to the Abbot and Convent of St. Edmund at Bury as far back as 1040, in the reign of Edward the Confessor, and Plumpton was a dairy and orchard farm to the Abbey. At the Dissolution, about 1540, the manor of Whepsted and all lands belonging to it, including Plumpton, were granted by the Crown to Sir William Drury of Hawstead, and his heirs, in consideration of 819l. 11s. On the partition of the Drury estate, in 1618, in consequence of the death of Elizabeth, sole daughter and heiress of Sir Robert Drury, who was betrothed to Henry, Prince of Wales, and is said to have died at the age of fifteen, of a box on the ear given by her father, this part of the property fell to the share of Diana, wife of Sir Edward Cecil." The property eventually came into the hands of Sir Thomas Hammond. As a favourite attendant and high official in the household of the Prince Regent, being his first Equerry, and Clerk Marshall of the Royal stables, Sir Thomas Hammond lived much in the gay world of the day, and adopted the rage for French fashions which prevailed in the Whig party of the time during Napoleon's career as First Consul.

Plumpton, which had been up to this time only a farmhouse with a good deal of timber in the building and with stonied old oak floors, was now transmogrified by a French architect into an imitation of a French chateau, six of the old rooms in three stories of the old house being

\* See Sir Wm. Parker's "History of Long Melford," quoting an account written about 1550.

cleverly added to, so as to give an outward appearance of unity of design. The house was thus altered and renovated between 1800 and 1807, and, being released from Lady Hammond's settlement in 1851 by her death, it was purchased by Mr. Bevan, who "renovated the roof and walls and made substantial repairs throughout, but, except dispensing with the ornamental parts of the outside, in no way altered it. With regard to the plan of the house, it is to be observed that the angles being at the points of the compass, it gives most pleasant aspects on all sides. N.E., S.E., S.W., and N.W., each gets the sun in turn, and, while no side is absolutely sunless, no side is exposed to the scorching heat of the full south."

At Ickworth another modern example was seen. The mansion consists of a central cupola with two long circular corridors leading from it to two pavilions, a plan more telling on paper than in execution. It was built chiefly for the reception of a fine collection of art treasures, which, however, fell a prey to the French in their journey to England. There are, nevertheless, many fine pictures in the house. The gardens are beautiful, and the view from the top of the cupola is most extensive. The Marquis of Bristol himself pointed out some of the chief objects of interest, and for the second time in the day the party experienced the hospitality of a host whose house they had invaded. The return to Bury was made by way of Little Saxham, where the church, with its round tower, is of some interest. Many of the churches in East Anglia have these round towers, which have puzzled antiquaries a good deal, efforts having been made to assign them to very early dates. Little Saxham, however, is clearly of Norman work, the bulk of the tower being of plain flint walling, while the topmost stage is well arched. The circular form was probably adopted to avoid the use of freestone quoins, which would have been necessary to bond in with the flints had the tower been square. The nave arcade is much later than the tower, and has some curious and elegant little corbels attached to the columns about 4 ft. from the floor.

On Friday, the first stay was made at Pakenham, where the restored church detained the visitors a few minutes. Most of them soon left for the picturesque hall, which presents a three-gabled front of red brick, with mullioned windows, and a large porch with canted corners. It is dated 1622, but no history of it is forthcoming. There, again, the detail is devoid of interest. The three gables, the decaying bricks, the tiled roof, and the colour, give all the interest. At Ickworth there is a good church, with a large variety of flint panelling; but here it is particularly observable how perishable is the beauty of this kind of ornamentation. The pattern is sunk square in panels of stone (which presumably would stand any fine tracery work), and then filled in flush with pieces of broken or cut flint. The sinking is not always deep, and in all the patterns sharp angles must occur where the flints cannot get good hold. The consequence is that much of the flint work has come out, leaving the panels in a bald and rough condition. The tower is said to have been built by Robert Schot, abbot of Bury, in 1470, a native of Ickworth. His name appears on the south-east buttress, in the panel below the weathering, just above the carves of the nave. There are the crown and arrows of Bury Abbey, and below:

MASR ROBERT  
SCHOT ABBOT.

It is rather curious that this church was built close to the precincts of an Augustinian priory, which, of course, had nothing to do with the Benedictine establishment at Bury. Some remains of the priory,—a room with a double row of vaulting and a vaulted corridor,—still exist. They are of much earlier work than the church (being Early English), and the deep hollow mouldings of the ribs, the clean vigorous curves of the caps, brought comfort to the soul of one of the party who has not yet succumbed to the "late and flat" wave.

At Bardwell is a very picturesque manor house of brick, timber, and plaster. The front towards the road is quiet and homely, while the crow's-foot gables are surmounted with chimneys of excellent design. The church is a noble structure, not particularly elaborate, not florid or ornate, but striking by reason of its simple dignity and noble proportions. It was a matter of general regret that the time

available was so short. At Stowlangtoft, too, there was only time to admire some of the carved woodwork when the party had to hurry off to Walsham-le-Willows. The church here is a fine building, in a beautiful churchyard. The north porch is noticeable, as it has chequers of stone and flints in diamond pattern, instead of as usual with horizontal beds. Of course there are the usual flint inlaid panels in the parapets and elsewhere. Inside there are some excellent hunch-ends, a good font, and a good rood-screen. The quarter-master's whistle, which collected the scattered sketchers, sounded all too soon: there was just time for them to fortify their resignation by reading an inscription on the north seat, "God's will be done in Hevun and Erthe," and away they had to fly to the carriages. In the pleasant evening air, between the glowing cornfields, or past the jovial harvest-men poised on the top of their great loaded wagons, the excursionists made their way home, and entered Bury from the last of their expeditions.

#### THE INTERNATIONAL FORESTRY EXHIBITION, EDINBURGH.

##### FIFTH NOTICE.

Our last acquisition, the Island of Cyprus, was celebrated in the ancient world, but under the sway of the Turk it declined greatly from its ancient wealth and importance. From the time the Turks became its masters, in 1570, when it was well-clad with timber, which sheltered the plains during summer from the sultry blasts which blow from the deserts of Africa and Arabia, until now, when the forests have almost disappeared, the fertility of the island has declined. Let us hope that under a more enlightened Government it may regain its ancient position, and prove a monument to the honour of its present rulers. The corn of Cyprus is of excellent quality; but wine is the staple product of the island. The wines are sweet, and require to be kept many years before they are fit for use. All the valuable kinds are white, the red being merely used *à la du pays*. The apricots of Cyprus are delicious, and may be purchased at 3s. a bushel; and many varieties of the gourd and pumpkin are produced. Upon the lofty chain of mountains which traverse the island from east to west, some good specimens of forest trees still remain. The once plentiful *Cupressus fastigata* is now rare; sections of it are exhibited, as also of *Cedrus Lebani*, *Pinus laricio*, and *Pinus maritima*, from which two last resin is obtained. There are also a few varieties of oak. The wood appears to be of good quality, and the sections indicate that the trees are of considerable size.

Marrubius is not productive of many useful vegetables, but depends mostly for supplies upon Boninion. The exports consist of coffee, raw sugar, cloves, cotton, and indigo. The surface of the island is composed chiefly of rugged and irregular mountains; from these flow numerous small streams which water the intervening valleys where considerable forests exist. The wood does not appear to grow to any great size, judging from the specimens exhibited, which embrace seventy different varieties. There are also shown two hundred specimens of fibre, some of which is very fine in texture.

When Great Britain took possession of the island of Singapore, in 1819, its population did not reach 200 persons,—mostly fishermen and pirates. It now exceeds 40,000, living under the guarantee of British protection, and is the seat of a flourishing trade. When the island came into our possession, it was well wooded, but, through the want of supervision, it is being rapidly deforested, and no attempts appear to be made to supply the defects by planting. Attention has now been drawn to the matter, and something may be done to suppress the wanton waste, and to provide new material. This is all the more necessary as one of the valuable timbers for building purposes in the tropics, the *Tampinis*, is rapidly disappearing. It is a hard wood, and resists the attack of the white ant. Amongst other trees are the Ballon or Johore Teak, the Daroo, and the Seriah, which grows to a considerable height. The forest products of Siam are abundant, and there is not a region of the world which produces fruits more various and more exquisite. About 500 specimens of natural woods are exhibited, amongst the chief of which are sandal-wood, ebony, teak, rosewood, and spari.

One of the most valuable medicines in the pharmacopœia is quinine, and great part of the bark of the chinchona tree, from which it is made, comes from Ceylon. As much as 7,000,000 lb. were exported from the island last year; specimens of it are shown in different stages of preparation. Amongst the specimens of wood exhibited which are forty in number, are beautiful samples of satin-wood and coccolnut-wood, and there is a box inlaid with calman-wood, which is very effective. Besides the specimens of chinchona bark, there is shown a collection of medicinal herbs and seeds. Amongst the most valuable of the Ceylonese plants is the cinnamon-tree, of which there are ten species, but only five of these are considered fit for use. The island is famous for its coffee, but, owing to a blight having attacked the plants, the produce has considerably decreased, although upwards of 200,000 acres are still devoted to its culture. Specimens of tea, the cultivation of which has recently been successfully introduced, are shown, as are also samples of sugar, tobacco, and cocoa. The wooded parts of the island are destructive to the health of strangers, and in them are found the boa constrictor, which is said sometimes to reach the length of 30 ft., and is free from poison; but there are some of the most venomous species, as the cobra di capella, a specimen of which is in the collection, together with stinging-birds, many of which are destructive to trees. From the Ceylon Almanac we gather that a considerable number of the accidental deaths occur from falling from trees and the bites of serpents. Ceylon is rapidly improving under British sway, and strenuous efforts are made to improve the intellectual and moral character of the people. The population numbers upwards of 1,500,000.

We are apt to associate China and Japan, two Empires which until recently were both jealously guarded against the intrusion of strangers,—but in one especial respect they differ materially. Whilst the Chinaman holds in contempt the outside "barbarians," his neighbour assimilates freely with other nations, and takes every advantage of the new fields of commerce open to him. The inhabitant of the "Celestial Empire" is a thorough conservative, adhering tenaciously to the manners and customs of his ancestors, and when he deigns to mix with foreigners and to adopt their costume for a time his pig-tail is sure to be hidden beneath the broadcloth which sits so uneasily upon him. The dweller in the land of the "Rising Sun," on the other hand, is a thorough-going radical. When he comes amongst us it would be difficult from his accent to discover his nationality, and he has the manners of a staid and respectable European.

Whilst China is not represented in the present Exhibition, and there are many products of the "Flowery Land" worthy of a place in it, Japan sends the largest and most perfectly arranged collection exhibited. These fill the whole space of both arms of the eastern transept, and are arranged with admirable precision and neatness. It is almost impossible, even were the space at our command not practically limited, even to allude to the numerous objects of interest which are met with. These include models of various erections in timber, and of peculiar modes of fencing, models of charcoal kilns, examples of the lacquer work for which the country is famous, brilliantly coloured, conventionally-treated landscapes, with birds of gay plumage perched on the branches of trees; photographs showing foresters at work, and how the trees are transported from the steep mountain sides, &c.

The mountainous islands which compose the Empire of Japan extend over 15 degrees of latitude, and the climate varies so that the country possesses a vegetation common to both temperate and tropical zones. The rocky soil is favourable to tree life, and the rainfall is abundant, so that on the plains bordering the sea, in the deep valleys and on the hills, which often rise to 6,000 ft., the natural forests contain numerous species of timber-bearing trees. From a chart exhibited, we learn that the Empire has an area of 38,563,718 chos, the cho being equal to 2,455 acres, giving about 95,000,000 acres. The forest area, excluding the Loo Choo and Bonin islands, is 11,866,620 chos, or about 29,000,000 acres, and this is held, in nearly equal portions, by the Government and by private owners. The native arboriculturists have

carefully mapped out the empire into five regions, each bearing different varieties of trees. In the first of these, where the temperature is high, the forests consist of broad-leaved evergreen trees, of which *Ficus Wightiana* is given as a typical example. In the temperate region are found the oak and beech and broad-leaved deciduous trees, along with cedars and arbor vitae, amongst which the magnificent tribe of *Thuys* and *Retinosporas* are of great utility. The pines and firs abound in the higher regions, of which the *Abies Veitchii* is chosen as the representative.

Many graceful dwarf varieties of the *Retinosporas* have been introduced into this country for ornamenting our lawns, whilst the camphor wood and keyaki are largely used in shipbuilding and cabinet-making. The members of the *Arbor vite* family, which with us are seldom of great size, and are used merely as ornamental features in pleasure-grounds, attain to great dimensions in their native mountains, and are largely used

shrubs from foreign countries. Tea, of course, is extensively cultivated, and the making of this beverage the Japanese consider they have reduced to a fine art. It was only, however, in 1879, that the first coffee-berries were brought from the Sandwich Islands, and sown for trial in Ogasawara, and so well have they thriven and increased that great hopes are entertained for the commercial success of coffee-growing in Japan. The Cinchona-tree, from which quinine is made, was introduced from India in 1878; but the climate appears to be too cold for it, though from one of the districts more favourable reports of it have been received. During 1880 and subsequent years large importations of the seeds of useful trees were made from Europe and America, and planted in the experimental gardens belonging to the Forestry department at Tokio. The number of species sown amounted to about 1,000. Some were failures, while others took favourably to the country, and of the latter class thirty

DRAINAGE UNDER DWELLINGS.

REFERRING to our remarks last week on the Sanitary and Insanitary Houses at the Health Exhibition, we may observe that the drainage of the Sanitary House is effected on the principles laid down in the paper on "Drainage under Dwellings," read by Mr. S. Flint-Clarkson at one of the Conferences held at the Health Exhibition under the auspices of the Royal Institute of British Architects, and reported in the *Builder* at the time (see p. 109, ante). This paper was illustrated by a number of drawings showing the drainage of actual buildings. These drawings were lent to Mr. Clarkson by the following among other architects, viz., Messrs. Batterbury & Huxley, Mr. J. Sulman, Mr. Ernest Turner, Mr. W. Henman, Mr. A. Young, Mr. A. H. Kersey, Mr. A. Webb, Messrs. Hooker & Hemings, Mr. E. C. Robins, Mr. T. E. Mundy, and Mr. T. Blashill. The plan we have reproduced was lent

by the cabinet-maker and builder; the timber is of fine texture and beautifully marked. Amongst the exhibits is a splendid slab of *Retinospora obtusa*, which attains a height of 130 ft., with a girth of 20 ft. It bears considerable resemblance to the red woods of California. Other examples of the same wood are yellow and some white in colour. Beautiful slabs are also shown of maple, yew, bird cherry, juniper, and *Cryptomeria japonica*, which latter only appears here as a mere shrub. The Japanese oak, of which there are several varieties, does not appear to equal English oak in quality, but from it the finest charcoal is produced. There are 302 specimens laid out for inspection, and there are two large cases containing a collection of veneers, each about the size of a playing-card, neatly fitted into separate compartments containing several varieties of the same species, all carefully labelled. In Japan, the Government Forestry Department is an important State institution, having attached to it a school of forestry, the curriculum of which embraces chemistry, surveying, botany, planting, and rearing of trees, besides natural philosophy. The school is attended by about 150 pupils, some of whom seek to qualify themselves for employment in the Government forests, whilst others are sons of landowners desirous of a knowledge of how best to manage the woods on the paternal acres. Large plantations have been formed under Government auspices, and every year the area of forest land is being added to,—the cedars, oak, spruces, and firs being the trees more generally planted. The systematic surveying of the forests is also a work that is being pushed forward, one of the maps exhibited, showing what is being done in that way. Within the last few years an important experiment has been made in the introduction into Japan of the seeds of trees and

specimens have been brought over for exhibition, the list including several firs, oaks, and maples, the birch, the hornbeam, the German larch, the lime, the ash, an Indian pine, and other trees, all of which will in time form an important addition to the timber supply of the country. Of these and other operations full information is contained in a series of reports,—1879-82,—of the Forestry Department of Japan, the forest literature and history shown embracing also treatises on botany and on the forest trees of the country, journals of the Japanese Forestry Society, and the Association for the Advancement of Forestry, and many instructive charts. There is also, it should be mentioned, an exhibit of trees which have been found useful for cultivation along sandy banks and the slopes of sandy hills, to prevent their destruction by denudation. At the present time the Japanese, in addition to supplying all their own wants,—which are great, as the houses in town and country are chiefly built of wood,—from their forests, export a good deal of timber to China. A little timber was imported from America, but it never amounted to much, and is on the decrease.

**Swimming-baths at Dulwich College.**—An addition is about to be made to the buildings at the new Dulwich College by the erection of swimming-baths. The site upon which the structure will be erected is at the south-west end of the College grounds, in close proximity to the gymnasium, and the building will be designed so as to harmonise with the present College buildings. The designs have been prepared by Mr. Charles Barry, and Mr. Mitchell, of Dulwich, is the contractor. The works were commenced about a fortnight since. A sum of 2,500*l.*, including a contribution by the Governors, has been raised.

by Mr. Ernest Turner, and shows new drainage arrangements in an old house in London, as carried out by him. This is a fair specimen of what is being done just now in the way of drainage under dwellings. Of course the plan of the house could not be remodelled, and it was only possible in the re-draining to make the best of things as they stood. Thus the scullery sink is not against an external wall, as it would be in a good new house.

THE HAMPTON HOUSE RESIDENTIAL CLUB.

This Club, situate in Hampton-street, Clarendon-square, has recently been opened by Lord Hampton, the president. The object of the club is to meet an admitted want by providing, at a moderate cost, but on a self-supporting basis, the advantages of a comfortable home combined with those of a club for young men engaged as students, or in professional or commercial pursuits. The building was specially designed for its present purpose by Mr. E. G. Salter, architect, and was commenced in the spring of 1882. The site is within a few minutes' walk of King's-cross, Euston, and St. Pancras Railway Stations, and the Railway Clearing-house. The main building consists of five floors, and the out-buildings of one story only. The accommodation provided includes sixty-eight bedrooms, reading-room, grill and dining room, coffee-room, smoke-room, refreshment-bar, manager's room, bath-rooms, laundry and other offices. There are lavatories and other arrangements specially for the ground-floor, and there are on each of the bedroom floors separate conveniences, which, for sanitary reasons, are detached from the main building. A separate wardrobe locker is assigned to each bedroom.

There is a hot and cold water supply on each floor, and in connexion therewith there is also a supply in case of fire. The house over the principal entrance is fitted up as bedrooms for the manager and servants. There is a large and cool cellarage. A site has been left for a billiard-room, should the tastes of the members of the club demand the addition hereafter. We append a ground-plan.

over the news-room, and is similar as to size and plan, though terra-cotta takes the place of granite as the material for the columns and arches, while the ceiling is vaulted in concrete, finished with plaster, and divided into panels by moulded ribs, the whole being decorated in colour. What may be called the nave of this apartment is set apart for the public, while a continuous counter incloses the aisles, which

Like Lavenham, this is a flint church, but depending for its decorative treatment to some extent on surface designs (arcading, &c.) worked out in stone and flints of different tones. The carved stone ornament is less prominent and less bold in character than that at Lavenham; and the total effect of the church is sadly spoiled externally by the bare and ugly eighteenth-century tower, which, however, we suppose, critics of a certain school would tell us ought to be regarded as of equal interest as an example of the taste of its day. It certainly is historically interesting to know that people in the eighteenth century knew no better architecture than this; but if they had left the damning fact recorded somewhere apart, instead of tacking it on to Long Melford Church, we could have better forgiven them.

Like Lavenham, Long Melford owed its foundation in great measure to the generosity or religious zeal of rich cloth-merchants, the Cloptons having been the family specially prominent as founders. The interior, as is well known, contains much fine and interesting work; the Lady-chapel being especially beautiful. A small bas-relief of the Offering of the Magi is on the north wall near the chancel. The church contains also a fine specimen of a Renaissance tomb, that of Sir W. Cadell, in the chancel. Lavenham and Long Melford were described at some length in the *Builder* a few years ago.

The Hampden House Residential Club.

An advertisement relating to the Club appears in another column. The experiment is one which has our best wishes.

Illustrations.

LEEDS MUNICIPAL BUILDINGS.

WE are enabled this week to give a perspective view and plans of these buildings, together with a view of the interior of the News-room in connexion with the Free Library section of the buildings.

The buildings, which were opened three or four months ago, have been in progress for about five years, and are situate in the immediate neighbourhood of the Town-hall, having their principal frontage in Calverley-street. Without staying now to describe the exterior of the building (which is clearly shown in the view), we will give a few particulars as to the internal arrangements of the building. As will be seen by reference to the plans, the Library and Museum Department has been isolated from the business offices, and has its separate side-entrance (in Centenary-street). The News-room is 80 ft. long by 40 ft. wide, and is divided into a broad nave and aisles (we quote from a long description given in a Leeds paper) by arcades of six arches, carried upon polished granite pillars. Each column has a granite base and a carved stone capital,—no two capitals being alike. The construction of the ceiling of this apartment will be readily apparent by a reference to the illustration. It consists of a series of segmental vaults springing from transverse wrought-iron girders, the surface of the vaults being of a sort of mosaic-work in hexagon bricks,—red, buff, grey, and blue, with golden bosses. The walls are tiled throughout, and relieved with medallion portraits in relief of Homer, Shakspeare, Milton, Goethe, Burns, Scott, Horace, and Macaulay. These medallions have been executed by Mr. Creswick, sculptor, London. At night, light will be provided by means of incandescent electric lights. The Lending Library is situated on the first floor,

contain the book-shelves. On the same level as the Lending Library is the Museum, 32 ft. square. On the second floor is the Reference Library, which extends over the lending library and museum, and has a height of 36 ft. from floor to ceiling, terra-cotta arcades dividing the room into nave and aisles. The roof is semicircular, and is divided into bays by wrought-iron principals carried on moulded stone corbels. Altogether, Leeds may be congratulated on its free library.

The main entrance to the Municipal Offices, in Calverley-street, gives access to a short flight of granite steps leading up to a vestibule, 23 ft. square, on either side of which are detached columns of Devonshire marble, with marble bases and capitals, carrying an entablature and cornice of Caen stone. The inner hall, reached through double swing-doors, rises through the whole series of floors, and culminates in a lantern light. The lettering on the plans sufficiently describes the purposes to which the various apartments are allotted, but as to the "Pay-offices," we may mention that it is 78 ft. long by 38 ft. wide, having a counter 92 ft. long. The central portion of the counter is to be given over to the Water Department, that on the right to the Rate Department, and that on the left to the Gas. Beyond the counter are rows of double desks for the use of the clerks of these several departments. Here (as in almost every room in the building) tiles have been largely used for decorative purposes. On the second floor are the rooms of inspectors, collectors, and other officials.

Mr. George Corson, of Leeds, is the architect, the general contractor was Mr. James Wood, and the clerk of works was Mr. Osborne.

LONG MELFORD CHURCH, SUFFOLK.

THE Church of the Holy Trinity, Long Melford, is one which is nearly always grouped with that at Lavenham, of which we gave a view last week; for they are kindred works in the same neighbourhood. This also was one of the churches visited by the Architectural Association on their excursion last week.

THE "MILLER" MEMORIAL HOSPITAL, GREENWICH.

This little hospital has been erected on ground adjoining the Royal Kent Dispensary, as a memorial to the late Canon Miller, the founder of Hospital Sunday. Owing to the very confined nature of the site, it was thought desirable to adopt the circular form of ward, by which means more free access of air and light is obtained to the wards than could possibly be the case with a rectangular form. The hospital at present consists of an administrative building, and one ward pavilion of two stories. In the future it is intended to add a corresponding ward pavilion on the ground adjoining southwards, of which the freehold belongs to the committee. Each ward is for ten beds, and has attached, but separated by a cross-ventilated lobby, w.c. and slop sink, and broom cupboard. The warming is by means of three Boyd's hygienic stoves, and to each ward are three extraction-flues, carried up side by side with the smoke-flues, from which they are separated by thin plates of iron. The floors are of iron and concrete, covered with wood blocks, and under every bed is one of Ellison's "radiator" ventilators.

The basement of the administrative building is occupied with stores and cellarage. The ground-floor contains a small operating-room, separation-ward for two beds, and ward, scullery, and bath-room. The first floor contains ward, scullery, bath-room, separation-ward, and bedroom and sitting-room for matron.

On the second floor are the kitchen offices, and two rooms for nurses; and on the top floor are a day-room for nurses, bath-room and w.c., and bed-rooms for nurses and servants.

In one angle of the site is a small mortuary and post-mortem room.

The buildings have been well carried out by Mr. J. L. Holloway, of Queen's-row, Peckham, under the superintendence of the architects, Messrs. Young & Hall, of 17, Southampton-street, Holborn.

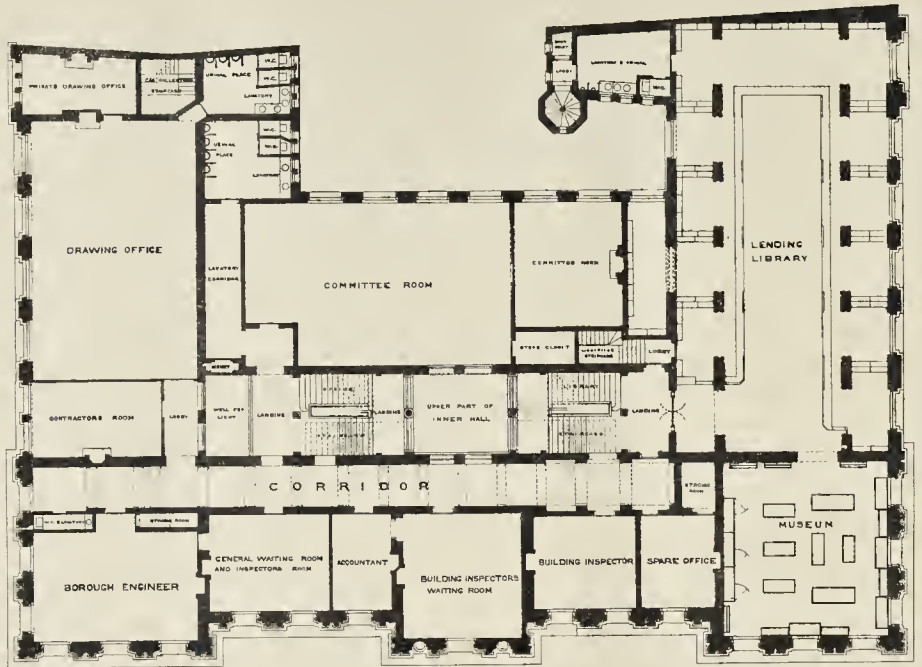

SKETCHES AT PLACES VISITED BY THE ARCHITECTURAL ASSOCIATION.

