THIS building, recently completed, stands at the top of Westow Hill, close to the Crystal Palace, having a frontage to the main road of 36 ft. with a return frontage at the side of 31 ft. The bank entrance is in the main street; the entrance to the manager's residence and the tradesmen's entrance being at the side. The entire space on the ground and basement floors is taken up with the banking offices, strong-rooms, book-room, clerks' lavatories, and cellars, the two floors above the bank forming the residence for the manager.

The materials used in the elevations are Lindley's red Mansfield stone on the ground-floor and in the main cornice at the top, and red Farnham bricks above the ground-floor, the pilasters and window dressings and all the brickwork at the corner being in gauged work.

The walls of the strong-rooms are formed of gauged brickwork in cement (with a tier of hoop-iron band laid between every course for greater security), and are lined with white glazed bricks. The roof is formed in strong cement-concrete, 14 in. thick, with 10 in. rolled iron joists embedded in it, 12 in. apart.

The internal doors and joinery of the bank, including the screens and desk fittings, are executed in American walnut. The brass work of the desk-rails, standards, and gas-fittings has been made by Messrs. Wenham & Waters, of Croydon, to designs specially prepared for the bank by the architect. The whole of the works, including the internal bank fittings, have been carried out by Mr. Martin Taylor, of Croydon. Mr. G. G. Woodward acted as clerk of the works, under the superintendence of Mr. Horace Cheston, architect, of Great Winchester-street.

#### THE EFFECT OF FREEZING ON CEMENT MORTAR.

IN a recent number of the *Builder* (see vol. lli., p. 255), the experience of German architects in the use of lime mortar during frost was given, from which it appeared that, if lime mortar is exposed to the action of frost for some days, it sets as firmly as mortar made in summer. This experience has been confirmed in the case of cement mortar by observations made in America, which reveal the fact that the behaviour of cement mortar in cold weather is even more favourable. From a paper read by Mr. Alfred Noble before the American Society of Civil Engineers, and published in the *Transactions of the Society*, we learn that in the construction of a lock at the St. Mary's Falls Canal (Michigan), between Lake Superior and Lake Huron, the laying of masonry was discontinued about the end of October in each year on account of the frequent recurrence of freezing weather. On the last day of work in 1877 mortars of Portland cement and of a good quality of American natural cement were used in adjoining portions of the wall. The same proportions of cement and sand, 1 to 1, were used in both classes of mortar. This masonry was laid during a slight rain. The following spring the surface of the Portland cement mortar was sound, showing perfectly the marks of the rain drops. The natural cement

mortar was disintegrated to a depth of from 3 in. to 4 in. In the same locality it was necessary to lay a concrete foundation for a movable dam in February. The weather was extremely cold, generally about zero. The mortar was made with Portland cement. Salt was used freely, but without retarding much the freezing of the concrete. The concrete was at once covered with a floor of timber and plank on which the masonry abutments were built. Samples of the frozen mortar set properly after being put in a warm place. There was never any settlement of the masonry, and within a few months the concrete sustained a pressure of 15 ft. of water without developing any leaks. In the construction of a bridge across Clark's Fork of the Columbia River, in North-western Montana, the caissons were filled with concrete during freezing weather. Portland cement was used. The proportion of cement to sand was 1 to 3. Within a week the laying of stone masonry was commenced on these caissons, and proceeded with as rapidly as possible, without apparent injury to the concrete, which had set firmly. In these cases the temperature had risen above freezing-point within two or three days after the concrete had been placed, and it had been permeated to some extent by warm air escaping through leaks from the air-chamber. The last case quoted by Mr. Noble is the St. Louis River Bridge on the Northern Pacific Railroad, near Duluth (Minnesota), where four small piers were built in the winter of 1884-85. During the laying of masonry for pier 1, the temperature varied from 0 to 20 degrees; during the building of pier 2 the temperature was about 20 degrees higher, and during the construction of the two remaining piers the temperature was occasionally above freezing-point. Portland cement was used throughout, the proportions of cement to sand being 1 to 1½ for face-stone, and 1 to 2½ for backing. During extremely cold weather salt was used freely in the mortar, and the sand was warmed (not made hot); but with the thermometer at 20 degrees the mortar froze quickly after being spread on the stone,—so quickly, indeed, that, if the stone, being set, could not be brought to a bearing by a little shaking, it was necessary to raise it again, scrape off the now frozen mortar, and spread a new bed. In setting the face-stone the mortar was kept back from the face an inch or so to facilitate subsequent pointing. A few weeks later, after there had been milder weather, an examination of the open edges of the mortar beds showed that the mortar used during the coldest weather had set firmly, and no difference could be detected by examination of detached fragments between the mortars in pier 1 and 4; that is to say, between that laid in the coldest and that laid in the mildest weather embraced in the period of construction of these piers.

In the discussion which followed the reading of the paper, some confirmatory results were given by other members of the society. Mr. G. S. Morrison mentioned an accidental experiment that occurred in the winter of 1885 in the work of the Omaha bridge (Nebraska). Mr. Morrison had a number of briquettes made of American cements and imported Portland cements, which were exposed to the air for twenty-four hours and then left in the customary way in a pail of water. Extremely cold weather set in, and the entire lot became a solid block of ice. When it thawed, the Portland cements were entirely uninjured, but the American cements were entirely ruined, some of them being reduced to mud. Subsequent experiments showed that the cements which stood freezing three days after they were made could stand freezing immediately after they were mixed. Mr. R. B. Stanton said that he had some experience in laying masonry in very cold weather. In the winter of 1878-79 it was found that a small pier on the Cincinnati Southern Railroad was defective. The pier was taken down and rebuilt with Louisville cement, and with the use of salt. The thermometer at the time ranged from 6 to 10 degrees below zero. The iron trestle was put upon the pier, and during the winter no change in the masonry was noticed. When, during the next summer, the trestle was removed, it was found that the pier had become so weak that it was necessary to reconstruct it. The salt came out and made the sides white, but the cement was as hard as if it had been laid in the summer, and there has never been any trouble with the pier. Mr. Stanton further stated that in the winter of 1881, at Denver, Colorado, in building the round house and shops

ows close to my sitting-rooms and along my garden, receives, amongst other offensive matters, the waste of a brewery, and the offensive drainage of some stables. When the rainfall is heavy, the nuisance is less pronounced; but in a dry season like the present, the stench combines all the odours that pervade Cologne.

Now, sir, for the moral of my tale. Year after year have I appealed to the Rural Sanitary Authority to construct a proper drain to take the drainage of the valley. In this valley there are eighteen houses, besides the brewery and stables I have mentioned. Year after year my complaint has been forwarded to the Parochial Committee by the Sanitary Authority.

The Parochial Committee wait till a thunderstorm has cleared the ditch, and then gravely report that no nuisance exists. One of my neighbours suggested to the Rural Sanitary Authority that the opinion of a sanitary engineer should be taken as to the sanitary needs of the village, and he offered to obtain such report at his own expense, provided the Sanitary Authority would carry out its recommendations. I send you cuttings from a local newspaper, the *Local Journal*, which will show you the spirit in which this reasonable suggestion is received. The suggestion that an engineer should be consulted was received with loud cries of "No, no"; and the suggestion that an engineer who made these subjects his study was more likely to form a just appreciation of the needs of the case was received with shouts of laughter.

Now, sir, I do not wish to dwell on my own grievances. I only put it forward as a typical case to show the weak points in the working of the Sanitary Acts.

To make these Acts efficient their power should be entrusted to skilled professional men, who should be empowered to carry out what they deem necessary despite all the objections that Bumbleton may raise. Until this is done the Acts will remain in many of the rural districts a dead letter until typhoid fever, cholera, or some deadly epidemic convinces even ratslayers that the laws of sanitary science are not to be defied with impunity.

ANDERCOMB WILSON.

THE REGISTRATION OF PLUMBERS.

SIR,—With reference to the recent resolution of the British Medical Association in favour of the registration of plumbers [see *Builder*, p. 286, ante], will you favour me with space to say that this Company has established a register for plumbers, by which the public may distinguish those plumbers who have the sanction of their qualification as plumbers in conformity with clauses 4 and 5 of the Company's conditions. The register, which embraces both masters and journeymen, now includes the names and addresses of several hundred plumbers in London and the provinces, and lists are furnished free on application. In connexion with the City and Guilds Institute special classes of instruction and examinations for plumbers, have been established, and, in co-operation with that Institute, this Company is using its utmost efforts to extend technical training among plumbers, who will be hereafter required to pass an examination in both the principles and practice of plumbing to entitle them to registration. This company is thus doing its part to the full extent of its available means, both to enable the public to distinguish those who are competent among the existing practitioners, and also to provide for the adequate training of the coming generation of plumbers. But it rests with the public authorities, architects, and the public generally, to help forward the movement by requiring that the plumbers they engage should have given evidence of their being qualified craftsmen. The benefits of the movement are, I hope, becoming more widely recognised, and we feel that the resolution of the British Medical Association should go far to impress the public with the fact that the medical profession are fully alive to the necessity of registering qualified plumbers in the interests of the public health.

STUART KNILL, Alderman (Master),  
1, Adelaide-buildings, London Bridge,  
August 27th.

INSCRIPTION AT WELLOW CHURCH.

SIR,—The inscription in the Hungrford Chapel, noted in your paper of the 20th, and referred to by "E. T. S." [p. 316, ante], runs thus:—

"For the love of Jhu and Marie is sake,—  
Pray for them that this lette make."

The suggestion that the meaning was "Pray for them that built this Chapel" was discussed by the members of the excursion party, as was also the suggestion that "lete" was a corruption of the French "let," a he'd, in which case the meaning would be "Pray for them that make their bed here," or "for them that lie here."

AN EXCURSIONIST.

\* 4. Plumbers (Masters and Journeymen) established in the trade prior to March 1st, 1888, are not necessarily required to undergo an examination. Admission is granted to such plumbers on satisfactory statement or proof of experience, according to the circumstances of each case. 5. All applicants who cannot satisfy the Registering Committee of their experience are required to pass an examination by a Board of Examiners, composed largely of practical plumbers.

CHURCH-BUILDING NEWS.

**Haigh.**—St. David's Church, Haigh, near Wigan, the new chancel of which was consecrated by the Lord Bishop of Liverpool, on the 3rd ult., was built originally from the designs of the late Mr. Thomas Rickman, one of the pioneers in the revival of Gothic architecture. The original church was a plain parallelogram, with a flat plastered ceiling and plastered walls, and plain pointed windows on each side. A few years ago Mr. Medland Taylor, of Manchester, was consulted as to what could be done at moderate cost with the existing church, and last year the work of actual building was taken in hand. A spacious chancel has been built, and on the south of it an organ and choristers' vestry projects transept-wise, and to the east of these is the clergy vestry. The chancel arch is pointed, but it is of very broad proportions, so as not to protest too much against the low flat ceiling of the nave. The chancel and the east wall of the nave are almost entirely of stone. Internally, the very effective streaked Runcorn stone is used. The chancel fittings are all of Danzig oak, and the screens in the arches adjacent to the chancel are traceried, and of the same material. On the north side, one bay from the east end, is a lean-to porch. In the floor-tiling are George Herbert's well-known lines:—"Bring not thy Plow, thy plots, thy pleasures thither, Christ Purged His Temple, so must thou thy heart." The gallery has been re-erected with open benches made out of the old framing. The benches in the nave are of pitch-pine. The plain plastered ceiling of the nave has been divided out into panels with wood mouldings and cusping. The chancel is lighted by two large casellabra brackets, north and south, the nave by eight pendants hung from the ceiling. The gallery, by some of the old gas standards. The funds for the work have been provided by public subscription, the Earl of Crawford, Mr. Rawcliffe, Mr. Fair, and others being amongst the larger contributors. The work has been executed by Mr. Winnard.

**Kennington.**—The Church of St. John-the-Divine, Vassall-road, Kennington, which was erected some years since from the designs of the late Mr. Street, R.A., is about to be completed by the erection of the tower and spire. This church has already cost upwards of 20,000l. The works for the erection of the tower have just been commenced, the foundation walls being carried to a depth of 10 ft. below the ground line. At the base the tower will be 25 ft. square, the height of this portion of the structure being 108 ft. to the cornice. It will be faced with red bricks, 2 in. thick, specially made for the occasion, with Bath stone dressings, and will be in every respect uniform with the architectural character of the church as already erected. At each angle of the tower massive buttresses having ornamental stone capitals will be carried up to within a few feet of the cornice. On each side of the lower portion of the tower there is a central Gothic window, 28 ft. in length. The upper portion will contain the belfry and floor of the bell-loft, and is intended to be fitted for a peal of eight or ten bells. The west entrance to the church will be immediately under the tower, the doorway being surmounted by a crocketed gable, with pinnacles on each side. The spire, which will be entirely faced with stone, will rise to a height of 104 ft. above the tower, the entire height of the structure from the ground line being 212 ft. The bell-loft will be reached by a winding staircase at the north side of the tower, in which it is proposed to place an illuminated clock and chimes. The structure is being erected from the designs of the late Mr. Street, under the superintendence of his son Mr. A. E. Street. Messrs. Dove Brothers are the contractors, and Mr. Osborne is foreman of the works. The tower is being erected in commemoration of the Queen's Jubilee.

**An Argentine Railway.**—The Argentine Government have ratified a contract with Mr. John Jackson, of Clement's-lane, London, for the laying of 450 miles of railway, at a calculated cost of two and a quarter millions of pounds. The permanent ways, all being of English manufacture, will consist of three separate lines.

STAINED GLASS.

**Chester.**—The large south transept window of Chester Cathedral, of which the stonework has been re-designed by Mr. A. W. Blomfield and carried out by Messrs. Thompson & Son, of Peterborough, has been filled with stained glass, and was seen for the first time on Sunday, the 7th ult. The restorations and stained glass are the gift of Lord Egerton of Taton. The window consists of seven large lights and tracery, and the subjects represented are the Crucifixion, Nativity, and Ascension, occupying the three centre lights, and sixteen subjects illustrating "Faith," taken from the eleventh chapter of Hebrews, are grouped around, filling up the lights on either side, the tracery being filled with a representation of the Angelic Choir. The window is designed in the spirit of "Old Glass," no attempt being made to copy the "Munich" or "Pictorial" school, Lord Egerton wishing to have a mosaic effect of colour, combined with figure drawing after the Italian Gothic school. The inscription reads as follows:—"To the Glory of God and in memory of William Tatton, first Baron Egerton of Taton, Lord Lieutenant, and Chairman of Quarter Sessions, County of Chester, died February, 1863. His son Wilbraham, Baron Egerton of Taton, restored this window August, 1887." The work was designed and executed by Messrs. Hoxton, Butler, & Bayne, under the architect's supervision.

**Copston Magna (Warwickshire).**—The east window of Copston Magna Church has been filled with stained glass in memory of the Toono family, at the cost of its surviving members. It has three lights, and contains the Nativity, the Crucifixion, and the Entombment, the traceries being filled with types of these events, the Burning Bush, the Pelican in her Piety, and Jonah devoured by the Whale, with the emblem of the Blessed Trinity, and monograms of the Holy Name. Under the main subjects are Three Angels holding scrolls inscribed with the words of the Apostles' Creed which refer thereto. The work was designed and drawn by Mr. N. H. J. Westlake, F.S.A., and produced by the firm of Lavers & Westlake under the direction of Mr. E. Swinfen Harris, F.R.I.B.A.

The Student's Column.

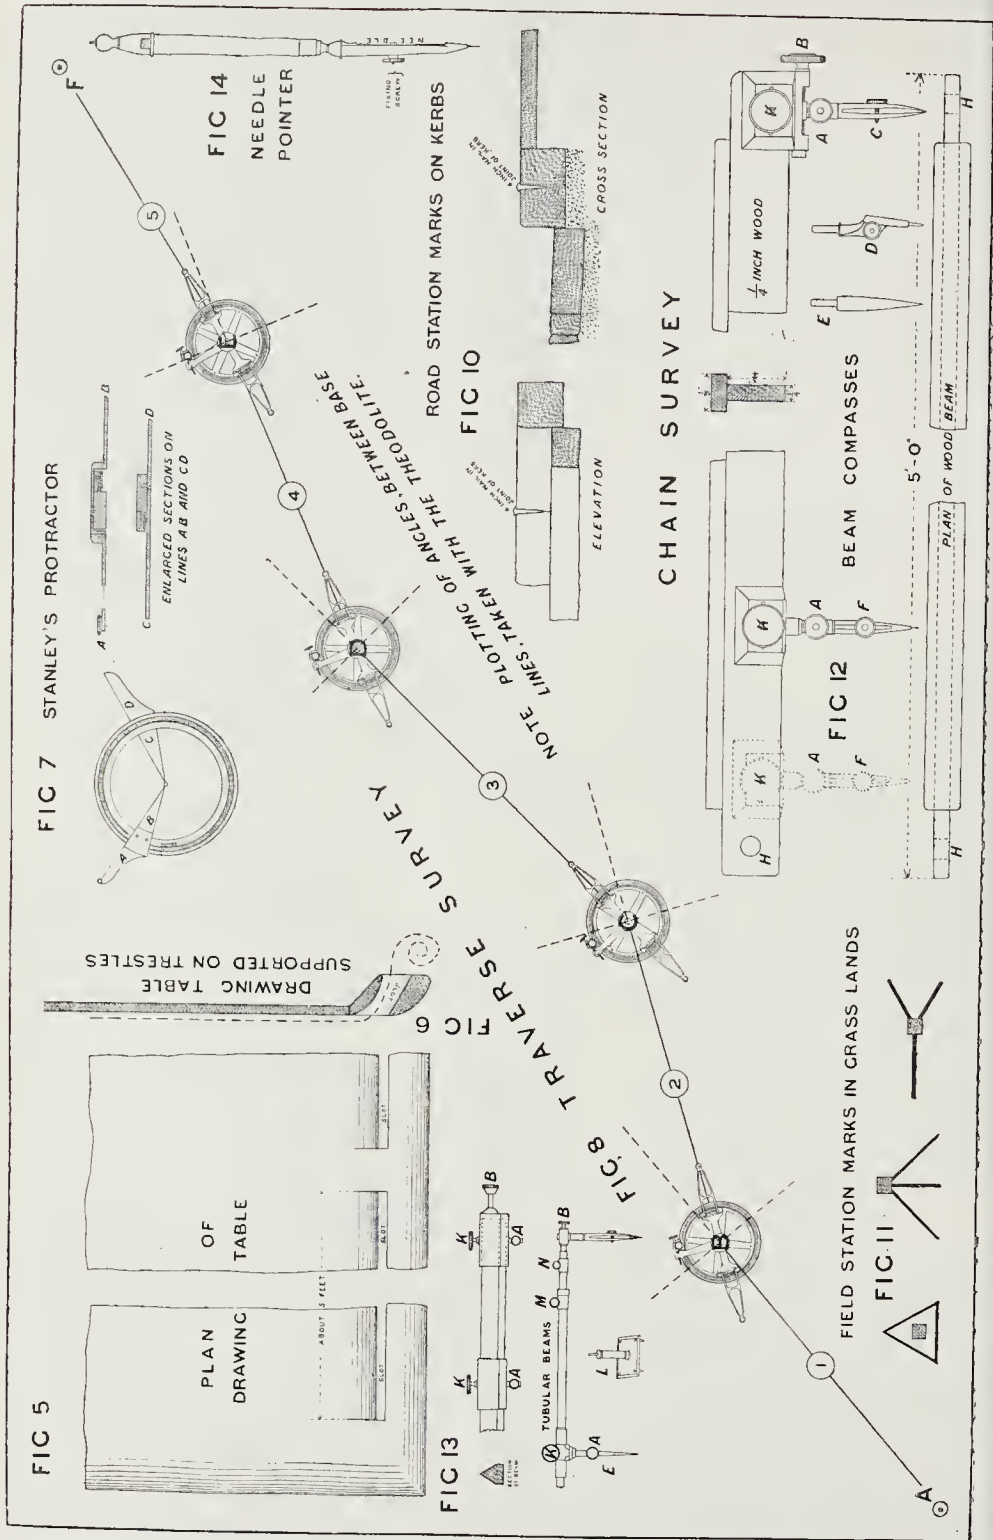

LAND SURVEYING AND LEVELLING.

N.—PLOTTING A PLAN.

FIG. 5 illustrates a good form of drawing table, having a slot or slots, as shown in the section, fig. 6, for the drawing-paper to slide into, when the draughtsman leans against the outer rail in the process of plotting. By the use of this precaution the drawing-paper is prevented from becoming creased when plotting at the top of the plan, as it can be pulled through the slot, as indicated by the dotted line in fig. 6.

Fig. 8 illustrates the plotting of the angles taken between the base-lines in a transverse survey by means of the circular protractor. The station pegs which are indicated in the field, as shown by figs. 10 and 11, are marked upon the plan with a small pencil circle, surrounding the station point, as shown at the termination of the base-lines, Nos. 1 and 5, in fig. 8.

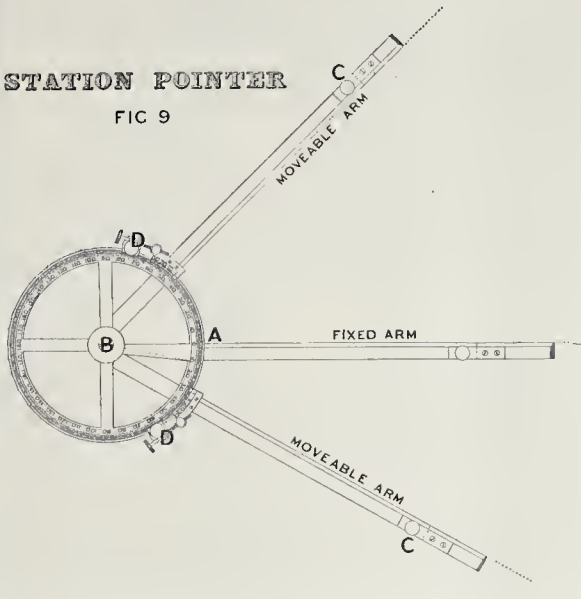

Fig. 7 illustrates Stanley's patent protractor, the construction being explained by its accompanying sections. By its use angles already plotted upon paper can be measured off without drawing in extra lines upon the map or plan. The instrument is formed of two concentric circular pieces. The outer of these circles is divided into degrees, and sub-divided either into halves or thirds of a degree, while the inner circle carries a vernier, which enables the operator to read to minutes. Two arms, as shown in plan and section, are mounted upon these two circular rings, and have each one of their edges radiating from the centre of the instrument. These arms can be moved to include any angle up to nearly 360°, the amount or size of which is then recorded by the index mark upon the scale of divisions. The instrument is made of metal, having the underside of the two radiating arms, and the lower surface of the outer ring, in the same plane, so that when the protractor is placed upon the plan, the arms can be set to the lines, between which the required angle is to be measured. If these

STATION POINTER

FIG 9

arms do not actually meet, the length of the arm permits the angle to be set without producing the direction of the lines in pencil to determine their point of intersection.

Fig. 9 illustrates a station pointer, which is used in a similar manner to a protractor, but it will be observed there are two radiating movable arms with verniers attached, one upon each side of a central arm fixed at zero. These arms marked C are each act by means of their respective clamp and tangent screw at D, to the required angle with the line B A. The instrument thus clamped is moved about upon the plan, until the edges of the fixed arms B C, B A, and B C respectively coincide with the points upon the plan which indicate the stations observed, when taking the two angles with B A in the field. By means of a needle pointer (fig. 14) the position of B can then be fixed. Lengthening pins to the arms are provided with the instrument for use when required.

The best form of beam and compasses for plotting long base-lines from chain measurements only, is shown in fig. 12, the top table forming the letter T, giving lateral rigidity to the beam. When only a straight edge is used to hold the beam compasses for a long measurement, it is apt to become bent horizontally while striking in the arcs, and the length of the radius is thereby shortened. Fig. 13 shows two other forms of beams, one of a triangular shape, and the other of a tubular shape, the latter with a universal centre-piece marked L, the top of which fits into one of the boxes in place of the points C or F. The tube between M and N slides within the tube between K and M, and the tube holding B slides within the centre tube from M to N. Clamping-screws marked K, M, N, are provided for fixing the tubes in position at the required distance.

Books.

*A Few Words on Portland Cement.* By A. MANUFACTURER. London: E. & F. N. Spon. 1887.

THE "Manufacturer" is Mr. D. L. Collins, of the firm of Gibbs & Co., Limited, who thinks, very reasonably, that in spite of the attention which engineers have given to Portland cement, the experience and opinion of a manufacturer who has been constantly handling it for many years, in the endeavour to produce stuff of a thoroughly good quality, ought to be of some value. The publication is a mere pamphlet of a few pages, and contains no superfluous words. The main point in it is the suggestion that the element of time is not sufficiently regarded at present in tests for tensile strength; or, rather, that its importance and significance are not rightly understood, and that cement

may be mixed so as to ensure a high tensile test at a short date, which, if tested a longer date, would be found to give a lower result from excess of lime. He also wishes to draw attention to the influence of circumstances, state of the atmosphere, and treatment by the manipulator, &c., as varying the results of tests from the same cement. Indeed, he gives comparative tests at seven days' age of the same cement in two cases made up by the same gauger, and tested apparently in the same neighbourhood, giving breakage at 372 lb. and 510 lb. respectively. His experience, he says, leads him to the conclusion that there is still very much to be learned about the laws which govern Portland cement; and in this probably the most accomplished engineering experts will readily concur.

*First Lessons in Science, designed for the Use of Children.* By the late Right Rev. JOHN WILLIAM COLENSO, D.D., Bishop of Natal, 1853-1883. London: W. Ridgway. 1887.

This book was written to give general ideas on the broader outlines of science to a class of adult natives in Colenso's diocese. The present volume, as we see from the original preface, was intended as the first of a series; it deals with the main facts of astronomy, including those which concern the figure and movements of the earth; others of the series, which we conclude was not carried farther, would have dealt with geology and other branches of science in turn. What was adapted to the comprehension of the African adult is supposed, we presume, to be pretty nearly equally fitted for assimilation by the English child; and certainly the book is admirably adapted to give a young reader his first ideas as to astronomical truths, in language at the same time simple and scientific; and no one will doubt that a mind so keen and eager as Colenso's would have kept abreast of the times in matters of this kind, and not deal out exploded theories to the youthful mind. It is curious, considering the terrible reputation as a "scoffing sceptic" which its author at one time enjoyed, that possibly the one objection which may be made to the book is that, for a scientific primer, there is a little too much religious preaching worked into it.

*The Duties of a Clerk of Works.* By JOHN LEAMING. London: B. T. Batsford. 1887.

This is a small book, giving in a very brief and pointed manner the outlines of a clerk of work's duties. A little less brevity would have been as well in some places; for instance, in the paragraph on "Concrete" (p. 22), it should have been mentioned that rough and angular fragments should be employed in preference to smooth or rounded ones (one of the most

important points in the production of good concrete), and, in the remarks under head of "Bricklayer," it might have been as well to give a reason for the direction, "See that cement is spread out and exposed to the air in a dry place before using it." The "clerk of works" will find the reason if he looks in the *Builder*, Jan. 3, 1885, "Student's Column," pp. 51, 52. The direction in regard to engaging a clerk of works, to inquire what he has previously done, "and engage none but those who have creditably superintended a building in that capacity," presents a certain difficulty, for in that case how is any one ever to begin being a clerk of works? Every man must have his first appointment in all branches of work. The quondam architect's assistant often makes a good clerk of works, says Mr. Leaming, "his knowledge of drawing and detail is of great advantage to him"; but "one of the disadvantages of this type of clerk of works is his possible interference with detail of which sometimes he knows more than his employer the architect, and is consequently tempted to deal with matters which are not in his province." That depends very much on what sort of man "his employer the architect" may happen to be; there are some with whom no clerk of works would venture to take such a liberty; others, certainly, who, conscious of their own shortcomings, might be grateful or indifferent. In a general way, however, our impression is that the engagement of a "quondam architect's assistant" as clerk of works is usually a capital thing for the said assistant; it enables him to complete his education in a practical direction,—at the expense of the architect's client. Even in such cases, however, a conscientious young man who means business and does his best, and takes care to get very full instructions from his principal, may be able to make mother-wit and close attention stand to a great extent in the stead of practical experience. The model clerk of works is only the development of experience; no one can really fill the office all at once. Let him begin on small and unimportant buildings, and so qualify himself for looking after the more complicated construction and conflicting interests in connexion with larger ones. And let him get Mr. Leaming's little book, which contains much common sense in a small compass, and will certainly be of use to him in the way of suggestion.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

9,186, Step Ladders. J. O. Nicholson.

According to this invention two or more ladders slide one within the other, with iron or brass or wooden guide strips fixed in the strings of one ladder and sliding in grooves in the strings of the other ladder. The strings of the bottom ladder are held together by dovetailed pieces across back edges, the bottom tread being a fixture, the other treads being pivoted on the back edge and chined into quadrant shape so as to allow them to turn back and upper ladder to slide up or down in front of treads. Back stays slide on the same principle. The ladder can be extended and fixed at any height.

11,583, Purifying Air and Cooling Rooms in Dwelling-houses. C. H. Joffie.

The ventilators which are the subject of this patent are screened by meshes of fine wire or cotton wool in layers, and the air is led through pipes submerged in tanks, whereby it is cooled. The admission and flow of air can be regulated at will, so that apartments may be kept at one desired temperature.

12,042, Casement or Fanlight Fasteners. H. J. Broadway.

These stays and fasteners are designed for holding the window firm in position when open, and giving greater security when closed. A bar or slide works on a flat bar or stay of metal, being held in position by an eccentric boss or lever which grips the bar, and so holds and fixes it in position. The stay or fastener according to this invention is simple and cheap.

17,158, Briquettes. S. P. Wilding. The briquettes are, by this invention, made from ore, small coal, coal dust, saw dust, &c. Molasses and linseed oil are used to bind the mass, which is then subjected to pressure. This mixture gives a briquette which is impervious to moist air or water, even when the surface is injured.

7,966, Inlaid Floors. W. Boeling.

By this invention the flooring plates are made with a top and bottom plate connected by means of cross battens, and with the intermediate space filled in with pitch, asphalt, or any suitable material. The plates are then laid as a floor, part being laid in concrete; as, for instance, a border or pattern across.

§ 648, Fireproof Column. A. W. Ramage.  
The outside shell of the column or stanchion which is the subject of this invention is of rolled steel quarter cylindrical plates or plates with flanges riveted together, and used in combination with steel stays. Cement or concrete is used to fill up the hollow fireproof pillar.  
9,808, Plumber's Portable Furnace. W. P. Thompson.  
This furnace is adapted for use with naphtha, gasoline, or any of the light hydrocarbons. The receptacle for the liquid fuel is in the base or lower part of the apparatus, which base forms the foundation upon which the other parts are mounted and into which they are connected. Provision is made for placing the irons while heating. The oil is fed to the burner through the lower standard by means of an air pump (after the manner of the mechanism of a moderator lamp) contained in the apparatus, and the flow of the illuminating fluid is regulated by a needle-valve.  
10,427, Cutting Edges of Wall-paper. J. & J. Eccles.  
The paper is drawn through rollers, and circular cutters at each end trim the edges as the paper passes through. The improvements are in the direction of simplicity and strength of working parts.  
2,291, Ventilating Apparatus. E. M. Young and G. B. Moss.  
In connexion with the fireplaces of the room chambers are placed for exhausting the foul air from the rooms or halls. The air-chambers becoming heated the foul air is drawn from the apartment and passes up the chimney-shaft.  
3,757, Hanging Doors and Casements. W. S. Pilditch.  
By this invention the hinges are so placed that by working a groove of a quarter circle both in one of the back edges of the door and a similar one in the corresponding edge of the door-post the hinges will to the necessary extent become embedded in the two quarter circles, and by this arrangement the edge of the door and that of the door-post is constantly maintained in such close contiguity that for all practical purposes prying joints are barred and draughts of air excluded. By a mechanical arrangement also, the door when required can be put back parallel to the wall without detriment or disturbance of the hinges. The leaf of the hinge is secured to a moulding or other elevation extending from top to bottom of the door and equal in height to the moulding of the architrave.  
7,438, Saws for Stone or Marble. E. Edwards.  
Sand is generally used in cutting stone. The blades or saws are, by this invention, so placed that they produce a rapid and continuous displacement of the sand under the rubbing action of the blades. Grooves are formed upon both sides of the blade so that they alternate with each other, or holes are pierced for the purpose of retaining the sand, and thus increase the cutting power of the saws.

NEW APPLICATONS FOR PATENTS.  
Aug. 12.—11,039, J. Kenyon and Others, Wind, Rain, or Dust Preventers for Doors.—11,045, A. Harris and J. Luckock, Window Fastenings.  
Aug. 13.—11,068, J. Speakman, Paint Restorers or Removers.—11,078, T. Shalley, Securing Sheets of Zinc or other Metal to Roofs.  
Aug. 15.—11,109, J. Carrett, Preventing Smoky Chimneys.—11,119, J. Guest, Axes, Adzes, &c.  
Aug. 16.—11,193, J. Halo and C. Simmons, Water-closet Fans and Traps.—11,196, E. Thomas, Door Fastenings.—11,205, H. Gregeen, Combination Cully-trap and Channel.  
Aug. 17.—11,221, J. Sington, Screws and Screw-drivers.—11,234, T. Carpenter, Sliding Chandeliers, Gasellers, &c.

Miscellaneous.

University College, Bristol.—This College has been recently enabled to make a notable advance in the matter of engineering education, owing to the generosity of local firms. At a meeting held in the early part of the present year, under the presidency of Mr Alfred Fry, the desirability of instituting engineering scholarships was considered. The practical outcome of this meeting was that most of the firms of the neighbourhood agreed to institute Bursaries or Scholarships at their works. The holders of these are to be nominated by the College authorities. Some will be awarded on the results of the annual examinations, while others will be reserved for deserving students who may be unable to pay the usual premiums required on entrance into the works. The educational scheme adopted at Bristol does not include any attempt to impart practical workshop instruction within the College walls, but the students spend six months (April to October) in each year acquiring practical experience in the works and drawing-offices of engineers in the West of England. This system is stated to answer so well that Messrs. Stothert & Pitt, of Bath, and the Bristol Wagon Works Company propose to make it obligatory on all their pupils to attend the College courses in the winter months for the first three years of their pupillage. Several firms have also signified their willingness to take College students for short periods, so that civil engineering and electrical engineering pupils may spend one or two terms of six months in works, while at the same time mechanical engineers may have experience in two or three different establishments during their College career. In return for these concessions, the Council of the College has decided to permit deserving apprentices or artisans, nominated by the local engineers, to attend the College courses at reduced rates. It is expected that about nine first-class scholarships and a larger number of second-class ones will be available during the coming session. The following are the names of the firms which have already placed at the disposal of the College authorities one or more Scholarship places in their works, on exceptionally favourable terms:—Messrs. Stothert & Pitt, Bath; The Bristol Wagon Works Company, Bristol; Messrs. Cox & Co., Falmouth; Messrs. Newall & Co., Bristol; Messrs. Willoughby Bros., Plymouth; Messrs. Bush & De Soyres, Bristol; Mr. Thos. Beckett, Atlas Engine Works, Bristol; Messrs. John Watts & Co., Bristol; and Messrs. Spencer & Co., Molksham, Wilts.

Isothermal System of Building.—This new system of building (according to the *Deutscher Dachdecker*), is principally based upon the employment of iron in layers between which isolating agents (air and materials of organic composition) are alternated in such a manner as to effect complete protection against cold as well as heat. The various parts of the buildings being constructed in factories, expedition and cheapness are insured. There is comparatively little brickwork, it being only used in the cellars, foundations, and chimneys. As soon as the last coat of oil-paint is dry, the house is ready for occupation. The building of such a house takes four to five weeks, and can be carried on in winter as well as in summer. The inventor of the system, Herr. Hielemann, of Berlin, claims, moreover, that it insures complete dryness, and a saving of about one-third in the cost of building. It is, however, only applicable to structures not more than two stories high, such as agricultural and industrial buildings, dwelling-houses, villas, workmen's dwellings, &c. Cottages with two rooms and cellars, &c., can be erected for 112/ 10s., this sum including stove, painting, paper-hanging, &c. Villas with five rooms cost 240/., and with eight rooms, 450/. Sheds, stables, and similar erections, can be put up from 1s. per square foot of surface built over. The use of oil-paint gives these structures a cheerful appearance. A building executed on this plan may be seen at the Berlin goods station of the Potsdam Railway.

**The Rebuilding of Chelmsford Workhouse.**—At a meeting of the Guardians of Chelmsford Union, held last week, the chief business before the Board was the consideration of the plans submitted for the rebuilding of the Union House. Mr. E. Corder (Chairman) presided, and there were twenty-six other Guardians present. At a previous meeting it is decided to ask Mr. F. Chancellor, Mr. C. Entwice, and Mr. F. Whitmore, architects, of Chelmsford, to send in plans for the new building. All three gentlemen did so, and the plans were referred by the Guardians to the Building Committee for examination. This committee now presented their report under—"The Clerk submitted to us three schemes and plans which he had received from the architects for the re-erection of the workhouse, bearing the several mottoes, 'Union is Strength,' 'Kelpie,' and 'Adaptation.' The committee having carefully examined the plans, it was resolved that they not recommend the adoption of the plans 'Kelpie.' The plans of the other two committees were then put to the vote, when there appeared six in favour of 'Union is Strength' and four in favour of 'Adaptation.' It was, therefore, resolved that the guardians be recommended to adopt the scheme and plans sent in with the motto 'Union is Strength.' After some discussion, the chairman moved, Mr. A. C. Veley seconded, and it was resolved, that the report of the committee be received and adopted. The closed letter bearing the motto "Union is Strength" was opened, and it was found that no accepted plans were those of Mr. F. Chancellor. The plans marked "Adaptation," which seriously competed in committee with those approved by the Guardians, belonged to Mr. C. Entwice; and those marked "Kelpie" to Mr. F. Whitmore. The Building Committee were then instructed to meet Mr. Chancellor and complete the plans and specifications for the local Government Board.

**The Stavanger Cathedral, Norway.**—In a recent article on the state of this cathedral in the Norwegian technical journal *Teknisk Ugeskrift* says:—"During recent years the work of restoring this celebrated Norwegian edifice, the second cathedral in Norway after that of Thronhjelm, has, thanks to the munificence of the corporation of this city, been almost completed, and the building is now one of the sights which no artistic visitor to Norway should miss, though the position of the town, by being somewhat out of the ordinary tourist track, has rendered this cathedral less known than its prototype at Thronhjelm. The cathedral of Stavanger was built in the middle of the twelfth century by one Reinold or Ragnhald, a monk from the Winchester Cathedral, who, by the order of King Sigurd Jerusalemfarer, brought over workmen from England for this purpose. This explains the remarkable similarity between certain parts of these two cathedrals, and also why the first cathedral was consecrated to St. Swithin, Bishop of Winchester, 37-862. In 1272 the cathedral was almost destroyed by fire, and it was not till the middle of the fifteenth century that it was fully restored. At that period it attained the greatest magnificence, having eighteen altars, &c.; but the reformation soon destroyed all this, and for three centuries the edifice remained to decay, stripped of all its interior ornaments. In the middle of the eighteenth century the whole interior was, by the order of some Vandal authority, "whitewashed," a process whereby all the fine Gothic tracery and ornaments were obliterated. It is curious to know that about the same period a similar outrage was perpetrated in the Thronhjelm Cathedral. Thus it remained until 1867, when some art-loving corporation of the city decided upon restoring the cathedral as near as possible to its ancient magnificence, on a plan submitted by a well-known Norwegian architect, Herr von der Lippe, and this work has since been carried out most satisfactorily, the principal and most arduous task being to remove the "whitewash" referred to. The nave, the oldest part of the cathedral, is over 100 ft. in length and about 50 ft. in width. It is built of grey granite, with sandstone cornices, window and door frames. In the manner of basilican churches, the nave is divided into two lower side naves and one central nave, 40 ft. in height, the whole being covered by a wooden roof. All along the centre of the nave run two rows of pillars, joined by arches, in Norman style, the latter bearing

on the inside zigzag tracery, whilst, curiously enough, the capital of one is ornamented with old Pagan Norse dragon tracery. On the west side there has once been a large tower, but it has been found impossible to rebuild this on account of the walls of the cathedral now deviating from the perpendicular. The choir, which in all probability dates from the fire in 1272, is 70 ft. in length, and with the same height and width as the nave. It is chiefly built of sandstone, and in the richest Anglo-Gothic style, and is one of the finest pieces of ancient architecture in Scandinavia. The roof is supported by Gothic pillars and groined, the windows being ornamented with beautiful foliage. In the east gable is a large, handsome stained-glass window, with figures of the four Evangelists. There is also a magnificently-carved baptismal font of sandstone, dating from the earliest time of the cathedral.

**The London Parochial Charities Act, 1883.**—By an Act of the current session the Ecclesiastical Commissioners, as owners, are authorised to sell about 53 acres of Clissold Park, Stoke Newington, to the Metropolitan Board of Works and the Hackney District Board, or to either of them, for preservation as an open space. The purchase-money is to be contributed by various metropolitan parish and district Boards, including the South Hornsey Local Board, into whose parish portion of the park extends. The Act further provides for a contribution not exceeding 47,500*l.*, being made out of the charity funds dealt with by the London Parochial Charities Act of 1883. The Coal, Corn, and Finance Committee of the Common Council have just reported in favour of the making of this last-named contribution. At a delegates' meeting of the London Trades' Council, held on Tuesday, 23rd August, in the Memorial Hall, Farringdon-street, a resolution was passed, on the motion of Mr. C. J. Drummond, Secretary to the London Society of Compositors, supporting the Charity Commissioners' scheme for erecting technical schools,— "in the best sense of the word,"—in various parts of the metropolis. It is proposed to erect the first one on the site of Farringdon, *olim* Fleet, Market, the cost to be defrayed out of the parochial funds of St. Bride's under provision of this Act.

CARLISLE.—Accepted for putting and converting into six dwelling-houses the old Whip Manufactory, for Mr. Jno. R. Armstrong. Mr. Charles Armstrong, architect, Carlisle.—

Table listing contractors and amounts for Carlisle projects, including Bricklayer and Mason, Carpenter and Joiner, Plasterer, Cement and Fireproof Floors, Plumber, and Painter and Glazier.

DARENTH (Kent).—For external painting and repairs to the Asylum for Imbeciles, Darenth, near Dartford, Kent, for the Managers of the Metropolitan Asylum District. Messrs. A. & C. Harston, architects, 15, Leadenhall-street. Quantities not supplied.—

Table listing contractors and amounts for Darenth projects, including A. Sewall, W. Puffe, Cullen & Co., Vigor & Co., G. Foxley, McLachlan, R. Proctor, and W. Radlow.

DARENTH (Kent).—For alterations and additions to the mortuary at the School for Imbecile Children, Darenth, Kent, for the Managers of the Metropolitan Asylum District. Messrs. A. & C. Harston, architects, 15, Leadenhall-street.—

HUCKNALL TORKARD.—For the enlargement of the Parish Church, Hucknall Torkard, Mr. Robt. C. Clarke, architect, Nottingham.—

Table listing contractors and amounts for Hucknall Torkard project, including Parnell & Son, Dennett & Ingle, Thompson, Hodson & Son, Rudd & Son, Vickers, Smith & Lamb, and Fish & Son.

KING'S LYNN.—For building furnishing store at King's Lynn (bricks and plate-glass being found by the proprietor), for Mr. Alfred Jermy. Mr. W. Adams, architect.—

R. Dye (accepted) £1,238 0 0 [Eight tenders were received, the amount of the highest being 1,820.]

LEYTONSTONE.—For the completion of the Bethnal Green Schools at Leytonstone, Essex, for the Guardians. Messrs. A. & C. Harston, architects, 15, Leadenhall-street. Quantities supplied.—

Table listing contractors and amounts for Leytonstone project, including J. & H. Cochs, Ingram & Son, H. & H. F. Higgs, J. Holland, R. Edwards, D. Brown & Co., W. Johnson, S. Grist, Jackson & Todd, and J. S. Robson.

LONDON.—For alterations and additions to the Robinck Tavern, Hackney-road, for Messrs. Bruce Bros. Messrs. Williams & Son, architects.—

Table listing contractors and amounts for Robinck Tavern project, including J. Anley, Thomerson, Ivory, and Jackson & Todd.

LONDON.—For the erection of factory and warehouse at Mount-street, Bethnal Green, for Messrs. Nicholson & Sons. Mr. C. H. Winter, architect.—

Jackson & Todd £25,570 0 0 \* Revised estimate accepted.

LONDON.—For the erection of the Olive Branch Tavern, Waterloo-road, for Messrs. Hart & Son. Mr. J. G. Finch Noyes, architect.—

Table listing contractors and amounts for Olive Branch Tavern project, including Patrick, Boyce, Patman & Co., Kilby & Gayford, Lawrence & Son, Canning & Mulliken, Spencer & Co., and Jackson & Todd.

LONDON.—For alterations and additions to the Colchester Arms, Salisbury-street, Jamaica-road, Bermondsey. Messrs. Williams & Son, architects.—

Table listing contractors and amounts for Colchester Arms project, including Staines & Son and Jackson & Todd.

LONDON.—For alterations and additions at George-yard, Soho-square, for Messrs. A. Goslett & Co. Mr. S. C. Capes, architect. Quantities not supplied.—

Table listing contractors and amounts for George-yard project, including Bush, Chappell, Lawrence, and Nightingale.

LONDON.—For gasfitting works at the Crown and Anchor, Finsbury.—

Table listing contractors and amounts for Crown and Anchor project, including Earl & Philips, Green & Son, Clark, and W. Winn.

LONDON.—For building new ball-room at 18, Salisbury-road, Dalston, for Mr. Hind. Mr. Wu. Shrobsbridge, architect.—

Table listing contractors and amounts for Salisbury-road project, including Dearing & Son and Anley.

LONDON.—For the erection of a house in Regent-gardens, South Kensington, for Mr. W. Wetherley. Mr. T. H. Smith, architect, 17, Basinghall-street.—

Mathews & Son £2,400 0 0 \* Exclusive of internal painting and decorations.

LONDON.—For rebuilding the Goat in Boots public-house, Fulham-road, and the erection of three houses and shops on site adjoining, for Mr. W. Prangell. Mr. T. H. Smith, architect, 17, Basinghall-street. Quantities by Mr. J. T. Wallford, 119, Buckingham Palace-road.—

Table listing contractors and amounts for Goat in Boots project, including W. Gregar, J. & J. Greenwood, Patman & Fotheringham, E. Lawrence & Sons, Holliday & Greenwood, Jackson & Todd, Spencer & Co., and Turtle & Appleton.

ORPINGTON (Kent).—For Mission Chapel at Crofton. Mr. St. Pierre Harris, A.R.I.B.A., architect and surveyor, 1, Basinghall-street, and Orpington.—

Table listing contractors and amounts for Mission Chapel project, including H. Somerset & Son and W. Holt.

PORTSMOUTH.—For reseating, alterations, heating apparatus, cleaning, and painting, &c., Daniel-street Wesleyan Chapel, Portsea. Mr. A. E. J. Guy, architect, 33, Lion-terrace, Portsea. Quantities by Mr. Jas. W. Stroud, 33, Lion-terrace, Portsea.—

Table listing contractors and amounts for Wesleyan Chapel project, including Matthews Bros., F. Francis, W. R. & C. Light, T. Bowler, Crook & Sons, C. Dye, F. White, E. & A. Spriggings, J. Crockerell, Outridge & Reading, Sossamell & Dowdell, T. Quick, and T. P. Hall.

PORTSMOUTH.—For reseating, gallery front, rostrum and painting and decorating the Wesley Chapel, Arundel-street, Landport. Mr. A. E. J. Guy, architect, 33, Lion-terrace, Portsea. Quantities by Mr. Jas. W. Stroud, Lion-terrace, Portsea.—

Table listing contractors and amounts for Wesley Chapel project, including J. Crockerell, W. Learmonth, W. Coltherup, Cleland & Purtee, B. Stokes, C. Dye, T. W. Quick, N. P. Hall, Scammel & Dowdell, and John Bottrill.

READING.—For erecting new house in Hamilton-road, Reading, for Mr. C. Batho. Mr. Jos. Morris, architect, Reading.—

John Bottrill, Reading (accepted) £375 0 0 [No competition.]

ROMFORD (Essex).—For erecting a cottage hospital. Messrs. Frank Brown & John S. Corder, joint architects, 9, Thorburn, Ipswich.—

Table listing contractors and amounts for cottage hospital project, including Hines, Hammond & Son, Dowling & Davis, and Booth.

SANDY ( Beds).—For the erection of Baptist Chapel, Sandy. Messrs. Fisher & Anthony, architects, 9, St Paul's-square, Bedford.—

Table listing contractors and amounts for Baptist Chapel project, including Kimberley, Banbury, Jacklin, Royston, Foster, Kempston, White, Harrison, Saini, Wicket & Walker, Page, Buckden, Rainford & Bartle, Petars, Potton, Woodman, Ellwood & Son, and Wade.

SOUTH SHIELDS.—For alterations to business premises, for Mr. T. A. Dry, jun. Mr. Henry Griever, A.R.I.B.A., architect.—

Table listing contractors and amounts for business premises project, including Jos. Wright, Gillilan & Hall, George Goddard, Nicholas Napier, John Yeates, W. J. Robertson, Stephen Sheriff, and John Shields.

WANDSWORTH.—For lifts at the Infirmary extension, St. John's Hill, New Wandsworth, for the Guardians of the Wandsworth and Clapham Union. Mr. Thos. W. Aldwinckle, architect, 2, East India-avenue, London.—

Table listing contractors and amounts for Wandsworth project, including G. Scott & Son, Geo. Johnson, Archd. Smith & Stevens, W. R. Dell & Son, Atwood & Co., T. Thomas & Sons, and Middleton.

WEST MARDEN (Sussex).—For completing house and stables at West Marden, Sussex, for Mr. Alexander Beale. Mr. William J. Martin, F.R.I.B.A., architect, Reading.—

Table listing contractors and amounts for West Marden project, including Robert Pink, J. & A. Gammon, Crook & Sons, Snell & Co., Cozens & Chase, and Joseph King.

WIX (Essex).—For the erection of new chancel, and restoration and reseating the nave, of St. Mary's Church, for the Vicar and Wardens. Messrs. Wainmore & Baker, architects, 35, Great St. Helena, London. Quantities supplied.—

Table listing contractors and amounts for St. Mary's Church project, including Alfred Coe, J. Grimes, Everest & Son, O. T. Gibbons, and A. Brown.

### Technical School and College Building.

THE large and practical volume brought out under this title\* by an architect who has made a special study of the subject, may be said to be a book for the times; for though the recently

proposed Technical Education Bill failed to pass, owing in great measure to its own inherently unsatisfactory character, there is no doubt that technical education is fairly in the air at last in this country, and that the provision of buildings for the efficient and convenient administration of this class of instruction is one of the special services which will be increasingly demanded from English architects for the next quarter of a century, and for which they will require to qualify themselves. Mr. Robins, the author of the present volume, and Mr. Waterhouse, the architect of more than one large and in the main successful technical school, have secured the honour of leading the way.

Mr. Robins logically concludes that before considering what is required in schools for technical education, it is well to come to some conclusion as to what technical education consists in and what is its main object. In regard to this there have been many different opinions, but the reasonable view, and the one which is likely to be adopted by the majority of those who give any thought to the subject, is that expressed by Professor Huxley, Professor Ayrton, and the late Professor Fleeming Jenkin, from each of whom are quoted (p. 13) expressions which practically all concur in the same opinion, viz., that the object of technical education is not to teach trades (which Professor Jenkin characterised as "a mischievous delusion"), but to give a training in the principles of applied science generally, with some more special instruction in that branch of science which bears more immediately on the trade which the student intends to follow; but not professing to teach him any of the special manipulation of his trade: that he must learn elsewhere.

It is obvious that an institution on a large scale, to give general instruction on applied science, would be one of a very extensive and complicated nature, including the provision of a great variety of what may be termed

"scientific plant." Indeed, the programme of a German "Realschule of the first grade," for students between the ages of ten and nineteen, is a little bewildering to the mind. It includes German, French, and English; a little Latin, and "plenty of mathematics"; a fair knowledge of natural history, chemistry, physics, &c.; and the list ends up with "history, geography, singing, gymnastics, drawing, machine-drawing, and religion."\* We do not find among the diagrams of apparatus given in Mr. Robins's book any plans or sections of the desks and apparatus for teaching religion, though we have no doubt the systematic German mind will have developed something of the kind. Apart, however, from the "religion," this curriculum, with its languages, history, and geography, is, of course, beyond the scope of a technical school, properly so called. And it is one of the points in which the book seems a little defective, that we do not find anywhere a distinct summary of what the author considers should be included in a Technical College, and of the accommodation required in such a building, and the best manner of arranging and planning the various departments, in themselves and in relation to one another. The reader can gather a great deal about the requirements from a comparison of the plans and descriptions of various existing buildings; but we have not found any definite description of the requirements for a model technical college; and the buildings illustrated to which the term "college" would properly apply, as establishments including the whole curriculum of a technical or scientific education, are not numerous. The majority of them are schools for special training in one or two branches of technical study; and in regard to these we observe that chemical schools and laboratories occupy by far the largest place: in fact, the great majority of the illustrations of *matériel* refer entirely to chemistry. One reason, of course, for this is that rooms and plant for chemical classes present special difficulties in planning and arrangement, owing to the necessity for a complicated service of taps, pipes, and sinks, and still more for a special and thorough system of exhaust ventilation to draw off foul gases; and no doubt the many ingenious contrivances which have been adopted to serve this latter end, as well as to form a perfectly convenient arrangement of tables, shelves, and seats, are of special interest, and represent that portion of the furniture of a science school which most emphatically calls for special knowledge and study on the part

of the architect. Nevertheless, there seems rather too much space bestowed on this branch of the subject in comparison with others which are hardly illustrated at all.

The programme of the *Polytechnikum* of Zurich (quoted page 18), comes nearest perhaps to the proper programme of a technical school. This Mr. Robins gives as including "Physics, chemistry, machine, engineering,\* architecture, drawing, modelling, agriculture, forestry, botany, &c." What remains to be added under the head of "&c.," of course, we cannot say; probably only unimportant matters. Architecture appears to us to be out of the proper scope of a technical college, which might as well in that case include ornamental design and other artistic subjects; but it is possible that "architecture" really means here "building construction." Our idea of the programme of a technical college would be to include physics, chemistry, and mechanics; physiology, botany, and mineralogy; mathematics, geometry, and drawing: the latter not in the artistic sense, but as the cultivation of the power of delineating on paper whatever it is desired to illustrate. The three first heads include the study of the forces of nature; the three next that of the facts in regard to the three great divisions of animal, vegetable, and mineral life (so to speak); the three last with the power of measuring and comparing imaginary and visible quantities or forces, and of delineation in intelligible form. Such subjects as engineering, architecture, agriculture, forestry, &c., appear to us to be beyond the proper scope of a technical college; they are the practical applications of theoretic knowledge to special ends; they are, in fact, "trades," and it is not the business of a technical college to teach trades. A man who intends to be an architect, an engineer, or a cultivator of land, should go to an architect's or engineer's office,† or to an agricultural school, from the technical college, bringing his general theoretical knowledge acquired at the college to bear on the special problems of his intended profession.

No college exactly on such a plan is figured among Mr. Robins's illustrations; but the mass of information, and the number of plans of various buildings which are given, will be of great use to any one in putting together a complete scheme, and as affording suggestions and memoranda as to what is needed in each department. We only complain that there is a want of systematic exposition. On p. 45, in the

\* So in text; probably the comma is a misprint, and it should read "machine-engineering," i.e., mechanical engineering.

† Speaking of course in reference to England, where there are no architectural and engineering colleges, except those for preparation for the Royal Engineers and for the Indian Public Works Department.

\* Technical School and College Building: being a Treatise on the Design and Construction of Applied Science and Art Buildings, and their suitable Fittings and Sanitation; with a chapter on Technical Education, by Edward Cookworthy Robins, F.S.A., F.R.I.B.A., &c. London: Whitaker & Co. 1887.

\* We heard a story of a well-known painter, who was educated abroad, lamenting that he had received a check early in life, from having "failed in chemistry and religion." It appears this may have been uttered in sober seriousness.

chapter on "Buildings for Applied Science and Art Instruction," we read:—"To proceed to details. It is desirable, in the first place, to note the particular accommodation required for some of the leading special subjects, number and relative portion of apartments; in short, the systematic general arrangement of the plan." This is just what we want, but we do not get it. We only get details about the arrangement of the chemical department, and then we go off to plans and descriptions of various foreign buildings. A great deal, as we have said, may be extracted from these; but to present a number of different examples for inspection, and merely let us pick what we can out of them, is hardly a complete manner of treating the subject.

In a general way, the English plans given in the book are much less formal and probably more utilitarian in arrangement than the foreign ones. They are mostly, it must be admitted, not such large buildings; but the French and Germans are, as might be expected, very much possessed with the idea of architectural symmetry in laying out buildings of this kind; the architectural arrangement seems to come first, as far as the main massing of the plan is concerned, and the groups of rooms are then fitted into it. This, it is needless to observe, is not the most practical or philosophical manner of going to work; and it is not surprising that we are conscious of waste spaces and passages that either "lead to nothing" or take an unconsciously round-about course in leading to something, in some of these Continental plans. The desideratum is, to have sufficient space for light and ventilation, without unduly long passages of communication, and especially to have those apartments which have to be used in conjunction with one another near together. Thus, in the case of one chemical laboratory, it is mentioned that the balance-room was at such a distance from the laboratory that the journey to it was always deferred as long as possible; which, we presume, implies that guess work was used in some stages of an analysis where accurate weighing would have been desirable.

There is a separate chapter on "Fittings for Applied Science Buildings," but this again is mainly occupied with chemical laboratory fittings. No doubt, for reasons above mentioned, these are the most difficult to deal with, and a great many sections are shown of various ingenious arrangements for carrying off noxious gases at once from the work-table, for the study of which we must refer the reader to the illustrations in Mr. Robins's pages. Two of the most efficient seem to be that at Finshury, designed by Dr. Armstrong and shown on plate 50, where there is a down-draught escape running, with a narrow opening, along the whole length of the draught closet, and the one in use at the South Kensington building, which is essentially the same form of outlet contrived so as to serve two sets of workers, the down-draught flue, with its two sides, forming a kind of partition down the centre of the table, each side forming practically a separate table. In nearly all cases a collecting hood is placed over the table, so as to catch the vapours and convey them to the extract flue. A very ingenious modification of the draught-closet is that invented by Professor Hofman, and shown in plate 47. When draught-closet flues pass directly upwards (which is sometimes, it may be presumed, a more convenient arrangement when an extracting system of ventilation is employed), it is found that condensed liquid and dirt are very liable to drop into the closet and vitiate experiments there being performed. The Hofman method takes the flue up with a bend towards the back of the closet at first, then under the vertical portion is formed a receptacle for receiving anything that may fall from the flue. In most of the recently-constructed large public laboratories, we are told, the flues from the various closets are all connected with the central flue, and the draught is produced either by a shaft with a furnace in it or by a fan, anent which Mr. Robins observes that no competing draughts should be introduced into a chemical laboratory; "no two opposite

ways should be provided for the escape of the air; and, as the draught-closets cannot well be too efficient, the whole of the air of the laboratory may be exhausted through them, but it is better to have additional outlets." This seems rather a contradiction. The author mentions elsewhere that in certain cases extract ventilation through the draught-closets has answered completely. As he says, and as every one knows, it is no use trying to extract forcibly through two separate systems of outlets, for that is merely making one a passage to the other, and in that case what do we want with additional outlets?

In regard to ventilation, the author is entirely for mechanical ventilation, as every scientific architect must inevitably be now, after all the evidence that has been before us, as to the relative efficiency of mechanical and what is rather absurdly termed natural ventilation. He seems to be against injection of air, though he quotes the testimony of Professor Carnelly, of University College, Dublin, to the effect that the system of forcing in air by air-pumps, over heated pipes, and allowing it to escape by the draught closets, instead of extracting from them by aspiration, had answered very well there. We should be disposed to prefer the extraction system,—in the case, at all events, of a chemical laboratory, where it is so requisite to remove gases instantly and by the most direct path. A hood opening into an extract flue would be more certain and immediate in its action of extracting gases formed in its neighbourhood, than a system in which general pressure of the air in the room was the agent. The gas formed by a special experiment might even, in that case, be dispersed to some extent before being forced up the nearest extraction-flue. From the chapter on "Heating and Ventilation," in which a great deal of information, not new mostly, is very conveniently summarised, it appears that the propulsion system at Finshury Technical College has developed various defects,—dust comes from the flues, which are pargeled, and the heating and ventilation are so closely connected that quicker ventilation cannot be had without additional heat: a point to make a memorandum of in regard to the working of combined warming and ventilation. At the City and Guilds Institute, the evil of dust has been obviated by using flues lined with a glazed surface. It is noted that at this institution the internal iron smoke-flue has been removed from the main ventilating shaft, "the experience gained at Finshury College proving its comparative inefficiency, and an extract fan has been fixed at the top of the shaft, worked by gearing from the engine in the basement": another point to be noted by those who trust to a smoke-flue up the ventilating shaft as an aspirator. As we have said, a great deal of information is collected in this chapter, and the wholesome example is quoted of Herr Baeckelmans, architect, of Antwerp, who refused to carry out the erection of the town hospital, because the Hospital Committee would not appoint an engineer to consider the plans with him, with regard to the heating and ventilation, before the foundations were laid. Honour to Herr Baeckelmans, and may we all be more like him! Among the various methods of ventilation noted and illustrated with varying favour by the author, is one which we venture to think is quite over-rated. This is the plan, described on page 167, of admitting fresh cold air through perforations in the bed-mould of the cornice of the room, and extracting through perforations in the upper member of the same, into an upcast flue with a cowl or a gas jet at the bottom, or into a smoke flue. This is recommended by Mr. Robson, who says:—"I can speak strongly in its favour for facility of application, lightness, economy of first cost, and self-acting properties." If the "pull" is a pretty strong one, we should imagine it would be very "self-acting," and that if those who recommend it will go up a ladder and smoke a cigar close to the inlet perforations, they will see the smoke taking the "girt" of the cornice and going the shortest way into the extract perforations. If it does not, it will be because the pull is a

very weak one, and in that case it is inefficient in another manner.

Among the special difficulties which have to be encountered in the design of a technical school, the most prominent, next to that of carrying off the fumes from the chemical laboratory, is the problem of providing, also in the chemical department, a perfectly steady table for the delicate tests carried on in the balance-room. We should hardly have thought the difficulty need be greater than that of mounting an equatorial telescope, though the author speaks as if it were. In one of the foreign laboratories he found the balance-room so planned as to be a passage from one room to another,—certainly a very stupid oversight. He mentions that in one case a satisfactory table had been formed by supporting it on beams under and disconnected from the actual floor. If this was successful, *à fortiori* a concrete table, built up from the foundations, and with the floor framed round it so as not to touch it, ought to answer. Of course, in cities there is a great deal of tremor of the ground to be reckoned with; equatorial telescopes of any consequence are generally kept out of cities. Professor Ayrton has been experimenting, it appears, with schemes for supporting tables on water, with the view, we presume, of escaping earth tremors; but so far without success.

A few "pictures" of technical educational buildings by the author are added to the work, but in general the illustrations are, as is fitting, severely practical; and the large number of details of fittings, very carefully drawn in elevation and section, are of great value and interest, whether regarded as precedents and models for adoption, or as suggestions for further improvement and thinking out of the subject. For the present, and probably for some time to come, Mr. Robins's book is the authority on the subject of which it treats, and is a record of a practical experience extending over a good many years, and turned to good account, though, as we have said, there might have been more logic and system in its arrangement. The volume is appropriately dedicated to Professor Huxley.

#### REPORT OF THE "SELECT COMMITTEE ON ADMIRALTY AND WAR OFFICE (SITES)."

WE have already commented on the miserable and discreditable result of the deliberations of the Committee above referred to. After going through the show of a large architectural competition, in which a design, open certainly to many objections, practical and architectural, was selected, the Committee have now recommended that the scheme for a new building should be abandoned, and that a piece of cheap patchwork should be made with an old building which has nothing to recommend it, and new ones in regard to which the main object seems to be to make a hid for popularity on the ground of economy, and to cut down the whole scheme to the level of the "cheap and nasty." Even on purely architectural grounds the decision, as we have already said, is one of which the country ought to be ashamed. But the detail of the report brings it out in an even more ignominious light. The existing main building of the Admiralty is notoriously an ill-designed and clumsy affair, not worth preserving on architectural grounds, and which could only be an excrescence on any design with which it might be incorporated. For this, of course, the general public and the legislative body care nothing, national architecture being one of the things which, in the eyes of the public and of politicians, is of no consequence whatever. But we do profess to be a practical nation, and in that light, at least, it may be matter for question with most reasonable people whether a very wise or rational thing has been done in proposing to retain and utilise, as part of an important public building, a structure which is stated, on good evidence, to have an essentially defective foundation,—the building is erected upon oak planking with sleepers laid upon it, and that oak planking lies upon a sort of mud

foundation containing water,"\*—which has already settled considerably; which is given a life of about seventy-five years at the best; which would probably settle further if any additional weight were placed on it; and which cannot be made practically suitable for its proposed purpose without raising one story and adding another; in other words, putting on that additional weight which the evidence shows that it will not bear. A more lame and impotent conclusion it would be impossible to imagine, or one saying less for the good sense or good taste of those who have arrived at it from such premises.

As usual in these cases, there is a good deal that is amusing in the proceedings, or that would be amusing to any one of a cynical turn of mind. There is no sort of evidence of architectural interest in the proceedings, the object of a great portion of which seems to have been to exhibit once more the cross-examining powers of one officious and vain busybody, whose sole object is to get, if possible, his own way. That Mr. Shaw-Lefevre has not got it in this case is certainly from no want of special pleading or of industry in examining and being examined. In his proposed "report," Mr. Shaw-Lefevre takes upon himself to affirm that it is "admitted on all hands" that the internal arrangements of Messrs. Leeming's design were excellent, and that there "is ample light and air to every part of it." He must be perfectly aware that there was strong dissatisfaction in many quarters among persons who have a claim to be called experts in such matters, in regard to the provision for light and air in the smaller courts, and that they were condemned in the strongest terms by those who know more about such matters than Mr. Shaw-Lefevre ever knew or is ever likely to know. As to the design itself, it was a very commonplace one, ornate but not noble; but though we should have had no pleasure in seeing it built, we cannot but feel, after reading the evidence in the report, that the conclusion come to is likely to prove an even greater *fiasco* than the result of the competition. An architect of genius might still make something of the proposed buildings, in a simple way, and apart from the old building it is proposed to retain; but then we are only to have the same architects, cut down to plain work. Of course, if any change had been made, the Messrs. Leeming deserved, as a matter of justice, full compensation; but we do not see that, when the scheme was abandoned, they had any absolute claim to be employed on the new scheme. However, they seem very desirous to be accommodating, and to carry out the building in any way which the authorities are pleased to prescribe; and that is no doubt one of the first of virtues in an architect, according to the English official mind.

From the lengthy evidence given by Mr. Shaw-Lefevre,—which consists, in fact, to a great extent, of a sort of essay in favour of his own views,—it appears that the objection to take Drummond's and Biddulph's banks was on the ground that the two firms had been allowed to build them without any intimation that the ground might be wanted by the Government, and that therefore there would have been something unchivalrous in dispossessing them. There is something in this, no doubt; but it is hardly what ought to stand in the way of a great public work. If it is the case that Messrs. Drummond offered their land to the Government before building, and got no reply, that is one more item of the blundering which has run through the whole history. Among other points in this "evidence" the witness is good enough to assure us that the competition was "a fair representation of the architectural talent of the country," and that he can speak on that point, as he alone knows the names beyond those of the nine selected. We do not know, it is true, the names of any other competitors except those who asked us to publish their designs; but we know who were some of those who did not and would not compete;

and we know that if the architectural talent of the country was fairly represented, the Committee did it great injustice, for one or two of the nine designs they selected for pre-emption were not only poor but absolutely vulgar. It is true we have Mr. Hardwick's evidence in admiration of the selected design; but Mr. Hardwick is the designer of Drummond's bank.

Among other points in the evidence, we observe that Mr. Shaw-Lefevre admits that in getting a vote for 10,000*l.* on account of the new building he intended to commit Parliament to that design, and to the employment of those architects. Did the members who voted know that? As Mr. Isaacs observed, it was, to say the least, "a very informal way of doing it." Among other curious points in the evidence is Mr. Taylor's theory, in regard to the lighting of the quadrangle buildings, that beyond forty-five degrees you get no more light even if the opposite buildings were removed altogether. He modified this in the next reply into the form that it is the "recognised angle for lighting a building" which is certainly a new way of putting it. It is what a man has a right to demand by law under certain circumstances, but does Mr. Taylor really believe that if a window is receiving light at an angle of 45 degrees over the top of an opposite building, that it will get no better light if that building is removed? He will not find many people who are in the habit of using their eyes to agree with him. Then Mr. Taylor, who gives evidence obviously in favour of Mr. Shaw-Lefevre's position, wants us to believe that it was quite a delusion to be shocked at the narrow, funnel-like appearance of the small courts as shown on the model (which gave many persons the first real idea of what the effect of building in this way would be); that this was the wrong way to regard it; that it would be quite different if you were down in the courts and looked up at the light. We should say that a well would look darker and deeper when you were down in it than when you were on the top; but it is not a mere question of light,—that is just the mistake; it is much more a question of ventilation, of having deep well-like receptacles in the interior of a building, which must inevitably become, in all still and warm weather, receptacles of stagnant and impure air.

Some question was raised by Mr. Isaacs in the course of the sitting as to the estimated cost of the alternative schemes, and we imagine that his questions and evidence (though very likely without his intending that result) operated a good deal with some of the committee in swaying them towards the economical conclusion ultimately adopted. Messrs. Leeming's original design was estimated at a cubical cost of 1*s.* a foot, and Mr. Taylor laid down that the alternative and much plainer building in which the old Admiralty was to be incorporated, would be 1*s.* 2*d.* a foot. This comparative proposition seems preposterous on the face of it; and Mr. Isaacs pointed out that the *Hôtel Victoria*, a building of about the same degree of decorative treatment externally as Messrs. Leeming's design, came to 1*s.* 6*d.* a cubic foot. His estimate of the possibility of executing the alternative buildings at 6*d.* or 7*d.* a foot was an excess in the other direction, unless they were to be of prison-like plainness. But 1*s.* a foot would hardly do for Messrs. Leeming's design. No doubt it would be less decoratively finished internally than a modern hotel,—for the most part at least; but all the elaborate arrangements for heating, ventilation, and sanitation which would be demanded in a great set of public offices of the present day, have a great effect in sending up the price, and we should imagine 1*s.* 3*d.* per foot would be nearer than 1*s.* Some of the ideas afloat in the Committee about cubing are rather curious. Sir William Harcourt seems to have got hold of a notion, derived, as he said, "from Mr. Denison's 'Book on Building,'" which is an authority on the subject, that a large building must necessarily be taken at a higher rate per cube foot than a smaller one. We can imagine that Sir Wm. Harcourt would be just the kind of person who would take "Denison's 'Book on Building'" to be an

authority; but the idea that a building with a proportionally greater amount of empty cubic space in it as compared with cube of walling, is to cost more per cube foot, is certainly original. Mr. Taylor endeavoured to set him right by putting in the saving clause that it would depend on whether the larger building had rooms of the same size as the smaller one, *i.e.*, a proportionately large number of small rooms and cross walls; but the matter does not seem to have been made clear. Mr. Shaw-Lefevre seems to have twisted this correction of Mr. Taylor's into another absurdity in the opposite direction, for he asks the questions (2008-9), "The rooms are lower, are they not? That would tend to add to the cost?"

Mr. Ewan Christian gave very decisive evidence:—

"My view is very decidedly that the site cannot be properly completed without the purchase of the two banks and of the houses which intervene between them. I consider that the purchase and the clearing away of those buildings is essential to the great improvement that ought to be made in connexion with this great public edifice. It is a magnificent site, and it would be a very great pity to spoil it for the sake of the saving that would be effected by leaving those buildings untouched."

Mr. Christian pointed out strongly the importance of taking advantage also of the occasion to widen the upper part of Whitehall, which could otherwise probably never be done, and said the losing the chance would be "a national misfortune." Few Englishmen probably would see it in that light, because few Englishmen understand the value to a city of such an improvement in its architectural effectiveness. Mr. Christian was one of the witnesses from whom the astute cross-examiner of the Committee could not get all the replies he wanted. The following little extract is amusing; the object of the questions being, of course, to show that Mr. Shaw-Lefevre's scheme was a splendid one, without the expense of purchasing the banks and widening Whitehall:—

"920. I presume you would be of the opinion that the façade to the Mall and to the Parade offers a very unusual opportunity for architecture?—Decidedly.

921. It is a very important site, is it not?—A most important site; that is the view I maintain.

922. Probably in London there is no more important position than would be occupied by a building with one frontage to Pall-mall and the other to the Parade?—Entirely so; and for that reason I want to see Whitehall widened.

923. I am merely asking you now about the Mall and the Parade; do you consider those very important frontages?—Most important frontages.

924. And that a building facing these two frontages would be a very important one in London?—I think that it would be one of the most important operations carried out during this century.

925. Do you think it unreasonable, therefore, that an important building should be placed there?—I do not think so at all; on the contrary, I want to see it very much; but that is the reason why I want to see Whitehall widened."

Mr. W. H. Smith was cross-examined in the same pertinacious manner; asked, for instance, if he thought it would be a wise course to extend a building with the admitted defects of the old Admiralty building? Mr. Shaw-Lefevre knew perfectly well that no one had proposed to "extend the defects" of the building; it was proposed simply to leave it incorporated in the new building. In his answers to this and other catch questions Mr. Smith was very practical, and in his objection to the useless columns projected in front of the original design, and their effect on the lighting of the rooms. But Mr. W. H. Smith's main confession of faith is irritatingly characteristic of what we have come to in England. "It would be much more economical," he observes, "to construct a building simply for purposes of business than for architectural effect. . . . I hope that public opinion will come round to erect what I should call a building for business purposes and not constructed for architectural effect." Public opinion, we fear, is only too ready to endorse such a sentiment, without waiting for any coming round. That is what we have come to; and a melancholy goal it is. We are a nation of shopkeepers; and the most eminent and successful shopkeeper of the day can see nothing to value in

\* Mr. John Taylor's evidence.

architectural splendour,—no consideration in regard to a great national building hut “how much can we save on it?”

## NOTES.

THE dreadful calamity at Exeter has, of course, brought out the usual fresh crop of suggestions and advice about the construction of theatres, which are repeated after each calamity and forgotten again till the next theatre conflagration revives them. Some of these are the mere unpractical fancies of frightened persons. Among the measures which really may be carried out with great advantage, and which are within practical possibility, are the lighting of all theatres by incandescent electric lamps, the provision of an iron fireproof curtain between the stage and the house, which should be used habitually at each performance, and the employment of some less combustible material than canvas for the scenery. The use of a fine wire gauze for painting on, which has been suggested, would, we believe, be practicable and beneficial, but it would be possibly too costly to be readily adopted, except where it was desired to keep the scenery for repeated and permanent use, when the superior lasting powers of the wire might do something towards restoring the first outlay. We do not believe actors would ever be reconciled to an iron stage floor to replace the hoards; and the effect upon the acoustic properties of the house would probably be bad. The daily use of the cut-off iron curtain is an important point, as the evidence in the Exeter case goes to show that the rapidity of the conflagration was mainly due to the flames being blown towards the auditorium by draughts from doors in the stage portion of the house. The suggestions for exterior balconies to which the audience could hetake themselves till rescued we do not think are very rational. If they were to be made safe against a sudden crowd they would be very costly to construct, and if audiences will get into panics there would very likely be as much loss of life from a rush to the doors on to the balcony,—and perhaps even from the crowd pushing those in front of them over the parapet,—as from the rush to the ordinary exit doors. It is, after all, in most cases the unfortunate people who kill themselves, and not the fire which kills them. The evidence in regard to the Exeter disaster, so far, seems to indicate that the exit from the gallery was decidedly inadequate; but it also leads to the conclusion that no one need have been hurt if people had kept their heads. To take military order and walk downstairs in step, three abreast or two abreast, or as many as the width of the stairs allows, is the thing to do; and two or three men with cool heads might induce a crowd to do this. Unfortunately the gallery, usually the most crowded part of the house and the furthest from the street, is generally occupied by just the kind of crowd which is most liable to go into an unreasoning panic. Until people can be cured of giving way to panics they will kill themselves whenever there is an alarm of fire in a theatre, and structural improvements will be of little avail.

WE have received a circular in regard to the aims of the National Association for the Promotion of Technical Education, which was inaugurated at a meeting held in London on July 1st of this year, and of which Lord Hartington is President. Among the Vice-Presidents and members of the Executive Committee are Professor Huxley, Professor Tyndall, Sir Lyon Playfair, Sir John Lubbock, Sir F. Bramwell, Sir Henry Roscoe, and others. The subjects which it is proposed should first engage the attention of the Association are at present tabulated as follow:—

“1. The encouragement of Educational Reform, whether by legislation or otherwise; to be carried out by the following amongst other means:—  
(a) The promotion in our primary schools of the better training of the hand and eye by improved instruction in drawing, in the elements of science, and the elementary use of tools. (b) The introduction of such changes in the present system of primary instruction as may be necessary to enable children to take advantage of technical teaching.

(c) The more extended provision of higher elementary schools, where technical education may be provided for those who are fit to take advantage of it. (d) The reform of the present system of evening schools, with special provisions for the encouragement of technical (including commercial and agricultural) instruction. (e) The development, organisation, and maintenance of a system of secondary education throughout the country, with a view to placing the higher technical and commercial education in our schools and colleges on a better footing. (f) The improvement of the training of teachers, so that they may take an effective part in the work which the Association desires to forward. 2. The formation of a central consultative body, which will give opportunities for conference between persons of various classes and from different localities, will form and influence public opinion, and will obtain public support for the furtherance of technical education. 3. The collection of information as to the existing means for carrying out the work of technical education, and the best methods of extending and organising it throughout the United Kingdom. 4. The preparation, in a popular form, of information to be obtained from Reports of Commissions, Consular Reports, and from various other sources (including, if necessary, special inquiries at home and abroad), for diffusion throughout the country.”

It is proposed to form branches in various industrial towns, and a circular letter has been addressed to those known to be interested in the subject, asking them to give the names of others in their town or district who would be able to give advice as to the work of the Association, and also information as to what has been actually done in the way of technical education in their own neighbourhood. This appears a business-like way of getting an enlightened public opinion on the subject, and promoting public interest in it, which is an almost necessary preliminary to getting any complete educational measure carried out.

IN the matter of absurd wrong-headedness, the Trades Union Congress appears to go from bad to worse. It now meets not to consider questions of trade, but to criticise political action from a Utopian standpoint of its own, on which the glorified working man takes his place as the centre of the universe. The usual clamour about an eight hours' movement was brought forward, on the principle apparently that the less work we do the more prosperous we shall be, and Mr. Broadhurst was taken to task for having presumed to vote against an eight-hours amendment in the Coal Mines Bill. Mr. Broadhurst, however, is not the member to put up with this kind of thing, or to allow himself to be dragged at the heels of a committee, and he gave the principal accuser, a certain Mr. Hardie, “frae the North,” an answer which must have made him feel rather small.

A NEW use has been discovered for the water of the river Thames as it is found near Blackwall. It makes an efficient ink. Whether the fluid is agreeable, or even inoffensive, in the inkstand is not stated. But letters have been written to the daily papers in this medium, and as they have appeared in print the ink has, at all events, remained legible when dry. The attention of the Home Secretary was called to this phenomenon in the House of Commons, on September 1st, and Mr. Matthews expressed the hope that “when the new works now in progress are completed the cause of complaint will be lessened, if not removed.” It would be consolatory to have the scientific ground for the hope stated. It seems not to have occurred to any one to ask for an explanation of the colour. The Metropolitan Board ought not to be surprised at its appearance. It is only the recurrence of what has taken place at Bradford, Northampton, Leicester, Clifton, Cheltenham,—in fact, everywhere where a mixture of lime with any iron salt has been applied to sewage. This fact has been brought before the Institution of Civil Engineers (“Minutes of Proceedings,” vol. 85, p. 223); not is the colour the worst part of the affair. The first action of the compound is apparently satisfactory, and clarification goes on rapidly. But after a sufficient lapse of time in the laboratory, or after a flow of four or five miles down the river, a secondary action commences, and the liberation of hydrogen gas causes an intolerable nuisance. At North-

ampton 62·30 grains out of 119·78 grains of foreign matter per gallon were precipitated by chloride of iron and lime, which removed almost the whole of the suspended matter in the sewage, while increasing that in solution. But the secondary action was so offensive that the Court of Chancery granted an injunction against the process, which was in consequence abandoned, as was the case in the other places mentioned. The treatment of the whole volume of London sewage by the same process may thus be not unreasonably expected to intensify the nuisance, which has thus far justified the warning given at the Institution of Civil Engineers.

THE subject of the Channel Tunnel has come up at the British Association in the shape of a report, drawn up by Mr. F. Brady, Mr. Pigou, and Professor Boyd Dawkins. The report is entirely in favour of the tunnel, so far as the behaviour of the ground, as far as the boring has been carried, is concerned. The authors of the report are contemptuous about the military objections, their report being obviously made in what are supposed to be commercial interests. But they do not touch on the subject of the means of properly ventilating a tunnel twenty-five miles long, with no possibility of intermediate upcast shafts. This, independently of the military objections, is one of the points which must be satisfactorily settled before things are allowed to go further.

THE Law and City Courts Committee recommend the Corporation to take no further steps at present to acquire the site of No. 84, Basinghall-street for the new Court, since they have failed to make satisfactory terms with the leaseholders and tenants. On the other hand, they advocate the adoption of some plans and elevations, in the Gothic style, as an alternative for some others in the Italian style, all prepared by Mr. A. Murray, acting architect. Mr. Murray's plans cover the present Court site, together with the Guildhall stores and land tax rooms, and are capable of extension so as to take in the new site of No. 84, Basinghall-street, if it be eventually secured. The cost of the initial buildings is estimated at about 14,500*l.* which should be added 1,500*l.* for fittings. A complete development of the scheme would involve an additional outlay of say 6,000*l.* The Committee accordingly ask for authority to draw for 16,000*l.* upon the City of London Court general fund wherewith to proceed with the erection of new Court buildings.

ADDITIONAL buildings are about to be erected by the Government at Edinburgh Castle, and, judging from past experience, we are not sanguine as to the result being a gain from an aesthetic point of view. We gather from the *Scotsman* that the Town Council, “in their capacity as Guardians of the amenity of the City, urged certain objections to the scheme.” The principal part of this scheme consists in the erection of a guard-house at the entrance to the ancient fortress, and certain adjuncts. “It was thought that the guard-room might have been more artistically designed, and fears were expressed that the screen wall would interfere with the view of the Castle Rock. It is not clear whether these objections took written shape, but recently, when the subject was revived, the Council were informed that the day of grace for lodging objections had passed, and that the scheme must be proceeded with as designed by the English officials.” The guard-house is to be in a “castellated” style of architecture, with loopholes, battlemented parapet, gables, and turrets, rising to a height of 50 ft., pierced by a circular archway. The upper floor is to be utilised as a court-martial room. Contracts for the building have been entered into, which will now be pushed on with all convenient speed.

NOTHING shows the unquenchable vitality of the United States so much as its railway mileage account for 1886 and part of this year. Notwithstanding strikes, droughts, and depression of trade, the enormous quantity of 10,000 miles is expected to be the sum

of this year's laying, more than ever has been known before except in 1882, when 11,568 miles were put down. This brings up the total of the American railway mileage to 141,900 miles, half of which has made its appearance altogether since 1874, 70,000 miles in thirteen years. As might be expected, some parts of the country are especially active in railway making, the Eastern or older States contributing little or nothing to the general stock, while the South (Texas particularly) and the North-West have been the busiest, showing the growth of population and industrial undertakings. The fact is that the Southern States, though pretty old in years, have practically only just begun their real commercial life (always excepting cotton), and so far are only on a par with younger States in the North-West, like Kansas and Dakota. Even at the very moderate estimate of 25,000 dols. per mile, including stations, put down for the construction of North American railways, the 93,750,000 dols. is a pretty large sum to disburse for carriage purposes.

AN interesting has-relief relating to the myth of Pentheus has just been published in the "Bulletino della Commissione Archeologica Comunale di Roma" (xv., 7). It was found during the excavations carried on by Sir Savile Lumley, the English Ambassador, in the Via Portuense. The figure of Pentheus occupies the centre of the design; in his right hand he holds a sword which he has just drawn from the scabbard he holds in his left. On either side of him is a Maenad brandishing a thyrsos and with a snake coiled about her left arm. The type of the design is much the same as that currently employed to represent Orestes pursued by the Furies, but from the fact that the two women hold thyrsi in their hands there can be no doubt of their Bacchic intent, and hence the youth they pursue must be Pentheus. The relief is executed in the pseudo-archaic style, and Sig. Borsari, who edits it, thinks that from the character of the tomb in which it was found it belongs to the first century A.D. Figured monuments of the myth of Pentheus are notably rare.

SINCE the discovery of the Pergamene frieze with the Gigantomachia, special interest has naturally attached to everything dealing with the mythology of the Giants. It might almost certainly have been predicted that Germany would shortly furnish us with an exhaustive treatise on the myth as it appears in literature and art. Such a treatise is in fact "Die Giganten und Titanen in der Antiken Sage und Kunst," just published by Dr. Maximilian Mayer,—a book which will be read by only a few, but referred to by many. Herr Mayer devotes the first part of his book to the literature of the subject. He gives all the variant saga of the Giants and Titans collectively, and of the several individual Giants and Titans whose names have come down to us. Next, he gives in chronological sequence the various forms of the Gigantomachia. Under the head of Art, he goes through, first, the description of works of art that have perished; then representations on vases, sculptures, and smaller monuments, such as terra-cotta gems and coins. The book is illustrated by three plates and a few woodcuts.

THE house, No. 42, Lothian-street, Edinburgh, which was formerly occupied by Thomas de Quincey, and where he died in 1850, has been distinguished by a tablet, composed of tiles with an ornamental border, the letters being in ivory white on an Indian red ground. The inscription is as follows:—

THOMAS DE QUINCEY,  
PROSE WRITER,  
Born 1785—Died 1850,  
LIVED HERE.

Something of a similar description is to be done upon a new building in course of erection in Chambers-street, upon the site of the house where Sir Walter Scott was born. The house where he resided in Castle-street might also be distinguished, and there are many others throughout the city which were occupied by

men of note where tablets might be inserted. The pillar which is to receive the statue of the Duke of Buccleuch, by Mr. Boehm, has been complete for several weeks; the statue and other sculptures are on the ground ready to be fitted up, but nothing is being done. A high canvas screen hides all within from view, and we are given to understand that things will remain *in statu quo* till the 6th of next month, when there will be a ceremonial inauguration and banquet.

BY the removal of some old houses at the south-west corner of Little Queen-street, Holborn, there is now afforded an excellent opportunity of making a great and long-needed improvement. The point in question is at the junction of Little Queen-street with Great Queen-street, and everybody who knows these streets is aware of the large amount of vehicular traffic which they take, and is acquainted with the great frequency of accidents and blocks, caused by the narrowness of Little Queen-street and the abruptness of the turn into Great Queen-street. We would commend to the notice of the Holborn District Board of Works, and others whom it may concern, the desirability of utilising part of the now vacant site by rounding-off the angle so as the better to accommodate the ever-increasing traffic. That the traffic is increasing is shown by the fact that these two streets now form part of the route of two lines of omnibuses, running between the King's Cross and Victoria termini. Great Queen-street and Little Queen-street certainly form an important link between main arteries for through traffic, and the improvement which is now possible may therefore, we think, be fairly regarded as "metropolitan" rather than "local" in character,—a distinction which, if recognised at Spring-gardens, would permit of half of the cost (which cannot be very considerable) being defrayed by the Metropolitan Board of Works.

FROM a report published in the *Nouvelles Annales de la Construction*, the total area of the streets of Paris, measured between the kerbs, amounted at the end of 1886 to 3,517,100 square metres (91,678,065 square feet), of which 6,252,000 square metres are laid in granite, 1,608,100 square metres macadamised, 302,000 square metres asphalted, and 355,000 square metres provided with wood pavement. The cost last year for relaying and repairs amounted to 11,000,000 fr. (440,000*l.*). To put all the streets of Paris into thorough order would require about 75,000,000 fr. (3,000,000*l.*), of which 15 millions would have to be spent in changing macadamised roads into pavement, and 60 millions in improving existing pavements. It has not yet been determined in what way the latter is to be effected. The hed of concrete under a pavement of stone cubes, which has been tried in the Rue St. Lazare, has not answered. The noise caused by the passing traffic has been increased, whilst the vibration is felt more than ever in the houses. It has been found, moreover, that the Yvette sandstone employed, notwithstanding its great hardness, is being crushed between the hed of concrete and the wheels of vehicles as between an anvil and a hammer. The experimental pavement laid down in the Rue de Rivoli, in which a layer of sand has been introduced between the hed of concrete and the stone cubes, in order to ensure a certain amount of elasticity, has proved more successful. Wood pavements appear to give every satisfaction at Paris, and they are now also to be introduced in the tracks of tramways.

THE surplus fund derived from the International Exhibition of last year at Edinburgh has not yet been disposed of. To aid in the building of a mechanical laboratory in connexion with the chair of Engineering in the University, for which a sum of 10,000*l.* is needed, Professor Armstrong has advanced a claim upon that fund. "No provision," says the Professor, "has been made for supplying the department with anything in the shape of a proper equipment for teaching appliances viewed from the modern standpoint,"—a state of things which he trusts will be remedied.

IN the series of "Öffentliche Vorträge," published annually at Basle, and which for the most part treat of scientific subjects, Dr. Hugo Blunmer, a Zurich professor, has a paper worth reading on the "Life and Education of a Greek Artist" (Lebens und Bildungsgang eines griechischen Künstlers). As he rightly says, to write the history of any individual artist would be impossible; we have no Vasari for Greek artists; hut to put together a sort of mosaic of scattered notices, and thereby construct for artist life as a whole a sort of conjectural biography, is a possible and by no means an unprofitable task. He has brought together a number of interesting details as to the status of the artist, his relation to his model, the relation of master and pupil, students' fees, the price of works of art, and the like. It will surprise many to learn that enthusiasts about art as the Greeks were, they nevertheless looked down with a frank contempt on the artist as a handicraftsman. This rule of general etiquette was, it is true, honoured in the breach: Pheidias was the friend of Pericles, and Lysippus the companion of Alexander: hut an artist hut to rise to pre-eminence before he rid himself of the social slur. The *locus classicus* on this point is, of course, Lucian's account of his own brief apprenticeship to art in the sculptor's studio. Lucian, the most susceptible of art critics, puts into the mouth of his dream-lady, Eloquence (a special pleader, it is true), this description of a statuary's life:—"By turning statuary you will become nothing but a low mechanic, living on the work of your hands, and confining all your hopes and desires to that alone; getting a mean and scanty subsistence in obscurity, poor and dejected, neither serviceable to your friends nor formidable to your enemies, neither courted nor envied by your fellow citizens: a low plebeian always, like the timid hare, in dread of your superiors, and looking up with adoration to the great and eloquent above you. Should you even become a Pheidias or Polycletois, all men will admire your skill, hut not one, whilst they are in their senses, will wish to change conditions with you; for, after all, you will be considered as a vulgar mechanic (*χρυσόμας*), who lives by the labour of his hands." Certainly the modern cult of the craftsman was not in vogue at Athens.

A CORRESPONDENT, writing in reference to our foot-note to the article on "Recent Excavations at the Acropolis" (page 319, ante), observes that *στεφανί* is not correctly translated a "wreath." It is not; a "circuit" would be the more correct expression. But when our correspondent goes on to defend the use of "stephane" as an English word, we are quite impenitent. There is an absurd tendency in the present day to invent new systems of nomenclature in art and archaeology (not to speak of such varieties as Alpine club slang, with its "arêtes" and "schrunds," &c.); South Kensington has a jargon of its own; Greek archaeologists threaten us with another. There are English words enough to describe most objects in art, without using hasted Anglo-Greek.

JUDGING from the report in *L'Emulation*, an architectural contemporary hailing from Brussels, of an excursion by a party of Belgian architects to Maestricht, Aix-la-Chapelle, and Cologne, recently, the architectural confraternity in that part of the world seem to have a gay and light-hearted manner of enjoying themselves and entertaining their *confrères*. At a dinner given to the visitors at the "Dragon d'Or" at Cologne, the usual toasts and speeches were varied by the singing of songs composed for the occasion. The chorus of one of them is sufficiently to the point for quotation:—

"Ob gothisch ob roman,  
Man fängt's mit trinken an,  
Ob Renaissance und Zopf,  
Es trinkt ein jeder Tropf,  
Rococco, Négrée,  
Das hat ein Jeder weg,  
Im Fläm'schen Styl, Pariser Styl, im Misch-  
maschstyl, mit Schnickschnack viel,—  
Bei allem Bruen, das ich nannte,  
Da trinkt man stets das aherkannte  
Das elegante und pikante,—  
Hooch  
La Société Centrale d'Architecture—Hurrah!"

ENGLISH ARCHÆOLOGISTS IN  
BRITANNY.

On the evening of Thursday, the 11th of August, the day but one following the close of the Salisbury meeting of the Royal Archaeological Institute, a party of the members, joined by several members of the Wiltshire Archaeological Society, started from Southampton for Cherbourg to fulfil an invitation given in the spring of this year to the members of the Institute by the Société Polymathique du Morbihan, asking them to visit their district in the south of Brittany, which is one of the richest in the world in prehistoric remains. We are indebted to a member of the party for the following account of the visit:—

The travellers arrived at Cherbourg early on Friday morning, the 12th inst., after a fine passage, and by midday reached Coutances, their first stopping-place, where they visited the cathedral, the churches of St. Nicholas and St. Pierre, and the public gardens. The present cathedral is stated to have been commenced in 1206, on the site of an earlier eleventh-century church, of which no remains are now visible. Whether this date be correct or not, the church is undoubtedly of early thirteenth-century date, and very nearly coeval with Salisbury Cathedral, which the visitors had seen only a few days previously. It contrasts with Salisbury by having a lofty lantern tower as an integral part of the design of the original builders; and the two churches show how the architects of France and England worked side by side, each carrying out the same principles. The cathedral was readily thrown open to the party, who, by the kindness of the authorities and of the Mayor of the town, had an ample opportunity of inspecting every part of it. The glorious lantern is too well known to require more than passing mention; but the exquisite foliage carving to be found in many parts of the church, but especially in the two lateral porches so singularly placed at the extreme west end of the nave, received, as it deserved, attentive study. It has up to the present happily escaped restoration, and should on no account be missed by any architectural visitor to Coutances. The demon of restoration, doing his destructive work all over France, is happily absent from Coutances just now. Some repairs are being done, chiefly to the north windows of the nave and to the lantern. A beautiful chapel on the south side of the choir is in a sadly neglected condition, but probably requires little more than cleaning and the removal of a mass of incongruous furniture. The other two churches of Coutances are often overlooked, but are both interesting. St. Nicholas, a large cruciform church, has choir and crossing of apparently late thirteenth-century work, with later nave, while St. Pierre, a Flamboyant church, also cruciform in plan, is surmounted by an octagonal lantern, Renaissance in style, the design evidently inspired by that of the cathedral, and showing how the architects of the sixteenth century could apply in their own style a design used in the cathedral by those of the thirteenth. In domestic work the city cannot be called rich, but there are very many old houses to be found which have so far escaped the hand of the restorer.

One of the great beauties of Coutances is its public garden bequeathed to the town, together with his house now used as a museum by a private citizen. After the fatigues of the day and the previous night, its quiet shade and fine view were exceedingly grateful to the English party. The visitors went on in the evening to Pont Orson, where they spent the night, visiting next day Mont St. Michel. This noble pile of buildings has now been taken over as a national monument by the French Government, who, although they allow no religious service within the walls, are busily engaged in putting the church and monastery through a process of restoration. The spirit in which this is carried out may be judged from the fact that after thoroughly scraping the First Pointed carving of the cloister, which was, perhaps, in beauty, second to no Gothic carving in the world, making all the shafts "as good as new," the ambulatory has been covered with a high-pitched roof of black glazed tiles having a broad band of brightly-glazed tiles coloured orange and blue carried horizontally half-way up the roof completely round the four sides of the square. The church is now in hand for complete restoration,—by no means the first time it has gone through the process, and it is much

to be feared that in a few months hardly a stone of the fine Norman nave and transepts, which, if correctly dated 1020, are among the earliest known specimens of Norman work left, will be seen in its original condition. The dormitory, which is placed in an unusual position on the east side of the cloister, and on the same level, is next to be taken in hand, after which the turns of the Salle des Chevaliers and the Salle des Moines will, no doubt, come. All who wish to see the Mount before this destructive process is carried out should lose no time in visiting it.

Pont Orson, where the travellers first saw Brittany, is generally overlooked by visitors to Mont St. Michel, but there is a good deal to be found there of interest to architect and archaeologist. The church has a Norman nave, with central tower, chancel, and transepts of later date. The sculpture of the Norman south door of the nave is very remarkable. The tympanum is plain, but in the middle of it is sculptured in low relief the figure of a man standing apparently with his hands on each side of his waist, while a bird, nearly as tall as the man, standing erect, with the end of his tail in the ground, and his two feet on the man's right hip, is pecking at his neck with his beak. The members were much puzzled by these figures, and would be glad if any of our readers could give an explanation of their meaning. In the north transept chapel is a sculptured retables of Renaissance work, representing scenes from the life of Our Lord in very high relief. It is much mutilated, and the kneeling figures of the donor and his wife in the lowest panel to the right of the spectator are almost broken away, but enough of them remains to identify their dress. Another large panel, worked probably by the same hand, is now at the side of the chapel under the window. These sculptures are stated to have been all removed from a destroyed chapel of a lapsed guild. The guild is said to have been founded in the thirteenth century. The church is almost paved with grave slabs of a very peculiar character. They are lettered with very large letters in relief, most of them having nearly the form of Lombardic lettering. These stones are mostly dated between 1600 and 1700, and go to show that the little village was a place of some importance during that century, a surmise borne out by the houses still standing. There are several good old houses left, especially an old blacksmith's forge in the main street. It may possibly be of sixteenth-century date, and is almost unaltered, with shingle roof and thick oak posts, by which generation after generation of horses have stood to be shod.

On their return from Mont St. Michel, the archaeological party left for Rennes, arriving there rather late on Saturday evening. Although great part of Rennes presents no objects of interest beyond those found in ordinary French towns, and is in consequence often avoided by architectural travellers, there is in the old parts of the town, which escaped the fire of 1720, a great deal of Domestic work left, dating from the fifteenth century downwards,—much mutilated, no doubt, but happily unrestored. This is chiefly to be found in the neighbourhood of the cathedral. The Rue St. Yves is almost entirely composed of old houses, and there is one especially fine example of a late fifteenth-century house a few doors up a small street turning out of the Rue de la Monnaie. Up a court, immediately opposite the west door of the cathedral, much concealed by houses, is one of the old city gates, in very fair preservation.

The cathedral is entirely modern, having been finished as late as 1847, but it contains some good modern wall-paintings in the choir. The other churches have little calling for remark. There is a good Late Flamboyant church, now desecrated, near the Quay and the Rue St. Yves.

The Museum was visited by the travellers, the custodian having been informed of their intention by the President of the Rennes Archaeological Society. It contains a fair collection of stone implements, but not much of local interest. There are some new cases filled with flint flakes, &c., from the neighbourhood of Dol, with a notice that the best specimens are withdrawn for further examination. We could not learn any particulars about these finds, but they may turn out to be of great archaeological value. We understand that it is intended to publish full information shortly. A great part of the afternoon was spent in the

Public Garden, one of the great beauties of Rennes, and on Monday morning the party started for Vannes by the first train.

They arrived at Vannes about midday, and were met at the station by Admiral Tremlet, an old and much-esteemed member of the Institute, under whose guidance the various places in South Brittany were visited. After seeing part of the town the party was received by the Comte de Limur at his mansion, and there shown the splendid collection of minerals, brought together entirely by himself. He especially called the attention of the visitors to specimens of jadeite from a vein he discovered some years ago at Rocquedas, a few miles from Vannes, and which bears a remarkable similarity to that of New Caledonia. He also pointed out some specimens of stactolites formed of oxide of iron, almost pure, from caves in Finistère, near the Pointe du Baz.

Later in the afternoon the archaeologists visited the museum of the Société Polymathique, and were there met by Dr. De Closmadec and other members of the society; but many others were prevented from attending by the fact that the 15th of August was the date of a religious fête, the Assumption of the Virgin, very strictly observed in Brittany. On their way to the museum the English met one of the church processions (consisting chiefly of children) which are so often seen here. Dr. De Closmadec, who was himself present at the finding of many of the treasures in the museum, devoted much of his time to going through it and explaining the exhibits. There are preserved the polished stone axes, &c., found in the Mont St. Michel, Carnac, the Batte de Tumiac, and in most of the more important dolmens and excavations made in the Morbihan district; and no museum in Europe is richer than that of Vannes in its own class of neolithic implements.

On Tuesday morning, August 16th, the party started in carriages for the peninsula of Rhys, which forms the southern shore of the Morbihan Sea, shutting it out from the Bay of Biscay. This peninsula is generally low and flat, but enjoys a very mild climate. It is about the most northerly part of France in which vines are cultivated, vineyards being entirely wanting at Vannes, Auray, and the other places visited by the tourists. There are large salt-ponds on the flat shores, the manufacture of salt from sea water and the breeding of oysters being about the only local industry except agriculture. After a drive of some ten miles the carriages stopped at the Castle of Sucinio, a well-preserved ruin, built by the Dukes of Brittany originally in 1250, but almost or entirely rebuilt in 1420. The moat is very well preserved; it is now dry, but holds some water in winter and probably in ordinary summers. Of the seven towers six remain with their curtain walls very perfect and still crowned by machicolations, but the battlements are entirely lost. In plan the castle was an irregular pentagon, the east face consisting of the gate and gate towers, two angle towers, one of which contained the well, and a tower in which was the chapel, between the gate and the well tower. The window of the chapel and the springers of the vault are well preserved, and the well and well-chamber are almost perfect.

Leaving Sucinio for Sarzean, the road runs for some distance parallel to a very high, ancient wall, apparently the boundary of a chase or park belonging to the owners of the castle. In this wall long strings of stones are occasionally found, set herring-bone wise, but this is not at all uncommon in Medieval buildings in this neighbourhood.

At Sarzean, where the halt for lunch was made, there is little of interest except a few old houses and farm buildings in the village, and a good Renaissance chateau a little way out of it. It was the birthplace of Le Sage, author of "Gil Blas," and the house in which he was born is still pointed out, but the part now visible can hardly have been built in his day.

The next place visited was St. Gildas, situated close to the open sea, on the southern side of the peninsula, and frequented in summer for sea bathing. This was the site of a very ancient monastery, said to have been founded by St. Gildas, in the sixth century, but more famous from having been once under the rule of Abelard. The transepts and eastern limb of the twelfth-century church, in the Romanesque style of the Loire and Angoulême, still remains, but the arches forming the chevret

have just been taken down and rebuilt, and the whole church is undergoing restoration. It is now used as the parish church. Some very curious capitals, supposed to be those of the nave arcades destroyed in the last century, are still in the floor,—two, one on each side of the door, being used as holy water basins.

The convent buildings are all modern, and are occupied by a few Religious who take in boarders during the bathing season, but these are expected to conform to rather strict rules.

From St. Gildas the party returned to Vannes by road, passing at a distance the Butte de Tumiac, one of the finest tumuli known, and one which some years ago richly rewarded the explorations of the Société Polytechnique. The chamber then discovered in it is now inaccessible, being filled up with débris from the mound above.

#### THE RELICS IN PICCADILLY.

SOME alleged sixteenth-century relics have been discovered in Piccadilly. They comprise, we read, a mass of parchment MSS., sporting guns, bronze armour, and a red granite tomb or sarcophagus. These articles were found in a series of arches at a depth of from 16 ft. to 17 ft. below the surface, in the course of excavations that are being made for the new premises of the Junior Travellers' Club, Nos. 96-7, at the south-western corner of White Horse-street, by the Badminton Club. Bearing in mind the history of this portion of the highway,—until comparatively recent times a country road,—it would seem that the things found can boast of but little antiquity. For, according to a copy plan, *penes nos*, of the Lord Berkeley's Estate, as surveyed in 1676, the modern White Horse-street stands in what was then known as the Stone Bridge Fields. These fields, being a plot of 9 acres, triangular in shape, were divided by the Ayo Brooke, or Tyburn, from the Shoulder of Matton Field (nearly 4 acres) and the Great Brooke Field (13 acres). The Tyburn here ran south-westwards, in its course from the Penneles Bank, at Hay Hill Farm, to the hollow eastwards of the Brooke Shott, where, at the ancient Cow ford, it crossed the highway to Bath, Exeter, and Western England. This hollow, latterly known as Stonebridge Close, is still plainly discernible both in Piccadilly and the Green, formerly the Upper Park. It often lay quite under water, and at times even the bridge failed to render the road passable, as for instance, when in March, 1692, Sir Robert Atkyns, Speaker, was prevented by the flood from attending an urgent meeting of the Commons. A contemporary account of Wyatt's rebellion describes the posting of cannon upon the eminence at Brooke Shott (where the Parliament afterwards planted a fort or redoubt, in 1643), and the placing of troops of horse along "the road [Piccadilly], above the new bridge over against St. James's." "Berkeley Fields," again, are set out in a plan of the Grosvenor Estate, as surveyed for building improvements, in 1723. The Brooke Shott, famous for its ice-houses and duels, was subsequently taken in for the plantation, or Wilderness, attached to the Ranger's Lodge, which R. Adam built in 1768. We find by a State Paper that in 1666-7 had been built the wall which, until about forty years ago, bounded the Green Park along its Piccadilly side. From various other maps and plans it clearly appears that until 150 years ago, at most, the northern side of Piccadilly, in this portion of the thoroughfare now so-called, was not occupied, save by some masons' yards, a few small tenements here and there, and one or two inns. Amongst these inns were the Hercules' Pillars, familiar to readers of "Tom Jones," and the Greyhound (its site bought by the Earl of Coventry in 1764, for 10,000 guineas), the Half-Moon, and the White Horse. The signs of the last two named are preserved in existing thoroughfares. The White Horse inn, its yard and paddock reaching at the back to Shepherd's, or, rather, Shepard's Market, was standing as late as 1752, according to Mr. H. B. Wheatley's "Round About Piccadilly." But the inn is unmistakably cited in Baldwin's "New Complete Guide for 1774-5." In John Lockie's "Topography of London, 1810," White Horse-street, Piccadilly, appears. Meanwhile the building of Piccadilly, as we now know it, had gradually extended westwards. In 1710 Bolton-street was the most westerly street in this quarter of the town. Bath House

at its corner (west) was built for William Pulteney (Lord Bath), but has been rebuilt by Alexander Baring, elevated Lord Ashburton, 10th April, 1835. The next turning is Clarges-street (1717-8). Just beyond, on the site of Carter's statutory works, stood Hertford House, once the Pulteney Hotel, which, having been originally built for the Earl of Barrymore by Novosielki and added to by Smirke, was re-erected, mainly with the existing stones, in 1851. The next is what is mentioned in the "New Complete Guide," *ut supra*, as Half-Moon-street, Hyde Park-road. Then comes White Horse-street. We may add that next east of Carter's statutory works, "near to the Queen's Mead House, in Hyde Park-road," was the workshop of John Van Nost, a maker of leaden figures, who came to England with King William III.

#### THE ANNUAL REPORT OF THE LOCAL GOVERNMENT BOARD.

THE Sixteenth Annual Report of the Local Government Board, 1886-87, just issued,\* is dated "June, 1887," so that, considering its bulk (including appendices it consists of upwards of 600 pages), it has made its appearance within what,—for a Government publication,—must be regarded as a fairly reasonable interval. The Report itself, signed by the President of the Board, the Right Hon. C. T. Ritchie, occupies 172 pages, and is divided into three parts, viz.,—I., Relief of the Poor and the Poor Rate; II., Local Government and the Public Health; III., Local Taxation and Valuation. It is with the second section that we and our readers are most directly concerned, from a sanitary point of view; but it is impossible to read through the Report without seeing that all three of the subjects enumerated are more closely affected by each other than is always remembered.

With regard to Poor Law Relief, it appears that on the 1st of January last the total number of paupers of all classes in England and Wales in receipt of relief was 822,215, of whom 201,598 were indoor and 620,617 out-door paupers. As compared with the returns of the 1st of January, 1886, these figures show a net increase of 9,201, or 1.1 per cent. on the total number of paupers. On the other hand, it is satisfactory (bearing in mind the continuous increase in the amount expended on the relief of the poor during the ten preceding years) to find from the returns that the cost of the relief of the poor during the year ending Lady Day, 1886 (£2,296,230) was 195,370*l.* less than in the preceding year. This expenditure represented an average charge of 6*s.* 0*d.* per head on the estimated population, being 2*d.* per head less than in the preceding year, and an average rate of 1*s.* 1*d.* in the pound on the rateable value of the property liable to contribute to the Poor-rate. The Report chronicles a fair amount of work in the shape of the erection of new buildings for poor-law administration, and enumerates several important new works of the kind which need to be taken in hand as soon as possible. Appendix B contains the reports of the several Poor-Law Inspectors. We notice that Mr. R. Hedley, the Inspector for the district comprising the Metropolis, confirms what was our view at the time of the "Mansion House Fund." He says he believes that the Mansion House Fund, which was hastily collected and hastily distributed in the early part of the year under review, "has had its effect in increasing the number of persons chargeable to the poor-rates,"—mainly, we suppose (though we do not notice that Mr. Hedley says so), because the existence of a big fund to be doled away attracted from the country large numbers of helpless or shiftless people who would not otherwise have come to London, but who, now they are here, are some of them a burden upon the rates, while others are in the overglutted labour market. It is not surprising, therefore, to find Mr. Hedley coming to the conclusion that a further increase of pauperism in the metropolis may be looked for, "unless in the near future we are favoured by a great increase in commercial activity." Although Mr. Hedley doubts the very exceptional character of the distress of the year 1886 in the metropolis, he says,—

\* I believe that the building trade in London was during the year perhaps more depressed than any other. I have

been told that there are many offices and warehouses in the City and central parts of the metropolis which are unoccupied, and I know that in some unions there are hundreds, say thousands, of empty houses.\*

The building trade of London must always be large, for purposes of removal only, but it is difficult to wish for a revival of activity in the covering of acre upon acre and field after field of the outskirts of London with row upon row of brick dwelling-houses; and I could gladly learn that many of those who have hitherto been engaged in work of that kind had been absorbed into other branches of industry."

These words are full of suggestiveness, and, in so far as they are directed towards the stopping of "jerry" building, we quite sympathise with them, though obviously it would ill become us to deprecate the growth of the legitimate building industries of the metropolis.

Turning now to the second section of the Report, viz., that dealing with "Local Government and Public Health," we find that since the constitution of the Local Government Board on its present basis in August, 1871, it has sanctioned the borrowing, by Urban and Rural Sanitary Authorities, of amounts reaching a grand total of 36,722,067*l.* By far the greater proportion of these loans has been sanctioned for the purpose of sanitary improvements in Urban Districts, to be executed under the provisions of the Sanitary Acts, the Public Health Act, 1875, and Local Acts and Provisional Orders. The remainder has been sanctioned principally for the execution of sanitary improvements in Rural Districts, or for improvement schemes in Urban Districts under the Artisans' and Labourers' Dwellings Improvement Act, 1875. Of the amount mentioned, thirty-one millions and a quarter have been sanctioned as expenditure for sanitary purposes in urban districts, 2,378,331*l.* for similar works in rural districts, and 2,213,353*l.* for expenditure under the Artisans' and Labourers' Dwellings Act. In addition, the Board has since its constitution sanctioned loans to joint boards to the amount of 950,284*l.* These loans are in respect of systems of sewerage and sewage disposal, or for the provision of hospitals. With regard to the appointment and salaries of sanitary officers, we are glad to notice the following passages in the Report,—

"In some of the cases in which we received applications for sanctions to appointments under our Regulations, with a view to the repayment of a moiety of the salaries of the officers out of the Parliamentary Grant, the arrangements proposed did not appear to us to be satisfactory, and we deemed it necessary to withhold our assent.

We have, in previous Reports, referred to the inadequacy of the salaries frequently proposed by Sanitary Authorities, and during the past year we received numerous proposals, when an office became vacant, to reduce the salary previously assigned to it. In many cases, however, the existing salaries did not appear to us to be more than adequate to secure the efficient discharge of the duties, and we therefore felt compelled to withhold our assent. We are fully sensible of the reasons urged by many Authorities for endeavouring to reduce local expenditure, and are desirous of co-operating with them in this direction whenever such reduction may be effected without impairing the efficiency of local administration. There are, however, other considerations to which we cannot but attach great weight, especially in those cases in which a moiety of the salary of the officer is repaid out of the Parliamentary Grant, for the proper distribution of which we are responsible.

The object of the Grant is not only to relieve the local rates by means of a subvention from Imperial Revenue, but also to secure the appointment of efficient officers by aiding the local Authorities to pay such salaries as will afford an adequate remuneration for the proper discharge of the duties which devolve upon the officers.

It appears that during the year ended on the 31st of March last, the sum of 71,953*l.* was distributed out of this grant in aid of the payment of salaries of Medical Officers of Health and Inspectors of Nuisances.

During the year the Engineering Inspectors of the Board held local inquiries in respect of 451 applications by Sanitary and other Authorities for sanction to borrow money for public works. We are glad to learn that the special Survey of Sanitary Districts which was mentioned in the Board's last Report as being in progress, in view of the possible introduction of cholera into this country, was continued during the year on the same lines as in 1885, with the result that upwards of 550 districts have now been visited, and the respective Authorities have since been communicated with as to the most pressing sanitary needs which the survey brought to light.

With regard to the third section of the Report, "Local Taxation and Valuation," it appears that the aggregate receipts of the Local Authorities during the financial year 1884-85, excluding loans, amounted to 43,819,181*l.* The total amount of loans out-

\* We are afraid that this state of things still obtains.

London: Printed for Her Majesty's Stationery Office by Eyre & Spottiswoode.

standing at the end of the same period was 173,207,968l., as compared with 92,820,100l. at the end of the year 1874-5,—an increase of eighty millions in ten years.

The appendices to the Report contain a great mass of detail as to the work of the Board and its officers, including the report on the Metropolitan Water Supply for the year 1886 by Major-General A. de C. Scott, the Water Examiner, appointed under the Metropolitan Water Act, 1871, in succession to the late Sir Francis Bolton. From this report we notice that "constant supply" has been greatly extended over the systems of nearly all the companies providing the metropolis with water.

#### REFUSE DESTROYERS AND THEIR RESULTS UP TO THE PRESENT TIME.

This was the subject of a paper read by Mr. C. Jones, Assoc. Inst. C.E., Ealing, at the recent annual meeting of the Association of Municipal and Sanitary Engineers, and the discussion of which was postponed to the district meeting held at West Bromwich on Saturday last. We quote some passages from the paper:—

It must be taken as an acknowledged fact that there is some difficulty in constructing a suitable furnace for burning refuse, and there is little doubt that the experience of many years gained by "Fryer's Destructor" has done immense service, if not actually made this particular system a success. Turning to the several inventions brought out, it would appear at first sight that the object sought to be carried out was simple and easily to be performed; but after trials sometimes extending over two or three years, and with different kinds of refuse at different towns, they have nearly all been at last abandoned. All these trials tended to show that we must move with the greatest caution in adopting any particular process.

Furnaces of the ordinary type were used in London districts and in Northern towns over thirty years ago, but most of these were built either by contractors or those who did not consider—in a scientific way, at any rate,—the action of heat, and how to utilise the small combustible portion contained in refuse to burn up the larger quantity of less combustible material. The shape and general construction of the fire-brick arches were wrong, the arrangements for feeding were bad, and the flues and passages for gases were designed more by guesswork than calculation. It is, therefore, no wonder that these proved to be only feeble attempts to introduce the principle of fire. It was found necessary to burn coal or other fuel in these furnaces in order to dispose of the refuse as collected, and they were ultimately used only for burning paper, straw, hampers and baskets, and other light materials, and several are used for that purpose at the present moment. One of these furnaces was built by the Corporation of Manchester about 1873, and many alterations were made from time to time. After three or four years' experiments, about the year 1876, Mr. Fryer, of Nottingham, appears to have come upon the scene of action and arranged with the Corporation for a trial of his furnace, which he named the "Destructor." This trial turned out sufficiently successful to induce the authorities to have another erected, and in a very short period they had no less than three large destructors built upon Fryer's patent.

The Birmingham Corporation followed next; then came Leeds and Bradford. These destructors have been seen by most of the members of this Association, and called forth a very able paper from our late esteemed friend Mr. Morant. About this date Messrs. Pearse & Lupton, of Bradford, invented a furnace for dealing with town refuse, and the Corporation (of which Mr. Pearse was then a member) allowed them 50l. for a six months' trial of their invention. These furnaces consisted of fire-brick arches, feeding hoppers, and regulating dampers, with perforated fire-brick walls at the back of each cell. The inventor claimed many advantages, and especially mentioned the perforated wall for dealing with offensive gases.

The trial appears to have been conducted upon fair lines. The Sanitary Committee instructed one of its officials to remain with them and note the quantity of work done, the wear and tear of cells, and the amount of smoke and smell given off; and the inventors were

allowed to engage their own men and work the apparatus in any way they thought proper. Although several improvements were made, and a fair amount of refuse burned, they abandoned the trial.

The next invention was that of Pickard, who had been employed by the Leeds Corporation as foreman at the Destructor works; he called his refuse destructor the "Gourmand," and it consisted of a large fire arch with two sets of furnace bars and two furnace mouths to one cell. Although there was nothing to favour this form of cell, there was certainly one part of his invention which is of the highest importance, and that is the flues and second fires; he conducted his gases from the cells down an horizontal flue and erected two ordinary fireplaces in this flue with the fires crossing it, or the fire-bars at right angles to the flue. If he had built his furnace carefully, and made continuous practical trials, he would probably have adopted several other features contained in the "Fume Cremator," and thus have solved that part of the problem in advance of the author.

Immediately afterwards Healey brought out his refuse furnace, and the author found that Mr. Healey was engaged as assistant to Mr. Bryan when at Blackburn, and the erection of a "Fryer" was carried out at the time. An agreement was made with the makers, and a furnace called Fryer's and Healey's destructor was erected at Bradford. The arches and furnaces were like Fryer's, and following in the steps of the two previous inventors it was attempted to purify the gases. The main arch was constructed hollow over the top; the gases were made to pass at the back of each cell down the sides and over the arches, and the high temperature of the arches and flues was to have destroyed the offensive gases. This, however, did not take place, and although this destructor has been altered and experimented upon at great expense, no advantages have hitherto been obtained.

Then followed Thwaite, with a boiler and refuse furnace combined. It consisted of a vertical boiler with a hopper in the centre at the usual place for the chimney, and the heat of the boiling water and hot gases were said to prepare the refuse for combustion.

Then came Young, of Glasgow, with his refuse furnace, consisting of an ordinary furnace with closed ashpits. Air is blown into this ashpit by a powerful fan, and combustion thus facilitated. The refuse burnt is composed of paper, straw, and light materials, and is readily consumed, whilst the cinders are picked out and burnt under an ordinary boiler. The author believes that Mr. Hewson, of Leeds, made the blowing of air under the ashpits a principal part of his patents taken out last year.

The next to enter the field was Mr. Wilkinson, of Birmingham; he had considerable experience with two kinds of furnaces, viz., Fryer's destructors and Fryer's carboniser, and it was thought his inventions would contain some advantages over those already used by his Corporation. They consisted of cells with fire-brick arches and flat fire-bars, with large double furnace mouths and a perforated wall at the back of each cell, similar to that invented by Pearse and Lupton, and Mr. Wilkinson spoke so high of their use that the Corporation of Blackpool were induced to erect one about two years ago. These furnaces have been found to cost a great deal for repairs, and will probably be abandoned and replaced by Fryer's this year.

The next inventor was Burton, who constructed a long single furnace with two fires, and the refuse was dragged through by a long endless chain, which was moved at intervals by a windlass as the refuse became consumed. It is evident that no great heat could be generated, or the chain would be burnt and the process stopped.

Then followed Stafford and Pearson, of Burnley, with the "Beehive," which is so familiar to our members that it is unnecessary to describe its construction.

In the valuable digest prepared by Mr. Clavey, of Brnton-upon-Trent, for his Board in 1886, under the head of Burnley, where the "Beehive" was born, in answer to the query as to whether "the destructor gives satisfaction," the reply is, "It gives every satisfaction"; but on turning to Leicester, where it was in the hands of one of our most experienced officers, I find the reply to the same question as follows, that "the Beehive did not give satisfaction, and had been demolished."

At Bradford, "the Beehive was abandoned within three months of its erection, on account of the excessive cost of working it."

Details are given in a tabulated statement supplied by Mr. Gordon as to the experiments carried out at Leicester with the Beehive, which did not give satisfaction. Turning to Richmond, where, in answer to similar questions, the reply is, "They had two Beehive destructors, which did not give satisfaction, and were closed on account of several law actions." The author took the trouble to visit the Beehive destructor at Burnley, thinking that he might be induced to have it at Ealing, and the answers just given justified the opinion he then formed. A few weeks subsequently to the opening of the Beehive at Richmond, the author was invited by the Vestry, who sought his advice in conjunction with Dr. Tidy, in connexion with a law action. The Vestry found that the best remedy was to close them.

The manufacturer of the Beehive subsequently invented the "Nelson." The author has no personal knowledge of this apparatus, but one was erected in the town of Nelson as a private speculation, and like the others referred to appears to have found no great favour.

Another apparatus was invented by Hardie, of Burnley, and consists of the old saddle boiler with an inclined furnace underneath, and he proposed to do away with chimneys by adopting the air-blowing principle, somewhat like Young & Co., Glasgow.

Mr. Jacob, Borough Engineer of Salford, designed a furnace for burning sewage sludge, also town refuse; but from what I can gather, the Corporation, after investigation, decided to erect a "Fryer" in preference. Its construction was upon the limekiln model, and is illustrated in a late volume of the "Proceedings of the Institution of Civil Engineers."

Next on the list is Ogden, of Burnley, with a refuse furnace constructed with two fires and a boiler over the top; he claims several advantages over all others; first, the burning of offensive gases by passing them through a coke fire, and also the carbonising of refuse and retaining its fertilising properties.

Finally, we have Horsfall, of Leeds, with an ordinary furnace with closed ashpit and the combustion maintained by a combination of steam and air being blown in under the fire-bars. This principle was tried in Manchester in 1876, in Warrington in 1880, and has been in use at Rochdale since 1881, under boiler furnaces that are burning screened refuse. There have been numerous other refuse furnaces invented, but as they have not been placed before the public, there is no need to name them.

Having enumerated, so far as has been ascertained, all the various destructors brought before the public, it is found that at the present time there are probably not more than about thirty of every description in use in England, varying in size from two to twelve cells, and the various models actually in use, so far as can be gathered, consist of Fryer's, Healey's, the Beehive, the Nelson, and the one at Birmingham known as the "Wilkinson." Consequently the subject appears at first sight to be one of great simplicity, but a few minutes' consideration will convince every one present who has had to deal with the difficulties that gather around this matter, that it is no easy thing to reduce into ordinary space the many questions that of necessity arise. Those who are engaged in the larger towns of England, such as Manchester, Birmingham, Leeds, and London, are fully alive to the immense difficulties which have to be coped with in settling what may be called the dustbin nuisance. Whilst our towns and the suburban parts of our district were content, and shoots were without difficulty provided, whilst sanitary science had not yet descended its nostrils to gather up every whiff borne upon every wind that tells its tale of what ought not to be, and whilst thousands of tons of refuse garbage were transported from our neighbourhoods and dealt with as circumstances might dictate or necessity require, in somebody else's neighbourhood, it was well; but that time has for ever passed away, and the absolute necessity of dealing with this growing difficulty has come home in a very painful manner to most of our local authorities, whether they be constituted under the powers of the Public Health Act, or the Metropolitan Management Act of London.

It is during the last ten or fifteen years these difficulties have principally cropped up; and

upon referring to data supplied by Mr. Santo Crimp, in which he includes some twenty-five towns (omitting Manchester and Birmingham, which were of still earlier date), it appears that among the early destructors erected was the one built in Leeds in 1877. The next in date are another at Leeds in 1879, and others in Heckmondwike and Warrington in the same year. These were followed by Blackburn, Bradford, and Bury in 1881; Bolton, Hull, Nottingham, and Salford in 1882; Kaling 1883; Newcastle, Preston, and Whitechapel in 1885; and I believe that Bournemouth, Batley, Longton, and Batterssea, with other towns, are now erecting or are upon the point of erecting destructors.

It was at one of the meetings of the Association at Leeds, under the presidency of the late Mr. Morant, that the author first saw Fryer's destructor, and the difficulty experienced at Ealing, not only with the house refuse, but with the sewage sludge, led the author to look for a remedy in the apparatus here seen at work. Very shortly his Board let him have the destructor, and a 2-cell destructor was built. The author then endeavoured to settle the sludge question, and can only repeat what has been said again and again, that he found the destructor absolutely certain in its work, and saw that he had secured a most valuable appliance, and one by means of which he could without difficulty rid himself of a most unendurable nuisance and without expense. It was soon found that a 2-cell destructor was not sufficient for the author's purpose, and consequently the next season two more cells were erected, and at the present moment the destructor at Ealing is dealing with the sewage sludge of a population of 19,000 and the house refuse of 22,000. The adoption of this mode of dealing with sewage sludge has produced a great deal of discussion and not a little difference of opinion. This author remarks refers more particularly to the Metropolitan Board of Works, who, having heard something of what the author was doing, tried some experiments for themselves, and, attempting to burn their sludge in a Hoffman kiln, signally failed, and Mr. Dibdin states that this was the cause of offensive effluvia and could not be carried out without a nuisance. The author cannot help expressing surprise that the Metropolitan Board of Works, with all their resources of wealth and engineering skill, should not have carried out their experiments in all integrity and with the best appliances that could be had. The dealing with the metropolitan sewage was a question of multiplication of power, and the author is still of opinion that the gigantic sludge barges now being built will have to give way to a more scientific mode of dealing with the difficulty than that of carrying the sludge out to sea and there precipitating it for the benefit of the finny denizens of the deep or to be encountered by unfortunate passenger vessels.

During the years the author has been burning sludge at Ealing he has never used a press, nor has he used any other fuel in the destructor than that supplied by the house refuse. A very few days after the sludge has been pumped on to the ash beds, all the draining and drying necessary has taken place, and the material burns readily. In corroboration I may quote an extract from Dr. Tidy's lecture at the Society of Arts, April 14th, 1886:—

"To my mind, the destructor has reached its highest state of perfection at Ealing, from the great thought that Mr. Jones, the Surveyor at Ealing, has given to it. His sludge there is mixed with house refuse, and burnt. Mr. Jones's view is that every town produces sufficient house refuse to burn the sludge. One has to notice the differences of destructors. I have seen a good many myself, and I should say the differences are mainly two; first, a certain escape of offensive vapours from the shaft, and I think those offensive vapours are mainly due to partial burning,—the destructive distillation, as a matter of fact, of the materials, instead of their complete destruction; secondly, the escape of fine sand and such like from the shaft at certain stages of the operation. I have seen those two nuisances very well marked, and I had occasion to advise on them on more than one occasion. I cannot help thinking myself that in Jones's destructor, where he places a muffle furnace or 'fume destroyer,' as he calls it, between the furnace and the main shaft, he has, in a great measure, met those two difficulties."

The author would call attention to one of the most valuable papers which has appeared in the scientific world upon this question, viz., the report made by the well-known scientist, Dr. William Odling, at the request of the Bradford Authority, who had both Fryer's and Healey's destructors at work. Those who have gone into this question closely know that one of the

difficulties to be contended with is one springing from the sensitiveness which is felt by the authorities of almost every town when the question of smell is introduced; although no one can, for a moment, expect to go into sewage works or the dustyard of any important town and find it smelling sweet as lavender. There does seem to be a very strong feeling that it is an impossibility to put up a destructor without creating an intolerable stink, and there has been admittedly some slight ground for the statement. Those who were in the committee-room of the House upon the Kensington Vestry Bill will remember the awful and heartrending accounts by some of the opponents of the scheme as they detailed the horrors that would arise in the erection of a destructor. This apparently happened at Bradford, and so Dr. Odling was called in to decide the question. The following are his conclusions:—

"1. The furnaces should be of the same general form and dimensions as those at present in use. They should not, however, be built in double blocks back to back, but in single blocks, so as to be readily accessible both at back and front.

"2. The drying up of the fresh refuse in the furnaces, before its actually taking fire, should be better provided for, and the moist vapour given off by the drying, instead of being allowed to escape at once into the main flue, should be caused to pass over and through the mass of actively burning refuse. This would effect several desirable objects. The incipient burning of the refuse would, in the first place, be less and less objectionable in proportion to the dryness of this refuse. Secondly, any possible offence from the discharge of the vapours given off in the mere drying would be provided for. Lastly, the passage of the moist vapour or steam given off in the drying, through the actively burning portion of the refuse, would tend to make this portion burn with a flame, a very desirable result as an aid to the destruction of the empyreumatic vapours given off in the stage of incipient burning. At present the foreman in charge occasionally delivers, with some such view, a jet of water on to the actively burning refuse, but the continuous passage through this burning refuse of the watery vapour given off in the drying of the fresh refuse would be far more efficacious.

"3. The opening into the flues leading from the furnace to the main flue should be so situated and arranged that the smoke and vapour given off by the incipient burning, together with a sufficient supply of air, should be caused, on its way into the flues, to pass over the most actively burning portion of the refuse, and thereby get almost, if not quite, completely consumed.

"4. The flue into which the products alike of the drying, the incipient burning, and the active burning first pass from the furnace on their way to the main flue should be of some length, but of no greater size than necessary, and be constructed with a view to their being maintained at as high a degree of heat as practicable. It is to these strongly heated flues that the complete destruction of any residue of unconsumed empyreumatic vapour can be entrusted. No amount of mere heating, however, will of itself cause their destruction. They must be sufficiently strongly heated in admixture with a sufficiency of air in order to effect their burning or destruction. The flues serving for this purpose might also be made available to aid in some measure the drying up of the fresh refuse passing into the furnace."

From the very first invention to the last, there have been attempts made to deal with the difficulties arising from the gases given off from burning refuse; and besides those named with the inventions specified, there have been many schemes tried both by the authorities who have them in use and the inventors. Fryer patented a method of water spray a few years ago; the water was distributed in a kind of shower by a revolving shaft in the centre of a chamber to which the gases were conducted like an ordinary shower-bath. Another invention was introduced by an engineer in Salford, who conveyed the gases over a long water channel and halted them with revolving discs or wheels. This invention claimed not only to deodorise the gases, but to precipitate and retain the ammonia in the water or other fluid. Mr. Hewson at one time strongly recommended this invention. All these experiments and inventions point to one end, and all of them were more or less puffed up; several corporations were unfortunately enough to give them a trial, probably led on by the sanguine statements of the makers; but we have the evidence and experience of our fellow-engineers who have worked them, which is of the greatest value to the members of this Association, and at once gives a clear and honest account of their capacity after they had left the hand of the inventor or manufacturer. In placing these facts before the meeting, the author has endeavoured to give them in a fair and practical manner, and with a desire to call attention to those inventors who have conceived the idea of passing gases through and into separate furnaces. It will, however, be seen that most of them simply suggested an ordinary coke furnace, and the author's first experiments were conducted with a fire of this kind; but although considerable power was found in such a furnace, there were many details which

required further development before practical success was attained.

An ordinary furnace was found to consume an enormous quantity of coke, and at once raised the cost of treatment to more than double, while the heat generated passed away into the chimney without utilising all its power to consume the offensive yet burnable gases. Therefore it was necessary to consider how an arrangement could be contrived which would reduce the consumption of coke and would effectually destroy offensive gases; in other words, a muffle furnace was wanted which could be retained at a very high temperature ready to receive the vapours and gases at any time, and keep them inside it sufficiently long to thoroughly deodorise them; and all this had to be effectually done with a small consumption of fuel, with no extra cost for labour, and with no great increase of wear and tear.

In his experiments the author found that gases were very similar to wind, and that by baffles they could be conducted in any direction; it was found that if they could be baffled and deflected without injuring the speed or draught, they might be kept sufficiently long in the furnace to consume and deodorise their offensive properties. It was also found by the regulated admission of oxygen that the fire could be maintained at one glowing temperature with a small consumption of coke and even breeze, and that it required very little attention. It must be left to others to say the author has succeeded in those very important points referred to by the following independent and disinterested authorities.

In evidence before a Select Committee of the House of Commons, Mr. T. Cordington, M.Inst.C.E., one of the Inspectors of the Local Government Board, said:—"He noticed improvements in many ways, and thought Fryer's with all the latest improvements was one suitable for doing its work, and considered the 'Fume Cremator' a very great safeguard against nuisance or annoyance, as it much increased the heat, and enabled a more thorough destruction of noxious gases and half-burnt paper and other things which escape."

Mr. Alfred Fletcher, Chief Inspector under the Alkali Acts, and Mr. John T. Harrison, Inspector under the Local Government Board; Mr. Alfred Fryer, inventor of the destructor, and numerous others, have spoken highly of the fume cremator; and I can only follow their remarks by inviting the members of this Association to come at any time and judge of its merits themselves.

Finally, the results have entirely, so far as the destruction of the gases is concerned, confirmed the view taken by Dr. Odling; and further, the whole of the machinery is worked by the steam obtained from this simple apparatus. The author need hardly remind engineers how valuable the results thus obtained may be where power is required, and the ease with which the power may be utilised as circumstances dictate.

The paper was supplemented by a selection from a mass of information the author has received upon the subject, contained in a report by Mr. W. G. Laws, City Engineer, Newcastle-on-Tyne.

We postpone our report of the discussion.

SHEFFIELD SOCIETY OF ARCHITECTS AND SURVEYORS.

A MEETING of this Society was held on Wednesday, 31st August, at the School of Art. Mr. J. B. Mitchell Withers presided.

The meeting was well attended, members were enrolled, and the following officers for 1887-8 elected:—

President.—Mr. T. J. Flockton, F.S.I.  
Vice-President.—Mr. F. Fowler, F.S.I.  
Treasurer.—Mr. J. B. Mitchell Withers, F.R.I.B.A.

Secretary.—Mr. W. C. Fenton.  
Council.—Mr. C. Hadfield, F.R.I.B.A.; Mr. C. J. Innocent, A.R.I.B.A., F.S.I.; Mr. J. D. Webster, F.R.I.B.A.; Mr. E. M. Gibbs; and Mr. E. Holmes.

It was resolved, on the motion of Mr. E. M. Gibbs, seconded by Mr. B. H. Wightman,—"That the Council ascertain the terms on which the School of Art Council would allow the use of their committee-room and library for reference."

A vote of thanks to the chairman concluded the proceedings.

### THE PROGRESS AND POSITION OF SANITATION.

LETTER FROM THE QUEEN.

MR. EDWIN CHADWICK, C.B., as President of the Association of Public Sanitary Inspectors, has received the following letter in acknowledgment of a Jubilee Address of congratulation presented to Her Majesty by that body:—

"Whitehall, August 23, 1887.

Sir,  
I have had the honour to lay before the Queen the loyal and dutiful address of the President, Chairman of the Council and Members of the Council of the Association of Public Sanitary Inspectors for England and Wales, on the occasion of Her Majesty attaining the fiftieth year of her reign, and I have to inform you that Her Majesty was pleased to receive the same very graciously, and to command me to express her gratification at the results referred to as springing from the administration of the laws dealing with sanitary matters to which she has signified her assent.

I have the honour to be,

Sir,  
Your obedient servant,  
HENRY MATTHEWS."

In the Address referred to, the Sanitary Inspectors, after expressing their grateful sense of the blessings they had enjoyed in common with other of Her Majesty's subjects during her long and glorious reign, set forth that:—

"As humble executive officers, we have been enabled to aid in the practical application of the new sanitary science which has been first developed during your reign, with the powerful aid of your lamented Prince Consort, by which mainly, and with as yet very rudimentary and imperfect executive arrangements, the general health of your subjects has been far advanced beyond that of any great State of Europe or of the United States of America; that the mean duration of life of all your subjects has already been augmented by three years and a half; that on the last year's population of England and Wales there has been a saving of eighty-four thousand cases of deaths and of more than one million seven hundred thousand cases of sickness over the average rates of death and the average sickness rates at the commencement of your Majesty's reign; that instances of general application have been presented of reductions of the death rates of the civil population by one-third and one-half; that by more complete applications of our science the death-rate of your Home Army has been reduced by more than one-half, and of your Indian Army by more than four-fifths, and that these experiences are available for the whole of the civil population of your Empire; that particular and decided examples have been achieved by the practical application of sanitary science, as displayed in district half-time schools, and by which far greater reductions of the present excessive infantile death-rates may be accomplished, and far greater reductions of the burthens of excessive sickness and deaths of all Your Majesty's subjects. By a further advance in the same lines, by superior sanitary education and inspection, it may be confidently anticipated that during the continuance of Your Majesty's reign still greater results may be achieved than those of the last half-century.

### Illustrations.

DECORATIVE SCULPTURE FOR THE  
INDIAN PENINSULAR RAILWAY TER-  
MINUS ADMINISTRATIVE OFFICES,  
BOMBAY.

THESE sculptured groups and statues have been executed in London by Mr. Thomas Earp, of the firm of Earp, Son, & Hobbs, for decoration of the exterior of the above-named terminal station, at Bombay.

The central figure of "Progress," 14 ft. in height, in three stones, is intended to hold in the right hand a flaming torch of copper, gilt, whilst the left hand rests upon a winged wheel by her side. This figure surmounts the central dome of the building.

The groups in the tympanum represent, the one "Science," embodying Astronomy, Electricity, Physical Geography, Medicine, Chemistry, Mechanics; the other "Trade," representing the central figure of Peace fostering interchange of relations between East and West, peace being an essential condition of Commerce.

The lion and tiger are for the gate piers of the entrance to the station, and measure 9 ft. 6 in. in length and 5 ft. 6 in. in height. The three groups below represent,—(1) "Commerce," the central figure expressing invitation and welcome, the left-hand figure holding Britannia's Trident, the right-hand figure with laurel wreath for successful enterprise; (2) "Agriculture": the central figure with cornucopia and ploughshare, "Plenty"; the left-hand figure with dibble and seeds, "Sowing"; the right-hand figure with sickle and wheat "Reaping"; and (3) "Civil Engineering," the central figure shown with cylinder of steam-engine; the left-hand figure "Military Engineering," with gunner's quadrant; the right-hand figure with screw propeller representing "Naval Engineering." These groups are 10 ft. in height and 8 ft. 6 in. in breadth, and in three stones each.

The figure of the Queen Empress (shown in annexed cut) is 9 ft. 6 in. in height, and in one stone. Her Majesty is represented in State robes and orders, holding in either hand the sceptre and orb.

Statue of Her Majesty, forming part of the Decorative Sculpture of the Indian Peninsular Railway Terminus, Bombay.—Mr. Thos. Earp, Sculptor.

In addition to the sculpture here illustrated there are decorative lions and griffins for the gables, and also nine large portrait heads, in circles, representing Lord Dufferin, Sir Bartle Frere, &c.

These works were carefully packed in strong iron-bound cases, and having arrived at their destination by steamer from London without sustaining damage, have now been placed in position.

The work has all been executed in Bath stone.

### NEW CHURCH AT STRATTON.

The new church now being built, from Mr. T. G. Jackson's design, at Stratton, in Hampshire, is to supersede a very mean modern structure of brick, which stands on low ground in Stratton Park. The new church, which is being erected at the expense of the Earl of Northbrook and the Hon. Francis Baring, is situated on higher ground, nearer the village. The materials are brick, with flint facing and dressings of Chilmark stone externally, and of chalk internally. The spire is of timber and shingled. The seats and other fittings are to be of oak throughout.

The contractors for the general work are Messrs. Parnell & Son, of Rugby, and Mr. R. Evans is clerk of works.

### NEW CHURCH AT NORTHINGTON, HAMPSHIRE.

The present church at Northington, near Alresford, in Hampshire, is a modern structure of no particular architectural interest, though it was improved to some extent a few years ago by Mr. Butterfield.

It is now proposed to replace it by an entirely new church, from the designs of Mr. T. G. Jackson, which is to stand a few yards away from the present site. The new church, which is to be erected at the expense of Lord Ashburton, will contain sittings for 260 persons, and will be constructed of brick, with flint facings, and with dressings of Chilmark stone outside and chalk inside.

Our illustration is taken from a sepia drawing by the architect, exhibited this year in the Royal Academy.

### CLUB-HOUSE, SHIPSTON-ON-STOUR.

This building is about to be erected by the liberality of Mr. Frederick Townsend, M.P. It contains billiard-room, reading-room, recreation-room, kitchen, &c., on the ground-floor, and a public hall above, approached by two staircases, and having an open timber roof. In connexion with the hall is a resting or green room, with an attic for stores, above. The walls are of red brick, the roofs covered with Broseley tiles. The timber is to be oak, cut upon the estate of Mr. Townsend, and the lowest tender (by Mr. John King, of Shipston-on-Stour) amounts to 1,064*l.* The architect is Mr. Ed. W. Mountford, A.R.I.B.A., of 22, Buckingham-street, Strand.

The drawing was in the exhibition of the Royal Academy.

### A VILLAGE SHOP AND FOUR COTTAGES AT DOULTING, SOMERSET.

THESE buildings are designed (the cottages being already built) for a site in the village of Doulting, which belongs to Sir Richard H. Paget, Bart., M.P., and is renowned for its quarries of the excellent "Doulting" stone as well as for the ancient "Abbott's Barn."

The accommodation in each cottage is, on the ground-floor, a porch, living-room (14 ft. by 11 ft.), kitchen, and pantry, and on the upper floor three bedrooms, each having separate access to the staircase. The shop is about the size of two cottages, and is situated facing the church and two main roads, and being in the curve of two other roads is in a prominent position. The oriel window lights a sitting-room, whence a very pleasant view is obtained.

The materials are, for walling throughout, Doulting stone from Messrs. Charles Trask & Son's quarries, "hammer-dressed," with finely-wrought window and other dressings; the gable copings, tops of chimney-stacks, &c., are of the harder or weather beds of the Chelney quarries. The roofs are covered with slates.

The ground on which the cottages stand naturally lies about 3 ft. above the adjoining road level, and an attempt has been made to turn this irregularity to account in the design. Mr. George J. Skipper, of Norwich, is the architect of the work, and Mr. F. W. Pullen, of Shepton Mallet, the contractor.

### Gilchrist Engineering Scholarships.—

We may draw attention to these scholarships, to be competed for at University College. The examination is intended to be such as can be passed by a well-taught school-boy fresh from school, and will be held on the 29th and 30th of September. Candidates must send in notice to the Secretary of University College of their intention to compete, not later than September 23rd. The scholarships are of the value of 35*l.*, and tenable for two years.

**The Lighting of the House of Commons.**  
Mr. Plunket, the First Commissioner of Works, in answer to a question put by Mr. Graham last week, said that there was no doubt that the use of gas in the cloister used as the cloak-room was doing a certain amount of injury to the stonework of the roof, and he quite agreed as to the advisability of substituting electric lighting. Unfortunately, there was the odious question of expense, and he had been for some time engaged in having estimates prepared which he hoped very soon to submit to the proper authorities.

Alterations and Additions to a Cottage at Haslemere, Surrey.—Mr. W. A. Pite, Architect.

#### COTTAGE, HASLEMERE.

THE illustration shows additions made to an ancient cottage at Haslemere, for Mr. Rayner Storr, who has rescued the premises from continuing as a double tenement.

The ground story is stone, while the upper part and roofs are oak framed and tile hung. The house has many levels. The work was carried out under the superintendence of Mr. William A. Pite.

The small drawing from which the cut is reproduced was hung in the Royal Academy Architectural Room this season.

#### MECHANICAL SCIENCE AND THE EDUCATION OF ENGINEERS.

IN the Mechanical Science Section of the British Association Meeting at Manchester last week, the President of the Section, Professor Osborne Reynolds, in the course of his inaugural address, reviewed the achievements in mechanical science accomplished since the last meeting of the Association in Manchester, twenty-six years ago. It was always difficult, he said, to arrive at a just appreciation of the relative importance of the events of our own time; and in any endeavour to review or take stock of the mechanical advance of the last quarter of a century, during which time things mechanical had divided the attention of the civilised world with matters political, it seemed very necessary to remember that as the mechanical age got older its relative activity was not to be gauged by the relative number and importance of such epoch-marking mechanical departures as compared with those which had distinguished past periods. However high or low an estimate we might form of the probable future importance of some of these inventions, and however much disappointment we may feel at the non-success which has attended some of the holdest and apparently most promising departures, such as the Crampton process for substituting a blast of coal dust for the ordinary furnace, or Sir Henry Bessemer's endeavours to prevent distressing motion at sea, there was still no ground for discouragement. For whether or not this period be

henceforth remarkable for what may be called the origination of new mechanical species, is a small matter compared with the fact that it had undoubtedly been remarkable for unprecedented achievements in the development of higher states of organisation in those mechanical species which were already in existence. There has never been a time in which mechanical revolutions had followed one another with such rapidity. In all the main departments of practical mechanics progress had been so rapid that appliances have been superseded long before reaching the term of their natural existence. . . . That the character and rate of recent mechanical advance were both exactly such as would be expected to follow, as the result of a deeper and broader knowledge of scientific methods and the principles involved, seemed to be the very best proof of advance in that other side of mechanical science in which this section took interest, or, more correctly, for which it exists,—the increase and spread of mechanical knowledge. Elementary education, whatever might be its subjects, must of necessity depend for its permanent existence on some source of higher knowledge in those subjects. Without raising such questions as whether there exist at present means of training efficient teachers in all the branches for which technical education is promised, or whether such means would be forthcoming as a result of the demand of teachers, he recalled the recent progress made towards a higher training in that branch of science which most directly relates to mechanical progress, and which, according to no less an authority than the late Professor Rankine, received its first impulse from the institution of Section G. Professor Gordon, who held the chair of mechanics in Glasgow University, was the first in this country to collect and embody in his lectures, and subsequently in a text-book, the important though scattered results of individual efforts to found the laws of practical mechanics on exact science. And at the time Rankine was speaking, the chair to which Rankine himself was called the same year was the only chair in this country from which such lectures were given. Since that time the appreciation of that science has steadily increased; other colleges took up the subject mostly as forming part of courses entitled engineering or naval

science. Amongst these was Owens College, in which, not till after the last meeting in Manchester of this Association, the leading engineers founded and endowed, which is more important, the chair which it has been my fortune to occupy for nineteen years. During the earlier part of this time both teachers and students were labouring under the disadvantage arising from the novelty of the subject,—the former having to make an almost arbitrary selection of what they would teach, and the latter not knowing exactly what it was they were going to learn. Gradually, however, by the help of experience from the somewhat earlier French schools and with the admirable works of Rankine as a foundation, the lectures or theoretical courses had become clear and distinct, while the advantage to be gained had become so generally recognised that of late years there had been almost a scramble to found new colleges to teach engineering, or to introduce such teaching into existing colleges; and most satisfactory to those engaged in the introduction of the subject was the fact that it was from engineers themselves that the interest and funds necessary for the work had come. Since 1867 the Owens College had received gifts and bequests from engineers, including those of the highest standing in the neighbourhood, of upwards of 150,000. It could not for one moment be doubted that this movement had been brought about by the conviction of the necessity of an education which, in its subjects and methods of teaching, was much more closely related than was the older system of the universities, to the actual work which the students may eventually be called upon to undertake,—that it was, in fact, evidence of the appreciation, by those having the greatest experience, of the necessity of higher scientific training for engineers. This was what engineering schools during their struggle for existence had endeavoured to supply. And in spite of the danger which seems to beset all schools as they become older, to fall into the academic or pure,—not because it is the most desirable to be learned, but because it is by far the easiest to teach,—in spite of this danger, such in this case is the pressure from without, that it may be hoped the schools of engineering and applied science might be kept up to the mark, both in extending our knowledge of the laws and principles

COSINE A = SINE(90-A)

which more immediately underlie the results of practical experience in art, and in teaching the methods of most useful application; and that while encouraged to offer every inducement to the attainment of a sound knowledge of the principles, they would not be allowed to fall into the fatally easy errors of carrying the abstractions of this science outside all possible application, or blocking the way by the insistence on impossible preliminary attainments in mathematics and pure science. To be hailed as one of the greatest inducements to keeping alive in engineering schools a real scientific interest in the practical work which is going on around them was the introduction of what are now called engineering laboratories, in which students might familiarise themselves with the actual subjects for which the theoretical work was undertaken, and have placed before them in their most naked forms the data and mechanical actions in which practical achievements depend, as well as being taught the use of all those instruments and methods of measurement which it was one of the first objects of these laboratories to extend and to perfect, and which measurements are now, as the result of a better knowledge of principles, rapidly displacing the older methods of arriving at conclusions in engineering. During the erection and fitting of the Whitworth Laboratory in Owens College, which was now on the verge of completion, it had been very impressive to see the goodwill shown toward the work by everybody who had had to do with it. Everyone who had paid attention to the history of mechanical progress must have been impressed by the smallness in number of recorded attempts to decide the broader questions in engineering by systematic experiments, as well as by the great results which in the long run have apparently followed as the effect of these few researches. He said apparently, because it

was certain that there have been other researches which probably, on account of failure to attain some immediate object, have not been recorded, although they may have yielded valuable experience which, though not put on record, has, before it was forgotten, led to other attempts. But even discounting such lost researches, it was very evident that mechanical science was in the past very much hampered by the want of sufficient inducement to the undertaking of experiments to settle questions of the utmost importance to general advance, but which had not promised pecuniary returns, scientific questions which involved a greater sacrifice of time and money than individuals could afford. To what all this might lead us to consider, but he ventured to end his address on the progress of mechanical science during the past twenty-six years by what appeared to him the most satisfactory conclusion, viz., that to such mechanical progress there is apparently no end; for, as in the past so in the future, each step in any direction would remove limits and carry us past barriers which have till then blocked the way in other directions, and so what for the time might appear to be a visible end or practical limit would turn out but a bend in the road.

Mr. W. H. Barlow, Past-President of the Institution of Civil Engineers, moved a vote of thanks to Prof. Osborne Reynolds, which was seconded by Mr. J. Abernethy, who remarked that the subject of technical education touched upon in the address was of the utmost importance. If we were to compete successfully with foreigners and Americans, the engineers of the future must be instructed, more than they had been in the past, in technical science or applied mechanics.

The resolution was carried.

### The Student's Column.

#### LAND SURVEYING AND LEVELLING. XI.—TRIGONOMETRICAL SURVEYING.

**T**wo any two straight lines, such as A C and B C, intersect one another at the point C, and if, from any point in one of the lines such as B C, at any distance B from C upon the side forming an acute angle with the other line A C, we draw a perpendicular to meet the other line A C, a right-angled triangle will be formed, in which B C will represent the base, A B the perpendicular, and the A C the hypotenuse subtending the right angle.

Mathematical tables have been formed, giving the ratio between any two adjacent sides of a triangle, so that by the aid of these tables, when we know the length of any one side, and the value in degrees and parts of a degree of either of the acute angles A C B or C A B, we can arrive at the length of the adjacent side forming the angle, and then, having arrived at the length of two sides of the triangle, we can easily determine the length of the third side, either by a further use of these tables, or by the application of the 47th proposition of the first book of Euclid.

The trigonometrical values furnished by the tables are denominated as follows:—(1) the sine of the angle, found by dividing the length of the perpendicular by the length of the hypotenuse; (2) the cosine of the angle, found by dividing the length of the base by the length of the hypotenuse; (3) the tangent of the angle, found by dividing the length of the perpendicular by the length of the base; (4) the secant of the angle, found by dividing the length of the hypotenuse by the length of the base; (5) the cosecant of the angle, found by dividing the length of the hypotenuse by the length of the perpendicular; and (6) the cotan-

TAN A = COTAN (90 - A)

SECANT A = COSEC (90 - A)

t of the angle, found by dividing the length of the base by the length of the perpendicular. In the triangle A B C the hypothenuse C represent the radius of a circle equal unity, then the sine of the angle will be expressed by the length of the perpendicular, and the cosine of the angle will be expressed by the length of the base. If the length of the base be a radius equal to unity, as shown in the diagram, then the length of the perpendicular will express the sine of the angle, and the length of the tangent will express the value of the tangent. Hence the names sine, tangent, secant, allied to these expressions, signifying a line opposite the angle, and secant a line touching the circle.

In the case of the angle C A B, the line C B would become the perpendicular drawn from point B, at a distance, B A, from the point intersection A, to meet the line C A in the point C, and B A would become the base on which the perpendicular would be drawn. Hence the sine, tangent, and secant of angle A C B become respectively the cosine, cotangent, and the cosecant of the angle C A B. Furthermore, it will be observed that in either angle the reciprocal of the sine equal to the cosecant, the reciprocal of the cosine is equal to the cotangent, and the reciprocal of the secant is equal to the cosine.

It will also be observed that whatever the angle of the triangle, provided the angles remain the same, these ratios will be by the principle of similar triangles remain the same; so that when the length of one side is known, the length of the other sides in any particular angle can be determined.

To facilitate the process of calculation, tables of logarithmic sines and cosines are published; to explain our subject, it will be sufficient

to refer only to the accompanying table of natural equivalents for whole degrees. Thus suppose we require the value of the cotangent for an angle of 62 degrees 27 minutes. By the tables,

Cot 62° = .53170  
Cot 63° = .50952

Difference for 1° = .02218.

Approximate difference for 27' =  $\frac{27}{60}$  (.02218) = .009981.

∴ Cot 62° 27' approximately = (.53170 - .009981) = .521719.

To calculate this accurately we must express the cotangent in terms of the sine and cosine, as the tables to which we have to refer only state, when single minutes are required, the values of the sines and cosines of angles; thus,

Cot 62° 27' =  $\frac{\cos 62^\circ 27'}{\sin 62^\circ 27'} = \frac{.4625225}{.8866075}$

The reduction of this vulgar fraction, which will be found equal to = .52176767, will show the value of the application of logarithms.

The approximate result, .521719, is seen to be correct for three places of decimals, but for application to the plotting of long base-lines the more accurate process must be applied.

**Caucasus Wood.**—A recent St. Petersburg journal comments on the increasing exportation of Caucasus wood, both nut-wood and palm-wood, which are sold by weight. The palm attains a height of 35 ft., and is not found in forests, but in isolated groups. The year 1883 showed exportations of nut-wood at 27,083 cwt., and palm-wood, 32,328 cwt.; while in 1885 the increase had run up to 36,370 cwt., and 61,252 cwt. respectively,—nearly double of the latter in the two years.

SANITARY CONGRESS AT BOLTON.

The tenth Autumn Congress of the Sanitary Institute of Great Britain will be held at Bolton from September 20th to September 24th. In connexion with it there will, as usual, be an exhibition of sanitary apparatus and appliances, which will remain open until October 15th.

The following is the order of proceedings:—

Tuesday, September 20.

- 1 p.m.—Reception by the Mayor, at the Town-hall.
- 1.30 p.m.—Public Luncheon.
- 3 p.m.—Opening of Exhibition by the Mayor.
- 8 p.m.—First General Meeting; Opening Address by Right Hon. Lord Basing, F.R.S.

Wednesday, September 21.

- Section I.—“Sanitary Science and Preventive Medicine.”
- 10.30 a.m.—Address by Prof. J. Russell Reynolds, M.D., F.R.S., F.R.C.P.
- 11 a.m. to 1 p.m.—Papers and Discussions.
- 8 p.m.—Conversations in the Town-hall.

Thursday, September 22.

- Conference of Medical Officers of Health.
- 10.30 a.m.—Papers and Discussions on matters which come especially within the province of Medical Officers of Health.

Section II.—“Engineering and Architecture.”

- 10.30 a.m.—Address by Prof. T. Hayter Lewis, F.R.S.A., F.R.I.B.A.
- 11 a.m. to 1 p.m.—Papers and Discussions.
- 2 to 5 p.m.—Ditto.
- 8 p.m.—Lecture to the Congress by Arthur Ransome, M.D., F.R.S.

Friday, September 23.

- Section III.—“Chemistry, Meteorology, and Geology.”
- 10.30 a.m.—Address by August Dupré, Ph.D., F.R.S., F.R.I.B.A.
- 11 a.m. to 1 p.m.—Papers and Discussions.
- 2 to 4 p.m.—Ditto.
- 5 p.m.—Closing General Meeting of Congress.

Saturday, September 24.

- Excursions in the morning.
- 8 p.m.—Addresses to the Working Classes by Major Lamoignon, F.R.S., F.R.I.B.A., Wynter Blyth, M.R.C.S.; and Henry Law, M.Inst.C.E.

### IS A CONSERVATORY OR GREENHOUSE A BUILDING?

KNIGHTLEY V. COLLINS.

This question was once more determined in the affirmative. The District Surveyor for Hammer-smith, Mr. Knightley, summoned Mr. Collins, of Cumberland Park, for erecting a large glass house, and omitting concrete foundations to the supporting walls. It seems that Mr. Collins had erected the house in question for his sons, who are florists, and contended that such structures were not buildings, but trade fixtures. The building in question is in the shape of the letter L, with a frontage towards the High-road of 27 ft., and a depth of 65 ft. The enclosing walls are of various heights, some 2 ft. 9 in., others 3 ft. 9 in., and some nearly 7 ft., with piers here and there 15 ft. above the surface of the ground.

Mr. Knightley presented a drawing of the structure, with a figure drawn by the side to serve as a scale of comparison, and called the attention of the Magistrate to section 6 of the Act of 1855, and contended that although in some cases it might be difficult to define what is a building, in this case that difficulty did not arise, as such structures as this were defined to be buildings, and as such partially exempted. He quoted the first part of sec. 6, and the 15th rule of the same section, and by-law No. 3, in support of his contention as to its being a building, and in justification of his demand for concrete.

Mr. Collins quoted the first rule of the first schedule, and contended he had complied with the law.

Mr. Knightley replied that the by-law directing concrete to be used, except the site be a natural bed of gravel, repealed the rule quoted by Mr. Collins. He also said that builders in his district could not plead ignorance of the law, as when the by-laws were first published by the Metropolitan Board of Works he had copies struck off, and when builders gave notice a copy was banded to them; he had distributed many hundreds, and Mr. Collins had had his copy. When the trenches were dug, Mr. Collins complained of being asked to use concrete. Mr. Knightley advised him to apply to the Board, who had relaxing powers, but he refused. Mr. Knightley then said, Mr. Collins, you must put in the concrete, but he refused that also; but when the decision was given against him, he then said he should apply to the Board. Mr. Knightley said he objected, as he was out of court by the effluxion of time, and asked for an order in the terms of the summons, which Mr. Bennett, the magistrate, granted.

### ARCHITECTS' PLANS DETAINED.

CLARKE V. COUSINS.

UPON the application last Monday, at Bow-street, of Mr. Luke, counsel for the complainant, an architect, at 3, Gordon-square, Mr. Bridge, after some discussion of the point of law, decided that an architect's plans of buildings about to be erected in South wark are not "papers relating to land" within the exception mentioned in 2 and 3 Vict., cap. 37, sec. 40, and accordingly ordered the defendant, a haulier, who had detained the plans, to deliver them up (or pay 14s., their value), and 3s. costs.

### "DUTIES OF A CLERK OF WORKS."

SIR,—Having had my money's worth in "Leaning's Quainties," I bought lately and have been reading Mr. Leaning's last little (very little,—equal to about three leaves of the *Builder*) and dear (very dear) book, "The Duties of a Clerk of Works."

The following items and extracts appear to me to require some further explanation from the author, if he will kindly so far favour us; or perhaps comment from yourself and your readers might be useful:—

P. 25, *lime Mortar*.—"Have it mixed in quantities sufficient only for daily use." It used to be "mixed fresh and used hot" in the specifications of my youth, but now most people more wisely prefer a large quantity of mortar to be made up, well heaped or covered, cooled as long as possible, re-heat, and used stiff. The hoasted Roman mortar was not made from day to day as required, and used sloppy, as newly-made mortar must be.

P. 36, "A void use of silicious lime for lathed work." I have heard the recommendation to avoid its use for the setting coat of ceilings, but I have never heard that it is to be avoided for the laying or pricking-up coat and the floating coats. Indeed, it is specially recommended by some for these purposes.

P. 36, "If floors are not strongly timbered, the laying of the floor-boards will often break the key of plastering of ceilings, and many of them will fall; but there is less danger of this if there are no ceiling joists." Mr. Leaning does not surely mean what is printed, from which his readers might infer that there would be less danger to the ceiling below from the vibration caused by missing the floor-boards above if the ceiling laths are nailed directly to undersides of floor joists, instead of to ceiling joists intervening between the plaster and the floor joists. At

any rate, we have always been taught to the exact contrary.

P. 43, *Painter*.—"Do not allow too much oil and turps to be mixed with the colours" (no mention here of lead, only colours), "especially regard this for surfaces to be varnished." Most people know that varnish cannot be properly applied over a full oil coat. The coat immediately under the varnish should be a flat one, containing little or no oil.

P. 44, "See that varnish is not diluted by the addition of turpentine." Would not this take off its gloss, which might be required in some exceptional instances? Is not the usual method to dilute with oil, not turps?

P. 44, "Where work is varnished, special attention to sining will produce best results." This requires the explanation that it applies only to unpainted work, or in some exceptional cases to old work painted or varnished, or both, when not re-painted or re-varnished. In new work, sizing between paint or varnish may save a coat of varnish, but is bad work. Is the idea to neutralise the oil in the undercoat of paint, which oil should not have been applied? ARCHITECT.