SOME particulars of the buildings and details which form the subjects of these sketches will be found in our account of the Association's Excursion (see pp. 223, 252, ante).

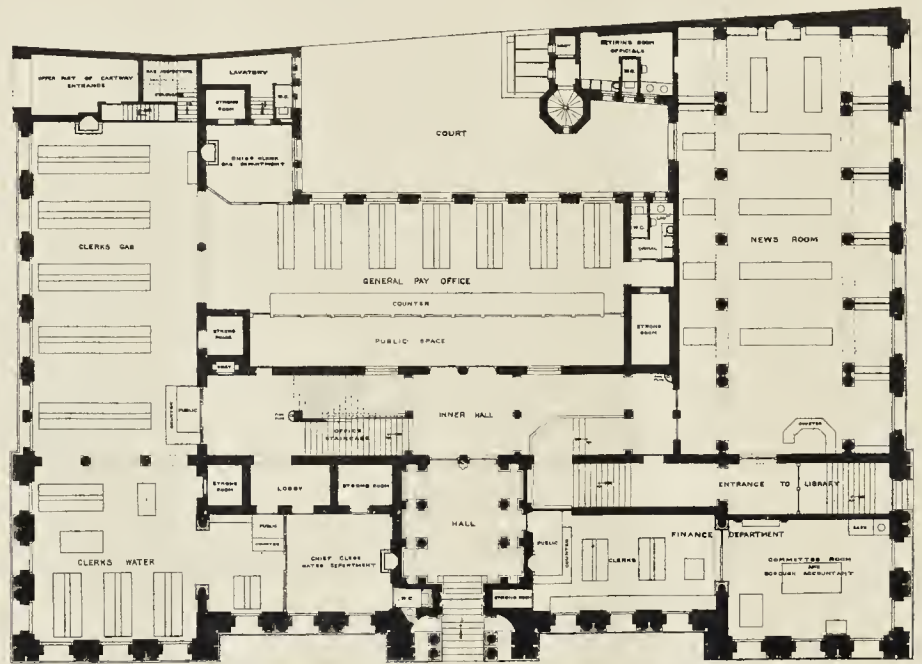

Organ Music at the International Health Exhibition. — Arrangements have been made for extra Recitals on the Organ of the Royal Albert Hall in connexion with the International Health Exhibition. They will take place daily from twelve to one, so as to afford to all who visit the Exhibition an opportunity of hearing this organ. In many cases the country visitors have to leave early, and are thus unable to avail themselves of the usual recitals at three and seven p.m.

THE SUMMER MEETING OF THE INSTITUTION OF MECHANICAL ENGINEERS.

A MOST successful summer meeting of the above Institution has just taken place at Cardiff. The members having been formally received by the mayor of Cardiff (Mr. Robert Bird), the President of the Institution, Mr. I. Lowthian Bell, F.R.S., gave his inaugural address. Taking "Iron" as his subject, he gave a short historical sketch as to its development into the various forms in which it is now produced, remarking on the great service rendered by mechanical science to the art of iron-making. Referring to the Bessemer process, he said it had revolutionised the means of obtaining iron in its malleable form; the product was purer, and the cost of conversion was less than that obtained by means of the puddling process. In the manufacture of Bessemer steel it was found advantageous to blow the metal until the bath, so far as metalloids were concerned, became malleable iron. The addition of a substance containing a readily oxidisable metal, such as spiegel-eisen or ferro-manganese, carried off the superabundant oxygen, at the same time that it restored sufficient carbon to give steel any desired degree of hardness or softness down to what, in the matter of carbon, must be regarded as malleable iron. The President next referred to the great superiority of iron over wood for shipbuilding, and to the introduction of steel into the construction of locomotives, and his interesting address was brought to a conclusion by some practical remarks on the subject of foreign competition and the labour question.

The Secretary then read a paper by Mr. J. McConochie "On Recent Extensions of Dock Accommodation and Coal-Shipping Machinery at the Bute Docks, Cardiff." These docks were visited by the members during the afternoon, and the various machines were seen in operation. First amongst these was the movable hydraulic crane for rapid coal-loading, constructed by Sir W. Armstrong, Mitchell, & Co. The chief novelty in this is Westmacott's coaling cradle, which may be described as a light platform suspended by chains, which takes its seat on an ordinary line of rails in any position. It is suspended on what may be called an anti-friction swivel, which enables a man to turn the cradle with a loaded wagon on it, thereby dispensing with turntables. Referring to the crane itself, the turning of the pillar and jib is effected by a pair of hydraulic cylinders, one on each side of the pillar, fixed to the base of the pedestal, which remains stationary. The chain from these cylinders passes round a drum at the foot of the pillar. All the motions are controlled by one man in a valve-house on the side of the pedestal. The pressure water is conveyed to the crane by movable and jointed pipes, which can be attached to hydrants placed at convenient distances on hydraulic mains along the quay walls. In actual work, it is found that with this crane a wagon of coal can be shipped in from two minutes and a half to three minutes; in fact, it must be held that, from an engineering point of view, the coal-shipping machinery is by far the most advanced and interesting thing to be seen in or near Cardiff.

The pumping machinery employed for discharging the water from the public graving dock consists of two centrifugal pumps, each working in a separate circular well and driven by a high-pressure horizontal engine and four lift-pumps, all fixed in one square well and driven by a direct-acting condensing engine.

On the second day the papers read were "Petroleum as a Fuel for Locomotives," by Mr. Thomas Urquhart, from Russia; and "Corrosion in Marine Boilers," by Mr. J. Harry Hallett, of Cardiff. Both of these were of a purely technical character, but we may add that for the prevention of corrosion Hannay's "Electrogen" was well spoken of. During the afternoon the members visited by special train some of the chief collieries in the neighbourhood, including the Great Western, Lewis's Merthyr, Cymmer, and Idwynnia. At the Great Western Colliery the underground haulage is done by means of compressed air, and steam is supplied to the air-compressor from the boilers, which are fired by the waste gases from fifty Coppée coke ovens. The pit is ventilated by means of a Guibal fan, 40 ft. diameter, and a Schiele fan is now being erected. The pit is 400 yards deep and equal to an output of about 1,200 tons per day. At the Lewis Merthyr Pit a Schiele fan

is used for ventilation, and Sheppard's coal-washing machine and crushers are used.

On the third day an excursion was made to the great ironworks of Dowlais and Cyfarthfa, passing on the way Pwllpant Quarries, from which most of the walling stones of the Bute Docks have been obtained. The Dowlais works employ nearly 10,000 hands. At the steel works there are six Bessemer converters and two blowing-engines, capable of producing some 5,000 tons of steel per week. There are also six Siemens furnaces; two steel-rail mills, rolling about 2,500 tons per week; and a large number of furnaces, puddling-forges, and bar-mills. One of the chief features of interest was a recently-erected coal-washing machine (Lubrig's patent), capable of washing 1,000 tons of coal per day. The cost of this machine, we are informed, was over 20,000*l.*

A number of the members visited the Penarth Docks during the day, and the very fine masonry in them was the subject of general remark. The blasting and dredging operations were also witnessed.

A *conversatione* at the Cardiff Free Library took place in the evening, when the Menefaus pictures and a choice collection of hooks and engravings were inspected.

On the fourth day various tin-plate and iron and other works were visited, and on the last day a visit was paid to the Severn Tunnel works, Portskewett, when the system of boring pushed and other operations were fully explained.

Some further particulars of the Dowlais and Ebbw Vale Works, which were visited during the week, as already mentioned, may be of interest.

The Dowlais Works.

The Dowlais Iron Works were founded in the middle of the last century, now very nearly 140 years ago. In the present day they present indications of their antiquity, although we believe all relics of their most primitive days have disappeared. Dowlais has always been energetically conducted, and, owing no doubt greatly to cheap labour and unlimited space, has been able to meet the competition of the more modern establishments further north. It is, perhaps, largely owing to the two economic features referred to that iron puddling is being still carried on here, apparently with fairly successful results. The Dowlais works can, however, claim an important place in the record of progress of the iron and steel industry, for it was here that the first steel rail was rolled, the plant by which it was produced being still in use. The works are divided into two parts, known as the old works or Dowlais proper, and the new or Ivor Works. On the occasion of the last visit of this Institution to Cardiff, just ten years ago, one of the Ivor furnaces had just been started, and was then getting into full blast. It was served by a Whitwell stove for heating the blast, an apparatus that was then looked on with more interest than at present, as fire-brick stoves, either on the Whitwell or Cowper principle, have become far more common during the last decade, and are now fast superseding the old pipe stoves, which will not heat the blast to a sufficient temperature for modern requirements. At the present time we believe four furnaces are in blast at the Ivor Works, whilst six are working in the older part of the establishment, which, however, contains the more modern appliances.

The Dowlais furnaces will not compare in size with the modern giants of the northern districts or with those of the United States, still a notable increase in height has taken place in South Wales since coke alone has been used as fuel. The largest furnaces at Dowlais at present in blast are between 65 ft. and 70 ft. high, and have boshes 17 ft. 6 in. in diameter. The hearths are 7 ft. 6 in. across, and the tops 12 ft. 6 in. These are cylindrical furnaces, and are bound with iron bands in place of having the outer casing of sheet iron, usual in cupola furnaces in other districts. Another furnace of the same description, but 10 ft. higher, is now all but completed, and will, no doubt, be shortly blown in.

The blast for these furnaces is heated by either Whitwell or Cowper stoves, and it is indicative of the growing popularity of hotter blast that several cast-iron pipe stoves are rapidly being dismantled in this part of the work. Perhaps it is as well here to mention that the Cowper stoves are composed of a casing of sheet iron, which is lined with fire-brick. Within this is a chequer-work mass of fire-brick. The waste gases from the furnaces

are carried to the bottom of the stoves by a suitable tube, and then pass to the top by means of an internal flue, at the bottom of which are inlet valves. Through these air is admitted in order to complete the combustion of the gases. The latter having passed to the top of the stove find their way down through the interstices of the chequer-work, and finally escape to the main chimney-shaft. When a stove has become sufficiently heated for the purpose the gases are shut off, and the blast from the blowing-engine, which is required to urge the combustion in the blast furnace, is caused to pass through the chequer work in an opposite direction to that taken by the flame, and will naturally become heated by contact with the perforated fire-brick mass. It will be seen that the stoves are intermittent in their action, at one time being heated and at another giving forth the heated blast. The Whitwell stove differs from that described, chiefly in the manner in which the heating surface of fire-brick is arranged, but both work on the regenerative principle above explained. With these appliances the blast is sometimes brought to a temperature of over 1,400 degrees Fahr., which it would be practically impossible to obtain with the old cast-iron stove. In the latter apparatus the waste gases are brought in contact with iron pipes through which the blast is urged, or else they are heated by special furnaces contained in them, in which coal is burned.

The blowing-engines at the Dowlais works are mostly of the beam-engine type. The largest is a compound beam-engine with steam cylinders, 42 in. and 60 in. in diameter, and a stroke of 10 ft. The blowing-cylinder is 12 ft. in diameter. The boiler pressure is 50 lb., and the pressure of blast about 3½ lb. per square inch.

Steel is made at Dowlais both by the Bessemer and Siemens-Dowlais system. There are three Bessemer pits of the ordinary sunk type, each having two eight-ton converters. This plant has been laid down for some time, and does not call for any special notice. The six Siemens-Martin furnaces will work with from six to eight ton charges. There are two furnaces to a pit. The rolling-mills are placed conveniently to the furnaces. In this part of the works a fine pair of engines, to drive a new rail-mill, are being erected. These have been supplied by Messrs. Kitson & Co. This, we understand, is the first instalment of considerable changes that are about to be made at Dowlais, the management having determined to keep in the van of progress. There are the usual coke ovens, coal-washing machinery, and repairing-shops seen on works of this character, but which it would be useless for us to attempt to deal with in the space at our disposal.

The Ebbw Vale Works.

These works are also of large area, extending for some considerable distance up the valley of the Ebbw. They were founded late in the last century by a Staffordshire iron master. For many years members of the well-known family of Harford were proprietors, and in 1844, about a century after Dowlais was started, Mr. A. Darby purchased the works, which he enlarged considerably, and for many years he carried on a highly successful trade under the style of A. Darby & Co. Just twenty years ago the enterprise was converted into a limited company as it now exists.

The company are lessees of nearly eleven thousand acres of freehold and leasehold mineral property. During last year their output of coal from the various collieries connected with the establishment was close upon one and a half million tons. The coke made amounted to over a quarter of a million tons, whilst nearly six million bricks were manufactured on the premises of the company. The production of iron and steel during last year in pig-iron and spiegel-eisen was 212,412 tons; and 131,780 tons of finished iron and steel, in the shape of rails, bars, angles, &c., were produced.

The Ebbw Vale blast furnaces are of the same type as those at Dowlais, being of cylindrical form, and hooped with iron bands. There are at present six in work, four are situated at the northern end of the works, and two others at the extreme south, or a distance of about a mile and a half apart. They have mostly Cowper stoves (three to each furnace), although there are one or two old pipe stoves still in use. The steel works are about halfway between the furnaces, and contain three Bessemer pits of the usual form, having two

eight-ton converters apiece placed on opposite sides. The metal, which is tapped from the blast furnaces is brought, in the case of the north furnaces, for about three-quarters of a mile. This seems a considerable distance to bring a ladle of molten iron, but is somewhat less than that at Barrow, where the furnaces are over a mile from the steel works. This distance, however, was far exceeded at the Ebbw Vale, when the Company had the Sirhowy furnaces at work. These are situated about seven miles from the steel works, and the ladle containing the charge of metal used to be brought that distance by railway, and the molten iron was then run into the converters. There are two fine pairs of blowing engines for these converters, one by Messrs. W. & J. Galloway & Sons, and the other by Messrs. D. Adamson & Co. The maximum pressure of blast used is 25 lb. to the square inch. There is also in the same engine-house a set consisting of three pairs of very fine hydraulic pumping engines, by Sir W. G. Armstrong & Co. These are used for the hydraulic cranes and hoists required in the Bessemer plant. The rolling-mills attached to these converters have eight Siemens gas-fired heating-furnaces, which are worked by hydraulic gear with drawing the ingots. The blooming rolls are 36 in. between centres, and are driven by a pair of 36-in. cylinder engines, geared 3 to 1. These are by Galloways, of Manchester. The mill-train has rolls with 30-in. centres, which are driven by a pair of vertical engines with 50-in. cylinders, geared 1½ to 1. The Victoria blast-furnaces, which are placed at the southern end of the works, are modern and well-designed erections. The blowing-engine house is a handsome and solidly-built structure, and contains two fine vertical engines, with blowing-cylinders 100 in. in diameter, by Messrs. Kitson, of Leeds. The gases from the furnaces are used for heating the steam-boilers supplying these engines. There are extensive ranges of coke-ovens on the high ground above the furnaces. The majority of these are on the Coppé principle, and are discharged by the charge being pushed out by steam machinery. The oven is simply a long straight tunnel with a door at each end. Both doors are opened and the "pusher-out" clears the whole contents. In the ordinary "drag-oven" the coke is dragged out by means of an iron bar which is placed on the floor of the oven before the charge is put in. In the latter the coke is watered in the oven, and this is said to have the effect of driving out a good deal of the sulphur; however this may be, the ordinary oven coke is a better colour than that of the Coppé ovens. The advocates of the latter affirm that the difference between the two cokes is mainly one of appearance, and that if Coppé coke be watered immediately it is pushed from the oven there is very little practical difference. It is perhaps worth notice that in the South Wales district, when coke is produced for immediate use, as at Ironworks, and not for sale, the Coppé ovens are, as a rule, in strong favour. On the other hand, at the collieries, where the coke is made to be sold, drag ovens are the rule. At only one colliery did we notice Coppé ovens, and this was in a case where the bituminous vein had been exhausted and a coal only slightly bituminous was being worked. Coppé ovens are especially well adapted for coking harder coals. We believe that these ovens were first built on an extended scale at Ebbw Vale. There are two or three other rolling-mills at Ebbw Vale. A har-mill, with a 12-in. train, is now being erected. This is to be driven by cotton rope, which is a new departure in rolling-mill practice. In the same building there is an 18-in. train. In another building a 36-in. train is in progress, in which some novelties are being introduced in the shape of hydraulic turning-over gear. There are extensive foundries, engine-fitting and erecting shops, smiths' shops, wood-working shops, and many other buildings of this description, the extent of which will be understood when we say that the Company make all their own rolling-mills and plant of this description, and many of the larger engines for working them. The thirty-two locomotives and 3,500 trucks owned by the Company are all kept in repair on the premises.

#### Designs Competition, Dairy Show, 1884.

The Secretary asks us to remind our readers that entries for the above close on the 25th inst.

#### FURTHER NOTES AS TO VENTILATING APPLIANCES AT THE HEALTH EXHIBITION.

In the Central Annex, between the Central Gallery (Science and Art) and the gardens, a number of ventilating appliances and arrangements are shown, either full size, or by means of models and drawings. At Stand 687 Messrs. George Wright & Co., of Westminster Bridge-road, show a model of their "Eclipse" ventilator for billiard and smoking rooms, which is designed for carrying off not only the products of combustion from the gas-burners, but the foul air from all parts of the room. Stand 688 is occupied by Messrs. Sharp & Co., of Holborn-viaduct, with their "Crown Ejector" ventilators as applied, not only to buildings, but to yachts. The same firm are exhibitors of soil-pipe ventilators and air-lift brackets, some of them in the form of capitals, so as to work in with the architectural features of interiors. They also show a new corona reflecting gas-burner. Messrs. Dick Radclyffe & Co., of Holborn, exhibit at Stand 690 some ventilated window-cases for ferns, flowers, &c. At Stand 691 is shown a model of a ventilating window-sash and frame, invented by Mr. Augustus Frere, F.R.I.B.A., with a view to the requirements of the dwellings of the poor, though it is capable of wider application. At Stand 692, Messrs. H. W. Cooper & Co. (Limited) have a very good display of their specialities in perforated, louvred, and sliding glass ventilators, with some excellent weather-tight metal casements of improved construction. The way in which both the perforated and the louvred ventilators are combined with coloured glass windows is worthy the attention of visitors. An improved hopper ventilator for skylights shown at this stand is especially worthy of note. Dr. P. W. Perkins Case, of Croydon, shows at the next stand (693) a self-regulating ventilator, combined with a shaft which turns up or down as desired. Another method of hilliard-room ventilation is shown by a model at Stand 694. It is exhibited by Mr. George W. Webb, A.R.I.B.A., of Reading, who claims to have achieved the task of automatically removing in the most direct manner the products of combustion, tobacco-smoke, &c., and of supplying fresh air without draught. Mr. George Fellows Harrington, of Ryde, I. W., exhibits (Stands 696 and 720) his system of sewer ventilation by means of shafts rising above the houses, the street ventilating gratings, such as those used in London and other towns, being abolished. Although there is much to be said in favour of such a system as that advocated by Mr. Harrington, its adoption would necessitate precautions which would not always be observed. There is considerable difference of opinion on this subject, but we are strongly inclined to think that the preponderance of the argument is in favour of the London method, properly carried out. Mr. B. Inisworth (Stand 699) shows his "double-current syphon former ventilator," and other ventilators on the same principle. Stand 699 is occupied by Messrs. John Smeaton & Sons, of Ludgate-circus, who show the "Kosmos" ventilators, of which a large one is exhibited in action. In this ventilator a small stream of water is made to impinge upon the periphery of a wheel, which is made in the form of a brush, and so sets in motion a series of revolving blades or fans. At Stand 700 Mr. Edward Wood, of Red Bank Works, Manchester, exhibits what are known as "Tobin's" tubes. Messrs. William Udal & Co. (Stand 701) exhibit Bruce's patent fanlight opener, a simple and effective apparatus which we believe we have noticed with commendation on some former occasion. Lieut.-Col. Thorneycroft, of Tottenham, exhibits a model of his house, the sanitary arrangements of which were fully described and illustrated in the *Builder* a few years ago, under the title "A Notable House." Mr. W. W. Nicholls (Stand 703) is the exhibitor of a safety window-frame and sash of which we spoke favourably a few weeks ago (see *Builder* p. 82, ante). At Stand 706 Dr. R. Neel shows his chemical punkah and chemical "lung" for fixing in rooms for the purification of the air. The lung consists of an endless perforated webbing which is made to pass over top and bottom rollers,—the bottom roller being fixed in a trough containing a solution of caustic soda, through which solution the fabric passes, and thus is obtained a considerable surface charged with a material which absorbs and

destroys noxious gases. At Stand 710 Messrs. Hayward Bros. & Eckstein, of Union-street, Borough, are exhibitors of Boyle's patent mica-flap outlet ventilators, and the Sheringham inlet ventilators, to be used in conjunction. These ventilators have been largely adopted for many years, and with the best results. The same exhibitors also show their "seui-prism" pavement-lights, the free use of which will bring daylight into corners to which it has not penetrated for years. Messrs. Josiah Moore & Sons, of St. James's-walk, Clerkenwell, exhibit (Stand 712) their improved glass louvre ventilators, as well as circular and sliding glass ventilators in various forms; they are too well known to need description or comment. Stand 713 is occupied by Messrs. Harcourt Thompson & Co., who show their ventilating ridge, and a new mercurial air-valve, which opens or closes according to the rise or fall of the temperature of the room in which it may be fixed. At Stand 714, Messrs. Meakin & Co., of Baker-street, show their self-acting sash-faster and opener, which for security, efficiency, and ease of working, are unsurpassed. The "Standard Sliding-sash," shown by these exhibitors, allows of the outside of the glass being cleaned by a person standing on the floor of the room, and in case new sash-lines are required there is no necessity for removing any fixed parts. Mr. W. P. Buchan, of Glasgow (Stand 715), shows his patent ventilating cowls and a model of a house ventilated on his system, by which provision is made for removing the products of combustion from every gas-burner, and for supplying air direct from outside to assist the combustion in the fireplaces. Mr. J. E. Ellison, of Leeds (Stand 717), shows his conical perforated brick ventilator, his patent radiator ventilator, and Stevens's chimney-tops and soil-pipe cowls. We have on previous occasions spoken of the efficiency of Mr. Ellison's ventilators. Messrs. J. M. Lamb & Co. (Stand 719) show their "Triumph" centrifugal air-pump exhaust ventilators, and their patent "Outer-section" fixed cowls, together with other appliances, all of which appear to merit the careful attention and examination of visitors. Particularly worthy of mention is a noiseless fan, which is shown in action in the Machinery in Motion Department. Messrs. C. Kite & Co., of Christopher Works, Chilton-street, N.W., occupy Stand 721, and exhibit their exhaust and inlet ventilators, and a model showing their application. Some of these, we believe, have been used in the Sanitary House at the Exhibition. A model of a house illustrating Messrs. Kite's system is exhibited by them. Their roof ventilators have lately been used for new Board Schools at Warwick. Particularly worthy the attention of householders is Kite's noiseless chimney-breast outlet ventilator, which is easily fixed, and, apparently, judging by tests we have witnessed, very efficient. The wall-inlet ventilators shown at this stand also deserve attention. These, or some similar appliances (we refer both to the wall-inlet ventilators and to the chimney-breast ventilator), should be fitted in every dwelling-room, especially where gas is burned. Stand 723, that of Messrs. Ewart & Co., of Euston-road, contains specimens of the "Empress" ventilator (of which we have on previous occasions spoken favourably) and the "Prince" chimney-pot. Mr. W. Lord, of Middlesbrough (Stand 724), shows his patent "Incline" chimney-cowl, which is fixed, and consists of a number of cylinders, on each of which are fixed six or more inclined channels or passages, and it is claimed that the action of the wind on these creates a powerful centrifugal motion up the interior of the cowl, and so assists its extractive power and prevents down-draughts.

In the Western Gallery (Machinery in Motion) Messrs. A. W. Kershaw & Co., of Lancaster, exhibit, at Stand 1,181, their patent pneumatic exhaust ventilators as applied to buildings, ships, and yachts. These appliances are used in conjunction with down-cast ventilators, and the system of ventilation thus obtained appears to be very efficient, and devoid of down-draught. These ventilators have, we are informed, been adopted at the Manchester, Sheffield, and Lincolnshire Railway Company's new offices at Manchester.

The New Burial-ground at New Brentford was consecrated on the 13th inst. by the Bishop of London. The chapel and other works have been erected from the designs of Mr. Chas. J. Gladman, A.R.I.B.A.

INTERNATIONAL INVENTIONS  
EXHIBITION, LONDON, 1885.

WE acknowledged last week the receipt of the prospectus of this Exhibition, which is to be opened in May, 1885, in the buildings now devoted to "The Healtheries." We now give some further particulars.