### PROVINCIAL NEWS.

**Chester-le-Street.**—The extensive building works commenced by the Chester-le-Street Co-operative Society two years ago are now on the point of completion. New shops, &c., for the following departments have been provided, viz.:—Drapery; boots, shoes, and hardware; tailoring, millinery, furnishings, butchery, and groceries; besides cocoa-room and restaurant, reading-room, library, and lavatories for ladies and gentlemen. Extensive stabling and cart-shed accommodation have been provided, together with cattle lairs and slaughter-house. Thirty-one cottages have also been erected, containing four and five rooms each, and the adjoining streets paved and sewered. The total cost has been about 14,000*l.*, excluding value of land. The work has been divided among various contractors, the principal being Messrs. J. Burnett & Son, of Birdley; Mr. Wm. Thompson, of Chester-le-Street; and Mr. John Yeales, of Jarrow. The architects from whose plans and under whose superintendence the whole has been carried out are Messrs. S. Oswald & Son, of Newcastle-on-Tyne.

**Chichester.**—Major Hector Tulloch, Inspector for the Local Government Board, held an inquiry on Tuesday last respecting an application made by the Corporation of Chichester for sanction to borrow the sum of 2,500*l.* for the erection of an Infectious Diseases Hospital. The City Surveyor, Mr. Stringfellow, produced the plans, which, the Inspector stated, had received the approval of the Local Government Board. Considerable opposition was raised by members of the Ratepayers' Association and others as to the site selected by the Council, and alternative sites were suggested, which, however, did not appear to favourably impress the Inspector.

**Heydon (Norfolk).**—Colonel W. E. G. Lytton-Bulwer, J.P., of Heydon Hall, is erecting, in commemoration of Her Majesty's Jubilee, a canopy over the well on Heydon village green. The moulded jambs, arches, and buttresses are of special made brickwork, from the works of Mr. G. Gntton, of Costessey; the roof is covered with pressed Broseley tiles, and is surmounted at its apex by a cut and shaped terminal covered with lead. A panel bearing an inscription, and a seat, will be provided in one of the sides. Mr. George J. Skipper is the architect.

**Street (Somerset).**—The Jubilee Committee of Street decided to commemorate the fiftieth year of Her Majesty's reign by erecting a new vestry-room for the parish. Mr. George J. Skipper, architect, of Norwich, designed the building, and Mr. F. Huieb, builder, has taken the contract for carrying out the works. Provision is made on the first floor for the vestry-room, committee, and strong rooms; on the ground floor are the entrance, waiting-room, lavatory, and w.c.; also fire-brigade station, and stores, and hearse-house adjoining. A caretaker's house is attached to and communicating with the rest of the building. The whole is built of local Blue Lias Lime stone with Ham Hill stone dressings, and is of late Gothic style.

### Competition for the New Government Buildings at Christiania.

—Nearly one hundred applications have been received from architects for prospectuses and plans of the new Government buildings to be erected at Christiania, to which we recently referred.

### RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

10,298, White Pigments. F. W. Lyte.

This invention relates to an improvement upon a process described in a previous specification, and has for its basis the use of soluble compounds of lead which are chemically combined with other lead bye-products so as to greatly increase the covering power of the paints made from it.

11,454, Kitchen Ranges. R. Hunter and John Turnhull.

This invention consists in providing in connexion with the fire-grate a movable bottom with improved devices for vertically raising or lowering and sustaining the same, so that the depth of the burning fuel may thereby be regulated, and a shallow fire be maintained in proximity to cooking utensils placed over it on the level of the hob by raising the movable bottom, and a deep fire, adapted for roasting and cooking in front of the grate, being obtained by lowering the bottom and filling up the grate with fuel. Suitable mechanism for raising and lowering the bars is fitted to each range for the above-mentioned purposes.

12,307, Fanlight and Casement Opener. H. Whiteley.

The opener for fanlights and casements, which is the subject of this invention, consists of a pivoted slotted bracket attached to the fixed frame of the casement or window. In the slot of the bracket is a runner attached to a bar or arm; at the other end of the bar or arm is formed a toothed quadrant, which is operated by a worm carried in suitable brackets and attached to the casement to be opened or shut. The worm is operated by a pull on the end of the bar or arm.

When the window is closed, the bar or arm is to the casement, clear of the window to be opened; on turning the worm one way it opens the casement by forcing out the end of the bar upon which the runner is carried, the runner passing along the pivoted bracket. By reversing the revolution of the worm the end of the bar carrying the runner is forced inwards, and the window is thereby closed.

12,401, Fastening Casements, &c. E. W. Taylor.

A rack or toothed bar with an automatic catch or clutch are the main features of this invention, which is described in minute detail in the specification.

12,526, Step-Ladders. R. Baird.

A step-ladder made in accordance with this patent is jointed or hinged in the middle, underneath the top step of the bottom or first half of the ladder are two sliding bolts, fastened together by a spiral spring, and shooting into sockets when the ladder is extended, so as to ensure its being rigid. When the ladder is to be used as steps the bolts are drawn inward, and the ladder then doubled; a quadrant keeps the two halves of the steps firm.

16,294, Sash-Fasteners. H. T. Bassett.

The object of the contrivance which is the subject of this patent is to prevent the window being forced by a knife or other instrument from the outside, and to draw the sashes closer together to prevent rattling. A screw is fixed so that when it is screwed up against the lever it cannot be moved nor the window opened.

9,246, Moistening Air and Ventilation. W. Thompson.

The improvements which are included in this patent refer to the use of special arrangements for injecting a jet or jets of water for ventilation and air-moistening purposes, applicable to the U-shape as well as to the flat cup-shaped ventilating apparatus. One strong jet is used, but is divided or disintegrated so as to ensure the full force of the spray. One cloud or sheet of water is formed by all the patterns of jets. This is afterwards broken up into spray, which moistens thoroughly the air passing near it.

### NEW APPLICATIONS FOR PATENTS.

Aug. 28.—11,557, J. Holt, Latches and Bolts for Doors.—11,624, J. Hanna and T. Shillington, Stoves.

Aug. 27.—11,664, J. Munier and N. Salvaire, Colouring or Staining Wood.—11,671, G. and A. Needham, Window-fasteners.

Aug. 26.—11,654, J. Tomkys, Attaching Door Goodman, Bricks for the better Flying of Woodwork, &c.—11,772, S. Spencer, Window Fastening.

Aug. 30.—11,742, J. Honeyman, Drain Pipes.—11,744, T. Crook and W. Ormrod, Brickmaking Machines.—11,745, W. Ormrod, Self-lubricating Mould for Brickmaking Machines.—11,752, J. Goodman, Bricks for the better Flying of Woodwork, &c.—11,772, S. Spencer, Window Fastening.

Aug. 31.—11,757, E. Bailey, Cupboard Turn.—11,828, W. Crozier, Locking Sash-fasteners.

Sept. 1.—11,833, R. Herrmann, Wallpapers, &c.

### PROVISIONAL SPECIFICATIONS ACCEPTED.

10,114, J. Wallas, Heads of Rainwater Pipes, &c.—10,446, C. Hows, Plaster of Paris.—10,481, S. Alley, and J. MacLellan, Water Meters.—10,562, W. Sargent, Water-waste Preventor for giving a

sh and After Wash.—10,608, F. Hemming, Wood  
boers—10,481, T. Bray, Syphon Water-waste  
venter Cistern for Water-closets.—10,704, C.  
cor, Combined Door Fastener and Indicator.—  
353, J. Gill, Machinery for Making Pottery,  
Pressing Bricks, &c.

COMPLETE SPECIFICATIONS ACCEPTED.

Open to Opposition for Two Months.

1,121, H. Harris, Window Fastenings.—12,330,  
Tylor, Waste Preventing Cistern for Water-  
closets.—13,537, D. Lyon, Flushing Apparatus and  
water-waste Preventor for Water-closet Cisterns.—  
119, P. Richards, Trapping Drains or Sewers.—  
80, C. Lator, Fixing Shots and Roll Caps of  
Paper, &c., for Roofing Purposes.—5,021, J.  
Fetschmann and J. Gouison, Flushing Cisterns for  
Water-closets, &c.—9,800, A. Boulé, Window  
Fasteners.—9,966, A. Eard, Door Bolts, &c.—13,587,  
Parsons, Fall Pipes and Fixing same.—13,692,  
Popplewell, Clamping Devices.—14,045, W.  
Anville, Electric Bells and Indicators.

Miscellaneous.

**Remuneration to Architects for Competitive Designs.**—Towards the close of the  
last year the following architects were invited by  
the trustees of the "Shannon Fund" to send  
designs for a new Church of St. Kevin, at  
Inglisland Park, viz., Thomas Drew, R.H.A.;  
E. Murray, F.R.I.A.A.; J.F. Fuller, F.R.I.A.A.;  
R. Carroll, F.R.I.A.A.; and A.G. Jones. The  
and being under the control of the Court of  
chancellor, a formal application was made to the  
ord Chancellor (Ashbourne) to the effect that  
if unsuccessful competitors should be remunerated  
for their time and trouble in preparing  
drawings. His Lordship, in response, expressed  
his opinion that professional men should not be  
asked to give their time and experience without  
being fairly remunerated, and he accordingly  
made an order that the unsuccessful architects  
be paid fifteen guineas each out of the funds in  
cont. As we have already stated, Mr. Drew  
ok first place, and Mr. Murray second.—*Irish  
Builder.*

**Douglas (Isle of Man).**—The proprietors  
of the Twemlow's Yard Property have awarded  
the first premium of 35l. to Mr. Clarke, archi-  
tect, of Liverpool, for the best scheme sub-  
mitted for developing the property to the best  
advantage for building purposes. The second  
premium of 15l. has been awarded to Messrs.  
Stephen J. Holliday, architect, and H. Bertram  
Nichols, A.M.I.C.E., of Birmingham, joint  
authors of the plans placed second in order  
of merit.

**The Standard Measure of Length in India.**—A  
rentor's telegram dated Simla, September 1,  
says that the Government of India has under  
consideration legislation fixing the English  
yard as the standard measure of length for  
British India, and also legislation for the  
punishment of false trade descriptions, on  
the lines of the Bill promoted by the British  
Board of Trade regarding fraudulent marks on  
merchandise.

**St. Edmund's Church, in Lombard-street,**  
has been lately improved by the removal  
of the old stone steps in the chancel. These  
have been replaced by steps of white marble,  
and the floor has been relaid with black and  
white marble tiles. The work has been carried  
out by Messrs. Arthur Lee & Bros., of Bristol.

**M. Chevreuil,** the distinguished French  
naturalist, whose researches in connexion with  
bees are known to many of our readers, has  
been entered upon his one-hundred-and-second  
year.

**Rapid Construction of a Chimney.**—*Dingler's Journal* records the construction, in  
the short space of fifteen days, of a factory  
chimney in Belgium, 92 ft. high, 5 ft. 6 in. in  
diameter at the bottom, 3 ft. 6 in. at the top,  
on the system known as Max Ferbeck's. The  
mode of construction is described as follows:—  
At the bottom of a pit 21 ft. 6 in. deep, 18 ft.  
long, and 16 ft. 6 in. wide, a layer of concrete  
1 ft. 4 in. deep, and consisting of equal parts of  
sand and cement, was spread out, and upon this  
bed five beams 7 in. square were laid. Then fol-  
lowed another layer of cement 1 ft. 6 in. deep,  
but consisting of one-third cement and two-  
thirds sand. Upon this foundation the base of  
the chimney was constructed of ordinary bricks  
up to 6 ft. above the ground, after which the  
work was handed over to the contractor,  
M. Max Ferbeck, who completed the chimney  
in twelve days with a workman and a  
labourer. Four different shapes of hooklike  
radial bricks in five sizes were employed, the  
bricks locking into each other two ways with  
their hooks. The mortar used was partly  
ordinary mortar, partly mortar mixed with  
cement; the pointing was done with cement  
mortar. The shaft was constructed without  
outside scaffolding. The sides of the chimney  
have a thickness of only 13 in. at the bottom  
and not quite 7 in. at the top. The total  
weight of the brickwork is estimated at 60 tons,  
and the total cost was 93l. of which 27l. was  
for freight and duty. It may be doubted  
whether the employment of a chimney base  
of the nature described, the use of different  
kinds of mortar setting at various degrees of  
quickness, and the rapid method of construction  
are to be recommended in building high  
factory chimneys.

**Sale of Properties.**—By direction of Lord  
Rodney will be put up for auction, on the 14th  
instant, at Hereford, the property known as  
Berrington, near to Loominster. The Hall is a  
fine mansion, built of stone lined with brick, in  
the Italian style, and stands in a park of about  
350 acres. The rest of the estate, corre-  
sponding to what is known as the "Home of  
the Herefords," includes some twenty-two  
farms, about 4,300 acres of land in all. The  
rental value is estimated at nearly 6,500l. per  
annum. On a later date will be offered also the  
two Yorkshire (North Riding) properties of  
Hilton Manor and the Hall, Sutton-on-the-  
Forest. The latter, consisting of a good old  
red brick house, and 3,600 acres of land, valued  
at 4,100l. a year, is of interest as associated  
with the memory of Sterne, who was for a  
while vicar of the parish. The parish, situated  
eight miles north from York, lies within the  
ancient Gallops forest. Hilton, between Yarm  
and Stokesley, is a former residence of the  
Earl of Burlington and the Duke of Devon-  
shire. The estate, watered by the Loven,  
comprises the whole parish of 1,360 acres, and  
yields a rental of 2,000l. a year. The advow-  
son of the living, worth 140l. per annum, goes  
with the freehold.

**A New Building Estate at Lowestoft.**—  
A property designated the Kirkley Cliff Estate,  
at South Lowestoft, has recently been laid out  
for building upon, and last week the first  
portion of the property, containing fifty-six  
sites, was offered for sale in a marquee erected  
on the estate by Mr. A. G. Noddy. Several of  
the plots submitted, having frontages to the sea  
of 20 ft., and depths of 135 ft., were sold at  
from 60l. to 700l. each, two corner plots of  
larger dimensions being sold for 150l. and 800l.  
each. The sale also included several marine resi-  
dences, and a number of shops and dwelling-  
houses erected on the estate by Messrs. Lucas  
Bros. of London. The marine residences, seven  
in number, on Cliff-terrace, facing the sea, said  
to be let at rentals of 75l. and 80l. per  
annum, were sold for 1,500l. each, two other  
villas realising 800l. and 500l. respectively.  
Eight residences, designated Kirkley Cottages,  
were sold at prices varying from 300l. to 800l.  
each, whilst fifteen shops and dwelling-houses  
realised 420l. and 450l. each. The total  
proceeds of the sale amounted to upwards of  
19,000l.

**New Museum at Brussels.**—The city of  
Brussels has acquired a new museum building  
by the reconstruction of the handsome Maison  
du Roi, on the Grande Place. The museum  
contains a vastly valuable collection of civic  
paintings and other *objets d'art* of the same  
nature, acquired by the city from time to  
time.

**The Increasing Use of Cement in Germany.**—The *Sprechaal* remarks that  
scarcely any German industry has made such  
progress within the last twenty years as the  
manufacture of Portland cement. Not only  
have cement tests and kindred topics been dis-  
cussed in trade journals from all points of view,  
but each factory has been trying to increase its  
output. With increased production comes the  
necessity for an extended sale, and thus  
attempts have been made to use cement for the  
entire construction of work in which it normally  
is only used as a binding agent. It is, however,  
urged that no substances are more liable to be  
affected by atmospheric influences than cement  
and cement concrete; and, moreover, that no  
other building materials are more dependent upon  
the conscientiousness of the contractor, sand  
and small stones being cheap and cement dear.  
About the end of 1855 the Prussian Govern-  
ment issued regulations enjoining as restricted  
use as possible of cement for clovated building  
purposes. This measure seems, however, to  
have had but little practical result. While  
defects in ordinary masonry can be seen during  
the period of construction or before the com-  
pletion of a building, such is not the case with  
cement work. A single cask of insufficiently  
binding cement may bring about the destruc-  
tion of an important structure, various in-  
stances being adduced in support of these  
assertions. The most serious point in con-  
nexion with this question is considered to be  
the use of cement concrete for purposes of  
drainage, special danger arising from the de-  
structive acids and alkaline influences to which  
such work is necessarily subjected. The favour-  
able reports which have from time to time been  
circulated as to the satisfactory results obtained  
in such cases by the use of cement are considered  
by the *Sprechaal* to demand a searching in-  
vestigation, it being considered that the work is,  
in many cases, too new to allow of its merits  
being decided upon the basis of present expe-  
rience. This article has given room to some  
interesting controversy in German technical  
circles, the importance of the interests ranged  
on each side of the question giving a practical  
force to the discussion.

**Protection of Theatres from Fire.**—  
Since the burning of the Opéra Comique, French  
and German technical journals have been  
largely discussing the best means to be adopted  
for preventing the spread of fire in theatres,  
and some of the suggestions set forth may be  
of interest and value in view of the terrible  
catastrophe at Exeter. Thus most of the  
French journals advocate the compulsory intro-  
duction of electric light in theatres, and that  
the scenery, &c., be made of fireproof materials,  
whilst one, the well-known *Génie Civil*, recom-  
mends the adoption of flock silk instead of  
canvas for the scenery. This material, the  
journals say, is somewhat more expensive than  
canvas, but possesses in return the advantage  
of being more durable and burning slower,  
almost like tinder. It further states that the  
Theatrical Committee appointed in Paris after  
the Opéra Comique catastrophe applied to a  
Dr. Gehring, an engineer, and mayor of  
Landshut, inviting him to furnish particulars  
of the theatrical scenery invented by him and  
patented some years ago. Dr. Gehring's  
scenery is made of metallic and semi-metallic  
wire netting, which may be painted on with the  
same facility as canvas, whilst being incom-  
bustible. Even under the greatest heat the  
material only glows and becomes charred. The  
Committee has since decided upon recommending  
the material for the scenery at the new Opéra  
Comique. The journal further draws attention  
to the automatic extinguishing apparatus  
adopted in certain American theatres, consisting  
of a great cistern of water, from the bottom of  
which pipes run in various directions. The  
latter are closed at the other end by means of a  
composition consisting of lead, tin, and bismuth,  
which melts at a temperature of 75°C., whereby  
water is immediately poured down in torrents  
on the place on fire. At the same time an  
automatic alarm bell warns the attendants of  
the danger threatening.

**M. Hugo Birger.**—The death is announced,  
at the early age of thirty-seven, of the cele-  
brated Swedish painter, M. Hugo Birger.  
Having studied at the Academy of Arts in  
Stockholm, he gained, in 1877, the Royal Gold  
Medal for his painting, "The Fall of Adam."  
Since then Birger studied in France and Spain,  
where he produced a number of works, which  
realised large sums in his native country.

**Hygienic Investigation in Stockholm.**

An article in the last reports of the Hygienic Board of the city of Stockholm contains a paper by Herr K. Sonden on a series of researches carried out last year on the purity and temperature of the air in a number of public buildings in that city, particularly where the electric light has superseded gas, which are highly interesting. In all twenty buildings were visited,—some two, three, or four times,—the method adopted in the research being the so-called Pettenkorf, a method whereby the purity of the air is determined by the amount of carbonic acid it contains. Beginning with the theatres, we find that in the Royal Grand Theatre, on the electric light being partially introduced instead of gas, there was a great improvement of the air both as regards purity and temperature, although the improvement was not so complete as in other theatres examined, as, for instance, the Court Theatre of Munich, where the electric light has entirely superseded gas. In the Dramatic Theatre, too, great improvement appears manifest since the gas-burners in the building were reconstructed so as to promote ventilation instead of, as before, increasing the volume of carbonic acid and raise the temperature. Thus, whilst four years ago, five per cent. of carbonic acid was not unusual with a temperature of about 30° C., the greatest amount noted last year was only 2.6 per cent., and the highest temperature 24° C. In the New Theatre, on the other hand, where a similar system of gas-lighting has also been introduced, and where, moreover, there is an air-fan, no improvement of the air has been effected, a result which the analysts cannot as yet explain, although they ascribe it to a bad circulation of air. However, of all the Stockholm theatres, the so-called Southern Theatre was found the worst, the amount of carbonic acid in the air on the second tier rising sometimes to six per mille, and the temperature to 30° C. This theatre is, however, situated in a part of Stockholm where the hygienic arrangements are very inferior. Turning to the churches and lecture-rooms, we find that in one of the former, during a meeting of the Salvation Army, the amount of carbonic acid rose to 6.22 per cent. In another church during evening service, the carbonic acid rose to 5.41 per cent., with a temperature of 24.8° C. In the Klara Church, the principal church in Stockholm, an analysis was made when the church was crowded, showing that whilst the temperature only varied from 16.3° at the beginning of the service to 19.5° at the end, the amount of carbonic acid rose from 1.75 to 5.7 per cent. Of other buildings examined may be mentioned one at the lecturo-hall in a public college, where the amount of carbonic acid in the air at the close of the lecture was 2 per cent., and one of the superior courts, where it was 6.25 per cent. The researches in factories, &c., embraced three snuff and tobacco manufactories, and seven printing-offices, and in the former the air was naturally greatly mixed with tobacco dust, whilst in one snuff factory every cubic metre of air contained half a gramme of fine snuff. In another tobacco manufactory, where the electric light had everywhere superseded gas, the amount of carbonic acid in the so-called rolling-room was, nevertheless, from 4 to 5.3 per cent. In some of the printing-offices the air was very bad, in one containing over 5.41 per cent., but in another, that of the *Stockholm Daily Journal*, it was only 0.5 per cent., viz., almost pure. It was found that where good ventilators had been introduced the improvement of the air was very marked. It is intended to continue these researches, as the Hygienic Board is of opinion that they will greatly tend to improve the sanitary condition of buildings where large numbers of people are occupied.

**Codnor Sewerage.**—A meeting of the ratepayers of this Derbyshire district was held on the 5th, to consider a scheme of sewerage submitted by Mr. W. H. Radford, C.E., of Nottingham, as an alternative to one previously drawn out by the Surveyor to the Basford Guardians, who are the Authority in the district. The ratepayers approved Mr. Radford's scheme as the cheapest and most efficient in their opinion: cost of works, 3,900l. The Basford Guardians, last Tuesday decided to send the two schemes to the Local Government Board, accompanied by an intimation that the local vestry preferred Mr. Radford's, and asking them to choose the best scheme.

**The Russian Portland Cement Trade.**

An article in the *Journal du Céramiste et du Chauxfournier* quotes a statement of the French Consul at Moscow that English, German, and Swedish cements are imported in relatively large quantities into Northern and Central Russia. Stettin cement is in special demand, and the Swedish mark, "three crowns," from Lomma, in the province of Skanska, is largely sold. English Portland cement sells at a price about equal to 3s. 1d. to 3s. 4d. per cwt. gross; the duty forming about a quarter of the price (10½d. per cwt.). German and Swedish cements range from 3 per cent. to 5 per cent. below the price of the English article. Russian cement is considered superior to English in quality. Government contracts stipulating its exclusive use. The principal markets for the sale of imported cement are St. Petersburg and Riga. Importation at the latter port has, however, sensibly diminished. At Moscow, the consumption of foreign cement is limited, on account of the competition of factories situated in the industrial district of the city. Amongst the principal Russian factories are the following:—

	Annual production.
1. Company succeeding C. C. Schmidt, Riga.	120,000
2. Cement Company, Podolsk	80,000
3. Cement Company, Fort Kund, Veeberg...	55,000
4. E. Liphardt & Co., Moscow (works at Tzouras)	20,000
5. Stanislas Cjochanorsky, Grodzetz (Poland)	50,000

By the Customs returns it would seem that the total imports in 1885 were 46,814 tons, against 53,289 tons in the preceding year.

**Extensive Building Operations in Hamburg.**—It is now four years ago, says a Hamburg journal, since the extensive building operations necessitated by this city joining the German Customs Bund were commenced, when, in order to provide sufficient space for the free trade harbour on one side and the duty dock on the other, some 20,000 inhabitants had to quit their dwellings. This great revolution took place in the old part of the town. From the returns now furnished for the four years to the end of 1886, it appears that a sum of 5,300,000l. has been expended in this undertaking, of which the German Empire pays 2,000,000l., extended over five years. Of the above-mentioned sum 3,350,000l. have been expended in erecting new buildings, and 200,000l. as interest on loans, making a total of 3,550,000l. The greatest outlay appears to have been in purchase of ground, under which item a sum of 2,000,000l. was expended on the Hamburg side of the Elbe alone. On the other hand, it may be mentioned that the "golden times" anticipated four years ago by our building speculators, artisans, and workmen have failed to put in an appearance, a circumstance which may be ascribed to the severe competition offered from beyond the city, the great influx of workmen from Silesia, Poland, and even Italy,—the latter working for a minimum of wages, though being excellent and reliable workmen,—and the means of transport becoming every day easier, which have the effect of lowering the price of labour as well as material. A large number of houses have been sold below their cost. For excavations and foundation work almost only foreign labourers were employed, chiefly Italians, their Hamburg *confères* showing a decided objection to hard work.

**Folding Steel Gates and Shutters.**—These, which are patented by the "Bostwick Folding Steel Gate and Shutter Co.," consist of steel shutters with the vertical bars connected by two or three series of short bars arranged trellis-wise, working on centres at the point where they intersect each other and the vertical bar, but with the ends of the cross pieces working loose in channels in the vertical bars. By this arrangement it is possible to push the whole of the vertical bars close up together, into a space of a few inches, and if necessary the whole, when closed up, can be further turned round on a hinge and lie against the window or door jamb, like an ordinary shutter. Among the advantages are security combined with ventilation, as the shutter can be drawn out and locked across a door or window without obstructing air or much light. The straight backwards and forwards motion in one plane, in closing up or pulling out the shutter, is a convenience, as the shutter does not interfere with curtains or blinds in process of being closed. The invention seems likely to be a useful one.

**Malhouse, Cardiff.**

A large malhouse now being completed for the Cardiff Mal Company, on the East Moors, Cardiff, contains four growing-floors, 110 ft. long 50 ft. wide, and two double-floor kilns, 85 ft. by 31 ft. The building is designed to work on the improved system introduced by Mr. Stopes, the well-known maltsters' engineer London. The ground, first, second, and third floors, are to be used as growing floor; the fourth floor as a harley-loft, and the roof a malt-store, containing 30,000 cubic feet storage space, besides a 10-ft. wide gangway running down the middle, the hays at each being used for screening-loft, store-tank, &c. In the harley-loft is placed a 6 h.p. Griffin patent gas engine, and the shafting for driving a hand-conveyor in the roof, elevators, sack-hoists. Four of Free's patent conical bottomed steeping cisterns are also in the loft, and between each pair is a small elevator for raising barley into the loft above, when it passes over screens into the steeping-tanks. Under these tanks are trap-doors in all the floors, whereby the steeped grain can be let to grow on any floor at the maltster's pleasure. The lowest floor of the kilns contains the furnaces, coal-store, &c.; also an office for the manager, a mess-room for the men, lavatory, &c. The floor above is a malt-store, containing 15,000 cubic feet of storage space, and on this again is the top of the furnace shaft, a hot-air dispersing chamber. Above this, at level with the top growing floor, is the low drying floor, of Fison's perforated tiles; at level with the harley-loft is the upper drying floor, of Hermann's patent wedge-shaped wood cowl is fixed on the outlets above, which are left open, except for pyramidal roofs supported on posts, to keep the rain from entering the kilns. The upper kiln floors are loaded by an elevator, and emptied by openings communicating with the lower kiln-floors. Thence the malt can either be passed through spouts into the malt-store beneath, or raised by another elevator to the hand-conveyor in the roof, by which it can be delivered over screens into the bins. The building is very substantially erected in brickwork, faced with red Pennock bricks. The floors throughout are of concrete, supported on rolled iron joists and cast-iron stanchions. The roof is arranged with a special view to storing malt, and is lined on the side and out with boarding. Upon the outside the boarding is laid tarred felt, and upon that the sleeping-tanks are laid, supported by battens and slates. The sleeping-tanks are supplied and fixed by Messrs. Goddard & Massey, of Nottingham; the kiln-floors by Messrs. Stopes & Co. of London; the machinery and gas-engine by Messrs. Spencer & Co., of Melksham; the architect's advising engineer being Mr. J. Gillett, of Penarth; the gas and water services by Messrs. Cross Bros., of Cardiff; the iron construction by Messrs. Williams & Sons, of Cardiff, under the general contractors, Messrs. Shepherd & Son, of Cardiff. The architect is Mr. F. Baldwin, 17, Church Street, Cardiff; and the clerk of work's duties have been very efficiently discharged by Mr. David Owen.

**Discovery of Sculpture by Thorwaldsen.** During the recent repairing of a house at Neurwall (in Hamburg), one of the most important business quarters of the town, two original works of art by Thorwaldsen have been discovered. The former owner of the house, Herr Hartzon, a dealer in artistic objects, was a friend of the famous Danish sculptor, and when the former, after the destruction of Hamburg by fire some forty years ago, rebuilt his house, Thorwaldsen presented him with four *hauts-reliefs*, representing the arts of painting, sculpture, architecture, and music, for the purpose of ornamenting the front of the building. Time and weather have, however, destroyed the two former, but the discovery of the latter has saved them from destruction, their restoration having now been taken in hand. There cannot, from the facts stated here, be the slightest doubt as to the genuineness of these works of art.—*Hamburger Nachrichten*.

**Extension of the Metropolitan Railway.** A further extension of the Metropolitan Railway was opened on the 1st inst. from Pinnet to Kingswood and Rickmansworth for passenger traffic. The line is in course of construction to St. Albans, Aylesbury, Oxford, &c. The company intend, it is said (in the daily papers) to extend their system as far as Birmingham. Can this possibly be true? If so, the company will require re-naming.

Strike of Joiners at Elswick.—On the 1st inst. about 200 joiners employed at the Elswick Shipyard of Messrs. Armstrong, Mitchell, & Co. came out on strike in consequence of a dispute as to the carpentering and joining work, the carpenters receiving a week more than the joiners.

"New Premises in the Haymarket."—With reference to these premises, described and illustrated in our last, we are asked to mention that all the stores,—chimney-pieces in marble and American walnut, as also the tile-hearths, &c.,—were supplied by Mr. N. Maurice, of Ramcar-road, Tottenham.

Exhibition of Painting and Sculpture t Brussels.—On the 1st inst. the king, accompanied by the Count of Flanders and Prince Baudouin, opened an exhibition of painting and sculpture in the galleries formerly occupied by old pictures. It will remain open until Nov. 1.

### Greek Sepulchral Monuments.

F the minor works of art that ancient Greece has left us, perhaps none have commanded such ready attention or such universal admiration as the large and constantly-increasing series of grave reliefs. Their full beauty can only be realised, it is true, at Athens itself, in the large collection in the Central Museum; and still better at the Hagia Sophia, where a number of the best specimens still remain *in situ*, and where the specialist will necessarily study them; but for the general public need not wander further than the (cellars of) the British Museum, or, if he desire full daylight, he may see in the South Kensington Museum casts of upwards of twenty well-selected instances.

Any one who looks at these reliefs for the first time will be struck, not only by their beauty, but by their extreme simplicity; here, at least, he will think, there can be little difficulty of interpretation,—we are in the presence of no recondite mythology. We have one a citizen with his dog; on another a mother and child; another, a lady with her toilette-box; another, a youth mounted on his horse,—everywhere humanity in its simplest and most natural aspects. If it were so, the present work would not be needed, except, perhaps, chiefly to call attention to certain special duties of execution, and to fix an easily-ascertained chronological sequence. The case is far otherwise; grave archaeological difficulties have arisen on the mature consideration of these apparently simple designs,—difficulties, the solution of which is necessary to their full understanding and realisation, and also, in addition, to their artistic appreciation.

As is well known, it is the intention of the Russian Archaeological Institute to collect together in one vast corpus all the available material, *i.e.*, the whole series of Attic grave reliefs. Till this is done no doubt a number of important parts must remain obscure, but fortunately we need not wait for the completion of this important work to lay down broadly the outlines of interpretation, though these may leave a wide margin for future notation and correction.

If we desire to understand the meaning of the later and finer reliefs (such as 5, 6, 7), we must go back to earlier work (*e.g.*, 1, 3), in which, while the technical dexterity is less, the utterance of thought is clearer and more precise. We have advisedly selected for our

series of illustrations, not in all cases specimens of the greatest beauty, but rather such a series as shall exemplify certain tendencies of thought and developments of tradition. We can, in a brief article, only summarise certain conflicting views, and register what we believe to be the present high-water mark of archaeological opinion. Those who desire a fuller conspectus will do wisely to read two papers on the subject, to both of which we and all who subsequently write on the subject must be deeply indebted:—(1) A paper on "A Sepulchral Relief from Tarentum," in vol. v. of the *Hellenic Journal*, by Professor Percy Gardner, who, in connexion with one particular monument, takes occasion to discuss the interpretation of the whole class to which it belongs; (2) Dr. Furtwängler's introduction to "La Collection Sabouroff,—Sculptures." In these two papers will be found references to the whole previous literature of the subject.

Fig. 1.

We turn to the first of our reliefs (fig. 1), a monument in itself quaint and curious enough to awaken curiosity. This relief is the earliest and the finest and the best preserved of a series of similar slabs found in 1877 in the neighbourhood of Sparta, a little to the south of the village of Chrysothra. It once formed part of the Sabouroff collection, and was bought by the Berlin Museum with the rest of the Sabouroff marbles; a cast of a similar relief, but of inferior workmanship, can be seen at South Kensington (cat. 20). The subject is clear enough. Two colossal seated figures are depicted, the front one of which, a man, turns full face and holds a wine-cup of the shape known as a kantharos. By his side is seated a woman who draws her veil about her with a gesture of natural modesty very frequent in early Greek art. She wears the peaked shoes of Asia Minor, the man wears sandals. Behind the throne-like chair a

bearded serpent uprears itself. To the seated pair two small figures approach, a man and woman, the man bears a cock and an egg, the woman a flower and a pomegranate; these details are hardly discernible in the small-sized illustration here given, though obvious enough in the original. The technique of this remarkable relief is so peculiar that it is impossible to pass it over in silence, though it is the meaning of the scene depicted that chiefly concerns us. The whole design is worked strictly in profile with the exception of the face of the seated man, which is turned full and which thereby dominates the whole relief. He seems to look not at the figures that approach but at the spectator. Further, and this can be well seen on the South Kensington cast, the design is cut in a succession of flat, superimposed planes, not modelled. It in fact suggests the technique of wood, not of stone. We turn to the interpretation, and first it is important to note the place of finding. The relief was found standing erect on a tumulus composed of earth and stones, and near to it was found a slab inscribed Ἑρμῆος, "of Hermes." There can be little doubt, therefore, that the enclosure was sacred to the Hermes of the lower world, the Chthonic Hermes. The symbols represented point also to the lower world; the serpent, cock, pomegranate, egg, and the dog and horse, which in certain instances appear, have all to do with the worship of the infernal deities. By what name precisely we are to call the seated couple it would be hard to say. The more mythology is studied the more clear it becomes that gods and goddesses, whose functions were almost exactly identical, were locally worshipped under different names; nay, indeed, that even in the same locality, owing to the importation of other cults, the same god could have two different names. In all parts of Greece we find a divine pair ruling over the lower world; the names of Pluto and Persephone were most widely adopted, but we have also at Eleusis two Chthonic divinities known only under the general terms of "The God" and "The Goddess" (ὁ θεός and ἡ θεά). We have also Zeus Chthonios and Ge Chthonia, and at Athens the cult of Neleus and Basileia; at Hermione we have Klymenos and Chthonia. We must, therefore, leave the precise names of the Chthonic couple undetermined, only being sure that they represent the double power, male and female, that in the lower world, by analogy with the upper, rule humanity.

But we are not at the end of the interpretation. If the relief here represented stood alone, the mythological meaning might suffice; but among the other analogous monuments are some which demand further elucidation. In one, notably, a dog springs

up against the knee of the seated figure, two others are inscribed with the names of mortals, *Ἰπποδάμης* and *Ἀσπυροδάμης*. Here we can scarcely suppose that deities are represented, and so a fresh perplexity is added. Perhaps if literature did not step in to help us, the right solution could never have been found. The seated figures are, in fact, in one way mortal, in another divine: they represent the *dead heroised*,—ancestors who are figured under the semblance of gods of the lower world. The Egyptians believed that the soul of the pious man was made in some mysterious way one with Osiris; and the Greek believed his dead ancestor ruled as a very living and real divinity in the world below. Alcestis when she died became "a blessed daimon," powerful to answer prayer. Her tomb was,—

"Like the gods  
Honour'd, a veneration to a world  
Of wanderers. Of the wanderers struck thereby,  
Who else had sail'd past in his merchant ship,  
Ay, he shall leave ship, land, long wind his way  
Up to the mountain summit, till there break  
Speech forth, 'So this was she, then, died of old  
To save her husband! Now a deity  
She bends above us. Hail, benignant one!  
Give good!'"

Fig. 2.

Nor was this any special canonisation, the meed of notable virtue; it was the ordinary state of the departed,—conceived of as mysteriously powerful because beyond the sphere of sense. Aristotle says the dead were reckoned as having become more powerful (*σπουδαιότερον ἢ τὸν ζῶντων*). Plato (*Laws*, xi., 927) says that "the souls of the dead have the power after their death of taking an interest in human affairs," "and therefore, men should have a fear not only of the gods above, but in the second place of the souls of the departed." It would be easy to multiply references of this kind. It is enough if we grasp the fact that the departed ancestor of any family of note became a sort of god, and was worshipped with a cult carefully prescribed and handed down from generation to generation. His tomb became a shrine, to which the pious descendant brought his offering. It was this ancestor worship that gave rise, no doubt, to many a local divinity, and it is this ancestor worship that is represented in the Sparta reliefs. The two tiny figures are the pious descendants who, no doubt, offered the relief with the double purpose of commemorating their ancestors and appeasing those Chthonic deities,—by whatever name they were called,—whose functions were in part shared by the dead man and his wife.

Our next relief (Fig. 2) takes us a step further in the same direction; we take it next not

because chronologically it is nearest, but because it illustrates a further development of the same belief. The marble of which the slab is made is Pentelic, but from the style it is presumably the work of a Boeotian sculptor, and it dates about the middle or end of the fourth century B.C. It belongs to a class of monuments not set up over tombs, but dedicated within the precincts of the burying-place. It is, in fact, a memorial tablet offered to the gods of the lower world. Such tablets were either fixed in the wall of the shrine or erected on a pillar. This one, evidently from the form, stood on a pillar, in the way frequently depicted on painted vases.

The analogy with the preceding monument is obvious. We have the heroic couple and the procession of miniature worshippers. The man, however, no longer simply holds a kantharos, he is regularly engaged at a banquet. He lies in Ionian fashion, his wife is seated by his side. A slave boy attends to draw wine from the amphora. Near the couch is a table heaped with the little, conical cakes, probably those which went by the name of "pyramids." Here, again, we have a mingling of the human and the divine, but the human seems to be getting

come to determine the order of priority, it is more likely that this element of the banquet was transferred from heroes to gods than *versus*, at least the custom of *libation*, i.e., pouring wine on the ground, can only have arisen in connexion with Chthonic cults. The tablet we have selected is again only one of a large series,—the same in type, but varying in detail,—and offering in many instances difficulties in the minutiae of interpretation in which we cannot now enter.

So far the two series of monuments we have considered have this common principle as their basis of their designs, that they represent the dead man as he is supposed to be after death, i.e., in heroised form with divine attributes and functions. We may say in passing that of the whole this manner of representation is characteristic of the Dorian stock. We now pass to a series of monuments actuated by another motive, i.e., the desire to represent the dead man as he actually was during life, but as we shall see, this class, in the main Ionian, could not be rightly understood without realising the meaning of the other; the more simple, human, and naturalistic of the second series are yet tinged with some flavour of the

Fig. 3.

heroising faith,—the types of the two series act and counteract on each other.

This is admirably seen in the monument selected for our third (fig. 3) illustration. It is the so-called "Leucothea" relief, from the Villa Albani; where it was found is unknown, but it is probably a piece of Attic work. The older school of interpreters, who were keen to scent mythology everywhere, held that it represented Leucothea nursing the infant Dionysos. But certainly no mythological interpretation is needed; it is a human mother, not a goddess, who with large tender hands takes her youngest born upon her knee and holds him,—a charming touch of realism,—at just a little distance that she may the better see the face which to her, at least, is lovely. It is a maid-servant, not a nymph, who waits with the elder children till the mother has looked her fill. Beneath the lady's chair is a work-basket of ancient pattern, for she is thrifty matron as well as loving mother. It is, however, instructive to note that the mother was mistaken for a goddess: she is seated in the chair of regal splendour with arms to it, always a note of dignity, and a foot-stool; if she were to rise to her feet she would overtop the maid-servant by nearly one-half, and though this may be due to the general principle of isoccephalism so carefully observed in the best Greek reliefs, yet it denotes also exalted rank. What, however, is most suggestive for our purpose is to

the upper hand. But for the crown on the reclining hero's head, and the approaching worshippers, the banquet might be that of a mere mortal. The cakes, indeed, have a somewhat sacred air, as this shape of cake is supposed to have been offered to Demeter. It is, in fact, the old story, the mortal conceived of as a god after death; the gods loved feasting, so the dead man when he is a happy daemon will feast at will. Plato (*Laws*, ii., 363) is severe on this widespread and comfortable faith. He says:—"Still grander are the gifts of Heaven which Museus and his son Eumolpos offer the just: they take them down into the world below, where they have the Saints lying on couches at a feast, everlastingly drunk, with garlands on their heads: their idea seems to be that an immortality of drunkenness is the highest meed of virtue." We are not concerned here with the morality of this heaven, though no doubt, being a conception perfectly honest and genuine, it was cogent as a motive power. What we have to notice is, that this feast of the heatified is only another evidence of their deification. It was part of the regular worship of certain gods, notably the Dioscuri and Æsculapios, who all of them are of the nature of god-heroes, that a table (*τραπέζη*) should be spread for them, and a couch prepared for their reclining; then when they had well eaten and well drunk, they were easy to be entreated. It seems probable that if we

compare this relief with the Spartan stela (fig. 1): manifestly they are the same in type, in art form; the seated regal figure, the approaching procession; but the severe hieratic ideal of god and worshippers has melted into the humanity of mother, children, and maid; it is the old form touched with a new meaning. This is the history of countless of the loveliest Attic compositions, an old Doric type softened into Ionian grace, an austere dogma transmuted into a human truth. Spoken of as one isolated instance, this may seem fanciful, but we venture to say that the more deeply Greek art is studied the more this traditional element is felt,—this habit of keeping the old form and informing it with a new spirit.

Fig. 4.

Fig. 5.

In a large number of reliefs the purely human element alone appears; thus in our fourth instance (fig. 4) we have the simple figure of a citizen leaning on his staff, a lekythos for his anointing on his wrist, and his dog beside him. There is nothing of the god here. This stela now stands in the Naples Museum, much disregarded, quite unphotographed (except by ourselves), a pure bit of early Greek work among a host of vulgar Greco-Roman reliefs. The modelling of the figure is obviously imperfect, specially in the right arm, but no one will deny that this very simple composition has the charm of a perfect sobriety and serenity. It is surmounted by an akroterion of great beauty. Looking on to the stela in figure 6, we may see how this architectural form of decoration speedily became corrupted by the introduction of a certain degree of naturalism. We may say in passing that these akroteria are of the utmost importance in the classification and dating of the stela, and also of no small interest in connexion with the history of the Ionic and Corinthian capitals, but such questions are beside the purport of the present paper. It may be also suggested that in the dog who so frequently appears on Attic stela we have a sort of echo or reminiscence of the symbolic, sacred dog who appears in the early type forms; not that he has here the smallest symbolic meaning, but that he was part of the traditional stock-in-trade of the grave relief-maker, and therefore apt to appear where he could appropriately be worked in.

Very similar in general conception to the Naples stela is our fifth instance (fig. 5), a monument found at Karystos, in Euboea, and now in the Berlin Museum. It once formed part of the Sabouroff collection. The most superficial critic will see at once its likeness to the style of the Parthenon marbles, and we have included it, not from any special interest in its interpretation, but for its intrinsic beauty, and because it shows more conclusively than any *à priori* reasoning how widely felt was the influence of Phidias.

Our last two instances have been long, narrow

stela, with one figure only, and such compositions seem to have been much in favour in the early part of the fifth century. They are singularly dignified and singularly unemotional. As a rule, they are purely human in intent, but sometimes, as where a maiden holds a dove, or a youth a cock, it is hard, indeed, to say whether there be not latent some notion of deification. Often, in all probability, the sculptor was as little clear on the matter as we are. We turn, last of all, to two monuments (figs. 6 and 7) both of great beauty, and which open up quite a new field of inquiry.

Fig. 6.

We take first the simpler composition (from a stela in Berlin), fig. 6. We have represented here husband and wife, Meneas and Menekraleia, clasping hands. The form of the letters dates the monument as belonging to the first quarter of the fourth century B.C. The drapery is distinctly post-Phidias, especially the fold of mantle thrown over the wrist of Meneas. The drapery also of Menekraleia shows that tendency to swirl the folds about the body which is very different from the august but somewhat non-natural schemes of

Fig. 7.

Phidias. In fig. 7 the central notion is the same; husband and wife again clasp hands, but the scene is amplified by the presence of a mourning attendant, and the style is grander and bears more of the stamp of the individual artist. The two principal figures, husband and wife, are inscribed Thraseas of the deme of Perthoidai and Euandria. The head of Thraseas is ideal, but with a touch of portraiture about mouth and nose. He is dressed in the simple bimation, leaving the breast exposed; in the original the working of the skin is beautifully executed, both on breast and arm, and the wrinkles of the hand-joints almost overstep the limits of permissible realism. The rendering of the maid-servant's

head and figure are very remarkable. She is a subordinate figure, and yet, by the accident of a traditional composition, she occupies the central position. Fearing that she may distract the spectator's eye the artist has literally only sketched her in, and she has quite the effect of being in a back plane, and yet the face is perfectly expressive and the sorrowful look is obtained by very simple means, by a prominence of the upper lid and a depression of the inner corner of the eye.

What is the action intended? Most people, at first sight, would say the parting of husband and wife, the visible image of the supreme *χαιρε*. Such was long the current interpretation; but there are obvious difficulties: both husband and wife are dead, their names are conjointly inscribed; further, it is noticeable that in these so-called "parting scenes" all expression of grief is confined to the subordinate figures,—slaves, attendants, and the like. Here, notably, only the maid-servant droops her head in grief, husband and wife look face to face with perfect serenity. Some would argue this is only the ideal calm of the thoroughbred Greek, and, indeed, this point is no doubt one to be considered. Whatever they felt, the Greeks disliked in art a rude exhibition of emotion; but this is not the real clue to the mystery. The scene intended is the *χαιρε* of meeting, not the *χαιρε* of farewell, the eternal all-hail of husband and wife. It is doubtful whether, in the best days of Greek taste, a sculptor would have allowed himself to depict on a funeral monument a scene of such vivid suffering as that of the earthly parting; to them, as to us, the supreme fact of life was companionship, and the supreme loss of death parting.

"Here we suffer grief and pain,"

the hymn says, and with a fine transition from the general to the poignant particular

"Here we meet to part again;"

but all that the Greeks felt or that we feel is not met for expression in art of the monumental kind, and they figured, therefore, here again as in the old Spartan stela, what *was to be*, the meeting in Hades: "in their death they were not divided." The slave might mourn; he was left behind, of no account, above or below; but the husband and wife are serene with clasped hands, for love is stronger than death. So it seems to us now in looking at this ancient gravestone, and probably, in fact, what happened was something of this fashion. The wife died, perhaps, first; her image was set up and her name engraved, and they made her seated on a chair after the pattern of the older lower-world goddess, and as the husband knew that he too must follow soon, he bade the sculptor make a gravestone with the two together, only his name was not graven yet awhile. Perhaps they planned it together before her death, and it comforted both their hearts with that strange mixture of faith and sentiment which humanity at all times finds so sustaining. We have to remember, indeed, that with the Greeks in the case of husband and wife love was far more of a social instinct than a romantic sentiment; but of whatever nature that love might be, we have in these gravestones with the clasped hands the image, not of severance, but of marriage for all time.

In conclusion, it is most necessary to guard against the supposition that the two several ways of regarding the dead man on his monument were successive developments. They subsisted side by side,—the one, perhaps, that of the people, the other of the educated few; the one obtaining ultimately on votive commemorative tablets, the other rather on actual sepulchral monuments. We must beware how we tabulate and date the shifting of human conviction, specially before the days when the analysis of sentiment begins. If we could have Socratically questioned the Greek of the fifth century B.C. we should speedily have reduced him to the confession of heliots logically incompatible,—the fine warp of his reasoned conviction tangled inextricably with a web of materialistic tradition.

## "THE HEALTH OF NATIONS."

**T**HE two volumes recently published under this title are rather difficult to define. The title-page title is given below.\* The outside cover bears the words, "The Health of Nations," in one corner, and "Edwin Chadwick" in another. In the preface Dr. Richardson says that "the author of the works herewith submitted to the public" did him the honour to entrust the publication to his care, leaving the selection and arrangement entirely to his responsibility. The title, "A Review of the Works," suggests that the book is a criticism of Mr. Chadwick's writings by Dr. Richardson. The terms of the preface imply that the book consists of a selection from Mr. Chadwick's writings. It does not appear, however, that either conclusion is correct. The book is really a *résumé*, or what is vulgarly called a "hoiking-down," of Mr. Chadwick's writings and opinions upon the various important subjects in relation to sanitary progress and general public well-being with which his name is so indissolubly connected. It takes a little while to find this out, however, when we are put on the wrong scent in two directions at once; and even when we have fairly discovered the principle of the volume, the result is rather confusing. We have a reference to an essay contributed by Mr. Chadwick to the *Westminster Review* of a certain date. The editor, as we suppose we must call him, proceeds to summarise the contents of this essay. The whole chapter is headed "Practice and Progress." The real title of the essay in question was "An Essay on the Means of Insurance against the Casualties of Sickness, Decrepitude, and Mortality," and this is quoted in the preamble of the chapter. Then commences a summary of its contents, interspersed with remarks by the "editor" under the sub-heading "Social History, 1828"; then a summary of another portion under a second sub-heading, "Practical Men" with which the chapter ends. But the next chapter, headed "The Value of Life," is, we find, on reading it, only another sub-heading of the summary of the same essay. Between this illogical arrangement, and the odd way in which what are apparently Dr. Richardson's own remarks are mixed up with Mr. Chadwick's, it is impossible to say which of them we are to regard as the author, and it requires considerable attention to find out at any particular paragraph whether we are reading Mr. Chadwick's or Dr. Richardson's words: in some places it is entirely doubtful. This method, or want of method, renders the book, well-intentioned as it undoubtedly is, a most confusing and irritating one to read. It would have been far more to the purpose to have reprinted entire some of the most important and typical of Mr. Chadwick's writings, with some historical notes as to the circumstances under which they were written.

The "editor" has, however, so far adopted a method that he does classify his subjects under some main headings. The first volume includes, "Political and Economical" and "Educational and Social"; the second volume is devoted to the sections "Sanitary and Preventive of Disease" and "Prevention of Pauperism and Poverty."

From our point of view the work of Mr. Chadwick as a great sanitary reformer is of the most interest, and it is in connexion with sanitation that he had, perhaps, the greatest reputation with the general public, so that Kingsley many years ago proposed in his "Yeast" (a social and sanitary novel) that he should be celebrated in a kind of modern "Æneid," it called the "Chadwickiad." It appears, however, that it was in connexion with the subject of life insurance that his thoughts were first turned towards sanitary problems. This was while writing the article we have already referred to for the *Westminster Review*, on "The Means of Insurance." He told Dr. Richardson that in the first part of his work he was merely

interested in the results of the calculations as they came out in reply to the questions he had formulated from general observation and induction. But as the labour progressed there developed what he termed the "sanitary idea," the idea that man could, by getting at first principles and arriving at the causes which affect health, mould life altogether differently, and "heat what hitherto had been accepted as fate."

The earlier fights of Mr. Chadwick in the cause of sanitation took place so long ago that at the present moment his name may be little familiar even to some who are unconsciously following in his steps; and he has, perhaps, had less reputation than most men who have done so much useful work, from his not being specially connected with any one line of work. As Dr. Richardson said in a paper he wrote in the *Social Science Review* five-and-twenty years ago, Mr. Chadwick made laws, but was not in the Legislature; did something for sanitation, but was not a doctor; had a hand in education, but was not a schoolmaster; and Dr. Richardson then prophesied that the future biographer of this man would be at a loss to classify him. It is, perhaps, in kindness to the future biographer that this *résumé* has been brought out. The doctor's own opinion of his hero's work is summed up in the title he has chosen for his book,—"The Health of Nations," selected inasmuch as there was nothing advanced in Mr. Chadwick's writings which did not bear on the happiness and well-being of the people. That is true; and, perhaps, the best definition of Mr. Chadwick's part in modern life would be to say that he was a great social and sanitary reformer.

The greater portion of that section of the book in vol. ii, which deals with sanitation and the state of dwellings, is extracted from the Report on the Sanitary Condition of the Labouring Classes of Great Britain, prepared by Mr. Chadwick as Secretary to the Commission of Inquiry, appointed in 1839, as to the causes of disease among the labouring classes of the metropolis and in other parts of the kingdom. Dr. Richardson extracts many chapters, in his own confused fashion, out of this Report, and it is singular to observe how very modern some of the remarks, made not far from fifty years ago, appear even at the present moment; in other words, how much the writer was in advance of the general knowledge and perceptions of his own day. Most of the propositions which have now passed into articles of sanitary faith are found stated here; and occasionally, on the other hand, we are struck by remarks in regard to the circumstances which originate disease, which remind us that this was half a century ago, and that proceedings now universally condemned were then the ordinary every-day way of doing things. The following passage is at least satisfactory as an indication that we have made some progress:—

"The sewerage of the metropolis, though it is a frequent subject of boast to those who have not examined its operations or effects, will be found to be a vast monument of defective administration, of lavish expenditure, and extremely defective execution. The general defect of these works is, that they are so constructed as to accumulate deposits within them; and the accumulations remain for years, and are at last only removed at a great expense and in an offensive manner by hand labour and cartage. The effect is to generate and retain in large quantities before the houses the gases which it is the object of cleansing to remove. . . . It may be mentioned as another instance of the absence of appropriate knowledge that has governed these structural arrangements that a large proportion of the most expensive sewers are constructed with flat bottoms. In proportion as the water is spread the flow is impeded, and the deposit of matter it may hold in suspension increased."

It is curious to read this now. One would have imagined that, apart from anything that could be called scientific study of the subject, ordinary observation and common sense might have warned men against flat-bottomed drains for a drainage carrying solids in suspension. But so it is; a thing is obvious to one generation which was quite overlooked by the preceding one; and that many facts in regard to drainage are obvious to every one now is in a great measure to be attributed to the influence

of the man to whom they were equally obvious fifty years ago.

The further chapters in this section of the subject deal with the condition of "Streets and Pavings," next "Water and Health," in the course of which, by the way, is the record of the fact that at one time there were three different water companies passing through the same streets of a considerable portion of London and competing with each other; of course, with threefold mains and so many separate systems of service pipes. The chapter on Land Drainage and Health is an admirable one, and we quite concur in Dr. Richardson's remark as to the simplicity and force with which the points are brought before the reader. "Ventilation and Work" includes a description of a tailor's work-room at that period, from which there is little doubt Kingsley took his description in "Alton Locke." "Overcrowding in Private Houses," "Medical Officers of Health," "Common Lodging Houses," and "Sanitary Dwellings for the Wage Classes" are among other branches of the subject which were treated of, and which form chapters in the present work. In the last-named chapter is a significant fact which might have its practical application now. In certain emigrant ships there were very bad sanitary conditions and very high death-rates till it was determined to contract with the owners not for the number shipped, but for the number landed alive and well at the end of the voyage. The effect was most striking; the shippers improved their sanitary appliances, and engaged officers of health to take care of the passengers, paying them also "by results." By these contracts we ensured to every poor passenger affectionate attendance, and at least one sincere mourner if anything happened to him." The result was the lowering of the death-rate by one-half. "A War-ship's Worth of Sanitation," a consideration of what could be done with the cost of one first-class man-of-war towards improving public sanitary conditions, is another point in this portion of the work. The chapter on the disposal of the dead is of interest; and in connexion with this subject it is worth while to mention a letter from Carlyle to Mr. Chadwick, in 1850, in which the Chelsea philosopher states, in his own characteristic manner, his long-felt approval of cremation as the most rational means of disposal of the dead.

The book, unsatisfactory as it is in form, should be read through by those who are interested in the subjects of which it treats, as giving information as to the history of a very important branch of modern progress, and of the part played by one determined and practical man in promoting it. Dr. Richardson admits that his friend evinced neither oratorical nor literary gifts in his statements of his theses by word or by pen; but he impressed you as a writer who always had carefully prepared facts behind him to justify all his conclusions; and of his determined attitude in pressing his convictions a dramatic idea is conveyed in a quotation from a semi-humorous article in the *Daily News* of August 19, 1846, referring to his evidence before the Poor Law Commissioners:—"Chadwick stands alone, dark and terrible as Milton's hero, confronting the whole three Commissioners, who are waxing more and more vehement," the evidence not being to their minds. And, indeed, Mr. Chadwick has never been one to incline to that time-honoured Governmental request, "Prophecy unto us smooth things, prophecy deceits." He may claim the distinction of having probably told more disagreeable truths than any Englishman of his generation; and he has had the satisfaction of living to see most, if not all of them, admitted and acted upon.

**A Big Walnut Log.**—The *Glasgow Herald* says that there was recently landed *ex S.S. Lord O'Neill*, from Baltimore, U.S., one of the largest logs of black walnut imported into the Clyde. Its extreme measure is 17 ft. long, 42 in. broad, containing over 200 cubic feet calliper measurement. To those interested in trees it will not only appear a rare but also a valuable specimen. It has been consigned to Messrs. Allison, Consland, & Hamilton, timber brokers, of Glasgow.

\* The Health of Nations; a Review of the Works of Edwin Chadwick, with a Biographical Dissertation. By Benjamin Ward Richardson. London: Longmans, Green, & Co. 1887.

## NOTES.

REFERRED last week to the question of the ventilation of the proposed Channel Tunnel. As a matter of expense, this is no inconsiderable item to be carried to the debit of working cost. But there is a much more serious question than that of the cost of ventilation. It is one which the advocates of the tunnel, whether scientific or otherwise, have conveniently left out of sight. This is, the degree to which the capacity of the tunnel for transport is limited by the fouling of the air by the consumption of coal. That limit, so far as our present engines for locomotive traction are concerned, is very narrow. We cannot put the weight of pure carbon that would be burned by an engine fitted for the tunnel service at less than 20 lb. per mile, and probably this estimate would prove far too low. But this consumption would liberate 73 lb. of carbonic acid gas per mile. A mile of tunnel will contain about two million cubic feet of space, or 160,000 lb. of air. The passage of two trains, whether following or crossing, through a mile of tunnel, would thus raise the proportion of carbonic acid gas from the normal rate of 4 in 10,000 parts, to that of 1 in 1,000 parts, which is not fit for respiration. In addition to the gas from the fire would be that formed by the respiratory process of the passengers. Thus, after the passage of every two, or at the outside three trains, the tunnel would be impassable in safety. Ten miles an hour may be taken as the practical limit of speed of an air current for ventilation; so that an interval of at least two hours must be allowed after each pair of trains to renew the air. Increasing the weight of the trains in order to reduce their number will not much mend the matter, as the consumption of fuel, and the formation of gas, increases with the weight of the train. Supposing, then, the impurity of the atmosphere not to be more than the proportion at which delicate persons begin to succumb, and that the ventilating apparatus is in good order to produce a current of air at the rate of ten miles an hour, the capacity of the tunnel will allow for the passage of twenty-four trains in the twenty-four hours, or about half the average frequency of the trains on the railways of the United Kingdom. How is the line to pay?

THE proprietors and lessees of theatres seem minded to make the best of the occasion of the late dreadful disaster to advertise each the safety of his own theatre, and the special provisions for the safety of the public which each has made, or is about to make. We have these confidences after every theatre disaster; and in general they are very much a repetition of the same statements as have been made on each previous occasion. Mr. Pinero is, however, entitled to the credit at least of novelty, in his proposal that before the curtain rises every evening the proprietor should come to the footlights and make a speech explaining to the audience the arrangements for exit in case of accident. This is a typical example of the wild kind of proposition which is apt to be made, and to find its way into print, when people's heads are full of the danger of theatres. Cannot Mr. Pinero realise that as long as such an address from the manager were paid any attention to, it would be the very thing to alarm nervous old women of both sexes, and put them all on the *qui vive* for imaginary danger, where it did not exist; and secondly, that it would certainly degenerate in a very short time into a mere ritual, to which no one would pay any attention? And if an accident or an alarm did take place, and the audience got into a fright, would they remember directions they had heard, any more than directions that were printed? Not they. Then another wiseacre, Mr. T. A. Brocklebank, writes to the *Times* to ask why the steps leading to the exit door cannot be made to lead *up* instead of *down* to the door, so as to give less encouragement and facility for rushes. It has apparently not occurred to Mr. Brocklebank that one reason against his proposition is that doors

are usually, for convenience, made on the ground-level. It is possible to render theatres much less liable to fire than they now are, and it ought to be insisted on (officially) that they should be so; but render theatres as fire-resisting as you can, as we observed last week (and as we perceive, our respected contemporary, the *Field*, urges in a very spirited and sensible article in its last issue), until people learn not to be such fools as to rush into panics, and trample each other to death on the first alarm of fire, no theatre, except an open-air one, will be really safe.

SINCE the foregoing remarks were written, one really important improvement has been announced by Sir George Chubb, in a letter to the *Times* of Wednesday. He states that his firm can now make doors which, while they can be locked so as to be secure from the outside, will give way at once on a push from the inside. This, we have ascertained, is an entirely new device, and is to be put into operation in the new theatre in the Strand, at the instance of the architect, Mr. W. Emden, who is to be commended for the attention he appears to be giving to provisions for public safety in the two new theatres in which he is professionally concerned. The invention is not yet, we are told, quite in a stage for publication, but we shall probably have further information to give in regard to it. In the meantime, however, we may say that, from inspection of a model of the apparatus, we are convinced that it is a perfectly good and efficient means of accomplishing what is desired. The push must be made on a special portion of the framing of the door; but by selecting the central lock-rail as the operating portion, and projecting it a little, no one can lean against the door without its opening as intended.

THE International Congress on Hygiene is to be held at Vienna from the 26th of September to the 2nd of October. Among the subjects of interest to our readers which are to be discussed are various reports, by reporters delegated from last year's Congress, on matters connected with sanitation. Dr. Gärtner, Professor of Hygiene at the University of Jena, is to report on the tests to be used to ascertain the hygienic condition of drinking-water and lavatory-water. "M. le Dr. Frankland, Professeur de Chimie à Yew-Ricgate" (so in the programme), will give a report on the purification of sewage discharge in connexion with the question of the contamination of river water; Dr. König, Professor of Agricultural Chemistry at Münster, and Dr. Müntz, Professor at the "Institut National Agronomique" of Paris, will present reports on the same subject. M. Durand-Claye, Engineer-in-chief "des Ponts et Chaussées" at Paris, and Major Humphreys, of Memphis, Tennessee, will present reports on the working of the Waring and Shone systems of ejection. The means for the provision of solar light and warmth to buildings will be the subject of reports by M. Clement, Physician of the Hôtel-Dieu at Lyons; Dr. Knauff, Professor of Hygiene at the University of Heidelberg; M. Trélat, whose name is well known to our readers; and M. Gruber, architect, and Professor at the "Ecole Supérieure du Génie" at Vienna. We have not space to give all the names of readers of papers and reports, but other subjects to be discussed are Instruction in Hygiene at Elementary and Secondary Schools; Isolated Hospitals and their Methods of Construction; Hygiene of Boats, especially those of the mercantile marine; Tests for the Sanitary Condition of Air; and the Use of Lead Pipes (by Dr. Hamon of Boulogne). Professor Corfield contributes a report on the question of some precautions against the spread of infectious diseases, but in general England seems to be taking a very small part in the proceedings. No doubt considerations of locality and language have something to do with this abstention. Vienna is not, geographically speaking, very central.

WHILE we in England are laboriously endeavouring to get money to commence the Manchester Ship Canal, similar undertakings are being carried on abroad with considerable determination and success. The chief one is the Corinth Canal, which is nearing its completion, having been commenced in 1882,—a period of five years. It was intended to have it ready by the beginning of next year, but unforeseen circumstances (as in Exhibitions) have intervened, and so the opening is postponed. Another great work (also in Greece) is the drainage of an enormous marshy district, known as Lake Copais, in Northern Boeotia, which, whatever the *modus*, or money, which the English company, who are the undertakers, get out of it, will give 27,000 acres of profitable land to the Grecian kingdom, and, so far, do somebody good. The opening is also recorded of a canal between Havre and Tancarville, on one of the Seine reaches between Havre and Rouen, with a branch to Harleur, at a cost of 1,000,000. A new basin of 523 acres, the basin of Du Belloy, connects the canal with the port, and the accommodation is so ample that it is expected that the goods freight between Havre and Paris will be reduced by two francs per ton.

THE catastrophes at the Opéra Comique and that at Exeter have caused a lively discussion in the Berlin press as to the chances of escape of the spectators in the various Berlin theatres in case of fire. The consensus of opinion appears to be that the conditions of escape are fairly favourable at the Opernhaus, the Schauspielhaus, and the Friedrich Wilhelmstadt Theatre, but very bad in all the rest. In the Opernhaus and Schauspielhaus the stalls may be emptied in a couple of minutes through four large doors opening outwards. The same is the case with the pit, at the back of the stalls, which has separate exits, whilst broad concrete staircases offer similar facilities for the occupants of the upper tiers and gallery. The Friedrich Wilhelmstadt Theatre, being quite a new building, deserves special mention. The architect has here paid particular attention to the causes of the Ring Theatre catastrophe in Vienna some years ago. From the gallery two broad concrete staircases lead down to the ground floor, besides which the people in the gallery may, through numerous unslatted windows, opening outwards, descend, by means of iron ladders, to the roof of the first floor, and thence, by a second set of iron ladders, into the garden below. From the stalls five specially-constructed doors lead directly into the garden, besides the two ordinary doors opening on the foyer. Moreover, the scenery and woodwork in the theatre are impregnated with some composition rendering them incombustible. In all the theatres of Berlin there are now iron curtains, and special reserve exits have been added, whilst oil lamps are lighted in all corridors, passages, and rooms during a performance, in case of accident to the gas supply. With the exception of the above-mentioned theatre, however, the rest appear to be as bad as can be. The *Berliner Börsen Zeitung*, in referring to this subject, states that in one theatre two pillars have recently been raised in the stall lobbies with a view to divide the human current in case of a panic, but which will undoubtedly do more harm than good. In another, the lobbies are so narrow, and the cloak-room is situated so awkwardly, that even under ordinary circumstances the spectators have at the end of the performance to stand closely packed for upwards of twenty minutes before they can get out. It would be impossible here for a single individual to penetrate the crowd. In certain other Berlin theatres the spectators can only reach their seats on climbing high, narrow staircases, and in one theatre the corridors and passages form a veritable maze. In consequence of these disclosures, all the leading Berlin journals now demand that there shall be at least two doors on each side of the ground-floor leading directly into the open; that all doors shall open outwards, and that every tier shall have special fireproof staircases, to be used only in case of fire, leading directly into the open

One journal also demands the entire abolition of stage boxes, and of the boxes slightly raised above the stalls, where such exist. Furthermore, it is demanded that the attendants, box-keepers, and other functionaries, shall be ordered, under heavy penalties, to remain at their posts in case of danger, and not be the first to run away, as was the case in Paris. These men, it is maintained, should be the last to leave the building, and they should offer the public the same example of coolness and courage as a captain and crew of a sinking ship. Finally, it should be the imperative duty of the firemen at all theatres every night to test the working of the water hydrants and the telegraph, and see that all doors intended for exit are unlocked. It is stated that in all Berlin theatres the iron curtain is tried every night, so that there is hardly any fear of this important protection failing, as was the case at the Opera Comique, through the rusting of the mechanism. Nevertheless, it has been proposed that the working of the iron curtain shall be intrusted to a man who is seated in front of it, and who, by a simple contrivance, is unable to quit his seat until the iron curtain has descended. Such an arrangement seems carrying matters to an absurd length; in short, it is panic legislation.

**THE** Burg Engineer and the Firemaster of Edinburgh have been instructed by the Lord Provost to examine the theatres and places of amusement, and to submit to the Town Council, as early as possible, a report of their examination, with any suggestions that may occur to them of improvements to aid in securing the safety of the public. This is, of course, an outcome of the recent disastrous event at Exeter. Similar warnings have been given before, which have caused a like temporary action, productive of no practical result, not only in Edinburgh, but elsewhere. Legislative enactment, stringently carried out, would probably be the most effective measure. Since this was written, Newsome's Circus, in Nicholson-street, has been burnt down, fortunately without loss of life.

**AN** appeal is made by the Committee for the Preservation of St. Botolph's Priory Church, Colchester, for funds to assist in such repairs as are necessary for the preservation of these beautiful and interesting remains, which have been for some time in danger of falling to further ruin in process of natural decay. Mr. Loftus Brock is the architect who has been consulted, and no one will doubt that in his hands necessary practical work will be combined with every care to carry out repairs without any injury to the archaeological value of the remains. In the course of his report on the present state of the remains, and the course to be taken with regard to them, Mr. Brock says:—

"The ruins consist of the piers and arches of the nave, the walling of the west front (the upper portions are gone), the base of what appears to have been a tower at the south-west of the front, of peculiar plan, and the walls of the north and south aisles.

The walling consists of brick taken from some ancient Roman buildings, in more or less of a fragmentary condition, of all sizes and thicknesses, fragments of roofing, and flue-tiles. There are also thin walling and masses of septaria. The whole is put together with mortar formed of poor sand, and it is not too good to resist the action of the elements. It is of very early Norman work. . . . The church having been unroofed since the siege, the effect of the elements for so many years upon the masonry, composed as stated, has been no more than might have been expected. The ruin is well suited over its whole surface, the joints between the Roman bricks are so open that a rule will pass in more than 6 in. in almost every joint, the masonry of the upper part of the nave-arcade is thoroughly separated from the mortar, parts of the outer rings of the remaining arches have fallen, and much of the remainder is so dangerous that entrance to the ruin must be denied to every one except such as may be willing to use the greatest care in inspecting. Parts of the west front, where there are two tiers of interlaced arching, have fallen; other portions may be expected to fall at any moment."

What Mr. Brock proposes is to strengthen the piers and supports in some places, to exclude the passage of wet through the walling by

grouting the loose masonry on top, and afterwards covering it with a mass of cement concrete spread to a slope to throw off the wet; to rebuild the portions of the arches which have recently fallen, in order to increase the lateral support; to cut out all loose portions of the walling, and to replace the same stones and brick in their original positions; to re-point the whole of the surfaces; to cover over the small remaining piece of vaulting to the south-west tower with cement concrete. Scaffolds have been applied, and some of the missing parts rebuilt solidly in cement; but the heavy work necessary to be done to the nave-piers, and to secure, in part, the west front, have, however, exhausted the funds at the committee's disposal; the pointing of the front has hardly been commenced, and the operations are at a standstill. Subscriptions will be gratefully received by the Rev. T. R. Corbett, Colchester, the Treasurer to the Preservation Committee.

**DR. DÖRPFELD'S** discovery of the older Athenic temple in the Acropolis raises a host of questions which the discoverer himself is the first eagerly to discuss. The *Mittheilungen* of the German Archaeological Institute at Athens publishes, side by side in the same issue (xii.), with delightful frankness, two papers, one by Dr. Dörpfeld, the other by Dr. Petersen, embodying views diametrically opposite. Dr. Dörpfeld starts the interesting hypothesis that when allusion is made to the "old temple of Athens" (*ὁ παλαιὸς ναὸς* or *ὁ ἀρχαῖος ναὸς*) the reference is not, as has always been supposed, to the Erechtheum, but to his own newly-discovered temple. Further, he thinks that the *ἀναθήσαστος*, the back chamber in which the bulk of the State treasure was kept, belongs to this earlier temple, not to the Parthenon. It is still more startling to hear that Pausanias actually saw and (in a partially corrupt passage) noted this temple. Dr. Dörpfeld gives a map, in which he marks the exact route taken about and up to this temple. Dr. Petersen will have none of this. The two papers deserve, and are sure to receive, much attention from Classical scholars as well as archaeologists proper.

**THE** last number of the *American Journal of Archaeology* (III., pl. xiii. and xiv.) devotes two beautiful coloured plates to the illustration of the Dieulafoy excavations, to which we recently drew attention. The monument selected is the remarkable enamelled frieze of Persian warriors. The explorer himself thinks we have in this frieze a representation of the famous body of troops known as the Ten Thousand, who were also called, Herodotus tells us (vii., 83), "The Immortals," for the following reason:—If one of their body failed, either by the stroke of death or disease, forthwith his place was filled up by another man, so that their number was at no time either greater or less than 10,000. Herodotus goes on to say that these Persians were "adorned with the greatest magnificence; . . . besides their arms, they glittered all over with gold, vast quantities of which they wore about their persons." Certainly the dress and accoutrements of the warriors of the frieze is of striking splendour and of excellent decorative effect. No idea of this effect can be obtained from any but a coloured reproduction. The warriors are depicted in profile. Each one carries on his left shoulder a bow and large quiver, elaborately decorated. The dresses are all cut of the same pattern, but very various in colour,—some gold embroidered with yellow or green starlike flowers, others white with various coloured stars. The low boots are gold or blue; the head-dress uniformly green. The plates are accompanied by a letter from M. Méanant, describing the excavations in general. The same number of the *Journal* has a paper by Dr. Waldstein on the school of "Pasioteles." He brings some additional arguments for referring to the Venus Genetrix and the Esquiline Venus to, if not Pasioteles, at least some sculptor of the Pasiotean manner. Greek art is this time somewhat slenderly represented. Out of seven original articles four are devoted to Oriental matters. One of

these papers treats of "Forgeries of Assyrian and Babylonian Antiquities." If the plates given are really facsimiles of such forgeries American buyers must be easily cheated. The paper would have appeared more appropriately in some purely popular journal. Mr. Frothingham's discussion of "a proto-Ionic capital and bird-worship," though it mainly concerns an Oriental cylinder, is of great interest, not only from the point of view of architecture, but also from the light it throws on the origin of an art form frequently found on Greek vases, *i.e.*, the Ionic column surmounted by a bird, raven, harpy, or siren.

**IN** reference to recent controversy about the age of the walls of Chester, we hear that, at a meeting of the Town Council of Chester on Wednesday, at which Sir Jas. Picton and Sir Henry Dryden were present, a letter from Mr. Arthur Cates was read suggesting that the wall on the Roodee should be entirely cleared for its whole length and the foundations carefully examined. Sir Jas. Picton addressed the Council in favour of the proposal, and said it should be regarded as a matter of national interest and one for which a public subscription might very well be opened. He did not consider that the citizens of Chester were fairly to be called upon to spend their money in finding antiquities for other people's study and interest, though, of course, they might contribute their share. Sir Henry Dryden, who, we may assume, did not oppose such a movement, entered, however, a very requisite caution as to the necessity of protecting the work from the weather if it were uncovered. The Town Council appear from the report that has reached us, to have been entirely in favour of facilitating such investigations, so that we may expect to have further information in regard to Chester walls before long.

**A** CORRESPONDENT writes:— "Mr. William Nelson, of Edinburgh, publisher, died at his residence, Salisbury Green, on the morning of Saturday last. He was a man of very cultivated taste, and his picturesque house, overlooking the Queen's Park, and commanding a view eastward to North Berwick Law and the Bass Rock, was stored with beautiful works of art; but he was far from being selfish in his love of the beautiful, and desired that others should share it. To him the City is indebted for various improvements, among others for the restoration of St. Bernard's Well and the adjoining grounds, and for the restoration of the ancient buildings in the Castle at present in progress. It appears that a few days before his last illness Mr. Nelson signified his approval of the finished drawings for the restoration of the Parliament House in the Castle, prepared by his architect, Mr. H. J. Blanc, and gave him instructions regarding certain proposed additions to St. Margaret's Chapel. The Argyll Tower is now almost ready to be handed over to the authorities; it has been restored in a very satisfactory manner. Although a public benefactor, Mr. Nelson shrank from publicity, and refused honours which were offered to him, preferring the pleasures of home to the allurements of office. He was most generous in his dealings with his employees, looking after them during sickness, and not losing sight of those dependent upon them in the event of their being overtaken by death."

**THE** *Albert Fine-Art Album*, of which two or three numbers have been sent to us (no publisher's name), appears to be a collection of a series of designs by Mr. Sapon Bezirdjian, whose name appears on the title-page, and who apparently is designer and publisher also. He states that "his object is to introduce to this country, and to the West generally, a pure knowledge of and taste for the best forms only of Oriental art." This is a rather ambitious mission, and we do not know whether we could accept all the designs in the numbers before us as representing the best forms only of Oriental art. In some of them the colour is very crude. Most of the designs, however, show good draughtsmanship and some originality. But Mr. Bezirdjian is under two misconceptions:

In the first place, there are a good many artists and architects in England who know, at all events, much more about Oriental design than we seem to be aware of; and secondly, what those who are interested in Oriental design want is not original designs made for the purpose of publication, but fine illustrations of the best types of existing work. If Mr. Bezirdjian will give them that, he will be more likely to find a public for the *Albert Album*.

THE "Goat in Boo's Tavern," No. 333, Fulham-road, at the corner of Park, once Lovers' Walk, is about to be rebuilt from the designs of Mr. T. H. Smith. Messrs. Turtle & Appleton are the contractors. The story of this sign, in its later guise a relic of Morland, is not a little curious. The tavern stands in what some thirty years since was known as Little Chelsea Village. In 1663 a house here was known as the Goat at Little Chelsea; and until the year 1713 it had the right of commonage for two cows and one heifer on the neighbouring Chelsea Heath. The original sign of the Goat is said to have been painted by James Christopher Le Blon, a Fleming, who is believed to have died, 1740, in a hospital at Paris. In the early part of last century a favourite sign for post-houses was that of Mercury with the legend "Mercurius Is Der Goden Boode." The words "der goden boode" became corrupted into "The Goat in Boots." The story goes that Morland, employed by mine host to re-paint this particular sign-board in lieu of discharging his drink-bill, equipped the goat with a whip, hanging-sword, jack-boots, and spurs. The sign-board has been painted again with tawdry embellishments, so that little or none of Morland's handiwork appears. There is one other tavern of this sign in London, at Stanhope-street, Euston-road.

THE neighbourhood of Annan, in Dumfriesshire, has become celebrated of late years, not only in the United Kingdom, but in America, for the red and pink sandstones raised in many large quarries there. We had occasion to allude to this fact in describing the "Red Corsehill" stone last year (see the *Builder*, vol. li., 1886, p. 894). We have now before us a sample from the Warmannie Estate Quarry, also near Annan, on which our opinion has been asked. It is a very fine-grained red sandstone, of the age known to geologists as Triassic or New Red, and is made of minute particles of quartz, which in themselves are practically imperishable. The first question in such a case is, What is the nature of the material (if any) which binds these particles together? For on this almost the whole of its weathering properties depend. In the case of many stones this could not be ascertained without a microscopical analysis, but here the semi-conchoidal fracture exhibited by the stone shows at once that silica is one of the cementing materials; whilst its red colour, its aspect, and the freedom with which it can be cut, equally demonstrate that it is also bound together partly by peroxide of iron, and partly by compression. Of these, the last-mentioned is the least desirable qualification, the first being a very good one. The silica existing as a cementing material is secondary in origin, and although it is not so durable as the crystalline quartz grains which it binds together, it nevertheless is a first-class cement. The stone is not quite such a dark red colour as the "Red Corsehill" which usually comes to the London market, but other tints are no doubt obtainable, as they are in most quarries. When treated with hydrochloric acid it does not appreciably effervesce, and the amount of carbonate of lime must be exceedingly small, that which is present probably existing in a crystalline form in minute particles of feldspar. It is very compact, takes a sharp angle, and is apparently very easily wrought, approaching in this respect the limestones.

AN exhibition of work done by the students who are taught at the Polytechnic Institution, which has been held during the last few days, was advertised as one which "should

be visited by all who are interested in technical education." As we observed last week, the teaching of special trades is not what we should define as the object of "technical education," properly so called; and as far as the evidence of results goes, it is the teaching of trades, or special kinds of manufacture, which is carried on at the Polytechnic. But there seems to be a good deal of useful and instructive work done. Among the exhibits we observe there are working drawings of building construction, plans and sections of houses, drawings of brick-bonding, and various details of iron construction. It does not appear, however, that the models for the teaching of this class of work are all irreproachable. It is clear that there are model drawings of some kind, as the same section of cornice is repeated by two different workers in their detail drawings, and shows the cornice stones most insufficiently bedded, in comparison with their projection: a cornice should never project more than its bed on the wall. Then, again, it can hardly be said that this is the most scientific method of forming the abutment of a

principal rafter on a tie-beam, but it appears to be passed by the authorities. The wood-carving work is good, and some of the plaster modelling that is shown is also very creditable. In the same room we observed a model of a hot-water circulating system for a house; good, only that there are two nearly horizontal lengths in the flow-pipe, a thing to be avoided if possible, as it checks the flow. The models of a king and queen post roof, near this, are deficient in that the method of framing is not shown in a workmanlike manner; the pieces are put together and painted over, so that it is impossible to see if the joinings are properly made or not, and it looks rather as if they were not, in which case the model is only a toy. Among the exhibits in the down-stairs room is a really admirable piece of work, in the shape of a bicycle, built by one of the students. Art handicraft seems to be the department least cultivated; we noticed a metal coffee-pot, "hammered work": very good workmanship, but bad and inelegant in form, totally without artistic spirit; and the same thing struck us in regard to other manufactured articles. Wood-carving, as an object in itself, is carried out with considerable taste and feeling; but applied art seems to be neglected or not understood.

#### FURTHER NOTES BY AN ENGLISH ARCHEOLOGIST IN BRITANNY.\*

WEDNESDAY, August 17th, was perhaps the most interesting day of the whole tour made by the party from the Royal Archeological Institute. The gentlemen to whom we were indebted for the notes already published sends us the following:—

On account of the tide an early start was necessary, and, punctually by six o'clock, the whole party assembled on the quay of the dock at Vannes to start by the little steambot engaged to take them to Lockmariaker. Here they were soon joined by the Vice-President and many other members of the Société Polymathique, the President being prevented from attending by a family bereavement. Some of the members of that Society joined the English party, the others following in a second steamer, and proceeded down the Rivière de Vannes for the Morbihan Sea, passing Ronques, the spot where the jadeite was discovered, the Ile aux Moines and Gavr Innis, both to be visited on the return trip. The two small steamers reached Lockmariaker, in a heavy shower of rain, early in the forenoon. This was almost the only rain the travellers met with during their visit to Brittany. After sheltering for some time until it held up, the members of both French and English societies together went on to the curious twelfth-century apsidal church of Lockmariaker. Outside they were shown an ancient cross with an inscription, said to be yet unread, standing against the wall of the churchyard. After waiting here for a short time, the party was taken charge of by M. Mabé, Inspector

under Government of Ancient Monuments in the district, who conducted them to the megalithic remains. It is hardly possible to mention these in detail, but first among them is the great menhir (vertical stone) named Men-er-Hroeck. This megalith, now fallen and broken in pieces, must have been, when upright and whole, nearly 65 ft. in length. It has sometimes been said that the pieces now prostrate formed not one, but two menhirs; but if any of the English visitors had even entertained a doubt upon this point, it must have been dissipated by the examination of the stones under the guidance of M. Mabé and Dr. de Closmadec. At Lockmariaker many of the members of the Institute saw for the first time those wonderful marks on the stones of the dolmens which have given rise to so much controversy. On the under side of the Dol-ar-Marchadourien is the outlined figure of the axe, so like the axe used in the present day by the Indians of North America and other aborigines. The horse-shoe shaped, L-shaped, and other usual marks, are found abundantly in the dolmens here, generally in the supporting stones, as also the so-called cup-marks,—little round sinkings in the stone a few inches in diameter. Nearly all the dolmens of this neighbourhood show traces of the tumuli which once covered them, and in many cases, though they now stand exposed, they are surrounded by the debris of their mounds. At Lockmariaker there are no alignments of stones, nor are any circles of stones found there; but the menhirs (upright stones) and the dolmens are the largest in Brittany,—perhaps in the world. The village stands on the site of a Roman city, up to the present unidentifiable, although the name of Dariorigum has sometimes been assigned to it. It is an accepted fact that in Brittany wherever any large number of prehistoric remains are found Roman remains are found also. Last year the ruins of a Roman temple were unearthed in a garden near the church, some portions of columns and the lower part of an altar being found. Only the last line of the inscription,—the usual votive dedication,—remained, and the visitors were informed that it is the only inscription found at Lockmariaker. It is much to be wished that the upper half, with the name of the deity, may come to light, but at present all excavation is stopped, and the site of the temple has been covered up.

The members of the two societies (English and French) lunched together in the public school in the rear of the Mairie, and were joined by the local clergy and others. After lunch, M. Le Chanoine Le Méné, on behalf of the Société Polymathique, bid the English visitors welcome in the kindest terms, and was seconded by Dr. de Closmadec in a learned and eloquent speech. The toast, which was drunk with enthusiasm, was responded to by Mr. Joseph Brown, Q.C., on behalf of the Royal Archeological Institute, who concluded by wishing success and prosperity to the Société Polymathique.

Immediately afterwards the party again took steamer and proceeded to the Island of Gavr Innis, the property of Dr. de Closmadec, and there visited a sepulchral chamber, still covered with its tumulus formed of loose stones, in the supports of which are carved the axe-heads and other designs which have been so often published. The axe-heads of this tumulus differ from nearly all the designs on the dolmens of the neighbourhood by being well and clearly cut in relief, whereas the other markings are merely outlined on the stone. Here is also the channel, some 3 ft. long and 4 in. deep, cut in the supporting stones of the chamber, the use of which is as great a mystery now as when it was first discovered. One thing only can he said, which is that the chamber in the tumulus at Gavr Innis shows that its builders had made an immense advance in the art of using tools of the same kind as those of the other over that shown by the builders of the other sculptured dolmens in the neighbourhood. The sculptured dolmens in 1832, when several tumulus was opened in 1832, when several broken hatchets of diorite, &c., were found; some of these are deposited in the Vannes Museum. Some interesting Medieval remains have also been found in the island. From Gavr Innis the Island of Er Lanic was seen in the distance, where the double circle of stones, in the form of the figure 8, may still be traced at low tide, but is almost lost in the sea.

On the way back to Vannes the party landed at the Ile aux Moines, and there visited the stone circle of Kergonan, the largest in the

\* See p. 358.

Morbihan, but much interfered with by farm buildings erected in the centre.

The morning of the following day was again spent in the Museum at Vannes, when the Curator, the Chanoine le Méné, together with Dr. de Closmadeuc, a second time favoured the visitors by showing them over it and explaining its contents. In the afternoon the party, accompanied by Admiral Tremlett, left Vannes for Carnac and Plouharnel. The sleeping accommodation in these two villages being but very limited, it was necessary to divide the travellers between them. The remainder of the day, with Friday, August 18, and the greater part of Saturday, were spent visiting the megalithic remains, which extend, with occasional breaks, for a distance of some four or five miles from Erdeven (some mile and a half west of Plouharnel) to near La Trinité, east of Carnac. From Mont St. Michel, near Carnac, an immense cairn or tumulus, composed of loose stones, and crowned by a small chapel, the best general view is obtained, and from its summit most of the alignments of stones are visible. This tumulus was opened in 1863 by the Société Polymathique, and at its foot are some interesting remains of a supposed twelfth-century monastery, discovered some years ago by the late Mr. James Miln. The alignments of Menec are those nearest Carnac, and consist of eleven lines of menhirs, ending near the farm of Menec in a semicircle. A little farther on, at Kerlescan, a quadrilateral enclosure of stones has its fourth side completed by a long barrow. There is also a quadrilateral at Courcoumo, near Erdeven. The many dolmens bearing sculptures were only visited; among others that in the park at Kerado, on the capstone of which is a rudely-outlined axe. Many of these monuments have now been purchased by the Government, and will in future be preserved from further destruction; but very many, and among them some of the most interesting, still remain in private hands. These are being broken up by the peasants on all sides, and are used simply as quarries whenever stone is required; in addition to this, much damage is yearly done to the dolmens by careless diggings in the earth at their bases, causing the supports to give way and the capstones to fall.

On the evening of Saturday, August 20, the party of archaeologists left Plouharnel Station for the quaint old town of Quimper, when they visited the cathedral, the western spires and great part of the towers of which were built from designs of M. Viollet le Duc. From thence they went on to Pont l'Abbé. This interesting little place was formerly the seat of a Carmelite monastery, of which the church remains in good preservation, as well as part of the abbey buildings. The cloisters, having got into a bad state of dilapidation, were removed a few years ago, to the great regret of all lovers of antiquities. From Pont l'Abbé the party drove to Penmarch, visiting the church on the way. The projecting headland is singularly like St. David's Head, in Pembrokeshire.

On their return the excursionists were most hospitably entertained by M. du Chatellier, at his château of Kernuz, when he showed them his splendid museum, brought together by himself and his father, the richest collection in the world in antiquities from the department of Finistère. After this they returned to Pont l'Abbé, where they dispersed, having had a most enjoyable and instructive excursion, and found many kind friends in Brittany.

#### TWO MODERN PARIS CHURCHES.

For some years Paris has erected very few religious edifices. The stoppage in this class of building, which has given France so many remarkable and noble architectural monuments, may be ascribed to two causes: the large number of existing churches, which are sufficient for present requirements, and the special bent of the administration, since 1879, in the direction of civil architecture. Accordingly, with the exception of the American Church not long since inaugurated,—and which is of course not a national building, being erected by the American community for themselves,—no new church has been erected in Paris since that of Notre Dame at Autueil, which dates from 1880.

This church was the work of one of the most eminent members of the Académie des Beaux Arts, M. Emile Vaudremer, who also designed the church of St. Pierre at Montrouge, of the

Church of Notre Dame, Autueil, near Paris.—M. Emile Vaudremer, Architect.

interior of which a lithograph illustration will be found on another page. These two churches, both based on the basilica form, represent therefore the most recent church architecture of Paris.

The church of Montrouge is the oldest, having been commenced in the last years of the Empire; the building was interrupted by the siege and the Commune, and was finally completed about twelve years ago. It stands at the acute angle formed by the Avenue d'Orléans where it intersects the Avenue de Maine. The plan of the site, narrow at the entrance façade, and very wide at the apsidal end, constituted a special difficulty in dealing with the design, which the

architect endeavoured to surmount by building a large square porch in advance of the nave, and giving great lateral extension to the transepts. The choir is arranged so as to allow of the side aisles being continued round it. In the centre is a ciborium decorated at the four angles with figures of angels, executed by M. Maniglier, and carried on polished marble columns. Above the entrance-porch is a clock-tower and campanile, about 150 ft. in height. The nave has a round-arched arcade of eight bays, on granite columns. Under the church is a large crypt, used as a religious school.

The total external length of the building, inclusive of porch and apse, is about 230 ft., and

the interior height of the nave is about 65 ft. The choir, however, is raised to a height of about 10 ft. The tower, the lower portions of the apse, and the cornices, window jambs, string courses, capitals of the nave, &c., are in hard shlar, the remainder in hammer-dressed work; the roofs are tiled. The timber construction is shown internally. The furniture and fittings are in waxed oak.

The painted decoration is entirely in low ones; the main portion of it consists of some mural paintings in the cupolas of the transepts, baded in monochrome. In the tympanum of the porch is a painting on porcelain, and a statue of St. Peter, by M. Maniglier; a fine group in marble, by M. L. Durocher; and various bas-reliefs of considerable merit. The windows are numerous and mostly treated in grisaille, are the design of an able pupil of Delacroix, M. Oudinot, who has executed many important commissions for the Government. The total cost of the building was about 1,900,000 francs, or 892 francs per square metre.

The Church of Notre Dame d'Anteuil is not yet completely finished, and has cost up to the present moment about 1,100,000 francs. Here gain M. Vandremere had to contend with a difficult site, very narrow at the facade and with a rapid fall towards the Seine. The general style of the building is somewhat based on the Romanesque architecture of the South of France. The plan takes the form of an elongated rectangle, with transepts, and terminating in a polygonal apse. The entrance facade, of which we give a view, is surmounted by a turret of very original design, rather more than 160 ft. in height. The total length of the church is a little over 200 ft.; the nave and transepts 60 ft. in height, the choir rising to nearly 90 ft. The declivity of the ground has rendered it possible to secure a crypt about 16 ft. high below part of the floor. The nave is divided into six bays of round arches, carried on stone columns, and the foundations are of concrete. The building generally, like that of Montrouge, is in rubbed stone for the tower, plinth, strings, and dressings, and of hammer-dressed stone for the filling.

In regard to decoration, up to this time the building is poor enough. In the crypt the visitor may remark a monumental bas-relief in marble, the work of Debay, and which came from the preceding church, as well as a "Mater Dolorosa" by Carpeaux, whose somewhat Pagan type of genius did not, however, lend itself very well to the representation of religious figures and feelings. In the transepts are some bas-reliefs in bronze, gilt, the gifts of some of the congregation. The figure of the Virgin and Child in the interior of the entrance porch is the work of M. Maniglier. The windows are filled with some good glass with figure subjects, executed by MM. Roussel, de Beauvais and Avenet, after cartoons by M. Theodore Maillot.

It should be added that, from want of sufficient funds the dome, which, according to the original design should have surmounted the crossing, has not yet been carried out. This, when executed, is to be composed of brick with stone bands, and lighted by circular-headed windows. It will rest on a polygonal subbase with pyramids at the angles, and will be surmounted by a cone-shaped lantern.

The former curé of Anteuil, the Abbé Lamazon, who was appointed Bishop of Limoges and is since dead, contributed largely to the building of this church, in support of which he gave altogether no less than 400,000 francs.

THE LIVERPOOL AUTUMN EXHIBITION.

THE seventeenth Exhibition of Pictures by Modern Artists, at the Walker Art Gallery, Liverpool, was opened on Monday, the 5th inst.

It contains in all 1,279 works of art, including oils, water-colours, architectural drawings, and sculpture.

There are, of course, on the walls several pictures from the late Exhibition of the Royal Academy, some of which have already been noticed in the *Builder*. Among them we find "The Christ Bearer," by Mr. W. F. Yeames; "Samson," the large and ugly picture by Mr. S. J. Solomon (which has been purchased by Mr. J. Harrison, of Liverpool, and presented to the Corporation for the permanent gallery; a very doubtful gift); "Carnation, Lily, Lily, Rose," by Mr. J. A. Sargent; "Whittington's Banquet," by the late D. W. Wynfield; "First

Boats away after a Gale," by Mr. H. Moore; Portrait of Baron de Worms, M.P., by Mr. F. Holl; "Robert Burns, November, 1785," by Mr. J. Hodgson; "Kyle Akin," by Mr. J. Brett; "The Love Feast," and "Callista, the Image-maker," by Mr. E. Long; "Dominicans in Feathers," and "The Old Tortoise," by Mr. H. S. Marks; and Mr. Ernest Normand's "Jealousy is cruel as the grave." This is a fair contribution for a provincial exhibition to have secured, and the best of the pictures above enumerated form, especially as to figure-subjects, the cream of the collection.

In going through the rooms of the gallery we also meet with a great number of works now seen for the first time by the public, well worthy attention,—and as a whole the collection is one of great and varied interest, and probably above the average. Among the previously exhibited pictures are also Mr. Hacker's "Pelagia and Philammon" from "Hypatia" (242), and Mr. Collier's "Lilith" (315), both of which will be remembered in the Grosvenor Gallery of this season.

"The White Lady of Nuremberg" (962), by Mr. Wyke Bayliss, an interior of a Gothic church with a shrine, is a fine picture. The effect of the stained glass, however, though rich in colour, is rather deficient in transparency, and the lights and shadows are somewhat scattered. The florid Gothic work is well given. "The Schoolboard at Home," by Mr. Faed, is one of his interiors with a female figure and children, the former of whom strongly reminds us of the very pleasing one exhibited at Liverpool last year under the title of "When the Bairs are in Bed," and which was bought by the Corporation, though the present figure is scarcely equal to its predecessor. "Helpless," by Mr. T. C. Gotch, and Mr. Ayerst Ingram (128), is a shipwreck on an immense scale, but the amount of subject is scarcely proportionate to the canvas it covers. The whole scene is a sort of study in light greys, and deficient in contrast of light and shadow. The wreck is well put in, as are also the foreground figures. No. 8, "A Penzance Trawler off the Cornish Coast," by Mr. John Frazer, is very pure in tone, and full of atmosphere. If it has a fault, it is that parts of the water in the foreground, though good in form and motion, are a little hard. Mr. C. Napier Hemy has two pictures, "The Traveller's Pant," a characteristic hit, the boat stem on, well drawn, and his usual green transparent water. "On the Harbour Bar," his second work, a water-colour, is not so successful, especially in the treatment of the sea, which is rather opaque, and the general execution of the drawing not equal to this artist's oils. Mr. E. Green's picture, "Sunrise at Jerusalem" (583), looking over the Pool of Hekziah, is fine in effect, and the architectural character of the buildings of the ancient city is well portrayed.

There are several very good works, both in oil and water-colour, having picturesque portions of street architecture for their subject. Among these may be especially mentioned "Summer-time in a Cornish Village" (536), by Mr. John McDougal. This drawing, a water-colour, is wonderfully bright and pure in its lights, and equally true and cool in its shadows, preserving the details of the buildings, while satisfying the eye as an effective work of art. In the same line follows Mr. Hampson Brown in his "Biston Village" (435), which, while it is a faithful transcript of the village scene, is a contrast to the former in being somewhat realistic and lacking its sunny and atmospheric effect. In "The Caryatides" (315), by Mr. H. Holiday, we have an architectural subject well drawn. It is given a moonlight effect. Exception might be taken to the greenish tone of the picture, but there is a fine feeling throughout it.

The strictly architectural drawings are, as before, accommodated in what the printed catalogue calls "The Vestibule," but which is, in fact, simply the staircase, where any one trying to study them is constantly interrupted by the passing and repassing of visitors to the rooms of the gallery.

Among a number of designs of local interest are those of Messrs. Lewis Hornblower & Son for the "Proposed Rebuilding of Rufford Hall," a good specimen of English Domestic architecture; and a "Design for Buildings in Victoria-street, Liverpool," by Mr. H. Sumner (1,197), is an example of the modern street architecture which is fast effacing the former

aspect of plain old Liverpool, as it was familiar to the resident of twenty or thirty years ago.

There are also a great number of other designs, many of them by Liverpool architects, apparently well adapted to their purposes, and many of them possessing considerable merit and originality of design.

"Graythwaite Hall, Windermere," for Lieut.-Col. Sanlye, M.P., is an effective design for a large mansion in the Elizabethan style by Mr. R. Knill Freeman. It was noticed in the course of our remarks on the Royal Academy architectural exhibits of this year, among which it had a place.

"Church for Rogerstone, Mon., Mr. Thomas M. Lockwood. This was also noticed in our review of the Royal Academy drawings.

"Stokesay Castle," Mr. James H. Cook. An exceedingly well-executed sepia drawing from a set which obtained the R.I.B.A. Silver Medal, showing a picturesque bit of black-and-white timber work mounted on the foundations and remains of the walls of the old castle.

"Lewis's New Premises, Ranelagh-street, Liverpool," Mr. Walter W. Thomas, architect, to replace those recently destroyed by fire. This is a design in white and red brick with tall clock-tower fronting the street, and working into the design the tower in the rear still standing. The lower story is an uninterrupted row of plate-glass windows, upon which the whole lofty superstructure appears to stand,—too common a feature in modern shop architecture.

"Wesleyan Chapel and Schools, Durham-road, Gateshead," by Messrs. C. O. Ellison & Sons. This is a Geometric Decorated design with high-pitched roof and tower and spire; the adjacent schools being kept in harmony with the principal building. The same architect also exhibit design for "Wesleyan Chapel, Palmgrove, Oxton," much in the same style as the foregoing, with bell-turret only.

"New English Proshytorian Chapel, Llandudno," Mr. T. G. Williams, architect, is an Early English design with some features of Geometric Decorated. It has a small tower and spirelet.

Messrs. Bare and Beckwith send a series of designs for "Villas at Spital, Cheshire." These are of the cottage orné type, with some black-and-white work introduced with good effect.

"The Hall and Billiard Rooms, Rannymede, West Derby," Messrs. F. & G. Holme, are two drawings in sepia of elaborately-decorated rooms of Classical character with richly-carved woodwork and panelled ceilings, well proportioned and good in detail.

"Testcombe, Fullerton," Mr. W. D. Caröe, is a picturesque design in English domestic Gothic with some black-and-white work introduced. It is an effective composition.

"Design for Commemorative Schoola and Clock-tower," Mr. Edward Hodgkinson. This was in the Royal Academy exhibition of this year, and was noticed in the course of our remarks on that collection.

"New Offices, Temple-court, Liverpool," by Mr. G. E. Carroll, is a good design for commercial buildings, in red brick with carved stone doorway and window dressings.

"Smoking room, Portland-place, London," Mr. W. D. Caröe. An effective interior, Elizabethan in character, panelled in wood.

"Design for a House in Aigburth Drive, Sefton Park, Liverpool," by Mr. James W. Crofts; and "House to be erected" in the same park, by Messrs. F. & G. Holme, are both of good design, in the mixed style so much adopted in our modern dwelling-house architecture, and seem well adapted to their sites.

"Design for Town-hall, Grantham," and "Design for Memorial Clock-Tower, Pier-head," both by Mr. E. Winter. The former is a Classical design in stone, relieved by marble columns at the upper story windows and doorway, and surmounted by a small clock-tower. The latter is a Gothic design, the clock turret being supported on four open arches, but it does not possess any very original features.

"A Small Country House," Mr. Ernest H. Jones, is a pleasing specimen of Domestic Gothic, with black and white timber-work introduced.

The sculpture is not an extensive collection. It includes model bust of Philip James Bailey, author of "Festus" (life study in plaster for proposed statue), by Mr. J. A. P. Macbride; "Puck" (plaster statuette), by Mr. Hargreave Bond; "A Child of the Lagoons," a bronze, by Mr. S. M. Fox.

## IMPROVEMENTS IN THE MANUFACTURE OF PORTLAND CEMENT.\*

So much has been said and written on and in relation to Portland cement, that further communications upon the subject may appear to many of the present company to be superfluous. But is this really so? The author thinks not, and he hopes by the following communication to place before this meeting some facts which have up to the present time, or until within a very recent date, been practically disregarded or overlooked in the production of this valuable material, so essential in carrying out the important works of the present day, whether of docks and harbours, our coast defences, or our more numerous operations on land, including the construction of our railways, tunnels, and bridges, aqueducts, viaducts, foundations, &c.

The author does not propose to occupy the time of this meeting by referring to the origin or the circumstances attendant upon the early history of this material, the manufacture of which has now assumed such gigantic proportions,—these matters have already been fully dealt with by other more competent authorities; but rather to direct the attention of those interested therein to certain modifications, which he considers improvements, by means of which a large proportion of capital unnecessarily involved in its manufacture may be set free in the future, the method of manufacture simplified, the cost of manipulation reduced, and stronger and more uniformly reliable cement be placed within the reach of those upon whom devolves the duty and responsibility of constructing works of a substantial and permanent character; but in order to do this it will be necessary to allude to certain palpable errors and defects which, in the author's opinion, are perpetuated, and are in general practice at the present day.

Portland cement is, as is well known, composed of a mixture of chalk, or other carbonate of lime, and clay,—such as is obtained on the banks of the Thames or the Medway,—intimately mixed and then subjected to heat in a kiln, producing incipient fusion, thereby forming a chemical combination of lime with silica and alumina, or practically of lime with dehydrated clay.

In order to effect this, the usual method is to place the mechanically-mixed chalk and clay (technically called slurry), in lumps varying in size, say, from 4 to 10 lb., in kilns with alternate layers of coke, and raise the mass to a glowing heat sufficient to effect the required combination, in the form of very hard clinker. These kilns differ in capacity, but perhaps a fair average size would be capable of producing about 30 tons of clinker, requiring for the operation, say, from 60 to 70 tons of the dried slurry, with from 12 to 15 tons of coke or other fuel.

The kiln, after being thus loaded, is heated by means of wood and shavings at the base, and, as a matter of course, the lumps of slurry at the lower part of the kiln are burnt first, but the moisture and sulphurous gases liberated by the heat are condensed by the cooler layers above, and remain until the heat from combustion, gradually ascending, raises the temperature to a sufficient degree to drive them further upwards, until at length they escape at the top of the kiln. The time occupied in loading, burning, and drawing a kiln of 30 tons of clinker averages about seven days.

It will be readily understood that the outside of the clinker so produced must have been subjected to a much greater amount of heat than was necessary, before the centre of such clinker could have received sufficient to have produced the incipient fusion necessary to effect the chemical combination of its ingredients; and the result is not only a considerable waste of heat, but, the clinker is not uniformly burnt; a portion of the outer part has to be discarded as over-burnt and useless, whilst the inner part is insufficiently burnt, and has to be re-burnt afterwards.

Moreover, the clinker, which is of excessively hard character, has to be reduced, by means of a crusher, to particles sufficiently small to be admitted by the millstones, where it is ground into a fine powder, to become the Portland cement of commerce.

This process of manufacture is almost identical

\* A paper read before the Mechanical Science Section of the British Association of Manchester, by Mr. Frederick Ransome, A.I.C.E.

in principle and in practice with that described and patented by Mr. Joseph Aspin in the year 1824, and though various methods have been adopted for improving the quality of the cement and for utilising the waste heat by trying the slurry previous to calcination, still the main feature of burning the material in mass in large and expensive kilns remained the same, and is continued in practice to the present day.

The attention of the author was directed to this subject some time since in consequence of the failure of a structure in which Portland cement formed an essential element, and he had not proceeded far in his investigation of the cause of the failure when he was struck with what appeared to him to be the unscientific method adopted in its manufacture, and the uncertain results that must necessarily accrue therefrom.

Admitting, in the first place, that the materials employed were considered the best and most economical for the purpose readily accessible,—viz., chalk and an alluvial deposit found in abundance on the banks of the Thames and the Medway,—and being intimately mixed together in suitable proportions, was it necessary, in order to effect the chemical combination of the ingredients at an intense heat, to employ such massive and expensive structures of masonry, occupying such an enormous space of valuable ground, with tall chimney-stacks for the purpose of discharging the objectionable gases, &c., at a great height in order to reduce the nuisance to the surrounding neighbourhood?

Again, was it possible to effect the perfect calcination of the interior of the lumps alluded to without bestowing upon the outer portions a greater heat than was necessary for the purpose, causing a wasteful expenditure both of time and fuel? And, further, as cement is required to be used in the state of powder, could not the mixture of the raw materials be calcined in that state, thereby avoiding the production of such a hard clinker, which has afterwards to be broken up and reduced to a fine powder by grinding in an ordinary mill?

The foregoing are some of the defects which the author applied himself to remove, and he now desires to draw attention to the way in which the object has been attained by the substitution of a revolving furnace for the massive cement-kilns now in general use, and by the application of gaseous products to effect calcination, in the place of coke or other solid fuel. The revolving furnace consists of a cylindrical casing of steel or boiler plate supported upon steel rollers (and rotated by means of a worm and wheel, driven by a pulley upon the shaft carrying the worm) lined with good refractory fire-brick, so arranged that certain courses are set so as to form three or more radial projecting fins or ledges. The cylindrical casing is provided with two circular rails or pathways, turned perfectly true, to revolve upon the steel rollers, mounted on suitable brickwork, with regenerative flues, by passing through which the gas and air severally become heated, before they meet in the combustion-chamber, at the mouth of the revolving furnace; the gas may be supplied from slack coal or other hydrocarbon burned in any suitable gas producer (such, for instance, as those for which patents have been obtained by Messrs. Brook & Wilson, of Middlebrough, or by Mr. Thwaite, of Liverpool), which producer may be placed in any convenient situation.

The cement mixture or slurry,—instead of being burned in lumps,—is passed between rollers or any suitable mill, when it readily falls into coarse, dry powder, which powder is thence conveyed by an elevator and fed into the revolving furnace by means of a hopper and pipe, which, being set at an angle with the horizon, as it turns, gradually conveys the cement material in a tortuous path towards the lower and hotter end, where it is discharged properly calcined.

The material having been fed into the upper end of the cylinder falls through the flame to the lower side to it; the cylinder being in motion lifts it on its advancing side, where it rests against one of its projecting fins or ledges, until it has reached such an angle that it shoots off in a shower through the flame and falls once more on the lower side; this again causes it to travel in a similar path, and every rotation of the cylinder produces a like effect, so that by the time it arrives at the lower and hotter end it has pursued a roughly helical path,

during which it has been constantly lifted and shot through the flame, occupying about half an hour in its transit.

To some who have been accustomed to the more tedious process of kiln-burning, the time thus occupied may appear insufficient to effect the combinations necessary to produce the required result; but it will be seen that the conditions here attained are, in fact, those best suited to carry out effectively the chemical changes necessary for the production of cement. The raw material being in powder offers every facility for the speedy liberation of water and carbonic acid, the operation being greatly hastened by the velocity of the furnace gases through which the particles pass.

That such is practically the case is shown by the following analysis of cement so burnt in the revolving furnace or cylinder:—

Carbonic acid, anhydrous.....	0.40
Sulphuric acid, anhydrous.....	0.26
Silica soluble.....	24.68
Silica insoluble.....	0.69
Alumina and oxide of iron.....	10.56
Lime.....	61.38
Magnesia, water, and alkalis.....	2.02
	100.00

Again, fineness of the particles results in their being speedily heated to a uniform temperature, so that they do not serve as nuclei for the condensation of the moisture existing in the furnace gas. The calcined material, on reaching the lower end of the furnace, is discharged on to the floor, or on to a suitable "conveyor," and removed to a convenient locality for cooling and subsequent grinding or finishing.

It, however, is not in the condition of hard, heavy clinkers such as are produced in the ordinary cement-kiln, which require special machinery for breaking up into smaller pieces before being admitted between the millstones for the final purpose of grinding; nor does it consist of an overburnt exterior and an underburnt "core" or centre portion; but it issues from the cylindrical furnace in a condition resembling in appearance coarse gunpowder, with occasional agglutinations of small friable particles, readily reduced to fine powder in an ordinary mill, requiring but small power to work, and producing but little wear and tear upon the millstones.

The operation is continuous. The revolver or furnace, once started, works on night and day, receiving the adjusted quantity of powdered material at the upper or feed end, and delivering its equivalent in properly-burnt cement at the opposite end, thus effecting a great saving of time and preventing the enormous waste of heat and serious injury to the brickwork, &c., incidental to the cooling down, withdrawing the charge, and re-loading the ordinary kiln.

Cement, when taken from the furnace, weighed 110 lb. per bushel. Cement, when ground, leaving 10 per cent. on sieve with 2,500 holes to the inch, weighed 121 lb. per bushel, and when cold 118 lb. per bushel.

When made into briquettes the tensile breaking strain upon the square inch—

At 4 days was.....	410 lb. per square inch.
At 6 days .....	610 lb. " "
At 13 days .....	810 lb. " "
At 49 days .....	920 lb. " "
At 76 days .....	1040 lb. " "

A cylindrical furnace, such as the author has described, is capable of turning out at least 20 tons of good cement per day of twenty-four hours, with a consumption of about 3 tons of slack coal. It will be readily understood that these furnaces can be worked more economically in pairs than singly, as they can be so arranged that one producer may furnish a sufficient quantity of gas for the supply of two cylinders, and the same labour will suffice; but in order to provide for possible contingencies the author advises that a spare gas-producer and an extra furnace should be in readiness, so that by a simple arrangement of valves, &c., two cylinders may always be in operation whilst from any cause one may be undergoing temporary repairs, and by this means any diminution in the output may be avoided.

The advantages accruing from the employment of gas-producers for such a purpose have been abundantly proved in steel and glass-making industries, where a saving of from fifty to seventy per cent. of the fuel formerly employed has been effected. The cost is small; they occupy little room, they can be placed at any reasonable distance from the place where the gas is to be consumed, any labourer can shovel the slack into them, and they do not require skilled supervision.

VITERBO. MAR. 31-1886

THE PHOTO SPACQUE & CO. 22, MARINE LANE, CANON ST., LONDON E.C.

INTERIOR OF SAN GIOVANNI IN ZOCOLI, VITERBO.—FROM A DRAWING BY MR. GERALD HORSLEY.

It is claimed by the author of this paper that the following are some of the advantages derivable from the adoption of this method of manufacturing Portland cement, as compared with the more complex system:—

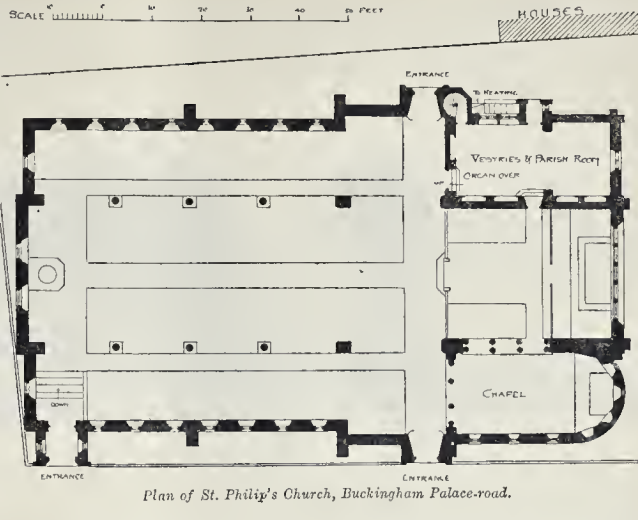

- (1) Economy of space,—the furnaces, with their appurtenances, requiring only about one-fourth the space of what would be occupied by the ordinary kilns for producing a given quantity of finished cement.
- (2) By continuous working, loss of fuel by cooling and subsequently re-heating of the kiln walls is avoided.
- (3) Economy of repairs, which are of a simple and comparatively inexpensive character and of much less frequent occurrence, as no racking is occasioned by the constant rapid changes of temperature.
- (4) Economy in first cost.
- (5) Economy in grinding, a friable granular substance being produced instead of a hard clinker, whereby crushers are quite abolished, and the wear and tear of millstones greatly reduced.
- (6) Economy of labour,—the conveyance to and the removal from the revolving furnace being conducted automatically by mechanical "elevators" and "conveyors."
- (7) Improved quality of the cement, from non-mixture with fuel, ash, or other impurities, and no over-burning or under-burning of the material.
- (8) Thorough control,—from the facility of increasing or diminishing the flow of crushed slurry, and of regulating the heat in the furnace as desirable.
- (9) Absence of smoke and deleterious gases.

It is well known that in some localities the materials from which Portland cement is made are of such a powdery character that they have to be combined, being moulded into balls or bricks previous to calcination in the ordinary way, thus entailing expense which would be entirely obviated by the adoption of the revolving furnace. This has been proved by the author, who has produced cement of a fine quality with a mixture of slag-sand from the blast furnaces of the Cleveland iron district,—prepared according to Mr. Charles Wood's process,—with a proper proportion of chalk or other carbonate of lime, which, in consequence of the friable nature of the compound, he was unable to convert in the ordinary cement-kiln, but which, when burnt in the revolving furnace, gave the most satisfactory results. The cement so made possessed extraordinary strength and hardness. It has withstood climatic influences for many years, and it has been a matter of surprise that ironmasters and others have not adopted such a means of converting a waste material,—which, at the present time entails upon its producers constant heavy outlay for its removal,—into a remunerative branch of industry, by the expenditure of a comparatively small amount of capital.

The demand for Portland cement has increased, and is still increasing, at a rapid rate. It is being manufactured upon a gigantic scale. Great interests are involved, large sums of money are expended in the erection and maintenance of expensive plant for its production, and the author submits that the development of any method which will improve the quality, and, at the same time, reduce the cost of manufacture of this valuable material, will tend to increase the prosperity of one of our great national industries, and stimulate commercial enterprise.

Works are in progress for manufacturing cement by this improved process, and the author trusts the time is not far distant when the unsightly structures which now disfigure the banks of some of our rivers will be abolished,—the present cement-kilns, like the windmills, once such a common feature of our country, will be regarded as curiosities of the past, and the manufacturers cease to be complained of as causing nuisances to their neighbours.

**Hope Chapel, Wigan.**—The Building Committee having advertised for designs for a new chapel, near the Market-square, received about a dozen designs from various architects. They ultimately selected, we hear, the one submitted by Mr. George Heaton, architect and civil engineer, of Wigan, as being entitled to the premium offered, viz., fifteen guineas. The cost of the building will be about 3,000l.

**Illustrations.**

**CHURCH OF SAN GIOVANNI IN ZOCOLI, VITERBO.**

THE view of the interior of this church is from a beautiful pencil sketch by Mr. Gerald Horsley,—a model of architectural sketching in pencil. As will be seen, it is a small Romanesque church of a good deal of interest and remarkable for its nearly unadorned simplicity of treatment.

**STATUE OF HANDEL.**

THE statue of the great composer, of which we give an illustration in this number, was exhibited in this year's *Salon*, and is intended to be placed in the vestibule leading to the grand staircase in the Paris Opera House.

The sculptor, M. Jean Jules Salmson, though his name is not much known in England, is an artist whose talent was recognised by the award of medals at the *Salon* as long ago as 1863 and 1865, and at the Great Exhibition of 1867. He is Professor of Sculpture at the Ecole des Arts Industriels at Geneva. Among his principal works in former years may be mentioned "La Dérivée," a bronze statue exhibited at the *Salon* of 1869 and now at the Luxembourg; "La Jgement de Paris," a polychromatic group in terra-cotta (*Salon* of 1869); "Phryné devant l'Aréopage," a bronze (*Salon* of 1870); "Henri IV.," a plaster statue for the Hôtel de Ville of Rochelle (*Salon* of 1875). We may mention also four caryatide figures representing Comedy, Folly, Satire, and Music, which form decorations to the façade of the Vandeville Theatre; "L'Innocence, L'Amour, et La Folie," a terra-cotta group the property of the Prince of Wales; and "The First Ascent of Mont Blanc," which was in this year's *Salon*.

In the statue of Handel, M. Salmson has very finely realised the character of the man, as known to us from the various biographical notices and records of his highly characteristic sayings and manners which are extant,—a man with a strongly-pronounced individuality, and a nature at once proud, defiant, and yet generous; and there is a sturdy power in the figure and expression which seems well in keeping also with the character of the composer's artistic productions.

**ST. PHILIP'S CHURCH, BUCKINGHAM PALACE-ROAD, LONDON.**

This church is now in course of erection for Canon Fleming, as a Mission Church to St. Michael's, Chester-square.

The Duke of Westminster gave the site, and has contributed largely to the building. The designs have been somewhat altered since the perspectives were made. The plan we give, however, is as executed. The materials used are Gainsborough bricks

for the outside facing, and stocks inside for plastering on; the core of the walls being of cement concrete, bonded with iron. Doubling stone is used for outside work and Corsham inside. The roofs are of pitch pine and fir, covered with Broseley tiles.

The flèche (which is loftier than shown on the view) will be covered with 26-oz. copper.

The church will be seated with chairs, and will hold about 800. The cost, exclusive of furniture, will be slightly over 6,000l.

Messrs. Macey & Sons, Strand, are the contractors. Mr. T. W. Creed is clerk of works, and the architects are Messrs. Domaine & Brierley, of York.

**SCHEME FOR THE DECORATION OF A DRAWING-ROOM.**

IN this scheme the painted frieze of peacocks is treated mainly in lines and greens on gold; it is divided into long panels by winged genii carved and gilded. The walls are hung with red figured silk in panels; the woodwork is in rosewood, with carved panels; the architraves, dado capping, and skirting are chosen. In the centre panels of the large doors are bronze medallion heads of Poetry and Music; the smaller panels being enriched by marble plaques in the cartouches. A frieze of Cupids and seahorses over the doors is carved and bronze gilt, with a central tablet of lapis lazuli for the inscription. JOHN T. SHAW.

[The design was hung in the Architectural Room at the Royal Academy of this year.]

**Proposed Registration of Edinburgh Plumbers.**—A meeting of the master plumbers of Edinburgh and Leith was held on the 9th inst., there being upwards of fifty masters present. The object of the meeting was to consider the subject of the registration of plumbers, which was laid before a previous meeting by a deputation from the Worshipful Company of Plumbers, London. The meeting unanimously approved of the registration of both masters and men, and appointed a committee of thirteen to represent them at a public meeting to be held under the presidency of the Lord Provost.

**The Borough Surveyorship of Doncaster.** On the 8th inst. a special meeting of the Council in Committee was held, to consider the applications for the position of Borough Surveyor. The salary is 250l. a year. There were 154 applications, which had been reduced to ten, and these were further reduced to five, as follows, who are to meet the Council on the 20th, when the final selection will be made:—W. Spink, Dukinfield; S. G. Gamble, Grantham; W. H. R. Crabtree, Rotherham, Resident Engineer of the Rotherham Waterworks, who obtained the highest number of votes; H. C. Crummack, York; and R. J. Duff, Doncaster, Assistant Borough Surveyor.

Jennings and Brewer's Patent Electro-Mechanical Apparatus for Indicating and Registering the Levels of Liquids.—Fig. 1.

**JENNINGS AND BREWER'S APPARATUS FOR INDICATING THE LEVELS OF LIQUIDS IN RESERVOIRS, SEWERS, &c.**

The object of this invention, which has been patented by the inventors and is manufactured by Mr. George Jennings, of Stangate, Lamheth, is to register correctly the fluctuations in level of water or sewage at any distance from the point of observation, as, for instance, in reservoirs some miles outside towns, or outfall sewers in low-lying portions of districts liable to flooding. In such cases the apparatus will be found of considerable use and in many instances invaluable, as it indicates truly what is taking place in the reservoir or sewer. It formed the subject of a short paper read by Mr. Walter Jennings at the recent Leicester meeting of the Association of Municipal Engineers and Surveyors. The following is a general description of the apparatus. The above illustration (fig. 1) shows the apparatus working in connexion with a reservoir in which is a cylinder and containing

Fig 2 shows the arrangement of the transmitter (marked D in fig 1). The weight G, when raised by the movement of the float, is held in position by a clutch on the lever A catching against a pin on the double revolving arm E. The weight G is released by the lever A when thrust out by a pin on the revolving disc B striking against the adjustable cam on the lever A at C, thereby releasing the weight G and causing the double arm E to revolve one half turn, when it is again caught and retained by a similar arrangement on the obverse side of the transmitter, so that at every period of rise or fall of the liquid in the reservoir the lever A, being alternately acted upon by the disc B, first releases and subsequently holds in position the revolving arm E. The latter, in revolving, presses together the two springs H for an appreciable space of time, thus completing an electric circuit.

Fig. 3 is a kind of isometrical bird's-eye view of the back of the transmitter, showing the commutator and the spindle to which is attached the shaft on which the pulley B rotates.

tooth and causes the wheels to revolve one section of the circumference and allows the opposite pawl to resume its former position, thus immovably fixing the escapement wheels A, which are fixed with the teeth opposite,

Fig. 4.

thus providing a similar action to take place when the current is reversed by the commutator.

The inventors claim that the apparatus is also applicable for denoting the direction and velocity of air-currents. Into this phase of the invention we need not here enter, but we may

Fig. 2.

the float A. The float is connected to a chain passing over the pulley B, the dead weight of the float being counterpoised by a weight attached to the other end of the chain. The pulley B is keyed to the shaft C, which sets in motion the mechanism of the transmitter D, and at every inch or other period or difference of level (as may be arranged) of rise or fall, an electric current is transmitted along the line E to the indicator or receiver F, which may be situated at any distance from the reservoir and is usually fixed in the engine-room at the pumping station. A recording arrangement, G, can be added, so that a permanent record can be kept of the varying levels during each week on a diagram attached to the revolving drum, which contains a clockwork movement.

Fig. 3.

Fig 4 shows the mechanism of the indicator or receiver when at rest.

Fig. 5 is an enlarged view of the upper part of the same mechanism when an electric current from the transmitter is received,—the rods H H having been elevated by the action of the electro-magnets, thereby lifting the levers G, G, to which are pivoted the pawls one tooth higher of the wheel A, at the same time a pin at the end of the lever G draws out the opposite pawl clear of the wheel A, and the current, passing through the coils J, attracts the armature on the end of the lever E, the reverse end of which is pointed at D to fit into the notched break-wheel B. Upon the current being broken the break is instantly released, and the pawl that has been raised upon falling engages a

Fig. 5.

mention that when the apparatus was exhibited and described at the meeting before referred to, the general opinion of the borough surveyors and engineers then assembled was that the apparatus is likely to prove of great practical and public utility, especially in indicating the level of water in sewers.

## ARCHITECTURAL ASSOCIATION

THE Architectural Association on Saturday, the 10th instant, made one of their vacation sittings at Ascott, the seat of Mr. Leopold de Rothschild, situated near Leighton Buzzard, the house being enlarged under the direction of Messrs. Dovey & Williams, architects.

The house was formerly quite a small farmhouse, and has been added to at various times. The present additions consist of a new billiard-room (the present billiard-room being converted to a dining-room), and new kitchen and offices, and large suites of servants' bedrooms and nurseries. The kitchen and sculleries are built with glazed bricks internally, with glazed brick cove to ceiling; arrangements are being made to light the whole of the building with electric light. The house still retains traces of its cottage origin in the height of the two stories, the ground-floor being 9 ft. and the upper floor 7 ft. high. The billiard-room, now a dining-room, is higher, and so also is the new billiard-room: both these rooms are panelled throughout in oak.

The external treatment is half timber and rough cast, with tile hangings; the garden frontage is very extended and picturesquely broken up by various projections.

The position of the house is very charming, giving a fine view across an undulating country to the Chiltern Hills. The gardens, which have recently been enlarged, are beautifully timbered and planted.

The stables, near the house, which is ranged over two yards, have thatched roofs, and are very extensive. They contained forty horses at the time of the visit, which constitute Mr. Rothschild's hunting stud, the racehorses being at the stud-farm and at Newmarket.

The stag-hounds are kept in another part of the grounds, and the kennels were visited, and great interest shown in the various arrangements for feeding the hounds. The pack, which consists of thirty-two hounds, were let out into the paddock for the benefit of the members, and were much admired.

In consequence of illness in Lord Rosebery's family, the proposed visit to Mentmore had to be postponed. The house is about four miles from Ascott, and can be distinctly seen from several parts of the grounds at Ascott. Instead of visiting Mentmore, therefore, the party proceeded to Leighton-Buzzard, and examined the fine parish church. This church is cruciform in plan, with a tower and stone spire at the crossing. The spire is remarkable for its ontasis and small broaching. There is a fine wooden rood-screen with curiously-carved dragons on the points of the cusps of the central arch, and bird crockets on some of the other arches. There are good stalls in the choir with return against the rood-screen.

## THE WALLS OF CHESTER.

SIR,—In your issue of the 3rd inst. (p. 320) there is an article by Sir James Picton, on the question as to whether the present walls of Chester show any trace of Roman work. As there has been, and still is, a great conflict of opinion on the subject, permit me, as one of the original promoters of the non-Roman theory, to say a few words in reply to Sir James.

His article may be divided into two parts, firstly, on the portion of the walls seen by the Archeological Institute last year; and secondly, on the new excavation, near the Phoenix Tower. Sir James says that at the Kaleyards the wall "is built on the old Roman lines." This has never been denied, in fact, from the Newgate angle to the Phoenix Tower, and thence to Morgan's Mount, the wall, as I have argued, both in my "Roman Cheshire" and elsewhere, is on Roman lines. Of the wall at this point (the Kaleyards), Sir James said last year, after both Mr. Shrubsole and myself had explained to him the result of the excavations made by the late Dean Howson at its base, that "it exhibited no signs of Roman work; the characteristic wide mortar joints of Roman work were wholly absent" (*Builder*, August 21st, 1886), and this was chiefly from examination of the large stones projecting at the base and in front of which the excavations had been made. But when Mr. Brook, on the 22nd ult., remarked upon the close joints of the stones at this point, "so close that he could not insert the blade of a pen-knife in them"

(*Chester Courant*, August 31st), Sir James endorsed his view and declared the wall Roman. As stated in my "Roman Cheshire," I believe the base of the wall at the Kaleyards to be of the time of Edward I., and I think Sir James will find similar close joints without mortar in portions of buildings of much later date.

Sir James further states that there was a "peculiarity" at the east end of the north wall: "a little above the surface the wall was double, with an interval between. This was pronounced to be Mediaeval work of uncertain date." This is exactly where Roman tombstones, &c., have been found in the wall from base to summit. The tombstone of a *Præfectus Castrorum* was met with 6 ft. above the ground surface, whilst a stone bearing two figures, one an ecclesiastic, has been found at the base and in the centre of the wall. Was the latter placed in position first? If so, according to Sir James's idea, it proves that the base must have been erected in post Roman times, the summit in Roman times, an inverse chronological arrangement.

The North Gate cornice, and wall adjoining, which I have described in "Roman Cheshire," as being composed of Roman stones, brought from some large building (the interior, which Sir James has not seen, is very like the hollow wall he describes above as "Mediaeval, of uncertain date"), he speaks of as being of Roman origin, with repairs and insertions of subsequent date. No one denies the existence of Roman stones in its face; but when were they placed there? We have every reason to believe, in the reign of Anne, when all this part of the wall was greatly repaired. The large stones on the Roodee are next referred to by Sir James. Last year, whilst helping him up on to the lowermost stone, he remarked to me, "This is no Roman wall." To him, and to the Institute generally, whom it had fallen to my lot to conduct round the walls, I explained the result of the excavations made in front of these stones, to the depth of 15 ft., a year or two previously, by order of the Mayor, and he expressly then stated that the stones could not be a Roman wall, but merely (as partial excavations had shown) a retainer to keep the bank from slipping. I believe, as I then and had previously stated, that the stones are Roman, taken from a large building. Sir James is perhaps not aware that at something like 100 ft. behind these stones the remains of a Roman villa lie buried, and if the stones were placed there in Roman times (which I do not for a moment think) it was to keep the ground on which the villa stood from slipping forward (as it has done in the immediate vicinity) into the estuary. They are entirely out of the line of the present walls, and the original wall of the castrum seems to have been far inside, to the eastward; and from the summit of the plateau on which the fortress was built the sloping ground to the Roodee is found to be full of the remains of villas (including that named above) and private graveyards, to the very side of the estuary, save *indicia* of the spot being extraordinary. A large number both of architects and archaeologists still hold the opinion I have named with regard to these three portions of the walls, and I believe that one or two publications on the subject are forthcoming.

It was a committee of experts, appointed by the Archeological Institute, who last year examined the walls generally, and especially the points named, and their verdict delivered by the Rev. Dr. Bruce (the historian, and for forty years the incessant explorer of the Roman wall) was that "nothing they had seen was Roman work *in situ*." I am glad to see that even Sir James partially confirms this verdict, for he says in his recent article, "The walls above ground are, for the most part, post-Roman, of various age." This was the great point contended for last year, but I have stated in "Roman Cheshire" and elsewhere, over and over again, that we may expect to find traces of the Roman foundations of the walls, and this was verified in March last by the foundation of the destroyed southern wall being encountered in Bridge-street. It was 8 ft. thick, formed of houlders set in concrete, and so hard that it was with the very greatest difficulty cut through in order to lay gas-pipes. But as to the portion just laid bare on the north face, a loosely-built wall, without mortar from base to summit, of stones of various sizes, though chiefly large ones, many of them taken from Roman build-

ings, others tombstones, friezes, cornices, &c., it presents no feature whatever of Roman construction. I am perfectly aware that in such works as the aqueduct at Nimes, referred to by Sir James at Chester, immense square stones were employed for building without mortar; but I will ask him the further question, Did he ever know of a Roman castrum whose walls from base to summit were built without mortar?

Mr. Roach Smith, in reply to a letter of mine, brought forward the fact of the foundations of Richborough, Reculver, and Lydney having no mortar, but he said nothing of the superstructure. That is a solid mass of stones, concrete, &c., from base to summit.

Instead of the controversy on this subject being "set at rest," as Sir James hopes, I fear it is only just inaugurated.

W. THOMPSON WATKIN.

Liverpool, Sept. 13, 1887.

SIR,—Allow me to suggest a course by which irresistible evidence, and not assumptive evidence, could be obtained, as to the fact that the excavations of August last "have entirely invalidated" the theory of Hyginus.

His life, in the early part of the first century, was before the time of Trajan, for the eastern Prætorium at Rome was constructed on the lines of Hyginus, A.D. 23, and gives a length and breadth of 2,320 ft. by 1,620 ft. This length is found in Chester from Newgate to Phoenix Tower; the breadth thence to Morgan's Mount; the other sides, or, rather, side and end, are now existing beneath two perpendiculars erected on these known base lines on the east and north; approximately, under Nicholas-street and its continuation, and in Pepper-street and through the centre of the garden of the Probate Court in Whitefriars.

Until these existing, yet buried, foundations are discovered, I hold that the theory of Hyginus was put into practice in Chester, as the discovery of the hypocæust in Bridge-street and Feathers-lane proves the site of the valentinianum.

Allow me to take exception to another remark in the article—"The Via Prætorium, intersecting the city in its length, crossed by the Via Principalis." The Via Prætorium led only from the Prætorian Gate (the North Gate, near Whitefriars) up to the Via Principalis (to the site of St. Peter's Church), and did not cross that street.

With these corrections, I cordially agree with the remarks.

GEO. ESPAILLE.

Stretford, Sept. 13, 1887.

## SHONE'S EJECTORS IN THE RECENT RAIN-STORMS.

SIR,—It was prophesied some time ago by certain unskilful engineers, who are very hostile to Shone's hydro-pneumatic system of drainage, that upon a very heavy rain-storm occurring at Westminster Shone's three ejectors, of 1,100 gallons aggregate capacity, and Atkinson's four gas-engines of four horse-power each, at the Houses of Parliament, would be overpowered and the basements there drowned. On the 17th ultimo a phenomenal and tropical rainfall occurred at Westminster, far beyond anything of the kind that has taken place in London for many years past, namely, of 0.59 in. in depth per hour, or 1.416 in. per day of twenty-four hours. As the area draining to the ejectors is 10 acres, the quantity of water draining therefrom to be ejected was 357 cubic feet, or 2,227 gallons per minute.

This quantity the three ejectors and the four gas-engines, all working together, successfully discharged, without any flooding whatever of the basement. It results from this fact that the ejectors received and discharged 1,113 gallons of water every half-minute during the storm. The lift was 20 ft. to the head of water in the main sewer outside, and 1,113 gallons of compressed air at 10 lb. pressure on the square inch were produced by the gas-engines and consumed by the ejectors per half-minute. I may state that for about two minutes the reserved storm water sub-way received about 2,000 gallons of water from the overflow thereto in the sewage manhole, which, however, soon drained away as the storm subsided.

I am glad to congratulate Mr. Shone on his ejectors performing their functions so admirably and so successfully. I felt assured that they would do so from what I had seen of their performance elsewhere. It was this that gave me confidence to recommend their adoption, under the peculiar circumstances, at the Houses of Parliament, in preference to ordinary pumps, whether centrifugal or otherwise.

JOHN PHILLIPS, C.E.

The Student's Column.

LAND SURVEYING AND LEVELLING.  
XII.—SETTING OUT LINES.

**Perpendiculars.**—A perpendicular in a horizontal plane to a base line may be set out with the use of a chain only, in the manner shown by figures 1, 2, and 3. A right-angled triangle is formed, having its sides in the proportion of the numbers given in the accompanying table to fig. 1; but the proportion of 3, 4, and 5 is generally selected, as the points of intersection at the angles are here more clearly defined than they would be if the proportion of the other lengths were taken. A distance of 40 links is measured along the base line in fig. 1 from the point at which the direction of a right angle is required. The assistants then hold the handle of the chain at V, and the 80th tally at U, while the surveyor holds the 50th tally, and pulls up the chain at T, so as to form the sides of the triangle T U V, respectively equal to 50 and 30 links with the chain. T U is thus set out at right angles to V U. If, instead of 40 links, 30 links be measured along the base line from U to V, then the 90th tally must be held at U to obtain a similar triangle as shown in fig. 2. Should the chain be suspected to be out of order, as indicated by the dotted lines in fig. 2, the exact direction of a right angle may be obtained by setting out the triangle upon both sides of a perpendicular and bisecting the distance marked by the 50th tally upon the chain to obtain the position of the full line, shown in fig. 2, between the dotted triangles. If the 50th tally comes to the same point in both cases it shows the method to have been correctly applied and the chain to be sufficiently accurate for the purpose. In fig. 3 an equilateral triangle is formed by measuring 25 links along the base line upon each side of the point at which the right angle is required, and while the handle at each end of the chain is held by the assistants at the points so arrived at, the surveyor pulls out the chain and marks the position of the 50th tally, through which the perpendicular line would pass.

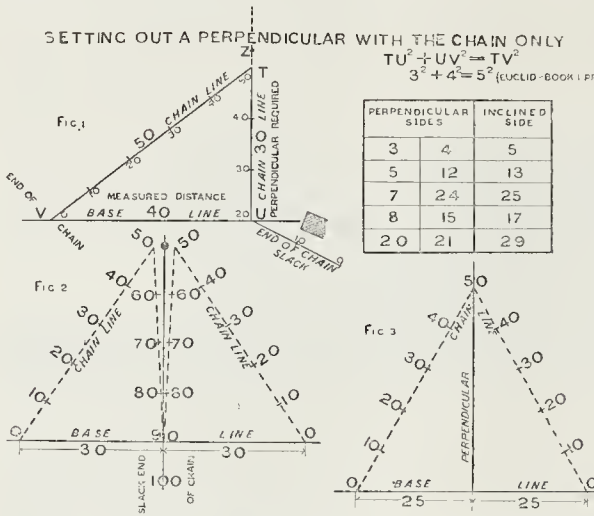

**Obstacles.**—Fig. 4 shows how the distance H I may be measured when a rectangle can be

Miscellaneous.

**Sale of Building Sites at Lee-on-the-Solent.**—A few days ago a large company attended a sale of building sites by Messrs. Lumley, at the new sea-side watering place of Lee-on-the-Solent. The prices realised for the several lots sold were double those obtained at the early sales of the estate. The number of plots offered was twenty-eight, of various sizes, several of them containing an area of half an acre and upwards. On the sale commencing, there was an active demand for the several sites submitted. Three shop plots in the High-street, near the pier, having frontages of 36 ft., and depths of 120 ft., were sold for 65*l*. each. Three other sites in Cambridge-road and Portsmouth-road, having frontages of 120 ft. and similar depths, realised 95*l*. each. Two sites in Portsmouth-road, containing an area of half an acre each, with frontages of 88 ft., and depths of 250 ft., were sold for 145*l*. and 155*l*. each. The highest prices obtained were 270*l*. for a block in Gosport-road, having a frontage of 392 ft. and a depth of 105 ft., and containing an area of nearly an acre, and 220*l*. for another block opposite, having the same frontage of 392 ft., and a depth of 80 ft., and containing an area of nearly three-quarters of an acre. The purchaser of these two plots was Mr. Clifton, of London. It was stated that the plots afforded sites for the erection of nearly sixty cottages with 14 ft. frontages. A number of smaller plots, having frontages of from 40 ft. to 70 ft., and depths of from 80 ft. to 100 ft., were sold at prices ranging from 40*l*. to 55*l*. each.

**Leaflets of Furniture.**—Under this title, Messrs. Walker & Sons, the well-known cabinet manufacturers of Bunhill-row, are now sending forth by instalments a preliminary issue of a portion of a new illustrated catalogue. The leaflets include illustrations of hall, library, dining-room, drawing-room, and bedroom furniture (most of it suitable in design), as well as a selection of Messrs. Walker's excellent wood chimney-pieces and overmantels. We have, on former occasions, spoken of the excellence of workmanship which characterises Messrs. Walker's productions.

**Church Fittings.**—A set of oak choir-stalls has been placed in Brewod Church by a former parishioner, in commemoration of his residence in the neighbourhood for twenty-three years. They were constructed by Messrs. Jones & Willis, of Birmingham and London.

**The Employers' Liability Bill.**—At the meeting of the Trades' Union Congress at Swansea last week, Mr. Inglis moved:—"That this Congress regrets that the Government has failed to carry out the promise to deal with this subject during the present session of Parliament, and urges upon the Parliamentary Committee to persevere with the matter until an amendment of the existing law is carried upon the lines of the measure promoted by Messrs. Burt and Broadhurst." Mr. Inglis went through the proposed amendments to the present Act, all of which he said he cordially approved of. The employer should be responsible for the negligence of any person in his service, because they knew it was an easy matter for employers to relieve themselves from responsibility by their definition of "the person in charge." It should also be made illegal for employers to contract out of the Act. He felt assured that the Congress would confirm the amendments proposed, and he trusted that the members of the Parliamentary Committee would use every effort to get them passed. Mr. Matkin (Liverpool), who seconded the motion, thought they ought to do something more than express their opinion, of which no notice would be taken. The Parliamentary Committee should impress upon members of Parliament in the various districts the necessity of passing the amendments proposed. Mr. Pitt (Glasgow) and Mr. Munro (Belfast) said they did not think that three years' compensation was sufficient in cases of permanent injury or death. Mr. Inglis said that the Bill provided for compensation up to 500*l*. After some further discussion, the motion was carried.

**Tasmanian Forests.**—The Hobart correspondent of the *Australasian Builder* writes:—"Our new Minister of Land and Works has promised to bring the conservation of Tasmanian forests into a practical shape. At present restrictions prevent the cutting and sale of timber either for export or for use in our own markets, the latter a very manifest absurdity, because when the cutting is restricted to legitimate use there is no fear that the abundance of timber we possess can ever be unduly depleted. A ridiculous instance of how the present restrictions work was recently given on the west coast, where a bridge is being erected across a river, the materials used being American and New Zealand timber, imported at a heavy cost, while along the banks on each side of the stream fine timber is growing in abundance,—blue gum, myrtle, stringy bark, and celery top pine,—all eminently suited for the purpose. It is proposed now to lay open a good many acres of pine-bearing land on the west coast for public use, which will be the means of yielding revenue to the public exchequer, and a great convenience to the building trade and the general community."

**Builders' and Contractors' Hardware.**—Messrs. F. W. Reynolds & Co., of 73, South-wark-street, have sent us a very well-put-up and useful trade book, entitled "Architects' Illustrated Catalogue of Builders' and Contractors' Hardware." It contains particulars of open and close fire kitcheners, portable and "self-setting" ranges, boilers, gas-cooking apparatus, slow-combustion and register stoves (many of them appropriate and good in design), "persons' grades," &c. This section of the catalogue is very complete. The catalogue also contains a large selection of Messrs. Reynolds's patent and other locks and furniture, brass-work, &c. Their new patent double-handed lever mortise and rim locks have much to recommend them. Stable fittings, sanitary appliances, and cast and wrought iron gates and railings are some of the numerous other goods figured and described in this very useful and presentable catalogue.

**Messrs. R. Waygood & Co.**—We have received from Messrs. R. Waygood & Co., the well-known engineers and lift-makers, a copy of the *Gazette* notice of the alterations in their firm, consequent on the retirement of the senior partner, Mr. J. M. Day, in favour of his son, Mr. Charles Day, who has for many years held a leading position in the business. We understand that, notwithstanding his retirement, Mr. Day, senior, will continue for the present to give the firm the benefit of his long experience in those departments which were under his more immediate personal control. The partners of the firm, as now constituted, are Mr. W. R. Green, Mr. H. C. Walker, and Mr. C. Day. The firm will continue to be known as "R. Waygood & Co."

**The Importation of Bricks and Tiles into Turkey.**—A correspondent of the *Manchester Courier*, writing from Constantinople, lays particular emphasis on the great demand for bricks, tiles, and draining pipes which he says exists in Turkey. Large quantities of solid and hollow bricks used to be imported formerly from Marseilles, but these are now produced in the country itself, and all foreign competition becomes impossible when such low-priced and heavy article has to bear freight, duty, and loss by breakage. Flat tiles 13*l* to the square metre are furnished by Marseilles, and are substituted in all new buildings, and are displacing the round tiles produced in the country, which break under a slight weight. About 2,000,000 of such flat tiles are exported annually from Marseilles to Constantinople. They weigh 2,550 kilos, and their price in Marseilles is about 76 fr. Freight per stonier may be reckoned at 10 fr. per ton, and at about 5 fr. by sailing vessel. These tiles are, therefore, burdened with 50 per cent. of expenses in the shape of freight, duty, &c., and yet prove a profitable article of exportation, at least at present.

**Glasgow Architectural Association.**—The usual monthly meeting was held on the 6th inst.,—the President in the chair,—when three short papers were read. The first of these, "Friezes and Pilasters of the Italian Renaissance," by Mr. Geo. Tindhope, ere dealing with the subject-matter in detail, was prefaced by a brief notice of the general principles regulating the choice and application of ornament. A second paper by Mr. Geo. Mackenzie considered the figure subjects introduced into the sculptured ornaments of the same style, particularly the examples of Della Robbia, Raffaello, Fibosole, and other masters. The third paper was by Mr. Wm. M'G. Petrie, and described the ornaments of one building, the Church of St. Maria at Brescia, one of the richest examples in Italy, illustrated like the preceding paper by numerous photographs, but supplemented by several sepia drawings. A short discussion ensued, followed by thanks to the several essayists.

**Architecture at the University of Sydney.**—From the *Sydney Morning Herald* for July 21st we learn that at a meeting of the Senate of the University of Sydney, seven applications which had been received for the position of Lecturer in Architecture during Michaelmas Term were received and duly considered. It was resolved, on the motion of the Vice-Chancellor, seconded by Professor Gurney,—"That Mr. John Sulman, F.R.I.B.A., be appointed to the office." Professor Gurney gave notice of the following motion,—"That Mr. Sulman be authorised to expend a sum not exceeding 100*l*. in preparing diagrams or drawings, &c., for use in his course of lectures on architecture." Mr. Sulman, whom we congratulate, is well known in London.

**New Railway Station at Gloucester.**—Mr. Jenkins, of Plymouth, to whom the contract was let at about 20,000*l*, last week commenced operations for the construction of the new Great Western Railway Station at Gloucester. A number of men are engaged in digging foundations on the ground in the rear of the houses in George-street.

**Grosvener Gallery.**—We are glad to learn from the *Athenaeum* that there is shortly to be an exhibition at this Gallery of the works of the Russian painter, Verestchagin, an artist of remarkably original genius, whose works are well worthy of more attention than they have hitherto received in this country.

### The Roman Wall in Scotland.

WITHIN thirty minutes' walk of the outskirts of Glasgow, on the north-west, and well overtaken by the five-mile radius from the Royal Exchange of that city, is still to be

found a small, but wonderfully-preserved portion of the military barrier which Antoninus Pius caused his legions to draw across the isthmus between the Forth and the Clyde, A.D. 140. Although thus at the doors of the citizens, so to speak, with an excellent public road hard by, its existence is not at all generally known to them,—perhaps not generally known even to those of them who are distinctly smitten by the infection of antiquarian research. The best parts of the Roman Wall between the Forth and the Clyde, as pointed out in a former *Builder* article, are to be found on its mid-sections between Kirkin-tilloch and Falkirk, the remains discoverable to east and west of this great central stretch having, as a rule, made more rapid progress to the goal of complete effacement. Nevertheless, both to east and west of this central stretch exceptional vestiges are to be found,—to wit, a carefully-tended portion within the park ground of Callendar House to the east, and to the west this other most interesting sample, situated quite within the suburban area of Glasgow, and now to be more particularly referred to. Examined on a modern map, the work of the engineers of Lollius Urbicus, the general who then commanded the imperial forces in North Britain, is found entering Stirlingshire from the east after traversing half the breadth of Linlithgowshire. Thence it passes into a detached portion of Dumbartonshire, which ultimately leaving, it dips for a mile or two just within the north-western border line of Lanarkshire, after that re-entering Stirling-shire at a narrow south-western spur of that county, and finally passing into Dumbartonshire mainland, where the western termination of the work has place.

From Kirkin-tilloch westward the remains are generally difficult of recognition, except to the practised eye; but on Ferguston Muir, within the south-western spur of Stirlingshire, above alluded to, and close to the point where the three last-named counties meet, there is a short strip which has been little affected by the hand of man since the date of its construction, in the year 140, and not very much by the influence of the elements. Ferguston Muir,

once of wide extent, borders the north-west turnpike out of Glasgow on the route to Strathblane and Aberfoyle. It is not quite five miles from the centre of the city, and near to the point in question the Loch Katrine Aqueduct cuts in upon the ground, crosses the site of the wall, and passes citywards. The major portion of it has long since been "de-moored" under the gradual advance of tillage operations and experiments. Quite recently the encroachments of suburban villa builders have further pared away what agriculture had spared, and, the upland being breezy and healthful here, if Glasgow flourishes as it has done, perhaps the whole of it is bound to go the same road some day. But that time is not quite come yet, and a small part of the moor remains, unmolested apparently for nearly seventeen and a half centuries, and with the trench of Lollius Urbicus scored across it about as plain as ever it was. A country road (which at this point is no less than the ancient military way itself,—that military way which accompanied the barrier over the whole of its length at a variable distance southward, rarely exceeding 150 yards, and traces of which are here and there still discernible), skirts the moor from the direction of New Kilpatrick, after crossing at right-angles the main turnpike above mentioned, and thence mounting a somewhat steep rise of the ground which here occurs. The small portion of the moor still undisturbed is bounded on the south by this parish road,—or forgotten military causeway, rather,—while to the west, and of very moderate acreage indeed, there is a field in tillage which is all that now shields the relic from the onward march of the villas with which the road is becoming fringed, the latest built and most advanced of these being only at the further breadth thereof, and perched right on the site of the all but rubbed-out Roman work itself. Fields in crop or grass adjoin to the north and east, and also on the other, or southern side of the parish roadway. The strip of virgin moor possesses, perhaps, barely 200 square yards of area in all, and from the road there is nothing out of the way to catch the eye, the Roman work being visible, indeed, in the swelling of the southern agger, but not in such a manner as, at that distance, to suggest anything more than the natural surface contour of a patch of unproductive ground. It is only when the wire fence has been furtively violated, and the one hundred and fifty yards' breadth to the north traversed, that the truth of the matter begins to be dreamed of. Such chanced, a few weeks ago, to be the incidental experience of the writer, who certainly knew himself to be not far from the line of the Roman vallum, and was unquestionably on the scent

for traces of it in thus incontinently constituting himself a trespasser, but had not the faintest notion that here, so far to the west, a really "good bit" was still existent. On gaining the summit of what seems at first but a broad natural furrow, but which is, indeed, the southern agger of the work, only a good deal flattened, the fosse or ditch at the feet of the spectator at once stands confessed, the bottom partially clogged, but still in well-defined measurements, and in shape and cutting virtually as the Roman digging implements left it. For a stretch of nearly three hundred yards the work proclaims itself in lines unmistakably bold, and at either extremity where the trench suddenly levels up into fields long under tillage, the course of the obliterated vallum is still discovered to the eye by a streak of differently-tinted vegetation, as if the throwing out of the ditch earth and (after some centuries) the filling of it in again had made a lasting mark on its capacity for grass growth. Across the unreclaimed portion of the moor the ancient barrier holds its way quite regular and unbroken, the fosse from 8 ft. to 10 ft. of clear depth, and at least 20 ft. wide from lip to lip. Measurements varied at various parts of the Roman wall in Scotland, according to the exigencies of the position for attack and defence, and here it has been by no means of quite maximum proportions, but rather of a size midway between the largest and the average. As a specimen, however, it is scarcely inferior to the best preserved portions still existing in the neighbourhood of Castleary, Roughcastle, and Tamfour, a little to the west of Falkirk. The main agger, or wall of earth, on the south brink is of course trained off in its angles and altitude by centuries of heating down action on the part of the elements; but it is there distinct enough over the whole of the 300 yards (or thereabouts) of moor remnant, and its summit level is still to be measured by feet. According to the plan followed by the Roman military engineers, the earthen wall, when making its way across morass ground, rested on a foundation of roughly-dressed stone laid in thinish courses of from 10 ft. to 18 ft. broad, and here such foundation exists still, to be unearthed by comparatively small exertion of spade work although concealed from the unaided eye. It is, indeed, well on record that from this point on Ferguston Muir eastward for about a mile the proprietor of the ground quite early in last century systematically levelled the main agger of the work, and in doing this filled up the fosse, in order to quarry and carry away a sufficiency of the Roman foundation stones wherewith to build the new park wall he had decided to erect, and in this wall surrounding the neighbouring demesne of Douglaston these

stones are to be seen to this day. The agger on the north bank, always of small size as compared with its southern companion, and certainly not continuous from sea to sea, is distinctly visible on the Ferguson patch; thickish turf grass clothes the whole, down even to the bottom of the fosse, the sides of which also afford growth space for some scanty shrubwood planted promiscuously by the unstudying hand of nature. The only modern contrivance traceable to the hand of man is an open runlet of small dimensions cut by some rural drainsman from end to end along the bottom of the trench (a ditch within a ditch), dry in summer, and in wet times carrying off the superabundant moisture to a neighbouring burn. For the most part devils in the course pursued, the Roman work is remarkably so in the section of which this Ferguson strip forms a fraction, more particularly after passing the site of the fort where New Kilpatrick now stands, and until that of Kirkintilloch is caught up. The land here is almost wholly reclaimed now, the very small fragment, above particularised, being about as belated a portion as any, although, considered as no more than a bit of waste ground, it also may be held as fairly drained. Morass surface must have been painfully abundant in the second century of the Christian era, however, and, as we now see, the Roman work perforce became uncommonly erratic of gait, perpetually zig-zagging in obtuse angles with the view of picking out the least unpromising of the rather unfavourable routes which were alone at disposal.

The Roman wall here, as elsewhere along its course, is locally known as "Grim's Dyke," and the story has been told times without number how that a Caledonian chieftain named Greme bore from his northern fastnesses in force upon the barrier of the invaders, throwing down a portion of it, and thus carving out a passage for himself and his followers, with the result that the people at once took to calling the rampart by the new name of "Greme's Dyke," and persevered in that ever after. In some accounts the actual spot where this alleged forlorn hope exploit took place is set down, but the whole story bears strong suspicion of gratuitous fabrication, the original author having most likely simply set his faculty of invention to work to account for the otherwise incomprehensible title of "Greme's Dyke," some centuries after the original signification of the word *Grem*, or *Graem*, or *Grim* had been forgotten. Doubtless, the Caledonians early found their way to the south of the barrier by simple dint of swarming into the ditch (for the most part dry), and climbing out of it again and over the agger on the opposite side,—a feat not calling for any extraordinary exertion on the part of mountaineers, at least, at points where the work was unguarded by soldiers,—but the special violation put to the credit of the mythical Greme must be held in the main as apocryphal, since, unfortunately for the ingenious hit of North British fiction, there are extant in England (Oxfordshire and Hampshire, for example) various bits of Roman work of similar earth-work construction, also known locally as "Grimes" or "Grimm's" Dyke. It is almost beyond all question that the term *Greme* or *Grimm* is generic; and that the

*Grem* of Scotland and the *Grim* or *Grimm* of the south of England (perhaps also the "*Grim*" of Grimby) are one and the same. It has been hazarded that the title is of Celtic parentage, and simply means the "black" dyke; but this effort at solution hardly affords satisfaction, for the aggers and ditch, although no doubt black and grimy enough when fresh from the spade, would speedily become covered with a growth of vegetation. However, by the title of Greme's Dyke or by any other name the wall of Antoninus Pius is but little noticed or discussed on the part of the people through whose towns and fields it passes. Population abounds in the neighbourhood of Falkirk, Kirkintilloch, the two Kilpatrick's, and Dunlocher, and especially where the ancient Roman work all but touches Glasgow, but probably out of the inhabitants of these places (Glasgow included) not one in ten thousand ever consciously saw a bit of it. The small portion above described is, of course, no new discovery, being well enough known to a handful of people. It is also duly mentioned in Horsley's "*Britannia Romana*," published in 1732 and recognised as well preserved then, but even so recently as 150 years ago good bits were much more plentiful than now, and the mention accorded is after all only a passing one.

#### NOTES.

**T**HE verdict of the jury on the Exeter Theatre fire, which all our readers will have seen in the daily papers of Thursday, is no doubt what may be called an indignation verdict, and on one or two points the remarks made are certainly very unreasonable; as, for instance, that if the architect had raised the roof of the auditorium it would have carried up the smoke and allowed the audience time to escape. This was in accordance with the evidence of one witness, but that was merely the witness's opinion, not a statement of fact, and no raising of the roof would have really made any appreciable difference in the collection of the smoke, unless it had been raised to a height quite unreasonable and such as would have injured the acoustic qualities of the theatre. But in general, the verdict, strong as it is, must be accepted, as far as we can gather from the evidence, as a just one. The licensing magistrates must bear considerable responsibility for their carelessness in not satisfying themselves that the changes they required had been carried out; but we fear it is impossible to deny that the main *onus* of the matter rests on the architect, Mr. Phipps, who, as a theatre-building specialist, ought to have been the person to be most urgent in insisting on every possible structural precaution being taken, whereas he appears to have adopted the opposite part of making light of the requirements and even promising things which he never took care to see performed. We do not say that any one is responsible for all the fatal result, because in the panic in which the gallery audience obviously were we believe they some fatal results; but there can be no doubt that it might have been owing to the structural defects in the building. The main factors

in this were the want of sufficient exit from the gallery, the want of a fire-resisting curtain at the proscenium (we purposely avoid the word "fireproof"), and the existence of the door in the wall between the stage and auditorium portions of the house, through which the smoke seems to have obtained direct access to the gallery stairs. The partition wall itself being thinner than the Board of Works' requirements did not affect the result in this case, though we hold that the wall between stage and auditorium portions should rather be 18 in. than 9 in. Of course, a theatre built as this was might have gone on safely for years, but a sudden fire finds out its weak points. We wish we could defend the architect, but we can see no ground for doing so. He seems to have gone into the matter with as light a heart as if fatal disasters from the burning of theatres had never been heard of. We regret this on more than personal grounds, since it casts a discredit on the architectural profession, which many ill-natured and illogical people will be eager to make the most of.

**A**LTHOUGH railways are of course made with the intention, or, at least, the hope of attracting commerce, very few have succeeded so far as the Canadian Pacific Railway in so short a time after its opening. Nor is it only the traffic of the country that it has monopolised, for that goes without saying, but it is that it has diverted already so much of the sea traffic. Japan, for instance, is having its trade revolutionised since the opening of the line, and particularly in the articles of tea and silk. Last year the great route for tea was through the Suez Canal, while the silk went to America *via* San Francisco. Now, however, the Canadian Pacific steamers take it for transport to Vancouver, and the *Vicc-Consul* at Hfio states it to be his conviction that in a very short time not only the tea, but a fair share of the general export trade, will go altogether by Vancouver. It is no wonder that the trade of some of the Japanese ports, such as Yokohama, should have increased during the year by 1,250,000*l.* One of the great increases, curiously enough, is in wine, the Japanese having, to a great extent, discarded their national bamboo umbrellas, and taken to making and wearing umbrellas and parasols on the European model.

**W**E hear that the Exhibition to be held at Glasgow next year will include one feature of remarkable interest. The promoters of the Exhibition, we are told, intend to do for sculpture what the Manchester Exhibition of this year has done for painting, and to form a representative collection of the sculpture of the last half-century. This is, indeed, news of interest to all lovers of art. At Manchester the splendid exhibition of paintings of the last fifty years was supplemented only by a few scattered works of sculpture, placed here and there as ornaments, but forming a very unimportant portion of the Exhibition. And it has been nearly the same in all similar Great Exhibitions, as far as we can call to mind. Sculpture has never been represented collectively on a large scale, and in a manner worthy of so great and intellectual a branch of art. The information reached us informally and in course of conversation, but we have no reason

doubt that it is correct, and we wish the management of the Glasgow Exhibition every success in so admirable a proposal. It will save many of us to Glasgow who might not otherwise go. It is to be hoped that the best advice will be sought in regard to the design, arrangement, and lighting of the sculpture galleries,—even more important with sculpture than with pictures.

It is now a month since the Act was passed empowering the Richmond Authorities to form a joint Board to carry out the scheme of drainage designed by Mr. Melliss and approved by the Local Government Board, but as yet there are no signs that even the preliminary steps are being taken to form this Board. Richmond is the greatest sinner in the matter of discharging crude polluting sewage into the Upper Thames, and for sanitary reasons which affect a much larger constituency than the residents of the immediate neighbourhood it is highly desirable that the Richmond Authorities should proceed with the carrying out of this approved scheme without a day's delay. It is true that the Act relieves these Authorities for three years of any of the liabilities as to the penalties attached to the discharging of crude sewage into the Thames, but this immunity may be swept away, even within the three years, if the Local Government Board be of opinion that there is "unreasonable delay in the preparation for, or the carrying out of, the works." The Chertsey Authorities have just been fined 50*l.*, at the instance of the Thames Conservators, for allowing unpurified sewage to pass into the Thames. Indications are not wanting that the Conservancy Board mean now to enforce more actively than ever the full requirements of law against delinquent Authorities. It will be seen from a recent issue of the *Builder* that Acton, another of the Thames Valley Authorities, has completed a new scheme of drainage, and is now passing a clarified effluent instead of polluting sewage into the Thames.