Division I. (Inventions) will include groups of apparatus, appliances, processes, and products, invented or brought into use since 1862, relating to:—1, Agriculture, Horticulture, and Arboriculture; 2, Mining and Metallurgy; 3, Engineering Construction and Architecture; 4, Prime Movers, and Means of Distributing their Power; 5, Railway Plant; 6, Common Road Carriages, &c.; 7, Naval Architecture; 8, Aeronautics, &c.; 9, Manufacture of Textile Fabrics; 10, Machine Tools and Machinery; 11, Hydraulic Machines, Presses, Machines for Raising Heavy Weights, Weighing, &c.; 12, Elements of Machines; 13, Electricity; 14, Apparatus, Processes, and Appliances connected with Applied Chemistry and Physics; 15, Gas and other Illuminants; 16, Fuel, Furnaces, &c.; 17, Food, Cookery, and Stimulants; 18, Clothing; 19, Jewellery; 20, Leather, &c.; 21, India-rubber and Gutta-percha, &c.; 22, Furniture and Accessories,—Fancy Goods; 23, Pottery and Glass; 24, Cutlery, Ironmongery, &c.; 25, Fire-arms: Military Weapons and Equipment, Explosives; 26, Paper, Printing, Bookbinding, Stationery, &c.; 27, Clocks, Watches, and other Time-keepers; 28, Philosophical Instruments and Apparatus; 29, Photography; 30, Educational Apparatus; 31, Toys, Sports, &c.

We give the detailed classification of one or two of the Groups:—

Group III.—Engineering Construction and Architecture.

Class 13. Roads.—Methods and materials for constructing and paving roads; cleaning roads and pavements; road-sweeping machines; rollers; apparatus for the removal of mud, snow, &c.; water-carts and other means of watering.

Class 14. Railways and Tramways.—Construction; excavators and appliances used for earth-work and tunnelling. Permanent way: rails, chairs, sleepers.

Class 15. Bridges and Viaducts.—Models, plans, and designs for arches, girders, suspension, trestle, and other bridges; apparatus used in construction.

Class 16. Docks and Harbours.—Models, plans, and designs for docks, harbours, piers, breakwaters, &c.; submarine constructions; diving apparatus; dredging machines; pile-drivers, screw piles; coffer-dams; graving docks; "patent" slips, caissons, pontoons, floating docks, hydraulic apparatus for working dock-gates, &c., gridirons, Buoys.

Class 17. Lighthouses.—Method of construction; appliances used in lighthouses and in lightships, fixed and floating light apparatus, lamps, sound signalling apparatus.

Class 18. Rivers and Canals.—Conservation and improvement of rivers; construction of canals; locks, lifts and inclined weirs.

Class 19. Water Supply and Sewerage.—Methods of collecting, pumping, storing, filtering, and distributing water; appliances for detecting and preventing waste of water, water-meter, water fittings, filters; sewers, sewage disposal and utilization.

Class 20. Reclamation, Irrigation and Drainage of Land. Drainage (natural and artificial) of low-lying districts; embankment and other land-irrigation works.

Class 21. Testing Apparatus.—Apparatus and instruments used in testing iron, stone, brick, concrete, cement, &c.

Class 22. Military Engineering and Fortification.—Military topography.

Class 23. Materials used in Building.—Bricks and tiles, machines for making them; concrete, artificial stone, cement, materials and appliances used in their production; asphalt; roofing felt, and other roofing materials; columns, girders, and other applications of metal in building; application of terra-cotta to buildings; preservative and fire-resisting materials, paints, &c.; for application to stone, wood, iron, &c.; methods of applying the same.

Class 24. Building Construction.—Models and plans showing methods of construction; non-combustible constructions; labour-saving and other machines and appliances used in building, scaffolds, elevators; fittings and appliances used in buildings, shutters, blinds, lifts, bells, speaking-tubes, &c.

Class 25. Heating, Ventilation, House-drainage, &c.—Sanitary appliances; ventilators; coals for chimneys, chimney-sweeping apparatus; apparatus for heating by steam, water, air, &c.; means of cooling air.

Group XXXIII.—Pottery and Glass.

Class 119. Kilns and Furnaces.

Class 120. Bricks, Tiles, Earthenware, &c.—Terra-cotta; architectural pottery; fire-clay goods; crucibles; drain-pipes; chemical and similar stoneware; materials, machinery, and apparatus.

Class 121. Porcelain, Majolica, and Artistic Pottery.—Biscuit-ware, faience; Farian; materials, machinery, and apparatus.

\* Having in view the wide range of this International Exhibition, and the limited nature of the total available area, it will be necessary to restrict as much as possible the amount of space which can be allotted even to the most important classes; and only under exceptional circumstances can applications be entertained for space for objects which have been shown in the Smoke Abatement Exhibition, 1881; the Fisheries Exhibition, 1883; or the Exhibition of Health and Education of the present year. The classes including such objects are marked in the classification with an asterisk.

Class 122. Crown, Sheet, and Plate Glass.—Window glass, mirrors, stained glass; glass mosaic; materials, machinery, and apparatus.

Class 123. Bottles, Table Glass, Toughened Glass, &c.—Materials, machinery, and apparatus.

Division II. (Music), is intended to include three groups, viz., XXXII., Instruments and Appliances constructed or in use since 1800; XXXIII., Music Engraving and Printing; and XXXIV., Historic Collections. But, as we suggested last week, and as will be seen by the foregoing details, the first division, Inventions, includes such a plethora of subjects, that it appears to be questionable whether adequate justice can be done to Music,—a large subject in itself, but which is not even mentioned in the title of the Exhibition.

Applications for space must be sent to the Secretary (from whom further particulars may be had) not later than the 1st of October. Applications from foreign countries and the colonies will be received up to the 1st of November.

CURIOUS FLOOR CONSTRUCTION.

SIR,—I enclose herewith a sketch of the construction of a floor, which I think is peculiar and unusual. It occurs in a very old house situate in King-street, in this town. As the sketch shows, the joists are laid so that they almost appear to radiate from a common centre, and they are mortised into two large beams which cross the house diagonally, from the

angle of the wall to the centre of the partition-wall against the next house. The method of laying the floor-boards is also peculiar; they are of great width, and mitred over the line of the last-named beams. The first floor overhangs from the girders supporting the joists. The dotted lines represent the floor-boards.

There is one other house with a similar construction within a few yards of this one, and evidently of the same date.

R. G. CARPENTER.

Duppas House, Croydon, Aug. 7th, 1884.

THE GUEST-CHAPEL, CROXDEN ABBEY,  
STAFFORDSHIRE.

SIR,—May I ask you to help those who are striving to obtain the preservation of the thirteenth century Guest-chapel of the Cistercian Abbey of Croxden? I learn on the best local authority and from Mr. Loftus Brock that it is proposed, with the consent of the owner of the Abbey lands, Lord Macclesfield, to remove this chapel and to erect on its site a new church, and that already its roof is removed and that its total disappearance rests on the decision of his lordship.

I must explain that in the middle of the eighteenth century the chapel was altered and repaired and re-roofed to do duty as the church of the little village grown up amongst and around the Abbey ruins. This beautiful thirteenth century ruin seems to be but little known, although not more than three or four miles from the railway stations of Rocester and Uttoxeter. The late Mr. Street knew and much admired it, and I have frequently visited it and sketched and measured its pure and beautiful detail.

I need not point out to those who have studied the Cistercian plan, such as Viollet-le-Duc gives, that a Guest-chapel formed an essential part of it, as it did, too, in the earlier Benedictine foundations.

We have not many examples of guest-chapels. The well-known one at Canterbury, now the chapel of St. Augustine's College, will occur to most of us, so beautifully reclaimed from the most degrading uses and restored for Mr. Beresford-Hope by Butterfield. Croxden Chapel never sank to this depth. Surely the old chapel might be retained, even as a ruin, as it was left by the Reformers, and the new church erected near it; or the chapel might be re-roofed and used as a parish room. Anything rather than destruction! It is true that the interior and the arrangements are squalid and mean, just as so many of our rescued churches were not many years ago, and that a new and proper church is required, but surely not at such a sacrifice.

The chapel is an oblong, with three south and one east lancet, and remains of south and west doorways. The lofty narrow lancets have bold chamfers and internal arches just as the rear western and southern windows of the Abbey Church close by. Its walls are built with red and grey sandstone blocks, as the church. In fact, it is part of one design by the original Cistercian architect. The interior walls have several coats of painted or tempera decoration, the first being on the stone.

Although there is no detail of such beauty as in the chapter-house entrance, the chapels, and other portions of the church and buildings, this chapel, in its harmonious simplicity, is characteristic of one well-thought-out design. Mr. Loftus Brock has in his possession a beautiful set of drawings of the chapel executed by a friend, which he would, I am sure, be happy to show to those interested, and who would be willing to help.

I cannot believe that the advocates of the destruction of the chapel do appreciate its architectural and archaeological interest (for there is a tradition that the building is comparatively modern, using old stones). Many of those in the neighborhood value it, however, and its destruction would be a grievous loss to them and to many of us.

H. HERBERT CARPENTER.

August 10, 1884.

THAMES COMMUNICATIONS.

SIR,—Your issue of the 9th inst. contained a paragraph on this subject, in which my name is mentioned as having voted at the last Court of Common Council against a proposed addition to the Bridge House Estates Committee's recommendation, which addition was to the effect that the Corporation should publicly advertise for designs for the new bridge, whilst three other architects who were present and took part in the proceedings voted with him. This statement, sir, scarcely does me justice.

The facts are as follow:—The Bridge House Estates Committee recommended that a new low-level bridge be constructed across the Thames at the Tower, whilst a strong feeling in favour of a subway existed.

The debate was continued at a special court convened for the purpose, the result of the division being 83 for the bridge and 58 for the subway, two

or three of the architects named voting in the minority.

Mr. Peebles then proposed his amendment to the Committee's recommendation, which gave a general impression to the majority that the object was a postponement for another year, and as I was, like Mr. Peebles, strongly in favour of a bridge, I represented to him the possibility of his amendment achieving the object of the minority at the same time adding that the chairman of the Committee had pledged his word to me that there would be an open competition for designs.

This assurance of the chairman I plainly saw would also have satisfied Mr. Peebles, as it did myself, but for a division having been called for by other members of the Court. Having such a pledge from the chairman, I considered I could confidently stand by the Committee's recommendation to the end, not knowing, of course, how other architects were going to vote. I must, therefore, not be judged as unfavourable to an open competition for so important a matter as a bridge across the Thames within the City of London; but I am afraid, without this explanation, a wrong interpretation will be given to my vote. In answer to this question of Thames communication, I would add that, although I consider a bridge to be far preferable to a subway, I do not for a moment think that a low-level bridge will meet all the requirements of the case.

The proposed new street from King William-street *via* the Monument to Thames-street, about to be constructed by the Commissioners of Sewers at a cost of 300,000*l.*, points to the absolute necessity of an outlet across the river for the low-level traffic; still, I am satisfied it will be a great mistake to altogether overlook the high-level traffic in and about the newly-constructed Eastcheap, the Tower, and the district eastward, which is manifestly increasing daily, and which, for the most part, if a low-level bridge only be constructed, will still have to go round by London Bridge. I, therefore, suggested to the Court the desirability of providing a high and low level bridge combined in one structure, say of iron, the high-level bridge to accommodate the traffic just referred to, whilst the low-level bridge could have openings for shipping, and at the same time provide for all the increasing traffic along the banks of the Thames both above and below London Bridge. H. H. BRIDGMAN.  
42, Poultry, E.C., 14th August, 1884.

#### THE SANITARY AND INSANITARY HOUSES AT THE HEALTH EXHIBITION.

Sir,—May I, through your columns, call the attention of the committee who arranged the "sanitary" house at the Health Exhibition to what, in my opinion, is a defect in the plumber's work, *viz.*, the carrying of the overflows from washing basins into the waste-pipes over the traps! My experience is that in nine cases out of ten the stoppage occurs in the trap itself, which, of course, renders the overflow useless at once. It appears to me that the proper course to pursue would be to run the overflow-pipe quite independently of the waste, in which case it would scarcely fail to act when wanted. A. ROWE.

#### A PARTY-WALL QUESTION.

THE DISTRICT SURVEYOR OF ST. GEORGE'S, HANOVER-SQUARE NORTH & CO. MESSRS. CURTIS AND CO.

On the 13th inst. Messrs. Cubitt & Co. were summoned before Mr. Newton at the Marlborough-street Police-court, at the suit of the District Surveyor, for not having complied with a requisition to carry up the east party-wall of No. 95, Piccadilly 15 in. above the gutter of that building (it being the highest building adjoining the wall, No. 94, Piccadilly being a lower building), and also to carry up the wall above any part of the roof of No. 95, opposite thereto, and within 4 ft. of it. It appeared that the defendants were carrying up the wall solid to the level of the underside of the gutter, at which level it was surmounted by an open balustrade, with plinth and capping, the plinth being solid to 7 in. above the gutter, with a thickness of only 6 in.

Mr. Redwar, barrister, appeared for the District Surveyor, and Mr. Lewis Coward, barrister, for the defendants.

Mr. Redwar submitted that the whole of the wall in question was a party-wall, although the buildings on either side were not of the same height, and for this reason, that while by Section 3 of the Metropolitan Building Act, 1855, the separation of buildings in different occupations might at first sight seem to be the one essential characteristic of a party-wall, Section 17 imposed the additional rule that every party-wall should be carried above the roof, flat, or gutter of the highest building adjoining the wall. He it was contended that there was an inconsistency between the definition in Section 3 and the rule of construction in Section 17, he would meet that by saying that Section 3 expressly provided that the definitions therein given must yield to the meaning of the context, which in this case was that every wall, which by dividing buildings of unequal height, became a party-wall, was, by force of Section 17, made a party-wall from its base to its top, since a party-wall must be carried above the highest building

adjoining thereto. This view was supported by the circumstance that "external wall" was defined in Section 3 as "an outer wall or vertical enclosure, not being a party-wall"; these last words clearly pointed to the contingency of some "outer walls" or "vertical enclosures" being "party-walls." He contended that Weston v. Arnold (L.R., 9 Ch. App. 1,084), which decided that a wall was a party-wall for such portion of its height as it actually separated buildings, and was an external wall for the remainder of its height, did not govern the Metropolitan Building Act, as it was decided on the Bristol Improvement Acts, 1840, 1847, which contained rules as to party-walls different to those in the London Act. In the case of Knight v. Pursell, (L.R., 11 Ch. D., 412), in which Mr. Justice Fry treated Weston v. Arnold as an authority on the London Act, it was not necessary to decide the point of the vertical extension of a party-wall, as the case related to lateral extension, which stood on a different footing, being governed by the definition alone in which separation was made the test, while in considering vertical extension it was necessary to read Section 17, with the definition.

Mr. Newton, without calling on Mr. Coward, decided that the wall was an external wall originally, and that it had been made a party-wall by the addition of a low building on the side of No. 94, but only to the point at which it separated the adjoining buildings; above that point it was an external wall. He accordingly dismissed the summons.

Mr. Newton, without calling on Mr. Newton said that he would not allow costs as against a public officer who was endeavouring to do his duty under an Act of Parliament.

#### AN ARCHITECT'S CLAIM FOR PROFESSIONAL SERVICES.

CHORLEY v. CROSSLEY.

THIS case was tried at the Leeds Assizes, before Justice Maulst and a special jury. By it, the plaintiff, an architect practising in Leeds, sought to recover the sum of 86*l.* 5*s.* 6*d.* balance of account for services rendered in connexion with two arbitration cases, in which he had appeared in the defendant's behalf.

The contention on behalf of the defence was that the charges were excessive, and that they were greater than the plaintiff had agreed to make.

After hearing the opening statements of counsel and the plaintiff's evidence, and before any other witnesses had been examined, the judge said that there was no answer to the claim, and a verdict was given for the sum of 50*l.*, in addition to the amount which the defendant had paid in court. His lordship certified for costs against the defendant, including those of a special jury.

#### CONTRACTORS' LIABILITIES.

JONES v. HUGHES AND ANOTHER.

AN action of considerable interest to contractors was tried at the Liverpool Assizes a few days ago, before Mr. Justice Day and a common jury. The plaintiff was the widow of one G. W. Jones, a labourer, and she claimed damages under Lord Campbell's Act against Messrs. Hughes & Stirling, contractors, of Liverpool, on the ground that her husband had lost his life through their negligence.

The circumstances out of which the action arose were as follow:—The defendants had taken a contract to pull down and rebuild the tower of St. Mary's Church, in Liverpool. The church was built in 1514, and had to be removed to another site in consequence of the land being required for the extension of the Lancashire and Yorkshire Station. At one end of the church was a tower 18 ft. square, the walls of which were over 2 ft. thick. At the height of about 40 ft. in this tower was a floor with a trap door 6 ft. square in the middle of it. The deceased man was at work on the 27th of May with four others, demolishing the walls of this tower, which were at that time about 44 ft. high. The stones of which the tower was composed, as they were loosened, were lowered by a screw-driven crane working from the ground, and the greater portion of the mortar and other rubbish was also lowered in skips. In the course of the work, however, a considerable quantity of debris accumulated on the floor. The deceased stopped on this floor in order to work with greater ease in prizing away one of the stones, and after he had been standing there some few minutes the floor gave way without any warning, and the man was precipitated to the ground and killed.

At the trial it was admitted on both sides that the floor was weak, the ends in the walls being rotten, and the notching of the floor-beams at the intersections being deeper than it should have been, and, in fact, the whole construction faulty. The plaintiff contended that the defendants could have, and ought to have, discovered the weakness; while the defendants contended that the weakness was a latent one which could not have been foreseen. Evidence was gone into at considerable length upon this point, but in the result it became manifest

From the evidence of Mr. Edward Hughes, one of the defendants, it appeared that he did not

authorise the rubbish being put on the floor, and did not know of its being put there, and further that the men themselves ought to have lowered the debris by the crane, instead of allowing it to accumulate on the floor.

As the plaintiff's witnesses were unable to contradict this evidence, the learned judge non-suited the plaintiff, remarking that the action ought to have been brought under the Employers' Liability Act in the County-court, and that he wished he had the power to make the plaintiff's solicitor pay the costs of the defendants.

#### CHURCH BUILDING NEWS.

**Bengeo.**—Several improvements have just been effected in Holy Trinity Church, Bengeo, near Hertford, which was built more than twenty-five years since from the designs of the late Mr. Benjamin Ferrey, F.S.A. The funds at disposal then only sufficed for fittings, &c., of the simplest character to the chancel. The Holy-table has been raised on a platform and a credence-table of Corsehill stone put. An elaborate polished brass altar-rail and standards have been added, and the whole of the chancel pavement and steps re-arranged and laid with Godwin's tiles from the architect's design. New English oak choir-seats, clergy-stalls, and prayer-desks have been supplied; also a handsome pulpit, with ornamental oak superstructure and moulded Corsehill stone base. The opportunity has been taken to give more space at the easternmost part of the nave. A choir vestry has been attached to the present vestry. In the churchyard handsome oak gates and brick and stone piers have been executed to the two entrances, with an arrangement for suspended lamps over them. The contractors for the building and other works have been Messrs. Geo. Ekins & Son, Hertford; for the oak fittings to the chancel, the pulpit, and the credence-table, Messrs. White & Sons, of Vauxhall Bridge-road; for the metalwork, Mr. Gawthorpe, of Long Acre. Mr. Edmund B. Ferrey, F.S.A., was the architect.

**South Muskham.**—The chancel of South Muskham Church, Newark, has lately been enriched by the addition of a reredos, consisting principally of coloured alabaster, divided into three canopied panels by columns of green serpentine marble. The central panel contains a cross of Irish red marble, upon pure white alabaster, the sides enclosing the "Agnus Dei" and Pelican, in white marble, upon the richly-coloured substructure. The additions to the church furniture include a handsome embroidered altar-cover, carved holy table, and tapestry side hangings. The whole of the work has been carried out by Messrs. Jones & Willis.

#### SCHOOL-BUILDING NEWS.

**Lincoln.**—The foundation-stone of the new City of Lincoln High School, St. Botolph's, Lincoln, was laid on the 19th ult. by the Rev. W. S. White, of Potterhanworth, in place of the Bishop of Lincoln, who was indisposed. The school is being erected to accommodate about 300 children. The work is being carried out by Mr. W. Wright, builder, Park-street, from designs by Mr. W. Scorer, architect, Bank-street-chambers, Lincoln.

**Temple Cowley.**—The Education Department having required additional accommodation for 100 children, the architect (Mr. A. Mardon Mowbray, Eastbourne) of the present school chapel was instructed to prepare the necessary plans, &c. The work has been commenced by adding on the west end of the present girls' school an infants' school, 40 ft. by 20 ft. 3 in.; an entrance porch, cloak-room, and lavatories for infants and girls; book-room, and offices. The style of the present building, Gothic of the early part of the thirteenth century, has been followed in the new part, the walling being of red brick, with blue Staffordshire brick bands and stone dressings, the roofs being slated, with red roll-ridge tiles on the top. The two school-rooms can be thrown into one for Divine service, penny readings, &c., by the removal of folding-doors, which can be converted into seats, the school desks being convertible into tables, and the infants' gallery into a platform. The flooring will be formed of wood blocks on a concrete bed. Mr. A. W. Collett, of Oxford, has undertaken the contract. The chancel portion will be added later on, also the school-house.

**Cambrian Archaeological Society.**—This Society commenced its thirty-ninth session at Bala on Monday.

## The Student's Column.

HINTS FOR THE STUDY OF  
THE HISTORY OF ARCHITECTURE.—VIII.

SARACENIC.

At the beginning of these articles allusion was made to certain threads of bright colour darting all over the architectural web instead of coming gradually into existence like others. Such a thread is that of Saracenic or Mahometan art, which suddenly begins, at the period to which we have now arrived, to invade the web in various directions. Being such an invasive thread, it has seemed best to become acquainted, first of all, with those styles that were invaded by it, and that is why the present arrangement has been adopted in preference to Fergusson's, who puts Byzantine at the end of his Handbook.

He classifies Saracenic architecture under the following divisions:—1. The Syrian, the earliest and most like the Byzantine of all the Mahometan styles, but of which few early specimens now remain. 2. The Egyptian, which may be called the typical style of the group, commencing at the same time and from the same originals as the Syrian, but, being practised without foreign admixture for ten or eleven centuries, it acquired a completeness, and, at the same time, an elegance greater than what is found in any of the others. 3. The Persian, a style whose origin it is difficult now to trace, but which, at its culminating point, rivalled that of Egypt in splendour, but not in elegance nor in true architectural propriety. 4. The Indian styles naturally form the next chapter. Their origin and history being perfectly well known, no difficulty can exist in tracing them to their source or marking their gradations, or in appreciating their beauties, which, in some respects, are nearly unrivalled. 5. After completing this survey of the Eastern styles, we return to that of Spain, a style differing so much from the others as to constitute a subject very complete in itself. 6. The last distinctive style is that of Constantinople, comprising merely those edifices which were erected by the Turks in imitation of Santa Sophia and other Christian churches of that city (Fergusson's Handbook, p. 379). There must be some very strong reason to account for such an extensive diffusion of a new religion started only 622 years after the birth of Christ, whose religion one would have thought to be sufficient for a much longer period, if not for ever. The human mind, however, seems to be insatiable, and the present day in England is not without its feverish want of change in religious matters: so we must hope that our clergy will, at all events, do their best to maintain our respect for their holy office.

According to Ramé, the seed sown by Mahomet,—or Mohammed, as his name is also spelt,—at the time of his mission in 622 A.D., called the Hejira, fell on very receptive soil in the minds of the Arabs, a Semitic race, who were persuaded that he was descended in the direct line from Ishmael the son of Abraham, and that he was sent by Allah, and that his God bore a complete resemblance to the God of the Jews.

The one temple of the faith thus founded, says Fergusson on page 383 of his Handbook, was the Kaabah at Mecca, towards which all believers were instructed to turn when they prayed. Consequently we shall find that in all the mosques,—or places of worship used by the Mahometans, Saracens, or Moslems, as they are variously called,—there is a special arrangement of space allotted for praying in the direction of Mecca. The chief object in this space is the Kibleh, a niche or recess in which the Koran (corresponding with our Bible) is kept, adjoining which is a mimbar or pulpit. There are some excellent plans to a large scale illustrating this in a paper read at the Institute by Mr. H. Carpenter in February, 1883. Indeed, this paper is especially interesting as it is about mosques which have been subsequently changed into Christian churches; just as Christian churches have been changed into mosques,—for example, our acquaintance Sta. Sophia at Constantinople,—with the usual addition, required by the Saracens, of several minarets or high towers, from the top of which the call to prayer is given, and which are an indispensable adjunct to any mosque.

Beginning with Syria, we find at Jerusalem two famous mosques, one built by the Caliph

Omar, in the fifteenth year of the Hejira, and which forms part of a larger one called El Aksah, built by Abd el Malek fifty-four years later; this is illustrated by Fergusson on pages 384 and 385. The other famous mosque, the Dome of the Rock, illustrated on pages 261 and 262 of Smith and Slater's book, is, they say, the subject of keen debate as to whether this is a nearly unaltered Christian building of the fourth century or a construction of Abd el Malek (above mentioned) in the year 688 A.D. The section shows a domical building erected over a rocky cavern, the entrance to which is guarded by tents supported,—not from the ground,—but by ropes attached to the capitals of the arcade.

There is a large mosque at Damascus; it was formerly the Church of St. John, and remained for some time the joint property of Christians and Moslems, both praying together in it, or, at least, on the east and west sides of a partition run through it.

The Syrian mosques are interesting to Englishmen from their connexion with the Crusades, or wars fought against the Saracens on behalf of the Christian cross (*crux, crucis*).

Taking the next country, Egypt, we find something more distinct and characteristic in the arrangement of the mosques. Some of these consist of a large open court-yard surrounded by arcades somewhat resembling our cloisters, but that the arcades are several rows deep instead of one, while on the side nearest Mecca these rows are further increased in number, so as to afford additional accommodation for praying in that direction. Such is the mosque of Amrou at Old Cairo, the plan of which is illustrated by Fergusson on page 388. Such also is that of Ebn Touloun, of which he gives a view on page 390, while Rosengarten gives, on page 201, a plan, section, and details of it. The section shows the cupola raised over the well that is usually provided for ablutions in the centre of the courtyard. Wooden tie-beams at the springing of the arches are a common feature in these mosques. The plan and section of the mosque and tombs of Sultan Barkook, on page 392 of Fergusson, introduce us to the Egyptian form of dome raised over these great sepulchral chambers "betraying the existence of a strong affinity to the tomb-building races in the rulers of Egypt at that time." The next example given by him is the Mosque of Hassan at Cairo, in which the courtyard is reduced to comparatively small dimensions, but has four gigantic niches opening out of it, almost like the nave, transept, and choir of a church, and, beyond the Kibleh, the huge tomb of the founder flanked by minarets, a very grand composition. He next mentions the Mosque El Moyed, erected in 1415 A.D. Smith & Slater give on page 259 an internal view of this mosque looking along the arcade nearest Mecca, and showing the Kibleh with its adjoining mimbar on the right side of the view, and thus explaining the liturgical arrangements very clearly. A mimbar may be seen at the South Kensington Museum. This also introduces us to the horse-shoe arch, a form which we shall find often repeated in Spain.

Lastly, Fergusson gives a plan, on p. 308, of the Great Mosque at Mecca, of which, of course, the principal object is the Kaabah, a small tower nearly but not quite square in plan, and the upper part covered with a black cloth, which is annually renewed. Next in importance to this is the Zenzen, or holy spring, which is said to have gushed out on this spot to the succour of Ishmael and his mother when perishing of thirst. Coste's "Architecture Arabe; ou, Monuments de Kaire," 1839, fol., illustrates this branch of the style.

Turning to Persia, no Saracenic building is to be found dating from the first six centuries of the Hejira. One of the earliest, says Fergusson, of which anything like correct illustrations have been published, is the Inareet or Hospital of Oulou Jami, at Erzeroum, a pointed arcade of two stories, surrounding on three sides a courtyard, the whole bearing some resemblance to a Christian Church. Tall arches facing the open air,—in fact, gigantic niches,—are characteristic of Persian Saracenic work, as are also the surface decorations of glazed bricks of the most brilliant colours, the Persians having always been remarkable for their excellence in polychromy. The form of arch affected by these people is slightly ogee, or, more correctly speaking, resembles an arch which starts with the respectable intention of being a four-centred or straight-sided Tador arch, and changes its

mind at the apex by curving upwards. We now come also to the bulbous domes, such as that over the Madrissa, or College of Sultan Husein at Ispahan. Flandrin et Coste's "Voyage en Perse," 1850, 2 vols., 8vo., is a good work to study on this subject.

India was invaded by the Mahometans in 975 A.D., but Fergusson says, on p. 413, from sources different from those which introduced the religion into other countries, and resulting in a combination of Tartar and Hindu architecture. He illustrates the ruins in old Delhi, around the tall column of Victory, erected by Kootub. Many parts of this building are, more correctly speaking, Hindu work, but the central range of arches which he illustrates, on p. 419, are Saracenic, and they are mentioned here in order to refer the student to an enormous graffito representation of them in the India Museum at South Kensington. The Minars in India differ from what we have hitherto seen in having sloping sides, and in their peculiar form of plan. Bulbous domes are not uncommon, and we find a mushroom bed of them in some places, such as the mosque at Mandoo, which are suggestive of the native Indian examples alluded to in a former article.

Of course, we must bear in mind that, in following out this Saracenic style in various parts of the world we are, chronologically speaking, stepping far ahead of our Lombard and Early Rhenish friends, this mosque at Mandoo having been built between 1305 and 1432 A.D. The next example given by Fergusson,—the mosque at Ahmedabad,—is very interesting as reintroducing the old Jaina construction of slabs supported on columns; on page 430 he illustrates a comparatively modern example,—the Great Mosque at Delhi, built by Shah Jehan in 1628 A.D. "It explains all the parts by which a mosque of this age was usually characterised,—the western part with its lofty centre, three domes, and two minarets, and the courtyard with its open colonnades, its towers at the angles, and three gateways, the eastern one being always more splendid than those on the north and south." An elevation of this mosque, called the Jumna Mosque, is given by Rosengarten on page 224, and it differs somewhat from Fergusson's view, being taken through the courtyard.

There are many fine examples of Saracenic tombs in India, the most important and beautiful of which was built by the same Shah Jehan to contain the remains of his favourite wife, Moontaza Mehal (see page 437 of Fergusson), and also a paper on the subject read at the Institute by Mr. Emerson in May, 1870. It is said that descriptions utterly fail to convey a true idea of this fairylike and yet most substantial building. It is covered by a bulbous dome, which, however, sinks into insignificance in point of size when compared with that built at Bejapoor over the tomb of Mahomet, who reigned from 1626 to 1660; that is to say, a few years before our St. Paul's was built. This dome is 124 ft. in internal diameter, and the thrust is most ingeniously counteracted by an inner overhanging gallery.

The Eastern Saracenic architecture having been examined, Fergusson brings us westward to Spain, invaded by the Moors in 711 A.D., and this branch of the style, besides being near home, is interesting from its mixture with Western Christian art. The first important building that was commenced by the Moors is the mosque at Cordoba, 786 to 796 A.D. This portion, built by Abd el Rahman and his son Hachem, is not unlike the Aksah at Jerusalem, which the Caliph is said to have been anxious to surpass, and consists of eleven aisles divided by arcades, and facing a courtyard. This arrangement was supplemented by eight more aisles added by El Mansour, 976 to 1001 A.D., so that there is a very forest of columns. In the middle of all this the Christians built a cathedral, and erected altars in various directions. The entire plan is given in Mr. Carpenter's paper, read at the Institute, with the various dates indicated by different colours.

The Moorish architecture consists of a peculiar arrangement of columns supporting an upper range of columns, whose height is occupied by intersecting cusped arches, but which are themselves surmounted by horse-shoe arches. The cusped arches are in other cases also repeated above, so that a great degree of richness is obtained. It should be remarked that the pointed arch appears nowhere in these Moorish examples at an age when its employ-

ment was universal in the East, thus showing, according to Ferrusson, "how completely the Saracenic architects followed the traditions of the country in which they found themselves. At Cordoba they never threw off the influence of the Roman arch, though further north the pointed arch is by no means uncommon. Girard de Frangey's "Monuments Arabes et Moresques de Cordone, Seville, et Grenade," 1839, fol., is the work to consult on this subject. At Seville there was another example of a mosque converted into a Christian cathedral; but the chief Moorish object of interest is the tower called the Giralda (from its weathercock), which is justly world-renowned. The present top story is of Renaissance date, and will not be confused with the Saracenic style of the rest. Gwilt gives illustrations from Lahorde's "Spain."

In Granada we come to another famous example, the Citadel and Palace of the Alhambra. Here we find the Moorish style carried to the very extreme of lightness and elegance. There is none of the cusp confusion of Cordoba, while we get the wonderful intricacies of honeycombed arches and vaults which were, no doubt, a development of the system of pendentives common to most Saracenic styles, and here carried out to their fullest extent. The reproduction of the Court of Lions in the Alhambra at the Crystal Palace will give a very good notion of this marvellous building, with its gorgeous coloured decoration on floor, walls, and roof.

The last country that we have to consider is Turkey. Constantinople was not conquered by the Mahometans till 1453 A.D., who here, as usual, adopted and suited to their purpose the style of the country in which they located themselves, and this they did by going to the fountain-head, namely, to Sta. Sophia, and founding their buildings upon the great creation of Justinian. The Mosque of Soliman, 1550-1555 A.D., is avowedly a copy of this church, not only in plan and form, but also in size, as will be seen from the plan given by Ferguson on p. 466. This is, therefore, a very forcible instance of the history of this "cuckoo" style, as it may be called; for it not only invaded the nests of the Christians and others in various parts of the world, but calmly assimilated the food which had been prepared for their beaks. It has turned out to be a bird of fine plumage wherever it has settled, and we shall now recognise the colour of its feathers when we come across them in pursuing the thread of Christian architecture from the point at which we left it in the last article.

## BUILDING PATENT RECORD.\*

### APPLICATIONS FOR LETTERS PATENT.

- Aug. 8.—11,050, R. Schomburg, London, Iron Bars for Fireplaces.—11,054, J. Rickard, St. Colum Major Corrugated Iron Roofing.—11,058, J. Jackson, London, Spring Clip to Fasten Stair and Curtain Rods.
- Aug. 9.—11,096, S. Cowan, Dalbeattie, Grease Traps.—11,097, C. H. Ellis, Exeter, Consolidating Granular Substances into Bricks, Artificial Stone, &c.—11,108, F. Bosshardt, London, Asphaltic Paving, &c. Com. by E. Dietrich, Berlin.—11,110, C. T. Cleaton, London, Bolts for Doors or Windows, &c.—11,113, J. Rosenthal and C. M. Rosenthal, Vienna, Fireproof Armoured Curtains for Theatres and Buildings.—11,116, D. Wilson, London, Construction of Fire Backs and Baskets of Portable Cooking Ranges.
- Aug. 11.—11,125, J. Suter, J. Whittaker, and J. Sheldon, Manchester, Fans for Ventilating, &c.—11,135, S. H. Sharp, Halifax, Imitating Stained-Glass Windows.—11,151, J. Miller, London, Manufacture of Bricks from Slag or Scoria from Blast Furnaces.—11,155, S. P. Wilding, London, Mastic or Cement. Com. by J. Aubrey and Count G. de Vauvassay, Paris.
- Aug. 12.—11,173, T. Horton, Birmingham, Roller-Blind Furniture.—11,176, F. J. Kellow and J. C. Rodger, Southampton, Walks.—11,186, E. Burton, London, Storing Dust and House Refuse, &c.
- Aug. 13.—11,224, H. A. Williams, Stratford, Fastening Window Sashes.—11,237, L. A. Groth, London, Warning Stove. Com. by G. Boretta, Ardanza.
- Aug. 14.—11,251, T. Garforth and W. Garforth, Mirfield, Triest Bricks or Stones together.—11,252, H. C. Board, Bristol, Heating Apparatus.—11,273, M. Underwood, Devonport, Double Dovetailing in Metal, Wood, Stone, &c., without Rivets.—11,276, W. Ayres, London, Weights for Cords of Sashes, &c.—11,288, W. H. Sleep, London, Sliding Sashes.

\* Compiled by Hart & Co., Patent Agents, 186, Fleet-street.

### SPECIFICATIONS ACCEPTED.\*

Aug. 12.—799, E. H. Harling, London, Window Fasteners.—1,641, W. R. Lake, London, Grates and Grate-bars. Com. by L. Bannister, Philadelphia, U.S.A.—5,994, W. H. Bates, G. Bidlake, and H. Faulkner, Leicester, Door-mats, &c.—8,395, W. G. Cannon, London, Hot-water Coils for Heating Purposes.—9,246, F. W. Coons, London, Engraving Marble and Granite.—10,019, A. Besson, Paris, Stoves.

Aug. 15.—9,308, G. W. Chambers, Rotherham, Stove Grates.

### ABRIDGMENTS OF SPECIFICATIONS

Published during the week ending August 16, 1884.

5,825, J. Shanks, Barrhead, Water-closets, &c. (Dec. 21, 1883, price 4d.).

The closet basin and trap are formed of earthenware, and in addition to the usual outlet at the bottom of the trap, another one is made on the outer side of the bend. In trouble-cases the flushing-cistern is formed inside the closet, at one side thereof.

5,870, W. Ross, Glasgow, Automatic Draining Apparatus. (Dec. 27, '83, 6d.).

Inside the tank is a beam lever, on one end being an inverted cup-shaped sucker and valve fitting over the outlet opening. The other end is weighted to over-balance the valve, and a spindle is connected thereto, on which is a sucker, above being a weight on a hollow spindle surrounding the central spindle, on which hollow spindle is a float-ball. The water is supplied to the tank at a certain determined speed, and the ball rises therewith, until it touches a bracket above, when a small spring valve is opened, by which air is admitted to the pan down the hollow spindle to the sucker, and as the vacuum is thereby destroyed the lever falls and the flush is effected.

5,940, J. C. Mewburn, London, Water-closets. Com. by J. E. Boyle and H. Huber, New York, U.S.A. (Dec. 31, '83, 6d.).

This is an improvement on Patent No. 890 of 1882 in making the descent of the flushing water create a vacuum in the top of the trap of the basin, thereby expelling the bowl. This is effected by leading the air-pipe from the trap up through the flushing-tank, and covering it with a bell, from which the air is exhausted by the descent of the water, and a vacuum caused therein until the bottom of the bell is uncovered by the tank being emptied.

5,949, F. Walton, Twickenham, Manufacture of Wall Decoration in Ornamental Relief. (Dec. 31, '83, 6d.).

The relief ornament of such surfaces as "Lincrusta-Walton" is coloured by being passed between two rollers, very accurately adjusted, one of which is covered by rubber, and the colour is applied to this rubber, which only touches the elevated portions. Colour is also applied to the whole surface and then rubbed off the higher parts by this roller, when another colour is applied thereto as before.

## Miscellanea.

**Extensions at Herne Hill Railway Station.**—In anticipation of increased traffic, and to meet present demands, the directors of the London, Chatham, and Dover Company are carrying out a very extensive enlargement of their important junction station at Herne Hill. The whole of the land belonging to the company on the east side of the station, which for several years past has been occupied as coal depôts, and which is upwards of 600 ft. in length, and about 80 ft. in width, is being absorbed into the station area. This land is considerably below the railway level, and the enlarged station area is carried on a series of arches,—twenty-five in number,—which will afford room for three additional lines of rails, and also provide space for a new central platform, upwards of 300 ft. in length. This platform will be reached by a flight of steps from a new underground approach on the east side. This approach is continued under the station area to the west side near the present booking office, and the steps leading up to the existing central platform are being entirely reconstructed and much widened, whilst the platform itself has been considerably extended in length. Several new waiting-rooms and other offices are in course of erection. The line is carried over Half Moon-lane by two iron girder bridges upwards of 60 ft. in width. When the works now in progress are completed the station will be almost double its former area. The contractors for the works are Messrs. Ball & Gammon.

**The Royal Cornwall Polytechnic Society.** At the fifty-second annual exhibition of this Society at Falmouth last week, the first bronze medal was awarded to Mr. W. E. Hill, of Stokes Croft, Bristol, for architectural designs, this being the highest award in architecture. The drawings exhibited by Mr. Hill consisted of designs for artisans' dwellings, entrance lodges, and for cottages especially adapted for miners, the latter attracting a large amount of attention.

\* Open to public inspection for two months from the dates named.

**Ventilation of Coal Cargoes.**—The committee of Lloyd's have received from the Board of Trade a report concerning the surface ventilation of the cargo of 2,000 tons of coal carried in the *Sutherlandshire*, from Hull San Francisco, last year, from which it appears that advantages arise from the fitting of tubes for enabling the master to ascertain the temperature of the body of the cargo, as recommended by the report of the Royal Commission appointed to inquire into the spontaneous combustion of coal in ships. This ship has not again left Hull for San Francisco with so good a success, and with the same fitting. Her commander, Captain Inglis, highly approved of them, and will continue testing the temperature. It is stated that, while the *Sutherlandshire* was at San Francisco, three vessels arrived coal-laden on fire, and that one of them, an American ship, had been on fire fifty-three days. When detained, the *Sutherlandshire* was fitted with a box ventilator on each hatch, with fore, main, and aft, passing down through the body of the coals. There was also one 14-in. iron cowl ventilator passing through the fore-castle and main decks, one trunk ventilator with skylight top leading through midship house and main deck, one 18-in. iron cowl shaft mainmast leading to the water tanks, and two 12-in. cowl through poop and main decks to store-room right aft. The alterations made were as follows:—The two aft ventilators were boxed, and continued through the store-room deck to the cargo at the main deck, and the trunk and fore-castle ventilators were accepted (being suitable for surface ventilation). The three wood box ventilators in the hatchways were removed, and testing pipes put in their places. A record was kept of the temperature of the cargo, and the figures may be seen at Lloyd's in the secretary's office.—*Iron*.

**Improved Ambulance Vans.**—With a view of avoiding risk of contagion in the conveyance of patients suffering from small-pox or contagious fevers to hospitals, Dr. Grayton, senior medical officer of the Metropolitan Asylums Board, has constructed an ambulance van of new and improved form. Instead of having open glass and wooden louvre shutters its apertures consist of a double layer of perforated metal, enclosing an absorbent material saturated with an acknowledged germicide or destroyer of the minute microscopic particles which tend to propagate disease. Fresh air is admitted through modified and improved "Tobin" ventilators of a horn-shape, with the larger end opening externally, whilst inside the van the smaller extremity of this air-tube is provided with a disinfecting air-chamber, constructed like those attached to the other apertures or windows. The Metropolitan Asylums Board use these ambulances for conveying small-pox convalescents from Hampstead to their river wharf, en route to the hospital ships off Purfleet.—*Daily Telegraph*.

**Liverpool and the Manchester Ship Canal.**—At the meeting of the Liverpool City Council on Wednesday, Sir William B. Forwood referred to the Manchester Ship Canal Scheme, and said the total expense of the Corporation in opposing it in Parliament was about 8,000*l.* The defeat of the Bill had saved the estuary of the Mersey, and averted a great calamity from Lancashire. He urged Manchester to abandon the scheme for a ship canal, and to go instead for a large canal for vessels up to 600 tons. He recommended the purchase and deepening of the present Bridgwater Canal. Sir William then referred in strong terms to the excessive charges levied by the railway companies for carriages loaded between Liverpool and Manchester. This was the real cause of all the dissatisfaction that existed. He asserted that the railway companies could afford to reduce the charges 30 per cent. without taking a penny from the pockets of the shareholders. He urged co-operation between Liverpool and Manchester to upset the railway combination and monopoly.

**Civil and Mechanical Engineers' Society.** The members of this Society had a most enjoyable excursion on the 14th instant to the East and West India Company's new docks at Tilbury. The party were conducted over the docks by the resident engineer, Mr. Donald Baynes. After the works had been inspected the party proceeded to the Clarendon Hotel for luncheon, and afterwards by special boat to Thames Haven to inspect the petroleum stores, over which they were conducted by the engineer, Mr. Wm. C. Street.

COMPETITIONS, CONTRACTS, & PUBLIC APPOINTMENTS.

Epitome of Advertisements in this Number.

COMPETITIONS.

Table with columns: Nature of Work, By whom required, Premium, Designs to be delivered, Page.

Table with columns: Nature of Work, By whom required, Architect, Surveyor, or Engineer, Tenders to be delivered, Page.

PUBLIC APPOINTMENTS.

Table with columns: Nature of Appointment, By whom Advertised, Applications to be in, Salary, Page.

Sanitary Institute of Great Britain.—The Autumn Congress is arranged to be held at Dublin, from September 30th to October 4th, 1884, and an Exhibition of Sanitary Apparatus and Appliances in connection with the Congress will be held in the Royal Dublin Society's Buildings, Balls Bridge, from September 30th to October 18th.

Proposed Art and Sanitary Exhibition at Eastbourne.—We have received the programme of the "Eastbourne Arts, Science, and Sanitary Association and Exhibition of Fine Arts," comprising "new decorative fine art for modern dwellings, tapestry, paperhangings, lace, furniture, clocks, improved scientific instruments, pottery, china, terra-cotta and glass, silver and electro goods, English and foreign carvings and paintings, metal-work, musical instruments, photography, electric lighting, and kindred inventions."

Enlargement of the Dulwich Picture Gallery.—The picture gallery attached to the old College at Dulwich is at present undergoing enlargement by the conversion of the south wing of the gallery buildings, which has hitherto been occupied as the Women's Almshouses. The added exhibition-room will be 19 ft. by 28 ft., and 25 ft. in height, with a lantern light in the centre.

Public Works at Newcastle-on-Tyne.—The Prince and Princess of Wales visited Newcastle upon Tyne on Wednesday, and opened an addition to the public park, where the Princess planted a tree, and they afterwards opened the new Natural History Museum and a Free Library. On Thursday they opened the new Coble Dene Dock.

TENDERS.

For the erection of the Paragon Theatre of Varieties, Mills Road, for Messrs. Crowder & Payne, Mr. Frank Matham, architect, Ivy-chambers, Bedford-row, W.C. Quantities supplied by Mr. Frederick Thomson, 20, York-buildings, Adelphi:—

Table listing tenders for the Paragon Theatre of Varieties with names and amounts.

For the repairing of Westhore Church, near Canterbury, for the rector and churchwardens. Mr. E. F. Loftus Brock, F.S.A., architect:—

Table listing tenders for Westhore Church repairs with names and amounts.

For the erection of a villa residence on the Mersca-road (Meyrick-crescent), for Mr. J. E. Reff. Mr. J. W. Start, architect, Head-street, Colchester. Quantities supplied:—

Table listing tenders for the villa residence with names and amounts.

For alterations at the Falcon public-houses, Bedford-road, Clapham, for Mr. H. Nohes. Mr. H. I. Newton, architect, 17, Queen Anne's Gate:—

Table listing tenders for the Falcon public-houses with names and amounts.

For three cottages at Wellington, Somerset, for the Misses Elworthy. Mr. E. T. Howard, architect:—

Table listing tenders for the cottages with names and amounts.

For alterations to Backways Farm, Wellington, Somerset, for Mr. W. Searle. Mr. E. T. Howard, architect:—

Table listing tenders for Backways Farm with names and amounts.

For alterations and additions to Wesleyan chapel, Irchester, Northants, Mr. Arthur Wells, architect:—

Table listing tenders for Wesleyan chapel with names and amounts.

For the erection of school buildings at Stoughton, for the Guildford School Board. Messrs. Welman & Street, architects:—

Table listing tenders for school buildings with names and amounts.

For shop and warehouse, Nos. 199 and 201, Lewisham High-road, for Mr. G. E. Haverat. Messrs. Romaine-Walker & Tanner, architects. Quantities by Mr. D. J. Brown:—

Table listing tenders for shop and warehouse with names and amounts.

For enlargement of George-street Chapel, Bromley-by-Bow. Mr. R. H. Hill, architect, 8, Clement-lane, Lombard-street:—

Table listing tenders for George-street Chapel with names and amounts.

For pulling down and rebuilding Nos. 36 and 37, Chalk Farm-road, for Mr. O. P. Thompson. Messrs. Alexander & Gibson, architects, 8, Great James-street. Quantities supplied by Mr. H. Burton:—

Table listing tenders for pulling down and rebuilding with names and amounts.

For alterations and improvements at 69, Folkestone-road, Dover. Mr. Arthur Wells, architect, 27, Chancery-lane, London:—

Table listing tenders for alterations and improvements with names and amounts.

For Fire Brigade Station, Bishopgate-street, E.C., for the Metropolitan Board of Works. Mr. Geo. Vulliamy, architect:—

For new Wesleyan chapel, Herne Bay. Mr. Charles Bell, architect. Quantities by Mr. H. Lovegrove:—

T. W. Hicklingham	£3,269 0 0
T. Cornelius	4,124 0 0
J. T. Adams	4,007 0 0
J. Smith & Sons	4,080 0 0
H. Brown	4,002 0 0
L. Shrabsole	3,998 0 0
Ames & Ford	3,822 0 0
C. W. Welby	3,885 0 0
H. Hill	3,885 0 0
W. Cozens	3,796 0 0
J. Holloway	3,773 0 0
W. A. Grubb	3,750 0 0
G. H. Denne & Son	3,700 0 0
J. Allen & Son	3,585 0 0

For alterations at the Rising Sun public-house, Dootford, for Mr. J. W. Dibbs. Mr. Henry Roberts, architect:—

Taylor	£668 0 0
Hubble & Tret	683 0 0
Holloway	649 0 0
Mower	612 0 0
Menger	407 0 0
Lang	393 0 0

Painting and Gilding.

Ruse	£111 0 0
Banks (accepted)	169 0 0

For alterations to the White Hart Tavern, King's-road, Chelsea, for Mr. J. J. Pope. Mr. Miller, architect.

Speake	£500 0 0	£387 0 0
Mark	411 0 0	472 0 0
Adams	413 0 0	437 0 0
Peck	431 0 0	431 0 0
Kirk	337 0 0	417 0 0
Ansell	365 0 0	360 0 0
King	395 0 0	359 0 0

\* Including new floors.

For various works at the Church of St. Mary, Spital-square, Mr. D. H. Dale, architect:—

Womner Smith	£579 0 0
Brady	518 0 0
Pritchard	500 0 0
Kidde	455 0 0
Hoare & Sons	431 0 0

For the erection of thirty-five cottages on the Shackwell Estate, Mr. D. H. Dale, architect:—

G. Dale, Thornton Heath (accepted)	£7,325 0 0
------------------------------------	------------

For detached villa on the First Portion of Stone Hall Estate, Oxford, Surrey. Mr. D. H. Dale, architect:—

G. Dale, Thornton Heath (accepted)	£2,500 0 0
------------------------------------	------------

For rebuilding warehouse, Charterhouse-square. Mr. G. Perry, architect:—

W. Shurmer (accepted)	£332 0 0
-----------------------	----------

For alterations, &c., at the Cripplegate Bank, White-cross-street, E.C. Messrs. Woodthorpe & Hammond, architects:—

G. Green	£814 0 0
W. Shurmer	693 0 0
J. W. Heaps	640 0 0
W. G. Larke	614 0 0

For alterations, &c., to the George and Dragon public-house, Hackney-road. Messrs. Bird & Walters, architects:—

G. Mower	£225 10 0
W. Shurmer	222 0 0
Jackson & Todd	220 0 0
J. Anley	215 0 0

For alterations, &c., at St. Andrew's Church, Bethnal-green. Messrs. Dollman & Allen, architects:—

B. E. Nightingale	£1,160 0 0
W. Shurmer	1,162 0 0

For extension of sewers, Brentford Drainage, Mr. F. W. Lacey, surveyor:—

Means & Prowse	£1,970 0 0
Means	1,695 0 0
Bottoms Bros.	1,684 0 0
Tuesman	1,649 0 0
B. Cooke & Co.	1,583 0 0
Nicholls	1,577 0 0
Brunton	1,336 0 0
Owen & Brown	1,331 0 0
Everett	1,315 0 0
Watt & Lovelace	1,288 0 0
G. Bell	1,272 0 0
Cutley	1,225 0 0
W. Williams, Wimbledon (accepted)	1,162 0 0

[Engineers' estimate, £1,350.]