WE are, of course, not going to make any suggestion at this juncture as to where liability lies for the miserable railway accident at Hexthorpe, but it is impossible to avoid a comment about the extraordinary and what seems to us, we confess, almost lunatic proceeding, which it appears is adopted by some railway managements, of suspending the block system on the days when there is an extra pressure of traffic. The block system was invented to insure trains against the disasters arising from one train overtaking and running into another that was stationary; a danger which was recognised as a serious one even when traffic was in a normal and regular condition. There comes a day when traffic has to be thrown out of its normal course and when there are extra chances of accident, and then the block system is suspended! Of course it may be replied that the working of the trains by flag signals is really a temporary block system on shorter lengths of line. So it is, if properly carried out; but to change the whole system suddenly, and to rely on a number of extra signallers, just at a time when there is extra risk on the line and when extra caution is required, does seem a most extraordinary proceeding. No doubt the passengers will grumble very much if they are kept waiting at a block signal box; nine-tenths of railway passengers are utterly ignorant and unreasonable in regard to the working of railways; but it is better that they should grumble in safety than be taken lighthearted into danger of a terrible death.

WE hear that Mr. H. A. Rogers, of New Southgate, has issued, in two large sheets, an etching of London, Southwark, and Westminster, as they appeared in the middle of the sixteenth century. The drawing is based upon N. Whittock's reproduction, or rather, as we should call it, amplification of Antony van den Wynegaerde's bird's-eye view,—sometimes known as the Sutherland view,—which is now preserved in the Bodleian Library at Oxford. When the Flenuing made his ink and sepia drawing, circa 1550, the spire of old St.

Paul's was *in situ*. But as regards the extent of the town, it is to be observed that many of the principal streets had but single lines of houses. In Rotherhithe, Lambeth, and Southwark there are scarcely any houses at all. Spitalfields, Goodman's-fields, and so between Ratcliffe and Wapping; Bloomsbury, and the ground between Pall Mall and Tyburn,—all is fields; whilst the greater part of Clerkenwell, Cripplegate, and Shoreditch parishes is vacant. Whittock's engraved drawing, to a smaller scale, though it makes a prettier picture than Wynegaerde's, cannot be taken as authentic for purposes of accurate topography, since it contains certain features which are not chronologically correct.

M. FOUCAUT, in the *Bulletin de Correspondance Hellénique* (1887, p. 129), publishes two inscriptions found at the Peireus, which have a very general interest, as they deal with the rebuilding of the Long Walls by Konon. They also help to settle the site of the Temple of Aphrodite (Aphrodision), mentioned by Pausanias. He says (book i., 5):—"Near the sea there is a temple to Aphrodite, built by Konon, when he obtained the victory over the fleet of the Lacedæmonians off Cnidus in Caria." The inscription dealing with the Aphrodision runs:—"In the archonship of Euboloides, beginning at the sign, as you go to the right in front of the gates of the Aphrodision, 790 ft.; Demosthenes the Boeotian was contractor, together with the supply of stone." The other inscription reads:—"In the archonship of Diophantos, in the month of Skirophorion, for jobs by the day (*τὰ καθ' ἡμέραν ἔργα*) paid for teams bringing stone, 160 drachmas; iron instruments, 53 drachmas." M. Foucart fully discusses the inscriptions and gives a plan of the portion of the topography of the Peireus to which they refer.

THE "Società delle forze Idrauliche," in its recent excavations at the so-called "Villa of Mæcenas," seems to have at length happily set at rest the name and purport of that problematical building. Nibby's conjecture proves now to be correct. It is no villa at all, but a part of the Heracleion, a temple of approximately the same shape as the Temple of Fortuna at Preneste. A fragment has been found bearing the inscription, "Æditui H(erculus) Victoris." Several "cippi" are inscribed "Curatores fani Herculis Victoris," also a fragment of a cornice in which the club of Hercules appears repeatedly as a decorative motive. As yet the full plan of the temple and the extent of its dependencies is not made out, but the Society, to whom the site belongs, intend thoroughly to explore the whole building. A provisional account appears in the *Notizie degli Scavi di Antichità* (1887, p. 25), by Sig. Luigi Borsari, who publishes a number of the inscriptions. A full account, with topographical map and architectural details, is promised shortly.

FROM the annual report of the Hellenic Society, just issued to members, it appears that the Council have determined to alter the form of the *Journal* of the Society to Imperial 8vo., and to include the plates with the text, instead of issuing an extra atlas of plates. A double folding page will be used where any illustration is required larger than the page size. The change will be for the better: it is troublesome to keep a periodical in a dual form. There is also to be added to the *Journal*, as soon as it can be arranged for, a supplement, giving a notice of new publications on Greek archaeology, and a summary of foreign periodicals. This will be a very valuable addition.

WE believe the last contribution to periodical literature by Signor Cozzadini (whose loss to Italian archaeology we have so recently had to deplore) was a paper in the *Revue Archéologique* on the very curious sepulchral reliefs in the Museo Civico at Bologna. The most casual tourist who has wandered through the Museo Civico,—we say advisedly the best-arranged classical museum in Europe,—must

have been struck by these reliefs. They are so unlike anything to be seen elsewhere. In fact, they are unique, found only in the necropolis of Felsina. Up to the publication of this monograph they were but little known to the general public. The most usual subject of the designs is the departure of the soul for the lower world. This is represented by a warrior in a chariot drawn by winged horses, or by a scene of parting. The style of the reliefs can now be conveniently studied in the four plates with which Signor Cozzadini accompanies his article. It has been his life's work to elucidate these antiquities at Bologna, and it is right that it should be widely known that the Museo Civico owes much of its perfection to his care.

WE have received some specimen plates of a work which is being brought out by Mr. E. L. Conder in illustration of the noble church of Long Melford, in Suffolk. The drawings sent us are admirably executed, and show the greatest care in the carrying out of the work, and if the whole publication is equal to these it will be one of the best of our monographs of English buildings.

THE Metropolitan Railway Company have, as we lately mentioned, opened their line to Rickmansworth, thus laying themselves out for a certain amount of purely country and long-distance traffic. Baker-street thus becomes a terminus, but of all stations in London it would be difficult to find one worse adapted for this purpose. To endeavour to carry on a long-distance traffic in a manner satisfactory to the public or the shareholders a proper terminus is necessary, and such a one should have been made at Baker-street before the Rickmansworth extension was opened. It was the more necessary to undertake this work because the present station, whether we regard that part of it used for the main-line traffic or that in which the northern trains arrive and depart, is the most inconvenient and unwholesome in the metropolis. After being nearly suffocated in the main portion, a passenger is almost squeezed to a pancake or pushed on to the permanent way when on the narrow platform of the St. John's Wood line. This want of accommodation at Baker-street is the more noticeable because the stations on the northern extension are large and well-designed buildings.

WE have received a prospectus of a proposed art exhibition to be held at Derby in the month of December and January next. It is to be divided into three sections: I. Non-competitive, for professional artists only, including the leading branches of the fine arts; II. Competitive, for local amateurs; III. Competitive, and open to professional or amateur artists alike and independent of locality. This latter class includes a variety of the minor arts to which lady amateurs are more especially devoted, such as paintings on opal, crysoteum painting, designs for Christmas cards, &c., as well as the more orthodox applied arts included under the term "art-needle work." There is likely to be a fine conglomeration of curiosities under this heading. There may very likely be a good collection in the non-competitive and purely exhibition section, as many artists are glad of a new opportunity of exhibiting their works at a time when most both of the London and provincial exhibitions are closed. But we do not augur much for the rest of the exhibition, and the selection of the judges is rather a puzzle to us. There are only three judges announced to pronounce upon and adjudge prizes for all this variety of work, and not one of them is an artist, as far as our knowledge of their names tells us. Mr. W. H. Coxs, F.G.S., of Bank House, Stoke-upon-Trent, and Mr. H. J. Fenton, Waterdale, Doncaster, are, we presume, amateurs taking an interest in art; Messrs. Raphael Tuck & Sons, fine-art publishers, whose names are well known in that capacity, form the third person of this trinity of judges. With all respect to these gentlemen, we think it is rather presumptuous of them to invite artists, professional and amateur, from all parts of the country, to submit works to their judgment for the award of medals; and if they have, as the phrase is,

"power to add to their number," they would do wisely to invite the assistance of one or two artists of known standing; they will be more likely to have a good exhibition in that case.

#### NOTES OF A HOLIDAY ON THE NORFOLK COAST.

WHEN Mr. John Knightley was so indignant with the Highbury apothecary for presuming to think that he ought to have taken his family to Cromer instead of to Southold for their health,\* he did not dispute the sanitary superiority of Cromer. It was the question of the expense and trouble of moving a whole family so long a distance in coaching days, which he thought he understood better than Mr. Perry. It appears from the episode, that Cromer was in Jane Austen's day a recognised superior watering-place, a proper place to go to if you could afford it. For a long time since then it seems to have been quiescent, remaining until very recent years beyond the limit of the railway system; now railway extension has brought it within reach of excursionists, while at the same time the temporary residence of royalty,—foreign royalty, it is true, but still royalty,—has sanctified it in the eyes of society, and during this autumn Cromer has been another "London-by-the-Sea," swarming with visitors, and its sands covered with cricket and lawn-tennis players. This over-populous condition, which we had not realised from report, would hardly have been an extra attraction. But the fates were kind to us: Cromer was "full up," as the tramcar conductors phrase it, but we could find accommodation at Overstrand, a couple of miles eastward along the coast.

Now, Overstrand turned out to be an ideal place for a seaside holiday. A splendid beach; no promenade or pier or any such mundane vanities, a few visitors dotted about, and a small native population of fishermen, frank-spoken courteous fellows, whose boats formed one element in the picturesque of the scene. The accepted type of boat in this part of the coast has a marked character of its own. As will be seen from the subjoined sketch, it has

not the usual square stern, but is sharp at both ends, the object being, we were told, to render them more manageable in heaving in rough weather, the sharp stern not being so liable to be kicked up by the surf when approaching the beach. The rowlocks, too, consisting of circular holes through which the oars are drawn, are quite peculiar to this part of the coast. They are capital little craft, keeping wonderfully dry on a breezy day, and will stand a great deal of rough weather. The method of shaping the upper planks, narrow at the ends and widening in the centre, is duly emphasised with true artistic propriety in the painting of the boats; generally the top plank is red or blue, the next white, which gives a marked character, quite distinct from the commonplace narrow stripe of uniform width with which boats are usually decorated. The method of conveying the boats up the beach after landing is a characteristic incident of the place; the straight, heavy, sea-oars (so different from the river type of oar) are passed through the circular rowlocks so as to project on each side of the boats, and six strong fellows in sou'-wester hats and big boots march up in step, three on each side, carrying the boat between them by the oars; and if Mr. J. C. Hook wants a new foreground group for one of his pictures he will not easily find a better or more picturesque one than this.

The coast here, on the round shoulder that juts out eastward of the Wash, looks nearly north, and looking out from the beach, there is nothing but sea water between us and the North Pole, a fact with which the keen sharp air of the landward breeze is quite in harmony. The shore lies beneath high cliffs with an undulating skyline, composed of soft clayey strata, which have been for centuries gradually going into the sea. The coast line is now the section of what were once undulating downs falling in

\* Tide Jane Austen's "Emma."

long slopes to the sea; at present, between Overstrand and Cromer especially, the slope is upwards towards the sea, as will be seen from the sketch, "Near Overstrand," looking along the coast towards Cromer. The wave of the land, so to speak, sweeps upwards, but has been cut off just at the crest; one can almost see in imagination the continuing lines of the contours

at Sidestrand, about a mile from Overstrand. On first seeing this ruined tower, shown in the sketch, in the middle of a deserted graveyard we supposed it to have been long ago dismantled, but the dates on the gravestones read as late as to 1854. On inquiry, we learned that the people were so much afraid of a landslide and of the church, about forty yards from the

as they once were. So great has been the advance of the sea, or rather the wearing down of the land by its action, that the site of the township of Shipden, under which Cromer was formerly included, has gone under the sea since the making of Domesday Book. Remains of the church of Shipden were formerly to be seen above water, off Cromer at low tide; and

edge of the cliff, coming down suddenly some day, that they declined coming to church, and the church was accordingly pulled down and the materials used towards the erection of a new one at a safe distance inland, the tower being left as a landmark for the fishermen. So there it stands amid the forgotten gravestones, the centre of a curiously melancholy scene. The round tower is of a type that is found here and there about the country, but only in very small churches (this tower is, perhaps, 35 ft. high); the form was evidently adopted, in these cases, for economy, to avoid the quoins at the angles necessary in building with flint pebbles, the staple walling material of the district.

It is a beautiful walk from Overstrand to Cromer over the high undulating downs, their margins relieved, on a fine day, against a deep-blue expanse of sea. Among the natural incidents of the neighbourhood is the abundance of poppies, which grow everywhere in profusion. One part of the downs close to Overstrand was glorious with wild vegetation of all colours, but the scarlet masses of poppies predominating; and it was curious to notice that on grey days, when there was no direct sunlight, their strong colour seemed more vivid than usual, their strong colour requiring no help from sunlight, while the other vegetation retired into neutral tints. On the margin of the cliffs, when the wind blew off the land, the swallows indulged in a little pastime, which we found quite as interesting as they did. They flew about in numbers under the lee of the cliffs to get shelter from the wind, but every now and then one would mount up above the cliff edges make a pretence for a moment of heating against the wind, and then stiffen its wings and enjoy the luxury of being fairly blown away with a sweep to leeward. It was evidently a recognised and popular sport in the swallow world, and a very pretty little spectacle it made.

Cromer as it was,—old Cromer,—is getting pretty well extinguished amid the new streets and houses growing up around the old town. The old portion is curious and characteristic; narrow-winding streets without footwalks, which a modern omnibus fills up as the giant and his horse fill up the street of the old French town in Dore's illustrations to Rabelais. The new houses are mostly in the accepted manner of the district for domestic architecture; flint walling with brick or stone dressings, and are in general in good taste. The only noticeable building is the church: a large Late Gothic church, very solidly built (apparently) of flint with stone dressings, howbeit the chancel seems to have fallen into ruins at some period, leaving only

were known as the Church Rocks. A Cromer fisherman informed us that last year they, for the first time, remained invisible at all states of the tide: so the church under the sea must be suffering further disestablishment. An example of the practical influence in the neighbourhood of this fragility of the coast line is shown in the old churchyard

the flint rubble core of one pier standing. The lancel is just now being rebuilt, the core of the old pier being incorporated in the new work, a proceeding of rather doubtful utility. No workman we spoke to on the building could tell us who was the architect directing the work, so sublime is the indifference of the building artisan on that point. The tower is a fine solid piece of work, on a considerable

at and about Runtun, two or three miles from Cromer. The traffic must be limited at present, since in offering a shilling at the Runtun hooking-office for a 6d. ticket back to Cromer, we were unable to get change without a special appeal to the station-master. Cromer, however, if things go on as they are, must soon overflow into neighbouring localities, and we fear our unsophisticated Overstrand will

silver such as the two spoons (history unknown) figuring here, and which seemed curious and pretty enough for illustration.

Architecturally speaking, we are in the region of flint building; but there are no ways than one of building flint walls. The employment of the wrong way, in a good many instances, has led to unhappy results, which have left their record behind. The wrong way is to build walls of rounded flints stuck into mortar of doubtful consistency, after the fashion of raisins in a plum-pudding, and with no through bond of any kind. The results are dramatically indicated in the remains of what was probably once the very fine, certainly very large and massive, tower of North Walsham, a few miles inland. This came down by the run fifty or sixty years ago, the west wall and half the north and south walls going, and leaving the remainder a gap-toothed ruin. The section of the walls thus exposed to view shows plainly enough why they fell; much more plainly, indeed, than it explains how they managed to stand for the best part of four centuries. The wall was a mere pebble-and-mortar pudding. But evidences of the same state of things appeared nearer to our doors. For, at Overstrand, there is but the ruin of the old church, and the new one, not many years old, is built close to it. Under the ivy of the old ruins are to be seen evidences that it was, on a small scale, a rather fine specimen of flint walling with inlaid decorative arcades and other like adornments. The church has two periods of history. First the eastern half of it got into such a crazy state, that, two hundred years or so after its foundation, this portion of the church was abandoned, and in the "churchwarden era" a cross wall was built cutting off and enclosing the western half of the church; the north and south entrance doors (for there were both) were built up as far as the springing of the arches, leaving the rest of the openings as triangular windows, and this portion of the edifice was accepted as the church. In recent times this portion also has become dilapidated, and the tower (still standing, and containing some good bits of detail) is said to be unsafe, and the new church, a prim little modern Gothic edifice, was built in the same precinct. This is not a very out-of-the-way history in itself; but it does rather strike one when one finds history repeating itself in other parishes on just the same lines. For instance, at Mundesley, five or six miles off down the coast, the church is now in the "second stage," as illustrated by the ruins of Overstrand; that is, the eastern portion is ruinous and unroofed, and the western portion kept in repair and used for service. At Antingham, again, a few miles inland, we noticed the same phenomenon of a ruined church standing close to a later one in use; the later building in this case seemed to be Late Gothic, and not a modern one; but we sighted it, to say truth, on the return portion of a twenty-mile walk, and in pouring rain, and considerations of time and the elements interfered with closer survey. But one carries away a general impression that the Norfolk coast is a region where a good many things are going to pieces, including the coast itself.

Among things, however, that show no sign of going to pieces, is the largest church-tower in the neighbourhood of which we are speaking, the grand and massive tower of South Repps, of which we have given a tolerably careful sketch. The rest of the church, externally, is uninteresting, and promised so little that we did not waste time by going inside; the tower is the great attraction. There are, as we observed, two ways of building with flints, and South Repps is emphatically an example of the *other* way. The flints are mostly squared and coursed (the labour of doing this must have been very great), the external and re-entering angles solidly built up in stone,—in the re-entering angles of the buttresses all the stones are worked in one solid piece for the two faces, leaving no joint at the angle; and such buttresses! such solid rock-like masses of walling, as it really does one good to see. The decorative details of the tower, as will be seen, are few and simple, but they are in the most refined taste,—not a touch of gimcrack anywhere, and worked out throughout in the most conscientious manner. The square traceried light in the middle stage of the tower is a very general feature in the towers of this district; it occurs in the same way at Cromer and Worstead, and other large towers; and even in so small a church as the

scale, and of the usual type of the larger towers of the district. We may give an illustration of it on another occasion. Internally, the nave is spacious and lofty, but somewhat bare and cold-looking; there are one or two small but interesting bits of brass in the floor. Westwards of the old town is quite a new district, and a new local line of railway has just been opened in that direction, one idea a connexion with which is that a new seaside "neighbourhood" may be achieved

not long retain its simplicity. One or two small rows of villas and shops (the latter as yet untenanted) look ominous of change already; the supremacy of the one shop in the place kept by "—, ropemaker and grocer" (that was the combination), will be contested; and the new villas will cut out the lodgings where, as at other great houses, such as Blenheim and Hampton Court, all the rooms opened one out of another, and where, among other waifs and strays of the past, we came on odd bits of

interesting little one at Erpingham, with its little sanctus bell-cot, the square light in the tower is not forgotten, though there it is reduced to a mere little port-hole with a single quatrefoil in it. The large west window at South Repps is of a remarkable and, as far as we are aware, unique design, in some of its points. Unfortunately, it is in reality in a very unhappy state, being almost entirely built up between the tracery (this was in that blessed

how the grand old tower seems rather to scorn it.

North Repps Church is a much smaller structure, remarkable mainly for the excellent workmanship of its walls. Trunch Church, the roof of which we have all admired in "Brandon's Open Timber Roofs" and similar illustrative books, is within a walk of Overstrand, and the roof, with its pierced-work spandrels, seems in wonderfully good preservation. The other lion

good one, but rather spoiled by its disproportionately high crocketed pinnacles.

It was impossible to be in the neighbourhood without a look once more at Norwich, dropping down by train over the level country, about which glide slowly the large sails of boats, floating on water mostly invisible from the railway, in a curious ghostly fashion. Norwich is not one of the largest or one of the most beautiful of our cathedrals, but it is certainly one of the most interesting, and reminds one again how remarkably various our cathedrals really are, in spite of similarity of general scheme and of certain classes of details. If the builders of modern Gothic churches had tried a little more of that kind of variety (even while keeping to pure orthodoxy of detail), they would have made a better thing of it. Looking at the apsidal end, with its flying buttresses, from the roof of the north transept, it occurred to us that possibly no one had sketched it from this point before. So, there it is,\* for what it is worth. We saw something else too, which we could not sketch, but the mention of which is not to be pretermitted. While "prospecting," as the Americans say, on the roof, a thunderstorm of the first order got up, passing away to the northward a little clear of the cathedral. Overhead came an enormous pile of thundercloud, as black as ink, except for those curls of white vapour which often accompany a cloud of this kind, and, as one may say, intensify its expression; against the cloud the cathedral spire, which seemed to go right up into it, actually glittered; below was the mass of trees in the Close all waving in the storm; to the north were constant flashes of lightning (we saw four separate silver streaks shake perpendicularly downward in the space of a second or two), and to the east a patch of clear bright sky, just by way of adding intensity by contrast. It was a Turner picture of the grandest type, with sound and movement added. It is not every day one sees a thunderstorm from the top of a cathedral; but it is well worth seeing when you do.

"churchwarden era," no doubt!) and cemented over, nearly half the tracery being broken out; but as the complete design of one side of the window remains projecting beyond the cemented face, we have ventured to restore it in the sketch. (The "Anti-scrape Society" no doubt would like to keep it as it is, as "an interesting memorial of the taste and feeling of our forefathers.") In all probability the angle terminations of the tower either once had, or were

of the church is the elaborate and rich late font-cover, of which the upper portion is much departed, but it must have been a fine and rich piece of work of its date. The church itself is disappointingly small in comparison with its repute, and not of much interest in its masonic details; there is a remarkably well-moulded doorway in the south wall of the chancel, which is in "the hooks." Knapton, a mile or two further on, with its famous roof, is also remarkably unattractive externally and as a building.

Among the larger churches of the immediate neighbourhood we are speaking of, Worstend and North Walsham are prominent. The latter, to the catastrophe of whose tower we have already referred, is poor externally, though big; but internally it is a very fine church, large and spacious, and with a fine though late arcade. Among special objects of interest in the church are some painted panels once forming portions of a rood-loft, or of the roof-loft, and some remarkably fine pieces of carving, also probably parts of an old rood-loft, which are at present hidden out of sight at the back of some seats at the west end. The chancel contains an exceedingly fine Renaissance tomb to one of the Pastons (of the family of the "Paston Letters"), of which we will give a drawing shortly, and a capital Renaissance chair is preserved in the vestry, of which a sketch is subjoined. A couple of large and exceedingly vigorous grotesque spout-heads, which once formed part of the ornaments of the tower, are also preserved in the church.

Worstend Church is of the same large and spacious type in the interior, and with a fine and well-preserved hammerbeam roof, which, however, has been bedevilled over lately with a coat of paint of an odious livid flesh-colour, apparently with the object of making the church lighter. Whoever did it may congratulate themselves on having gone far to destroy the dignity and impressiveness of the interior. There is a rood-loft *in situ*, but very much restored and patched up, containing panels painted with figures after the same manner as those to be seen at North Walsham. There is a considerable amount of inlay decoration in stone and flint on the exterior of this church; arched and quatrefoils, &c., from some of which latter, by the way, the flints have fallen out, having been too superficially inserted. In general, however, the exterior masonry is firm and solid, and the tower is a

intended to have, crocketed pinnacles, like those of its neighbours at Cromer and Worstend; but we cannot help feeling that it is better without them; they would have spoiled the massive character of the whole. As a matter of proportion, the tower is perhaps a little too high for its width, or too narrow for its height; but it is a monument of fine and conscientious mason's work. At the turn of the road opposite the churchyard is what modern taste would call a charming example of a Queen Anne red brick dwelling-house; but it looks a little prim in that neighbourhood, and some-

#### SANITARY EXHIBITION AT BOLTON.

THE Health Exhibition which was opened on Tuesday afternoon in the fine Drill Hall in Silverwell-street, Bolton, in connexion with the Tenth Autumn Congress of the Sanitary Institute of Great Britain, is, if not quite so large as some of its forerunners, a fairly good and typical Exhibition, and the citizens of Bolton and the neighbouring towns may find in it specimens of most of the best sanitary appliances and materials now before the public, as well as exemplifications of the best methods of fitting and construction. Like preceding Exhibitions under the auspices of the Sanitary Institute, and unlike others too numerous to mention, the Exhibition was ready by the time appointed for the opening ceremony, a result partly due to the requirements of the judges, and partly to the labours of the Curator, Mr. E. L. Box.

The Exhibition is divided into five classes, viz., Class I., Building Materials, Machinery, and Construction; Class II., Water Supply and Sewerage; Class III., Heating, Lighting and Ventilation; Class IV., Personal Hygiene, Foods, and Disinfectants; and Class V., Miscellaneous. Each of these classes is subdivided into a number of sections, but inasmuch as a great many of the exhibitors have goods on exhibition coming under several sections, we will, to save needless repetition of exhibitors' names, proceed to notice the exhibits stall-by-stall so far as may be necessary.

At Stall No. 1 Messrs. Manlove, Alliott, Fryer, & Co., of Nottingham, exhibit a model of Fryer's furnace, known as the "Destructor," for burning town refuse. This model and other models and drawings of kindred apparatus in the Exhibition, to be hereafter referred to, will be looked at and compared with interest now that the question of the disposal of towns' refuse is becoming, in more than one sense, a "burning" one in many localities. The subject was recently treated of by Mr. Charles Jones, the Surveyor to the Local Board of Ealing, in a paper read before the Association of Municipal and Sanitary Engineers and Surveyors, a summary of which appeared in the *Builder* a fortnight ago, and of the discussion on which we give a report this week. The same exhibitors

\* See Engraving in this week's issue.

show, amongst other things, one of Washington Lyon's admirable steam disinfectors.

Stall No. 2 is that of the Lumley Brick Company, Fence Houses, Durham, who exhibit some very good white and coloured enamelled bricks, together with fireclay goods. At Stall No. 3, Mr. R. de Solderhoff, of Cardiff, exhibits a drawing showing the construction of his patented "Incinerating Sludge Furnaces," to be used in conjunction with the operation of cooking, i.e., coke-making. The patentee locates his incinerating furnaces between coke ovens. In a small pamphlet which has been printed by the exhibitor, he gives the following results as having been obtained during fifteen weeks' work with two furnaces, each 14 ft. long, at Leyton:—Weekly average weight of wet sludge put into the two furnaces, 25 tons 6 cwt.; weekly average weight of ash taken out of the furnaces, 4 tons 17 cwt. 0 qr. 20 lb.; weekly average weight of coal used, 7 tons 11 cwt.; weekly average weight of coke obtained, 5 tons 1 cwt. We cannot here enter further into detail about these furnaces, but they appear to be worth attention. Whether their operation is productive of any nuisance we do not know. What do the Leyton people say?

Mr. James Gregson, of Bolton, Stall No. 4, shows a very good arrangement for fixing rain-water and other pipes to walls, so as to permit of the ready renewal of a single length. The pipe is kept well away from the wall, and the ears or lugs are provided with slots of a reversed key-hole shape, i.e., having a circular hole, with a vertical slit opening from the top part of the hole. Each length of pipe is suspended on large flange-headed galvanised iron nails, the heads of which are admitted through the circular part of the "keyhole," the pipe then dropping down to the extent of the length of the vertical slit referred to, which admits the stem of the nail, securely holding the pipe in position. The lugs or ears are attached to the socket at the top of each length of pipe, and while the socket is two or three times as deep as the sockets of the common rain-water pipes, the spigot end of the length of pipe above only drops half-way down into the socket, thus leaving more than sufficient play or power of telescoping between each length of pipe to allow not only of any length being readily lifted out and replaced, but to permit of the ready fixing of the lengths whatever may be the irregularities in the courses of brickwork. The lugs or ears can be readily applied to the ordinary rain-water pipes, thus keeping them away from the walls, though without affording the vertical play which is given by the deep sockets of Mr. Gregson's patent pipes.

At Stall No. 5 Messrs. James Richmond & Co., of Burnley, exhibit a model of the "Nelson" town-refuse destroyer. Close by is shown a model of T. & T. Vicars's improved self-acting smokeless furnaces, for the use of which there is great scope in Manchester and the surrounding districts.

Messrs. Doulton & Co., of Lambeth (Stall 27), have a very good display of sanitary appliances and materials, besides their "Peto" fireproof flooring, which was fully described and illustrated by us on the occasion of the Leicester Exhibition, two years ago.\* It is a method of flooring which is well worthy of the attention of architects, and we are able to announce that it is to be used throughout in the rebuilding of Mr. William Whiteley's recently destroyed premises in Westbourne Grove. We think it probable that if, unhappily, future fires break out in the premises now being rebuilt, they will, by the aid of this system of construction (coupled with precautionary measures as to the situation of staircases and lift-shafts), be confined to one floor,—supposing that incendiaries have not free scope to fire more than one floor at a time; for simultaneous outbreaks of fire due to accident alone are very unlikely to occur. Messrs. Doulton also exhibit their patent safety house drainage pipes, which are made in extra long lengths of 3 ft., thus diminishing the number of joints. These pipes are made of the best stoneware, with a highly-enamelled surface both inside and outside, and are connected together by their patent self-adjusting joint, which we fully described and illustrated last year in our account of the Sanitary Exhibition at York.† This joint, while being self-adjust-

ing and flexible, is perfectly watertight, and has been found very valuable and helpful in laying drain-pipes in wet ground, as at Acton and elsewhere. Messrs. Doulton exhibit the application of these pipes, thus jointed, as soil-pipes, so that stoneware may be used throughout a building for closets, traps, soil-pipes, and drains, thus avoiding difficulties and objections to the jointing of metal and stoneware. The elasticity in the joints to which we have referred allows of settlements or deflections in the lines of piping,—whether used horizontally as house-drains, or vertically as soil-pipes,—without the joints ceasing to be air-tight or watertight. Those who have not already made themselves acquainted with this system of jointing (in which no cement is used) should do so, as it promises to effect quite a revolution in drainage work. Another useful sanitary appliance shown by these exhibitors is Hellyer's patent "Anti-D" trap made in stoneware.

Exigencies of space compel us to break off here, but we will next week conclude our account of the most notable appliances and materials in the Exhibition, which will remain open until and inclusive of Saturday, October 15th.

The report of the judges of the Exhibition made the following among other awards and recommendations:—

*Medals and Special Certificates.*

- Bennis, E., Bolton.—Smoke-Preventing Stoker and Cannel Furnace.
- Lovibond, J. W., Salisbury.—Tintometer.
- Constatine Bros., Bolton.—Dr. Jaeger's Sanitary Clothing.
- Hop's Dry Closet Company.—Dry Earth Closet without Separator.
- Doulton & Co., Lambeth.—Peto Flooring.
- Manlove, Allott, Fryer, & Co., Nottingham.—Washington Leyn's Steam Disinfecter.
- Greenall & Co., Manchester.—Steam Washer.
- Doulton & Co., Lambeth.—Self-adjusting Joint for Stoneware Pipes.
- Morrell's Sanitary Company, Manchester.—Morrell's Cinder-Sifting Ash Closet.
- White, W. P., & Co., London.—Nicholl's Soot and Salt Closet.

*Certificates of Merit.*

- Haslam, J., Bolton.—Hand Fire Extincter.
- Maritime and General Improvement Company, London.—Loeb's Respirators.
- Gregson, J., Bolton.—Removable Rain-water Pipe.
- Vause, J., & Son, Bolton.—Shanks' Reliable Water-waste Preventer; Craig's White Enamelled Sinks; Rufford's Enamelled Fire-Clay Bath; Shanks' Imperial Lavatory; Shanks' Wash-Out Closet and Cistern combined, for country use; Shanks' Tubal Wash-Out Closet; Shanks' Urinal with Filling Finisher; Cast-Iron Smooth-bore Drain Pipes and Fittings.
- Cuerden, R., Bolton.—Shanks' Reliable Water-waste Preventer; Shanks' Imperial Lavatory; Morrison's Spray Lavatory; Shanks' Tubal Wash-Out Closet.
- Hemby & Co., Manchester.—Through Colour Linoleum.
- Maritime and General Improvement Company, London.—Portable Electric Glow Lamp.
- Control Air Propeller Company, Bolton.—Humidifier and Air Inlet.
- Morrell's Sanitary Company, Manchester.—Cinder-Sifting Dishes.
- Doulton & Co., Lambeth.—Stoneware Safety Pipes, in long lengths.
- Parkinson, Sweeney, & Co., Manchester.—Airtight Soil-Pipe with Slide Catch.
- Robertshaw, J., Manchester.—Laws' Pathway Rubbish-Receiver.

*Exhibits Selected for further Practical Trial.*

- With regard to the following [among other] exhibits, the Judges are unable to give their decision until they have submitted the exhibits to a more complete and extended practical examination than is possible before the opening of the Exhibition:—
- Doulton & Co., Lambeth.—Improved Siphon Flush Tank.
- Vicars, T. & T., Liverpool.—Mechanical Stoker.
- Milton Syer, London.—Siphon Waste Preventers, Nos. 1 and 2.
- De Solderhoff, R., Cardiff.—Incinerating Sludge Furnaces.
- International Water and Sewage Purification Company.—System of Water and Sewage Purification.
- Beze, G., Bolton.—Chamberland-Pasteur Filter; Slack & Brownlow's Filter.
- International Water and Sewage Purification Company.—Aromatic Disinfecting Powder and Liquid.
- Calvert, F. C., & Co., Manchester.—Soluble 70 per cent. Carbolic Acid.
- Kirkham, J. W., Bolton.—Blackman Air-Propeller.
- Control Air-Propeller Company, Bolton.—Air-Propeller.
- Wood, E., Manchester.—Air-Propeller.
- Rothwell, J., Farnworth.—Air-Propeller.
- Eolus Water-spray Company, London.—Keidel's Hydro-Ventilator.
- Maigren, P. A., London.—High-pressure Filter; Water-Suiting Process.
- Lakin, R., Manchester.—Compound Carbolic Powder and Carbolic Crescol.
- Manlove, Allott, Fryer, & Co., Nottingham.—Fryer's Destructor; Johnston's Dryer; Ferman's Dryer.
- Wood, E., Manchester.—Exhaust Outlet Ventilator.
- Rite, C., & Co., London.—Turret Ventilator, and Counter-poise Chimney-breast Ventilator.
- Cuerden, R., Bolton.—Hale's Ventilator; Banner's Rotating Ventilator; Banner's Inlet Ventilator; Chronite Disinfectant.

\* Exhibits which have already received medals at the previous Exhibitions of the Institute are excluded from awards of Medals, but those exhibits to which a second medal would otherwise be awarded receive special certificates, and these are distinguished in the list by asterisks.

- Houghton, J., Liverpool.—Ereka Chimney-sowl.
- Rothwell, J., Farnworth.—Revolving Screw Combination Ventilator.
- Eolus Water-spray Company, London.—Stafford's Ventilator; Pollock's Downcast Ship Ventilator.
- International Paint Company, London.—Sanitary Magnetic Fire-proof Paint.
- Macpherson, D., & Co., Manchester.—Foschow Enamel.
- Bolton Paint Company, Bolton.—Oxide Paints.
- Asbestos Fire-proof Paint Company, Manchester.—Asbestos Fire-proof Paint.
- White, W. P., & Co., London.—Soot and Salt Urinal.
- Doulton & Co., Lambeth.—Anti-D Stoneware Trap.
- Hargreaves & Barclay, Oldham.—Eclipse Gas Governor.
- Stott & Co., Manchester.—Combined Gas Governor and Cut-off Valve.
- Fournies, H., & Co., Manchester.—Regenerative Gas Lamp.
- Eolus Water-spray Company.—Capell's Fan.

The following exhibit, which has gained a certificate, is deferred in competition for the award of a medal:—

Galloway, J., Bolton.—Lightning Fire Extincter.

The following, which have gained medals and starred certificates at previous Exhibitions, are now so well known and their merits are so fully appreciated, that the Judges do not think it necessary to make any further award to them:—

- Moule's Earth-Closet Company.—Moule's Earth-Closet.
- Calvert & Co., Manchester.—Pure Carbolic Acid.
- Hargreaves, H., Bolton.—Porter Edinburgh Sewer Trap.
- Vause, J., & Son, Bolton.—Buchan's Disconnecting Trap and Access Pipe.

The report is signed by the judges, viz. :—Mr Rogers Field, B.A., M.Inst. C.E. (Chairman); Mr. A. Wynter Blyth, M.R.C.S.; Mr. W. Essie, C.E.; Mr. Henry Law, M.Inst. C.E.; Mr. J. Wallace Peggs, A.M.Inst. C.E.; Mr. H. Saxon Snell, F.R.I.B.A.; Mr. Ernest Turner, F.R.I.B.A.; and Dr. Louis Parkes, Secretary.

ARCHITECTURAL ASSOCIATION VISITS.

THE Architectural Association, on Saturday, the 17th inst., made a vacation visit to Minley Manor, near Farnborough, the residence of Mr. Currie. The original house was designed by Mr. Clutton, and is a florid example of Gothic treatment, with a good deal of French feeling. The present additions are from the designs of Messrs. Devey & Williams, and comprise, in addition to extensive remodelling in the interior of the house, a chapel, kitchen, offices, stables, orangery, and entrance-court. The chapel is built with square random Kentish rag, dressed to quite a smooth face, and worked with a very fine joint. The upper part of the wall has squared flint panels. The chapel is surrounded with a cloister. The dining-room is panolled with wood, treated in the Renaissance style, with a very rich wooden mantelpiece, and at the end of the dining-room is a smoking-room, with oak panelling in character with Mr. Currie's detail. The staircase, which is arranged around a thick wall, is hung with French tapestry. There is also some good French ironwork in the house.

The afternoon was devoted to a visit to Bramsbill House, Hampshire, the residence of Sir William Cope.

The present house was built by Edward, Lord Zouche, 1605 to 1612, which latter date is on some of the ornamental stack-pipe heads, with the initials E. Z. (Edward Zouche), from the designs of John Thorpe. The house is supposed to be built on some of the foundations of an older house, built by Thomas Foxley, who was a contemporary of William of Wykeham. This older house was probably built round a courtyard 100 ft. by 80 ft., and Thorpe almost filled up this inner space, there being only a narrow well some 12 ft. wide left in the centre of the house. There is a tradition that the house was intended to be purchased for the residence of Henry, Prince of Wales, the eldest son of James I., and the ornament over the oriel window in the principal front is thought to be the three feathers of his crest.

The house is built of red brick and Headington stone. Many of the mullions, however, are of brick and plastered.

The entrance-hall has a fine screen, decorated with shields, on which are painted the arms of the Cope family, and at the upper end of the hall is a dais. From this end a staircase is reached, and, passing beyond the staircase, are three rooms, used as dining-room, drawing and billiard-room. The staircase is an oak staircase that was brought from Eversley Manor by the present owner. On the first floor to the left is a splendid drawing-room with an elaborate plaster ceiling, having a double pattern with pendants. The mantelpiece is a very pure Italian Renaissance design in two stories, the lower Doric, the upper Ionic, in red and white marble, the hearth having a red and white

\* See *Builder*, Sept. 18, 1885, p. 416, and Dec. 19, same year, p. 877.  
† See *Builder*, Oct. 2 and 9, 1888, pp. 481, 539.

marble pattern similar to the mantelpiece, and the dog-irons and grate are evidently of contemporary design. The tapestry in this room is from designs by Rubens. The next room has a fine plaster ceiling of rather simpler pattern and good chimney-piece; beyond this is the long gallery, which extends the whole depth of the house. This room is panelled with dealblocken moulded panelling, and contains an interesting collection of curios of all sorts. The legend of the mistletoe bough used by Haines Bailey and Rogers, is associated with this house, but Sir William Cope stated that no bride in the family had ever died on the day of her marriage, and the only way he can account for the origin of the legend was that an ancestor who lived in Italy a long time probably bought a chest in which an Italian lady is said to have died under circumstances somewhat similar to the ballad. This chest, of which a photograph was shown, is not at present in the house. The Morgan family at Newport, Monmouth, also claim this legend, and show what purports to be the original chest. To the right of the staircase is the drawing-room over the hall, a charming room with the circular bay over the entrance, from which a fine view is obtained. The ceiling in this room is elaborately wrought. Opening out of this room through a four centred arch is the chapel, which is quite a museum, and contains a fine piece of tapestry dated as early as 1450. But the principal feature of the house is the terrace, which measures 194 ft. in length, and has at either end a double-arched summer-house. All the pictures of this restore the balustrade, but Sir William, who has had the coping carefully examined, is of the opinion that the short pieces at either end are all that ever existed. The time allowed was all too brief to do justice to the house, and the best gave a cordial invitation to pay another visit next year.

PROFESSOR T. HAYTER LEWIS ON THE  
LAYING-OUT OF TOWN AREAS.\*  
SANITARY INSTITUTE OF GREAT BRITAIN.

In availing myself of the privilege of addressing the members of this Congress in this active and stirring town, which is spreading itself out in every direction, I have thought it well to bring before them a subject of great interest, but which has not been hitherto much discussed, viz., the extension of our great cities and the erection of new ones; and to suggest such a course as would ensure that such requirements as are now considered to be necessary for their healthful occupation may be provided for at the outset.

Of the conditions to be noted in selecting a site for a new city, you have descriptions by writers of all ages, from Vitruvius in the first century, to Dr. Parkes in his well-known work of our own time. But this is a subject too large for a short address, and it is of the extensions only that I wish now to speak. They have, almost invariably, been carried out by speculators without any general definite guiding plan, with little or no forethought for future extension, and with slight provision for supplying the inevitable future wants of the inhabitants. Thus, in course of time, spaces have to be cleared out for churches, schools, institutes, baths, and such like edifices as are now required for a large population, and clearances have to be made to allow for its free breathing. The extension of the cities takes place in different directions and from different motives.

The well-to-do citizens leave their smoky town and confined houses to form new suburbs, where they may breathe freely in their open gardens.

The artisans cluster together at first for cheapness and for nearness to their work. Then comes over-crowding and then Sanitary Acts, and then suddenly the neighbouring fields are invaded, and acres of ground are covered with new small houses, put up as a speculation in the cheapest way, with just so much breathing-space as the local by-laws (if there be any) will allow.

Now if this be the time of activity in building new towns and extending old ones, it is also pre-eminently the time of activity and power in corporate bodies. From Town Councils to Vestries, from Trade Guilds to Trade Unions,

\* From the Address given by Professor T. Hayter Lewis, F.R.I.B.A., as President of Section II., Engineering and Architecture, at the Bolton Congress of the Sanitary Institute.

from companies formed for their own benefit and companies formed (all honour be to them) for the benefit of their fellow-citizens,—an active part is being taken in public work.

New and extensive powers are being acquired and exercised by Corporations for the sewage, the supply of water\* and of gas, for providing open spaces, regulating the width of streets, and even the height of rooms and size of windows. Your own by-laws are sufficient evidence of this.

Now I simply wish to extend these powers. I wish that when it may appear evident to a Corporation that any district will require before long a large accession of houses for a population which is clearly increasing to an overflow, such Corporation shall have the powers (and I think that public opinion will require it to exercise them) to acquire control over the requisite land,—to formulate a general plan, giving the width and direction of the streets,—to provide spaces for such public buildings as are certain to be required in a well-regulated community, and for such open spaces as are required for its healthy enjoyment.

My scheme is not a very grand one in any respect; I simply want to provide at first for those requirements which must eventually be provided, which can only be fulfilled at a great cost, and even then imperfectly, if not so provided at first. I do not even suggest that the Corporation should build, but that it should give general guiding directions, leaving the working-out to private persons, or to such companies as have of late done so much good in building dwellings of various classes, from the highest to the lowest.

To show that such powers as I have indicated might well be called into being on behalf of even a high-class district, I might have brought before you the earnest attempt made, some thirty-five years ago,† by the late Professor Cockerell, R.A., to obtain a public control over the proposed buildings at Hampstead, a suburb now covered with houses.

As I was reminded by my friend, Mr. Rogers Field, the Professor drew out a design by which the whole of that suburb might have been built over on one definite plan, utilising the various hills and valleys, so as to take every advantage of its picturesque beauties. Public opinion was not ripe for such a course then, and this grand opportunity was lost.

[Professor Lewis then described, with the aid of a map, a district of London, and the mistakes made in laying it out, and proceeded to point out in detail on another map the manner in which the same district might have been laid out, by forethought, so as to accommodate the same number of persons with more convenience for traffic and with greater attention to provision for healthful and enjoyable life. The details of Professor Lewis's remarks, however, can hardly be intelligibly followed apart from the diagrams, and we proceed to the more general remarks arising out of the subject.]

I now ask you to hear with me whilst I enter, in some detail, as to the public works and buildings for which provision should be made. I assume that, as a matter of course, the sewers, water, and gas supplied, will be provided in the usual way, so I need not detain you as to these.

In the first place, I would set aside a strip of land outside the whole district for the park, which I take for granted would ultimately be required, no matter what the rank of the adjoining houses may be. Its distance from the furthest point would be about that suggested by Mr. Besant, viz., half to three-quarters of a mile. The size which I suggest here is about the same as that of the Hesketh Park at Southport, which is in one of the best parts of the town, and much smaller than the one here. The position of this open space would provide well, also, for the future extension of the town, and would afford the advantages obtained in the same way as, e.g., at Hastings, where the pretty St. Andrew's Gardens, starting from the old town, pass round at the back of the houses, and are continued to St. Leonards, making an admirable belt of free open air and foliage. Neither in this case, nor in that of public buildings, do I propose the work to be undertaken at the first, but only so to arrange, at the first, that the sites shall be so reserved as to be available when required. As to these, I need do no more than mention offices for the

local authorities, and the library, reading-room, science and art schools, and other buildings required for the particular locality.

In the arrangement of those public buildings it would be difficult to take a better example than that of Southport, whose Lord-street and Albert-road form one of the prettiest vistas that I know (I trust that Birkdale will pardon me for classing it with its neighbour)—and I use the word "prettiest" advisedly, as I could not, of course, compare it with such grand thoroughfares, each unrivalled in its way, as the High-street of Oxford, or Princes-street at Edinburgh.

At Southport the chief public buildings are located behind a group of trees, and I know of few more pleasing views than that of the spires and turrets of Christ Church, the Presbyterian Church, and the municipal and other buildings, towering above the foliage, whilst between the trees the buildings themselves are picturesquely seen.

Outside the park I should place the infirmary and convalescent home, a position in which they would have free light and air. If any one suggests that such a position would be too public, and lessen the enjoyment of the park, I would refer him to your own infirmary and children's hospital (the latter the gift, I believe, of your townsman, Dr. Chadwick, and his family), and ask him whether, as a simple matter of landscape effect, to say nothing of the value of such an outlook to the patients, he would wish this picturesque building, designed by one of your able townsmen, Mr. Kull Freeman, to be removed. Or, again, think of the charming way, and without the slightest feeling of sadness, in which the promenade at Southport ends with such a building, whilst at two such different places as Manchester and Hastings the Infirmary forms one of their most prominent buildings. Next to your noble Town-hall and the old churches, the most prominent building is, I think, the market. I do not, of course, propose any such grand building as yours for my district. It might be open at the sides, but covered, as at Preston and Blackpool, or be enclosed as here and at Southport, or St. John's at Blackpool. I know that many towns of importance (I may, I think, name Norwich and Cambridge amongst them) have still little more than open and uncovered market-places, healthy-looking and pretty, with fruit, and flowers, and vegetables, on a fine day; but we often have quite other days in our country, and the attempts at covering up and protecting the stalls then turns the market-place into a wretched collection of tumble-down huts,—I had almost said as bad as Fleetwood. If the quarter be chiefly for artisans, public wash-houses will be indispensable, and, in any case, no matter what the class of inhabitants may be, I look upon public baths also as a provision which can scarcely be valued too highly. For these baths and wash-houses I have suggested no definite site, as this would depend so very much on the kind of inhabitants.

Nor have I marked out definitely sites for churches, chapels, or schools. All these are provided for in the district as it exists, and sites would undoubtedly be claimed for and provided, whatever the general plan might be.

I come now to some other details, as to which I may not possibly have your assent. First, as to drinking-fountains. That such small ones as are now commonly seen should be provided, you will doubtless quite approve. There are many excellent examples in most of the towns in these parts, each combining a drinking-fountain with a public lamp, and being really an ornament to the streets. But I want something more than these, as much for the sake of health as for ornaments to the town.

You know well enough that all the water in use for your houses is stored in cisterns; and although in past times these cisterns were looked upon as being worthy to be seen, and so were ornamented in a way which is now the envy and admiration of workmen and artists alike, they are now rough ugly things, stored away out of sight in any convenient closet or loft which will hold them, and for all their owners know of them they may be considered as the property of the spiders. You depend upon your plumber to clean them out once a year. Perhaps he does; perhaps he doesn't. You are none the wiser. But imagine what often happens in the houses of a poorer class. I need not go into details, but I say that a good supply of water, pure for drinking, is an element of health which ought to be provided

\* Bolton Corporation Waterworks, 1881, and Bolton Corporation Acts, 1872, 1877, and 1882, pp. 8, 24.  
† *The Builder*, vol. xi. (1853), p. 417.

and that you cannot provide it in a better way than by fountains. These, in what are now called "the Dark Ages," formed some of the chief ornaments of a town, and I see no reason why they should not do so now.

I don't want to bring in such vast bodies of water as were brought through miles of aqueducts into Rome, or such lavish displays as you have seen, e.g., in Paris, or even such things as our fountains in Trafalgar-square. Nearly all these send their waters into the drains.

There are fountains even now in most of our towns,—a very elegant one at Southport, for example; but, again, with all the water running to waste; whereas in some of the most picturesque Medieval examples, it came out in small useful jets, as I would have them here; and I feel no doubt that, by a skillful arrangement of gas jets, the effects of frost might be prevented, and a great boon thus conferred in winter, on rich and poor alike; whilst, by a skilful design, they could be some of the most pleasing ornaments to the town that could be conceived. And, as part of the water must go to waste, send it to feed a small stream in the park, like the one here or at Hastings.

Another accessory I must mention is that of seats placed at intervals between the trees. I shall, no doubt, have the same objection made to them as to the trees, and my answer would be the same.

Then, to complete my plan, I would have a small open space opposite to each railway station. Now we have to see, before entering into the question of the kind of houses to be provided, how much the plans which I have suggested have trespassed upon the space now occupied.

I have laid out my main roads in very much the same general direction as the present ones, though in less circuitous lines; but I have made them 60 ft. wide instead of 40 ft., and have set apart spaces for public buildings, &c. The smaller streets I have made 40 ft. wide, the width required by the Model By-laws being 36 ft. The space which I have assigned to the park need not be taken into my calculation, as it is altogether outside that now built on; and I think you will readily see that the great waste of space necessitated by the irregular plan of this district, as now actually existing, would allow to a very great extent, if not altogether, for the extra space which the suggested re-arrangement would require.

As to the general arrangements of the streets and houses, I will call your attention to some methods, unusual to us, with which one meets abroad. I omit any notice of you on the Continent, and I shall take, as examples, one of the northern towns in Europe, Hamburg, and one of the southern ones, Naples. Several years since, I was commissioned to make a detailed report on the former town, for one of the principal Insurance Offices (the Union) of London, and I was thus led to see more of it than, perhaps, most of the people who visit it. The arrangement is peculiar. The main streets are wide, and give to a casual passer-by scarcely any indication of their affording access to any other streets. But a nearer inspection shows numerous doorways, so low and narrow that they appear to lead only into cellars, and through which you have often to descend by steps, and these lead into the streets behind, locally named Hofes, which we should call alleys, and which are, of course, completely closed against ventilation from the main street. They vary from 20 ft. to as little as 5 ft. in width, the houses in the wider streets overhanging on each side and being densely populated. They usually abut on canals, and when these are dry the result in hot weather may be imagined. This arrangement, intended, no doubt, to bring different classes of people together, reminds one of the Wynds of Edinburgh, but with all their evils intensified, and a worse result could scarcely be imagined. Very many of these have been demolished, but a large number still remain.

I take you down now to the sunny south at Naples, where the same attempt has been made. It is not in my province now to describe the ordinary houses there, of the horrors of which Sig. Gallenga and Mrs. Oliphant have given most vivid descriptions, but only the particular class to which I have alluded, and which may be seen to perfection in the drive through Forici. The streets throughout are wide, and lined for the greater part of their length with

frames of macaroni bung out to dry, and many more will no doubt well remember both the sight and the smell. The houses on each side are several stories high, the first floors (*piani nobili*) having wide balconies, and altogether having a cheerful look and being tenanted by well-to-do and often wealthy people, whose apartments are entered from an internal court approached from the street by a lofty carriage gateway, through which one has lovely glimpses of beautiful gardens sloping down to the Bay of Naples. But the lower stories throughout, close on the ground, are tenanted by humbler classes, their rooms entered from the street. Here, again, we meet with an attempt to combine the classes, and thus to prevent one neighbourhood being given up to the poor and another to the rich.

But again this fails. The lower rooms have no windows or other openings at the back, and derive the whole of their light and air from the street. The state of the inner rooms, usually parted off by a curtain as sleeping apartments, in the heat of an Italian summer may be imagined; and these rooms are not inadequately described by Mrs. Oliphant as "dark caverns with one vast door, giving all the light that can penetrate." Were it not that the people live almost entirely in the open air, they must be decimated. The same arrangement will be found in most other Italian towns, but in them there is, usually, some opening, however small, at the back.

Something of the same kind would appear to be adopted, judging from the plan only, in a flourishing town in our own country,—viz., Great Yarmouth, the arrangement of which is very peculiar, and unlike that of any other English town with which I am acquainted. I show a drawing of this, enlarged from one which was kindly drawn for me by Mr. Arthur Hewitt, an architect in the town, who has supplemented the Ordnance Map by many important details. The main streets are wide and well ventilated, and lined with good houses (mostly shops) several stories high; and running between these streets at intervals of about 45 ft. are long narrow alleys, termed Rows, out of which lead houses of an inferior class. Looking at the plan only, this would seem to be no better than Hamburg; but in reality they are vastly better. The entrances are open for their whole height to a wide street at each end, or to the spacious quay; the alleys are cleanly kept and well paved, the houses in them are low, so as to intercept the light and air very slightly, and each has a small court attached to it; and the whole arrangement, so far as I can ascertain, is not prejudicial to health. Nevertheless, the narrowness of the streets does, no doubt, to some extent, clash with the golden rule which Dr. Richardson put very strongly in his well-known lecture at Crofton (1879): "Make the sun your fellow-workman," which is much the same as the Italian proverb, "Where the sun does not enter the doctor does."

Now, in remodelling our district, what system shall we adopt as to the houses? The first question is as to their number of stories. This subject is a serious one, for hundreds of acres near our towns are now being covered with two-storied dwellings, clustered close together in populous neighbourhoods, or semi-detached when more in the suburbs. As to this, I do not wish to lengthen my paper by going into any argument, but I must briefly allude to some of the leading facts. The governing idea in respect of the self-contained houses of two stories is, of course, that of privacy, or, in the better class of houses, the absence of stairs; but in many of our new London squares one large open space, garden, or yard (according to the class of house), is common to all; and the separate houses are being largely superseded by the dwellings in flats. At the first sight the two-storied houses would appear to have the recommendation of ensuring a less dense population than in the many-storied ones; but I wish to consider the subject on the basis of the same number of inhabitants in each case, the area gained by the extra stories being appropriated to open spaces in the way of yards or gardens, so that no question as to the bearing of the density of the population upon their health will arise here.

In considering the relative merits of the different styles of houses, the first fact which presents itself is, that with those of two stories only, the whole of their inhabitants must live and sleep either immediately over the ground or directly under the roofs.

I need scarcely say that the nearer to the earth the ground-floor is the cheaper it is to build, as less height of wall is required; and the consequence is that the floor is raised a few inches only above the street level, and the occupant has only that space between him and the earth. The rest of the inhabitants must live and sleep directly under the roof,—not a very pleasant experience even in well-built houses, whether through the heat of summer or cold of winter; and very many here, doubtless, know what is the case where the house is run up cheaply merely to sell. In point of economy of building, and of course of rent, it must be borne in mind that, though the thickness of the lower walls must be somewhat greater in a high house than a low one, one roof will cover, and one foundation hold up, four or more stories, as well as they will cover and hold up two.

As to the general feelings with respect to the subject, I recall and agree with the words of my predecessor, Professor Roger Smith, in his address at Glasgow in 1883,\* that the system of flats is opposed to the general feeling; and I agree with him, also, when he says that they are not so unpopular now, and have many advantages.

Of course, the height of houses, whether in flats or separate, varies very much, buildings of five, six, or seven stories being common enough,—my own house has six; but I propose, in the comparative plans which I show, to limit our consideration to four stories, which is the limit suggested by Professor Robinson, in his address at Newcastle, 1882.† My plan shows, first, the actual spaces at present occupied by two blocks, each of fifty-eight two-storied houses, and their open areas of streets and yards; and, secondly, the space which would be occupied and the area gained, if the same number of inhabitants lodged in half the number of houses, but four stories in height. The contrast as to open spaces is rather striking, and with increased height the size of that space will of course increase.

One thing more. In his well-known address in 1879, Dr. Richardson spoke of his ideal cities as competing with each other in the beautiful as well as the useful, and I have spoken all the way through of doing what we have to do in the streets, the buildings, the fountains, in such a manner as to give a cheerful aspect to the scene, and afford some scope, however slight, to the feeling of beauty which is inherent in mankind, whether for colour or form, for a flower or a building, and not to offend the eye by the mean and the ugly.

Years back, in the prime of his life, Mr. Ruskin pointed out, most forcibly "that it is chiefly by private and not by public effort that a city is adorned, and that it did not matter how many beautiful public buildings it may possess if they are not supported by and in harmony with the private houses (and, I may add, of the factories) of the town," and if it be held that all we have to do is to provide houses which shall be fairly comfortable, whether for rich or poor, and that rows of such houses will answer all the purpose if built with windows large enough and numerous enough, and that nothing else in them need be studied, then I say that our town lacks one great feature which might conduce to the pleasure of its inhabitants, and in neglecting that we have neglected one means, however slight, towards that healthful mental state which helps the bodily so well.

#### Masonry and Construction.

Mr. Lawrence Harvey's valuable class instructions on the subject of Geometry as applied to Masonry and Construction will be resumed at the City and Guilds Institute, on Monday evening, from October 17th. The instruction is divided into three courses. The first course comprises the lessons given last year, by which a general idea of the different methods of stone-cutting will be obtained. In the two following courses, the applications of geometry and drawing will be more kept in view, and the exercises of cutting made subordinate to that. The present course deals with only half the subjects which a complete course of scientific masonry should treat, and it is hoped that a higher series of lessons will be initiated next year.

## THE BRADFORD WATER SUPPLY.

The following is the preliminary report of the Bradford Waterworks Committee, submitted to the Town Council last week, as to the scheme for additional water supply. After stating the circumstances under which, after the drought of 1884, the Committee, considering it necessary to provide an extended area of water-supply, instructed their engineer (Mr. Binnie) to go thoroughly into the whole subject, the report says the first investigation, directed to the utilisation of our existing Parliamentary powers, proved that the works authorised by them would be as expensive as the works already executed, and that as they had been designed merely as additions, none of them would prove more than temporary expedients to overcome present difficulties, and that the advantages gained by their construction would be exhausted nearly as soon as the works could be completed. Pending the investigations which Mr. Binnie was making, a pamphlet was published by Mr. Paterson and sent to each member of the Council respecting a scheme in the Masham district. Mr. Joseph Smith and Mr. Rooke also kindly suggested a scheme on the Cragg Brook, a tributary of the Calder; and various other gentlemen contributed other suggestions of more or less value through the newspapers or otherwise. The whole of them received the most careful consideration. Without entering into unnecessary details, it may be stated, as the result of Mr. Binnie's investigations, that the Cragg Brook scheme presented very serious difficulties; and that the only practicable schemes which would meet the requirements of the Corporation were a supply from the Wharfe at Buckden, and a supply from the Masham district, so laid out as to deliver the water by gravitation and without pumping into the Heaton Reservoir, and so designed as to give a service reservoir at some point near the town. The Committee deemed the matter of such importance as to require personal investigation, and therefore the Buckden district was inspected by the whole Committee, and the Masham district was inspected by the Works Sub-Committee. It being the opinion of the Committee that the choice of site for the new works must rest between the Buckden and Masham schemes, they considered it proper that, on a subject of such importance to the town, and likely to involve heavy expenditure, it would be wise to obtain the opinion of Mr. Hawksley as to which of the two schemes was preferable. It was known that Mr. Hawksley had on former occasions to make himself familiar with the peculiarities and distinguishing features of each of these districts in reference to other schemes for the supply of other towns, extending back as far as 1854. His authority on the subject was invaluable; and, accordingly, in the early part of last year, the whole subject was laid before him, including the scheme suggested by Messrs. Smith & Rooke, and Mr. Paterson's pamphlet. The instructions to Mr. Hawksley were to give the Committee his unbiased opinion after duly considering all the materials laid before him and making such inspections of the districts as he thought necessary; and, accordingly, having considered all the information laid before him, and having visited the sites, he attended the Committee on Tuesday, the 30th of August last, to state his views. He advised that the Cragg Brook scheme was impracticable, on account of the small supply that would be derived therefrom, and of the enormous opposition that would be met with; and as regards the Buckden and Masham schemes, that although a copious supply could be obtained from Buckden at a little less cost than from Masham, it was harder water than that from the latter district, and that the Masham water was much better adapted for the supply of the manufacturing industries of Bradford. He did not apprehend any formidable opposition to either scheme, and found that the Masham scheme would enable the Corporation to adhere to their system of giving compensation by separate gathering-ground and separate reservoir, whilst at Buckden the Corporation would have to undertake the supply of a guaranteed quantity daily to the mill-owners. In these views Mr. Binnie fully concurred. After enumerating the several grounds of agreement in opinion on the part of Mr. Hawksley and Mr. Binnie, the report adds that whilst Mr. Hawksley was before the Committee, a number of questions were put to him, and

amongst them whether he had considered Mr. Paterson's pamphlet, and in reply he stated that he had done so, but considered the scheme suggested by Mr. Binnie to the Committee as the better. At the same time he added that it was not his business to come into conflict with any of the gentlemen who had kindly volunteered projected schemes, but it was simply his duty to tell them which, in his opinion, was the best course for the Corporation to adopt. As the Council will naturally wish to have some information supplied as to the cost of the alternative schemes of Buckden and Masham, the Committee have to state that the estimated expense of the Buckden scheme would be 1,133,250*l.*; and for the first instalment 831,250*l.*; in the case of the Masham scheme, the cost would probably be 1,292,000*l.*, the first instalment required would be 966,000*l.* In conclusion, the report states that the Committee have felt very great anxiety on this business. They are unanimously of opinion that the supply of water ought to be such as will meet the growing requirements of the town, not only as regards purity, but also as regards softness, and they are equally unanimous in their desire to avoid embarking unnecessarily in any costly enterprise, but they are convinced that an increased water-supply must be obtained so as to meet the growth of the population and trade of the district, which, before the construction of any large works, certainly requiring from eight to ten years for completion, will, in the ordinary course of things, outrun any present available supply.

## MR. J. HAMBLET'S BRICKWORKS.

On the occasion of the recent West Bromwich meeting of the Association of Municipal Engineers, a visit was paid to Mr. Joseph Hamblet's Piercy brickworks, at the Albion. The visitors were met by Mr. Hamblet and his nephew, who conducted them over the works, explaining without the slightest reserve the various processes in making bricks, tiles, and fancy articles. First came the blasting process in the marl-hole, where great quantities of marl and rock were blasted by dynamite and conveyed by tramway to iron wagons and thence to the grinding-mills. One of the most remarkable features of the marl is the fact that (according to the report in the *West Bromwich Weekly News*) it is suitable for either red goods or blue, and every article manufactured is from exactly the same clay, the only difference being in the length of time in burning, the hardest and most durable being caused by increasing and longer continued heat, the blue bricks being exactly the same as the red, only burned longer. The rock and marl, some of the pieces being of great size, is tipped into and passed through two pairs of rolls into the first mixing-pan and watered. Then it goes through another pair of rolls, after which it is conveyed by endless bands into a fourth pair, and passed into or brinded bricks. For the best blue facing and paving bricks, the marl and rock in a plastic condition is passed through a fifth pair of large rolls, through another mixing-pan, and conveyed by an endless elevator band to the machine, and made into the best blue bricks for paving, &c. Upwards of 200-horse power is employed in the various processes of manufacturing. The bricks are taken from the machine in harrows by women and youths, and put on flues heated by fire, where they remain until sufficiently dry for pressing or otherwise. Mr. Hamblet's patent steam presses are excellent, being worked by friction discs, which are computed to give a pressing strain of 120 tons on each brick or paviour when in a semi-dry state, and any pattern can be pressed on the face of them. It is claimed that the bricks finished by this process withstand the highest crushing strain for bricks yet known, viz. 1,064 tons per square foot, as tested by Kirkaldy. Copings for walls are here made by means of wood moulds, some of the stock kinds being made by steam press. The kilns, — known as Scotch kilns, — are lined all over the insides with firebricks, but are soon destroyed by the heat required for the burning of flue bricks. About a fortnight is required to fill, burn, and empty, the bricks being subjected to the fire for about eight days and nights. They are afterwards loaded into boats and conveyed by rail to various parts of the country. One of the most interesting processes is the manu-

facture of encaustic tiles and terra cotta of every description. The fancy tiles have the patterns pressed on to them by a very simple but interesting process, some of them having to undergo as many as six different pressings. The ridge and chimney-pot machine is a very interesting one, and the articles are stated to be superior to the ordinary hand-made goods. Mr. Joseph Hamblet has recently added several branches of trade to his extensive works. Foremost of them is the architectural terra-cotta department; here there are being produced at the present time great blocks of richly foliated and delicately modelled red terra cotta of the finest surface, and as true as blocks of stone. Great technical skill is required in the manipulation of these blocks, and locally it is anticipated that South Staffordshire will soon be in the van of the clay trade in artistic productions as well as in the enduring material with which Mr. Hamblet's name has been associated.

## Illustrations.

## WINDOW, CHESTER CATHEDRAL.

THE large south transept window of Chester Cathedral, of which the stonework was re-designed by Mr. A. W. Blomfield, has been filled with stained glass, the gift of Lord Egerton of Tatton. The subjects represented are the Crucifixion, Nativity, and Ascension, occupying the three centre lights, and sixteen subjects illustrating "Faith," taken from the eleventh chapter of Hebrews, are grouped around, filling up the lights on either side, the tracery being filled with a representation of the Angelic Choir. The window is designed in the spirit of "Old Glass," no attempt being made to copy the "Munich" or "Pictorial" school, Lord Egerton wishing to have a mosaic effect of colour, combined with figure drawing after the Italian Gothic school. The work was designed and executed by Messrs. Heaton, Butler, & Bayne, under the architect's supervision.

## NEW FREE LIBRARY, NORWICH.

The building shown in our illustration is now being erected on Knight's Hill, Lower Norwich, for the Lambeth Libraries Commissioners, and is the first of several new libraries which are in contemplation. The site adjoins the new Post Office premises. The front is to be built of red bricks relieved with Ham Hill stone and terra-cotta, the arches and other parts being of gauged work. The pilasters over the main entrance will have busts of some men eminent in literature; all the other carving is to be emblematic of the use for which the building is erected. In the basement are lavatories, a large book-store, heating-chamber, &c., and over the front portion is a librarian's house. The fittings have all been specially designed by the architect, and the bookshelves are adjustable to any size book. Every book in the library will be shown on the indicator which is on the counter. The floors will be of wood blocks, and the ventilation, warming, and lighting have been carefully considered.

The builders are Messrs F. & H. F. Higges of Loughborough Junction, S.E.; the architect is Mr. Sidney R. J. Smith.

## FOLKINGTON MANOR, SUSSEX.

The view of this house, the residence of Mr. T. E. A. Gwynne, J.P., shows the additions that have been made and those that are proposed (shown in the plan by a grey tint). A visitor who knew the estate a few years ago would no doubt be sorely puzzled to recognise it now. The old public road passed within 20 yards of the drawing-room windows, the old cramped stables were close to the front door, and the mansion was so shut in as to be practically hidden. Now the site of the road is occupied by flower-beds and terraced gardens, the old stables have been pulled down, and the hunters and hacks are stabled in luxurious quarters shown in the view. When the dining-room and library are completed the mansion and its belongings will without doubt be one of the most perfect in Sussex. Mr. Gwynne is his own contractor, employing a regular staff of estate workmen, by whom the work has been carried out in very substantial and creditable manner. The architect is Mr. Peter Dollar.

SUGGESTED AMENDMENTS IN  
SANITARY LAWS.

THE Right Hon. Lord Basing, F.R.S. who (thru Mr. Selcher-Booth) was President of the Local Government Board from 1874 to 1880, is President of the Congress now being held at Bolton under the auspices of the Sanitary Institute of Great Britain, and on Tuesday evening he delivered the opening address of the Congress, from which we extract the following:—

For my own part, I do not wish to appear before you as an optimist or a pessimist,—certainly not as an optimist. Passing by for the moment the question of the standard or ideal at which we should aim, I find plenty of material for legislation, change, and improvement stored up in various ways, and ready to be put forward when time can be afforded for anything except questions affecting the condition of Ireland. The more important of these (of which I shall presently give a catalogue) have been derived by what I have already described as the most legitimate and satisfactory of all methods, viz., from applications to Parliament on the part of private Bill promoters, mostly our larger and more populous cities and towns, during the last six or eight years. I have twice during that period acted as chairman of the Parliamentary Committees to which the more important of these Bills have been referred; referred, however, with the view of curtailing rather than encouraging exceptional legislation, and of moderating the tendency to extravagant expenditure by means of borrowed money. Many of the provisions mentioned in the list have been conceded, others are so far recognised as needful to be provided that they will undoubtedly be included in the next, nay I hope the approaching, amendment of the Public Health Act, 1875.

I well remember, amongst the most striking and comprehensive of the applications which have been made to Parliament of late years, an elaborate consolidation and amendment of the Bolton Improvement Act, which, together with some others of the like authority, has exercised no small weight in the process of selection to which I have alluded.

Although the Public Health Act, 1875, may be said to be complete as a general measure, so far as regards the accepted sanitary requirements at that time, subsequent experience has shown it is now capable of amendment in several important particulars.

The following are some of the amendments which have been suggested:—

1. The importance of separating sewage from surface water is now recognised.

The Act is, in its present form, practically prohibitive of schemes for that purpose; and power is therefore wanted to enable Local Authorities to provide a dual system of drainage. The Corporation of Reading were so sensible of the importance of this arrangement that they were mainly induced by a consideration of it to promote their local Act of 1881.

2. Provisions are needed to prevent injury to the structure of sewers and their obstruction, and the evolution from them of specially noxious vapours from chemical works, &c.

3. It has been frequently urged that communications between drains and sewers should be undertaken by the Local Authority, at the cost of the owner, instead of by the owner. The central authority should be empowered to decide upon the junction of the sewers of one Authority with those of another.

4. Local Authorities might have power to regulate, in addition to materials, size, &c., the ventilation and height of sleeping-rooms, the trapping and junction of drains, &c., in connexion with dwelling-houses. More powers are also needed with regard to enforcing the repairs of vaults, &c., under streets. Provision is also needed for the regular inspection of houses during their construction, to see that proper materials are used.

5. Provisions would seem desirable for prohibiting the construction of rooms over privies; and power might be given to impose a penalty on persons who, after notice, neglect to repair or cleanse their water-closets, earth-closets, privies, or ash-pits.

6. Local Authorities, who undertake or contract for the removal of house refuse, cannot make by-laws relatively to such removal. They should have power to make by-laws ancillary to this work so undertaken by them or their contractors.

7. Larger powers should be given to Sanitary Authorities for the protection, both within and beyond their limits, from pollution of water courses from which they derive their water-supply; and lords of manors might be empowered to make grants of waste lands for purposes connected with water-supply.

8. Parliament has very generally accepted in local Acts proposals for the prohibition of the use as dwellings of premises constructed, and ostensibly intended, solely for use as "lock-up shops." There might now be a general enactment to this effect.

9. A Local Authority should have power to cancel the registration of a common lodging-house. They cannot do so now.

10. Back-to-back houses should be prohibited in future.

11. Power should be given to proceed against offenders when an article of food has been found unfit for use after it has been sold, or where it has not been exposed for sale, but delivered under contract.

12. Many local Acts empower the Local Authority to disinfect houses. This might now be made general.

13. A considerable number of Local Authorities have obtained Acts enabling them to require medical practitioners to notify any occurrence of dangerous infectious disease. Power should be given to the central authority to clothe Local Authorities with this power in application, so that they need not incur the expense of a local Act for the purpose.

14. Sanitary Authorities should be authorised to issue notices and advertisements warning the inhabitants against conduct likely to spread infectious disease.

15. It is desirable that some power should be given to remove to hospitals persons attacked with infectious disease, when isolation is not otherwise practicable.

16. Local Authorities should be enabled to provide, temporary shelter for members of a family in which infectious disease has appeared, whilst the house is being disinfected and cleaned, and to provide nurses for attendance upon persons suffering from infectious disease.

17. A penalty should be imposed on persons ceasing to occupy houses where there has been infectious disease without previous disinfection or notice to owners, or making false answers.

18. Bodies of persons dying in hospital of infectious disease not to be removed except for burial, and corpses not to be carried in public conveyances other than hearses.

19. The Medical Officer of Health should be empowered to enter a house where he has reason to suspect the existence of infectious disease on obtaining a magistrate's order.

On the other hand, I certainly do not wish to appear before you as a pessimist, and I feel bound, as the final result of my experience, such as it has been, to say, that, having regard to the comparative novelty, and to the difficulty and obscurity of the subject, to the dislike of control, and to the great expense attending works of sewerage and water supply; still more, when we remember the disinclination of Parliament to turn aside from the more striking and generally interesting matters which make or mar the fortunes of Governments and parties,—I feel more than satisfied, on looking back over a period of thirty years, to find that so much has been really accomplished. At this moment, my apprehension undoubtedly is that, in the anxiety to escape from the irksomeness of detail, and in the hurry to establish local government, generally on a wider and more popular basis, mischief may unwittingly be done through misappreciation of the difficulties under which that which now exists has been built up, and of the great risk which may be run if such central control as is really still required were to be hastily surrendered.

But, further, that a pessimist view is really unjust and untenable, statistics abundantly prove. I have already given more than sufficient for my case, but I will take the liberty of borrowing, what I am sure our veteran champion, Mr. Chadwick, will readily lend, a few of the more striking illustrations which he gave to the world on a recent occasion when celebrating the Jubilee of Sanitary Science:—

"The present reduced annual death-rate for the metropolis may be stated at 10 in 1,000, but the sanitary engineer could undertake its reduction by 5 in 1,000, and at a cost greatly below the existing insurance charges for sickness, loss of work, and death. On what experiences, it may be asked, are the statements as to that conclusion based? The answer may be, that they are based on that which has been done for the common lodging-houses,—old buildings, once the seat of pestilences, but now cleared of

them by very rudimentary sanitary measures; and on what has been done in blocks of buildings in the metropolis, and in old urban districts, such as Salisbury, where the death-rate, as high as 40 in 1,000, has been reduced to 16 in 1,000; in Dover, where 25 in 1,000, is now about 14; in Rugby, where 24 in 1,000, is now under 12; in Creighton, where 28, is now 10 to 15; in Matlock, where 18, is now 9."

Mr. Chadwick then proceeded to make some remarks leading up to the important subject of the economy of sanitation which he has recently worked into shape, and which I trust he may be able to lay before this conference, no branch of the subject being more likely to influence the popular imagination.

These and similar statistics have been put before the Sanitary Institute by Presidents and other speakers year after year, but they cannot be repeated too often. The period of activity is too soon followed by a relapse into apathy, and even when, through the agency of epidemics or other exciting causes, the time for constructive legislation comes round again, we shall find that the growing tendency to disparaging and fault-finding criticism on the part of public writers and speakers, coupled with the spirit of obstruction which now seems to be paramount in Parliament, will render the task of the Government increasingly difficult. They will accordingly require all the backing which public opinion can confer, enlightened as it must be by efforts such as this and other kindred associations are making, to carry them safely through the rocks and quicksands which will most assuredly beset their progress.

The address which I have thus ventured to lay before the Congress has been couched, for the most part, in abstract terms. But we must not forget that we are meeting in one of the most thriving industrial centres of the great county of Lancaster, and I trust that considerable attention will be given to the application of sanitary science to the needs of the populations which have grown up in these manufacturing districts. The cotton manufacturers have exercised no small influence in times past over the financial policy of the country. If the wealth and prosperity which followed, and in some degree flowed from, that policy, have caused an aggregation of human beings in and about the central towns to multiply with a rapidity and to an extent prejudicial to healthy conditions, it is here that we should look for activity in remedial measures, and a ready recourse to all that can be done in the way of amelioration. Can it be said that the result is perfectly satisfactory? Is not the death-rate higher than it should be, and that even in Bolton, which is more healthy than many places that might be named hereabouts? Does it not, for instance, compare unfavourably with that of London? And, if so, do we find earnestness and discrimination on the part of the local authorities in pressing forward remedial measures, and acquiescence on the part of the people in submitting to the necessary expense? I have referred to the Bolton Improvement Act; but there are few towns of any size in the County Palatine which are not provided with similar facilities in the same way, and all are subject to the provisions of the Public Health Act, which, in the greater part of Lancashire, is doubly effective, as the sanitary districts are mostly of an urban character. In fixing their Congress at Leicester the year before last, the Sanitary Institute was not afraid to heed the lion of anti-vaccination in his den (to little purpose, I fear, if the statements of a letter in yesterday's *Times* are well founded). Let it not be said that we come only to prophesy smooth things at Bolton. We know the energy and capacity of the Lancastrian population. We must not shrink from holding up before them the highest ideal, and, I may add, the material advantages which are involved in determined efforts after sanitary improvements. Thus our visit to the North may become, as we should desire, a useful stimulus locally, as well as a signal manifesto of the principles we profess, and of the great national objects we have in view (applause).

Mr. H. Shepherd Cross, M.P., in moving a vote of thanks to Lord Basing for his address, expressed the indebtedness of the country to sanitarians, by whose labours and researches improvements in sanitary conditions had been brought about with the result, not only of diminishing the death-rate, but of preventing sickness. And it should, he thought, be more often borne in mind that the reduction of the death-rate did not half express the advantages which the nation gained from the labours of the sanitarians. Let them remember the amount

of sickness which was prevented by the observation of sanitary conditions, and the consequent gain to the community, as contrasted with the privation and penalty which often followed through the illness of the wage-earner of the family, even when the illness did not terminate in death. He thought the Congress was much indebted to Lord Basing for his excellent address, in which he had clearly traced the course of recent sanitary legislation and its results,—results which the noble Lord himself had some share in bringing about (applause).

Professor J. Russell Reynolds, M.D., F.R.S., President of Section I. of the Congress (Sanitary Science and Preventive Medicine), in seconding the motion, said that he was glad to find that there was a growing opinion in favour of the compulsory registration of disease as well as death, and when that opinion ripened into action, and complete statistics of disease were collected, some more than doubtful assumptions, based upon or deduced from mortality statistics, would be corrected or verified, while the increased precautions which would inevitably follow from the publication of such statistics would, no doubt, tend to reduce death-rates still further. Speaking as a physician, he was able to testify that,—until within the last few years especially,—nothing could be more slovenly, not to say dishonest, than the way in which the existence of disease of an infectious sort had been concealed. As illustrating the importance of having statistics not only of deaths but of disease, he might call the attention of the Congress to the fact that while much was being said just now as to the prevalence of scarlet fever in London, the mortality had, happily, not been high; indeed, during the present epidemic the mortality from that disease had been below the average of previous years. The proposed compulsory registration of infectious disease, to which Lord Basing had referred in his address, was thus a matter of the greatest importance (hear, hear).

The motion for a vote of thanks, having been put to the meeting by Professor Corfield, was carried by acclamation.

Lord Basing, in acknowledgment, referred to the labours of Lord Norton (formerly Sir Charles Adderley) in connexion with sanitary legislation and administration.