For alterations at the Lord Lyndhurst public-house, Lyndhurst-road, Peckham, for Mr. Burney. Mr. Henry Roberts, architect:—

Sly	£737 0 0
Taylor	733 0 0
Holloway	719 0 0
Hubble & Tret	690 0 0
Menger	672 0 0
Mower (accepted)	628 0 0

For a pair of semi-detached houses and boundary walling at Merton, for Mr. John Crook on order of Mr. Joseph Kirby. Mr. James Hunt, architect, Stockport. Quantities by the architect:—

J. Kellett, Marple (accepted)	£30 10 9
-------------------------------	----------

Special Notice.—Lists of tenders frequently reach us too late for insertion. They should be delivered at our office, 48, Catherine-street, Strand, W.C., not later than four p.m. on Thursdays.

### Archaeological News from Rome.

**ARCHAEOLOGISTS** who visit Rome for business or for pleasure know most surely, and if they be Englishmen, most sadly, that if they want the latest and most reliable archaeological news they must

mount the Capitoline Hill and seek it at the Prussian Imperial Archaeological Institute. Archaeologists who stay at home wait year by year with impatience for the Report issued by that Institute. This Report for the past year, 1883, now lies before us. It appears as usual in triple form,—a "Bulletin," containing the business of the Institute, and a detailed account of the excavations undertaken,—in this instance at Palestrina, Vulci, Pompeii, Corneto, and Orvieto. The importance of this "Bulletin," dry though it may appear to the uninitiated, can scarcely be over-estimated; in it are recorded with the most minute precision month by month the circumstances of discoveries, just those details of place, surroundings, condition, and juxtaposition, for want of which so many of the objects in our old-established museum lose full half their scientific value. Next we have the "Annali" of the Institute, an illustrated issue devoted to the discussion of selected objects. It contains the best archaeological opinion in Europe on the facts registered in the "Bulletin." These two issues are made complete each year by the appearance of the "Monumenti," a magnificent folio atlas, containing, in engraving, in phototype, in chromo-lithographs of remarkable accuracy and beauty, reproductions of the most important monuments discovered.

The field covered by this splendid publication is very wide. It embraces topography, architecture, sculpture, bronzes, terra-cottas, vase paintings. The Monuments of 1883 contain plans and sections of the Rostra of Augustus, recently brought to light in the Forum, two painted sarcophagi from Clazomena, terra-cottas from Tarentum, two sarcophagi from Tarquinii, adorned with reliefs representing contests of Amazons and Centaurs with Greeks; a number of curious Sardinian antiquities of Egyptian style; fragments of inscriptions from Capena; a vase from Orvieto, with a curious representation of Heracles and Silenus; and lastly, the beautiful statue of Bacchus recently discovered in Hadrian's villa.

To some of these subjects we hope to return, but for the present it is this statue of Bacchus which claims our attention. The statue was found in a hollow space beneath a staircase in the part of the villa commonly known as the library. It is singularly well preserved, only the right hand missing. Its great beauty and merit were recognised at once, and casts were promptly made, of which one is at Berlin, a second at Strasbourg, and, as we had occasion to notice some months ago, a third in the new cast museum at Cambridge.\* We spoke then of the diversity of opinion among archaeologists as to the style and date of the statue. No one had as yet spoken with authority; indeed, such opinion as was expressed was expressed with the utmost timidity; all felt they had to face a difficult problem. In the present number of the "Annali" Professor Michaelis devotes a long and very interesting article to the analysis of the statue, and if he has not spoken the last word on the subject he has, at least, said all that can be said in the present state of our information. The statue itself is reproduced in two heliographic plates, giving four views, two front and two back. It represents a youth standing with the weight of the body thrown on the right leg, the left hanging behind in the Polyceleitean attitude. The right hand is raised, and held, no doubt, some attribute; the left hangs down. Over the right shoulder is thrown a nehris, tied by the two paws of the fawn, and falls, back and front, with studied symmetry. This nehris, of course, marks the figure as belonging to the Bacchic cycle. The ideal beauty of the head, the total absence of any heast-element, pointed ears, snub nose, shaggy hair, prevent the supposition that the youth is a satyr. There remains no doubt that he is the god Bacchus himself, represented in his later aspect as a beautiful, effeminate youth. A number of problems arise, which Professor Michaelis raises and solves one by one. What did the god hold in his right hand, now broken? Probably, judging from certain marks remaining on the marble,—a two-handled wine-cup or kantharos, a frequent attribute of Bacchus. From the direction of arm and eyes, it is further probable that he was in the act of pouring out the wine. This supposition is further borne out by the fact that a statue of Bacchus in this very attitude was executed by the ancient sculptor Calamis, and its general pose and motive are preserved for us on a coin

\* The statue is seen in our No. III. view of the Sculpture Museum at Cambridge (*Builder*, May 24 of this year), a figure on the right in the background, next to the sculptured drum of the column from Ephesus.

of Tanagra. Next arises the question, Have we before us an original or a copy? If a copy, was the original of marble or bronze? The practised eye can detect by certain peculiarities of technique a copy from a bronze; and Prof. Michaelis thinks we have here such a copy. He calls attention to the stump of a tree introduced to support the figure, and greatly spoiling the beauty of line of the lower limbs. Some such support frequently is added to marble copies of bronze originals, the more tenacious bronze needing no such aid. Similar meretricious supports are given to the long pendent folds of the nehris. Had the original been of marble, it would have been quite easy to avoid any such necessity. Further, in the chiselling of the nehris there is a sharpness peculiar to bronze technique.

Last and most important comes the question to what date and school the work is to be assigned. At first sight, as Prof. Michaelis owns, the statue strikes one as an echo of the manner of Polyceleitus. The position on one leg, the delicate balance of half the body at rest and half in motion, the right hand lifted and the left leg drooping, the so-called chiasmus scheme, the slightly-inclined head, all recall Polyceleitus. But, rigidly examined, the proportions of the limbs do not correspond to the Polyceleitean canon, as we know it in the Doryphoros,—the legs especially are too slender and graceful, the foot too short. Still less,—excepting for the softness and grace inseparable from the conception of the youthful Bacchus,—has it the true Praxitelean ease and flow and charm. Place the statue by the side of the Praxitelean Hermes, and we feel the difference at once. We cannot follow Prof. Michaelis through the details of his argument; it must suffice us to state his conclusion. He believes the statue to be a work of the eclectic school, the post-Alexandrian manner which selected and combined and advisedly imitated the style of hygone manners, which sought to revive the manner of the best Attic and Argive work. This eclectic tendency is discernible by a sense of unreality, of effort, of restraint; its archaisms are conscious instead of naïve. It is also marked by a want of harmony which creates uneasiness in the spectator,—an uneasiness felt by every trained eye in looking at this statue of Bacchus. This want of harmony Professor Michaelis discerns in three respects:—first, the mingling of the unmasculine and feminine elements necessary in an effeminate type, is inharmonious,—opposite characteristics are harshly juxtaposed rather than naturally blended; second, in the actual anatomy there is a good deal that is incom-

patible,—e.g., the strength and size of the thorax is incompatible with the slender legs; third, as regards the face, the severity and fixedness of the expression, and the artificial archaism of the band, are out of harmony with general modernness of the figure and the morbidity of the skin. The elaborate treatment of the hair deserves further notice,—it has no parallel in male statues, only one in female,—that is in the hair of Elektra of the well-known group of the so-called Orestes and Elektra of the Naples Museum. That group, on grounds which are beyond dispute, is attributed to the eclectic school of Pasiteles. Prof. Michaelis does not go so far as to attribute the new Bacchus to the school of Pasiteles; but the analogy of the hair is a definite point for a very interesting comparison. The cast of the Bacchus in the museum at Berlin stands near the group of Praxitelean statues. It would be instructive to see it placed in Pasitelean surroundings. Though the verdict of archaeologists in general will in all probability agree with that of Prof. Michaelis, in stamping the Bacchus as eclectic, its extraordinary beauty will not be denied; indeed, the slight touch of delicate consciousness under severe restraint will to some eyes only enhance its charm.

#### THE METROPOLITAN BOARD OF WORKS AND LONDON THEATRES.\*

**T**HE Board has now dealt with the whole of the London theatres, with the exception of the theatre at the Crystal Palace, as well as most of the principal music-halls. In some instances the theatre has been closed by the action of the Board, in others it has been rebuilt, in others alterations have been effected at a cost varying from a comparatively insignificant to a very large sum, and in no single instance has it been found that some alteration was not required. In the case of one theatre, the Strand, a sum of nearly 15,000*l.* was expended in remodelling the interior, and providing additional exits, including the purchase of adjoining property for the purpose of providing the necessary accommodation. A portion of this sum will probably be recouped by re-sale of the ground, but the money had to be expended in order to rebuild the theatre, and the recoupment is more a matter of calculation than of certainty.

The theatres which were considered by the Board to be unfitted for the reception of the public were the Prince of Wales's Theatre, the Royalty Theatre, Hengler's Cirque, Clapton Park Theatre, and the Criterion, and an intimation was sent by the Board to that effect to the Lord Chamberlain, who thereupon declined to renew the licences in respect of these places. With regard to the Criterion Theatre, very strong representations were made to the Board, and the owners, having expended a very large sum in carrying out certain alterations to the building, the Board advised the Lord Chamberlain that, in their opinion, the licence of this theatre might be renewed, and the licence was renewed accordingly. The cost of the alterations to this theatre, in order to meet the views of the Board, was about 10,000*l.*, exclusive of the installation of the electric light, which cost about 2,500*l.* in addition.

The Royalty Theatre, which was originally built for performances by Miss Kelly's pupils, on the site of a garden in the rear of her house in Dean-street, Soho, was rebuilt in 1832-3, from designs by Mr. Thomas Verity, and was reopened in the spring of 1833. The Prince of Wales's Theatre and Hengler's Cirque are closed, and the Clapton Park Theatre is only opened occasionally, being chiefly used for amateur performances.

One of the earliest theatres dealt with by the Board under the powers conferred by the 11th section of the Metropolitan Management and Building Act Amendment Act, 1873, was the Lyceum Theatre. This theatre was built for Mr. Arnold, in 1834, from the designs of Mr. Chas. Beazley, an eminent architect and prolific dramatic author. The theatre occupies an extensive site, with a considerable frontage

upon Wellington-street, Strand, and extends back to Bursleigh-street. The pit entrance is in the Strand, and the gallery entrance and the stage entrance are in Exeter-street, on the north side of the theatre. The premises have been enlarged from time to time since they were first built, and recently received considerable additions by the absorption of the rooms formerly occupied by the Beef Steak Club, which now form part of the premises of the theatre. The gallery staircase was narrow and inconvenient, and it was a standing joke that the architect forgot the staircase, and that it was added after the completion of the building. This is inconceivable, and there being a similar story told of several other buildings, it may be safely relegated to the realm of legendary lore, together with the story of the body of the boy who was murdered by the Jews, which floated up against the stream to Bacarach,\* of which story there are numerous variants. The explanation of the narrowness of the old gallery staircase is that the owner of the theatre intended to purchase additional property in order to construct the staircase, but that being disappointed in his intention, he was reduced to construct it in the inconvenient form in which it remained from the completion of the theatre until the year 1832.

The Board served a notice upon the owner of the theatre requiring the gallery staircase to be reconstructed; the proscenium wall to be carried up to a height of at least 3 ft. above the roof, and he carried down through the cellar in order to effectually divide the stage from the audience portion of the theatre; that the carpenter's shop in the roof, which extends over the auditorium, should be separated from the auditorium by a fire-resisting floor; that additional means of exit should be provided from the pit and the dressing-rooms on the north side of the theatre premises.

The only means of egress from the pit of this theatre was by a passage-way, a portion of which runs under the first floor of a public house fronting upon the Strand. The pit will accommodate about 800 persons, and, in the event of a fire occurring in any of the houses abutting upon the passage-way out of the Strand, the only means of escape for the audience would have been by climbing over the barrier between the pit and stalls, and making their way into Wellington-street by the stalls corridor, or by passing over the stage. The importance of providing sufficient means of exit for the persons employed behind the scenes may be estimated from the fact that during Mr. Irving's management as many as 600 persons have been engaged upon the stage, or in connexion therewith. During the run of "Romeo and Juliet" it was stated that, excluding the acting company and the persons employed in the front of the house and the dressing-rooms, there were forty musicians, sixty carpenters, sixty men employed in the working of the gas and lime light, 250 extras and supers, and forty artists and artisans employed in the painting-rooms and property-shops.

The cost of the alterations suggested by the Board was estimated at about 1,200*l.*, exclusive of the cost of reinstating fittings and decoration.

The owner of the theatre appealed against the notice served by the Board, and the First Commissioner of her Majesty's Works and Buildings having appointed Sir Henry Hunt, C.B., to act as arbitrator, the appeal was heard at the Surveyors' Institution, Westminster, in July, 1882; by Mr. Meadows White, Q.C., and Mr. F. G. M. Freeman, representing the Metropolitan Board of Works; and Mr. Merewether appearing for the owner of the theatre. The arbitrator, after hearing the evidence adduced upon both sides, and making two inspections of the theatre, made an award confirming in effect the requisitions made by the Board, certain modifications being allowed in the manner of execution of the works, chiefly

with a view to the convenience of the owners. The works ordered by the arbitrator's award were carried out within the time specified, without occasioning interruption to the performance.

The award of the arbitrator in this case settled the question of the proscenium wall, as to which there was some uncertainty, and this precaution was insisted upon by the Board in the case of other theatres dealt with under the Act. The owners of Drury Lane Theatre appealed against the Board's notice, mainly on account of the requirement with regard to the proscenium wall, but this requirement was confirmed on appeal.

It is a singular fact that in no single instance was an old theatre found to be provided with a proper proscenium wall to divide the audience from the stage. In some cases,—as, for example, at Covent Garden, Drury Lane, and the St. James's,—there was no wall, but merely a partition of wood, to which slabs of concrete had been added by the recommendation of the Lord Chamberlain; in others, the wall was carried up to the underside of the roof, but not through the roof, as at the Gaiety; in others, as in the case of the Lyceum, the Adelphi, &c., the wall had been carried up to the top of the proscenium opening, but had not been continued down under the stage so as to effectually separate the audience portion from the working part of the theatre. Covent Garden Theatre was rebuilt as late as 1858, under the superintendence of the late Mr. Edward Barry, at a cost of about 70,000*l.*, and it is surprising to find that the necessity for this separation was not recognised at that date. It is now agreed, by those most capable of forming an opinion on the subject, that by the erection of a proscenium wall carried up above the roof, and carried down to the foundations of the theatre, the risk to the public, in the case of an outbreak of fire in a theatre, is greatly diminished. This was insisted upon by Mr. Phipps, in his evidence before the Fire Brigade Committee in 1877, and the construction of a proper proscenium wall forms part of the regulations as regards construction imposed by the municipal authorities of all the capitals and large cities of the Continent.\*

It may here be remarked that it is a mistake to suppose that Continental cities are in a better position than London as regards the regulation and supervision of theatres and places of public amusement. In Paris, the supervision of theatres was until recently governed by rules framed in the year 1828, slightly enlarged in 1864 and 1868, and it was not until May, 1881, that the present regulations were promulgated. The Berlin regulations with regard to theatres at present in force are dated June 29th, 1881. The Vienna regulations were made in the same year. The Hamburg Theatre Regulations are dated 1877; the Russian Regulations are dated as late as March, 1883, but it is not known if they have been made obligatory. In all countries, even the most despotic, the difficulty has been experienced of reconciling the alterations necessary for securing the safety of the public, with a proper regard for the vested interests of the proprietors of places of public

\* In a note to a paper read by Mr. E. M. Barry before the Royal Institute of British Architects, February 6th, 1880, on the "Construction and Rebuilding of the Royal Palace, Covent Garden," the author, referring to the destruction of the old house in March, 1856, remarks that it had been stated that the entire removal of a cross division wall, and arch over the proscenium at some period, probably long subsequent to the original construction of the building, allowed the fire to spread through the roof of Sir Robert Smirke's Covent Garden Theatre; certainly he adds, "had such a fireproof division across and above the roof remained, a check might have been given to the flames, so that the firemen on duty at the house might possibly have subdued them at the first outbreak." It was sought to guard against the possibility of fire being communicated to the auditorium from the roof by constructing the roof and its external covering of incombustible materials, but it never seems to have occurred. Mr. Barry to revert to Smirke's expedient and separate the roofs by a brick wall,—the only effectual mode of separation. It has been a ground of complaint that since the erection of the proscenium wall draughts are occasionally in the auditorium when the curtain is raised, in consequence of the cold air accumulating in the upper part of the stage, and not finding any outlet into the space over the ceiling of the auditorium, the cold air falls through the warm air in the body of the house, and causes inconvenience to the audience. The remedy for this defect would be to properly warm the stage to the same temperature as the auditorium, how to provide proper outlets in the roof of the stage, protected by cowls.

\* "And that's the town of Oberwesel, where the boy was murder'd by the Jews; Whose body floated up the stream to Bacarach, tho' some refuse To credit the tradition, as a different edition Is extant in nearly all the towns you pass upon the Rhine." ALBERT SMITH.

\* See p. 248, ante.

amusement, and this problem appears to have been found very little less difficult of solution in St. Petersburg than in Paris and London. It will be observed that the St. Petersburg regulations with regard to site are not retrospective, and only apply to new theatres.

The latest regulations with regard to theatres are those drawn up by a Commission appointed by the St. Petersburg Municipal Council. This Commission, which consisted of two engineers, one architect, and the chief of the St. Petersburg Fire Brigade, was appointed in 1881, shortly after the catastrophe at the Ring Theatre at Vienna, and their report is dated March, 1883. All new theatres must be isolated, and must have windows and doors upon all the four sides; the walls, ceilings, and roofs must be of incombustible materials; the staircases and landings must be spacious, nowhere less than a stride across, and single steps are not permitted; all doors must open outwards; dwelling-rooms are not allowed in any part of a theatre; not more than four tiers are allowed above the pit level; central passages,—not less than 4 ft. 8 in. wide, and side passages 3 ft. wide,—are to be provided in every part of a theatre; the widths of the corridors and vestibules are strictly regulated; cloak-rooms are to be provided near the entrance vestibules; pass staircases are not allowed; the proscenium is to be fitted with a fire-resisting curtain, and an opening, with a superficial area of at least 50 ft., provided in the roof of the stage; every theatre must have a lightning-conductor. The lighting and heating arrangements are minutely regulated. The scenery and the light dresses of performers are to be rendered unflammable. Every theatre must be placed under the control of a responsible person, who shall have the requisite number of assistants, who must be present during every performance, as well as one hour before and one hour after the same. Every new theatre upon its completion must be certified by the executive Commission specially appointed by the Municipal Council for the control of theatres.

The greater part of these regulations are applicable to existing theatres, either at once or at the expiration of terms varying from six months to twelve months from their confirmation, with the exception of the regulation with regard to the site and the construction of the walls, ceilings, and roofs of incombustible materials, which are not obligatory on existing theatres.

It is an important distinction that the cost of any structural works required by the Board under the Act of 1877, giving the Board control over certain places of public entertainment, falls upon the owner and not upon the lessee or occupier. The term "owner" is defined by the 250th section of the 18th and 19th Victoria, c. 120 (The Metropolitan Local Management Act, 1855), to mean the person for the time being receiving the rack rent of the premises in connexion with which the word is used, whether on his own account or as agent or trustee, or who would so receive the same if such premises were let at a rack rent.

As regards Covent Garden Theatre, the Board's requirements included the building of a proscenium wall; the covering of the floors in the roof of the theatre with fire-resisting materials; the construction of an additional staircase on the south side of the theatre; the closing of the doorways between the theatre and the Floral Hall adjoining with iron doors; fixing handrails on both sides of all staircases, and making all doors to open outwards. The Board's notice in this case was not appealed against, and the works were carried out during the recess at a cost of about 4,500l. This sum is, perhaps, the largest sum that has been expended upon a theatre on structural alterations alone at the instance of the Metropolitan Board.

The alterations considered necessary by the Board in respect of Drury Lane Theatre comprised the building of a proscenium wall; the complete separation of the carpenter's shop over the stage from the space under the roof of the auditorium; the provision of handrails on both sides of certain of the staircases, and the strengthening of certain of the existing

handrails; the alteration of certain doors, and the formation of an additional exit from the upper gallery. The notice was appealed against by the owners, the chief contention being with regard to the proscenium wall, and the arbitrator (Sir H. A. Hunt) confirmed the notice, with some unimportant modifications.

The proceedings with regard to these three theatres will give some idea of the course of action taken by the Board with regard to the other London theatres, the requirements of the Board being in other cases of a similar character, but varied, of course, by the circumstances of each case.

The total amount expended by the Board in the carrying-out of the Act of Parliament up to the present date is about 3,700l. This must be considered to be a moderate amount, looking to the number of buildings that have been surveyed and the extent of the alterations which have been effected under the Act. The estimated amount of the expenses of the Board for the current year is 1,000l. The official cost of the Act is thus about 100l. for each theatre, which will, probably, be viewed by the public as not being an excessive amount for securing their comfort and safety. Great apprehensions were expressed by several of the witnesses who were examined by the Fire Brigade Committee in 1877 as to the cost of a proper supervision of the Metropolitan Theatres, and it was generally agreed that it would be impossible to obtain an efficient control over all theatres without the creation of a new department, and that the cost of such an establishment would be very great. It has now been shown that the apprehensions expressed with regard to the cost to the country of the superintendence of theatres was unfounded, and that an existing municipal body has been able, by a slight increase in its staff and with a very small amount of inconvenience to the managers of theatres, to carry out some very important alterations, the value of which will be felt by the public in the event of the occurrence of a fire or panic. These alterations have been effected in an unobtrusive manner, the public having been, for the most part, unaware that any changes had been made, and attention not having been called to the subject no unnecessary alarm has been created.

It is to be hoped that the action of the Board will silence those alarmists who are continually declaiming against the dangerous condition of London theatres, and that Mr. Dixon-Hartland and those Members of Parliament who think with him, will be satisfied that all that is possible to be done under the existing law has been done. It may well be that some further legislation on the subject is necessary, and, in particular, that the dual jurisdiction of the Lord Chamberlain and the Metropolitan Board of Works should be abolished, and one central independent authority substituted; but, until public opinion pronounces distinctly in favour of this alteration, it is useless to expect any reform in this respect.

LONDON WATER.\*

**H**IS pamphlet, which is the latest contribution to the literature of the much-discussed subject of the London water supply, is an attempt "to compress within reasonable limits the chief facts,—historical, physical, and scientific,—bearing on the question at issue," with a view to facilitate the comprehension of the principal points involved therein by the parties most interested. Though there is but little new matter imported, yet the results of the various scientific investigations hitherto carried out have been succinctly collated, so that any intelligent consumer of London water may, if he is able to reconcile satisfactorily to himself the widely different conclusions which have been drawn from those investigations, arrive at some idea of the quality of the article for which he is called upon half-yearly,

\* "A Review of the Present Condition and Suggested Improvements of the Metropolitan Water Supply." By A. De C. Scott, Major-General Royal Engineers. London: Chapman & Hall, 1884.

without option, to pay. In the Parliamentary history of the water companies with which the author introduces his subject, a summary is given of the items which made up the amount of thirty-three millions sterling with which it was proposed in 1880 to buy up their interests, but which failed, together with the subsequent attempt of the Metropolitan Board of Works to pass a Bill for enforcing the sale of water by meter. Doubtless the proposed purchase-money seemed at the time an exorbitant valuation of the water companies' property, and totally disproportioned to the capital cost of their works. If viewed only in the light of the existing and future profits derivable by the shareholders, it was, perhaps, a not inequitable valuation on the part of a Legislature whose loose ruling empowered the companies to increase the value of their property by arbitrarily raising their customers' rates without any obligation to afford a corresponding equivalent in the quantity or quality of the article they supplied. If that ruling is still to hold good for all time, then a fatal mistake was made when the original proposal was thrown over; but if it is in the power of the Legislature, and there is any intention to exercise that power, to relieve the population of London from a burden to which there is seemingly no limit, then no further time should be allowed to elapse before action takes the place of profitless discussion which promises to be interminable.

In the chapter on "The Theory of the Physiological Effects of Polluted Water," the author enters into the arguments of the two contending parties who respectively advocate and oppose the use of the Thames and Lea as sources of supply for the metropolis. These arguments have more than once been presented to the readers of the *Builder*, and only lately the lectures read at the Society of Arts Conference held at the Health Exhibition contained the most recent contributions to the subject, some of which, notably the important paper by Professor Sorby, are, however, not to be found in General Scott's pamphlet, which gives a fairly impartial summary of the results of experiments and investigations made by the most distinguished chemists of the day in the detection of chemical impurities, and how far they fall by chemical means at arriving at safe conclusions, although the author seems to have been unaware of, or to have overlooked, the help that can be secured in any modern laboratory fitted up for biological research. No chemist can detect the bacteria or bacilli, or other septic or disease germs with which the scientific world is so much occupying itself; whereas, with the aid of a test tube, containing sterilised gelatine solution, a proper needle to inoculate it with any germ that water may contain, the presence of such microscopic organisms is at once revealed, even without the aid of a microscope. It is evident, then, that the discoveries made by the biologists are destined to play a most important part in the solution of the vexed question of water purity, for while the chemist is only able to pronounce on the presence of purely chemical matter, the biological investigator detects the living organism, though at present it is doubtful how far its connexion with any specific disease has been accurately defined.

Too little importance seems to be ascribed to the process of oxygenation, or, more popularly, of aeration. It is a well-ascertained fact that a tumbler of water impregnated with disease germs will, after a certain moderate degree of exposure to air and light, become innocuous; and, therefore, before pronouncing definitely on the unfitness of the Thames as a source of supply, surely it is not beyond the resources of engineering science to devise some means by which a sufficiency of aeration may be given to river water so as to render it perfectly wholesome. The statement so often brought forward as to the impurity of the Thames above the intakes of the water companies, and repeated in General Scott's pamphlet, was stoutly denied by one of the Thames Conservators at the late Conference. We can ourselves, from recent personal expe-

rience, testify to the absolute clearness of the water at Chertsey; and if, in a year of extreme drought like the present, when the volume of the Thames is less than it has been for many years, the water for potable purposes is so good, it can scarcely be questioned that in average years, when the volume is considerably greater, its quality cannot be inferior. Doubts are expressed, based on experiments made on the Irwell, Mersey, and Darwen, as to the degree of purification exercised in sewage-contaminated water, after running a course of eleven to thirteen miles; but, as pointed out by General Scott, various sources of error must always operate in such experiments. Water flowing with a sluggish current over a smooth river bed will not receive the amount of aeration which a mountain stream bubbling over a pebbly or rocky bed does; but place a weir across the same river, and let the same water be passed in a moderately thin film over its crest and be broken up afterwards on the rubble apron below, and the amount of aeration it will have received will at once be seen; so, mere distance of flow does not afford a sufficient criterion to determine the question at issue. If, therefore, the water companies would introduce some artificial expedient for aerating the water pumped from the river before discharging it either into their subsiding reservoirs or their mains, the quality of their water would be still further improved. The great practical test, however, remains, as we lately observed, in the fact that as long as the death-rate of a great city like London remains as low as it is at present, there cannot be much the matter with its water supply, especially when there are so many other causes operating for the spread of disease; and so long as this holds good, it seems inexpedient to search for our supply from more distant sources.

While, however, we cannot hold with the conclusion at which General Scott has arrived as to the necessity or even advisability of drawing a supply for the metropolis from the mountain districts or from the lakes, we have no hesitation in pronouncing on its engineering feasibility. Any works of the kind that may have to be undertaken are as nothing in comparison with the scale on which the grand water projects of India and America, not to mention those of neighbouring Continental States, have been carried out. There is one consideration, however, with reference to the Thames supply which is not noticed in the pamphlet, viz., that if, as in all probability it will be, a further volume has to be taken from it for the supply not only of the metropolis, but of the principal towns in the river basin, the Conservators should insist on the supply being first stored in the upper reaches, otherwise the lower reaches of the river will be most injuriously affected, especially in regard to navigation. The sites of such storage works would afford the best opportunity possible for effecting the requisite degree of aeration, and so supply, were it necessary, an additional argument for the construction of such works. Unquestionably, it would, if possible, be better to avoid altogether, the discharge of sewage, pumped or otherwise, into the Thames, especially in its lower reaches; and, therefore, if possible within any practical limit as to cost, the sewage of the Thames Valley would be best disposed of by conveyance direct to the sea, as that of the metropolis itself must inevitably be eventually carried thither.

Most persons will heartily endorse the remarks that General Scott makes as to the necessity for the constitution of a representative authority for the whole metropolis, including its suburbs, having plenary power to deal with the question of water supply, and as to the inadvisability of postponing the settlement of this question until the passing of the London Government Bill, which has already been shelved to the Greek kalends. We would, however, be disposed to go still further and to again insist on the necessity for the constitution of a central water authority, not for the metropolis only, but for the regulation of the waters of the entire United Kingdom.

## NOTES.

**L**ORD RAYLEIGH'S address at the opening of the British Association at Montreal on the 27th was one of the specialist, not one of the comprehensive or all-round types of presidential address which have usually been most favoured, and which perhaps best answer the real end of a general inaugural address on such an occasion. But to survey even the outlines of all science so as to give a comprehensive sketch of the position attained and the progress made since the preceding year of meeting, is given to few indeed, and is likely to be the gift of fewer still as each department of scientific study increases in significance and complexity. Lord Rayleigh only did, therefore, what most future presidents will probably be obliged to do, in confining himself to the subjects (mathematics and physics) which he made his special study; and he succeeded in bringing out the practical relation of recent discoveries to actual and every-day life in a manner calculated to interest even the more unscientific among his hearers, though some parts of the address can have been hardly "understood of the people." We shall probably have more special remarks to make in regard to the bearing of some of the sectional papers and discussions on our own subjects, when letters can have crossed the Atlantic, and we shall be no longer dependent on telegraphic summaries, which will probably be all that our hard-worked "dailies" will be able to give us of the majority of the papers read in the various sections.

**F**ROM the German School at Athens comes the following *resumé* of the excavating work of the year. In the Piræus the foundations of a large building of Hellenistic date have been laid bare. Inscriptions found on the spot make it probable that the excavators have lighted on the local shrine of a Thiasos of Dionysiasts. Full details are to be given by M. Dragatis in the next issue of the modern Greek publication, the *Archæological Ephemeris*. It seems a pity that important discoveries should be discussed in this but-little-known tongue. In the same periodical will appear a dissertation on the last excavations made at Olympia by H. Dunitzidis since the site was handed over to the Greeks. Some new fragments of the pediment groups have been discovered. The Athenian Archæological Society has been conducting excavations at Epidaurus under the supervision of M. Kabbadias. This rising Greek archaeologist was trained in Germany; let us hope his report will appear in German, the common tongue of archaeologists. The French School has recommenced its work at Elateia, where a shrine of Athene Kranadia is being laid bare. Dr. Schliemann's excavations at Tirynth have come to an end. The results will appear in a special volume.

**T**HE *Irish Builder* hopes that the construction of the new museum will be made an opportunity for utilising native stone and other materials. Portland stone has answered well in the Dublin atmosphere, it is true, but "in the ruins of Moyné Abbey there is native oolite which has stood the test of several centuries, and there is still a remarkable sharpness in the carving and cutting." And in the matter of granite and marbles there is, as we all know, a great variety of tone, surface, and colour obtainable. Our contemporary observes that the facing of Leinster House, to which the new building will be contiguous, is native granite, procured at Dalkey or at Wicklow, and obviously means to suggest the employment of this material in the new building. The question of the use of granite for an enduring building is thus being mooted in Dublin, as it has been mooted in London (for more directly practical reasons) in regard to the New War Offices. It must not be forgotten, however, that granite requires a special architectural treatment, in regard to which no systematic attempt seems to have been made, unless it be in some of the street architecture of Aberdeen; and a building designed for

freestone would have to be entirely remodelled in style and detail for granite. But the idea expressed by our contemporary should not be lost sight of. The great wish of many patriotic Irishmen for the employment of native art and native materials has been sometimes shown in a manner at variance with true artistic and political economy,—e.g., in the various attempts to create an artificial market for Irish lace, but the use of the building stone of the country for the buildings erected on its soil is, in general, both commercially and architecturally advantageous. There is a certain harmony between a building stone and the aspect of the country in which it has grown; and the employment of local materials conduces also to character in architecture.

**T**HE lack of water, or the fear that this element will become very scarce, has found in this hot summer a prominent place in the mind of dwellers of the country. It is, therefore, a fitting time to point out how shamefully the supply of water is wasted in the country. We by no means wish to assert that throughout many weeks of dry weather, even the most hountiful store of rain-water may not run short. But one thing is quite certain, that many dwelling-houses and farms have absolutely no store of rain-water except such as is to be found in some small cisterns and old-fashioned wooden barrels. Every dwelling-house and farm should, on the contrary, be supplied with a large slate cistern (we do not, however, insist on the special material) capable of holding many gallons of water, and it should be placed below the surface, and all roof water should flow into it. When such water stores exist they enable farmers and householders to have, at any rate, a long-continuing supply, and where there is a considerable expanse of roof even a single thunderstorm will produce much water. It is unnecessary to dilate on the saving of labour and the enormous advantages of these underground stores; but it is remarkable that innumerable houses and farms throughout England are without them. We unhesitatingly say that they should be found at every residence and homestead in the country.

**I**N regard to the subject of ballooning, and the recent French experiment in steering a balloon, it may be noted that the analogies of nature are adverse to the attainment of artificial flight by means of a balloon. We do not mean by way of detail, but by way of principle. The theory of a balloon is that of levitation—that is to say, of counterpoising gravity by displacing a given bulk of atmospheric air by a lighter gas. That the latter method involves the exposure of so large a surface to atmospheric currents as to require great force to overcome the resistance of a rapid breeze by fans, screws, or other mechanical means, is well known. But the point to which we refer is this. In the flight of every bird or insect the weight of the animal is directly utilised for maintaining it in the air. At the will of the bird the feathered surface that it exposes to the wind can be so inclined to the movement of the latter as to make the creature rise or fall at will, by the direct action of the wind, without any visible motion of the wings. From the deck of a vessel a gull may be watched hovering, for many minutes together, without one flap of its wings. The bird, at such times, is a living kite, its power of self-balance producing the effect of the string of the kite in maintaining a certain inclined position relative to the wind. And although some birds of the swiftest flight have an extraordinary area of wing surface in proportion to their weight, others, of equal or even superior power of flight, have very little wing surface in proportion to their weight. Thus the problem of flight has been solved by nature in many ways, but in all of them the gravity of the living creature, far from being destroyed or counterpoised, is an essential element of its mechanical action. The inference that we draw from this is that the opposite principle, that of levitation, is not likely to be followed with mechanical success, except on rare occasions.

THE Executive Committee of the Annual Liverpool Picture Exhibition have taken a step this year which is equally spirited and admirable. The opening of the exhibition, of which the private view takes place to-day (Saturday), inaugurates the new rooms gained by the extension of the "Walker Art Gallery," and the committee have started the idea of having representative exhibitions of the works of the leading art societies of the kingdom, each in a room allotted to it. The exhibitions which will thus be represented over again in Liverpool by a selection from the works of the year in the Grosvenor Gallery, the Royal Society of Painters in Water-Colours, the Royal Institute of Painters in Water-Colours, the Royal Hibernian Academy, the Institute of Painters in Oil Colours, the Dudley Gallery Art Society, and the Society of Painter-Etchers, and the Liverpool Academy of Fine Arts. All this is in addition to the general exhibition (which we presume will include a fair proportion of the Royal Academy works of the year); and there is a special room besides for architectural designs. Each room has been under the arrangement of two or three members of the Society concerned, and the architectural room is under the charge of three Liverpool architects, Messrs. E. Kirby, Charles Aldridge, and A. Cusshaw. As far as we are aware, nothing so comprehensive has ever been attempted at an annual provincial exhibition; and the experiment deserves special note, not only on account of its immediate interest, but also as one out of other signs of the growing tendency to break through the barriers of centralisation, and to establish new centres in the provinces. This is a kind of movement which we expect to see progress. Birmingham has become a political centre; Manchester has been for some time a musical centre, giving concerts equal to any in London, chiefly owing to the talent and energy of one man; and now Liverpool seems bent on becoming an art centre, and has certainly made an important step in that direction by the comprehensive scheme for this year's Exhibition.

WE have had sent to us by Mr. Stanley, the well-known optician, the ingenious and theoretically correct instrument figured here, for dividing a line or a space into

equal parts without measuring off. Suppose the space between the lines *a* and *d* is to be divided into thirteen parts, the lower limb, *B*, of the folding rule is adjusted to the lower line, and the upper limb opened till the division marked 13 cuts the upper line; the sliding portion, *C*, is then moved along till the mark on it coincides with the "13" mark, and by means of small pin-points on the lower side *C* is fixed in its position. *A* is then slid along it so that each division on it coincides successively with the cross-mark on *C*, and at each such position the limb *B* presents its edge in the correct place to draw the dividing line. The instrument is the invention of a lady, Miss Marks, an ex-student of Girton College. In a non-professional paper in which it was mentioned we observed that it was thought necessary to make a sort of "point" of the fact that a lady was the inventor. We know better than to pay Girton too poor a compliment; but, at the same time, we may point out that in saying the instrument is "theoretically" correct we mean to imply a certain question as to its practical value. It is a scientific way of getting what is wanted, and dividing out with a pair of hair-dividers is a rule-of-thumb way; but, practically, Miss Marks's instrument requires a certain care in the using to ensure accuracy, and has a liability to practical error which

increases with the decrease of the angle at which it is used; and we venture to think that a practised draughtsman would divide out scales and other similar measurements with a pair of dividers as correctly (more correctly in small distances) and twice as rapidly as he would do it with the "line-divider" to adjust.

"CASSELL'S Technical Educator" is, as all the world knows, and as is indeed stated on its title-page, the technical series of "Cassell's Popular Educator," and contains a great deal of useful information, sometimes scientific, sometimes more or less empirical. But what demon whispered to the director of the publication to go out of his proper "technical" line in Part VII, and to "have a taste" in decoration? The excuse seems to have been the presence in the same number of some articles on colour by that eminent authority, Professor Church. But it is one thing to theorise correctly about colour, another thing to give examples of coloured decoration, which is done in a fearful and wonderful chromo-lithograph frontispiece, illustrating three specimens of "cornice, ceiling, and wall colouring." The colours of dado and wall, as mere colours, are far too strong for surfaces unbroken by ornament,—they would be simply violent in themselves, and irrespective of design; and as to the design, and the details of colouring of the cornice and ceiling, they are too ludicrously dreadful to speak of. *Ne sutor ultra crepidam*; which, freely translated, means, "The Technical Educator had better not meddle with art."

MAJOR MARINDIN has reported to the Board of Trade on the Penistone accident, to the effect that it was due to the breaking of the web of the crank-axle, and that in his opinion the accident was one that could not have been foreseen or provided against. In the letter of this judgment we believe all competent persons will concur; but as since that accident we have had more than one breakage of a crank-axle while running, it certainly seems time that the question should be positively asked whether crank-axes and inside cylinders are desirable for fast-running engines, and whether the recorded facts of the breakage of crank-axes do not justify legislative regulation in this matter. Major Marindin also states that the lamentable consequences of the accident might have been mitigated by a quickly-acting and powerful continuous break; but this we think more open to question.

THE Rector of St. John's, Clerkenwell, calls attention to the desirability of saving the disused burial-ground attached to St. John's Church, Clerkenwell, as an oasis in that crowded part of London, where trees and shrubs may be planted and kept up for the pleasure of those living in a very poor neighbourhood, and a place of repose and refreshment to the eye and mind thus provided. He has offered the ground to the Holborn Board of Works, but they "do not want it"; he has sought help from the Metropolitan Boulevard Society (who, from their title, should be the right body to apply to), but has only received "good advice." 500*l.* would do what is wanted. Such a sum for such a truly philanthropic purpose ought to be forthcoming.

IT may interest some of our readers who believe in Art for the People, to hear that the fine sculptural group of "Isaac and Esau," by Mr. E. R. Mullins, which formed the last of our illustrations of the sculpture in this year's Academy, has since the close of the Academy been on loan at an East-end church, (St. Jude's, Whitechapel), where it stands at the east end of one of the aisles, and has not only attracted considerable interest on the part of the congregation, but became also the "text" for a sermon.

A BRIDGE over the ornamental water in Regent's Park has been commenced, Mr. Killingback being the contractor for the masonry, and Messrs. Hill & Smith for the ironwork. In the paragraph communicated to

the *Times* nothing is said about the designer of the bridge, so we presume this is to be evolved from the artistic minds at the Office of Works. It might have been thought that in what are specially ornamental grounds some effort might be made to obtain a design from an artist-architect such as would add to the attraction of the place. The new bridge may turn out to be an ornament, but we cannot feel very sanguine about it. The bridge is described as "to be constructed with ornamental latticed girders, with moulded Portland stone pilasters at each end"; and we know pretty well what sort of commonplace that means.

BURY ST. EDMUND.

WHEN Mr. Evelyn went to stay with my Lord Chamberlain at Euston, in 1677, he was fetched from Bury in my Lord's coach-and-six; and a day or two afterwards, hearing that a friend of his, Lord Croft's, lay dying at that town, he went over to visit him. When he had done his duty by his noble friend, he took a stroll "to see this ancient town, and the remains of that famous monastery and abbey." He records his impressions in a very few words—"There is little standing intire save the gate-houses; it has been a vast and magnificent Gothic structure, and of greater extent. The gates are wood, but quite plated over with iron. There are also two stately churches, one especially." What Mr. Evelyn saw two centuries ago, may still be seen to-day; but we, who live in an age of investigation, can probably tell more of the history of the ruins than could that gentleman, though he had lived two centuries nearer than we do to the time when they still had a history.

We quoted a fortnight ago Fuller's testimony to the magnificence of the abbey, how "the sun shined not on a fairer," and we then gave a very brief account of how the establishment gained its position as the premier abbey of England, from the extreme sanctity of the remains of St. Edmund and the wonderful miracles they brought. The royal saint quite overshadowed his predecessor, Beodric, who gave his name to the first collection of dwellings on the site,—Beodric's Worth,—and the mansion of the Saxon lord, as Jocelyn of Brekelond relates, became the dwelling of the infirmarer of the abbey, a subordinate official, whose duty it was to look after the sick monks.

The first temple enshrining the sacred remains was of wood,—a large church, built more than 150 years before Harold died at Hastings, pierced with foreign arrows, as St. Edmund had been before him; but so soon as William the Norman was seated on the English throne he gave what help he could to the abbot, who was then building a vaster structure over the Saxon saint. Towards the end of the eleventh century the great church was finished, and fragments of it remain to this day,—not much, indeed, by which any date can be assigned to the work, but the curious in such matters may still see a moulded base to one of the great columns by the tower, whose flat and clumsy profile proclaims it to be of very early work.

This church was, indeed, an enormous affair. It was 472 ft. long inside, exclusive of the chapels at the east end,—longer than St. Alban's by 22 ft., longer than Durham Cathedral by 58 ft.; only 2 ft. shorter than Salisbury, and 17 ft. shorter than Westminster Abbey. The neighbouring cathedral of Norwich could have been placed hoddly inside it, with several feet to spare all round. Peterborough was only 8 ft. longer; Ely was 45 ft. The interior was of massive, heavy, Early Norman,—a barbarous style, strong, stern, and unrelenting, like those who used it. The sorrow experienced in beholding the ruins of so large a church is much mitigated on reflecting how grim the lines were of which they are the reminiscence. At the crossing of the nave and transepts was a large central tower. At the west end were five others. Truly, a magnificent group for the eyes of Abbot Sampson to rest on. The west front must have been one of the finest in Europe. It was a more magnificent Lincoln, a worthy companion of a complete Ely. When Abbot Sampson had finished the two flanking octagonal towers, he must, indeed, have felt proud to be the lord of such a fabric. He was a fortunate man, this Abbot Sampson, to whom it was permitted to build towers, and stables, and brew-houses to his heart's content, in the

crisp, clean, vigorous Early English, as simple, supple, and healthy as the bare limbs of little children. But all trace of his work is gone, except the concrete masses of the west wall, which might be of any date, and against which a modern house has leaned itself in a picturesque but unsoftened manner.

The site of most of the church can be identified with the aid of a plan, but without it the task would be one of hopeless conjecture. As it is, however, a little patience will enable you to traverse the length of the nave to the great central tower, and even to stand on the spot where the most sacred bones of the martyr rested for many centuries. By way of the north transept you may reach the chapter-house, whence the Lord Abbots issued their fiat; and the great cloister, which lent its name to the high-caste cloister monks, in contradistinction to the common herd of *obedientarii*, or officials. Further on the kitchen chimney-corner may be traced, and the porch and angle staircase of the cellarer's house. Fragments of the abbot's own house are also to be identified, and perhaps the piers of the infirmary cloister. But it all looks like masses of concrete. The line of a wall now forms but a bank, the floors are deeply covered over with turf. Well might one exclaim with the German students in one of their Gesellige Lieder,

"O Jerum, Jerum, Jerum!  
O'quam mutatio rerum!"

From the fields once devoted to silence and meditation now sometimes soars the rocket; instead of the shrine of St. Edmund, one may behold the fiery wheel of St. Catherine; the ancient tapers of the altar would pale their ineffectual fires before the modern Roman candle; and over the spot where cowed monks were wont to pace, foot-floated, heavy-handed lads and lasses play a game called "kiss-in-the-ring." But, indeed, all those who care for antiquities may be glad that this is so. For had not the precincts of the ruined abbey been turned into public gardens, the ruins would hardly have been so well preserved.

All is not in ruin, however. The great gateway that was built at the same time as the circumscathing wall, early in the twelfth century, still remains; as also does another gateway built to defend the abbey against the burgesses. To realise the relations existing between the abbot and the townspeople, it is necessary to consider how great a man the abbot was. He was a peer of the realm. He owned no jurisdiction less than that of Rome itself. Were all the kingdom under an interdict, he had power, with closed doors indeed, "without ringing bells, and with a low voice, to celebrate divine offices." When King John was excommunicated, and the whole kingdom lay as dead beneath the blasting interdict, one small spark of life remained at Bury, where the abbot, with a low voice, still celebrated divine offices. Within a mile of the abbey every way the abbot was supreme,—he owned everything. Outside his stone walls were little besides wood or mud huts. A few stone houses there were, but not many. The townspeople were harassed by every species of toll and tithe and fine that the mind can conceive. The very refuse that lay in heaps before every door of that insanitary age was claimed by the abbot or his cellarer. At length, in the year 1327, for some reasons not recorded, but, like Antiochus's pretended stripes, they were no doubt "mighty ones and millions," the townspeople rose en masse, both men and women; from every village came large contingents; and at length about 20,000 persons hurled themselves against the abbey walls, led on, among others, by one Alicia Lickish. They broke down the gates; burned Abbot Sampson's Early English stables and brew-house; beat and wounded the monks; seized the abbot, who was away at one of his manors; robbed him; nay, positively shaved him, and carried him over seas till he was ransomed by his friends. One result of this outbreak was greater freedom for the townspeople. Another was the beautiful gateway of the abbey, built with all manner of niches for peaceful saints, and loop-holes for warlike arrows. Built first and foremost for defence, and secondarily in honour of the saints, but withal so beautiful that no one has had the heart to destroy it.

Besides the two gate-houses there remains a stretch of wall along the north side, built about 1230. It leads to one of the most interesting features in Bury,—the Abbot's Bridge,—of

about the same date. This bridge is a double or even triple erection. An inner series of arches carries a footway, an outer series carries the wall itself, while without this are flying buttresses, between which and the wall there is room to walk. It is said, not without reason, that planks were stretched from pier to pier, thus affording a footway outside the walls; but the structure, as now existing, throws no decided light on the matter. What with the double set of arches and the flying buttresses, however, the Abbot's Bridge is singularly picturesque.

The best preserved of all the remains of the former glory of Bury, however, are the two churches of St. Mary and St. James, the last built and longest lived. There was a third church, but all traces of it have disappeared, and had so long ago as Thomas Fuller's time. Both St. Mary's and St. James's are long churches, but, if one is to speak the thought of one's heart and defy the public opinion of Bury, they are not of the first order. The nave of St. Mary's is poor in detail, and even its length is against it; for, had it been shorter, there would have been less poverty. Its roof, however, is extremely good,—quiet and dignified. The nave of St. James's is not quite so long as St. Mary's, and has one arch less; its detail is decidedly better, and the whole effect, though it be heresy to say so, is more pleasing than that of its sister church.

St. Mary's, however, is the more interesting of the two, historically. It has some large tombs to Sir William Carew and Sir Robert Drury; but after the monument to Elizabeth Drury in Hawstead Church, or the Cordell monument at Melford, or the Kytson tombs at Hongrave, these tombs are Rabelaisian in their coarseness. An interesting tablet marks the last resting-place of Mary Tudor, daughter of Henry VII., widow of Louis XII. of France, and wife of Charles Brandon, Duke of Suffolk. Her history is a pleasant romance. Loved from infancy by the gallant and accomplished duke, she was married unwillingly, and for state reasons, to the aged King of France. Death came, but, like him in Schubert's song of "Death and the Maiden," he came "nicht zu strafen"; for luckily he spared the girl and took her aged husband, and forthwith she returned to her native land and married her first love. Her arms still adorn the entrance-gateway of West Stow Manor House, where they were placed by a devoted adherent, Sir John Crofts. This royal lady was originally buried in the abbey church, but on the destruction of that building, her body was removed to St. Mary's, being one of the few things that survived amid the universal desolation.

It is interesting to observe that neither of these churches had a fine tower. St. Mary's has a small one, but St. James's has none at all. This is hardly a matter of surprise, seeing that immediately behind it rose the five great towers of the west end of the abbey church. Indeed, it is somewhat curious that St. James's should have been built so close in front of the grand façade, which it must have half concealed.

Of the town of Bury itself not much need be said. Its architectural interest hardly extends beyond the precincts of the abbey. There are a few remains of Mediæval work; among them a house said to have been a Jew's house before the time of Abbot Sampson, who had all the Jews expelled. There could never have been much beside wood houses, and few of these survived the great fire of 1608. Fuller says the town "is sweetly seated and finely built," and, *mutatis mutandis*, the same may be said now. But the great glory of Bury must always be the memory of its abbey. Through five centuries it had but few rivals in dignity. The very name of its patron saint struck terror into guilty consciences and stayed the hand of the spoiler. Its abbot held the fate of thousands in his hand. Now, of all the names on its proud roll scarcely one is remembered. Abbot Sampson, indeed, lives in the pages of one of his obscure monks; but the others,—who knows or cares anything about them?

"But yesterday the word of Cesar might  
Have stood against the world; now 'tis but heere  
And none so poor to do him reverence."

But, though a man's name dies, his work, if worthy, will live; and if one might but leave behind one anything so excellent as the Gate-house or the Abbot's Bridge, one might well suffer one's personality to evaporate with equanimity.