#### REFUSE DESTROYERS AND THEIR RESULTS UP TO THE PRESENT TIME.

A fortnight ago (p. 360, *ante*), we gave the substance of a paper on this subject read by Mr. Charles Jones, Surveyor to the Local Board of Ealing, at the Leicester meeting of the Association of Municipal and Sanitary Engineers and Surveyors. In the discussion which followed the reading of the paper,

Mr. Lemon (Southampton) said,—I, together with my friend, Mr. Jones, visited Leeds, and went back rather impressed with the value of the destructor; and, with other members of the Town Council, succeeded in getting a destructor erected. At the first blush of the thing, a destructor looks like an expensive and wasteful article. In Southampton the refuse was sold for about 1s. 6d per ton. The cost of the destruction, you have been told by Mr. Jones, is about 1s. per ton. Thus the actual loss is about 2s. 6d. per ton. This is rather a large item in the expenditure of a town, but on the other side you get the advantages from the burning of the refuse. This, I think, ought not to be lost sight of. In conversation with Messrs. Fryer the other day, I found that in towns where the power generated is utilised, the loss is remarkably small. I do not think, according to what he told me, that 20 per cent. of the towns in England where destructors are used turn the power generated by burning the refuse to any advantage. Now Mr. Cartwright, the Borough Surveyor of Bury, in the paper read by Mr. Santo Crisp, gives some results hearing on this point. He says that sixteen tons of refuse daily would enable an 8-horse-power indicated engine to be worked twenty-four hours by the steam generated. If you work this out, you will find it is  $\frac{1}{2}$ -horse-power per ton. I think that is a very simple and useful fact to remember. In my own borough the amount of refuse burnt daily is about 50 tons, and we get about 30-horse-power, a somewhat higher result than that given by Mr. Cartwright. But you must bear in mind that the quality of refuse varies considerably during the year. I do not think Mr. Cartwright has

over-estimated the power, and if you take his datum, which is a very simple one, you will have something on which you can found your calculations. If the refuse of Leicester, which has a population of about 140,000, were utilised, you would get a useful effective power of about seventy horses. This is a thing which ought not to be overlooked; and this is to be set off against any increased expenditure in the use of a destructor. As time is short, I will turn to the burning of sludge. I do not agree with the conclusions of my friend Mr. Jones as to the burning of sludge. I do not think that is the solution of the difficulty. In my own borough, we had a very long litigation with cement manufacturers, and that was occasioned by the complaints of their works being a nuisance to the neighbourhood. Now, if the burning of the mud of cement is a nuisance, under careful management, I am quite certain that the burning of sludge containing about 90 per cent. of water must be a nuisance, unless it is very carefully managed indeed. I should hesitate, myself, to adopt the method of burning sludge referred to by Mr. Jones. I have seen his works; they are admirably arranged and excellently managed. But, as to burning sludge with the refuse, I must say I do not think it is the right thing to do. However, he gets rid of a nuisance, and that is saying something for him.

Mr. Hewson (Leeds).—I am glad of the opportunity of speaking, because I wish to do some service to the Association. I am not here to advocate any of the processes named by Mr. Jones; I am here simply to give the Association the benefit of my experience on this subject, to state what the Leeds Corporation have done. You have been told that the Corporation of Leeds were the first Corporation to build destructors. About the working of these destructors, the management of them, and my experience of them, I think I can give a few useful notes to those who have destructors but have not had much experience, and those who may have destructors. At Leeds, we had no sooner built the destructor than, of course, there were complaints of the disagreeable smell from the chimney. I ought to say that the destructor is built practically in the centre of the town, where there is a dense population; and you can readily conceive that if there were any cause of complaint, we should soon hear of it. There being cause for complaint, we did soon hear of it. The Corporation naturally endeavoured to remedy the evil by raising the chimney. But that did not remove the evil. There were still discharged out of the chimney quantities of disagreeable fumes and dust. For a certain distance around the works, according to the direction of the wind, there was a sort of "salting and peppering" constantly going on. From that time to the present this difficulty has existed, and to get rid of it has been the primary object of the different experiments we have made. To get rid of this dust, we first of all made recesses in the horizontal flue which passes between the two rows of furnaces. The flue, I ought to tell you, is something like 6 ft. wide with sunk recesses on the right and left, forming stove chambers for the dust passing along to deposit in. We found this did not answer because of the smallness of the provision. We found, indeed, that after two days these chambers were filled with dust, and the nuisance was as bad as ever. The result to-day is this:—We make these recesses in the bottom of the flue as large as we can, but every Sunday we clean out the bottom of the shaft,—that is, the bottom of the chimney. Notwithstanding that we make the horizontal flue the length of this room, the 6-ft. chamber at the bottom of the chimney-shaft, after a week's work, is pretty nearly stopped up. In fact, there is a struggle between the draught and the specific gravity of the dust, until there is only just enough space to allow the heated fumes to escape, no doubt hearing with them a great quantity of dust. Well, gentlemen, this dust difficultly remains with us until to-day. With a view of getting rid of it we visited Mr. Jones's crematory at Ealing a fortnight ago, and were very pleased with the result. We were told by Mr. Jones that he got a very high heat,—1,500°, whereas at Leeds we only got 700°. Therefore his crematory is very effective, because if you get a furnace at 1,500°, through which these fumes have to pass, you will necessarily get a great deal more perfect combustion. That I think will be patent to all of us. With regard to the nuisance of the smoke, there is

another thing we have found it necessary to do, and that is to watch very carefully the charging. The men very much preferred to charge the ten or twelve cells right away, and then light their pipes and go and skulk for an hour or two. They preferred that system to the one we have now adopted in Leeds of charging only a pair of cells at a time. We used to charge the cells as quickly as the men cared to do it, every 2½ hours. The cells are huck to back, and we now make them charge every twenty-four minutes. The result is that we do not have coming out of our chimney-stack for half the time large volumes of disagreeable fumes from the cells being charged regularly. Only a very small quantity is now visible. By this system, too, we get a more uniform heat. Under the old system, immediately after the general firing the temperature went down 150 degrees. Among the other things we tried to secure better combustion was that of making a great number of holes in the fire doors, so as to let in a quantity of oxygen over the fire, and to make this more effective we put in bafflers on the soffit of the arches. These we secured to the arched roof by pieces of sheet iron, which would have the effect, when the current passing through these holes struck against these bafflers, of throwing it down upon the fire. These were very useful, and the two things together did a great deal towards giving us a redder fire and less dead matter on the top of the burning fire. The committee wished to do something better, for still we had complaints; we then raised the chimney-stack 30 yards higher. Even to-day, however, the fumes which come from the top are very heavy, and when the wind is quiet the lee side of the country suffers from a very disagreeable smell, within a radius of perhaps a mile,—the peculiar dry smell of burning wet, dank, vegetable matter. We tried after this a system of blowing. I laid round the whole of a block of ten furnaces a line of 12-in. pipes, and out of each of these I took a junction of 10 in. into each ash-plate, and I got the mouth of each ash-plate bricked up round each junction. Well, of course, when I came to utilise this system I found I had not the necessary power. Although we consumed 50 tons of refuse per day, I found we had not more power than some sixteen or seventeen horse-power,—that is, break power outside the engine. I then wrote to the most noted men in the country who make blowers,—who make this a speciality and supply large blowers. I got from three firms estimates of the cost of machinery and blowers sufficient to do the work, with a guarantee that the machinery would be sufficient to produce the necessary blasts in each of the cells. But it came to this, that I really could not undertake it without 50 horse-power at command. A system of blowing into an enclosed ash-plate practically requires 5 horse-power per cell. After the pipes had been laid, whilst thinking about this and talking over the question with the man who had done the work, he said, "What do you think about putting a steam jet under each fire-grate? Rip your machinery out, and take steam actually to the work to be done." I replied, "We will try it." Well, we have attached it to a pair of the cells, in the manner you see in the section before you. A steam pipe is turned into an open pipe which passes into the built-up ash place. We found that, acting in a sense after the manner of an injector, it induces a current of air to pass under the fire-bars, which gives me most readily over 1,500 degrees of heat. The effect upon the fire, of course, is much more rapid consumption and much more flame, due to the admission of hydrogen in the shape of steam. This, in fact, is what we are doing now. When I speak of a jet of steam I speak of a quarter of an inch jet, and a pressure of anything between 25 lb. and 30 lb. The committee have ordered me to attach the system to the other furnaces; but, at a meeting which we had the other day, we were not quite sure whether it would not be better to adopt a system of furnaces like those attached to Mr. Jones's crematory. One of the members of the committee, not a scientific man, but a hard-headed Yorkshireman, put a very plain proposition. He said, "I know, of course, that heat is heat, but that will not do everything. I can understand that heat will make substances break up, and reorganise themselves as different gases, but I can understand that heat might not be a perfect cure. I cannot help thinking that if these fumes were passed through clean fire they would really come out less harmful

man if passed through high heat where the iron was not clean." Personally I am not chemist sufficient to deal with this aspect of the question. However, as some testimony to Mr. Jones's efforts in this matter, I thought I had better name it. Then as to cost: I may say we have made all sorts of attempts in the way of economy in dealing with our destructors. We have two destructors, so that the carting is so great as if we only had one. But I cannot get the cost any lower than 10d.,—that is, including every charge for capital and depreciation. I think I have now told you all we have done; as to the future, whether the steam we have at present will be sufficient for the ten tells yet remains to be seen. I think it will, because we know we can now work 15 to 18 horse power continuously, in the way of making mortar. We certainly ought to be able with double the heat. If we raise the heat up to 500 degrees through the twenty-four hours, these units of heat are obliged to go somewhere; and if we utilise them by putting them into water, we shall have a better supply of steam in proportion.

Sir Robert Rawlinson.—This question of refuse destruction is so important that I have induced the Local Government Board to permit me to authorise one of the inspectors to undertake the collection of information on this point. I entrusted this to Mr. Codrington, one of the inspectors, whose report has not yet been completed. He has been visiting the various places, and I dare say he has come into contact with some of you gentlemen. He is getting together such information as he can obtain on this point.

The discussion of the subject was resumed at the recent West Bromwich meeting of the Midland District of the Association, when

Mr. Andrews, of Bourne-mouth, stated that after a good deal of inquiry they had erected there a destructor on the principle advocated by Mr. Jones, and started it last week. It cost them about 3,000*l.*—600*l.* for three acres of land, 900*l.* for the ironwork, and 1,500*l.* for the brickwork and chimney-shaft; the latter costing about 500*l.*, and being 137 ft. high.

Mr. Dent, of Nelson, said that with the "Beehive" destructor they were destroying refuse at a cost of 1*s.* 3*d.* per ton, apart from the cost of the cremator.

The President (Mr. Gordon) remarked that taking the cost of destruction at 1*s.* per ton, they had to add to that the cost of carriage to the place. If they could reduce that cost it appeared to him they would do much to end the difficulty found in getting these destructors accepted, and the destruction of noxious emanations, so that destructors could be erected in the centre of populous localities, was involved in that. That was claimed to have been attained by Mr. Jones. But he was not sure they had arrived at the best method yet. Still, they owed a debt of gratitude to Mr. Jones for the pains he had taken in working up the subject, and the information he had laid before them.

COMPETITIONS.

**Helston Public Rooms.**—The Helston Public Rooms Company invited architects by public advertisement to submit plans and specifications for their new buildings, and offered a premium for the best design. Twenty architects competed, and the committee appointed to report upon the drawings advised the adoption of the design bearing the motto "St. Michael," the author of which is Mr. Charles E. Dyer, of Plymouth. The new buildings will occupy a central position, upon a site part of which is at present occupied by the Old Grammar School. This building is a well-built and substantial structure, and possesses more merit as an architectural composition than the majority of buildings of its period. It has, in addition, many interesting associations connected with it, and on these grounds, and upon the score of economy, it has been considered advisable to retain and embody with the new building the more important portions of it. In addition to the reading-room and library (to which the Old Grammar School is devoted) the buildings will comprise a business-room, a large committee room for the use of friendly societies, smoking and billiard rooms, and a large hall, with suitable retiring-rooms.—*Western Morning News.*

**Kingswinford Board Schools.**—In the competition for the new schools at Mount Pleasant,

Quarry Bank, Brierley Hill, for the Kingswinford School Board, the Board have accepted the design submitted by Messrs. G. B. Nichols & Son, of Birmingham, and have given them instructions to proceed with the contract drawings.

THE WALLS OF CHESTER.

Sir,—The question is not what the eminent antiquaries, whose names are published by Mr. Thompson Watkin [p. 411, ante] as supporting his theory of the age of the walls of Chester, thought in 1886; but what they think now, after the publication of the impartial verdict of Sir James Picton, Mr. Loftus Brock, and the meeting at Chester of the Archaeological Association.

At the Congress of the Archaeological Institute the evidence brought forward by Messrs. Shrubsole and Watkin was of an *ex parte* kind; and Mr. Shrubsole, from his long residence at Chester, was accepted, too hastily, as possessing a correct knowledge of the age and character of the walls. I know that some of the gentlemen then marshalled on the side of the Jacobean theory are now opposed to it; and we do not see one writing to support it.

The partial construction of Roman town walls with the monuments of an earlier time has been long well known as of frequent occurrence. I may instance Bordeaux, Dijon, Sens, Narbonne, in France; and Arlon, in Belgium, so well described by Mr. H. Schermans, President of the Court of Appeal at Liège. The walls of London afford an example in this country, as the Guildhall Museum, through the exertions of Mr. J. E. Price, will testify. All these walls appear to have been partly built by the Romans with these sculptures. It was at first supposed that the portions containing sculptures were reparations, but additional evidence appears to show that they are of the age of the walls themselves.

All the sculptures found in the walls of Chester are Roman. That adduced by Mr. Watkin as a Medieval ecclesiastic is a Romano-British girl holding a mirror, an example of which from the walls of Bordeaux I have given in my *Collectanea Antiqua*.

Mr. Watkin says I have said nothing of the superstructure of the walls of Richborough, Reclwyd, and Lymne. Surely it is not needed for me to repeat in such a discussion what I have published over and over again. They are faced with small squared stones, and bonded at intervals with tiles. The Chester walls have large squared stones, and no tiles. This was adduced by Messrs. Shrubsole and Watkin as evidence for their not being Roman. They did not consider the walls of *Isturium* (Aldborough), nor those of the *castra* to the north, nor the Great Wall itself. C. ROACH SMITH.  
Strood, Sept. 19, 1887.

Sir,—Mr. Thompson Watkin, in your issue of the 17th, refers to the jointing in the unmortared masonry of the walls of Chester and to some (alleged) change of opinion on the part of Sir James Picton when I "remarked upon the close joints of the stones." The words referred to convey the impression that Sir James's opinion was suddenly expressed, and after this piece of evidence only had been adduced.

Such was not the case. As I have elsewhere said, nothing could be more complete than were the facilities, not only for Sir James, but for all our members present, to see the work laid open for observation, and for all to form impartial and unbiased opinions. It was only at the close of the long tour of inspection, and after the last of the evidences had been inspected, that he summed up the results of the visit, and his opinion was expressed. I heard it then for the first time.

I have no need now to notice many of the other points named in your correspondent's letter, since I shall have many other opportunities of doing so, but it may be of service at this stage of this interesting discussion if I refer to what he says of the section of the wall at the position named, west of the Phoenix Tower, one of the places laid open by the excavations. My doing so will render a better idea of the nature of the wall to your readers who may not have inspected the work, and he of service for future discussion. The wall of Chester here consists of a massive base of huge stones,—sandstone, set without mortar, having fairly close joints in front (outside the city), and resting on solid rock, which is, beyond the wall,

scarped to a considerable depth to form the external ditch, the site of which is now the canal. The foundation consists of a projecting course, bedded level in the rock. There is then an irregularly-chamfered plinth, from which the wall rises to a height of about 10 ft. without mortar, and 8 ft. with mortar, the whole having a considerable batter inwards. There is then a neatly-worked chamfered course, and the wall terminates in an ordinary parapet, breast high, coped with a double splayed course. The whole of the interest in this discussion centres in the lower part, the unmortared masonry. This is of coarsed work, laid fairly horizontally, but with a tendency to follow the inequalities of the ground. The stones are of great size and weight, some being as much as 5 ft. in length. The thickness at the base is about 8 ft. The upper mortared portion consists of smaller stones, generally in poor condition, while the reverse is the case in the lower part. On the inner side are clear traces of a sloping bank of earth, which appears at some time to have formed a means of manning the wall, such as we see, of Roman date, at Silchester; of Medieval date on a Roman base, at Chichester; and of Medieval date entirely, at Great Yarmouth and many other places. On this bank, on the inner face, a rough supporting wall, 7 ft. high, is built with mortar, having no foundation at all, and with hardly any sort of bond or support from the solid wall of masonry, but exhibiting the open joint described by Sir James. The inner face of the wall has been apparently removed before the formation of this wall, although its face originally may never have been so smooth as the outer one, consequent upon the hacking of earth. Earth now fills many of the interstices of the unmortared stones, which I hold to be Roman, but whether formed so or the result of percolation, I am unable to say, although I think the latter.

This inner wall carries the present paved way within the parapet, which forms the well-known and greatly enjoyed promenade which goes all round the city.

It is in the unmortared part of the wall that the recent remarkable discovery of Roman inscribed, moulded, and sculptured stones has taken place,—a discovery which is still in progress, for hardly a single day seems to pass without some fresh result being obtained. Not a single stone has been found in the mortared part of the wall.

This distinction is not alluded to by your correspondent, but since it is so significant as to the date of the wall it is of importance to be stated. It was in this part that his "ecclesiastic" (so called) was found.

Such is, briefly, the wall which is referred to. While this is the description at the point named, it is in fact the same generally all round the city wherever it has been opened, the most apparent differences being that near the north gate the unmortared masonry rises much higher and ends in a moulded cornice; that at the Roodeye it goes down very deep, and the plinth has not yet been met with, and there is some mortar to the large stones; and elsewhere, as at the Kaleyards, the foundation consists of layers of small stones set in puddled clay where there is no rock. There are, however, many technical details to be referred to, and since their discussion will be so well understood by the tribunal of your readers, I will speak of them fully as soon as your correspondent will favour me with some more definite statement than he has yet done as to what he considers to be the age of the oldest portion of the wall. I need not trouble him relative to the small part called the Kaleyards wall, which stands by itself, the present wall of the city here making a small irregular bend, and thereby leaving it outside the line. This, I understand him to say, is Edwardian in date. His statement as to the other parts is not so clear. In a recent number of the *Chester Courant* he believed it to be the work of some Puritan builder. In his recent letter, p. 411, he states its date to be "in the reign of Anne." We are both referring to the large Roman stones on the face and at the base of the wall. Will he kindly tell me (1) which of these statements he considers most likely to be true? (2) Do not his remarks apply (as I understand them to do) to the whole of the walls of Chester, the Kaleyards wall alone excepted? The period he may name will imply the building at that time of the whole of the wall, since these stones form the base and the portions above the base.

I will conclude these remarks promptly on being favoured with replies to these two inquiries, and I hope my reply will be sufficient to convince the majority of your readers and perhaps even your correspondent that wherever the unmortared stones occur there is Roman work *in situ*, especially since he already admits that the site of the walls is Roman, that the large walling stones are Roman, although removed from elsewhere, and that the cornice next the north gate is also Roman, but under similar conditions. As he must be aware, each of these three important items has been denied, and their assertion was among the principal things to which I had to address myself at Chester (*mutatis* the removal theory).

E. P. LOFTS BROCK,  
36, Great Russell-street, W.C.

#### SAFETY IN THEATRES.

SIR,—Amongst the many letters written lately respecting the safety of the public in theatres, the true cause of accidents has often been lost sight of. Suggestions are being made generally of safety from fire, whereas it is not a question of fire simply, from water curtains to the proscenium are undoubtedly useful in case of fire on a stage, always provided they are kept in working order and used when required.

It is, however, not merely a question of fire, as witness the disastrous accident at Sunderland and elsewhere, where accidents and loss of life occurred from panic only.

Amongst the many proposals are the following:—  
1. Outside balconies. This is really impracticable. In the first place, it would spoil the elevation, and again a rush from the inside on to the balcony means death as certain as down a staircase.

2. Going up steps to exit. This is a good idea, but unfortunately cannot be applied to a gallery.

3. Doors to open outwards by pressure from the inside is a good suggestion, as you remark in your last issue, but is no new idea; such doors are at present in use and have been so for some years.

4. Wide staircases are a great mistake, people cling to the handrails on either side, and in the rush persons in the centre are almost sure to be pushed down by those behind.

5. And lastly, it cannot be too strongly impressed upon the minds of theatrical managers—a second exit in case of a panic is almost an absurdity, as any playgoer will admit upon giving the matter careful consideration. Suppose the public to be admitted to the gallery up a certain staircase; in case of panic, where will they rush? Not to a different staircase to which they entered, he exit printed over it in letters ever so large. They will endeavour to go down the same staircase they entered by; they are certain that leads into the street. Other exits may not do so, or doors may be locked and bolted at the bottom. The public have no faith in second exits. Again, if the public were admitted by two separate staircases, confusion would still arise: the playgoer again makes towards the door he entered. There would doubtless be less crushing, and more persons would escape.

The only way I can see out of the difficulty is to make a very broad staircase, as already suggested, but with this addition—a newel wall, say about 4 ft. 6 in. high (so that a person could look over it), should run down the centre of it, forming, as it were, two separate staircases side by side, each say 5 ft. wide. The audience on entering can then see that the two staircases are real exits, the doors being side by side both at entrance and exit. No pass doors, as they are called, should be allowed to enter this staircase from other parts of the building. The staircase should be built of concrete, and enclosed by brick walls from top to bottom, with a concrete flat or roof over (no daylight is required in theatre staircases), thus making it absolutely fireproof, provided it be lighted either with oil lamps or electricity, so that in case the gas fails, the public can see their way out. PLAYGOER.

\* \* In regard to suggestion 3, we may observe that the form of door referred to in our note (p. 387) is entirely new in the principle and manner of working it. In regard to 4, the *Builder* has repeatedly and strongly pointed out the danger of too wide staircases without a centre balustrade. As to No. 1, we entirely concur with our correspondent.

#### "SHONE'S EJECTORS IN THE RECENT RAIN-STORMS."

SIR,—In your issue of September 17th [p. 411] there appears a letter, signed "John Phillips, C.E.," in which an attempt is made to controvert statements about the incapacity of the Shone installation to deal with the rainfall, made at a meeting of the Society of Engineers by engineers to whom the epithet of uncivil is applied. As I was one—I believe the only one—who made the statements referred to, I feel sure you will allow me space to reply to the letter signed by Mr. Phillips.

My views were backed up by incontrovertible

arguments, stated plainly and straightforwardly, but without the slightest taint of rudeness or discourtesy. If Mr. Shone and his friends cannot bear honest criticism without indulging in personalities, they should neither read papers nor write letters challenging public discussion.

The statement made by myself was simply this, that the cellars of the Houses of Parliament would be worse flooded than they have been before if 1 in. of rain fell in one hour, when the maximum height to which the sewage has to be raised from the elevators is equal to 4 ft. Mr. Shone may well say "Save me from my friends!" The contents of the letter prove, beyond question, that the cellars under the a-signed condition would be flooded. Accepting Mr. Phillips's statement that the four gas-engines and three ejectors could deal with a rainfall of  $\frac{3}{4}$  in. in an hour, with the exception of 2,000 gallons, it follows that the remaining two-fifths must be stored up somewhere within the precincts of the palace, *i.e.*, in the sewers and cellars. If 2,227 gallons per minute is the result of rainfall at the rate of  $\frac{3}{4}$  in. per hour, an increase of two-fifths would add 1,484 gallons to the rate of flow per minute, or a total during the hour of 89,040 gallons, so that storage would have to be provided for 91,000 gallons before the surface of the sewage in the metropolitan sewers because, previously to the Shone installation, there was a slight flooding of the cellars, when the height of the surface of the sewage in those sewers corresponded with the 20 ft. lift of the Shone installation.

The description of a rainfall of 0.59 in. per hour as a tropical storm is a gross exaggeration, the writer of the letter. A fall of 1 in. per hour is not by any means uncommon, and rain has been known to fall in the neighbourhood of London at the rate of more than 3 in. per hour for a period of fully half an hour. If, therefore, any of the archives of the Houses of Parliament are stored in the basement, it is mainly the duty of the officials in charge to remove them to safer quarters.

The whole contents of the letter are, however, from beginning to end a tissue of mistakes. Unless the official reports are wrong, although the whole area occupied by the Palace is ten acres, the rainfall from eight acres only enters the sewers. Certainly Mr. Phillips cannot object to my taking the lesser area as the basis for discussion, the surface of a rainfall of 1 in. per hour on eight acres is equivalent to 3,025 gallons per minute; as that if the three ejectors could discharge against a 20 ft. maximum head 2,200 gallons a minute, as Mr. Phillips affirms they did, reservoir capacity for 48,000 gallons only would suffice to prevent the flooding of the cellars. In the installation there are two ejectors of 300 gallons capacity, and one of 500 gallons. So that Mr. Phillips's statement that the three ejectors contain 1,100 gallons is correct. The discharging capacity of the ejectors does not, however, depend upon the capacity of the ejectors, but on the size of the inlet and discharge pipes, and the power expended in discharging them. Now the size of these pipes is the same in all the ejectors. Why, then, did Mr. Shone specify the 500-gallon ejector, seeing that it can discharge no more per minute than either of the 300-gallon ejectors?

At my request the foreman in charge of the works measured these pipes, and told me that the outside diameter was only 6 in. This I found to agree with the diagrams in the pamphlet presented by Mr. Shone to the members of Parliament. The inside diameter cannot, therefore, exceed 5 in. In order, therefore, that the three ejectors should discharge 2,227 gallons a minute, each must discharge 742 gallons a minute, which means really discharging 371 gallons in fifteen seconds, if the times of filling and discharging are equal. The velocity of discharge in the 6 in. pipe must, therefore, have been nearly 30 ft. per second. Leaving out of consideration the resistance due to friction and valve motion, the head necessary to produce this velocity would be 14 ft., which, added to 20 ft., the dead lift, makes up a total of 34 ft. The corresponding air pressure is 15 lb. to the square inch. Taking into account the neglected resistances, the result claimed by Mr. Phillips could not have been produced with less than 18 lb. air pressure. Of course an equal pressure would be required to produce the same inlet velocity, or the surface of the sewage in the pump must have been at least 4 ft. above the top of the ejectors. How does Mr. Phillips reconcile this with the statement that only 2,000 gallons were stored at the end of the hour in the subway above the 12-in. pipe?

I shall be obliged if Mr. Phillips will state how the height of the sewage in the metropolitan sewers was ascertained. There are no means of doing this within the precincts of Speaker's Green, except the pump connected with the ejector, and if the statement that 2,000 gallons only were stored in the laboratory is correct, the surface of the sewage in the pump can never have been more than 6 in. above the 12-in. pipe.

I have carefully kept within the limits of the question raised by Mr. Phillips's letter, but if challenged, I am quite prepared to maintain the correctness of all the statements I made at the meeting. I enclose my card, and beg to subscribe myself as one of the

MISCELLANEOUS UNCLE ENGINEERS.  
September 20th.

#### RE LITTLE QUEEN-STREET.

SIR,—I observe in the *Builder* of the 10th inst. a "Note" drawing attention to the desirability of effecting a public improvement of the roadway of the angle of Little Queen-street and Great Queen-street, and I therefore write to inform you that the Board of Works for the St. Giles District, in which district the property is situated, has for several months been negotiating with the owners for the acquisition of the property for that purpose, and an pleasure to add that such negotiations are likely to be satisfactorily completed and the improvement carried out.

G. WALLACE, Surveyor to the Board,  
197, High Holborn, W.C.

#### A CURIOUS POSITION.

SIR,—Will you allow me to ask any of your readers if they ever were in a scrap like the following; and if so, how they got out of it?

A year or two ago a gentleman was about to build four houses,—two pairs,—to cost about 2,000 each pair, using my plans and specification and copying the pair first begun. My position was, of course, ridiculous, but I was powerless; as soon as I got up a floor, he got the builder to build the same in all respects with the second pair, and so he continued to do, till both pairs were finished, and the owner refused to pay me a farthing for the second pair. If none of your readers have been in a similar difficulty, may I ask you to give your opinion on the point?

A. B. C.  
\* \* The question is essentially a legal one, and the legal right of the client to act as he did depends, we should imagine, a good deal on the precise wording in which the commission was given. If our correspondent means to press the matter, he had better consult a lawyer and give him full particulars.

#### REFUSE CREMATORS.

SIR,—In your issue of the 10th inst. (p. 360), I notice a report of the paper read by Mr. C. Jones, of Baling, before the Association of Municipal and Sanitary Engineers. He has rightly found that certain local authorities have discarded the cheaper forms of destructors, which he names, but he omits to state that the cost of working his "Fume Cremator," as at present constructed, is so excessive that in one place at least it has already fallen into disuse. \* I would point out the "fume furnace" on his patent No. 8,690, dated July 18th, 1885, is not novel, as my patent, No. 7,703, dated June 25th, 1885, covers the entire substance of his so-called invention. As a matter of fact, a furnace cremating an almost limitless class of refuse was built and worked several months prior to July, 1885, at South-street, Bradford, and it is now working in connexion with four of my refuse cremators, Mr. Wilde, the manager of the Bradford Corporation destructors, being the real inventor of that furnace. Should evidence of this be required, it will be forthcoming, as also the fact that the use of separate coke fires has been found to be very costly where steam is not required. Mr. Jones is entirely wrong in his remarks about alterations of and experiments made with my cremators at South-street, Bradford, as the accompanying extract from a letter from the Borough Surveyor clearly proves:—

"Borough Surveyor's Office,  
Town-hall, Bradford,  
February 25th, 1887.

Dear Sir,—... Your South-street Destructor has for over three years done the same amount of work with the same degree of efficiency as Fryer's Destructor at Hamerton-street, in proportion to the number of cells. Complaints were, however, made by residents in the neighbourhood of each destructor, about a nuisance or smell arising from the vapours and fumes discharged from the respective chimney-shafts; in order to remedy which your South-street Destructor was altered, and various experiments and made several alterations at your South-street Destructor, but with little or no success.

The experiments were tried at South-street in preference to nearly another destructor, not because the nuisance was greater from your destructor than from Fryer's, but merely because it was more convenient, both on account of its position and on the score of economy.

The South-street Destructor is set in use at present, simply because the Corporation have a very convenient and suitable tip for the dryer portion of the misdean refuse made in that locality. This tip will probably remain open for nearly another twelve months after which it is intended to resume operations at South-street. ... Yours truly,  
(Signed) J. H. Cox.

B. D. Healey, Esq."

The report of Dr. William Odling is freely quoted by Mr. Jones, but he does not appear to be aware of the fact that, when Dr. Odling asked to be put in communication with one of those to whom

\* It seems a little odd that at Burnley the "Beehive" works as satisfactorily as the "Fume Cremator" does at Baling, proving the local interest in each.

radford furnaces were constructed, I was the person called in to confer with him and the Borough Surveyor. It is desirable to have more positive information from disinterested authorities as to cost fuel for the "Fumes Cremator." As to generating steam by the otherwise waste heat, most engineers now what can be done in that direction, but many difficulties do not arise from the use of a cremator, they build, and consequently the cost of fuel in such cases is very great.

My Economic Duplex Cremator, patent No. 9,342, D. 1886, which is constructed to burn its own wastes, is provided with large reversing valves similar to those used in a Siemens gas furnace. The fumes from the green refuse in one grate are passed over the grate of the adjoining furnace. This arrangement carries out in the fullest degree the conclusions arrived at by Dr. Odling in his report of September 9th, 1885, to the Bradford Corporation. The furnaces are charged alternately, so that one grate of a pair is always at a good heat when the other grate is giving off its smoke and vapour. I enclose full description of this furnace for your future reference.

B. D. HEALEY, Assoc. M. Inst. C. E.  
Liverpool, September 15th, 1887.

#### PROVINCIAL NEWS.

**Ashburton.**—The foundation-stone of a new cottage Hospital was laid at Ashburton, on the 9th inst., the site being situated on the eastern outskirts of the town, near the Newton-road. The building will have a south frontage of 00 ft., with a depth of 50 ft. in the centre, but the side wings will not have so great a depth, being only one story high. There will be four wards, all of which will be on the ground-floor, and on each side of the entrance the matron's apartments will be situated. Next to these rooms will be other small wards for special cases. At one end of the ground-floor will be the male ward, and at the other extremity will be the female ward. There will be two large and two small wards, the larger being 13 ft. 6 in. high, and will each contain four beds. The small wards will be 10 ft. high. On the ground-floor will be the operating-room, which will be at the back; and near to it a bath-room will be provided. At the back of all will be a kitchen and laundry. The second floor will be used as the committee-room and servants' apartments. The building will be fitted with all conveniences, and the ventilation and sanitary matters will be special attention. Mr. P. E. Macey, of Old Bond-street, London, is the architect; the contract for the erection being taken by Messrs. Furrell & Roberts, of Plymouth, for the sum of £1,240.

**Kingston-on-Thames.**—An extensive range of new buildings, forming a depot and warehouses, as just been erected at Kingston for Messrs. Hickford & Co., the well-known carriers, as a centre for their increasing business in the district. The building has a frontage of 80 ft. and a depth of 87 ft., thus covering a ground-area of about 7,300 ft. It is between 40 ft. and 50 ft. in height, and contains four floors. It is faced with red Chelmsford brick, relieved by moulded brick string courses and dressings of Portland and Corsehill stone. The ground-floor arches of the gates and windows are all in blue Staffordshire and red gauged brick, the window lights being all of wrought iron. In sitting in the foundations it was found necessary to go down to a depth of about 15 ft., which is about the level of the bed of the Thames. On the ground-floor there are two large goods sheds, both sheds being covered in with massive iron girders and joists, upon which is laid a concrete floor, forming a fireproof screen between the goods sheds and the depositors overhead. On this floor there is a large extent of stabling. The whole of the floor is paved with Norwegian granite cubes laid on a bed of concrete. The first, second, and third floors contain large warehouses, shut in by iron doors, and approached by fireproof staircases. The rear side of the block contains the agent's residence, and also the offices for carrying on the business of the centre. The building has cost upwards of 8,000. Messrs. Bressy & Middleton Walters, of Bishopsgate-street Within, are the architects, and the contractors are Messrs. Harris & Wardrop, of Limehouse. Mr. Thrush has acted as clerk of the works.

**Ryde.**—The Ryde Art Society will open its eighth annual exhibition on the 25th inst., under the presidency of Sir William Levinge, Bart. The judge of the competition works will be Mr. Drinkwater Butt.

**Southampton.**—The second annual exhibition of the Southampton Art Society will take place

early in October at the Philharmonic. The private view and a *conversation*, with an address by Mr. G. D. Leslie, R.A., will be on the 11th, when a good show of the works of local and other artists is expected. Among the exhibitors will be Major-General Lacy, the President; Messrs. Thomas Skeats and H. Masters, of the Ordnance Department; Mr. Drinkwater Butt, Mrs. Keary, &c.

**Westbury (Wilt).**—Extensive additions are now being made to the Angel Factory, Westbury, Wilts, for Mr. W. H. Laverton, which comprise thirty new looms, engine and boiler houses, &c. Messrs. Taylor & Challen, of Birmingham, are the engineers. Messrs. Halliday & Anderson, of Cardiff, are the architects.

#### CHURCH-BUILDING NEWS.

**Aberystwyth (Glamorgan).**—A mission church is about to be erected here, from the designs of Messrs. Halliday & Anderson, architects, Cardiff and Llandaff.

**Bickington.**—The new reredos recently erected in the newly-restored parish church of St. Mary's, Bickington, three miles or so distant from Ashburton, has just been wholly completed by the introduction of some sculpture by Mr. Harry Hems, consisting of figures of angels upon pedestals at either side of the base of the central gable, and of three large panels carved in high relief. The scene of the Nativity is in the centre, whilst angels swinging chandeliers occupy the flanking panels at either side. The parishioners are indebted to the Rev. William Smith, their vicar, for the gift of the work.

**Kilburn.**—The Church of St. Paul, Kilburn-square, has just been reopened, after extensive alterations and repairs. The old high pews have given place to modern seats of polished pitch pine, a new aisle has been made in the centre of the nave, a new choir vestry has been made under the south gallery, and the chancel window has been considerably enlarged. The chancel platform has been enlarged, and the altar-rails set forward, and the building has been fitted with Keith's patent heating apparatus. The whole of the interior has been repainted and decorated. The old flooring has been taken up, the accumulated rubbish of fifty years has been carted away, lime concrete has been spread over the whole surface, of the ground, and, after making provision for the free circulation of fresh air beneath, new flooring has been laid. New slating has been put on the roof, and new lead gutters, the old bad compo. has been cut away and replaced by new, the clock face has been renovated, and the whole exterior face of the building has been repainted. The work has been executed from the plans and under the direction of Mr. Alexander N. Hansell, by Mr. R. A. Yerbury, of Kilburn, at a cost of about 930.

**North Witham (Lincolnshire).**—For some months past the parish church has been under repair, and was completed and re-opened on the 15th instant. The nave and chancel are of Norman work, the tower and spire, windows, and roof being of late fourteenth-century work. The walls have been underpinned, and all stone-work carefully repaired, new buttresses, organ-chamber, and vestry being added. The roofs have been reconstructed to old pitch in Dantzic oak, the old lead being recast in churchyard and relaid. The whole of the interior fittings are of oak. The inside walls have been repainted. Mr. Wade, builder, St. Neots, executed the works, under the direction of Mr. Withers, architect, London.

#### RECENT PATENTS.

##### ABSTRACTS OF SPECIFICATIONS.

11,637, Dry Glazing. M. Macleod.

According to this invention, an improved sash bar of zinc or other soft metal is used. This bar is so formed as to allow for the insertion of an iron rod or pipe, or is strengthened by bars of metal or other rigid material of T or H rail, or other forms. Upon this are sprung or slid caps of zinc retained in their places by rivets or by clasps of steel, &c., sprung over the outside of the cap when it is in place. Drip channels are provided for, and brackets or lugs for carrying the improved forms of sash bars are also described.

12,514, Window Sash Fastenings. T. E. Lane.

This fastener is mainly designed to prevent the opening of the windows from without, and for rendering them perfectly draught and snow proof, and

obviating the rattling in windy weather. A lever latch or catch is so made that when it is pulled forward it wedges the sash fast, and slips into a recess fitted to receive it, and by a turn of the front screw the whole fastening is effected.

13,035, Gas Chandeliers and Fittings. G. J. Williams.

The object of this invention is to dispense with the water-slide by employing folding rods or hollow arms jointed like lazy tongs. The arms of the said lazy tongs are hollow, and the gas is led along and through these. Weights are fitted as in ordinary chandeliers.

13,416, Lead Pigments. J. B. Hannay.

It is claimed that by this invention a pure or nearly pure amorphous sulphate of lead is obtained by treating lead compounds, ores, slag, waste, &c., in an improved furnace and by the addition of iron pyrites. A very pure white is said to be obtained.

3,431, Improvements relating to Water-closets. James Duckett.

In these closets, waste water, such as surface, roof, or slop water, is utilised. The trap of the closet is formed with an opening or space, the bottom of which is on a level with the surface of the water, and so large that articles deposited in the trap and incapable of being flushed through the same may be readily removed. The trap and framework for carrying the tipper are constructed of one piece of earthenware, so as to prevent leakage in the joints and to obtain a better base.

6,381, Cement Blocks, &c. F. O. Ferguson.

Instead of the iron or lead pipes attached to buildings, blocks or bricks with hollow tubes or perforations are, according to this invention, used, each fitted so as to form a continuous pipe in any direction, and jointed in cement. This will obviate the necessity of painting, &c., and the tube is far less subject to changes in temperature.

9,908, Cowl or Chimney Cap. H. F. Henry.

According to this invention, a Y-shaped cap is fitted so that the products of combustion will be divided and deflected outward in their passage through the cap. Shields or plates and cones are fitted so as to obtain the greatest force of wind for exhausting the chimney shaft.

#### NEW APPLICATIONS FOR PATENTS.

Sept. 9.—12,195, R. & G. Ellis, "Dog" for Fastening together Timber.—12,207, J. Cartland, Bolts for Doors, &c.—12,239, R. Johnson and T. Benton, Hand Saws.—12,247, A. Spamer, Shaping and Trimming Slate.

Sept. 16.—12,266, J. Bradshaw, Chimney Pot.—12,271, J. Davies, Brick Kilns.—12,279, E. Williams and J. Morgan, Domestic Fire-grates.—12,291, W. Fraser, Automatic Door Closer.—12,301, A. Van Rualte, Steam File Drivers or Hammers.—12,307, J. Peckover, Stone Saws and Sawing Machines.

Sept. 12.—12,328, A. McVie, Fireproof Curtains for Theatres and other Buildings.—12,341, E. Kirby, Window Fastenings.

Sept. 13.—12,362, P. Barrett, Counterbalancing Window Sash.—12,377, T. Sharp, Preventing the Spreading of Fire in Theatres, &c.—12,383, B. Cooker, Protection for Gas-piping in case of Fire.—12,420, G. Paxton, jun., Corrugated Sheet Metal Roofs, &c.—12,434, F. Alford, Ventilator.

Sept. 14.—12,466, R. Hunter, Locks for Doors and Gates.—12,467, A. Winrow and H. Tandy, Brickmaking Machines.—12,488, J. McConnell, Ventilating, Warming, Cooling, &c.

Sept. 15.—12,534, W. Ducker, Portable Buildings.—12,538, G. Redfern, Tile-making Machines.—12,539, G. Redfern, Draught, Wind, Rain, and Fog Excluders for Doors and Windows.

#### PROVISIONAL SPECIFICATIONS ACCEPTED.

10,548, W. Burt and C. Pavn, Sliding Window Sashes, Panels, &c.—10,556, T. Back, jun., Brick and Tile Making Machines.—11,007, C. Riss Bonne, Staircase Lift.—11,045, A. Harris and Others, Window Fastenings.—11,321, W. Harrington, Adjusting and Attaching Door Knobs to Spindles.—11,624, J. Stanna and T. Shillington, Stoves.—10,969, W. Akerman, Roofing Tiles.—11,265, H. Baugert, Flush Bolts.—11,566, R. Breumel, Door Furniture.—11,863, D. Kempeon, Drawback and Rim Locks.

#### COMPLETE SPECIFICATIONS ACCEPTED.

##### Open to Opposition for Two Months.

13,139, A. Berriman, Preventing the Escape of Gas when Taps are left accidentally open.—13,984, W. Lindsay, Moulding Bricks or Blocks.—14,206, R. Lee, Fastenings for Windows.—14,674, W. Scott and Others, Portland Cement, &c.—15,012, H. Macevoy and Others, Portland Cement.—3,390, J. McKee, Register Grates or Stoves for House Fireplaces.—11,839, F. Lyte, Manufacture of Pigments.—14,848, G. Barker, Ventilating Buildings.—15,144, W. Phillips, Water Taps.—9,783, A. Bayer and C. Mott, Cramp for Flooring and Other Woodwork.

### The Student's Column.

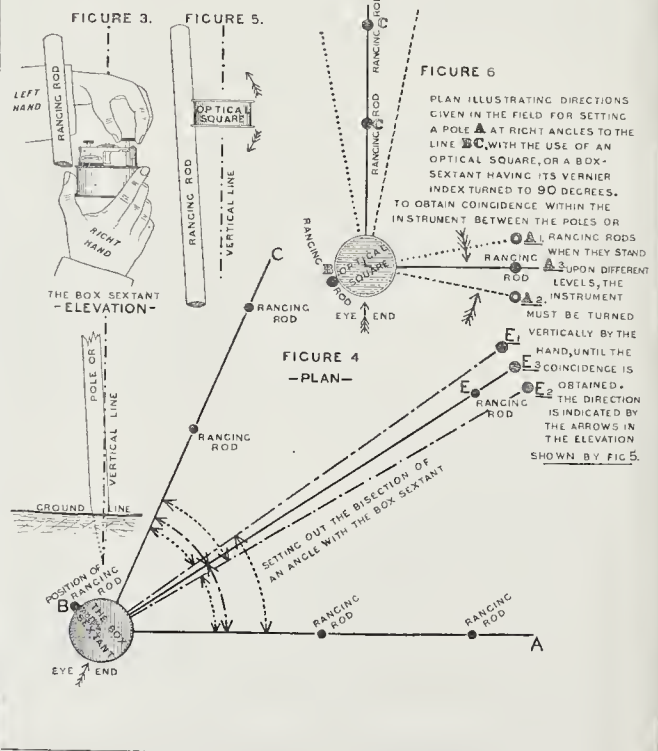

#### LAND SURVEYING AND LEVELLING. XIII.—SETTING OUT CURVES.

THE method illustrated in Case 2 may be adopted when the angle between the tangent lines at their point of intersection is less than  $120^\circ$ , and the radius of the curve to be set out is less than five chains, or 330 ft. The point  $B$  at the intersection of the base-line  $BK$  and  $BJ$  having been determined by placing a ranging rod at  $B$ , so as to appear in the direction of these two lines; a certain distance, say one chain, or two chains, is measured from  $B$  to  $A$ , and the same distance from  $B$  to  $C$  along these base-lines. If the distance between  $B$  and  $C$  be then measured and bisected in  $D$ , and the line joining  $B$  to  $D$  be also measured, we shall have formed two right-angled triangles,  $BDA$  and  $BDC$ , the length of the sides of which will now be known. These lengths can next be employed to calculate the required lengths of the sides  $BF$ ,  $BE$ , and  $BG$ , in the triangles  $BEF$  and  $BEG$ , where  $FE$  and  $FG$  represent the radius of the curve  $FHC$ ; and  $BF$ ,  $BG$  represent respectively the lengths of the tangent lines drawn from their point of intersection to the commencement and end of the curve. It will be seen that the triangle  $BDC$  (or  $BDA$ ) is similar to the triangle  $BEG$  (or  $BEF$ ), because the angles at  $B$  are common to both triangles, and the right angle  $BDC$  (or  $BDA$ ) is equal to the right angle  $BGE$  (or  $BFE$ ).

The required radius is decided upon by experiment. If it is necessary for the curve to pass through or near certain points, such as  $F$ ,  $H$ , and  $G$ , a longer radius would be found to increase the lengths of the lines  $BF$ ,  $BH$ , and  $BG$ , while a shorter radius would reduce the lengths of these lines.

The same length for the tangent lines may be arrived at by the process illustrated in Case 3, but the operation is here assisted by taking the angle between the tangent lines at their point of intersection with an optical instrument, and afterwards calculating the required measurement for the length of the line  $BF$ ,  $BH$ , and  $BG$ , with the use of trigonometrical tables (see *Builder*, Sept. 10, pp. 376, 377).

In the triangle  $BGE$  (fig. 2),  $BG$  would

resent the base, G E the perpendicular, and E the hypothenuse, of a triangle for determining the correct trigonometrical expressions be employed. In the triangle B F E we have F as the base, F E as the perpendicular, and E as the hypothenuse. To determine the length of the tangent lines, B F or B G, we assume a radius which fixes the length of the pole of the triangle denominated as a "perpendicular," and then we calculate the length of the "base," by the application of the equivalent finished by the tables for "the length of the pole divided by the length of the perpendicular," a triangle having the angle F B E. Similarly to determine the length of B H, we calculate the length of the hypothenuse from the assumed length of the perpendicular in the triangle, and subtract from the length of B E the length of the radius H E.

Fig. 3 shows the method of holding the box tangent over the point B in fig. 2, when taking the angle A B C. The value of the angle so obtained is bisected, and the direction of the pole B E is set out by placing a ranging rod anywhere in the line B E, so that the angle B A is half the angle A B C. The position of this line B E should be checked by setting it at the line B E, from the side B C. If any difference is found by this checking, in the position of the pole to be placed upon the line bisecting the angle, A B C, we have only finally fix the pole E midway between the two points arrived at, after taking the half-angle parately upon each side of B E, as indicated by the dotted lines in fig. 4. But when two poles are set up for view upon each of the lines B A and B C respectively, and the pole at E is carefully pulled upon one side out of the perpendicular, as shown in fig. 3, to enable the centre of the instrument to be vertically over the point B, and at the same time in line with the two poles viewed, the angle A B C may be taken with sufficient accuracy by means of a sextant to obtain the half-angle correct enough for all practical purposes.

To determine intermediate points in the curve between F and H, and between G and H (fig. 2), we can apply the formula given in Case 1 (*Builder*, Sept. 17, p. 412), for the measurement of offsets from the tangent lines F B and G B, it will be observed in the diagram which illustrates Case 1, that so long as the tangential angle B A D remains comparatively small, the length calculated for B S may be measured on D at right angles to the tangent line, to determine a point in the curve. Hence, substituting the term "distance" measured along the tangent line for the term "chord" in the equation (Case 1), we obtain for Cases 2 and 3 the formula,—

$$\text{Offset} = \frac{\text{distance}^2}{2 \text{ radius.}}$$

**Books.**

*Common Health.* By B. W. RICHARDSON, M.D., F.R.S. London: Longmans, Green, & Co. 1887.

For the thousands of those who daily move about in their various occupations and constitute our population, how few give even a passing thought to the art of living, beyond what applies to their immediate wants and pleasures. In devoting of any special time or attention to acquiring knowledge on such a subject would seem to many actually ridiculous. The majority of people live their lives in easy ignorance with things as they find them, and he little trouble to acquaint themselves with the physical problems of life. There is no cause now for their being ignorant of the fundamental laws of health, for Dr. Richardson's little book, which he has appropriately dedicated to Mr. Godwin (the late Editor of a *Builder*, one who has spent so much of his life in trying to get people to look at the truth in regard to sanitary matters), will bear more than one reading, so startling is the matter and so binding on the attention.

Dr. Richardson commences his dissertations *in vitro*, and shows into what mistakes we fall during the seedtime of health; perhaps he rather overdraws the picture, for if we are to accept his view as the normal state of things, we would seem matter for wonder that any children at all emerge from that perilous position, let alone in the proper condition of mind for after-life. To childhood succeed vacation and recreation, the latter of which only look upon as a matter of convenience,

while the education is piled on with ruthless disregard to the too often weakly frame that has to bear it; and now that the system of competitive examinations, which formerly only applied to boys and young men, is extended to girls, the evils indeed are more patent than ever. Dress, in all that relates to health, naturally has a chapter devoted to it, and as naturally brings woman to the fore as to her capabilities for nursing and as a sanitary reformer. Upper and Lower, or in other words, London as it should be, is deeply interesting, although perhaps a little Utopian, especially as to the renovation of Upper London. However, it is good to hear such plain speaking as Dr. Richardson gives us, even if a little exaggerated (as all "prophets" do exaggerate), and let us hope that the advocated reforms may soon follow.

*Notes on Concrete and Works in Concrete.* By JOHN NEWMAN, Assoc. M. Inst. C. E. London: E. & F. N. Spon.

A VERY practical little book, carefully compiled, and one which all writers of specifications for concrete work would do well to peruse. The author does not lay down his own opinion without proof, but he gives quotations from various indisputable authorities, and then draws evident conclusions from them. The book contains reliable information for all engaged upon public works. The author deals with the question of the comparative fineness and weight of Portland cement. He shows that to specify too heavy a cement is to invite a manufacturer to deliver residue, and that a weight test alone, without naming a specific degree of fineness, can give no certain indication of strength. He draws attention to the importance of specifying either the number of meshes per lineal inch in a sieve measuring both ways, or else to state the size of the wire in a sieve, and the size of the openings when used for testing the fineness of the grinding in a cement. He recommends that a detailed analysis of the composition of Portland cement should accompany its delivery at the works. The time at which cement is weighed, whether immediately upon its receipt from the manufacturer's or after some days' storage, is also seen to exert an influence upon the result. The period and conditions required for tests of neat cement are further enlarged upon. In a series of very elaborate and useful experiments made by Mr. Grant, of the Metropolitan Board of Works, when acting as resident engineer for the main drainage works of the metropolis, the cement was required to pass through a sieve of 400 holes to the square inch, and the weight of the shifted cement had to be 110½ lb. per struck bushel. At the Dover Harbour works the same degree of fineness was required for a cement weighing 120 lb. a bushel. The cement employed is often stated to be required to pass through a sieve of 2,500 meshes to the inch, leaving a residue of only 10 per cent. These references show how different are the general opinions that are entertained upon the subject, and yet how often, when concrete work is to be specified, the designer takes up the first specification he can lay his hands upon, and blindly copies it, supposing it will be adopted. A perusal of Mr. Newman's valuable little handbook will point out the importance of a more careful investigation of the subject than is usually supposed to be necessary. The author's chapter upon sand, gravel, and stone is thoroughly practical. He also deals with the shipping and air-slacking of cement, the composition, mixing, and setting of concrete in different situations, and the depositing in place by barrows, blocks, and bags.

*Designing Wrought and Cast Iron Structures.* By HENRY ADAMS, M. Inst. C. E., M. Inst. M. E. London: 60, Queen Victoria-street. This little pamphlet, consisting of thirty pages and two large folding plates, forms Part IV. of an instructive series, and contains notes, calculations, tables, stress diagrams, and working drawings for a trussed fir beam with a rolling load, a cast-iron stanchion calculated to bear a required dead load, and the consideration of the arrangement and calculations required in riveted joints. Such pamphlets, containing actual examples which occur in practice, properly worked out, are of great value, but we regret the occurrence of certain misprints, such as on p. 6 the expressions  $\frac{Wl}{70}$  and  $\frac{Wl}{140}$  ought certainly to be reversed for a distributed and

central load respectively. On p. 11, line 2, in describing holding-down bolts, the letter "t" is omitted in the copy before us. On page 12, under the heading "Weight of Structure," the angle-iron 4 in. x 3 in. x ½ = 2 x 2.5 cub. in. x 1 ft. 7 in. long, should be 26 lb., not 8 lb. On p. 13, the item cast-iron strut (exclusive of pattern), 60 lb. at 2d. would be 10s., not 10s. 6d. as stated; and the item, wrought-iron in bolts, nuts, washers, tie-rods, and short pieces angle-iron, weighing 2 cwt. 0 qr. 17 lb. at 20s. would cost 2l. 3s., not 2l. 2s. 1d. Also, same page, the item for flanged rail and bending, 3 cwt. 0 qr. 16 lb., at 10s., would come to 1l. 11s. 6d., not 1l. 11s. 7d. Again, on p. 25, under the heading "Cost of Stanchion," the weight should be 0.31 tons, as stated on p. 12. The decimal point is omitted on p. 13. The author has probably entrusted the working out of his results to an assistant, and not checked them with sufficient care himself. Those who are studying the subject for the first time, can not be otherwise than puzzled at these blemishes, which we trust may be corrected in a future edition.

The author would have done well to explain the introduction of the constant in the expression  $\frac{Wl}{140}$  upon page 6. His remarks upon the use of

double rods in page 9 are very practical. There is an unfortunate ambiguity in the author's description of cruciform and  $\perp$  section stanchions. We think the expression "least breadth," which is usually adopted in the application of Gordon's formula, would be more intelligible than "diameter over arms" upon page 16. When comparing the strength of a cruciform section upon page 18 with a hollow cylindrical column, the author seems to have forgotten that at the commencement of his chapter he led us to judge that he would have said something about the relative strength of an  $\perp$  section. According to Hodgkinson's experiments, the relative strengths are in the following proportions, all the pillars being of the same weight and length and rounded at the ends (see "Phil. Trans." 1840, pp. 413-445).

Hollow cylindrical pillar	— 100
$\perp$ shaped stanchion	— 75
$\perp$ shaped pillar	— 41

Hence the author's remark of "nearly double the strength" upon page 18 applies only to the cruciform section.

**STAINED GLASS.**

*Andover.*—Three stained-glass windows have been placed in the chancel of Christ Church, Swannell, Andover, to the memory of the late Lieut.-Col. Earle. They represent our Saviour's sayings of himself,— "I am the Bread of Life," "I am the true Vine," and "I am the good Shepherd," and were designed by Mr. P. H. Newman. When funds are forthcoming it is proposed to fill the other windows of the building with illustrations of Scriptural allusions to agricultural subjects, as appropriate to the locality.

*Dundee.*—We learn from the *Scotsman* that Messrs. Barnett & Sons, glass-stainers, Leith, have just completed for St. Joseph's Roman Catholic Church, Dundee, a large memorial window, which consists of three lancets, having overhead a circular light in which is represented a dove (emblematic of the Holy Spirit) hovering over the group of figures below. The latter consists of the Virgin with the infant Jesus in her arms, and in the side lights sitting and kneeling figures of saints. The Virgin is represented standing on a globe on which the greater part of the western hemisphere is faintly outlined, her foot upon the head of a twining serpent. In the side lights are representations of St. Anna, St. Joseph, St. John, and St. Dominic. These are flanked by two smaller lancets containing figures of St. Andrew and St. Patrick.

*Taunton.*—A memorial window on the north side of the chancel of the Church of St. Mary Magdalene, Taunton, has just been erected by Messrs. Clayton & Bell. It is a three-light window, representing St. Mary, B.V., in the central compartment, St. Joseph being in the western, and St. John in the eastern light. It is stated that the oak screen, which originally stood in the church, has been erected in Bampton parish church, which has lately been reopened after the completion of repairs and alterations.

*Wangford.*—The old parish church at Wangford, Suffolk, has lately been restored, and a

four-light west window has been erected to the memory of the late Earl of Stradbroke, by the members of his family. The window represents "Our Saviour driving the Money-changers from the Temple" in the left-hand light, while the two centre openings are occupied by the subject of "Solomon Building the Temple" (as appropriate in reference to the recent restoration of the church), and the fourth light represents "The bringing back of the Ark to the Temple by the Priests." These three subjects are surmounted by Perpendicular canopies, having in each case a corresponding base. There is some very intricate tracery in which floating angels bearing shields, with the "Alpha" and "Omega," and emblems of the four Evangelists form the principal part. The window was designed and executed by Messrs. Gibbs & Howard, of London, under the superintendence of Mr. E. L. Blackthorn, architect, of Winchester.

#### RECENT SALES OF PROPERTY. ESTATE EXCHANGE REPORT.

SEPTEMBER 12.	
By WOODS & SMELLING.	
Rotherhithe—13, Prince's-street, freehold .....	£275
By SCROFIELD & EVANS.	
Marylebone—12, Great Chesterfield-street, 11½ years, ground-rent 13s. ....	249
SEPTEMBER 13.

Kingston-on-Thames, Birkenhead-avenue—The residence called "Brooklands," 89 years, ground-rent 10s. 1s. ....	270

#### Miscellaneous.

**Automatic Controlling Appliance for Lightning Conductors.**—The *Electrotechnischer Anzeiger* remarks that lightning conductors have been found defective in one respect, there having been no means of ascertaining whether lightning has been conveyed through them. According to a method patented by Messrs. Hoyer & Glahn (of Schönebeck, on the Elbe), an insulated copper wire is introduced into the conducting apparatus and is wound round an iron core. The core ends in a plate, over which a small magnetic steel plate is suspended. The latter communicates with a registering appliance, by which its movements are recorded. When a current of electricity passes through the conductor the iron core becomes magnetised and attracts the corresponding pole of the small steel plate. After the cessation of the magnetic action the small plate will remain in its position on account of the attraction existing between one of its poles and the iron core previously mentioned. From the position of the indicator it will then be possible afterwards to determine whether lightning has passed through the conductor, and in what direction. In order to restore the appliance to its original condition the indicator is turned back, the small steel plate being thus liberated and again suspended. It is stated that several hundreds of these appliances are already in use.

**Excavations of the Ancient City of Sybaris.**—According to a statement recently made in a Naples journal, the Italian Government has decided upon granting the funds required for excavating the site on which the ancient city of Sybaris stood, the home of the Sybarites, situated in the bay of Taranto. In a work on "Great Greece," the well-known French archaeologist, M. Lenormant, clearly and distinctly fixes the site of the city destroyed some 2,400 years ago, so that no more difficulty is anticipated in finding it than was the case with Olympia. By the bay of Taranto, in the domain which has justly been called Magna Græcia, Sybaris was the leading city, excelling in wealth and magnificence any other Hellenic colony along this lovely coast. However, as is generally known, the effeminate Sybarites were conquered by the inhabitants of the sister town Kroton, the city of Pythagoras. It was razed to the ground, and the ruins caused temporarily to disappear by diverting the waters of the river Kratis across the site. In the course of centuries a layer of earth nine metres in thickness has been formed over the ruins. The destruction of the city took place in the year 510 B.C., but it is nevertheless believed that objects may still be found among the ruins which will give a vivid picture of Hellenic culture and life at that remote period, perhaps as vivid as those of Rome at a later period rendered by Pompeii, particularly as the latter was only a little village, whilst Sybaris was the principal city of the Hellenic colonies in Italy. The ruins of the city are situated near the railway station of Buffalonia, in the fertile valley through which the river Kratis runs, close to the little town of Cassano.

**Destruction of Zinc from Contact with Brickwork.**—The *Deutsche Bauzeitung* remarks that in the Berlin Market Buildings, Nos. II. and III., zinc roofing, which had been laid upon brickwork without the employment of any intervening substance, exhibited after a short time perforations and other signs of injury. These were more particularly apparent at the eaves, and only at the portions where the zinc had been in immediate contact with the brickwork. Analysis proved that the latter contained soluble salts to the extent of 1.14 per cent., and that this proportion was sufficient to cause the injury which had resulted. The destructive process had, moreover, been hastened in its operation by damp from the brickwork which had not completely dried. The use of a layer of *carton-pierre*, or similar material, between the zinc and the brickwork is consequently strongly advocated by Herr Schulze in the above-named journal.

**Whicheor Memorial.**—Our readers will be interested to know that a memorial to the late Mr. John Whicheor, F.S.A., who died January 9th, 1885, aged sixty-one years, has been erected by his widow at Kensal Green Cemetery, where it forms a conspicuous object, the height being 12 ft. 6 in. The material is Portland stone, and the design is by Mr. E. R. Robson, F.S.A.

**Sale of Building Land.**—On Thursday evening last, at the King William the Fourth Tavern, East Greenwich, a sale was held of sixty-one plots of building ground, in Marsh-road, and a newly-formed street leading therefrom, and called Azof-street. The plots were mostly of 15-ft. frontage, and those with a depth of about 50 ft., realised from 42l. to 45l.; those with a depth of 75 ft. to 90 ft., 52l. to 55l. Three front plots, 16 ft. 6 in. frontage and 80 ft. in depth, realised 63l. each. Most of the plots were sold, all of which were charged with a contribution of 4l. each towards roads and sewerage.

**Action of Frost upon Fresh Mortar.**—The *Deutsche Bauzeitung* recently quoted the results of experiments made at Schandau as to the effect produced by adding salt in various proportions to the water used in mixing mortar; the fact that mortar made with sea water resists frost better than that made with fresh water having suggested these tests. Samples were subjected to variations in the winter of at least 14 degrees between day and night temperature (the latter descending as low as 17° F.). Those which had been mixed with fresh water were found after twenty-one days' exposure and seven days' sojourn in a heated room, to have lost their consistency, while those with which salt had been mixed (up to the proportion of eight per cent. of the water) possessed various degrees of resistance, indicating the efficacy of the admixture.

**Registration of Plumbers in Manchester.**—The master and operative plumbers of Manchester last week respectively met to consider the question of registration in the trade, and each meeting has declared in favour of the scheme. The matter is one of considerable public moment, and the present movement is intended not only to raise the status of the craft, but also to afford the public some protection against bad workmanship. The "Worshipful Company of Plumbers" is one of the London Guilds that has endeavoured to make itself really useful to the trade it represents. It is 500 years since the Plumbers' Company made an ordinance that "no one of the trade of plumbers shall meddle with works touching such trade except by the assent of the best and most skilled men in the said trade, testifying that he knows how well and lawfully to do his work, so that the said trade may not be scandalised or the commonalty damaged and deceived by folks who do not know their trade." He would he a bold man who ventured to assert that there are not instances within this district,—not to go further afield,—where the commonalty is "damaged and deceived by folks who do not understand" the trade of plumbing. To say that there are incompetent men and incompetent masters in all trades may be true, but is neither consolatory nor a good argument against the adoption of any feasible plan by which efficient plumbing may be secured. Probably no artisan holds the keys of disease! in his grasp so completely as the plumber, who by good workmanship may exclude forces inimical to health, or by his incompetency may give entrance to malign influences that inflict suffering and even death upon their victims. As the result of the Congress convened by the Plumbers' Company at the Health Exhibition, there has been established a "General Council to secure the greater efficiency of plumbing and draining work in dwelling-houses." This Council includes representatives of the trade and of the general public, and its Registration Committee decides upon the claims of all candidates to be considered masters of their craft. The man who satisfies an impartially constituted body receives a certificate as a registered plumber. Degrees are becoming more varied in form, and R.P. will give the public to understand that the rightful owner of that literal addendum has given substantial proof that he is a master of the art of plumbing. Much will, of course, depend upon the constitution of the Local Council. The Manchester masters have elected twelve representatives, the operative plumbers have nominated the same number, and at a subsequent meeting the public will be asked to appoint a third dozen. In this way the interests of the trade and of the community are harmonised, and the competent workman is duly recognised, and the public safeguarded from absolute ignorance and incapacity.—*Manchester Guardian.*

**Paint for Soft Boards.**—The *Thonindustrie Zeitung* quotes a receipt for a paint, equally effective and durable, which can be applied with an ordinary brush to soft boards:— $\frac{1}{2}$  lb. good jordan's glue,  $1\frac{1}{2}$  oz. powdered hichromate of potash,  $\frac{3}{4}$  oz. aniline brown, 2½ gallons water. These materials are mixed in a metal pot and six hours afterwards heated to boiling point, the mixture being applied at a moderately warm temperature. The object of postponing the heating is to allow the glue to expand and dissolve easily without burning, its cohesive properties being thus unimpaired. In a few days, under the influence of daylight, this coloured paint becomes quite waterproof and insoluble. The above quantity, which would be sufficient for five medium-sized rooms, costs about 3s.

**Protection of Lightning Conductors on Chimneys.**—The *Illustrirte Zeitung für Electroindustrie* recommends the following method of protecting the copper wires of lightning conductors on factory chimneys from being affected by the fire gases to the influence of which they are subjected. The wires thus exposed should be first provided with an insulating covering of india-rubber, over which a protective composition should be applied of the thickness of 2-5 lines of an inch. The latter is prepared by mixing ground fire-brick with finely chopped straw and clay-water into a moderately thick paste. After the composition has dried, asbestos string should be wound round it so as to prevent its crumbling away.

**Romney-on-Sea.**—The Littlestone Estate, which three-quarters of a mile of the town of new Romney, has been laid out as a new watering-place, the land having been disposed of for that purpose by the Corporation of that ancient borough, one of the original Cinque Ports. Between forty and fifty houses have already been erected, and others are being built on the parade facing the sea. The whole of the land is freehold, with the land-tax and redeemed. On the 9th inst. the first portion of the estate was offered for sale at the Railway Station Hotel, Romney-on-Sea. There was a good attendance of visitors, the South-eastern Railway Company having run a special train from Charing Cross and Cannon-street. About eighty plots were laid, including a site for a large hotel on the Parade. This plot, 150 ft. by 150 ft., which realised 950*l.*, was sold subject to the condition that the purchaser is to erect a hotel in accordance with plans approved by the licensing authorities, and for which a provisional licence has been granted. Four corner plots on the Parade, 30 ft. by 80 ft., were sold, three for 25*l.* per plot, and one for 120*l.* Twenty other plots on the Parade were sold; these were 20 ft. by 80 ft., and they realised from 95*l.* to 105*l.* per plot. The other land offered was situated in new roads, at right angles with the sea-front, viz., the Littlestone-road, direct from the sea to Romney to the sea (the railway station in this road, midway between the old town and the sea), the Queen's-road and the Victoria-road. In the Victoria-road and Queen's-road, plots 20 ft. by 150 ft. were sold for 50*l.* per plot. In the Littlestone-road plots 20 ft. by 80 ft. were sold for prices varying from 50*l.* to 57*l.* 10*s.* per plot. With the exception of the hotel plot, the buildings on all the foregoing plots are to be private houses. Near to the railway station in the Littlestone-road fifteen plots were sold for shops, 18 ft. by 120 ft. these realised prices varying from 65*l.* to 75*l.* per plot. It is proposed to offer a second portion of the estate for sale in the spring of next year. The roads of the new town are already completed by gas. The promoters of this enterprise for changing an old Cinque Port which has been quite recently, been without a railway station nearer than fourteen miles, expect that the very extensive sands extending to Dymchurch, three miles to the north, and to Longness, five miles to the south, will prove a great attraction to visitors. At places these sands are nearly a mile wide at low-water, and a country folk tell of races once having been held on them, and they are now used as a playing ground by the neighbouring gentry.

**Copenhagen.**—At the last meeting of the Corporation of Copenhagen, it was decided to erect a new town-hall in that city. It will be situated in a central position facing the Haymarket, and continued to the West Bridge. The building will be located the whole civil administration of the city of Copenhagen. As, however, designs and estimates have to be invited for the new hall, and decided upon, it is probably that the work of erection can be taken in hand before the early part of 1889. On the same occasion the subject of improving the overcrowded and unsanitary part of the city was discussed, as well as the extensive building operations decided upon to be effected during the next few years. There are to be erected a new prison, new workhouses, and barracks, besides which the market-places are to be regulated, the fire-brigade extended and reorganised, the hospital at the Blegdamsenged, and the water and gas supplies of the city extended and improved. The total cost of these extensive works is estimated at about 1,000,000*l.* It was also stated that there were then over 4,000 residences (flats) in Copenhagen, most of which were intended for the humbler classes, being 750 more than the same period of 1886. The medical and hygienic journal *Ugeskrift for Læger* (weekly journal for physicians) recently discussed the proposal for new hospitals in and near Copenhagen, and expressed the opinion that it would far more preferable to erect a number of all buildings than on large one.

**The English Church at Copenhagen.**—A stained-glass windows in the chancel of the church have been presented by Sir Francis Cook, and the west windows by his Excellency Hon. Sir Edmund Monson, K.C.M.G., her Majesty's Minister in Denmark, the whole work being by Messrs. Heaton, Butler, & Bayne, of Brick-street, London.

**The New Post-office Buildings in St. Martin's-le-Grand.**—Active preparations are being made for the commencement of the new Post-office buildings in St. Martin's-le-Grand, and this week the second sale of the materials of the buildings to be removed has taken place. Messrs. Horne, Son, & Eversfield disposed of the materials of the Queen's Hotel, the building known as the Railway Receiving Offices, together with a large block of warehouses and other premises in Angel-street, Bill and Moutb-street, and King Edward-street, previous to the demolition of the buildings and clearing the site. The block at the corner of Bull and Moutb-street and King Edward-street, and also a large block between Angel-street, King Edward-street, and the churchyard of St. Botolph, Aldersgate-street, have already been taken down; and when the materials of the buildings sold this week are removed the entire site for the intended new Post-office buildings will have been cleared, with the exception of the French Protestant Church, which still remains standing, owing, we learn, to a difference between the church authorities and the Post Office as to the sum to be paid by the latter in compensation. It is stated that the Post Office authorities have offered 20,000*l.* for the church and grounds, but that the representatives of the church want 31,000*l.*, and the probability is that the claim will have to be decided by arbitration.

**Proposed Agra Water-works.**—A plan for furnishing Agra with a pure supply of water has been under discussion for some years. Heretofore, however, it has been but a scheme. Now that the Municipality have resolved to push forward the project, it may be considered that there is every prospect of the inhabitants seeing their wishes fulfilled. The source of supply is to be the Jumna, which will provide comparatively clean water, and in sufficient quantity, during ten months of the year, the discharge falling in the hot weather, i.e., May and June, to about 50 ft. per second; and, in addition to the decrease in the supply, the water at this season contains an amount of organic matter. The system of filtration has not been finally settled; the choice is said to lie between the lime and metallic iron processes. The distribution of water is to be effected through twelve miles of piping, furnished with stand-posts on three patterns, viz., the ordinary one with two or four taps, those with roofs and cattle-troughs for bazaars, &c., and others for filling bullock *mussaks* to provide a supply for the outskirts of the town to where the pipes do not lead.—*Indian Engineer.*

**A Dust Destructor for Hornsey.**—The Hornsey Local Board, on Monday night, decided, with only one out of fourteen members in opposition, to adopt the scheme of their surveyor and engineer, Mr. T. de Courcy Meade, C.E., for the erection, at a cost of about 12,000*l.*, of a destructor for cremating the dust and house refuse of the parish of Hornsey, which contains a population of 40,000. Mr. Meade submitted a set of elaborate plans, and his scheme, which was characterised as a most complete one, was adopted in its entirety. The destructor is to be fitted with the Jones's Fume Cremator, and it was asserted by several members who have inspected in various parts of the country that, built upon the lines laid down by the Surveyor, it cannot possibly create any nuisance to the inhabitants. The site selected is on a piece of land abutting on High-street, Hornsey, in close proximity to the mortuary recently erected by Mr. Meade.

**Institution of Mechanical Engineers.**—An ordinary general meeting of this Institution will be held on Friday evening, the 30th of September, at 25, Great George-street, Westminster, by kind permission of the Council of the Institution of Civil Engineers. The chair will be taken by the President, Mr. Edward H. Carbutt, and the discussion will be resumed on the paper read at the Spring meeting on the 17th of May last, by Major English, R.E., entitled "Experiments on the Distribution of Heat in a Stationary Steam-engine." The following paper will be read and discussed, as far as time permits:—"On Irrigating Machinery on the Pacific Coast," by Mr. John Richards, of San Francisco.

**Metallurgy.**—A series of lectures and demonstrations on metallurgy will be commenced at King's College, London, on October 10th, by Professor A. K. Huntington, with the assistance of Mr. W. G. McMillan as demonstrator.

CONTRACTS AND PUBLIC APPOINTMENTS. Epitome of Advertisements in this Number.

CONTRACTS.

Table with columns: Nature of Work, or Materials, By whom required, Architect, Surveyor, or Engineer, Tenders to be delivered, Page.

PUBLIC APPOINTMENTS.

Table with columns: Nature of Appointment, By whom Advertised, Salary, Applications to be in, Page.

HAMPSTEAD.—For building an additional story and other works at West-hill Lodge, Hampstead, for Mr. Horatio Webb, Mr. George Edwards, architect:—

HORSMONDEN (Kent).—For alterations and additions to Sherwood House, for Mr. J. G. Hodgkin, Mr. Thomas Potter, architect, Sevenoaks. Quantities supplied:—

KETERING.—For the erection of club premises in Wellington-street, Kettering, for the Kettering Working Men's Club. Mr. H. A. Cooper, architect. Quantities supplied by architect:—

LAMBETH.—Accepted for pulling down and rebuilding The Angel public-house, Lambeth-walk, for Mr. J. Craigon, Messrs. Stock, Page & Stock, architects, 9, Denmark-street, London Bridge, S.E.:—

LLANDAFF.—For the erection of a billiard-room at Llandaff House, Llandaff, for Mr. John Gunn. Quantities by Mr. Norman Wight, Cardiff. Messrs. Halliday & Anderson, architects, Cardiff and Llandaff:—

LONDON.—For alterations and additions to No. 29, Wimpole-street, W., and stables in rear, for Mr. Leonard Baker, Mr. Alexander Payne and Mr. F. M. Elgood, joint architects:—

LONDON.—For alterations to The Dun Cow, and building two shops adjoining in the Old Kent-road, for Mr. T. Hill, Mr. J. C. Reynolds, architect. Quantities not supplied:—

LONDON.—For fitting up stabling at Pear Tree-street, Goswell-road, E.C., for Messrs. Carter, Paterson, & Co. (Limited), under the superintendence of Mr. William Eve, Union-court, Old Broad-street, E.C.:—

LONDON.—For erecting workshop, &c., at Whistler-street, Drayton Park, N., for Mr. R. C. Halse, under the superintendence of Mr. William Eve, Union-court, Old Broad-street, E.C.:—

LONDON.—For the erection of workshops, warehouses, and show-rooms, in the Westminster Bridge-road, for Messrs. Geo. Wright & Co. Mr. Alfred Parnocott, surveyor, 156, Westminster Bridge-road, S.E.:—

LONDON.—For repairs, &c., at No. 1, Vernon-place, Bloomsbury, for Mr. Cronin, Mr. T. W. Willis, architect:—

LONDON.—For alterations and additions at No. 78, Goswell-road, for the London Provident Building Society, Mr. T. W. Willis, architect:—

LONDON.—Accepted for pulling down and rebuilding The Angel public-house, Lambeth-walk, for Mr. J. Craigon, Messrs. Stock, Page & Stock, architects, 9, Denmark-street, London Bridge, S.E.:—

LONDON.—For alterations and additions to No. 29, Wimpole-street, W., and stables in rear, for Mr. Leonard Baker, Mr. Alexander Payne and Mr. F. M. Elgood, joint architects:—

LONDON.—For alterations to The Dun Cow, and building two shops adjoining in the Old Kent-road, for Mr. T. Hill, Mr. J. C. Reynolds, architect. Quantities not supplied:—

LONDON.—For fitting up stabling at Pear Tree-street, Goswell-road, E.C., for Messrs. Carter, Paterson, & Co. (Limited), under the superintendence of Mr. William Eve, Union-court, Old Broad-street, E.C.:—

LONDON.—For erecting workshop, &c., at Whistler-street, Drayton Park, N., for Mr. R. C. Halse, under the superintendence of Mr. William Eve, Union-court, Old Broad-street, E.C.:—

LONDON.—For the erection of workshops, warehouses, and show-rooms, in the Westminster Bridge-road, for Messrs. Geo. Wright & Co. Mr. Alfred Parnocott, surveyor, 156, Westminster Bridge-road, S.E.:—

LONDON.—For repairs, &c., at No. 1, Vernon-place, Bloomsbury, for Mr. Cronin, Mr. T. W. Willis, architect:—

LONDON.—For alterations and additions at No. 78, Goswell-road, for the London Provident Building Society, Mr. T. W. Willis, architect:—

NORWOOD.—For repairs and alterations to seventeen houses, at Norwood, for Mr. C. Blake, Messrs. J. & J. S. Edmeaton, architects and surveyors:—

ORCHY (Northants).—For the restoration of All Saints' Church, Orton, Northants. Mr. H. A. Cooper, architect, Kettering:—

PADDINGTON.—For repairs, &c., to No. 12, Talbot-square, Paddington, architect:—

PAIGNTON.—For the erection of a photographer's shop and dwelling-house, on the Girston Estate, Paignton, for Mr. Rawlings, Mr. S. Woodbridge, jun., architect, No. 310, High-street, Brentford:—

PENGE.—For alterations and additions to Fern Lodge, Oakfield-road, for Mr. Chas. W. Jefferies, Mr. Alfred Parnocott, surveyor, 156, Westminster Bridge-road:—

ST. LEONARD'S-ON-SEA.—For the erection of new premises, Grand Parade, St. Leonard's-on-Sea, for the London and County Banking Company (Limited), Mr. Richard A. Hill, F.R.I.B.A. (Powell & Hill), architect:—

SOUTHWARK.—For rebuilding premises in Park-street and Stoney-street, Southwark, for Messrs. White & Son, Messrs. J. Anson & Son, architects:—

STRAITFORD.—For the erection of a manufactory at Stratford, Essex. Mr. Edward Monson, jun., A.R.I.B.A., architect, Acton:—

STREATHAM.—For the erection of a new picture-gallery at Park Hill, Streatham-common, S.W., for Mr. Henry Eate, Mr. Sidney R. J. Smith, A.R.I.B.A., architect, 15, York-buildings, Adelphi:—

SUTTON (Surrey).—For alterations and additions to Camden House, Sutton, for Mr. S. Ezekiel, Mr. E. Douglas Hoyaland, architect, 45, Fenchurch-street, E.C. Quantities supplied by Mr. T. Marcus Houghton, Imperial Buildings, Langrate-circus, E.C.:—

TOTTENHAM.—For works in connexion with the widening of Green-lanes, at certain points between the parish boundaries of Finsbury Park and the Alexandra Park, for the Tottenham Local Board of Health, Mr. W. A. H. de Pape, engineer:—

TOTTENHAM.—For the erection of an engine and boiler house, chimney-shaft, water-tower, &c., at the Longwater Pumping Station, for the Tottenham Local Board of Health, Mr. W. A. H. de Pape, engineer:—

TOTTENHAM.—For the erection of a photographer's shop and dwelling-house, on the Girston Estate, Paignton, for Mr. Rawlings, Mr. S. Woodbridge, jun., architect, No. 310, High-street, Brentford:—

NOW READY. F. W. REYNOLDS & CO'S ARCHITECTS' ILLUSTRATED CATALOGUE. Of Contractors and Builders' Hardware, comprising Kitcheners, Ranges, Tiled and other Stoves, Chimney-pieces, Tiles, Locks, Brass-foundry, Ironmongery, Sanitary Goods, &c., &c. 160 pages, and containing over 600 Illustrations. A copy sent post-free on receipt of Trade Card. F. W. REYNOLDS & CO. Wholesale and Export Hardware Merchants, 73, SOUTHWARK ST., LONDON, S.E.

### The Proposed Nicaragua Canal.

For late years so much attention has been paid to the progress of the Panama Canal that the consideration of the rival scheme, the subject of this article, has been comparatively neglected. The United States Government have from time to time caused official surveys to be made across Nicaragua with the view of constructing a canal from the Caribbean Sea to the Pacific Ocean through that country, and we will now endeavour to describe the results achieved.

The general direction taken by all the surveys is from Greytown on the Caribbean Sea to Brito on the Pacific side, taking advantage of the Rio San Juan, Lake Nicaragua, one or two minor streams, and the Rio Grande. They vary considerably, however, as to the methods of constructing the canal, as well as in important details of the line of route. Every scheme comprising the main construction must necessarily have Lake Nicaragua as a summit level of the canal, whilst the Rio San Juan being the outlet of the lake (on the eastern side) must also be largely utilised. The lake is about ninety miles long and from thirty-five to forty-five miles wide, and in the rainy season of 1878 its surface attained an elevation of 110 ft. above the mean level of the sea, which is no doubt a fair maximum. From this it will be seen that a canal without locks is impracticable. The chief points to be attended to, then, are how to convert the Rio San Juan into an arm of the lake in such a direction as to obtain the smallest number of locks, with as little expense, and in as short a distance as possible, on the one side; and as to which of the valleys is to be taken in conjunction with the Rio Grande, with the same objects, on the other.

Col. O. W. Childs, a well-known American engineer, in 1850-51, made the first careful instrumental survey for a canal along this route for the "American Atlantic and Pacific Ship Canal Company."

In 1872-73 Commander E. P. Lull, U.S.N., made a more extended survey, and he proposed that the canal should be made from Greytown, through some small lagoons and hills, joining the San Juan at the junction of that river with the San Juanillo, as indicated by dotted lines on the plan (see next page), and along the valley to Lake Nicaragua, thence across the lake joining the Pacific by means of the valleys of the Rio del Medio and Rio Grande,

to Brito. The total distance of the route would be 180.76 miles, of which 61.7 miles would have to be cut. It was proposed to work the canal by means of twenty-one locks with four dams, the length of the summit level being 102 miles, and the estimated cost of the whole 52,577,718 dol.

In 1880 the United States sent another expedition, under Mr. A. G. Menocal, civil engineer, U.S.N., with a view to further examine the ground on the western section from Lake Nicaragua to Brito. The survey of 1872-73, as we have seen, proposed to make the canal by way of the Rio del Medio and Rio Grande. At the same time it was perfectly well known that the Rio Grande could be approached from the lake up the Rio Lajas. No matter which of these two streams were utilised, the position of the nearest lock to the lake, or, in other words, the westernmost extension of the summit level of the canal, would be identical. The deepest cuttings required to reach this point are, by the Lajas route, 43 ft. 9 in.; by the del Medio, 134 ft.; the length of the respective routes being 17.27 miles and 16.33 miles. The estimated cost of the latter route, however, exceeded that of the former by several millions of dollars; but after mature consideration, and by reason of better natural surface drainage (so essential to the stability of a work of this kind, built in a country subject to a large rainfall), the Rio del Medio route was favoured by the surveyors. On this line no watercourse of considerable size would be taken into the canal, and as its watershed is so small, no fears were entertained of damage from freshets. On the Lajas route the conditions were dissimilar. The Rio Grande, which is a mountain stream of extensive and rapidly-inclined watershed and precipitous channel, approaches the canal from the south-east, and turning to the north-east passes through a narrow valley of a width but little greater than that required for the canal. The channel of the river has an average width of 60 ft., and a depth of from 15 ft. to 20 ft. Col. Childs proposed to receive this stream into the canal by a waste-weir, and he estimated its maximum flow at 5,670 cubic feet per second. Mr. Menocal, in the course of his examination of this district, however, shows that the maximum flow may be as great as 10,000 cubic feet per second; whilst it is clear that so large a volume of water could not be received into the canal, at a time when least needed as a feeder, even under the most favourable conditions of flow, without danger to navigation, and to the stability of the works. This was the greatest objection to the Lajas route, and for the time it was deemed almost insuperable.

The principal object of Mr. Menocal's survey was for the special purpose of ascertaining the practicability of turning the Rio Grande into the Lake, thereby leaving the narrow valley now occupied by its channel across the divide, free for the construction of the canal. This was shown to be quite possible by making a dam across the river and cutting an artificial channel for it into the basin of the Lajas, as shown on the plan. Furthermore, this survey showed the expediency of cutting an artificial channel near the mouth of the Lajas in such a position as to cause the waters of that river to enter the lake about one mile south of its present mouth, thus leaving its bed at this point free for the canal.

The head-waters of the Rio Grande having been disposed of, it is evident that provision must be made for its tributaries. Of these, it is proposed to receive the Espinal (just above the highest lock) into the canal by means of a waste-weir. The other streams would be allowed to empty themselves as at present into the main channel, but in some cases where it seems advisable the canal would cut across sharp curves of the river, and artificial channels would then have to be made to accommodate it. It is proposed to pass some small brooks from the northward under the canal to the river. Seven waste weirs are to be constructed at suitable points for the discharge of surplus water. The survey of 1872-73 proposed to overcome the difference of level between the lake and low tide at Brito by making eleven locks; whilst that of Mr. Menocal provides only four locks, as will be seen on the plan. The lifts proposed are as follows:—For lock No. 7, a variable lift of from 24.2 ft. to 33.18 ft., depending on the state of the tide; for No. 6, 29.7 ft.; for No. 5, 29.7 ft.; for No. 4, 26.4 ft. The estimated cost of the work, following out Mr. Menocal's scheme, is much less than that by way of the Rio del Medio. The survey of 1880 in the main confirmed that of 1872-73 in regard to harbours at either end of the canal, about which there seems to be no serious difficulty.

In 1885 Mr. Menocal was ordered to make another survey, the operations of which were to be confined to the re-location of the eastern section of the canal. Two important modifications of the location of the 1872-73 survey were contemplated, either of which would, if found to be practicable, shorten the distance very materially, simplify the engineering problem by the elimination of sharp curves and by a reduction of the watershed that had to be provided for by the old location, and diminish the cost considerably.

One of these changes consisted in the construction of a dam just below the confluence

of the San Juan and Sarapiquí, by which 22½ additional miles of the San Juan could be made navigable, and the actual canal excavation from the dam to Greytown reduced to about 21 miles through a comparatively level country. Col. Childs had proposed to raise the waters of the river about 14 ft. by the construction of a dam at that point; and later, in 1879, M. Blanchet, an enthusiastic Frenchman, had proposed to convert the river above that point into an extension of the lake by the construction of a dam, 74 ft. high, at the same place.

The other proposed change consisted in taking a line from Greytown direct to the valley of the river San Francisco, and through this valley to the San Juan, instead of joining that river near its confluence with the San Juanillo. The alteration would, of course, necessitate cutting through the divide between the valleys of the San Juanillo and San Francisco.

The first mentioned project failed; for a hill on the right bank of the San Juan, which at first seemed favourable enough, was shown to be surrounded by swamps, and not connected with a continuous range into the interior; whilst on ascending the Sarapiquí for 10 miles no high land was found on either side. It was, therefore, discovered that to raise the water of the San Juan by a dam at that point, as had been so often proposed, was impossible.

The second project fared much better. A systematic survey was carried up the Rio San Francisco and its tributaries leading eastwards, with a view to finding the easiest pass across the divide. About three miles from the San Juan that river divides into two

At length, a suitable way was found across the divide, and the line advanced over it and down the precipitous eastern slope, where a river valley fortunately was found trending for some distance in the direction of Greytown. The elevation of the divide between the western and eastern flowing waters is 280 ft., but as it was found impossible to plan the canal so as to conform to all the turns of the valley, the proposed line cuts several spurs which rise a number of feet above this height. The amount of blasting and excavation required at this point is very considerable, and forms the most expensive item in the estimates; 7,760,312 cubic yards of solid rock must be excavated, the cost of which is estimated at 11,640,468 dollars.

On the eastern slope of the divide, it will be necessary to have a lock (No. 3 on plan). This is the highest lock proposed by the scheme on going from the lake towards Greytown; the summit level of the canal, therefore, is to be preserved from lock No. 4 on the western section to lock No. 3 on the eastern, a distance of 144.8 miles. In order to maintain this level, however, several considerable works have to be executed, the three most important of which are: (1) the construction of a dam across the San Juan, so as to raise its waters to the required height; (2) the cutting through the hills which divide the San Juan from the head of the valley of the San Francisco; and (3) the erection of an embankment across the San Francisco between the place where that stream receives its main tributary and the San Juan.

The site of the dam was fixed at a suitable spot sixty-four miles from the lake (as shown on plan) between two opposite steep and rocky

to insure its safe navigation at night. With ample water power at several points this can be done with but little expense. In 22.37 miles or 57 per cent. of the canal in excavation the prism is large enough for vessels in transit to pass each other; the remaining distance in which large vessels cannot conveniently pass is so divided that the longest is only 3.67 miles in length. The daily water supply is much in excess of that actually required for working the canal. A railroad will be constructed from Greytown to the dam across the Rio San Juan, and between the Lake and Brito.

The estimated cost of the whole is 64,036,197 dollars, which includes 25 per cent. for contingencies and many minor expenses which we have not alluded to. The estimates of the survey of 1872-73 calculated on the same basis and deducted shows a difference in favour of the location of 1885 of 16,921,980 dollars.

The accompanying diagrams represent the designs for the tail-gate of Lock No. 3 of the proposed Nicaragua Ship Canal following out the scheme of Mr. A. C. Menocal in his Report of the 1885 survey. At first he intended to recommend iron sliding gates for all the locks, but for the one in question which, as we have seen, is proposed to have a lift of 53 ft., such gates would not answer. The tail-gate of this lock, with a total height of 88 ft., of which 58 ft. would project out of the water when the lock is empty, required additional provision to counteract possible wind pressure and guide it safely across the chamber. Some difficulty was experienced in setting this point, but eventually Mr. R. E. Penry, Mr. Menocal's principal assistant in the survey, suggested a rolling

branches; the main stream takes a north-westerly direction through a broad and comparatively level valley confined by two ranges of hills, the elevation of the river being about 60 ft. above the sea, having a mean width of about 50 ft. between its clay banks, and a flow in the dry season of not more than 100 cubic feet per second. The other branch, or tributary, runs in an easterly direction through a wide level valley, and in its course receives two or three small creeks. A great deal of attention was paid to this district. It was previously entirely unknown, even to natives. Much of the work was carried on in wet swamps, where travelling was fatiguing in the extreme, officers and men being compelled, in many instances, to go over long distances hurried to the waist in mud and water, with a very uncertain bottom to stand upon. At the summit of some of the elevations, high trees were climbed, in order to obtain a view of the country and make sketches of the high ranges surrounding the valley, and in Mr. Menocal's report he states that this method of obtaining information as to the topography saved much labour, and contributed in a great measure to the favourable results accomplished by the party. He suggests that in making an extensive and detailed topographical survey of that region, where the engineer can only ascertain what lies 10 ft. ahead of him by cutting his way through the dense vegetation, the construction of towers of observation on several prominent points, and perhaps reconnoissances by balloon, would be the means of obtaining readily, and at comparatively small expense, information which would require, by the system he was compelled to adopt for want of other means, many months of arduous labour.

hills, extending on either side to the mountains in the interior. The dam is proposed to be 52 ft. in height, and it will convert the upper valley of the San Juan and that of the San Carlos (a tributary) into an extension of Lake Nicaragua. The valleys of the San Francisco and its chief tributary will also be filled with water, as the hills above alluded to can easily be cut through, and it will be equally practicable to construct the embankment across the San Francisco. The last-mentioned work is proposed to be 6,500 ft. long on the crest, and 51 ft. maximum depth. It having been shown to be possible to extend the summit of the canal to Lock No. 3, the only remaining difficulty is to get rid of the drop to the tide level of the Caribbean Sea. This, Mr. Menocal says, can be done by making three locks, as shown. The drops of these are as follows:—For 26 ft. From Lock No. 1 to Greytown the Lock No. 3, 53 ft.; for No. 2, 27 ft.; for No. 1, canal would pass across the flat basin of the San Juanillo, cutting that stream in several places, and the swamps of the lagoon region. An artificial channel must be cut, south of the canal, to divert the San Juanillo, and another, north of it, to give the Benard lagoon and its tributaries an independent outlet to the sea.

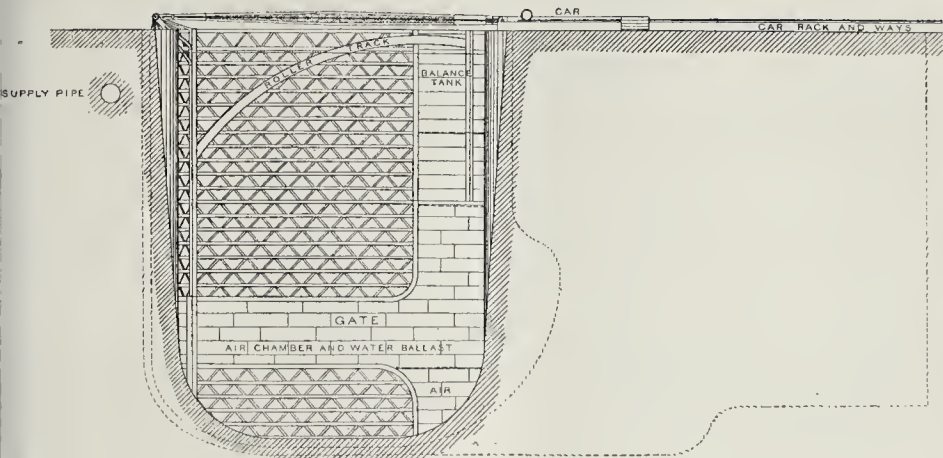

We have now traced the route as proposed by Mr. Menocal from the Pacific to the Atlantic. Its total length is 169.8 miles, of which 28.98 miles are to be excavated canal, and 130.82 miles navigation by Lake Nicaragua, the Rio San Juan, and the basin of the Rio San Francisco; and there are to be seven locks. The time required for a vessel to pass through from Greytown to Brito is estimated at thirty hours. The minimum radius of canal curves is 4,000 ft. Provision has been made for illuminating the route by electricity, wherever necessary, so as

gate which seems to fulfil the requirements of the case.

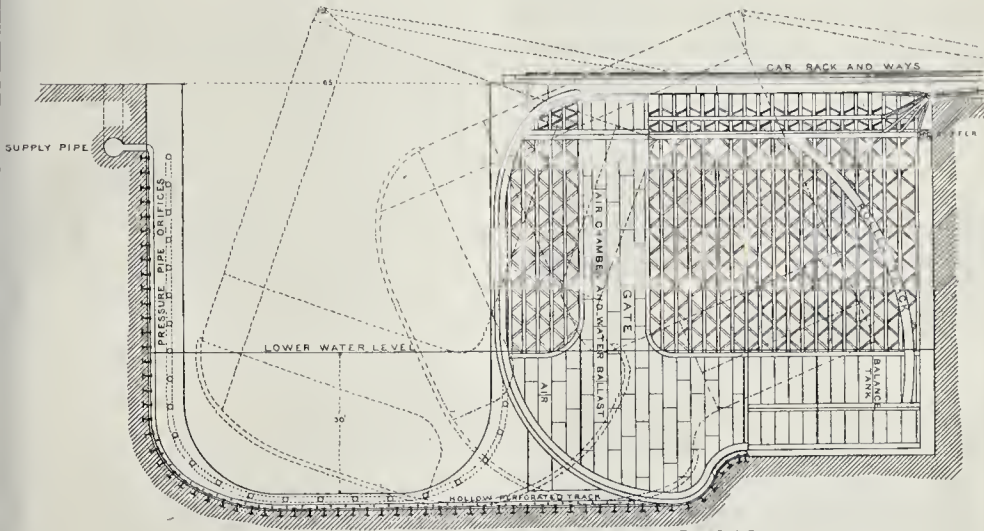

In describing this Mr. Menocal says that the principal device consists of a rolling or tumbling gate; a lateral recess in one side of the lock-chamber into which the gate retreats when opened; rails upon which the gate travels; a car spanning the recess and travelling backwards and forwards upon a track laid on the top of the lock; and a rod strut, or pivoted truss, connecting the car with the gate. In shape, the gate may be described as a rectangular upper portion resting on a curved lower portion, the inner or rear part of this curve being a quadrant of a circle of such radius that the length of the arc of the quadrant is equal to the width of the lock, so that the travel of the gate in rolling through 90° will carry it entirely within the gate recess. The lower part of the gate, to a point 1 ft. or 2 ft. above the lower water-level, and the inner or rear side of the gate will be built as a watertight compartment, to contain a shifting water ballast; the remainder of the gate being open trusses, plated on the down-stream side; the centre of gravity being kept by this means near the centre of the arc on which the gate rolls, and the balance more perfectly maintained. The gate travels preferably on rails raised above the floor of the lock in order to prevent any accumulation of foreign materials upon their surfaces.

Flanges upon the curved bottom of the gate prevent any lateral movement, and any possibility of slipping backward or forward during manoeuvring is precluded by four chains, each equal in length to the arc of the rolling quadrant, arranged in pairs, one pair being attached at one end to the gate at the upper extremity of the quadrant (the

Rolling Lock Gate for Proposed Nicaragua Canal.

gate being closed and erect), and at the other end to the bottom of the lock directly under the lower extremity of the rolling quadrant. The other pair is placed in the reverse direction, and both pairs are so arranged that one unwinds at the same rate that the other is wound up when the gate is in motion.

The action of the connecting-rod or truss will be seen from the diagrams. It is attached to the car, which is a rigid rectangular frame, spanning the gate recess, and supported on trucks travelling on two rails placed at right angles to the axis of the lock, one on each side of the gate recess. Motion is given to this car by a compressed air or hydraulic engine situated on the car, which drives a shaft bearing two drums, and each of these drums carrying several turns of a fixed cable. The gate and car are worked backward and forward by simply reversing the motion of the drums.

One of the most novel points in the gate is that the displacement of the lower water-tight compartment, when the gate is bearing on the rails, will always be largely in excess of the weight of the gate; therefore it is necessary to admit water, and it will be seen that the amount of it may be so regulated that the gate shall exert a pressure of 5 or 50 tons on the rails, or shall just touch them without exerting any pressure at all; in other words the gate may be adjusted to any weight. It may be worked, therefore, with the expenditure of but little more power than is necessary to give it motion. The minor details of the diagrams will sufficiently explain themselves.

In Mr. Menocpi's estimate of the cost of the canal he has simply provided sliding gates for the other locks, though eventually the rolling gate may be universally adopted.

#### NOTES.

**T**HE verdict of manslaughter against the engine-driver of the train which caused the Hexthorpe disaster was a foregone conclusion for every one who could understand the meaning of the evidence. But it shows astonishing blindness and want of perception on the part of the coroner and jury, that they should have entirely passed over, as a matter not worth comment, the conduct of the Railway Company in taking off the safeguard of the usual "hock" working on the very kind of occasion when such a safeguard is above all needed. We have commented strongly on this in a previous number, and we are glad to see that since then the *Times* has also done so in a leading article on the catastrophe. The engine-driver was the person directly culpable, no doubt, as if he had obeyed his orders the accident would not have happened; but a railway company which alters the whole system of working the traffic at the very moment of danger, and takes off the attention of its drivers from the usual system of signals to a temporary and much inferior system (for flags held on the road level are much more easily missed than signals on the ordinary elevated post,—which the driver, besides, knows where to look for), cannot escape the verdict of heavy moral responsibility, and it appears to us to be a matter for legislative interference. A characteristic incident of the inquiry,—what might be called an amusing incident if the occasion had been a less serious one,—was the benevolent speech of the Chairman of the Manchester, Sheffield, and Lincolnshire Railway, Sir E. Watkin, who graciously consoled the relatives of the unfortunate victims with an assurance that his Company did not intend to contest any claims for compensation, well knowing that his Company had not the shadow of a case for contesting them.

**A** REPORT has just appeared on the condition of the working classes which cannot fail to offer much that is interesting, as all information about them must be, although, at the same time, it is rather negative in its character, and, what is worse, not altogether reliable in what it tells us. The main object of the Report appears to be directed

towards the distress which was said to prevail about the time that there was such an outcry last year, and as one parish was as good as another for the purpose, four different industrial districts in London were chosen, containing about 200,000 population. Of course, the whole of these people were not applied to, and out of the rest a good many failed to furnish the necessary information. Altogether, about 29,500 were amenable to being questioned. Of these, 73 per cent. were or had been generally in work, and 27 per cent. out of work, the greater part of them being dock labourers. These latter, indeed, have been worse off than any class of workmen since October 31 last year, when the inquiry was commenced. In the building trade, some of the items look rather formidable, the total of the unemployed dock labourers being 89 per cent., masons and bricklayers 79, painters and glaziers 72, cabinetmakers and turners 61, carpenters and joiners, and blacksmiths and coppersmiths, 29 per cent. Dr. Ogle, of the Census Office, states that there is a marked tendency in many of the answers, especially in the poorer classes, to over-estimate the expenses and under-estimate the resources.

**T**HE Metropolitan Board of Works re-assembles this week, after the recess. The *agenda* paper contains a great many items, but only two or three of them are of general interest. Among the communications to be received is a letter from the Strand District Board of Works "expressing a hope that the Board will not permit any building to be erected on any part of the open space at the Piccadilly end of Shaftesbury Avenue." We have already expressed our hope that nothing of the kind will be permitted. After this bit of common sense from the Strand District Board of Works it is the more unpleasant to read the next item on the *agenda* paper, which refers to a "memorial from residents and ratepayers of St. Mary-le-Strand, asking the [Metropolitan] Board to take into consideration the necessity for widening a portion of the Strand by the removal of the Church of St. Mary-le-Strand." It is but just to the Strand District Board of Works to say that the parish of St. Mary-le-Strand is only one of three parishes represented by the District Board, whose collective wisdom will, we trust, outweigh the proposals of the "residents and ratepayers" of St. Mary-le-Strand. We should like to see their names. To refer to another item on the *agenda*, not very pleasant reading to the majority of the Board must be the "letters from the Vestries of Kensington, Camberwell, Shoreditch, Clerkenwell, Paddington, Hammersmith, and Fulham, and the St. Saviour's, St. Olave's, and Holborn District Boards, in favour of the appointment of a Royal Commission to inquire into the Board's past and present system of dealing with surplus lands, &c." We cannot help thinking that the Board would have gained in public opinion if it had consented to the appointment of the proposed Royal Commission a few months ago. To appoint a committee of its own body, as it did, is very much as if it said, "Let us inquire into and report upon our own conduct." We make the foregoing excerpts from the *agenda*, and supplement them by a running commentary, in full remembrance of the indignation expressed by a member of the Board at what he was pleased to term the "monstrous" conduct of "a paper published on Friday morning" (which answers to our description) commenting, in paragraphs and articles "which must necessarily have been written the day before," on the proceedings of the Board! Does not the member in question know that the *agenda* for the Board's meeting on Friday is always sent to the editors of the London papers on Wednesday? For what purpose is it sent, if not for the public information? Does not the honourable member know that an even more august body than the Metropolitan Board of Works, viz., the House of Commons, issues its "Orders of the Day," "Votes," &c., in advance of its sittings? And did he never read articles in the daily

papers based upon those documents, or forecasting the result of a debate or a division?

**P**ROFESSOR CORFIELD, in a letter to the *Times* of the 26th, explains that at the conference of Medical Officers of Health he did not say, as reported, that "there was not a medical officer present who was not better able to certify (as to the sanitary condition of houses than any half-dozen members of the Institutes of Civil Engineers or Architects," but that, with the exception of some half-dozen engineers who have paid special attention to the sanitation of houses, any properly-qualified medical officer of health was better able to give an opinion as to the sanitary condition of a house, even as regards its drainage arrangements, than any number of civil engineers. Professor Corfield is good enough to make some exception in his remarks as regards architects, and to admit that they are becoming "alive to the importance of constructing houses that are fit to live in." This is very kind of him, but we must still take exception to the view that medical officers are always and all round better judges of such a matter than an architect or engineer. The medical officer knows in what hygienic state he wishes the building to be, but he is by no means necessarily an equally good judge of the efficiency of the mechanical aids provided to regulate draining and ventilation. Many a specious-looking patent contrivance is brought forward, with all kinds of promises as to what it will do, which to any man of mechanical knowledge shows its inherent weakness at once; and on such a point an engineer or an architect is unquestionably a better judge than a man who has had medical training only.

**A** REPORT has been drawn up by Mr. A. Strachan, the able Surveyor to the Chelsea Vestry, on the question of dust collection, and has been printed and circulated, as touching on a matter of public interest. It appears that, in consequence of a number of complaints from inhabitants of Kensal Town about the non-removal of dust, the dust contractor had a special order to clear the dust on certain days from every house in the district, and men were put to check the work done. This supervision disclosed, in the first place, the fact that the contractor had omitted calling at 632 out of a total of 3,180 houses. But the returns of this and of a further and more vigorous collection, when it was proved that every house was called on for its dust, disclosed the fact that for 359 householders who allowed the dust to be removed, no less than 2,549 refused; in round numbers, one in eight saw no necessity for a weekly removal of dust. The answer in many cases was that the dust-hin was "not full yet." The Surveyor proposes that in these circumstances an effort should be made to abolish the brick dust-hin, holding about a cubic yard, and to have zinc covered pails substituted, of such a size as will hold the dust for one week only. The frequent removal would be a necessity then, and the emptying of the zinc pail itself into the cart, instead of carrying out the refuse in separate baskets, would be a much more cleanly method, and give less chance of the scattering and leaving about of unwholesome matter in the process of removal. Mr. Strachan adds the following recommendation:—

"That a few persons be proceeded against before the magistrate for refusing to allow the dust to be removed. By Sec. 126 of the Metropolitan Management Act, 1855, a penalty not exceeding 5*l.* is made the liability of every occupier who refuses or does not permit the dust to be removed from his premises when the dustmen call. The intention of this section was to prevent the householder disposing of his dust to any other than the proper dustman, for it had a monetary value in those days. The section, however, is yet in force, and it can be applied to-day to the higher purpose of compelling the removal of the dust for sanitary, if not for monetary, considerations."

"Is that the law?" as Shylock says. If so, we hope it may be put in force without delay, for the good of the subject, in all quarters of London. The oddest point about the matter is that seven persons out of eight, in a whole

arish, should be so foolish as apparently almost to resent the offer to remove from their houses rubbish which is not only a nuisance, but the keeping of which may be even dangerous to their own health, as well as that of their neighbours.

**SIR SAUL SAMUEL**, Agent-General for New South Wales, has just purchased, for the State House Museum, in Sydney, some interesting and authentic relics of Captain Cook's voyage in the *Endeavour*. Cook gave these to Sir Joseph Banks, who bequeathed them to Dr. Robert Brown. The latter stored them in his Museum, No. 17, Dean-street, Soho, at the rear of, and attached to, Banks's residence in Soho-square. Having lain forgotten during many years in a closed-up cupboard, they were discovered in 1859 by Mr. John Calvert, a subsequent occupant, who bought them, together with other articles associated with Captain Cook and with Banks's domicile here. The house of Sir Joseph Banks, in Soho-square, is No. 32 formerly No. 30, and now the Hospital for Diseases of the Heart. Subsequently to his death here, on the 19th of August, 1820, it was occupied until 1855 by the Linnean Society, founded in 1783, who removed hither from Gerrard-street, Soho. Banks and Dr. Solander, a pupil of Linnæus, were appointed naturalists on the exploring expedition under Lieutenant James Cook's command, which sailed in the *Endeavour*, 370 tons, from Plymouth Sound (1768), to make discoveries in the Pacific and South Seas, and to observe the transit of Venus at Otaheite on June 3rd of the following year. The books and herbarium of Linnæus were offered to Banks for 1,000*l.* They were purchased by Sir John Smith in 1784, at a slight advance beyond that sum, on Banks saying he could not afford to seize so golden an opportunity. Banks devised this house to the Linnean Society. Herein he used to give his week-day breakfasts and Sunday evening *conversazioni* to the Fellows of the Royal Society, whereof he was elected President in 1777, in succession to Sir John Pringle. The name of Banks does not occur in the list of subscribers to "A Voyage to the Pacific Ocean," 1776-80, by Cook and King, edit. 1784; and is not mentioned in that work. The "Mrs. Cook, Mile End-road," is the Captain's widow, then an inmate of the Trinity Almshouses there.

**I**N the course of the construction of a drain at Rome, from the Piazza della Carrette to the Flavian Amphitheatre, the workmen have discovered two large fragments of a fine marble frieze which is thought to represent a Gigantomachia. The two slabs are published in phototype in the last number of the *Bullettino della Commissione Archeologica Comunale* (xv. 8), with an explanatory article by Signor C. L. Visconti. The frieze is undoubtedly of great interest, and of the finest Græco-Roman style, dating probably about the time of Augustus, but we venture to doubt if it represents a Gigantomachia. Since the Pergamene excavations there has been a general tendency to find Gigantomachias everywhere. One of the persons represented is a charming figure of Artemis in short chiton and high boots; she is just in the act of drawing an arrow from her quiver, and the whole pose is closely analogous to that of the "Diana of Versailles" with this peculiarity that the new Artemis is winged. Near her stands a head-draped matronly figure, with the head veiled. Signor Visconti calls her Gaia, the Earth Mother; but her attitude of complete repose is utterly at variance with the regular tradition of the Gaia of the Gigantomachia, who is uniformly represented as a turbulent and agonised suppliant. At the right side of the first fragment the lower part of a figure remains, and a hand holding a mallet, with which he seems to be cutting at a tree, behind two figures, with torches and excited drapery, evidently Furies or Moenads. We can offer no satisfactory solution to the problem; but Signor Visconti's explanation seems to us not only improbable, but impossible. Influenced by his own theory as to the Giganto-

machia, Signor Visconti is inclined to think that the frieze formed part of the elevation of the Temple of Terra, the Earth, founded by the Consul Publius Sempronius, during the war against the Piceni (A.U.C. 484), rebuilt under the auspices of Cicero, 697, and probably again restored by Augustus. Here, again, though the supposition is interesting, anything like proof is wholly wanting.

**I**N clearing the ground for the new Post-office buildings at Aldersgate it is to be hoped that some efforts will be made to examine, if not, indeed, to preserve, a notable relic of the old London Wall. That structure now stands as the southern boundary of the disused burial-grounds of St. Botolph Without, Aldersgate, and Christ Church, Newgate, which have lately been opened for public recreation. This wall is a portion of the length,—Stow gives its measure as 66 perches,—that lay between Aldersgate and Newgate. It is unquestionably a piece of the City wall. But we cannot agree with the *Times*, which says in a recent article upon "Roman London," that "the line of the City wall was, so far as is known, never changed from the time of its first erection." For the original City wall lay entirely within a later line of defence. Long before London received the honourable style of "Augusta" a strong rampart had been placed around the *Atræ* or *Pretorium* which the Romans had planted on the left bank of the Wall brook; and which had Lang bourne to the north and Dowgate and Billingsgate at its southern angles, west and east respectively. This too, be it observed, at a time when the river's northern shore lay further inland than at present. Whether that fortified settlement formed the principal Roman station is open to discussion, since Ptolemy has placed London in the territory of the Cantii, that is, on the southern shore of the Thames. But numerous discoveries tend to show that extensive suburbs had surrounded the citadel by the time of Constantine, and, *teste* Sir William Tite, the later and quite encompassing wall was built during the period 350-369 A.D. Constantine II. and Julian the Apostate were Emperors of Rome in that interval. Circumscribing an area rather less than the 390 acres of Hyde Park, the length of this City wall is variously computed by divers authorities. The return southwards to Mountfitchet (at Blackfriars) from an angle by the present infirmary of Christ Hospital, may be accounted for by the circumstance that here extended the Fleet's steep bluff, along whose elevation the wall was carried. Again, in terms of Edward I's charter *ad hoc* to the Black Friars, it was enlarged so as to include the precincts of their Dominican monastery in its south-western limits. A re-entrant angle was made at the present corner of Little Bridge-street and St. Martin's-court, Ludgate, where, until lately, a portion of the re-constructed wall, east and west, remained above ground.

**A**T the last session of the Berlin Archaeological Society Dr. Furtwängler read a paper which should be widely useful to all amateur collectors of antiquities as well as to the professional archaeologist. He dealt with the unhappily now widespread fraudulent terra cottas from Asia Minor. With the exception of gems there is, perhaps, no class of antiquities as to which deception is so easy. A certain modernness of style even in the originals makes falsification comparatively easy. Unless, however, the impostor is a well-trained archaeologist,—a combination happily rare,—he is sure to blunder in the minutiae of style, and he is apt to introduce motives which do not appear actually until the time of Renaissance work. Such motives Dr. Furtwängler classifies. They principally occur in schemes of drapery, the shape and decoration of armour and utensils. Further, there is another pitfall open to the unwary manufacturer. He sometimes introduces motives which he knows to be antique, but which from other sources it is ascertained were out of fashion at the time, e.g., Charon and his boat, a motive which had disappeared by the date of the originals. Dr. Furtwängler's

long and exhaustive study of terra cottas in connexion with the Sabouroff collection make his opinion of great weight. A report of the paper appears in the Berlin *Wochenschrift*.

**C**ONJECTURE is still busy with the restoration of the Hermes of Praxiteles; indeed, it is a problem of which, till some lucky discovery settles the question, archaeologists are not likely to weary. Flach, in his article on Olympia in Banmeister's last issue of the *Denkmäler des Klassischen Alterthums*, maintains that Hermes is conceived of as cupbearer to the infant god. As such he holds a rhyton, and the little Dionysos a "phiale." The rhyton is natural enough, but the motive of the baby god holding the "phiale" is too formal to be acceptable. We are glad to learn (from the *Berliner Philologische Wochenschrift*, 1887, 38), that Professor Milchoeff, while he brings his high authority to support the rhyton, disallows the "phiale." Hermes, he thinks, holds the rhyton, the little wine-god leans forward to try and get it, but Hermes seems to say, "Not yet; not yet." There is no pouring out of a libation,—a notion utterly inconsistent with the general conception of the group. A paper by Professor Milchoeff, in support of his views, is promised shortly.

**S**OME notable changes have recently been made in the matter of archaeological appointments. Dr. Henzen's recently-lamented death left open, perhaps, the most important and influential archaeological position in Europe,—the Directorship of the German Institute in Rome. This is to be filled by Dr. Petersen. To undertake his new duties, Dr. Petersen resigns the headship of the German Institute at Athens. This falls,—and the appointment must be matter of universal congratulation,—to the eminent architect, Dr. Dörpfeld. Last, but for the future of classical archaeology in England all-important, Professor Percy Gardner leaves the Medal Room of the British Museum to fill the Professorship of Archaeology in Oxford, a chair reconstituted since the resignation of Professor Ramsey. There is great work to be done in Oxford, and there are, happily, no two opinions as to whether Professor Gardner is the man to do it.

**W**E fear that Dr. Lee has not done much good to the cause of economy in Lambeth by his letters in the *Times* against the purchase of land for the proposed Vauxhall Park. We have no doubt he meant well, but it is pretty clear that he has been wrong in some of his facts as to the market value of the land in question. It must be admitted that the fact of a member of the Lambeth Vestry being the owner of the land is, as those in favour of the purchase admit, "unfortunate," and one cannot but think that there has been something "providential," from a Vestry point of view, in the idea of a park at Vauxhall being just now started; but it hardly follows that the purchase of the land and the formation of a park may not be a benefit to the neighbourhood for all that. We imagine it will be so.

**T**HE Richmond and Twickenham Local Authorities, finding that the Thames Conservancy Board refuse to admit the justice of their complaint as to the deplorable condition of the river Thames in their neighbourhood, are organising concerted action for the purpose of promoting a Bill in Parliament for the construction of the often-discussed lock and weir. The Lock and Weir Committee of the Richmond Vestry are now inviting and receiving ideas and proposals from engineers as to a structure which will meet these two conditions,—give the inhabitants in this neighbourhood all the water they desire in the river at low tide, especially during summer; and disturb as little as possible the tidal flow of the river at any period of the year. The contention of the residents of the Richmond district is that, although the recent dredging operations have had the effect of deepening the centre channel, this draws the water from the side shallows and leaves long stretches of muddy banks exposed to view at low tide; and

that these operations have, in fact, been gradually lowering the general level of low tides to such an extent as to expose the foundations of the railway bridge at Richmond. Artists now complain that the river element in the beautiful landscape prospect from Richmond Hill is being destroyed, owing to the narrowing of the stream brought about, not only by the dredging operations, but the filling up of some of the broad reaches, such as that opposite Ham House, with shingle. It is contended that, although all this work is no doubt favourable to the purposes of navigation, the question should be brought to an issue whether the Thames Conservancy Board, in view of the enormous and yearly increasing number of persons who use this portion of the river for purposes of recreation and health, should be permitted to sacrifice the interests of this portion of the community to those of Trade and Commerce. This is, no doubt, a question to be asked. All the engineering authorities to whom we have spoken on the subject are in unison as to the belief that another weir would be detrimental to the tidal portion of the river, by diminishing the "demand," as it is termed, for water, and lessening the scour, and leading to the detriment of the navigable channel in the lower portion of the river; and some, at least, of those who hold this opinion are men of exceptional experience in river engineering. We entirely agree, however, in the opinion that a weir at Richmond would be an immense boon to that beautiful locality in itself, and that the beauty of Richmond is getting seriously deteriorated by the present state of the river; and if it can be satisfactorily shown that a weir can be placed there without injuring the lower river, no one would be more glad to see it than we should.

THERE is satisfaction in noting that our capital city is now, whatever defects still remain, quoted in high (or hygienic) places as a model of sanitary conditions. At the Hygienic Congress at Vienna, Herr Pettenkoffer, lecturing on hygienic education and the necessity of spreading hygienic principles among all classes of society, largely quoted English authorities, and in alluding to the English proverb, "Cleanliness is next to Godliness," remarked that the statistics of the mortality of London show how hygienic piety has been rewarded by Heaven. Here is comfort and encouragement indeed for apostles of hygiene, toiling in the narrow way that leadeth unto life.

#### LETTER FROM PARIS.

THE holiday period in Paris does not take effect, at all events, at the Champs de Mars, where the Exhibition works have proceeded vigorously during the last month. The glass roof of the "Galerie des Expositions Diverses" is just finished, and the great machine gallery is now being taken in hand. The footings for the skewbacks of the immense arch-shaped girders are being formed, and in a short time the huge curves of the wrought-iron principals will be rising into the air. On the other side the levelling of the surface of the Champs de Mars is proceeding, in preparation for the plantations and ornamental gardens which will extend up to the terraces of the Palace. M. Alphand, to whom Paris is indebted for the creation of its modern promenades, has undertaken the personal direction of this portion of the works. The Eiffel Tower proceeds, the four iron columns pursuing their parallel course upwards and growing visibly before the eye. Eight hundred tons of metal have already been placed in position. The whole tower will absorb about 6,600 tons, and at the rate at which the work is going, a height of 75 metres will probably be reached by the end of the year.

In connexion with the Exhibition, it may be mentioned that two architects, M. Lahgée and J. Gilbert, are to submit to the Municipal Council, which has appointed a special committee to deal with it, plans for an "Hôtel International" intended for the delegations of working men who are expected to come to Paris during the year 1889.

We spoke in our last of a grand panorama

which M. Alfred Stevens and M. Gervex were preparing in view of the Exhibition. As a pendant to this, M. Castellani, who has made a speciality of this kind of exhibition, has undertaken the production of an extremely complicated panorama, which he entitles "Tout Paris," and which will certainly be one of the curiosities of 1889. It was to M. Castellani that we were indebted for the curious panorama of the "Monde Anté-diluvien," established in the Jardin d'Acclimatation, and which has fallen a prey to fire. There is also an interesting restoration of the Bastille in process of construction near the Champ de Mars, in the Avenue Laboulaye, which will include not only the too-celebrated fortress, but also the street and the Porte St. Antoine, and the other contiguous streets, with a faithful reproduction of the houses, shops, and signs of the period. This resurrection of a defunct corner of Paris is being made from authentic documents, and in a most realistic manner.

For some time public opinion has been excited by acts of vandalism of the same kind as that of which Carpeaux' famous group of "La Danse" was a victim some fifteen years ago. If it is the fact that political and religious feeling is the cause of the injuries done to statues in some cases, such as the breakages at Luneville and the hostile manifestations made against the statue of Voltaire recently erected in the Jura, one cannot protest too much against acts which give evidence of a spirit quite at variance with civilisation. But there is a kind of financial vandalism which is quite as annoying in its results, and which has succeeded in spoiling the new St. Lazare railway station. Considering the building at the angle of the Rue de Rome, and seeing the pickaxe employed in the demolition of the long pile of houses bordering the Rue St. Lazare, one hoped, according to the designs of M. Lisch, to see extending along the street a fine monumental façade worthy of the importance of the structure and of the situation. And what has happened? The wealthy company of the "Chemins de Fer de l'Ouest," for whom apparently the æsthetic side of things has no interest, while leaving M. Lisch to build his façade, has decided to raise in front of it, along the border of the street, an immense Terminus Hotel 100 metres long and 20 metres high, which will completely mask the station, and present nothing to the eye but an immense square block of stone. The idea of a terminus hotel is a very good one in itself, of course, but it should have been placed at the side, not in the front as it is, to destroy the view of a fine architectural work. It is much to be hoped that the State or Municipal Authorities will interfere, in any future case of the same kind, to prevent such a piece of architectural spoliation of Paris for a mere question of £. s. d.

It is now fifty years that we have been repairing and restoring the Sainte Chapelle, and scaffolding has masked its beauties for half a century. The limited resources at the command of the Commission des Monuments Historiques chiefly account for this unfortunate delay of the work, the completion of which even now seems still a long way off. We may record, however, a vote of 50,000 francs towards it, which will enable M. Boeswillwald to complete the upper portion before long, when it is to be hoped the Government will see its way to further pecuniary sacrifices.

M. Deck, whose appointment as Director of the establishment at Sèvres we announced recently, has taken a step which has given great satisfaction to all the artists and artisans at work there. Under M. Deck's predecessor they were under a rule of military precision during the whole time they were in the establishment, which they could only enter or leave at regulation hours. This annoying discipline has been abolished by the new Director. "Piecework" is re-established, and the painters and modellers attached to the establishment enjoy from henceforth the liberty they have long demanded, and which is in fact almost necessary to the carrying on of artistic work; and under M. Deck's rule we may expect to see Sèvres a genuine atelier, and not a mere "fabrique."

The question of the housing of the Opéra Comique Company is now settled, and in a few days its members will be installed in the Théâtre des Nations, the house which saw the first representation of Gounod's "Faust." As an epilogue to the melancholy tragedy, they are occupied at the Hôtel de Ville about the monn-

ment to those who perished, which is to be erected at Père La Chaise, over the burial space given gratuitously by the Municipality. In the same well-known cemetery there is also to be inaugurated a funeral chapel which M. Aldrophe, the architect, has been commissioned to construct over the tomb of M. Thiers, the former President of the Republic.

This monument, on which M. Chapu and M. Mercié have worked, rises by the side of the cemetery chapel, at the summit of the hill situated opposite the principal entrance of the necropolis. It is of rectangular form, built in Renaissance style; the façade 9 metres in length, and the height 14 metres. In the centre of the principal façade is an arcade, closed by a bronze gate, opening between two Corinthian columns on granite pedestals, and which carry a complete entablature and attic. In the centre of the attic a tablet of green marble bears the following inscription in gold letters: PATRIAM DILEXIT; VERITATEM COLUIT. In the interior four large arches sustain a domical cupola, with a central window, which gives a dim light at once to the chapel and the crypt under it, which is surrounded by a stone balustrade. Access is given to the crypt by a staircase of thirty steps. The cupola is decorated with figures symbolical of Science, Literature, Eloquence, and History, sculptured by M. Mercié on the surfaces of the four pendentives. At the back of the chapel is placed a fine group by the same sculptor, representing "Thiers répondant à l'appel d'immortalité." This short account will in itself give some idea of the importance of this funeral monument, which, from an artistic point of view, is undoubtedly the most remarkable thing in Père La Chaise.

Besides the new Hôtel du Mont de Piété, at the angle of the Rue du Rennes and the Rue du Regard, and which is to be opened in January next, there are several important buildings in prospect. There is, first, a new hospital to be erected in the 10th Arrondissement, and the construction of a new Mairie in the 15th Arrondissement, in place of the wretched little house hitherto devoted to the municipal service of one of the largest districts of Paris. This latter will undoubtedly be the subject of a public competition.

The Municipal Council for its part has decided, as we have already mentioned, on the erection of a School of Typography, to be called the "École du Livre," which is to be built in the 13th Arrondissement, on ground situated at the angle of the Boulevard d'Italie and the Rue de Gentilly. M. C. Lucas, whose name is well known to our readers, has been commissioned to prepare plans for this great establishment, the construction of which will offer, on account of the slope of the ground, considerable difficulties. When the plans are completed and approved by the Prefect of the Seine, they will be submitted to the Municipal Council, which has already created many professional schools in Paris, such as the "École d'Ébénisterie," the "École de Serrurerie" and "de Mécanique," the excellent results of which can now be appreciated. It is also announced that the State proposes to create a Museum of Oriental Art in which all the Oriental work now in the Louvre will be collected, along with that in the Palaces of Compigne and Fontainebleau. This new museum is, however, still only an ideal project, and considering the limited resources of the Ministry of Public Instruction, it is not easy to predict whether or when it can be realised.

It may be of some interest to English readers to give the programme of the course of Instruction in Architecture which has been laid down for M. de Baudot, for his new chair at the Trocadéro, the proper locality for which would be the École des Beaux-Arts.

The course, which fills what has hitherto been a serious gap in the official instruction programme, will include three parts:—

1st part. Exposition of methods of construction, employment of materials, building apparatus (*appareil*), construction and planning of buildings, vaulting, carpentry, removal of rain-water, design of buildings in reference to their purposes; their artistic expression, their decoration, their proportions; drawing and design of mouldings; sculpture in its relation to architecture.

2nd part. Restoration of buildings. Explanations of the restorations undertaken under the auspices of the Commission des Monuments Historiques since its foundation; works required in underpinning; shoring; nodes and

systems of scaffolding; general conduct of building operations.

3rd part. Study of the relations between the Middle Ages and the Renaissance; comparison of buildings of these two periods with each other and with the monuments of earlier epochs.

This course has received the complete approbation of the Commission des Monuments Historiques. It will be supplemented by photographs and drawings, and visits to buildings in progress. M. de Bandot proposes also, by way of giving a practical turn to this new experiment, to organise competitions, the winners of which will have the opportunity of doing work for the Commission and on diocesan buildings.

The "envois" of the students at the Villa Medicea, according to the new regulation of the Académie des Beaux-Arts, will be exhibited for eight days during the latter half of the month of October. In the section of architecture M. Esquie, a four years' pupil, has sent a restoration of the villa of Hadrian at Tivoli; M. Redon (third year), a drawing of the actual state, and a restoration of, the Temple of Concorde; M. d'Espouy (second year), a considerable number of water colours, among which are some interesting studies of interior decoration, as well as some details of the Campo Santo at Pisa; and M. André (first year) has sent drawings of the Tomb of Cecilia Metella and of fragments found in the Forum of Trojan. In the commencement of October will be exhibited the forty-five designs sent in for the Troyon Competition. The premium is 1,200 francs, and the successful work becomes the property of the State. The Académie des Beaux Arts has awarded the Jean Leclaire prize of 1,000 francs to MM. Conin and Marcel Berger, pupils of M. Gandet.

Among other artistic news we may mention the intended transformation of the Arènes de Lutèce into a public square; the discovery at Beaumont-sur-Oise, near Paris, of a Gallo-Roman cemetery; the opening of an Exhibition of Ancient and Modern Engravings in the Galerie Georges Petit, to remain open till the end of November; and lastly, the Commission for two Bnats in Marble for the Opera House, that of Féliçien David by M. Steiner, and that of Tagliani by Mme. Laure Coutan.

The death is announced of an architect of talent who was little known to the younger generation of the present day, but who had a legitimate reputation at the commencement of the reign of Louis Philippe.—Daniel Ramée, who has died at the age of 81. He was much occupied for the Monuments Historiques, and to him we owe the restoration of the Palais de Justice of Beauvais, as well as of many curious churches, such as that of Saint Vulfran at Abbeville, Notre Dame de Noyon, the Church of St. Riquier, that of Sonlis, &c. He was also a very learned writer, who has left numerous works, among which we may mention a general history of architecture, a dictionary of terms used in architecture (in four languages), a history of "Monuments, Anciens et Modernes," a monograph of the Cathedral of Notre Dame de Noyon, &c., &c. He was, in every acceptation of the word, a good man and a conscientious artist and lover of his art.

P.S.—The departure of the Ministre des Travaux Publics for England is announced, accompanied by the Directeur des Chemins-de-Fer. They are to visit successively Liverpool, Glasgow, and Edinburgh, and the London Docks and the Metropolitan Railway. The moving cause of the expedition is understood to be the question of the Paris Metropolitan Railway, which must come before the Legislature again during the ensuing Session.

**Heavy Lightning**—Lord Grimtborpe, a propos of lightning conductors, with his customary courtesy, writes to the *Times* of his opponent's (also a correspondent to the leading journal) desire to "display his own smartness," and speaks of that opponent's opinions as "mere nonsense, due to his ignorance." He concludes, "If he wants the last word, he is welcome to it." Lord Grimtborpe's last word (if really the last) is preferable.—*Punch*.

**Removal**.—Mr. Henry Bassant, parquet floor manufacturer, has removed from 18 Wellington-square, Oxford-street, to new and more commodious premises, 83, Charlotte-street, Fitzroy-square, W.

#### FURTHER NOTES ON THE SANITARY EXHIBITION AT BOLTON.\*

We conclude our notes of the exhibition now being held at Bolton under the auspices of the Sanitary Institute of Great Britain.

Messrs. Carshorne & Co., of the Cement Works, West Hartlepool, exhibit (Stall 6) specimens of cement and concrete in their various applications, and one of Fajja's patent cement-testing machines. The next Stall (7) is that of the Bolton Paint Company, Limited, who have on exhibition some pigments of good colour, together with dryers, varnishes, brushes, and painters' tools generally. The Asbestos Fire-proof Paint Company (Stall 8) exhibit the applications of their material; and some floral panels, stated to be executed with it, seem to show that it is capable of being used in any colour, so that in skilful and artistic hands the best results may be obtained. The Buttermere Green Slate Company, of Koswick (Stall 9), show a piece of roof covered with their slates, which are admirable in texture and colour. At the next Stall (No. 10) the Bell Hill Fire Clay Company, Darwen, exhibit some very good white and coloured enamelled bricks.

Hardie's furnace for burning town refuse is shown in model and by drawings on Stall 13. To describe it in detail would take up more space than we can here devote to it, but the inventor claims that by its use the materials to be burnt are dried in a close chamber, the noxious vapours and gases generated being drawn through the furnace and there consumed, thus avoiding all nuisance. Mr. Hardie's invention is well worth examination at the present time, when increasing difficulties are felt in the disposal of the refuse of large towns in a manner at once economical and inoffensive. We do not pludge ourselves, without further examination, and without learning the results of practical trials, that Mr. Hardie has solved the problem, but he has, at any rate, contributed some suggestions towards its solution.

At Stall 14 is exhibited a model of a double ash-closet, submitted by the Scavenging and Sewage Committee of the Borough of Bolton as a suitable apparatus for use in Lancashire towns where there is no water-carriage system of sewerage, or where water-carriage is only in partial operation. The model represents what appears to be a very simple and effective apparatus. At the next stand, Messrs. James Duckett & Son, of Burnley, exhibit what they call their patent "self-acting water-closet," which is entirely flushed with waste-water. It is only applicable to situations on the ground floor or in the basement, and when it is located on the ground-floor, the "pan," which is oval on plan and vertical in section, is two or three times as deep as the ordinary bopper, in order, while keeping the normal height of seat above the ground-level, to get the trap at a sufficient depth to be flushed by the waste water from slop-sink and yard. No arrangements are made for flushing the sides of the deep vertical oval "pan" which we have described, but it could probably be cleaned by other means when necessary. In the arrangement which would be most often found practicable, the inventor leads the sink-pipe through the house-wall and discharges it over a grid which covers the tilting-box or chamber, which is in stoneware. Inside this tilting-box is the tilting-tank, a scoop-shaped vessel, also of stoneware, nicely poised on brass or gun-metal trunnions so as to tilt and discharge its contents when full, and to immediately return to its position for re-filling. The liquid discharged by the tilting-vessel passes along a trapped stoneware drain-pipe laid at a fall beneath the yard, and so enters the trap at the bottom of the closet "pan" before described, and flushes it. The surface-water from the yard, as well as the rain-water from the roofs, is made to pass through the grid and tilting-tank, and so all available waste-water is made use of for flushing the closet; but there seems to be no provision for catching grease and solid matters coming from the sink, the presence of which might create in time a stoppage in the trap under the w.c. A useful little detail connected with this appliance consists in the brass bolts and nuts which, while effectually preventing the removal of the grid by children, readily permit of its removal when it is necessary to examine the tilting chamber or tank. Other closets of this type, though differing in details, are shown by

other exhibitors, but it is hardly necessary to describe them.

Various forms of dry closet are shown, including the British Sanitary Company's earth closet, Morrell's cinder-sifting closet apparatus and cinder-sifting dustbin, Nicholl's antiseptic sanitary closets, and Monte's earth-closets, all of which have been frequently described and are well known to our readers.

At Stall 20 the International Water and Sewage Purification Company (Limited) exhibit a section of their magnetic spongy-carbon filter as used at the Acton Sewage Works, recently referred to at some length in our columns.

Close by (Stall 80), Mr. J. W. Lovibond, of Salisbury, exhibits a very ingenious instrument which he calls the "Tintometer," which is used not only to determine the colour of water, but is capable of use in a variety of industries,—brewing, dyeing, and bleaching among others. The water of the Croyal shows very badly under the test of this instrument. Those of the Irwell and Thames are not shown.

In the annexe to the Drill Hall there are only one or two exhibits of any interest to our readers. The most notable of these are the "Control Air-propeller," shown by the Control Air Propeller Company, and a very well devised inlet for warm and moist air,—a necessary condition for work in cotton-mills.

While speaking of ventilators we may mention that the Abolus Water Spray Company have, as usual, a very good display of their varied and efficient appliances for warming and ventilating.

Messrs. C. Kite & Co., of Chalton-street, exhibit their admirable under-roof ventilators, and their excellent silent automatic counterpoise ventilator, of the merits of which we have spoken on previous occasions. The latter apparatus is noiseless in action and extremely sensitive, and is now being adopted for the inlets to drain-ventilating pipes, in order effectually to prevent unpleasant consequences (where such inlets are near to windows) in the event of a reversal of the direction of the current of air in the pipe.

Messrs. J. Wright & Co., of Westminster-chambers, exhibit their now almost indispensable fireproof fixing-blocks, of which the latest application is their use as floor joists,—the "fixing-blocks" when so applied taking the form of continuous lengths of the material of which they are made embedded in or keyed into the concrete, the floor-boards being nailed direct to the continuous fixing-blocks thus provided. A specimen piece of floor so constructed is shown by the exhibitors.

Mr. C. H. Sidebotham (Stall 22) exhibits some useful sanitary fittings, but the pedestal closet in stoneware, to be flushed by waste water by a tipping arrangement, does not appear to be by any means perfect. A novelty, shown by this exhibitor, is Wright & Son's "Hair-dressers' Complete Hot-Water Apparatus," which contains in the centre a hot-water boiler, with receptacles for hot-water and soap and brush-holders for three customers at a time. The hot-water receptacles are fitted with wastes, and altogether the apparatus is exceedingly compact and convenient.

Mr. B. Cunden and Messrs. James Vause & Son are large exhibitors, but the articles and appliances they exhibit are, for the most part, those of other makers, and are very well known.

We have now touched upon most of the principal typical exhibits in the departments in which our readers are most fully interested. But Class IV., "Personal Hygiene, Foods, and Disinfectants," is an exceptionally large and interesting one.

We gave a list of the awards in our last. The exhibition will, as then stated, remain open until the evening of Saturday, October 15.

**Changes at the Local Government Board.**—We have reason to believe that, in fulfilment of a recent Treasury minute of reorganisation, some considerable changes will soon be effected in the engineering and medical staffs of the Local Government Board.—*Sanitary Record*.

**Stables at Folkington Manor.**—In our notice of this mansion, which we illustrated in our last, it should have been stated that our last, it should have been stated that the fittings of the stables were supplied by Musgrave & Co. (Limited), of New Bond-street and Belfast. They embody all the latest improvements in such fittings.

\* See *Builder*, p. 422, ante.

The above clauses provide ample means for recovery of the cost of construction of such works as bring the supply into the houses or to stand-posts, whether such supply is obtained by a Rural Sanitary Authority direct or by agreement with a neighbouring Authority or water company. Nothing in these sections, however, provides for cases in which the geological formation or altitude of houses to be supplied prevents the supply of water by means of pipes, either to stand-pipes or into houses. Section 3 of the Public Health (Water) Act, 1878 (framed upon the evidence given before Mr. Alexander Browne's Committee), was intended to deal with cases in which the supply can only be obtained by draw-wells or hand-pumps; but this section has, it appears to me, not been used to the extent which might have been expected, on account of the opposition generally found in rural districts, based on the objection on the part of a ratepayer well supplied with water in one part of a parish to pay for the sinking of wells or fixing of pumps for the benefit of others, perhaps several miles distant. It is true that the Framers of the Act in question foresaw this difficulty, and apparently intended that Sub-section 5 should meet it. Sub-section 5 is as follows:—

"Where the owners of two or more houses have failed to comply with the requirements of the notices served on them under this section, and the Authority might under this Act execute the necessary works for providing a water supply for each house, the Authority may, if it appears to them desirable, and no greater expense would be incurred thereby, execute works for the joint supply of water to those houses, and apportion the expenses as they deem just."

In Section 3 power is given to cause works to be executed (wells to be made) at a cost not exceeding 8l. 13s. 4d., or, in certain cases, 13l. for each house. If water were in all cases sufficiently near the surface to enable a separate well for each house to be sunk for this sum, there would be no difficulty in recovering it by means of a rate of 2d. or 3d. per week on the property benefited. But it is precisely in such districts that a sufficiency of wells (though not necessarily pure) already exists.

It is for cases in which the wells have to be 50 ft., 100 ft., or more in depth, that the power of charging the cost on the property benefited rather than on the whole parish is desirable. At first sight nothing would appear easier than to deal with the matter as follows under Sub-section 5.

Suppose there are ten houses sufficiently near together to use one well, and that such well be made and provided with a pump, or windlass with bucket, chain, &c., at a total cost of 130l. If each house-owner paid 13l. or 3d. per week (Section 3), a water-supply for those ten houses would be provided at the cost of those benefiting from it, without increase of rates, or those receiving no advantage from it, and dwelling perhaps miles from it. For reasons which I do not propose to discuss, Sub-section 5 is not so read, the result being that works are seldom carried out under this section,—a thing much to be regretted, as I believe that much of the opposition which retards, and in some cases prevents entirely, the adoption of some form of public water supply, would be withdrawn if it were possible to work under this section. I do not venture to suggest any special alteration or modification in the wording of this section, but I have drawn attention to the matter, as I believe it to be one with which the future of village water-supply is closely connected.

**A Perpetual Calendar.**—We have received from Messrs. Gordon & Gotch, the publishers, a "Perpetual Dial Calendar," consisting of two cards, turning on the centre, one over the other, and so arranged as to give the day of the week for any date from the year 1753 to the year 2005. It is ingenious, though the only practical advantage of such a thing is when it is required to find the day of the week for a date either far back or far in advance of the existing year, which it is some times necessary to do.

**University College Architectural Lectures.**—"Education, Cultivation, and Examination" is the comprehensive title selected by Professor Roger Smith for the opening lecture of his courses at University College, to be delivered at half-past seven on Wednesday next, the 5th of October. The subject will, of course, be treated mainly as it bears upon the study of architecture. The classes will begin the following week.

#### ARCHITECTURAL ASSOCIATION VISITS.

THE last vacation visit of the Architectural Association was made on Saturday, the 24th inst., to a house in Cadogan-place, built from the designs of Messrs. George and Peto. The exterior is a picturesque treatment of Flemish character, built with red brick and buff terra cotta. The entrance lobby is arranged with a mezzanine bondoir, which is approached by a separate staircase from the hall and opens out into the drawing-room with an arched, forming a kind of gallery. The drawing-room has a very rich plaster ceiling; the staircase is framed of oak, wrought all over with carving; the dining-room is panelled with oak, the upper panels being covered with carving; the billiard-room, over the dining-room, has an open timber roof of oak with a lantern light, a charmingly sunny effect being given by covering the lantern with silver and bronze lacquer; the boys' room, off the billiard-room, is to be panelled throughout. The whole of the house is arranged with a double system of electric and gas lighting, the electricity being generated under the stable by a dynamo and eight-horse-power gas engine. The stables, which are in the rear of the house, and are fitted for eight horses, can be reached by a passage from the dining-room,—a very ingenious piece of planning. The entire house is full of the most piquant and picturesque features, and is certainly the most interesting and complete specimen of a modern town house that the Association has visited. The interest felt was evidenced by the large number of members who attended the visit.

#### Illustrations.

#### DECORATIVE PAINTINGS FOR THE CHURCH OF ST. GREGORY, SUDBURY.

THE designs published in this number are to be painted as wall decorations in this church; they are designed by Mr. Aveling Green, and are to be executed in spirit fresco. The figures are life-size. The following brief notes on the history of the church and neighbourhood, for which we are indebted to Mr. Green, may be of interest:—

The town of Sud- or South Bury was the principal borough of South-east Anglia as far back as A.D. 797, when "The Anglo-Saxon Chronicle" mentions the death of Bishop Alfrin at Sudbury. About the year 970 Æthelric founded a hospital, giving a moiety of Northoe to St. Edmund's Bury and the other to St. Gregory's, Sudbury. Not long after this the Lady Editha, widow of Bethnoth, Duke of East Anglia, bequeathed the land at Weadinga Felder (Waldingfield) to St. Gregory's Church, Sudbyngensis (Sudbury), as her sister had desired on her death-bed. The Count Be(r)thnoth most bravely resisted the Danish invaders, and was killed in battle at Ely, and gave a fine piece of tapestry on which she had worked her husband's exploits. In Domesday Survey St. Gregory's is said to possess fifty acres of land and fifty of meadow. The Manor of Sudbury, with many others was conferred by William I. on Richard de Clare, afterwards Earl of Gloucester and Hereford. Its first charters were granted by this powerful family. In the reign of King John, Amicia, Countess of Clare, gave this church and its property to the Prioress of Eaton, which grant was ratified by Henry II.

Coming down to the later half of the fourteenth century we are probably contemporary with the present building, for it was purchased from the Nuns of Eaton by Simon de Sudbury, afterwards Lord High Chancellor of England and Archbishop of Canterbury, and finally beheaded by the rabble of Wat Tyler's rebellion in 1381.

The present church is mostly in the Early Perpendicular style, and has a very fine tower with a peal of eight bells. It underwent large alterations in pre-Reformation times. The chancel arch is of an earlier date than the piers which support it, and has been spread open to suit its present position. Simon raised the roof of the nave and built the clerestory. The north arcade belongs to A.D. 1350, and the south may be as late as 1530. The fine chancel, with its lofty Perpendicular windows, is 62 ft. long by 21 ft. wide. Its size and length and noble altar may be due to the fact that Simon

of Sudbury established close by the church his father's house stood, now occupied by the Union House. The twenty oaken "Misereere" stalls still retain their original position. The chancel contains a remarkably fine font-cover of rich tracery and tabernacle work, over 12 ft. high, richly painted. This church had fallen into very serious decay, and thirty years ago was closed as being dangerous, but it has been gradually restored to something like its pristine glory under the guidance of Mr. Butterfield, freely and generously given. The area of the church is mainly seated with chairs and every seat is free.

#### "PROPOSED CHURCH OF ST. MICHAEL"

THIS church was designed to be built of stone throughout, and upon ground sloping, so that the eastern chapel would be on a lower level than the rest of the church. Steps from the chancel aisles would lead to a passage under the higher level of the chancel, and so in to the chapel, which would also have an external door.

The drawing from which it is taken was exhibited at the last Royal Academy Exhibition. The author does not give us any information in regard to the locality of the building, and we therefore publish it as an Academy exhibit, with the title under which it was accepted at the Academy.

#### ALL SAINTS CHURCH, SOUTHBEND-ON-SEA.

THE church, of which a view is given in this number, is built of red brick both inside and out. The roofs are covered with Broseley tiles of a purple tint. The accommodation, when complete, will be for 468. The church is seated with chairs. All the roofs inside are boarded on the face of rafters, and ribs planted on the face of boarding, and spaced out into different panels for future decoration. This is done on account of the gun-firing in the neighbourhood, which would bring down the plaster from the roofs. The architect is Mr. James Brooks.

#### THE MONUMENT TO THE LATE MR. WHICHCORD.

WE give this week a view of this monument in Kensal Green Cemetery, referred to in our last issue, which has been designed by Mr. E. R. Robson to the memory of the late Mr. WhicHCord, Fellow and Past-President of the Royal Institute of British Architects.

#### FOUR SOMERSETSHIRE TOWERS.

THE four towers shown here are reduced from measured drawings by Mr. J. Gerhard Tiarke. They are good examples of the architectural characteristics of this class of towers.

#### NORTH PORCH, HARFLEUR.

THE town of Harfleur, as every one knows, is situated a few miles from Havre, and was formerly the chief port at the mouth of the Seine, but, owing to the silting up of the channel, it has been left high and dry, and Havre has taken its place. The town was taken in 1415 by Henry V., after a forty days' siege, and the tradition is that Henry vowed to erect a church in memory of his triumph.

The north aisle of the church, with its fine porch, of which we give a sketch, and the tower, were probably erected in pursuance of this resolve. The body of the church has suffered so much from repairs and decay, that its interest has been nearly obliterated. There are some good timbered houses round about, and the whole place is delightfully picturesque.

F. W.

**Surveyorship, Tiverton.**—On Wednesday, the 21st ult., Mr. John Siddalls, Surveyor and Inspector to the Brownhills Local Board, was elected by the Tiverton Town Council to the office of Borough Surveyor, at a salary of 225l. per annum.

**Balusters and Newels.**—Messrs. Carter & Aynsley send us a volume of designs of balusters and newels kept, we presume, in stock. They do not show anything new or original, but may be useful to select from when it is not deemed necessary to go to the expense of making such things from special designs.

N THE "SANITARY REGISTRATION OF BUILDINGS BILL, 1887.\*

As the Sanitary Registration of Buildings Bill, 1887, has received a good deal of attention in some quarters, while its importance as affecting householders seems to have been lost sight of by those most interested in its provisions, a few remarks on what is proposed to be effected by the Bill may not be inopportune. The object of this Bill is stated to be the compulsory registration of the sanitary condition of all buildings used for certain specified purposes, and the voluntary registration of any other buildings.

A very strong feeling exists, it is thought, that the general sanitary condition of buildings is not what it should be, and as there is at present no means, short of having the building inspected by a professional man at some expense, which enables an intending occupier to know anything of the sanitary condition of the house he proposes to rent; and as, in the case of hotels, asylums, and other buildings of this description, even this protection is not afforded, for it is obviously impossible for every visitor to an hotel, every father who sends his son to school or college, to have the sanitary condition of such buildings examined; it is, therefore, thought that if the owners and occupiers of such buildings could be obliged or encouraged to have their properties inspected, and these inspections registered, such an arrangement would give confidence to the public, and would be of general advantage, both to the users of the buildings and to the owners and occupiers; and it is hoped that when these advantages become apparent, owners of houses not included in the list of those which must be registered compulsorily, would see that it is to their advantage to have their properties registered, and would voluntarily take the same course.

Should it be found possible to draft a Bill which would effect this change in the liability of owners, and oblige them to be able to show the satisfactory sanitary condition of their property at any time, and to do this in a simple and efficacious manner without throwing any undue burden on any person or class of persons, it seems pretty clear that a public benefit would be the result. But whether the Bill lately before Parliament would have the desired effect, or would in itself be a public benefit, may be doubted; and the writer is of opinion that the objections to it, as at present drafted, are many and serious, and it is with them that he now proposes to deal briefly.

The Bill provides that hotels, schools, colleges, hospitals, asylums, and lodging-houses shall be put in a satisfactory sanitary condition and registered; but if it be necessary that these buildings should be certified by a licentiate in sanitary practice, it is equally, if not more, necessary and important that boarding-houses, restaurants, bakeries, butcheries, dairies, and places of whatsoever description where food is collected, stored, or manufactured, and whence it is distributed, should come under the same category. The first-named places are all more or less subject to publicity in cases of illness or epidemic, but how much evil may result from faulty sanitation in the latter, who can say? To trace any illness arising from bad drainage in the buildings named in the Bill is comparatively easy, in those indicated by the writer exceedingly difficult; yet these latter are entirely omitted from the provisions of the Bill.

The Bill is one of registration only; and although the Local Government Board is specified as the authority under which the Bill should be put in force, if it be enacted, no power is given to that body beyond the registration of the acts of the Licentiates in Sanitary Practice, who, so long as they act up to certain very vaguely defined requirements specified in Clause 10, have a free hand and are answerable to nobody, and do not draw their power to act from any authority save that of the Bill itself, and their own ability to obtain a certificate or licence. This seems to be rather an invidious position for a Board entrusted with the supervision of sanitary matters, and as registering machinery only is required, the writer suggests that such machinery already exists in the

persons of the Registrar-General and his Registrars of births, deaths, and marriages; and that this machinery might be used with less friction and to more advantage than that indicated in the Bill.

It is left an open question in the Bill as to who shall bear the expense of the alterations rendered necessary by its provisions, and it may be inferred that, as the occupier would be the person who would have to pay the penalty if the work were not done, and as he would be more easily reached than any other person, he would be made to bear this cost. This does not seem to be just, as, if there be an obligation on the part of somebody, as is certainly implied by the existence of this Bill, that buildings should be in a sanitary condition, such obligation must surely rest with the owner of the building in question; it is, therefore, suggested that it should be a provision of this or any similar Bill, that the occupier should have power to recover from the owner in the same or a similar manner as is provided in Clause 97 of the Metropolitan Building Act.

In like manner no provision is made for the localising of the charges which would be incurred in enforcing the provisions of the Act, in printing and forwarding notices, in registering Licentiates and buildings, and in carrying out the necessary examinations; it is, therefore, suggested that fees should be charged for each of these acts, with the exception of printing and sending notices, and that any expense incurred beyond the amount provided by the fees should be supplied by the department of the Registrar-General, and should be under his control.

In the Bill before us, it is provided that (1) Members of the Royal Institute of British Architects, Members of the Institution of Civil Engineers, and Members of the Royal Institute of Architects of Ireland, who are registered in accordance with this Act as qualified in sanitary practice; (2) Architects and Civil Engineers who have been in practice three years at the passing of this Act, and who shall before the 1st day of January, 1890, prove to the satisfaction of the Local Government Board that their practice as architects or civil engineers has been a *bona-fide* one, and has included the designing and carrying out of constructive works; (3) Sanitary associations incorporated by licence of the Board of Trade; (4) Medical practitioners registered as qualified in sanitary science; (5) Persons who are medical officers of health at the passing of this Act; (6) Such other persons as the Local Government Board may consider qualified, shall receive licences in sanitary practice, and that these licences shall be given free of cost to those who come under Sections 1, 4, and 5 of this clause.

What is intended by the words, "who are registered in accordance with this Act as qualified in sanitary practice," and "registered as qualified in sanitary science," is not very clear. If it be intended that Clause 9 is to refer to those after whose designation this limitation is placed, it refers to the members of the three leading institutions, who must be examined by examiners, themselves unlicensed and unregistered, appointed by the respective institutions, before they can receive licences to practise; while architects and engineers who do not belong to any institution have merely to satisfy the Local Government Board of the *bona fides* of their practice and experience. Sanitary associations and medical officers of health are under no limitations at all, and any other persons whom the Local Government Board may consider qualified will receive licences to practise. If this be the true reading of Clauses Nos. 7, 8, and 9, it is so manifestly absurd that it does not require further comment, especially as medical practitioners are required to be qualified in sanitary science, not in sanitary practice,—a very different thing,—and no provision is made by examination or otherwise for their registration as having this qualification.

If the interpretation given above be the true one, then the order of precedence stands as follows:—1. Sanitary associations; 2. Medical officers of health; 3. Such persons as the Local Government Board may consider qualified; 4. Architects and engineers not members of one of the institutions named; 5. Members of the institutions; 6. Medical practitioners.

The highest place in the list is taken by sanitary associations, who, as corporations, have no knowledge whatever of sanitary matters; who do not deal with these things themselves, but

through their subordinates and officials; who are practically exempt from the penal clauses which are introduced for the punishment of those who contravene the provisions of the Bill; and who are, as corporations, simply collections of business men, who, by joining forces, are able to employ qualified experts to do the necessary work; and who, again as corporations, are able to advertise themselves, which the qualified expert, who does the work, is by professional etiquette prevented from doing. The claim of any corporation to receive a licence in sanitary practice is so utterly absurd that the writer does not think it necessary to carry the argument further, and presumes that he has failed to attach their true meaning to these clauses.

If, however, it be intended that all the persons mentioned should receive licences, the position is not much better; there are other professional members of the institutions named fully as well entitled to practise in sanitary science as their brethren who have attained to full membership, and they cannot do this as corporate members of these institutions, but must get their licences under Section 2, as other architects and engineers. Sanitary associations still retain an equal position with professional men; medical practitioners may be qualified in sanitary science, but are not, unless in a few isolated cases, in sanitary practice, and are therefore not qualified to inspect and superintend work, which, perhaps, more than any other requires practical knowledge to ensure its excellence. Medical officers of health labour under the same disabilities as medical practitioners, and are besides hampered by their official position, and the other persons should not exist as other persons; if they wish to practise they can do so as professional men, or not at all.

To follow these arguments to their conclusion, it is considered that only corporate professional members of the institutions named, to which may be added the Institution of Civil Engineers of Ireland, who have reached the age of twenty-seven years, should receive licences on application; that architects and engineers who come under Section 2 should satisfy the examiners in the same manner as it is here provided that they shall satisfy the Local Government Board; that all other persons shall be required, to pass an examination before they can receive their licences; and that the words "corporations" and "associations" should be entirely removed from the Bill.

If such vague and meagre minimum requirements as those contained in Clause 10 be considered to be a sufficient protection to the public,—and this can only be the case if it be thought that the understanding on this subject is so thorough and general that there can be no difference of opinion,—why introduce any such clause at all? If, on the other hand, this thorough and general consensus of opinion does not exist, it is absolutely necessary that the specification should be as full and ample as it possibly can be on broad lines; and this can be no hardship to anybody, for if the consensus of opinion be general, the specification will be followed naturally and without effort; if the consensus of opinion be not general, or if there be any sanitarians who are ignorant of modern requirements, it is the more necessary that there should be a complete and binding specification, to which reference can be made and from which no divergence can be permitted.

In Clause 14 it is provided that after the lapse of five years a building shall be considered uncertified; also that any alteration to any building which affects the sanitary arrangements of such building shall render the certificate null and void; but no provision is made for enforcing the publication of such alterations, which might easily be carried out without their coming to the knowledge of the Sanitary Registration Authority, or of any person interested in preserving the satisfactory sanitary condition of any building. It is suggested that the builder or any person who carries out such alterations should be bound to inform the Sanitary Registration Authority of such alterations being made, under penalty as for misdemeanour in case of non-compliance with these requirements. As the enactment of such a Bill as that under consideration would be likely to give rise to much advertising of ability and readiness to certify for the condition of buildings by those who are not prevented by professional etiquette from taking this course to make themselves known, it is proposed that a clause should be introduced rendering it penal,

\* On the "Sanitary Registration of Buildings Bill, 1887." From a paper by Mr. Reginald E. Middleton, M.Inst.C.E., M.Inst.M.E., Vice-President of the Civil and Mechanical Engineers' Society. Read at the Congress of the Sanitary Institute of Great Britain at Bolton.

by loss of licence or otherwise, for any licentiate to advertise, or allow to be advertised, his ability and willingness to grant certificates, otherwise than as is provided for in the Bill, that is to say, by the published lists of licentiates; also, as abuses might arise from licentiates who were owners or part-owners or otherwise peculiarly interested in buildings certifying for their own property, it is thought that provision should be made against this danger, by enacting that no licentiate shall grant a certificate for any house or building of which he is the owner or part-owner or in which he has any pecuniary interest other than as an adviser in its construction.

It is not thought advisable that any penalty should be recoverable before a justice of the peace unless he be sitting in court.

The writer trusts that these few remarks may be sufficient to stimulate discussion, and that thereby valuable information may be obtained which may result in a Bill being drafted and eventually enacted, which shall be satisfactory to all persons interested.

#### A NEW CEMENT-GRINDING MILL.

ONE of the most important of building materials in the present day is Portland cement, and its extensive use in the many purposes for which it is employed renders every means of improvement in its quality and in the cost of production a matter of widespread interest to the building trades. In former days the cement was far less carefully burnt than is now the universal practice; and in those days it was sold as it was ground and came from the mills. Now, on the other hand, the practice of sieving has got firm hold amongst the manufacturers, and the tendency to finer and finer sieving increases. The milling thus becomes a serious part of the commercial production, and many firms have made considerable expenditure on trials of new machinery, but hitherto with little practical results. Amongst those who have tried to keep themselves in the van of progress are Messrs. Booth, of Borstal, on the river Medway, which, with the neighbouring Thames, may be looked upon as the birthplace of the Portland cement industry, which has attained to immense dimensions, although the origin itself is within the memory of this generation.

This firm has recently put up one of the composite edge-runner mills of Messrs. Dutrulle & Co., and on Monday, the 10th ult., a large party of cement-makers and factory-managers were present at a crucial trial of the apparatus, which was made by Messrs. Taylor & Neate, at their engineering works at Rochester.

The idea of the new mill is a very simple one: so much so, indeed, that (as is the case with so many good practical inventions) the moment it is seen one wonders that it has never been put into practice before. It may be briefly said to be two pairs of edge-runners working in the same pan. But it is rather more than this, for one couple is composed of two runners of unequal diameters, each running on its own bed, whilst the other pair are runners of equal diameters running on one bed common to both. These beds are in the form of rings, steps. The smallest and lightest runner, on the upper and inner circle, takes the broken-up clinker as the feed falls in. From this step the first crushing is swept by a trailing rake, or scraper, on to the second step, where the materials get crushed down again by the second-sized runner. From this, again, the crushed material is raked off in like manner on to the outer ring, where the two largest edge-runners pulverise it to an almost impalpable powder. The elevators take the final ground materials up to circular sieves, with very fine meshes; and the residue, after sifting, is returned to the mill. No doubt a good deal of the success attained is due to the hard and roughly crystalline structure of the steel used for the facings of the runners, and which wears to an almost granitic surface. But it is clear also that this composite mill is doing the work of three ordinary mills at once, without the time, labour, and expense which would be incurred in transferring the loads under treatment for considerable distances from one ordinary mill to another. Or we may say that the stuff must be kept for at least three times the length of period in a common mortar-mill to grind it down to the same degree of fineness. In fact, more than three times the period would be required, because in the common mortar-mill there would always be a thicker load in the

pan, the intermingled dust in which would keep the surfaces of the edge-runner and the bed apart, and so diminish the speed and capacity of reduction by the mill-stones. In the new mill the full value of the first two runners is got upon the first and second break-downs; and finally only small materials in a thin layer come under the action of the finishing rollers, which are, in this way, able to crush down very rapidly, through the nearness of their surfaces with that of the mill-bed. The Borstal machine is closely housed in a wooden casing, and the whole occupies a very compact space indeed.

In the trials the speed of feeding was very fast, but not too much so for excellent results to be obtained, as was thoroughly demonstrated by the sievings themselves. It is clear, however, that by a little experience the feed can be absolutely adjusted to the exact degree of milling to which the materials should be subjected; and with such care in the setting of the speed of feed, perfect uniformity would be attained in the cement produced. The feed is made direct into a hopper leading to the mill. Of the mill itself, the bed is permanently fixed, and both couples of runners revolve round a central vertical shaft, which can be driven either at top or at bottom by crown-wheels and pinions. The indicator-diairams were taken at the trial by Mr. Neate; and the weighing and sifting was supervised by Mr. Hollick, of Greenwich, one of the visitors present, and well experienced in the manufacture of cement. The results of the engine-power were:—Mean speed of the horizontal two-cylinder engine, 67·4 revolutions per minute; average gross power of right cylinder, 35·5 indicated horse power, of left cylinder, 33·3; total, 68·8 indicated horse power. The power exerted by right cylinder in overcoming friction of the engine and shafting was 11·93; of the left cylinder, 10·87; in all, 22·8 indicated horse-power. The net power, therefore, absorbed by the mill in grinding the materials was, as obtained by deducting friction horse-power from gross horse-power, 46 indicated horse-power for the half-hour run.

The results of the weighing and sifting tests, as weighed by Mr. Hollick, were 39·25 cwt.; the temperature of the cement by centrifuge thermometer, 37·5 degrees; by Fahrenheit thermometer, 99·5 degrees; the weight per bushel, 117 lb. The residue from the cement on sifting through a 150 by 150 mesh sieve, 40 per cent.; through a 80 by 80 mesh sieve, 24 per cent.; and through a 50 by 50 sieve, 12·5 per cent. The net power absorbed per ton of cement ground per hour will be 11·72 actual horse-power.

There were present amongst the visitors and experts Mr. Johnson, of Northfleet; Mr. Courtney, of Sittingbourne; Mr. Hall, of Rugby; Mr. Weigner, Mr. Forney, Mr. Craske, and many others, as well as the patentee, Mr. Dutrulle, and a favourable opinion was expressed without exception by all the practical men.

#### THE WALLS OF CHESTER.

SIR,—In reply to Messrs. Roach Smith and Loftus Brock, in your last number [p. 441], I will reply as briefly as possible, considering the amount of ground to be travelled over.