#### THE ANCIENT AQUEDUCT AT SAMOS.

At the close of his charming account of the tyrant Polycrates, Herodotus tells us (book iii., cap. 39-60) that he had lingered over the story of the Samians because in their island were three of the most wonderful works he had ever seen. First and foremost of the three was a tunnel bored through a mountain 150 fathoms high. The length of the tunnel, he goes on to say, was seven stadia, the height and the breadth 8 ft. each way. Through the whole length of the tunnel there went a second tunnel 20 cubits deep and 3 ft. wide, through which the water is carried along in tiled pipes and conveyed to the city from a great spring. The architect of this tunnel was a Megarean, Eupalinos by name, son of Naustrophos.

It has been the fashion of late to regard the father of history as the wildest of romancers, but the fact of the execution of this tunnel, surprising though it seems as a work of the sixth century B.C., has been placed beyond doubt by recent excavations. Travellers since the beginning of the present century have known of its existence; a short notice of some of the obvious points in its construction appeared in the *Academy*, Nov., 1832, p. 335, and finally, during the spring of the present year, it has been thoroughly investigated by a member of the German School at Athens, Dr. Ernst Fabricius. He finds, as we might expect, that except for a few trifling errors in measurement, the actual remains tally closely with the account of Herodotus. His account is as follows:—

The aqueduct falls naturally into four divisions. (1) The spring itself, with the building over and about it. (2) The portion of the aqueduct leading from the spring to the intervening hill. (3) The tunnel proper through the hill. (4) The aqueduct from the hill to the town.

Fortunately, about the spring itself there had never been any difficulty. There is only one spring of any considerable size that did correspond to the "Great Spring" (*ἀπό μεγάλη πηγή*) of Herodotus. This spring is marked by three chapels to St. John, known among the natives of the island as the "Hagiades." There is no doubt, therefore, whence the aqueduct started. It is between this spring and the port of Samos, the modern Tigani, that the mountain ridge intervenes. Never was a town worse situated with respect to its water supply. Either the mountain must be tunneled or the water led round the base by a long awkward circuit. Portions of the well-housed structure still remain, and are, in fact, still used by the natives. It consisted, in fact, still used by fifteen pillars. Second comes the portion of the aqueduct between the well and the tunnel proper. Here the conduit was about the height of a man, partly hewn out of the solid rock, partly built up out of masonry. It is about 853 metres in length. Lying about in this part have been found large quantities of cylindrical tiles, no doubt either the brick pipes (*σολήρων*) mentioned by Herodotus, or at least their modern successors.

Third, we come to the tunnel proper. The merit of having discovered the actual mouth of the tunnel belongs to the present abbot of the neighbouring monastery of the Hagia Trias. For five months he and a fellow abbot of the Monastery of Stanoros superintended the labour of fifty workmen, and laid bare the entrance and a part of the tunnel itself. It would be much to the advantage of the inhabitants of the modern Tigani if the work could be completed and they could be supplied with good drinking-water after the same fashion as their ancestors of the time of Polycrates. Unfortunately the investigation of the actual tunnel is still in part, owing to the insufficiency of the props, a matter of considerable danger. On the south side it is accessible for 500 metres, on the north for 100 metres. Except at the entrance and the exit, where it is supported by masonry, the tunnel is bored through the solid rock. Abundant marks of hammer and chisel still remain, the work never having been finely finished. Along the walls niches are frequently found, and in some the very lamps remain which served to light the workmen. A little to the south of midway an interesting fact comes out. About 425 metres from the mouth, in a southerly direction, the tunnel ends in blank rock. It is clear that the boring was begun

from the two sides of the mountain. A slight error was made, and hence one of the bores comes to this blank end. The error was rectified by digging down till the lower bore was struck, and, just as we should expect, we find that at the meeting-point the tunnel is, instead of being just large enough for a man to stand upright, as high as 4 to 5 metres. At either end of the tunnel proper the walls are, as we said before, supported by masonry. On the north side much more masonry is needed for support than on the south. There is evidence that at first the supports were of wood, ultimately replaced by solid stone.

It is this third portion of the conduit, *i.e.*, the tunnel proper, that alone aroused the admiration of Herodotus. We remember he says that within the tunnel there is a second tunnel or dyke 20 cubits deep. Such is in reality the case. The water does not flow through the tunnel, but in a deep ditch dug beneath it. It is at the bottom of this ditch that the brick pipes are laid. Unhappily, Herodotus gives us no clue to the reason of this curious and complicated arrangement. Dr. E. Fabricius conjectures that this second arrangement was made after the first tunnelling, and in order to correct some error in the necessary level of the water supply. The tunnel seems to have been in use in Roman times, small chambers hewn in the rock seem to be Roman work. They supplemented the aqueduct, however, by a second supply of water brought round the mountain. We have also traces of early Christian influence. About 20 in. from the central meeting-point of the two bores we come upon a small rock-hewn chamber, in which are a number of white marble pillars and some marble slabs, all much incrustated with stalactites. On one of these, when cleaned, were found unmistakable traces of a Byzantine style of ornament. No doubt the little chamber was used as a shrine. Last, we come to the fourth section of the aqueduct, the portion that leads from the tunnel-exit to the town. The end of the main conduit has never been found, probably it came out near the shore, where good drinking-water would be specially needed. Close to the harbour lay the ancient Agora, and according to an inscription found huilt into the walls of the modern Tigani, there was in this Agora a stoa which contained two elaborate klepsydre, or water-clocks, which told the water-drawers month, day, and hour. As there is no spring in the neighbourhood of Tigani which runs the whole year round, we may reasonably suppose that these marvellous klepsydre were worked by the water that came through the tunnel of Eupalinos. Possibly the tyrant Polycrates had a taste for the marvellous in water-clocks as well as rings.

THE WARMING AND VENTILATION OF FRENCH SCHOOLS.

THE determination to render education compulsory throughout France, which was unanimously approved after the establishment of the Republic, has helped to develop considerably those sciences that contribute to preserve the health of those who live in large institutions. The educational movement was in reality a political, we might almost say a military, movement. It was based on the hope that the day might arrive when France would regain her military ascendancy; but it was felt that a successful war could only be waged by an educated people. Yet, on the other hand, physical education was recognised to be as necessary as mental training, and, therefore, unprecedented attention was given to the hygiene as well as to the curriculum of schools. Good light, a plentiful supply of air, constant exercise, abundant food, sufficient warmth, and even improved drainage, were all recognised as forming the fundamental conditions of a national regeneration. And now that some years have elapsed since this movement originated, work has been done, and new schools have been built, that redound greatly to the credit of the French nation, and must infallibly contribute to the improvement of the rising generation. We have just visited some of these modern institutions, and they merit the attention of English architects. Apart from the general adoption of the unilateral light in most schools, the system of warming is based on a rational conception which has given the best results.

At the instigation of Professor Emile Trélat, the distinguished architect, and with the assis-

tance of Messrs. Genest and Herscher, the well-known engineers, the Society of Public Medicine and Professional Hygiene drew up a report and propounded the general principles that should govern the warming and ventilating of schools, &c. These principles, which we are about to describe, have left the domain of theory, for they are applied on a large scale throughout France. Of course the first stipulation is that schoolrooms should have windows on both sides, so that a through-draught may be created as soon as the class is over. But, apart from this, the great object is to create as many inlets of pure air as possible with corresponding outlets. This end is attained by admitting large volumes of air slightly warmed, instead of a small quantity at a high temperature. Further a condition is imposed to the effect that each class-room should be independent of its neighbour, and capable of being warmed or not as circumstances may arise. How this programme has been carried out we were able to see for ourselves by visiting two typical schools in Paris; the first, in the Avenue Rapp, frequented for the most part by the children of the workpeople employed at the Government tobacco factory, and the second a middle class school in the Rue d'Amsterdam, known as the Lycée Condorcet. In both cases, the disposition of the rooms was very similar and the unilateral light secured. To the left of the pupils the wall had large bay-windows overlooking a wide court or the street. On the right-hand side of the entrance-door and smaller windows carefully closed with wooden shutters, so that no conflicting rays of light should enter during class time. In all cases, the door gave upon a verandah or open passage, protecting the wall from the sun, but at the same time offering none of the inconveniences of a corridor. The warming and ventilating had been installed by Messrs. Genest and Herscher, in keeping with the principles accepted by the Society of Public Medicine. In the Avenue Rapp each class-room had a stove placed in the corner nearest to the outer wall and the master's desk. The chimney, instead of being taken up to the ceiling, ran horizontally along the outer wall, immediately below the window-sill. Being enveloped by a metallic casing, it is impossible to touch the chimney. A sort of elongated heat-box is thus created, fed with fresh air brought in directly from the outside by intakes made through the wall. The casing is, of course, perforated throughout, and the air, warmed by passing over the outside of the stove-flue, enters the room. It does not suffice to warm a room, but it tends to the even diffusion of the warmth. In old schools it often happened that while one pupil near to the fire was scorched another at the other end of the class was almost frozen. To prevent this, the pure air admitted should be at as low a temperature as possible. If it is warmed too much it will rise up to the ceiling before the pupils have had time to breathe it. Even if the air be chemically pure, we know that it has an unpleasant, often an unhealthy, effect, when warmed too much; therefore to avoid the necessity of over-heating the air, the idea of protecting the walls against the refrigerating action of the external temperature was suggested. If the wall is warm, colder air may be introduced within the room. Again, a cold wall will determine a down-current of the vitiated air that has collected in the upper portion of the apartment. When, however, the flue from the stove runs horizontally along the outer wall, it counteracts this influence, it neutralises the chilling effect of the large windows. Further, the heat of the smoke and the products of combustion being utilised, a great economy in fuel is attained. The chimney or flues, after travelling horizontally along the outer wall of the room, is conducted upwards to the roof; but it passes in the centre of an air-shaft, and the remaining heat of the flue is further utilised to extract the foul air from the school. For this purpose the shaft has an opening near the ceiling of the room, and gas-burners placed within are sometimes employed to increase the suction. This system is very economical, is easily carried out, and well suited to small rural establishments. At the Avenue Rapp it is applied on a large scale, but the elementary character of the school increased the necessity of economy.

Counting fifty pupils for each class-room, the installation of the heating and ventilation amounts in cost to 13 or 20 francs per pupil. It must be borne in mind that the material employed is very dear and heavily

taxed in Paris, and that the workmen's wages are higher than in any other part of France. The outlay would not be so great in rural districts. As for working expenses, these need not be taken into consideration, for there are no attendants, the master himself adding coal to the fire whenever necessary. A coal yielding very little smoke is used. It is extracted from the Charleroi or Pas-de-Calais Mines, and is commonly called *gailleterie*, and might be compared to our Cardiff coal. In Paris it is sold at 11. 12s. to 11. 16s. the ton. Nevertheless, in spite of the high price for fuel, the cost for warming and ventilating the primary schools installed in Paris in the manner we have described, only amounts to two centimes per head per day. This is equal, in other words, to a penny per day for five pupils. These figures will compare most favourably with what has been done in England; and, though we have not had an opportunity of testing whether the warmth given in winter is sufficient, we found a plentiful supply of fresh air in the many class-rooms we entered during the great heat of July.

More perfect, but more expensive and elaborate, the warming and ventilating of the Lycée Condorcet is a good illustration of the modern system and of the newest improvements. The class-rooms, so far as light and ventilation are concerned, are disposed in the same manner; but they are warmed by steam under slight pressure. The steam is generated within a multitubular boiler of the Nacoy de Willebræck type, so as to avoid all risk of explosion. From the basement, where the boiler stands, the steam goes straight up to the attic, where it passes through a reducing valve. This apparatus is round in shape, and divided by a copper disc or plate, which becomes either convex or concave as the pressure or expansion pushes one way or the other. By the movement of this plate the steam supply is so regulated as to be always at a very low pressure. This has the advantage of insuring an even distribution; otherwise the steam, if at high pressure, would rush into the first opening instead of travelling slowly but surely over the whole building.

In the place of the chimney from the stove we have two steam coils passing along the wall of the class-room. The upper and larger coil gives off a considerable quantity of heat. It is placed as near as possible to the bottom of the window to counteract the chilling influence of the large surface of glass. The fresh air from the outside is admitted at a height of only a few inches from the floor, and here it is only slightly warmed by passing over the second and much smaller steam coil. The air is really not warmed, the chill only is taken off. The side walls are also warmed by a steam coil; thus no down-draught can occur, and the pupils are enveloped all round with heat that radiates upon them, and that is distributed in proportion with the causes of cold. Thus the same temperature is noted in every part of the room. The fresh air entering almost on a level with the floor is warmed and vitiated as it rises and comes in contact with the pupils. But then it continues to travel upwards till it reaches the ceiling, where it is drawn off by shafts communicating with lanterns in the roof containing gas-burners or other contrivances to accelerate the up-current.

Further it should be noted that the whole of this system is regulated from the outside without in any way disturbing the pupils during their studies. An attendant goes the round periodically of each class. A small opening in the wall, protected by glass, enables him to see a thermometer placed within the class-room; and, according to the degree of heat recorded, he turns the steam on or off. The fact that the supply of heat for each room is in this manner absolutely independent is a most important consideration. One class-room, crowded with pupils, may require ventilating rather than warming. At the same time the next room may be differently situated, and, exposed to colder winds and with fewer pupils, would want very much more artificial heat. These exigencies are met by the use of a steam trap, invented for this express purpose and applied to each warming apparatus. This trap allows the escape of water and air into the main return pipes, but retains the steam. There is, consequently, no counter pressure from the return main pipe, and, therefore, the supply given to any one room can be entirely stopped or resumed at will. Such modification in no wise affects the neighbouring rooms. Now that these

facilities have been created, the greatest severity is displayed in the matter of maintaining even temperature. For the winter months this is fixed at 15 degrees to 16 degrees centigrade (55 to 60 F.), and, if a variation occurs exceeding one degree centigrade either way a reprimand, and even punishment, is inflicted.

The Lycée Condorcet is a superior school, built in a very crowded district, with places for 600 pupils. The impossibility of obtaining sufficient land rendered it necessary to build to the height of four stories. The installation of the apparatus, &c., for warming and ventilating amounted to 4,050*l.*, or a little over six guineas per head. The working expenses for coal, the stoker, the attendant, &c., amount to 340*l.* per annum, but, of course, the results attained are far more probable than in the primary schools, where a mere stove alone is employed.

#### THE CAMBRIAN ARCHAEOLOGICAL ASSOCIATION.

The annual congress of this association was held last week, when Sir Watkin Williams Wynn took the chair, as president, and opened the proceedings of the thirty-ninth annual meeting.

On Tuesday an excursion was made up the left bank of Bala Lake to Castell Corndochan. The Rev. W. Hughes, the local secretary, read a paper, in which he referred to the leading objects of the day's excursion,—Caergai, Castell Corndochan, and Llannwchlyn Church. "Llannwchlyn" was derived from its position above Bala Lake. Llan-nwch-y-Llyn, the church above the lake. In early times, he said, the word "Llan" was not only applied to churches, but it also signified the spot surrounding the church. The existence to these days of so many Llan's bearing the names of Welsh saints, such as Llanduduo, Llandewi, Llandaff, and Llandrinio, showed the independence of the early British Church of the Church of Rome, and that she had a noble army of saints and martyrs to boast of long before Augustine came over from Rome, A.D. 596, to preach the Gospel to the pagan Saxon. The parish of Llannwchlyn was one of much archaeological interest, not the least point in which was that the historical river Dee rose in it under the hill called Dnallt, and not at Pantgwyn, as was sometimes supposed. Some writers asserted that the Dee did not acquire the name at any higher point than where it emerged from Bala Lake; but the tributaries to the lake are so well defined that one of them must be the Dee. The tributaries are the Twrch, Afon, Llan, or Little Dee, the Llyn, and the Llafar. The Welsh name of the Dee was Dyfrdwy, which was variously derived, Dyfr-dwy-afon, from the fact of its springing from two sources. Giraldus called it Deverdora. Might not, he asked, the word "Dee" be an Anglicised form of "Da," and "Deva" a Latinised form of the Anglicised word "Dee"? No river in the kingdom presented a more fertile source for archaeological research than the Dee.

Caergai, the next place of interest in the day's excursion, was described by Mr. Hughes. Camden said it was at one time a castle, built one Cain, a Roman, while the Britons assigned it to Gai, foster-father of Arthur, which seemed to be the view adopted by Spenser. In that case, Caergai would be a British and not a Roman fort. Pennant, however, favoured the theory that it was a Roman fort, and mentioned the discovery of many coins there. Roman tiles had been found in abundance about the houses and fields, and round bricks may be seen now, probably the remains of hypocaust pillars. Traces also remained of an old Roman pond diverging towards Mons Hirri through Prysam, Castell-y-Wann, Mvel Strodyd, Cwm Pryser, and Lwm Helen. Castell carni Dochan, the next place of interest, was described as situated on an imposing situation, on a precipitous projection of Ifud-helyg-y-Moch. The ruins form an inner parallelogram, 24 ft. by 20 ft., with walls 6 ft. thick, defended by a wall of loose stones and other walls. The bare walls simply remain, and there are no architectural details. The portion now exposed probably formed the dungeon and cellars of an old fort, perhaps a fortress in times of trouble. Diggings were made in 1828 and 1872, but only charcoal, burned soil, bones, and pieces of lead were found. At the foot of the Castell carni Dochan is a place called "Ller Llys," or place of the Court, or Manor-house. Llannwchlyn

Church, the last but not the least interesting object in the day's excursion, was dedicated to St. Daniel, and, with the cathedral of Bangor and the parish church of Hawarden, were the only churches in North Wales that bear the name of the first Bishop of Bangor.

At Llannwchlyn Church the objects of interest were a curious brass almsplate, an old oak-covered baptistry, shaped like a hip-bath, and a full-length effigy of a knight in armour with a hound at his feet, and the inscription, "Hic Jacet Iohannes ap Gruffyd ap Madoc ap Iorworth culus an. m. P. itur Deus Amen. Anno Dni. mcccxx." The records of this church appeared to be in a very sad state of neglect from damp and mutilation, those previous to 1675, so it is said, having been presented by a rector of the parish about the beginning of this century to some shoemaking friends of his who found the vellum useful for trade purposes! A move was made from this place for Llangower, a small church between the road and the lake, where a dilapidated old timber structure was pointed out as a fairly representative horse-bier upon which the coffin used to be borne palanquin fashion, the bearers being horses placed between shafts 5 ft. 8 in. long by 2 ft. 3 in. across. The coffin rested on eight elm "thwarts," some of which in the present instance appeared to have been recently replaced. Plis Rhiwaeodg, an old mansion believed to have been once occupied by Llywarch Hen, the poet-prince of those parts, early in the seventh century, was next visited. Colonel Evans-Lloyd read a brief but highly interesting paper on the place and its history.

On Thursday, the 21st, the members visited the Vale of Llangollen, and were occupied in investigating the ancient remains of the neighbourhood. The chief point of interest was a "tommen," or Roman mound of observation, situated a short distance from Macntwrog, called Tommen-y-Mar (*Herri Mons*). This Tommen-y-Mar is a conspicuous tumulus within a large parallelogram formed of a strong vallum and ditch. On both sides of the tumulus another strong vallum has been thrown up, dividing it into two equal parts. The approach to this is well guarded by lines of defence, and in one portion a section of Roman paved way, four yards in width, was hit upon. At a distance of a few hundred yards to the north-east, and near the point where two Roman roads cross each other, is a very fine amphitheatre nearly circular, the distance north and south being 114 ft., and east and west 104 ft. These have before been noticed and have been described in the journal *Archaeologia Cambrensis*. A visit was also paid to the ruins of Cymmer Abbey, which lie hidden amid trees, and which form part of the buildings of a farm-house. From the confirmation charter of Llewellyn ap Iorworth, Prince of North Wales, dated 1209 (according to Dugdale's "Monasticon"), to the Abbot and monks of Kemmer, of the Cistercian order and Benedictine rule, serving God and the blessed Virgin, it appears that the abbey was founded by Heredyd and Gruffyd, the sons of Cymran (referred to above), and that associated with them, probably as a late benefactor, was Howell, the son of Gruffyd. The form of the building is unusual for a Cistercian building. The plan is not cruciform, but consists of one continuous long nave and western tower. At the west end is an arcade opening into a chapel, the walls of which are continued to the east end of the church and form a lean-to, but shut out from the church. It may probably have been a sacristy. There are no remains of cloisters, and the chapter-house and other buildings have disappeared, but a little to the west of the church stands the ancient guest-hall or Abbot's hall (now used as a domicile), and has an open oak roof. Other buildings are also to be seen at the west end, but east of the guest-hall.

On the 22nd the excursion was among the Berwyn mountains, and the antiquities in the district around Llangollen were also examined.

After visiting Llantysilio Church, the travellers reached Valle Crucis Abbey,—a ruin romantically situated in a leafy hollow among the hills. The stone fragments have been carefully collected together and placed as nearly in their original positions as practicable on the carefully-shaven turf which now takes the place of the paved floor of the abbey. A slab in the south wall of the nave records that by permission of the proprietor the leveling and clearing of the ruins of the abbey was

effected under the superintendance of Arthur Viscount Dungannon, of Brynkinalt, and Mr. W. G. Wynne, of Penarth, and occupied from May, 1851, to May, 1852, Mr. Penson, of Oswestry, being the architect. The chapter-house, on the south side of the abbey, was still left untouched; it was in fact used as a farm-house up to the spring of 1883, and the walls and fine vaulted roof were plastered over. All this has now been removed. Over the chapter-house were the dormitories of the monks, and in front of the chapter-house still runs a clear stream of water, as it has done by repute for ages past. In the restoration of the chapter-house a curious plan was adopted for preserving a memorial which is believed to have no proper connexion with the abbey itself. This is a monumental slab on which the vinn, Maltese cross, &c., are carved, which is built into the south wall over the central one of three recesses. The church is of the usual cruciform type,—an aisleless presbytery, transepts, with two chapels forming an eastern aisle to each. There was a low square tower over the crossing, and a nave of six bays, with two side aisles. The extreme length is 165 ft.; length of transepts from north to south, 98 ft.; width of nave and aisles, 67 ft. 6 in.; width of chancel, 30 ft.; and of the transepts, 30 ft. The two end gables stand out almost perfect, and the north and part of the south walls of the chancel remain as described in the Journal of the British Archaeological Association.

Another important feature in the day's programme was Castell Dinas Bran, which is locally known as "Crow Castle," and which proves a most conspicuous object, as seen from the Vale of Llangollen, in the neighbourhood of that town. It stands on the summit of a conical hill 600 ft. high, among other surrounding mountains. Its broken walls and jagged turrets, as seen from below, form a striking feature in the landscape. It must have been impregnable against any attack when fortified in the days of rude warfare. Its early history appears to be unknown, but, according to history, it was in 1200 the residence of Madoc ap Griffith, the founder of Valle Crucis, from which it is distant only two or three miles. Madoc, it appears, became a traitor to his king, and when he afterwards gave in his submission it was readily accepted, for the probable reason that the sovereign was aware of the impregnable of his castle, to which he had retired.

We are partially indebted to reports in the *Cambrian*, the *Western Mail*, and the *Times*, for the foregoing particulars of the proceedings of the Congress.

**Messrs. Seeley's New Premises in Essex-street, Strand.**—The east side of Essex-street in the Strand is at present undergoing an architectural improvement by the erection of an extensive block of new buildings for Messrs. Seeley & Co. of Fleet-street, two well-known publishers. The building, 62 ft. in height, and 45 ft. in width, will have an attractive and richly-carved frontage, the elevation towards the street level comprising four lofty stories, besides dormers. The building up to the second-floor is faced with Portland stone, ornamented at the angles and between the windows with Minton Hollins & Co.'s herring-bone red tiles in varied patterns. The elevation is enriched with elaborate carving and sculpture on the entablatures. Within pediments above the second-floor windows are allegorical figures, whilst other parts of the frontage are filled in with devices emblematic of literature, science, music, and the arts. The panels at the foot of the several windows are likewise all filled in with foliage. The whole of the carving and sculpture is being executed by Mr. Mullins. The first and second floors contain ranges of five-light projecting bay windows, ornial in form. The upper portion of the frontage, containing the third and fourth floors, is faced with red brick, and the elevation is surmounted by an ornamental central pediment, 12 ft. in height above the main cornice. The roof will be covered with pea-green slates. The basement, ground, and the third and fourth floors are intended to be entirely occupied by Messrs. Seeley & Co., whilst the first and second floors will be let as offices, to which there is a separate entrance. Mr. H. C. Boyes, of Bow Churchyard, is the architect, and Messrs. J. & J. Greenwood, of Maltby-street, Bermondsey, are the contractors. Mr. W. B. Lee is foreman of the works.

DESIGN FOR WAR OFFICES:  
BY MESSRS. PANSON & SON AND  
F. T. BAGGALLAY.

**W**E publish this week another of the designs submitted in the Preliminary Competition for this important building; the elevation shows the Whitehall front, and to this is added a perspective sketch by Mr. Baggallay showing the grouping towards the Park. We may take the opportunity of saying that in other cases in which the authors of designs in the first competition wish for the publication of their drawings, we shall be glad to publish also a perspective drawing of the design if the authors like to furnish it, so as to put them on more even ground for comparison with the nine selected designs, the illustration of which we shall commence next week, and which will all be shown in perspective.

The present design has, as we think all our readers will agree, points of very great merit in the architectural treatment: the angles are powerfully accentuated, and contrast finely with the more elegant treatment of the intermediate spaces; and in these again the treatment of the four stories is very well contrasted, and a very picturesque effect is given by the continuous range of small columns and arcaded windows beneath the cornice.

We give the following extracts from the architects' report, which will serve to explain their own intentions in their own words:—

"The authors have adopted the Italian style, freely treated, as being best adapted to a public building. They have found from their large experience that it gives the greatest amount of light to the rooms and corridors, is easy of construction, and it will certainly be more in harmony with the National Buildings in the immediate neighbourhood than any other style. The treatment is simple, but they believe it will be effective, and they have carefully avoided useless ornament as being costly and unsuitable to the atmosphere of London.

On the south and west side overlooking the Horse Guards Parade an arcade is introduced so as to give increased grandeur to the building, and also to afford facilities for viewing the troops on holiday or state occasions. As will be seen by the drawings, this arcade forms no structural part of the building, and might be, if deemed desirable, entirely omitted, and a terrace only formed on the ground-floor level.

The authors have grouped the buildings round one large quadrangle, which, in their opinion, is a nobler and more convenient form of treatment than several small courts, and gives the maximum of light and air.

Private staircases and entrances have been provided for the Commander-in-Chief, the Secretary of State for War, and the First Lord of the Admiralty.

The glass-covered courts, which are one of the chief features of this design, and by which the corridors are, to a large extent, lighted, are roofed over with glass at the level of the ceiling of the second floor. They will be found to form very handsome and striking features in the corridor, besides being excellent ventilating shafts and a means of distributing heat, as pointed out in the special clause on that subject.

The draughtsmen's offices are on the third floor, and by the arrangement of windows on that floor which we have adopted, each draughtsman will have a window to himself, a point to which special attention has been directed in the instructions.

It was proposed to face the whole of the buildings externally with grey Aberdeen granite up to the level of the plinth, and above that height with Portland stone, as these two stones have been found by long experience to stand the effects of the London atmosphere better than any others."

The plan is open to considerable objections in detail, and the desire for architectural dignity and uniformity seems to have led to the window-space being too contracted, and the windows being inconveniently placed in many of the rooms. The merit of the design is therefore architectural rather than practical. When, however, we compare this with one or two of the designs (considered purely as designs) which it has been thought proper to include among the "sacred nine," we may certainly question whether the doctrine of considering plan as everything, and design as nothing, may not be carried too far.

SKETCHES AT PLACES VISITED BY THE ARCHITECTURAL ASSOCIATION.

Of the four small sketches at the top of the left-hand side, one shows a corner of Hengrave Hall, with its cupola-topped turret. These turrets occur at every corner, and larger editions flank the entrance. Last week we gave

part of the oriel window over this entrance. To-day we give, in the right-hand corner, some of the very fine mantling from one of the Kytson tombs in Hengrave Church. It will be seen that the shield bears the same arms as that on the corbel to the oriel window mentioned above. Another of the four small sketches shows a group of cottages at Melford, typical of the old-fashioned Suffolk cottages. The two churches, Hawstead and Livermere, are also typical of the smaller churches of the neighbourhood. They have no aisles, only nave, chancel, tower, and porch. Hawstead was the church of the Drury's, and contains some of their monuments. There is also a fine late pulpit, of which we give one panel. Livermere was not visited by the excursionists *en masse*, but a small detachment went thither and to Troston on an off-day. Livermere contains several things worth seeing. The benches are quaint: there is a good late pulpit, a handsome panelled font, a hold wood roof to the porch, and a remarkable wood cornice to the chancel roof, in which Renaissance shields are enclosed in Gothic tracery. Troston, of which we give a measured drawing of the porch, is another small church. It contains some wall-paintings inside, but the south porch is its most notable feature, and is a very good specimen of the flush-panelled flint work of the district. Another specimen of this distinctive work is given in the clearestory of Woolpit Church. Here we have not only the flint panelling, but the chequerwork which is to be frequently seen, and which is particularly effective. It will be observed that the patterns of the panelling necessitate often very much cutting of the flints, and in many cases the flints have fallen out from the minute intersections of the stone lines. Last week we gave other examples of flint panelling from Fornham All Saints and Wetherden Church. From the latter to-day we give a bit of mantling from the Sulyard tomb (see right-hand top corner). Another sketch shows the entrance to Rushbrooke Hall. The porch forms the middle stroke of the **E** which represents the plan of the hall. It is the only portion which has any detail to speak of. We gave last week a view of the end of the top stroke of the **E**, and a bit of the railing round the moat. From Coldham Hall we give to-day two scraps of detail, which may be said to exhaust all there is. The remaining sketch shows part of the tracery of the Spring pew at Lavenham.

LEEDS MUNICIPAL OFFICES.

WE give this week two more interior views of this important new building. One shows the office staircase (see plan in our last number), in which the stairs are constructed with wrought-iron beams and joists filled in with concrete, and finished with cast-iron risers and treads laid with the tesserae. The stair parapet is of Hopton Wood stone, and the walls are lined with tiles to a certain height. The soffits of the stairs are finished in plaster.

The other illustration shows the Central Hall, the walls of which are built of Caen stone, and the pillars are of Devonshire marble.

NEWCASTLE-ON-TYNE:

NEW PUBLIC BUILDINGS, DOCKS, ETC.

NEWCASTLE-ON-TYNE was *en fite* last week, on the occasion of the visit of the Prince and Princess of Wales, who, on the 20th inst., opened the Jesmond Dene portion of the Armstrong Park,—which is, for the greater part, the gift of Sir William Armstrong to the Corporation. It is mainly situated on the north-eastern slopes of the narrow valley through which runs the Ouse Burn. The tract of land is two miles in length, and as its entire superficial extent, including that of Sir William Armstrong's latest gift, is only about 104 acres, the fact that it is but a long and very narrow belt stands confessed. But (according to the *Newcastle Chronicle*, to which journal we are indebted for these particulars) so richly is it wooded, and so thoroughly hidden are its boundaries, that its real limits are never visible, and it appears to be many times its actual size. The park is in three sections, the limits of which are marked by intersecting public roads. The first section is the Heaton Hall Estate, of 22½ acres, acquired from Mr. Addison Potter for 12,562*l.*, in March, 1878. The second is Sir William Armstrong's first gift of land to the public parks, namely, 26 acres of the Jesmond

Estate. This section is contiguous to the first, and comprises the narrow slopes between the Heaton Hall ground and the old Benton-road. The third and last section is made up of Sir William Armstrong's second and most valuable gift to the city, namely, about 54 acres of land on his High Jesmond Estate, presented by the donor in February, 1883.

The New Museum.

On the same day the Prince opened the new Museum. The old Museum of the Natural History Society of Northumberland and Durham was for many years an educational centre of the utmost importance to the locality; but, being entirely built-in on all sides, only a very small portion of the erection was visible from any point of view, and the main entrance was at the extremity of a narrow lane. The members were, many years ago, keenly alive to the unsuitable nature of their building; but the difficulties attending upon a change of quarters were very serious, and it was not until the early months of 1879, when the site known as St. James's came into the market, that decisive steps could be taken for the erection of a new Museum. The site in question is a triangular piece of land occupying the space between the North Road, on the eastward, and the old Moor road on the opposite side. The apex of the triangle points towards the Barras Bridge, and the base is marked by a boundary wall which separates the ground from that occupied by the Virgin Mary Hospital for Freemen. When the question of buying the land first arose, an old house, with an ivy-covered terrace in front, stood upon the spot. The ground was, in Mediaeval times, a portion of the site of the ancient hospital for lepers, and a few scattered remains of that building have been discovered in the course of the recent operations. These relics include portions of the mouldings of an arch, showing dog's-tooth ornamentation, and they have been carefully put together and placed in front of the new structure. The price asked for the site was 6,000*l.*, and this sum was given for the purchase of it in October, 1879, by the late Colonel John Joicey. But the tenure of the land was only leasehold with right of renewal, and it was resolved to get it enfranchised. The cost of this procedure was 2,000*l.* additional, and Colonel Joicey also contributed that amount. Thus the site was acquired before the Christmas of 1879, and no time was lost in procuring designs for the building. The architects employed were Messrs. J. Wardle & Son, of Ridley-place, and the plans were supervised by Mr. John Hancock and other gentlemen interested in the affairs of the society. The interior of the structure is laid out in three large transverse apartments, which are lighted from the top, and surrounded by a system of corridors. These latter also give admission to rooms for the curator, for the committee, and for classes, and lights of stairs lead from them to the galleries which run round each of the apartments. The rooms are each 104 ft. in length, but the central one is 50 ft. in breadth, and the first and third ones are each 40 ft. 6 in. broad. The cost of the entire structure, with its internal fittings, was a trifle over 40,000*l.* The contractors for the fabric were Messrs. E. B. Reed & Son, of Newcastle, and this firm also supplied part of the fittings; but the greater portion of the work of furnishing and fitting up the interior was executed by Messrs. Rolson & Sons, of Northumberland-street and Spital Tongues, and Messrs. Sopwith & Co., of Northumberland-street and Sandyford-road.

The Reference Library.

After leaving the Museum, the royal visitors proceeded to the Public Library, where they opened the new Reference Library, the contents of which, relating to every branch of art and science, are detailed in the *Chronicle*, only to make us regret the more the superfluity of our great and wealthy metropolis in leaving whole districts as large or larger than Newcastle without such valuable aids to progress. The new Reference Library threatening to interfere with the Carlisle Tower, as to the proposed removal of which there was much opposition, the Lords of the Treasury sent down as Commissioner Mr. E. J. Smith, who, after holding a public inquiry on the 18th of April, 1879, made his report to their Lordships, who shortly afterwards advised the Town Council that the application for borrowing powers had been acceded to. They (the Lords of the Treasury)

considered that the retention or the removal of the Carliol Tower was a purely local question, and that after an inquiry on the ground by Mr. Smith, one of their Commissioners, their lordships saw no grounds for interference. In February, 1880, a contract was entered into with the late Mr. George Bailey, for the erection of a new building from the designs of Mr. A. M. Fowler, leaving out the Carliol Tower, which was removed on the 20th of May, 1880, "to make way for a building more in keeping with the progress of the times." The Carliol Tower, although it occupied the site of one of the old towers of the town wall which surrounded that part of Newcastle, preserved in itself no vestiges of antiquity, as it had been entirely restored from the foundation almost within the century. It was declared by no less an antiquary than Dr. Bruce unworthy of retention. In the meantime, the lecture-hall of the Mechanics' Institute was arranged as a provisional lending library, and the educational work of the institution was continued in the upper rooms of the building.

*The Albert Edward Dock at Coble Dene.*

The Coble Dene Dock, opened by the Prince of Wales on the 21st inst., is the latest of the many improvements so energetically carried out by the Tyne Commissioners. Coble Dene Dock, situated a little to the west of North Shields, comprises in extent 26½ acres, and will be mainly used for the accommodation of the import trade. After the Act was obtained for the construction of Coble Dene Dock, and before commencing the working drawings, extensive borings were made, which resulted in a resolution to change the position of the entrance. It was begun further inland than was at first contemplated, which had the effect of increasing the outer basin. The working drawings, prepared by Mr. P. J. Messent, Engineer to the Commissioners, and approved by the late Mr. J. F. Ure, their former engineer, were completed in May, 1874. The delay was occasioned in consequence of the alterations made by the borings. Shortly afterwards the works were commenced by the Commissioners' own men, and they went on rapidly until they were delayed by the failure to obtain the Act for additional powers in 1876. The second application in 1877 was successful, and the work was resumed with activity. Last year operations were so far completed that the water was let into the lock. The gates and sluices of the lock were then used for admitting and letting out the hoppers attending the dredgers which were employed in further completing the deepening of the dock. A length of quay and dock is about 3,000 ft. A new river wall about 1,500 ft. long can be used as a quay from the river. The total excavations, a large portion of which has been done by the dredgers and steam navvies, comprise 2,620,000 cubic yards. The total quantity of granite used in the entrances, quays, walls, and other erections is 343,782 cubic yards, the granite and other ashlar used at the entrance-steps and coping being 335,000 cubic feet. The greenheart used in the construction of the gates amounts to 36,600 cubic feet. The tidal entrance is 80 ft. wide, and the lock 60 ft. wide, each having gates to it made of greenheart. The depth on the sills of the tidal entrance and the upper end of the lock is 15 ft. at low water, and 30 ft. at high-water spring tides. The depth on the lower sill of the lock is 21 ft. at low water, and 36 ft. at high water, so as to enable vessels to be locked from and to the river at low-water spring tides. The length of the lock between the gates is 350 ft. Grooves are made outside the gates for caissons, by which the length of lock may be increased to 400 ft., or more if necessary. The whole of the work has been done by the Commissioners' workmen, without contractors, including the heavy gates of greenheart, which were constructed at the Commissioners' works at Howdon yard. The hydraulic machinery in connexion with the gates and other appliances are the manufacture of Sir William Armstrong & Co. At the north end of the dock there is a coal-shipping staith of sufficient length to tide a vessel 400 ft., and on each side two vessels of 250 ft. long. The staith is provided with four spouts on each side, and extensive standage ground connected with the North-Eastern Railway and the Northumberland collieries. Mr. Messent has patented an apparatus for shipping coals without breakage, and it will be applied to one of these spouts.

OBITUARY.

*Mr. Thomas Wisedell.*—The *New York Times* announces the death, on the 31st ult., of Mr. Thomas Wisedell, of whom it speaks as "the leading theatrical architect of this city, and for his age one of the foremost architects of this country." Mr. Wisedell was born in London, in September, 1846, and early in life he became a pupil of Mr. Robert J. Withers. While still with Mr. Withers he attracted the attention of Mr. Vaux, of the firm of Vaux & Withers, of New York (the latter of whom is a brother of the London architect), who was on a visit to England, and was by him induced to go to America. That was in 1868. For many years thereafter he was a valued assistant to Vaux & Withers, and in 1879 he became a member of the firm of Kimball & Wisedell. For the past eight or ten years he has, under the direction of Mr. Frederick Law Olmsted, designed the architectural features of the improvements of the Capitol grounds at Washington. In connexion with Mr. Kimball, he has designed and built many well-known theatres in this and other cities. Among these are the Madison-square Theatre, Harrigan & Hart's Theatre, and the Casino, at Broadway and Thirty-ninth-street, in New York; the Springfield Opera House, at Springfield, Mass., and the Yonkers Opera House, which was opened last spring.

*M. de Nittis*, the well-known French painter, died almost suddenly on Saturday, of a chest disease, at the early age of thirty-nine. M. de Nittis was born at Barletta, near Naples, but went whilst very young to France, and was essentially a Parisian.

*The Marquis de Mesgrigny.*—The *Athenaeum* announces the death, at the age of forty-eight years, of M. le Marquis de Mesgrigny, the painter of French river scenery.

*Dr. Moritz Thausing.*—The *Academy* reports the death of Dr. Moritz Thausing, who had been in ill-health for some time past. He was keeper of the Albertina Collection at Vienna and professor in the university of the same city. The work by which he will be known is his "Life of Albert Dürer," first published in 1876, of which a second edition appeared only a few months ago. An English translation was issued by Mr. John Murray in 1882, under the editorship of Mr. Frederick A. Easton.

*M. Leonard Lugardon*, the *doyen* of Geneva painters, has just died at the age of eighty-three.

COMPETITIONS.

*New Municipal Buildings, Burnley.*—Mr. Waterhouse, A.R.A., having been elected by the architects competing for these new buildings to award the three premiums due, according to the conditions, to the authors of the three designs judged most worthy, reports that, after carefully examining each of the designs, with the aid of Mr. Windsor, the surveyor, he is induced to recommend the design of Mr. Henry Holton, of Dewsbury, for the premium of 200 guineas; that of Mr. George Corson, of Leeds, for the 100 guinea premium; and that of Messrs. G. Natress and F. G. Coward, of London, for the 50 guinea premium. Mr. Waterhouse adds that, in making these awards, he endeavoured to consider the compliance of the various designs to the instructions—their artistic excellence,—convenience of plan,—constructive skill shown in each design,—the way in which the difficulties of the site had been overcome,—and lastly, their comparative cost. Though nearly all the competitors thought their designs could be realised for the sum at their disposal, it is clear that some of them would be far less costly than others. The artistic treatment of some of the elevations he regards as far above the usual average, though they were unfortunately not always accompanied by the best plans. The success of the competition is, he thinks, largely due to the evident fairness with which its conditions have been prepared.

*School of Science and Art, Lincoln.*—A new school of science and art is proposed to be erected here, at a cost of 7,000*l.*, that amount having been raised by private subscriptions in this place. It is to be built on land given by the city, worth about 1,000*l.* Designs having been invited in competition for three premiums, viz., 100*l.*, 50*l.*, 25*l.*, sixty-five designs have been

sent in, and the building committee have requested Mr. Charles Barry to act as their adviser in making a selection of the three best.

*Chestnut Drainage.*—The Chestnut Local Board have awarded the premium for the best scheme for the sewerage of their town to Messrs. Gotto & Bessley, and a further premium to Messrs. W. P. Orchard & E. van Putter for the second best. There were twenty-six sets of plans submitted.

ILLUSTRATIONS OF RECENT PATENTS.

5,727. Improvements in Apparatus for Measuring Water and other Liquids. William H. Tooth.

The important question of the measuring of water supplied to the household is dealt with by this invention, which offers a mechanical solution of the problem by an improved water-meter. The chief advantages claimed by the inventor are accuracy and simplicity of construction, the meter not being liable to get out of order. A chamber, tank, or cylinder is fitted with two valves, one at top and one at bottom, and having weighted levers connected together by a vertical rod on which a tube carrying a float slides freely. The plug of either of the valves is connected to a ratchet mechanism operating an index. The connecting-rod of the valves is screwed up with set screws or nuts to the proper position for registering the quantity of water

which is allowed to pass the cistern at each operation. The upper valve is the inlet, and the lower one the outlet valve. A plan of the apparatus is given (fig. 1), shown as fitted to a cistern or tank. A front elevation, with the ratchet mechanism removed, is given in fig. 2, the side elevation of the same being shown by fig. 3. Fig. 4 is a perspective view, showing the meter attached to an ordinary supply cistern. Detached views of parts are given, figs. 5 and 6, and a section of the valve is represented by fig. 7. In the drawings all the letters

FIG. 7.

refer to similar parts in each figure; *a* is the vessel, and *b* the inlet valve, *c* is the outlet valve at the bottom of the chamber or tank. The levers, *f* and *g*, weighted by *h* and *i*, are connected by a vertical rod, *j*. A tube, *l*, slides on the rod, and carries a float, *m*. The weights, *n* and *o*, at the end, are to counterbalance the weight of the rod. The lever of the lower valve, *c*, is fixed upon the spindle, *p*, but the lever of the upper valve works freely on the spindle, *q*, and is provided with an escapement, shown in figs. 5 and 6, for preventing the inlet valve from opening before the outlet valve is closed, and vice versa. The rising and falling of the float, *m*, strikes on *x*, the pallets of the escapements, and operating a ratchet and pawl from an arm, *z*, on the valve lever, *a*, serves to actuate the indexes on the dials *e*. The meter being fixed to any reservoir of which the capacity is known, the inlet valve, *b*, is connected with the water main. The chamber being empty, the outlet valve being closed, and the inlet open, water from the main will pass into the chamber *a* of the meter through the inlet valve. As the level of the water rises, the float *m* will be raised, and when the chamber is nearly full, or the given quantity of water has been admitted thereto, the tube *l* of the float presses on the under-side of the regulating nut, and raises the rod *j*. The lever *g* is then oscillated, and when the vertical portion *h* makes an angle of about 22 degrees, the slot *z* will have moved over the end of the lower lever and the float *m* will raise the lever, and open the valve *c*, the weights will fall, and while the lower outlet valve is thus opened, the upper valve will be closed, and by the mechanical arrangement of tappets and spindles (as shown in the section, fig. 1), the pallets of the escapement are lifted, and the index hand is moved as the measured quantity of water runs off

FIG. 2.

FIG. 3.

FIG. 4.

FIG. 5.

Tooth's Patent Apparatus for Measuring Liquids.

at the outlet valve, *c*, into a supply cistern, or is drawn off, as in figures 1, 2, and 3. The action of the escapement affords a certain measurement as the arm *z*, each time that the lever *d* is raised, rotates the ratchet to the extent of one tooth, and the amount of water which has passed through the chamber *a* is indicated on the dial *e*, each division of the index showing the quantity of water which has been allowed to flow into the cistern at each operation.

5,821, Improved Process for Working Marble and Stone. George Murray Morgan.

The methods usually employed in the manipulation of stone and marble for building and decorative trades are by manual labour with the primitive hammer and chisel. In this invention machinery is brought to aid in the sawing, moulding, or carving of stone or marble. The elevations and details are given in our illustrations, which will make the method perfectly clear. The marble to be worked is fixed by wedges, by cement, or by a box (A, fig. 1),

upon a travelling-table, B, which moves backwards and forwards by reversing gear. This traversing movement is automatic, and arranged so that on the termination of the forward and backward travel of the table B the strap is automatically shifted from one pulley to another, and the motion of the table reversed. Over this traversing table are fixed vertical side frames, D D, carrying the traversing tool-box slide, E, upon which one or more tool-boxes, F, rest, and which are capable of transverse adjustment to any required position by means of the leading-screw, G. A tool-rest, H, upon this tool-box, F, is fitted with the usual vertical movement, controlled by the screw, K, and in this tool-rest the multiple roughing-tool (figs. 2 and 3), or the finishing-tools shown in figs. 4 and 5, are fitted by

FIG. 2.

FIG. 3.

FIG. 4.

FIG. 5.

clamps and nuts. The traversing table under the fixed tool-rest carrying the cutting-tools is utilised to cut the moulding upon the surface of the marble or stone to any required shape. Several tool-boxes may be fitted upon the transverse tool-box slide E, and several different pieces of marble or stone may be cut and moulded simultaneously. In roughing out marble or stone, a multiple series of tools *h* (fig. 2), ground to diamond or angular points, are used. From the brittle nature of the material, a pointed tool effects the removal of the rough cutting labour, and consequently most expeditiously. The tools are of considerable length; and with their cutting-edges kept comparatively

close to the tool-rest, in order to render them very rigid, and they are ground with a cutting-edge at a somewhat more acute angle than that generally used for cutting cast iron. A finishing tool is shown in fig. 4, and a right and left handed tool for each half moulding alternatively adopted, is also shown in fig. 5. To avoid chipping at the end of the piece of marble or stone a cast-iron open three-sided box, with its end M-shaped to the form of the moulding is used (fig. 6). One end (M) is adjustable upon

the end of the box, so that when the piece of marble is embedded in the box, the movable end is brought close up to the end of the marble or stone moulding, and securely held there in position. The strip of marble or stone moulding is thus supported at its ends by the ends of the cast-iron box, and is, consequently, prevented from chipping. To fit the moulded portions together, as in the case of a fender, a circular saw in a sliding-frame is sometimes mounted over the bed of the said machine, so that the saw-frame can be set to the desired angle with the work, and the ends be trimmed by traversing the saw, which at the same time is rotated at a suitable speed over the work as it lies upon the bed.

### THE INTERNATIONAL FORESTRY EXHIBITION, EDINBURGH.

SIXTH NOTICE.

BRITISH GUIANA, as seen from the sea, is represented as suggesting the idea of one vast forest, parts only of which are cleared for cultivation. Although the Gold Coast is situated almost immediately under the line, the thermometer is seldom known to rise above 93°, and the average heat of midsummer ranges from 85° to 90°. The soil along the coast varies from a light sandy or gravelly nature to a fine black mould and loamy clay, and beyond are seen the highlands crowned with lofty trees and thick underwood. Advancing from the shore it is found that as we proceed the richness of the soil increases, and when a distance of six or eight miles is reached, it seems fit for any species of cultivation. Fruits in infinite variety abound, and many of the trees grow to a height of 100 ft.; they consist of almost every variety of such as are valuable for hardness and durability, as well as of others which are richly veined, capable of taking the finest polish, and well adapted for all sorts of ornamental furniture, while others yield valuable dyers or exude balsamic and medicinal oils. Wild animals and beasts of prey are abundant. These comprise the ferocious jaguar, the congar or red tiger, the tiger cat, the crabdoggo, the great ant-bear, porcupine, armadillo, sloth, opossum, different species of deer, lizards, chameleon, &c. Of the serpent tribe there are various species, from the large ahoma snake, which sometimes grows to the length of more than 20 ft., to those of the smallest description. The feathered tribe also abound, amongst which are seen the crested eagle, vulture, owls, butcher-birds, parrots, the toucan, pelican, tiger-bird, wood-pecker, humming-birds, &c. One of the most disagreeable frequenters of the forest is the vampire-bat, which grows here to an enormous size. Insects, such as mosquitos, ants, and centipedes, abound, and in the rivers are abundance of edible fishes.

The wild beasts and birds are not represented in the exhibition, but there are examples of the reptilia, including an interesting specimen of the iguana, which bears a marked resemblance to the dragon as represented in Medieval times; it is, however, an innoxious creature, subsisting upon a vegetable diet, and is considered by the natives a great delicacy. The fish of the rivers present an equally old-world look; in capturing them, either by lines or by shooting them with arrows, the natives display great dexterity. Of the trees, one of the most valuable is the *Mora gigantea*, the wood of which is hard and resembles teak. The tree sometimes attains the height of 300 ft., and a girth of 18 ft. It was at one time extensively used in this country for shipbuilding purposes, but since iron has come to be so much used for that purpose the demand for it has fallen off; still it is found to be well suited for railway sleepers, for which purpose it has been used in Demerara, Barbados, and Trinidad, where, from the hitter principle which it contains, it is found free from the attacks of insects.

In Georgetown this wood fetches about 4d. per cubic foot. Another wood possessing the

quality of resisting insect attacks is that known as the Greenheart. It has a specific gravity of 75 lb. to the cubic foot, and is most valuable for the construction of piers, jetties, &c. Specimens which have been under ground for a century as the foundation of houses are exhibited, and these appear as sound as when first laid down. The collection embraces upwards of 100 varieties of the trees which abound in the colony, which are generally of good size and excellent texture. Amongst them are various examples of cedars, forty-eight varieties of which, all beautiful in their markings and colour, are wrought into a table. There is shown a portion of a tree called the Yariro, which is peculiar in its growth, resembling a clustered Gothic shaft. These shafts are cut downwards by the natives, and are easily formed into paddles, for which purpose they are well fitted, owing to the fibrous nature of the wood and its freedom from cross grains. The walla, a hard and resinous wood, is valuable for coopers' work, and there are many others which space and time are not at command for referring to.