Mr. Smith, whose letters are always worthy of study and consideration, says it is not the question what the Archaeological Institute thought in 1886, but what they think now. Just so. I have been in communication with many of the members, and they by all means hold the same opinion they did in 1886. Mr. Smith names the impartial verdict of Sir James Picton and Mr. Loftus Brock. The former of these gentlemen, in his last letter on the subject (*Liverpool Courier*, Sept. 17th), says that he will pronounce "no opinion as to the date or the builders" of the walls, but waits further investigations. As Mr. Brock was the only other speaker at Chester, it follows that his *ipse dixit* was by some, perhaps, tacitly acquiesced in (though very few actual members of the Association were present, the bulk being Liverpool visitors), whilst the anti-Roman party were, as I have said elsewhere, by agreement silent.

As to the Jacobean theory, I have never said a word about it one way or the other; but as to the writers on the non-Roman side, they are, at least, as numerous as those on the other. More will be, however, forthcoming immediately.

Mr. Smith quotes a number of examples in

France, &c., of walls built up with the fragments of Roman monuments, but there has been in the cases of many of these towns much discussion, and much doubt as to the age of the walls so built. With regard to the two London instances (Tower-hill and Canonie-street), Mr. J. E. Price, who, on behalf of the Corporation, superintended the excavation of the latter, says in his published report that both may be of the thirteenth century. With the exception of the mortar, they are both similar to Chester.

That the sculpture which Mr. Smith says is a Romano-British girl holding a mirror is not so is the verdict of 99 out of every 100 persons who have seen it. Nearly every one recognises it as a maie, most as an ecclesiastic, and many see the remains of a nimbus round the head, with a vessel holding the consecrated wafer in the hands. It may, no doubt, be perfectly true that Mr. Smith has engraved in the "Collectanea Antiqua" the figure of a girl holding a mirror found at Bordeaux, but it is not like the stone named.

Mr. Smith refers again to the *castra* at Richborough, &c. He said at first that these *castra* had no mortar in their foundations, and consequently that they resembled the wall newly laid here at Chester. I pointed out that they were solidly cemented from summit to base, whereas at Chester there was no mortar whatever, nor had there been, and I asked him if he ever knew of the wall of a Roman *castrum* (not other buildings or aqueducts, &c.) in which there was no mortar used from base to summit? He has not yet answered the question, but says that at Richborough, &c., there are small stones with tiles, and at Chester the stones are large. It is not a question of the size of the stones, or the presence or absence of tiles. Did he ever see the wall of a Roman *castrum* built without mortar? He alludes to the Roman wall, &c., saying I had not considered its large stones. Why the great wall is a solid mass of concrete; the size of the stones is a secondary question. Dr. Bruce, the historian of the wall, has distinctly said that "he did not believe that the Romans ever built a wall without the use of mortar." Mr. Smith will surely accept testimony like this from such a quarter. And with this may be put Mr. Smith's own words on the Chester walls ("Collect. Antiq.," vol. vi., p. 43), "A question naturally arises, not why the prevailing features of Roman mural masonry should be so uniform and so marked, but why that at Chester should form an exception to the general rule." The excavations just made, and those made three or four years since, have answered the question by showing that the wall is not Roman. Mr. Brock, following suit to Mr. Smith's words as above, said in his address at Chester that the Romans had introduced "novelties" into Roman architecture when building this north wall at that place. Has Mr. Brock, any more than Mr. Smith, seen a similar wall in a Roman *castrum*? Has he ever seen in the wall of such a *castrum* a cornice projecting some 18 in. on the exterior, as if purposely to assist an escalade? Or if the Romans had introduced such a feature, would it have been preserved all through the Middle Ages and the Parliamentary war, when it would have been more than ever of advantage to besiegers? Mr. Brock's remarks as to Sir J. Picton I have anticipated in the *Academy* of last week, and replied to in what I have said above on Mr. Smith's letter.

But if this wall be Roman, what will Mr. Brock say to the portion west of the North Gate? In 1883, the inner face of this fell down, and when the necessary repairs were made it was resolved to cut a new passage (or gate) through it. In doing so, it was found that the wall (proper) was, beneath the pavement, nearly hollow; some little distance lower, between the external and internal faces, there was the lower part of an internal older wall, formed of rudely-shaped stones, some 6 in. square, with a quantity of poor mortar, and a "filling in" like the rubble walls of old churches, but percolating water had removed this to the depth of 6 ft. and had thus been the means of bringing down the present interior face. Competent judges decided that this wall was probably Edwardian, but that it could not be earlier than late Norman. The decayed wall was supported to half its height on the outer face by a much newer and sloping one, acting as a buttress, from 4 ft. to 6 ft. wide at the base, and sloping

\* I leave out of the question the town-walls in France, Belgium, &c., which, says Mr. Smith, names as built up of monuments, as the origin of these is disputed.

o a point, which had never been bonded to first name. Mr. Shrubsole passed his arm the space between them. This buttressing was composed of fragments of Roman stones, friezes, split columns, bases, and betones, one of the latter, with an inscription in good preservation, being removed from with close joints and no mortar, much resembling the wall lately laid bare near the creek Tower. Was this low, sloping, and tressing wall of earlier date than the wall which it supported? The mouldings were all new to the inside. Some of the fragments now in the Museum, and I have engraved m, as well as the inscribed tombstone, in "Roman Cheshire." Here is an almost counterpart of the wall lately laid bare, will Mr. Brock assert that the buttressing was Roman, whilst the main one was beyond question of Mediaeval date? A little beyond one of the towers of the wall (Pemberton's tower) there is an inscription which tells us that in 1708 "divers wide breaches in these walls were rebuilt and other decays therein repaired, two thousand yards of the pavement were new flagged or paved, and the whole drained, regulated, and adorned at the expense one thousand pounds or upwards." The vices of the buttressing wall, it being comparatively little worn, suggests at once that it is part of the reparations named as being effected in 1708, for the breach made by the elementarians was certainly not left open that date, whilst as to the *adornments* I take cornice to the east of the north gate to be one them. The wall here was found some three four years since to be exactly like what Sir Picton has described it a few yards distant, double, with an interval between. This was announced to be Mediaeval work of uncertain date. But it was so from the rock surface, though Roman, have been removed from elsewhere. And if so many Roman stones were dug about Chester, as King in his "Vale of the Mersey," and even Dr. Stukeley in his "Itinerary," inform us, there is little difficulty in understanding that the "buttressing" wall I have spoken of, and the cornice and stones at the North Gate, were among the repairs noticed taking place in the reign of Anne. I have felt upon all these at greater length in "Roman Cheshire." I will not dispute Mr. Brock's measurements, &c., but I have not at present time to go into them. The stone reaching the "ecclesiastical" square was, I think, found in the "unmortared" part, near the base of the wall, and near its centre. I hope Mr. Brock will gather from this and my former letter that I believe the newly-excavated portion of the north wall to have been constructed in its present state (or mostly so) immediately after the siege, the North Gate cornice and walls of the "buttressing" wall during the repairs Anne's reign, whilst as to the Roodey stones do not recognise them, either above ground or below 15 ft. beneath ground (where they are usual), as a wall in any sense. They are beside the Roman area, at the corner of a large creek, where the clay bank would be particularly liable, from the tide of the estuary, to have the water of the creek, to be gradually shed away, and they have been placed there to prevent it. Perhaps also they may have been as the abutment of a bridge which crossed the creek, and of which the base of the responding abutment, with possibly intervening piers, may yet be found beneath the creek on which the present walls are built. On old maps, the creek was still a large one Elizabeth's time.

I believe in finding foundations of the Roman walls of Chester, as Mr. Brock does, on the east and north sides, but they will be like those only discovered on the south side, of solid masonry set in massive concrete, with possibly sandstone blocks and tile layers above them.

W. THOMPSON WATKIN.

Liverpool, Sept. 26, 1887.

S.—If I were "at all hazards" to advocate Roman theory, I could find in the removal the northern wall of the *castrum* to its present line from that of Abbey-court, and subsequent enclosure of an extra-mural cemetery ("Roman Cheshire," pp. 87-8), a reason for the presence of Roman tombstones in the northern wall. But that wall is not of Roman date, and at the time the cemetery was inclosed stones would not be so desecrated.

"SHONE'S EJECTORS IN THE RECENT RAINSTORMS."

SIR,—I have read the letter of your correspondent who styles himself "Miscalot Uncivil Engineer," which appears in your last issue [p. 412], in reply to Mr. John Phillips's letter which appeared in your issue of the 17th inst.

Mr. Phillips's primary object in writing to you was, as I believe, to prove the adequacy of the new ejectors—(1) from his own point of view as the engineer who originally suggested them; (2) from the point of view of the Select Committee of the House of Commons which elected to act upon his suggestions.

You will agree with me, Sir, that to judge fairly of the success or non-success of the works at the Houses of Parliament, and of the relative worthlessness of the statements of your correspondent, your readers ought to know what I undertook to do at the Houses of Parliament. Because, if I can prove that I have done what I undertook to do for the Government, I fail to see why, except on one hypothesis, your correspondent or anybody else should deny to Mr. Phillips and myself the gratification we think we are justly entitled to enjoy, in doing for the sanitary world, through you, what notwithstanding the prophecies of a certain clique of engineers to the contrary, the works carried out are, in reality, a great success.

Those of your readers who are really desirous to understand in principle and in detail the nature and character of the important works carried out at the Houses of Parliament, I would respectfully refer to the illustrated "coloured edition" of a work which I have just published through Messrs. E. & F. N. Spon, descriptive of them.

For my present purpose it is sufficient to say that the maximum quantity of sewage and rainfall in combination, which I stated to the First Commissioner of Her Majesty's Works and Public Buildings, that the four *Adkins* gas-engine air-compressors, and the three pneumatic sewage-ejectors, working together, would receive and discharge into the Metropolitan sewer, when that sewer was surcharged with storm-water to the greatest extent ever known or recorded, was 1,200 gallons per minute. Now, the question is this,—Did the gas-engine air-compressors and the pneumatic ejectors discharge this quantity, as Mr. Phillips would have you believe they did, and considerably more, on the 17th ult., when there was a rainfall at the rate of 0.59 in. per hour, or at the rate of 14.16 in. in the twenty-four hours?

I believe they did, because the surface area drained into the ejectors is ten acres, more or less, and this consists for the most part of roofed and paved surfaces over which the rainfall would and does pass extraordinarily rapidly. Of course, if the rain passed from this area to the ejectors as quickly as it fell, the quantity with the sewage would be equal to 2,230 gallons per minute.

Now, whatever the rate was at which that rain reached the ejectors,—and I know from experience it must have been nearly as rapidly as it fell,—the ejectors dealt with the whole of it, with the exception of about 2,000 gallons, as stated by Mr. Phillips. This quantity overflowed, as it was designed to overflow, into what remains of the big old sewer, which is retained specially for the temporary storage of such heavy downpours as I am describing. Not a drop got into the basements.

The Meteorological Office at Westminster gives the rainfall as being 0.59 in. only, whilst Mr. Symonds records it as being 1.42 in. in Camden-square, N.W. The data thus obtained furnish incontrovertible proofs that the plan put down at the Houses of Parliament is able to deal with much more than 1,200 gallons per minute,—the quantity which I stated would be the maximum quantity it would deal with.

In this connexion I desire to state that Sir Robert Rawlinson, in his evidence before the Select Committee of the House of Commons appointed to inquire into this subject, gave it as his opinion, that if pumps, when duplicated, were provided to deal with a maximum quantity of 400 gallons per minute, they would be more than sufficient to deal with the rainfalls stated by the officials of Her Majesty's Office of Works, &c., to be the rainfalls that give trouble, &c.

It is manifest, therefore, that, as I provided power to deal with three times this quantity per minute, and more, the works carried out must be deemed to be adequate for all reasonable rainfalls emergencies; and, if so, is it not almost nonsense for your correspondent to write about "the incapacity of the Shone installation to deal with the rainfall"? What rainfall I ask. Three inches per hour, as stated by your correspondent?

Is there any engineer, in his senses, who would provide pumping power to deal with 3 in. of rainfall per hour, or 11,344 gallons (off the ten acres) every minute, in or out of England?

Your correspondent persists in stating that the inlet and delivery pipes of the Houses of Parliament ejectors are 5 in. in diameter. I ought to know,—and I again assure your correspondent, for the last time, that they are 6 in. in diameter; and as he admitted at the meeting of the Society of Engineers that the installation, as existing at the Houses of Parliament, would deal with 1,000 gallons per minute; and as the capacity of pipes to receive and discharge sewage varies as the square root of the fifth power of their diameters, it follows that

the installation after all, according to your correspondent's own calculation, will deal with 1,577 gallons per minute.

ISAAC SHONE.

SIR,—From your correspondent's letter at p. 412 in last week's *Builder*, he evidently thinks that I was present at the meeting he refers to. I had to say I was not, and know nothing of the assertions he indulged in at that meeting.

For some years past certain engineers have opposed the adoption of Mr. Shone's ejectors, not by fair criticism, but by distorted statements. It is charitable to suppose that some have done this because they are unacquainted with the true principles and capabilities of the ejectors, and therefore are unable to distinguish right from wrong in regard to them.

Your correspondent has mistaken the 6-in. receiving and discharging pipes of the ejectors for 5-in. pipes. On this false datum he has soared away into the regions of imagination, and it would be unprofitable labour to follow him in his wanderings. The ejectors are now largely in demand, and the more their merits are known and understood, the more they will be employed.

In my former letter, at p. 411 in the *Builder* of the 17th Sept., I described a few undeniable facts in regard to what the ejectors successfully accomplished during a most trying ordeal on the 17th August. It is very likely that during the two minutes when the 2,000 gallons of water overflowed into the subway reservoir, twice the registered rainfall in Westminster came down, namely 2 + .59 = 1.18 in. per hour, for at Battersea and at Camden Town more than 1½ in. per hour was registered during the same rain-storm. With the probable rainfall of 1.18 in. per hour, the basements of the Houses of Parliament were not flooded, nor would they have been had 2 in. per hour fallen for a short time, as the subway reservoir would have contained the surplus water which the ejectors could not then have discharged without the head of water therein reaching the basement levels.

Whoever has a desire to know what the performance of the ejectors was on the day referred to,—and was far beyond what they were designed to perform,—would do well to refer to my previous letter.

JOHN PHILLIPS, C.E.

REFUSE DESTRUCTORS AND CREMATORS.

SIR,—My attention has been drawn to a report of the paper read by Mr. Jones, of Ealing, before the Association of Municipal and Sanitary Engineers at West Bromwich. [See *Builder*, p. 303, ante.] I consider Mr. Jones's criticisms on all destructors, but one most unfair, and I take it that his paper, as a whole, is more in the form of an advertising lecture than a *résumé* of what has been accomplished by "refuse destructors and their results up to the present time."

I do not intend to wade through the whole of what I term an egotistical production of a self-styled "Author," but rather to refer to the remarks on the system named the "Beehive," which I have patented.

Mr. Jones says, "In the valuable digest prepared by Mr. Clavey, of Burton-upon-Trent, for his Board in 1886, under the head of Buryley, where the 'Beehive' was first used, he is born in answer to the query as to whether 'the destructor gives satisfaction,' the reply is, 'It gives every satisfaction'; and on turning to Leicester, where it was in the hands of one of our most experienced officers, I find the reply to the same question as follows, 'That the 'Beehive' does not give satisfaction.'"

Now, Mr. Jones throws a doubt on the accuracy of the reply from Buryley, but I can inform him that the answer above quoted is perfectly correct, and was returned by me, and I defy Mr. Jones or any other person who has visited Buryley and inspected the "Beehive" to give any evidence to the contrary.

He also refers to Richmond and Bradford, but has not been sufficiently explicit in his details to show the reason why the "Beehive" has failed at these places; and I consider this a want of fairness on his part. Nor can I understand how Mr. Jones should be of the opinion, through his visit to Buryley, that the destructor was not a success; though I can now account for its non-success at Richmond, when it has to be judged by a critic who had an interest in another similar invention.

How is it Mr. Jones has not told us more about his own cremator and its working at Blackburn?

In looking over the columns of the *Blackburn Standard* of February 5th, 1887, I find these remarks applied to the so-called Cremator:—"Since the last Council meeting I have examined the Cremator, and found it doing little or no work at all. The nuisance was as bad that week as it was before."

This is a quotation from one of the Councillors of that town, and I presume it applies to this celebrated Cremator as patented by Mr. Jones, who went to Blackburn to inspect it after its erection in December last, and approved of its working.

In conclusion, I consider that if Mr. Jones wishes to criticise inventions, he should go into all the facts of the case, and not pick out matters detrimental to one and of value to others.

JOHN E. STAFFORD.

**SETTING OUT CURVES**

CALCULATION OF OFFSETS—IF R=RADIUS, AND L=LENGTH OF THE TANGENT LINE MEASURED FROM THE BEGINNING OR THE END OF THE CURVE TO THE POINT WHERE THE OFFSET IS TAKEN, THEN THE LENGTH OF THE OFFSET =  $R - \sqrt{R^2 - L^2}$

—TABLE OF OFFSETS FOR CURVES—

POSITION OF OFFSET	LENGTH OF TANGENT LINE	LENGTH OF OFFSET IN CHAINS
M N°1	Rx17.36	Rx1.60
N N°2	Rx34.20	Rx6.10
O N°3	Rx50.00	Rx13.40
P N°4	Rx64.28	Rx23.40
O N°5	Px76.60	Rx35.80
L R N°6	Rx86.60	Rx50.00

NOTE—TABLES FOR SETTING OUT CURVES BY OFFSETS ARE PUBLISHED BY E. & F. NEWMAN, LTD. THE OFFSETS IN THESE TABLES ARE BASED ON THE FOLLOWING ASSUMPTIONS:—(1) THE CURVES ARE OF 40 TO 5000 FEET RADIUS; (2) THE TANGENT LINE IS 100 FEET LONG; (3) THE CURVE IS SET OUT BY THE METHOD OF THE TANGENT LINE; (4) THE CURVE IS SET OUT BY THE METHOD OF THE TANGENT LINE; (5) THE CURVE IS SET OUT BY THE METHOD OF THE TANGENT LINE.

FIGURE 2 RADIUS=R LENGTH OF CHORD HC=C

$EJ = \sqrt{R^2 - L^2}$  AND  $JF = R - EJ$   
 $KL = \sqrt{R^2 - JK^2} - EJ$   
 $MN = \sqrt{R^2 - JM^2} - EJ$

$EO = EC^2 - OC^2$   
 OFFSET CB = RADIUS - EO

**THEATRE DOORS.**

SIR,—Your correspondent "Playgoer," in his otherwise admirable letter [p. 442, ante], is mistaken in saying that the form of door-fastenings arranged by me at Mr. Walter Emden's suggestion "is no new idea."\* You were good enough to inspect the full size model of the arrangement, and as a result of that inspection the *Builder* says that the invention "is entirely new in the principle and manner of working."

The object sought and now obtained was to have a concealed fastening which (1) would give way upon pressure being applied against the inside of the door; (2) could not be opened from the outside except by its own key; but (3) could never be locked, either on the inside or the outside, so as to prevent inside pressure opening the door.

If your correspondent will kindly call here and see the simple apparatus he will be in a better position to judge of its merits; or if he will state where such doors, as he thinks, have previously been in use, I shall be glad to inspect them and see wherein the new door differs.

GEORGE HATTEY CHUBB.

**"DESIGNING WROUGHT AND CAST IRON STRUCTURES."**

SIR,—I thank your reviewer for pointing out some printers' and clerical errors in Part iv. of "Designing Ironwork." W<sub>1</sub> on p. 6 should be W<sub>2</sub> 270 the constant being taken from previous notes of actual weights. The other corrections are self-evident.

I do not wish to retort with a "tu quoque," but in the review \*\* should be H; p. 12 should be p. 24; and the reference to p. 13 is imaginary.

HENRY ADAMS.

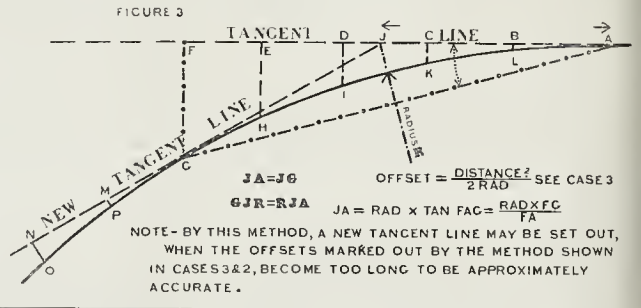

\*\* We are glad to receive the author's correction of the formula upon page 6. Our other references to pages agree with the copy sent to us; but we acknowledge that the section shown thus H by our printers was intended by us to be thus, H, as pointed out by Mr. Adams.

**SELENITIC MORTAR.**

SIR,—Our attention has been called to the advice given in Mr. Leaning's book, "The Duties of a Clerk of Works," to "avoid use of selenitic lime for lathed work," and to "Architect's" letter which appeared in your issue of Sept. 10th [p. 378].

We find that practical plasterers who understand the use of selenitic, entirely concur in "Architect's" views, and are strongly in favour of using this material with proper proportions of hair and putty for both the pricking-up and the floating coats on lathed work.

\* We pointed this out in our comment on "Playgoer's" letter.—Ed.

NOTE—BY THIS METHOD, A NEW TANGENT LINE MAY BE SET OUT, WHEN THE OFFSETS MARKED OUT BY THE METHOD SHOWN IN CASES 3 & 2, BECOME TOO LONG TO BE APPROXIMATELY ACCURATE.

Capital work of this kind is being done with scientific every day, and we suspect some had work, done either by inexperienced men or with an inferior quality of scientific, is the cause of Mr. Leaning's veto.

CHARLES NELSON & Co., Limited, Manufacturers of Selenitic Cement.

**ARCHITECTURAL ASSOCIATION.**

SIR,—Will you kindly allow us to call attention through your journal to the elementary class for the study of decoration and ornament, which will be commenced this session under the guidance of Mr. Cole A. Adams. The first meeting will be held at No. 9, Conduit-street, on Thursday, October 13th, at 6.30 p.m., when the course of study to be pursued will be explained. Students wishing to join should send in their names at once to the Secretary, Mr. Walter H. Hewish, 14, Holden - terrace, Grosvenor-gardens, S.W. The fees and rules will be similar to those of the other elementary classes.

THOS. EDWARD PRYCE, } Hon. Secs.  
 FREDERIC R. FARROW, }

**The Student's Column.**

**LAND SURVEYING AND LEVELLING.**

**XIV.—SETTING OUT CURVES.**

HERE great accuracy is not required, the application of the formula derived from Case 1 may be adopted, by the method shown in Case 3, for setting out offsets at right angles to a tangent line. The first offset nearest the junction of the curve with the tangent line is thus easily calculated, being equal to the length measured along the tangent

line, divided by twice the radius of the curve (see fig. 3), and if the remaining offsets be set out at the same distance apart, measured along the tangent line, the succeeding offsets, Nos. 2, 3, 4, and 5, will be respectively equal in proportion to the square of these numbers, or 4, 9, 16, and 25 times the length of the first offset. As the middle point in the curve is approached, the tangential angle between the chord and the tangent line increases, and the amount of error in the length of the offset so calculated will also be increased. This error can, however, be kept small by setting out a new tangent line as shown in fig. 3.

When the angle formed at B is smaller than that shown in Case 4, fig. 1, it will probably be found a more convenient mode for setting out the curve, to adopt one of the following methods—(1) In the case of a radius not greater than one chain, to divert one or both of a portion of one of the lines A B and B C, making them parallel to one another. Then mark out a semicircle between them by twisting the chain round from the centre of a line set out at right angles to the tangent lines, which line will join the beginning with the end of the curve. (2) In the case of a radius over one chain in length, join any two points K and L in the tangent lines B A and B C, and calculate the lengths B K and B L in fig. 1, from the following formulas:—

$BK = KL \frac{\sin B L K}{\sin A B C}$   
 $BL = KL \frac{\sin B K L}{\sin A B C}$

Then proceed as in Case 3. If the tangent

ts F and G be joined by a chord line F G curve might also be set out by offsets measured from the chord, as shown in Case 4. The middle point J is found by measuring the length of the chord H G and bisecting it. distance J M or J K to the points M or K which offsets are required is next measured, the square of the distance is subtracted from the square of the radius. The square root the result is then determined, and from it is subtracted the square root of the radius squared as half the chord squared. This is expressed in the formulae given upon the diagram.

If the point of intersection of the tangents is inaccessible the application of the rule for finding the distances B K and K L (1) becomes necessary when Case 3 or Case 4 is adopted. Where obstructions occur in the line of the curve itself, the application of the method shown in Case 4, fig. 2 is often desirable.

In fig. 1 the true measurements for setting a curve are given, the distances along the tangent line from the beginning or end of the curve being respectively equal to the half radii, or the sines of the angles at the centre of the circle for a radius equal in length to a link unit; while the length of the offsets at right angles to the tangent lines are found by subtracting from a unit of measurement the cosine of the angles at the centre of the same circle. If, as shown in fig. 1, the angles taken at the centre of the circle be equal—that is, if the angles taken be extended by equal chords,—the points marked on the curve will be at equal distances apart. If the distance in links measured along the tangent line by the chain the offset to be assured by a tape or rod will amount to  $\frac{1}{2} \sqrt{R^2 - T^2}$  expressed in links. Tables are published in a form suitable for carrying in the pocket which give the length of various offsets stated distances for different radii.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

11,766, Apparatus for Inducing Draught in Chimneys. T. Carter and W. B. Tully. According to this invention, compressed air or steam forced through jets inside the funnel or chimney is used to induce a current of air for draught or ventilation.

13,436, Improvements in Spirit Levels. J. Harrington. This invention consists of a slide, made of brass or horn for protecting the glasses of spirit levels, is fixed underneath the plate immediately or in the spirit-glass. The slide is sometimes used protecting the glass only; or it may, if desired, made the whole length of the level, in which case is used and figured as a scale.

13,555, Ventilation of Buildings. J. Horrocks. The idea of this invention is to pump fresh air through pipes of any length by means of a steam or engine fixed at one end. Means are taken to infect and deodorize the air as it passes through the pipes. The system is to be worked in sections, and the air being turned in at one end the foul air forced out by the fresh pure air and escapes into a atmosphere by means of a tall stack or such applicable appliance. It is thought possible to bring to a City of London country air for the better ventilation of dwellings.

13,698, Door Furniture. J. Brownrigg. By this invention a small bush with a flange is secured to the door. The rose is then fixed against the bush with the face, but with the bush protruding.

A screw spindle is pushed through the door, and an other loose rose is screwed along the spindle against the fixed rose. The face of this loose rose is slightly sunk to receive a thin washer and the shoulder of the loose knob. When these are screwed tightly up all works smoothly, and the action is simple and durable.

16,105, Outlet Ventilators. J. Craig. The bottom part of the ventilator is formed of an long funnel, the top of which is divided into two or three equal parts, one part on each side, diverged in an angular direction, which forms the fan. A funnel is fixed on the inside of the ventilator divided into two or more compartments, according to size of the ventilator. An intercepting channel is inserted into the bottom funnel in a position to catch anything that may descend from the top funnel and discharge the same at the open outlets at each end.

19,817, Material for Covering Walls on Floors. By this invention it is claimed that paper of a kind more than usually suitable to receive embossed patterns is made of wood pulp and straw pulp

varied proportions, as different degrees of hardness or resiliency are required. The pulp mixture is made into strong paper, in the usual way, and this paper, before it has dried and set, is embossed by passing rollers or pressing blocks. When dried the pattern or protuberances retain their form. Felt or fabric may be cemented on or between layers of the paper.

10,250, Wood Screws. C. D. Rogers.

According to this patent, the diameter of the core or bottom of the screw (at the commencement of the screw thread nearest the head) is made to gradually increase up to its intersection with the head, thereby forming a conical shank. The thread is of the coarse gimlet kind most useful for wood screws.

NEW APPLICATIONS FOR PATENTS.

Sept. 16.—12,570, W. Foster, Connecting Pipes to Water-closet Basins, &c.

Sept. 17.—12,603, W. Baird, Fastenings for Doors of Theatres, Halls, &c.—12,614, J. Hird and J. Ford, Casement Windows and Doors.—12,618, P. Aytton, Combined Door Springs and Pneumatic Checks.—12,632, J. Lyman, Paint.—12,638, A. Rammage, Flooring or Decking for Bridge Work and Building Construction.—12,640, F. Barnett, Self-lowering Metallic or other Fireproof Material Shutters for Prosceniums of Theatres.

Sept. 18.—12,654, H. Lomax, Fasteners for Windows and Doors.—12,651, L. Chinnery, Window Sash Silencer.—12,695, C. Groombridge, Automatically Closing Gates and Doors.—12,710, D. Grove, Portable Buildings.

King's-cross—17 to 24, North-avenue, 47 years, ground-rent 21l. .... 580

Barnsbury—20, Offord-road, 63 years, ground-rent 1l. .... 490

SEPTEMBER 23.

By BAKER & SONS. Sussex, Slinfold—Freehold farm buildings, and 254a. 3r. 36p. .... 4,640

Bromesbury, Salisbury-road—The residence called "The Oaks," 81 years, ground-rent 15l. .... 1,900

Spitalfields, Lamb-street—Freehold ground-rent of 20l. per annum, reversion in 63 years ..... 870

High Holborn—A profit rental of 250l., increasing in four years to 300l. per annum, 42 years, ground-rent 50l. .... 4,270

MEETINGS.

MONDAY, OCTOBER 3.

Society of Engineers.—Mr. R. J. Hutton on "Stability of Factory Chimneys," 7.30 p.m.

Clerks of Works' Association (Carpenters' Hall).—General quarterly meeting, 8 p.m.

TUESDAY, OCTOBER 4.

Parkes Museum (Lectures for Sanitary Inspectors).—Dr. Louis Parkes on "Water Supply, Drinking Water, Pollution of Water," 8 p.m.

WEDNESDAY, OCTOBER 5.

University College.—Professor Roger Smith's Opening Lecture in Architecture, 7.30 p.m.

Builth's Foremen and Clerks of Works' Institution.—Ordinary meeting, 8.30 p.m.

Liverpool Engineering Society.—Mr. F. Huleston on "The Coal Shipping Appliances of the Port of Liverpool," 8 p.m.

FRIDAY, OCTOBER 7.

Architectural Association.—Conversation at the Westminster Town-hall, 8 p.m.

Parkes Museum (Lectures for Sanitary Inspectors).—Professor R. Robinson on "Drainage Construction," 8 p.m.

Miscellaneous.

The Pulsometer Engineering Company are about to bring out a new and simple automatic pumping-machine for lifting sewage or other liquids from one level to another. The machine is likely to be of much service in town sewerage works where difficulties of level have to be encountered. The machine is worked, at a very small expenditure, by the pressure of water obtained from the street water-main. It is automatic in action. The presence of sewage is necessary to set it working, but when the flow of sewage ceases the pump comes to a standstill. We have this week seen one of these machines in action at the Company's Works, Nine Elms, Yauxhall. At the same time, we had an opportunity of noting the great adaptability to almost all conceivable conditions of contractors' work, of this Company's now well-known pumping appliance, the Pulsometer, which requires no staging, but can be slung or suspended down a shaft, or in any other situation, the steam-pipe being led down to it. Their deep-well pumping engine, "The Deane," is direct acting, and is admirably adapted for raising water from contracted shafts, artesian wells, &c. Another speciality of the Company is the "Thames Filter," the filtering medium being sponge, which is cleaned by simple mechanism. A large installation of these filters has been fixed at the works of the London Hydraulic Power Company, where about 10,000 gallons of water per hour of Thames water are filtered by them to a defined standard of purity, thus saving the heavy cost of a supply from one of the water companies. Filters for swimming-baths and other purposes are also made by the Company.

A New Gas Boiler for Conservatories.—Mr. C. Shrawbury, of Newgate-street, has lately brought out a new gas boiler for conservatories, which he calls the "Reliance." Now that the sharp frosty nights are approaching this boiler, it appears to us, will be found well worth examination. It is claimed for it that it may be placed in perfect safety inside the conservatory, as there is an equal pressure of air on the inlet and outlet pipes. The outer case of the boiler is made air-tight, and all the air for the supply of the burner is drawn down the inlet pipe from outside the conservatory and is led into the bottom of the air-tight outer case of the boiler. The pipe for the escape of the products of combustion is led out of the top of the case, thus keeping up a syphonic action in the pipes and case, maintaining the pure air in the conservatory. This boiler was patented as recently as July last, but was previously carefully tested throughout the whole of last winter by the patentee in his own conservatory, and found to answer well, we are informed, under all conditions and changes of weather.

**Sale of Building Land at Cromer.**—On Monday last a large and important sale of building sites,—the second during the present season, took place at Cromer, where a considerable impetus is at the present time being given to building, not only within the area of the old seaside town itself, but also in the neighbourhood immediately around. The property submitted to competition on Monday comprised the second portion of the Suffield Park Estate, belonging to Lord Suffield. It consisted of 142 lots, divided into sites of various sizes, for the erection of different classes of houses, the frontages ranging from 15 ft. to 40 ft., with corresponding depths, three of the plots, which were exceptionally large, having frontages of 50 ft., 93 ft., 130 ft., and 155 ft. The property offered is situated in a charming valley, with the Lighthouse Hills and the rugged and majestic cliffs immediately to the north-east commanding a picturesque view of the German Ocean, with the shore nearly 100 ft. below the lofty cliffs, the scenery inland to the south-east and south-west being equally picturesque. Messrs. Baker & Sons conducted the sale, in conjunction with Messrs. Spelman, land agents, of Norwich and Yarmouth. Mr. Baker, in introducing the property, enlarged upon the natural beauties and attractions of Cromer, which, he observed, was fast becoming the most favorite watering-place on the north-east coast. On the sale proceeding every lot was rapidly purchased, the smaller lots, having 15 ft. frontages, averaging about 12l. each; those having 20 ft. frontages 15l. each; those with 25 ft. frontages from 31l. to 32l. each; and those having 30 ft. frontages from 40l. to 45l. each. An hotel plot having a frontage of 57 ft., and a return frontage of 90 ft., realised 100l., and the three large plots above referred to were sold for 135l., 140l., and 145l. each. The entire proceeds of the sale amounted to about 3,800l.

**Economic Geology.**—A series of thirty lectures on this subject is to be commenced by Mr. G. F. Harris, F.G.S., at the Birkbeck Institute, on Wednesday evenings, commencing October 5. The lectures are intended especially to give practical as well as theoretical geological information to architects, civil and mining engineers, builders, &c., and deals, among other subjects, with the selection of stone for building purposes, experiments in testing durability of stone, crushing weight, absorption of water, chemical and microscopical analysis, weathering, &c.; the distribution and shape of the water-bearing and non-water-bearing strata in England and Wales; water-supply from lakes and rivers; reservoirs, analyses of water, rainfall, filtering; canal and railway cuttings and embankments, landslips, faults, and drainage; concrete, cement, lime-kilns, mortar, &c.

**Lightning Conductor Tests.**—Amid some disputes about lightning conductors recently by people who do not all know what they are talking about, the following from a letter signed "J. A. Fleming" in a recent number of the *Times* is a suggestion worth keeping in mind:—"Not only is it necessary to have a properly fitted conductor or system of conductors to every valuable building, but it is above all things necessary to have a periodical electrical test applied to the conductor in order to ascertain if the earth plate is making 'good earth.' The proper manner of doing this is to run a second isolated cable parallel to the conductor and making contact with it near the top. This testing cable should have a separate earth plate. A simple electrical test, applied easily, will then enable an observer to state whether that conductor is an efficient lightning protector, or only an additional source of danger."

**A New Italian Canal.**—Two members of the Italian Parliament, Signori Fazzari and Morandini, have presented to their Government a plan for a new canal, navigable for large vessels, through the province of Catanzaro, whereby ships bound from the Tyrrhenian into the Ionian Sea will save the detour around Sicily, or the passage through the Straits of Messina. The canal would be thirty-five miles in length, and will follow the course of the rivers Anzio and Corcusa, and by regulating the waters of these two rivers it is estimated that 80,000 hectares of land will be reclaimed, an area sufficient to cover the interest on the capital required for the construction of the canal. The new waterway, the promoters maintain, would be of great value to vessels trading in the Levant and Black Sea.

**Engineering, &c., at University College, London.**—We notice from the prospectus of University College, London, Engineering Department, that the work of this College commences for the Session on the 5th of October. The instruction in Surveying and the lectures in the various branches of Civil Engineering are given by Prof. L. F. Vernon-Harcourt. The general lectures on Engineering and Machine Design, as well as the work in the engineering laboratory, are in the hands of Professor Alex. W. Kennedy. In this laboratory, the arrangements of which formed a principal subject of the paper on "The Use and Equipment of Engineering Laboratories," read by Professor Kennedy before the Institution of Civil Engineers last winter, students go through for themselves during the session a systematically-arranged course of experimental work in connexion with elasticity and the strength of materials, the efficiency and economy of steam boilers and engines, the appliances for which have been considerably extended during the last few months. Electrical Technology is under the care of Professor Fleming, by whom (with Professor Carey Foster) a dynamo installation has lately been fitted up for the purpose of practical experimentation in "applied electricity." Economic Geology is treated as a special subject in a short course of lectures by Professor T. G. Bonney, and Chemistry as applied to Engineering and Architecture in a course by Professor Charles Graham. In addition to these matters directly connected with engineering, the College provides ample instruction in all the sciences on which engineering is based, mathematics, mechanics, physics, chemistry, geology, &c., and very special attention is given to graphic methods of calculation as applied to scientific and technical problems in the lectures and drawing class of Professor Karl Pearson.

**The Sanitary Condition of Large Cities.**—Dr. Jacques Bertillon, chief of the Paris Bureau of Statistics, publishes in the *Revue d'Hygiène* a comparative statement of the sanitary condition of the chief European and American cities during 1886. The author gives the proportion of deaths per 100,000 of the living population for certain preventable diseases. The proportion of deaths caused by typhoid fever was as follows for French cities:—Besançon, 205; Toulouse, 118; Marseilles, 108; Nancy, 65; Bordeaux, 60; Paris, 46; Lyons, 40. These are high figures as compared with those for certain cities of other European countries. The proportion per 100,000 was, in Liverpool, 34; Manchester, 33; Brussels, 29; Dresden, 18; London, 17; Amsterdam, 16; Berlin, 16; Edinburgh, 15; Copenhagen, 13; Leipzig, 11; Vienna, 11. A few large cities, however, suffered more severely from this disease. At Saragossa the proportion was 128; St. Petersburg, 113; Milan, 71; Philadelphia, 65; Baltimore, 46. The great outbreaks of smallpox during the past year are shown by the following figures, giving the number of deaths per 100,000 of the population, viz.:—Marseilles, 573; Buda-Pest, 358; Saragossa, 221; Rome, 128; Rheims, 110; Zurich, 106; Milan, 61. Some of the figures for scarlet fever were:—Hanover, 285; Buda-Pest, 127; St. Petersburg, 93; Glasgow, 68; Leeds, 57; Brooklyn, 51; Liverpool, 47; München, 34; Leipzig, 28; Berlin, 21; Paris, 18; London, 17; Vienna, 16; Lyons, 13; Amsterdam, 6; Marseilles, 5; Rome, 5. For diphtheria some of the figures were:—Grenada, 491; Nürnberg, 240; Brooklyn, 170; Dresden, 169; Marseilles, 163; Berlin, 128; Buda-Pest, 128; Hamburg, 123; Philadelphia, 113; Leipzig, 110; München, 86; Amsterdam, 74; Paris, 73; St. Petersburg, 63; Rome, 52; Lyons, 38; London, 33; Edinburgh, 32; Glasgow, 29; Liverpool, 21. The above diseases appearing generally in epidemic form, an otherwise healthy city may show a large death-rate for any particular year. It is otherwise with such diseases as consumption, for instance, of which Dr. Bertillon gives statistics which do not vary much from year to year. The highest proportion occurred at Buda-Pest, where 708 died of the disease in 100,000 inhabitants. Then follow Vienna, with 664 deaths; Nürnberg, 482; Paris, 470; Marseilles, 448; Lyons, 444; München, 390; Dresden, 387; Berlin, 334; Lubriecating, U.S., 315; Rome, 212. Of American cities, New Orleans had the highest death-rate, 382; Brooklyn following, with 313; and Philadelphia, with 296 deaths per 100,000. With the exception of Belfast, where the pro-

portion was 472, the large cities of the United Kingdom show very favourably compared with Continental cities, Glasgow having but 278; London, 202; and Edinburgh, but 193 deaths from consumption out of 100,000 inhabitants. The figures given above,—taking into account changes which have been mostly for the better,—prove that the greatest mortality from consumption exists in large Austrian cities, the smallest in English cities. The death-rate from scarlet fever were highest in Germany from diphtheria in Spain and Germany, from small-pox in France and Austria, from typhoid fever in France and Spain. It is satisfactory to find that the death-rates from all the causes mentioned in English cities are amongst the lowest.

**Schools, Formby, Lancashire.**—The schools attached to St. Mary's R.C. Church, Formby, have recently been enlarged, and two additional class-rooms have been built in the same style as the existing buildings. Crosby light pink bricks have been used for the general walling, with Edwards's Raabon red and blue bricks in strings, arches, buttresses, weatherings, &c. The interior is plastered throughout with a cemented dado. Roof principals are exposed, stained, and varnished. The work has been carried out by Mr. Edward Blackburn, builder, of King's-road, Bootle, from plans by and under the superintendence of the architect, Mr. Fred. H. Peate, of Liverpool.

 Bishop Bros., Birling ..... 498 10 0  
 Seark, Southam Green ..... 450 0 0

\*SPECIAL NOTICE.—Lists of Tenders frequently reach us too late for insertion. They should be delivered at our office, 46, Catherine-street, W.C., not later than 12 Noon on THURSDAYS.

TO CORRESPONDENTS.

Registered Telegraphic Address, "THE BUILDER, LONDON."

R. B. & Son.—A. R.—G. F. H.—W. W. L. (received).—C. N. & Co.—G. H. C.—W. F. (most of these suggestions are perfectly unsuitable. You cannot count on securing in a crowded town, a site for an ordinary theatre with three sides open, except at a cost which would be prohibitive).—H. W. F. (should send amount).—A. J. H. (too late).

All statements of facts, lists of tenders, &c., must be accompanied by the name and address of the sender, not necessarily for publication. We are compelled to decline pointing out books and giving addresses.

Note.—The responsibility of signed articles and papers read at public meetings, rests, of course, with the authors.

We cannot undertake to return rejected communications.

Letters or communications beyond those news-items which have been duplicated for other journals, are NOT DRESSED.

All communications regarding literary and artistic matters should be addressed to THE EDITOR; all communications relating to advertisements and other exclusively business matters should be addressed to THE PUBLISHER, and not to the Editor.

PUBLISHER'S NOTICES.

Registered Telegraphic Address, "THE BUILDER, LONDON."

CHARGES FOR ADVERTISEMENTS.

SITUATIONS VACANT, PARTNERSHIPS, APPOINTMENTS, TRADES, AND GENERAL ADVERTISEMENTS.

### Our National Maps.

**N**T seems somewhat strange that the national maps of a kingdom such as ours, the mother of vast colonies, to whose inhabitants every foot of British soil is, or should be, dear and sacred, and who are destined to hand down to a remote posterity, not only our language, our customs, and our laws, but also our local histories and traditions, should be only now, at the close of the nineteenth century, nearing their completion, and that it is only now that the colonist is able to procure an authentic and explicit map of the parish where his forefathers lived and died, where he himself, perhaps, first saw the light, and the names of whose homesteads, woods, fields, streams, commons, and winding lanes have been handed down to his children as household words.

Turning from a perhaps somewhat poetical view to one of a practical nature, it seems still more strange that a business-like nation such as ours should have ignored to so late a period in its history the immense advantages to be obtained from a national survey of the kingdom, and that the War Office, the county, parish, city, town, and village authorities; the railway, canal, gas, water, mining, and other companies; fishery boards, land-owners, tenant farmers, parochial clergy, and others, to say nothing of antiquaries, students of history, geology, mineralogy, botany, &c., should only recently be able to obtain efficient and authentic maps of the parts of the kingdom in which they may be interested.

While the National Survey has been in hand generations have come and gone, and though its late commencement and its still more tardy execution are to be regretted, delay has allowed the use of recent discoveries of science, and the Ordnance Survey authorities have thus been enabled to present us with a finished work which, even in 1867, was rightly pronounced by competent French authorities to be "sans précédent et qui devrait servir de modèle à toutes les nations civilisées."

Our national maps, faithful and true pictures as they are of the land of our inheritance, with all its venerable histories and traditions, are yet far from being sufficiently known, appreciated, or understood, even by those whose training should naturally enable them to value the skilled execution displayed, or delight in the remarkable collection of geographical,

historical, topographical, and antiquarian detail that is laid before them.

In time, doubtless, those interested in the training of the young,—the men and women of the next generation,—will appreciate the parish sheets of the Ordnance Survey, which can now be procured at such trifling cost, and, mastering the details themselves, will learn with surprise what a valuable source of instruction the maps can be made; how great a love for home and country can, by their aid, be evoked; and what healthy interest in the study of history, botany, geology, &c., can be called into existence and steadily maintained.

Country walks, fishing excursions, visits to ancient objects, or historical sites can be, step by step, traced on the map; distances, areas of fields, woods, and commons, noted and compared; heights, inclinations of roads, falls of streams, can be observed; and memoranda made as to the haunts of the *fauna*, and as to the localities of different botanical and geological subjects. In short, in careful and appreciative hands, the parish sheets of the Ordnance Survey could be made to play a most important part in the education of the young, for, apart from the instruction to be derived from them in regard to archaeological and historical study, who can doubt the good effect of children being early trained to observe heights and distances, and to judge of areas, especially in the case of boys who are destined to follow many of the professions,—to become military commanders, engineers, architects, or surveyors?

Of the various classes of national maps issued by the Ordnance Survey Department, there are three of chief importance, viz., those on the respective scales of

$$\frac{1}{10560} \quad \frac{1}{2500} \quad \text{and} \quad \frac{1}{500}$$

or, in other words, on the scales of 6 in. to the mile, 25·344 in. to the mile, and 126·62 in. to the mile, which said scales are further designated as the county, parish, and town scales.

It is much to be regretted that instead of the county scale of 6 in. to the mile ( $\frac{1}{10560}$ ), the slightly larger scale of 6·336 in. was not used, and of which the equivalent is the fraction  $\frac{1}{10000}$ ; for then we should have had the parish scale an equi-multiple of the county scale, just as the town scale is of the parish,—an immense advantage, but one which engineers and surveyors can, perhaps, alone fully appreciate.

Unfortunately, the country was, in the early days of the Survey, too much wedded to the duodecimal subdivision of the lineal foot, and to the octave subdivision of the inch, for

Parliament to sanction such an innovation as a 6·336 scale; and so we were doomed to have in our county sheets 1 lineal inch representing 10,560 lineal inches on the ground, instead of the more readily handled, more easily subdivided, and more promptly reckoned number of 10,000 inches.

The credit of proposing the  $\frac{1}{2500}$  scale for the parish sheets is due to Capt. Dawson, R.E., who in 1837 strenuously urged its adoption.

In 1853 the question of the scale was still undecided, and the Treasury consulted the most eminent scientific societies and men of science in the kingdom on the subject, with the result that opinions were divided in favour of a scale of 24 in. to the mile and one of three chains to the inch, the latter being the scale on which the old, unofficial, and consequently very inaccurate, maps had been prepared for the use of the Tithe Commissioners.

If these two scales be, by the simple rule of proportion, converted into fractions, they will appear as  $\frac{1}{2640}$  and  $\frac{1}{2376}$

The supporters of the  $\frac{1}{2500}$  scale now seeing their chance, urged that their scale was a mean between the two proposed scales; that having been the scale sanctioned by Napoleon I. for the Cadastral Survey of France, it had been found admirably suitable; that it was easily divisible; and, finally, that one square inch on a map of this scale exactly represented one English acre, which last fact, considering the scale is of French origin, is somewhat curious.

It was thus the even now much-wondered-at and ignorantly-abused scale of 25·344 in. to a mile ( $\frac{1}{2500}$ ) came into use.

The town scale of  $\frac{1}{500}$  happily followed, and to this scale all towns of more than 4,000 inhabitants are laid down.

Our city and town authorities require to be furnished with a block plan, amongst others, of all new buildings proposed to be erected within their jurisdiction. At present there is no particular scale, except a minimum one, prescribed for such block plans, but with the splendid town maps now furnished by the Ordnance Survey Department, city and town authorities would do well to require all block plans sent in to them to be on a scale of

$$41·66 \text{ ft. to the inch } \left( \frac{1}{600} \right),$$

so that such plans could be at once transferred to their own maps, by which means the latter could be properly and effectively kept up to date.

Architects, in many cases, prepare their

drawings on a scale of 8 ft. to the inch, which is equivalent to  $\frac{1}{96}$ . If, however, a scale of  $\frac{1}{100}$  were used, their drawings would be on a scale exactly five times the size of the Ordnance town scale, and thus we should have our buildings, our towns, and our parishes all laid down in harmony with each other, to very great national advantage and economy. Not, however, until the decimal subdivision of the fact is generally adopted in place of the present tedious and troublesome duodecimal subdivision can such a change be looked for.

The system of the Ordnance scales having been discussed, it will be interesting to note how the kingdom has been divided and subdivided for the purpose of giving the public plans of convenient size, and suitable for ready reference; and the following explanation, though in reality the order is inverted, will, perhaps, suffice.

Parallel north and south lines being drawn at a distance from each other of six miles are crossed by parallel east and west lines at intervals of four miles, and the whole kingdom is thus broken up into rectangular sections, each containing twenty-four square miles. These sections, being laid down on a scale of 6 in. to the mile, give convenient sized maps of 3 ft. by 2 ft. The sections of which each county is composed are known as its county sheets, and are designated by Roman numerals. Small key county maps, on which all the parishes are delineated, are published, showing where these rectangular sections fall and the numbers of the same, and thus one is able to select at once the particular sheet or sheets required.

Again, each county sheet is subdivided into 16 equal rectangular sections, numbered consecutively from 1 to 16, and these sections being laid down on a scale of  $\frac{1}{2500}$  give us

what are known as parish sheets. For each parish a key map is also published, and by its aid all the parish sheets which go to form the complete map of the parish can be at once selected; and since the scale of  $\frac{1}{2500}$

is nearly four times the size of the 6 in.  $\left(\frac{1}{10560}\right)$

scale, each sixteenth portion of the latter, when redrawn to a scale four times as large, will give a map almost the same size as the parent map, which size, as we have seen above, is very convenient.

The quantity of ground shown in a parish sheet is the sixteenth part of twenty-four square miles; that is,  $1\frac{1}{2}$  square mile or 960 acres.

Where any town containing more than 4,000 inhabitants exists on the parish sheets, these sheets are subdivided into twenty-five equal rectangular sections, and each section being enlarged five times, *i.e.*, to a scale of  $\frac{1}{500}$  attains the exact size of the parent sheet. These sections are numbered consecutively from 1 to 25. Each town is provided with a key map, similar to the parish key maps, and hence the town sheet or sheets are readily selected.

In purchasing Ordnance sheets through a local agent, or ordering the same from London, care must be taken to quote the correct number (Roman numerals) of the county sheet required. Should a parish sheet only be wanted, its proper number, which lies between 1 and 16, must be written after the Roman number of its parent county sheet; and should a town sheet be required its proper number, lying between 1 and 25, should be written after the number of its own parent parish sheet.

In order to comprehend the system on which the parish sheets are drawn recourse must be had to the "Book of Reference" published for every parish, which contains an index map of the parish, an explanation of all the terms and symbols used, and the area, to the thousandth part of an acre, of every field and enclosure.

The Ordnance Survey Department has taken a wise and advanced step in giving the areas

of all the enclosures in the kingdom in statute acres and decimals of acres only, thus finally abolishing "customary" land measurement, and tending to do away with the subdivision of English acres into roods and perches. Allusion has been already made to our tedious and troublesome subdivision of the lineal foot; the same objections stand good against our present subdivision of the acre, and equally, if not more so, against our cumbersome ton of 2,240 lb., with its subdivisions into hundredweights, quarters, and stones. The American and Canadian system of expressing all weights in pounds only, until the "short ton" of 2,000 lb. is arrived at, is much to be admired, and probably a change in our system of weights and measures in the direction shown would do more to further the collection of valuable agricultural statistics than generally could be believed.

It will be noticed that in addition to a scale of feet, the Ordnance maps are also furnished with a scale of chains and links. Gunter, the mathematician, more than two centuries ago, conferred a benefit on his country by the introduction of a chain of such a length that ten square chains, *i.e.*, an area ten chains long by one chain broad, were equal to one statute acre. Gunter's chain, the length of which is 66 ft., is divided decimally into 100 links, and hence 100,000 square links represent one acre. Thus the acreage of any piece of land can be found by simply multiplying the mean breadth in links by the mean length, and dividing the product by 100,000, the answer being the acreage to a thousandth part of an acre.

For ready reference to Ordnance sheets a convenient method will be found to endorse on each of the four corners of the back of every sheet its proper numbers, and the sixteen subdivisions of each county sheet being rolled together will thus form one family or group, whose surname is, as it were, the Roman numeral of the county sheet. The different families of each county being then placed in numerical order, any particular sheet required can be at once selected. The town sheets, similarly endorsed, should also be rolled together. The small index or key maps of the county, parishes, and towns should be kept at hand, when a glance will suffice to show the number of any particular sheet that may be required.

In our national maps the hedges are delineated by a single line only, this line denoting the centre of the hedge, and to which the acreage of each field is calculated.

It has been objected that the actual acreages are not thus always shown, since, in practice, some hedges are included and some excluded in computing areas of fields; but the Ordnance Survey Department has nothing whatever to do with the boundaries of private property, and rests content with endeavouring to produce a perfect picture of the kingdom, such as would appear from a balloon exactly over every point of the same. This picture, in convenient sections, is on sale to the humblest farmer and to the smallest land-owner, as freely as it is to the wealthiest proprietor, and at a price astonishingly small.

France was long before us in the execution of her Cadastral Survey, but the maps of the same are not published, as ours are, for sale to the public, and thus that nation is deprived of almost all the immense benefits we enjoy. Without our national maps, giving, as they do, an accurate impartial plan of the whole of the kingdom on a fixed scale, with identical styles of drawing and with identical symbols, a proper system of land transfer and registration would be impossible, and on the final passing of the present Land Transfer Bill the importance of the national maps will become increasingly manifest. For the benefit of the public it may then seem desirable to permit the sales of local Ordnance sheets at the post-offices, and to exhibit in each post-office the index or key maps.

For those who wish to go more fully into the study of the subject, we may recommend the valuable work on "The Ordnance Survey of the United Kingdom,"\* by Lieut.-Colonel

White, R.E., published last autumn,—a book which should be read and studied by every lover of his country.

#### "LES ARTISTES CÉLÈBRES."

NDER this general title there has been appearing for some time a series of short biographical and critical notices of eminent artists of all ages, by various authors, written in French, and published in Paris, but on which the name of a London publishing house also appears. They form very pretty octavo volumes, in a vellum cover of artistic design, and the contents bear out the fair promise of the exterior, at all events as far as the literary portion of the work is concerned. The main facts in the lives of the artists dealt with are given in a readable form; but a higher value is given to these biographical essays by the admirable spirit of critical analysis of the art and the artist which pervades them. The illustrations are not all that could be desired, the slight and rather crude engravings serving rather as memoranda than as illustrations of some of the more celebrated works referred to. On the other hand, a good many reproductions of facsimile sketches, hitherto unpublished, are scattered about the pages, and these, which can be adequately represented by an inexpensive process, are of real interest.

The volumes, so far as we have at present from time to time received them, deal with the genius and works of Pheidias, Donatello (we name them in chronological order), Ligier Richier, Palissy, Callot, Rembrandt, Edelinck, Lamour, Reynolds (this is the last one which has appeared), Prud'hon, Delacroix, Decamps, Fortuny, and Regnault: the respective authors' names are given below.\*

In regard to the great Athenian sculptor, M. Collignon remarks with truth that it is more easy to relate the legendary than the real history of Pheidias (the French writers still retain the spelling "Phidias," which has been nearly abandoned in Germany and England), and the essay is, in fact, in the main a critical analysis of his known work, accompanied by illustrations mostly taken from the British Museum treasures, and which are better executed and more worthy of their subject than is the case in some of the other volumes of the series. The author makes no attempt at restoration of the pediment sculptures in the illustrations, but gives illustrations of some cognate groups, such as a "dispute of Athene and Poseidon" from a vase found at Kertch, and coins representing statues of Athene, which may give the general reader a better idea of the probable original and complete form of the central group of the west front, and of the colossal statue in the interior of the temple, than he could get from descriptions alone. The general question of the arrangement and signification of the groups is too large a subject to go into a notice of a work which is only one of a series; M. Collignon devotes a good deal of space to it, and concurs with Mr. Waldstein in regarding the figure in the library of St. Mark at Venice, and of which a cast has been placed among the Elgin marbles in our Museum, as probably one of the west front figures of the Parthenon; at all events, as certainly the work of Pheidias. M. Collignon

uches on the question, what was the precise art which Pheidias himself had in the execution of these two great series of sculptures. Personal execution of the whole with his own hand was, of course, out of the question. The French critic seems to incline to the opinion that Pheidias himself modelled the whole in clay, giving the execution in marble to various sculptors in his atelier; that unity of conception and feeling, with difference in handiwork, is the evidence given by the work preserved to us; and there is a certain distinction between the style of sculpture in the different figures, which is larger and bolder in some, and more minute and delicate in others. But in the main one's feeling is that since assistance must have been employed in producing the whole, the general unity of effect in the execution is marvellous, and is an indication of the extent to which Pheidias was able to impress his own style and feeling on his subordinates.

The life of Donatello, who may be called the Pheidias of the Early Renaissance, comes not suitably after that of the great Greek. To be sure, Donatello was an artist who lived in an incomplete or chameleon period of art, while Pheidias represented a period of manhood; but Donatello's greatest work, the St. George, presents, as M. Mintz observes, a grand simplicity of pose "which would have enchanted the Greeks themselves," and which places the work intellectually in close relation with the finest Greek work in an æsthetic sense, while there is that may be termed a moral beauty about it of which the Greek mind had hardly a conception. In his numerous bas-reliefs, moreover, Donatello shows a close artistic relationship, though unknown to himself, with such work as the Parthenon frieze: there is the same low relief, the same severity of line, the same delicate perception of the conditions and capabilities of bas-relief, and we never see one of Donatello's works of this class without thinking of the Greeks, though here again we find a tenderness and holiness of sentiment to which Greek art presents no parallel, the feeling represented in such a word as "holy" having, indeed, as far as we have any evidence, no place or existence at all in Greek art and literature; some of the Greek grave reliefs, of which we said something recently, come nearest to it, though here the feeling is rather pensive than religious, in the post-Christian sense of the word.

Considerable interest attaches to the essays on Delacroix and Decamps, those two remarkable artists of the earlier part of the century, when French painting was in a more healthy and vigorous state than it can be said to be now. It is curious at the present moment to read that the works of Delacroix evoked the most violent hostility for a long time from critics and from the artists of the old school, on account of their revolutionary style and revolt from the classic models of the "École." The best-known works of Delacroix would be regarded by most critics now as quite within the most orthodox canons of art, but his biographer, M. Veron, evidently regards him as a somewhat erratic genius, since he draws a contrast between the character of his work and of his life, the violent and tragic character of his paintings and the calm and well-regulated conditions of his own existence. It appears, however, that Delacroix so far carried the enthusiasm of his artistic side into his life as to have been at all times a very effusive friend or admirer of the people he loved and the things he admired. His portrait, with what the French call a strongly-marked "meridional" character, accentuated by his tangled mass of dark hair, indicates this kind of nature. As far as his art was concerned, our own judgment would be that he was a remarkable instance of an artist essentially romantic in style and feeling, but working within the strict lines of artistic form and propriety, combining passion and emotion with a remarkable degree of artistic balance and self-control. His "Waterloo," of which a reduction from an etching is given, is an example of this. This is a work of great pathos; a dark hill-side, a wounded man, and two dead horses, that is all; it tells its tale with great effect, but there is no straining after

the dramatic in it, nothing stagey or overdone. Among the works from which illustrations are given, and which are not much known, is his series of illustrations of "Faust," of which the scene of the death of *Valentine* is illustrated, and also the broad and powerful pen-sketch made for a title-page to the set. Among the illustrations of sketches, the finest in the book is the "Education of Achilles," a most vigorous design, representing the young Achilles astride on the back of the centaur, who is galloping away from the spectator, and pointing with his hand at some mark at which Achilles aims his arrow, the figures of Achilles and the centaur both with a conscientious impulse and bend in the same direction, which gives wonderful force to the composition. Delacroix was at war with the Académie set, or rather they were at war with him, for most of his life, though he received a tardy election at last. In connexion with the subject of the Academy elections, the author relates a story about another artist, M. Rude, who was invited by two members, X. and Y., to apply for admission to the Académie. He was balloted out, and heard from X. that Y. had voted against him. He charged Y. with this on meeting him, saying he had learned it from X. "Well," was the reply, "X. did not vote for you either, for you had not a single vote,"—an interesting illustration of the ways of Academies.

Delacroix was born in April, 1798; his brilliant compeer, Decamps, about five years later, as he said himself, "on the third day of the third month of the third year of the century." The volume devoted to Decamps is disappointing in the selection of the illustrations, in which rather disproportionate place is given to his earlier satirical and caricature work, very clever in itself, but not the kind of thing we connect with the name of Decamps. Of his more serious works the selection does not seem very judicious; at any rate, we have seen finer things of Decamps' than any of which illustrations are given here, except perhaps the "Christ in the Prætorium," the original of which we have not had the good fortune to see, and of which the engraving given is a very poor one, but which appears to be a remarkable Rembrandtish kind of work, an energetic contrast of expression between the calm face of Christ and the various vulgar and mocking figures around, brutal both in attitude and expression. It is a pity that a good illustration of "The Patrol at Smyrna" (one of Sir Richard Wallace's pictures) was not given; it is certainly one of his most characteristic works. The illustration of "Christ Crossing the Lake of Genesareth," which is a well-executed one, gives a good idea of his special power in landscape; as also the smaller engraving "Paysage en Syrie," with its square masses of white buildings in the foreground. M. Clément comments on the manner in which Decamps used architecture in combination with landscape and figures in his paintings.

"Ce mot d'architecture ne doit d'ailleurs pas être pris dans son sens ordinaire. L'architecture n'est pas là pour sa beauté, comme dans les vues de Canaletto, ou dans les paysages de Claude Lorrain; elle n'y est pas non plus pour servir de Théâtre à l'action, comme c'est le cas dans les peintures décoratives de l'École Vénitienne, et en particulier dans celles de Paul Véronèse. C'est là muraille, grande, nue, muette, projetant son ombre mystérieuse sur les portions du tableau vivement et franchement éclairées. L'ombre portée, héritage des peintres Espagnols, pierre angulaire de la doctrine de Decamps, joue là tout son rôle. L'harmonie n'est pas détruite par les contrastes les plus violents; l'œil passe, presque sans transition et sans être blessé, de la lumière la plus ardente, la plus éclatante, à des ombres intenses, transparentes, et profondes. Les figures se détachent dans les démodités par des tours de force de science et d'adresse. Ici le sujet importe peu à Decamps; une rue de village en Italie, une cour de ferme en France, un porche d'église avec une mendicante, quelques animaux sur la fumée, un intérieur de boutique à Smyrne ou à Beyrouth, tout lui sert à poursuivre cette lumière, ce protégé, dans ses infinies modifications."

It is true also, in another sense, that "the subject mattered little to Decamps," since he was one of those peculiarly artistic artists, so to speak, to whom a subject is merely an opportunity for artistic effect, not for any story, still

less for any moral. His fine head, of which a good portrait is given, expresses this completely; it is the head of the draughtsman, the man with an eye for effect in everything, but as far as possible from an artist with a theory or a mission. The military character in his physiognomy, visible in this portrait, is still more brought out in that capital group of the leading French artists of his period, half soldiers half painters, in Mr. Armistead's relief on the Albert Memorial.

Of another gifted artist, who was indeed, too unhappily for the country which has lost him, both painter and soldier, Henri Regnault, we have no space to say more than to direct the reader's attention to this sympathetic sketch of his life and works by M. Roger Marx. A good engraving is given of the bust of Regnault from the monument in the École des Beaux-Arts,—and what a head it is! The very ideal of intellectual manliness and vigour. A good many facsimiles of his studies are given; some admirable sketches of dogs, and a brilliant study for an illustration to De Musset's "Nanoua." Perhaps the force and originality of Regnault's genius are best shown in his "Judith and Holofernes," which is such a contrast in its terrible realism to the conventional Judith of respectable painters. His "General Prim" is an ardent young man's piece of bravado; of tremendous spirit, but still bravado; and his "Execution in a Moorish Palace" we always regretted; it is too brutal; and if the Prussians had not cut short his life he would possibly have lived to think so himself.

Among the less famous subjects of these essays, the sketch of the Lorraine sculptor, Ligier Richier, is of considerable interest, and the small outline engravings of his works show, in many cases, great though rather naive originality. The very best, perhaps, though in a sense rather painful, are the figures of the penitent and impenitent thief, from the Church of St. Pierre at Bar-le-duc; these, by the way, we observe are only "attributed" to him. He was born somewhere about 1500. The thin volume on Jean Lamour, by M. Cournaud, gives a good many illustrations of his elegant Louis Quinze grilles, gates, and lanterns. M. Vachon gives some account of Callot, the master of grotesque, with a number of characteristic examples, including a facsimile of his large etching of the temptation of St. Antony (a subject after Callot's own heart), and another of the well-known print showing the Pont Neuf and the old tower of the Porte des Vesles, with a big basket let down from it like a gigantic spider at the end of his line. The life of Prud'hon, one of the cold and pretty classicists of the eighteenth century, has the merit of being better illustrated than some of the lives which would have been better worth good illustrations. Reynolds, described as "le plus célèbre, mais, à nos yeux du moins, non le plus illustre" of English painters, is treated of by M. Chesneau with a certain enthusiasm for many of his works; M. Chesneau, indeed, admits that his portraits taken *en masse* are a wonderful collection, but he accuses Reynolds of having almost always in his eye some ideal model, Murillo or some one else, rather than the sitter he had in reality before him. What the author means he illustrates rather well by instancing as an exception the "Lord Heathfield," where he thinks the artist was really carried away by patriotic admiration for the commander and for the occasion, and gave a truly unaffected and grand picture of a great commander, without affectation or pretence. Among the portraits of women he thinks Reynolds's *chef d'œuvre* is "Nelly O'Brien," but he does not say which Nelly O'Brien. He winds up:—"En un mot, il s'exhale plus souvent des œuvres de Sir Joshua Reynolds une odeur d'atelier, d'huile, et de vermis, qu'un parfum de réalité." We can understand the grounds for this opinion, but we think it is pushed rather too far.\* The

\* As a set-off against this, it is related in the Life of Delacroix that on first coming to England and seeing the works of English painters, he was so struck with the style of Constable that he forthwith almost repainted the picture he was then at work on, the "Massacre de Scio," in an effort to emulate the vigour and freedom of the English artist's technique.

illustrations given from Reynolds's works are mostly very poor, and do no justice to the originals.

Taken generally, however, these are a very interesting and valuable set of monographs, written with true critical perception, and forming very pleasant and thoughtful essays in artistic biography.

## NOTES.

**P**ROFESSOR MARSHALL, in a letter to the *Times* of Monday, proposes that, in order to lessen the danger to the audience from fire breaking out on the stage, the stage should be ventilated from the auditorium, and that a number of extractors should be placed over the roof of the stage portion of the building, openings below in this portion being kept closed, and thus a continual current should be drawn from the auditorium on to the stage. The whole object of this absurd and unpractical suggestion is to obviate the tendency of the fire to spread towards the auditorium, as an iron curtain, though useful, as Professor Marshall admits, may not be let down at once; that is, some one may be stupid or may not do his duty. And so, for no better reason than this, the actors are all to breathe the air the audience have already breathed, and to have direct ventilation cut off from them, and the whole movement of the air is to be set up in such a direction as to militate against the acoustic properties of the house! Did it never occur to Professor Marshall that it is more difficult to make yourself heard against a current of air than speaking with it? or did he never hear that the securing of a ventilation current from the stage side towards the house (not from the stage area itself, but from that direction) is a decided help to the acoustic qualities of a theatre? Really between the nonsense that people write to the daily papers and the nonsense that has been sent to us (but which we, at any rate, know better than to waste type on), it seems as if most people had gone out of their minds on the subject of theatres, and had forgotten that one object of a theatre is that people should hear and see a play in it. One person writes to us to know why all theatres are not built entirely of concrete and iron, and with an iron floor and hearers for the stage. Let him try it, and see how actors and audience will like it, and how many letters will appear in the *Times* abusing architects for building theatres in which actors cannot make themselves heard. One of the few sensible and practical letters we have seen on the subject is that of Madame Marie Roze in the *Times* of Wednesday, suggesting that the first thing to be thought of is improving the state of things behind the scenes; taking gaslights away from dangerous proximity to combustible materials, and making the attendants who have charge of lights and of those criminally responsible if anything goes wrong through their neglect. Electric lighting (incandescent lights) behind the scenes is the most practical step towards safety from accidental conflagration of scenery, &c.; and the general adoption of that system on the stage at all events, if not in the auditorium, would render theatres a great deal safer.

**B**AD as the public health is just now in London with so much scarlet and enteric fever prevailing, it should be a subject of heartfelt congratulation that the cholera has so far given us the go-by, although it still hangs about Southern Italy and Malta in an unpleasant manner. There was a most interesting discussion at the recent Vienna Sanitary Congress on the subject of quarantine, the uselessness of which was generally conceded, while England was specially singled out as the country which has taken the lead in demonstrating its intility, by never imposing quarantine on people or things arriving from India, where most of the cholera has its source. The theory of contagion arising through water supply was disputed by Professor Gruber, while, on the other hand, Dr. Spatuzzi, of Naples, pointed out how that city had enjoyed

comparative immunity ever since the new waterworks had been finished. Professor Pettenkofer lectured on the influences which, in his opinion, locality and season had upon the disease. Of course, entire immunity on such a subject could not be expected, though it was satisfactory to hear from some of the greatest Continental authorities of the day, that we in England are considered to be on the right tack in sound and logical treatment.

**T**HE Local Authorities of Croydon are carrying on a systematic house-to-house sanitary inspection, evidently with all the beneficial results upon public health which have attended similar steps in some of the suburban districts. A pleasing feature of these inspections is that the owning and occupying public, recognising more and more the importance of such work, are putting forth now a helping instead of a frustrating hand to the sanitary officials. A large proportion of inhabitants no sooner hear that such a step is to be undertaken than they invite the authorities to examine the sanitary condition of their houses, and in very few cases has the surveyor to issue the threatening legal notice to remedy the discovered defects. It appears from the annual health report of Croydon that nearly 5,000 houses, large and small, have been visited during the year, and with only one or two exceptions have the owners failed to comply with the simple note of the Surveyor, pointing out the sanitary defects and the necessary remedies. The work appears to have already perceptibly decreased the death-rate. The death-rate for the seven weeks ending September 10th last was 14.15 per thousand of the population, notwithstanding that at this period of the year the rate of infant mortality is high in consequence of the hot weather. The death-rate for the year was 14.52 per thousand, though the mean rate for the preceding ten years was 16.72. The death-rate of Croydon is, according to the Registrar General's return, about 2 lower than the rate this year in the ring of suburbs round London, 3.28 lower than the smaller towns and country districts of London, and 4.78 lower than England and Wales generally. It may be added that in Croydon 461 of the better class of houses were inspected during the year, and 63 had defects in sanitary arrangements, such as would allow the escape of sewer gas into the house. As many as 239 were inspected at the special request of the owners; of these 85 were free from defects, 79 had defects which permit of the escape of sewer gas; and the others had only minor defects. 3,884 small houses or cottages were inspected: 884 of these were in an insanitary condition, but chiefly owing to dirt,—4,460 re-inspections were made to secure the execution of the necessary remedial work. It seems that the drainage defects were almost exclusively found in the older houses, and that in new properties, as a rule, the approved sanitary arrangements have been carried out.

**T**HE small diagram appended shows the principle of a method of extract ventilation patented by Messrs. Young & Moss. The following is the inventors' description:—

"A grating is placed near the ceiling line, from which a pipe descends in the brickwork of the chimney-breast to the floor level, and then enters a small chamber or cylinder, through a syphon (all the apparatus being placed out of sight behind the fireplace); a short pipe is taken from this chamber, and communicates with the chimney-flue, terminating just above the fireplace opening; the action of the draught (which is greatest at this point) on the end of this pipe, combined with the heating of the cylinder which is in contact with the fire, helps to draw rapidly off the vitiated air from the top of the room into the cylinder, and from thence into the chimney-flue. No reverse action is possible, the cylinder serving as an effectual trap and disconnecter. In summer, in ordinary rooms the fireplace opening is better closed up, as by this means the draught up the flue is materially increased. Where the chimney-flues are defective, a gas jet may be placed within the cylinder."

We have always upheld that vitiated air should be extracted from the upper part of a residential apartment, to which it naturally gravitates (or levitates), and not be coaxed down again; and this system has this recommendation; and

from personal inspection and testing we are satisfied that it does create a decided and pretty powerful extract draught even without the aid of the fire or of any other artificial heat near the upcast pipe. With the fire as a further assistance there would seem to be no possible doubt of its efficiency, unless the draught of the fire itself up the ordinary flue should act

Elevation

Plan

as a pull the reverse way of the system; this we have not tested, but we should think this result improbable. As to the function performed by the cylinder the inventors themselves do not seem quite clear, but they state as a fact that without the intervention of the cylinder it refuses to act, or is liable to do so, and that the result is the same if the upcast pipe is taken from the top instead of from the lower portion of the cylinder. The extract, of course, presupposes a corresponding area of inlet, but this is not dealt with as part of the patent. We inspected it under every disadvantage, with a temporary fixture and no artificial heat to stimulate the flow, and under those circumstances it is an efficient and pretty powerful extractor from the upper portion of the room, without any mechanical appliances.

**A** GOOD deal of excitement is being caused at Athens by the report of a discovery at Mantinea. The excavators there have come upon three large sculptured slabs, with a representation of the contest between Apollo and Marsyas. Marsyas appears with the Phrygian flute, his proper attribute; Apollo with the lyre. The two are surrounded by the Muses, who are present as judges. The great interest of the slabs consists in the possibility of their identification with the designs in the pedestal of a statue seen and described by Pausanias (book viii.) in his account of his visit to Mantinea. He says:—"And the Mantineans have a double temple divided down the middle by a wall. In one part there is a statue by Alcámenes of Esculapius; the other is the shrine of Leto and her children. Praxiteles made the statues in the third generation after Alcámenes. On the basis of these there are *Muse and Marsyas playing on the flute.*" If Praxiteles made the statues, did he not also carve the pedestal? The reliefs are described as of the utmost beauty of execution. They are to be taken to the Central Museum at Athens. True, Pausanias only saw one Muse; but then, perhaps, he only looked at one side of the pedestal.

**W**E have not had an opportunity as yet of making an inspection of the Roman remains at Tockington Court Farm, near Bristol, but, if we accept the detailed account published in the *Bristol Times and Mirror* of the 1st of this month, the discovery is one of no little importance and interest. It is

d to read that the first discovery of Roman remains on the farm, by a mason employed some alterations in the buildings, was in 84, and that, though the discovery was so appreciated that it was decided to cover the mosaic pavement discovered lest it could be injured by the frost (the discovery having been made in the winter), after it was done everything about it was forgotten till a few weeks ago Mr. Smith, the former tenant on this part of the estate, was reminded of it by coming on some Roman remains while cutting a drain across his yard, and this led to a renewed investigation and to the finding of some large pieces of mosaic pavement, one of them, according to the Bristol journal before referred to, of about 14 ft. by 10 ft., as well as another of about 18 ft. square, and elsewhere a portion 9 ft. long by 10 ft. wide. The place has evidently been the site of a large Roman villa, and as to the precise value of the remains, of course, we will express no opinion without a special examination.

WE reviewed some time back (vol. iii, p. 491) at considerable length Drs. Furtwängler and Loeschke's last issue of *Lykônische Thongefässe*, and expressed at the time our warm adherence to their view at the Mycenaean antiquities generally were of autochthonic (Achaean) origin. This view we retain unshaken, but it is only fair to note that it has been recently very ably advocated by Drs. Dümmler and Studniczka. The German archaeologists have a way of running and also fighting in couples, which denotes rather the magnitude of their undertakings than any individual inadequacy. The point stoutly maintained by these two last combatants is that the Mycenaean antiquities are not autochthonic, not Achaean, but in the main foreign and of Carian origin. The arguments to and fro are too complex to be summarised, but the paper which embodies them could not remain unnoted here, and deserves to be carefully read. It appears in the *Mittheilungen des Archäologischen Instituts Athen*, xii., Nos. 1 and 2.

THE Carpathian vases noted (p. 83) in Dr. Furtwängler's work just cited have been presented by Mr. Paton to the British Museum. The *Classical Review* for October, a number which well maintains the high level of interest of the journal, gives a list of further acquisitions. In addition to the above vases, Mr. Paton gives the Assarlik antiquities discussed in the *Hellenic Journal* (viii. 64-82), and three other vases of the Mycenaean type. After these the most interesting acquisitions are a lekythos (oil-flask) from Tarentum of secular technique, white on black with details in buff; a large hydria in the so-called Thucydidean style, with frieze of warriors, horsemen, &c.; and a curious bronze plaque decorated in panels, each panel containing a pair of nude figures. This plaque is apparently a rough and probably late imitation of the sort of bronze work found at Olympia. The *Review* continues its full yet concise summaries of foreign Classical periodicals, literary and archaeological.

THE series of notes by "A Foreign Artist and Author in England," which are in progress in the pages of the *Art Journal*, accompanied by many excellent sketches, deal this month with Chester, coming, therefore, rather *apropos*, just when such a discussion on the Walls of Chester is being carried on; though the coincidence appears to be quite accidental. The author (M. Villars, a Frenchman, we presume) does not go into questions of archaeology, but deals with the artistic and picturesque aspects of the places he visits. The article this month includes a sketch on the Walls of Chester, and another on the Rows, both exceedingly faithful to the locality. Mr. Villars comments, with some excusable sharpness, on the fact that when inquiring in the city as to the existence of any art or archaeological museum, he was sent to the little worthless collections in two of the old turrets on the walls which are misnamed museums, and that no one gave him

any information of the existence of the recently-formed Museum and School of Art in Chester, of which he only heard from a friend a few days after his visit. M. Villars rather criticises, and we think with reason, the habit of erecting modern buildings in the Rows in direct imitation of the old half-timber houses; the intention he thinks is praiseworthy, and shows an appreciation of the picturesque element in the ancient structures, but he considers the contrast in tone and appearance between the old thing and the obviously modern imitation has a very unsatisfactory result. These articles in the *Art Journal* should be looked at by those who are interested in seeing how our towns and villages appear, both as regards architectural and human character (for there are plenty of capital figure sketches), in the eyes of an obviously clever and cultivated foreigner.

THE College Hall at Worcester, which has been lately restored under the care of Mr. Christian, was reopened on Monday last. Now serving for the purposes of the Cathedral, or King's, School, this fabric had been the Monastery refectory. Its upper portion dates from the fourteenth century, whilst the lower floor, with its undercroft, is two hundred years older. Henry VIII. gave to the Dean and Canons' charge a boys' school which would seem to have existed here concurrently with the original establishment of the see. According to Smith and Onslow's "History of the Diocese" (1883), this see dates from 630 A.D.,—Æthelred being then king of the Mercians,—when Bosel was consecrated first bishop. Bosel had for his church, in the old borderland of the Hwiccas, or Wiccians, that of St. Peter, founded by Saxulph, bishop of Lichfield. Wolstan, twenty-fifth bishop, rebuilt the church in 1030. Amongst its more celebrated bishops in early days were Oswald and Dunstan. The refectory stands against the southern side of the cloisters, and has lately been used for the Festivals of the Three Choirs. During the course of its restoration a staircase leading up to the roof and some blocked-up windows were discovered. The Ecclesiastical Commissioners meet the expense of the new works, which exceeds 5,000l.

THE *Art Journal* announces that its "Art Annual" for 1887 will be devoted to the life and work of J. L. E. Meissonier, "whose pictures fetch such fabulous prices." We are very glad they have chosen so good a subject, but why tag it with the statement about "fabulous prices"? That has certainly nothing to do with the artistic value of Meissonier's work, nor does that remarkable artist need any such ad captivandum statement to draw attention to his works. The literary portion of the work is to be done by Mr. Lionel Robinson. The principal illustration will be a photograph of "La Rixe," one of the most popular and one of the cleverest of the artist's works, as a representation of vigorous action, though not one of those in which his peculiar genius is shown in its finest aspect.

THE *Indian Engineer* for September 3rd gives a description and plans and sections of the new swimming-bath in process of construction at Calcutta. The bath itself is 100 ft. by 35 ft., enclosed in an oblong building with an iron roof, with the necessary offices, waiting-rooms, &c., at the entrance end, and dressing boxes ranged along one side of the bath. The retaining walls of the bath are stepped from 2 ft. thick at the top to 4 ft. 6 in. at the bottom, and under the bath is a bed of concrete 2 ft. thick. The retaining walls, as far as we can gather from the description, are of brick, these and the bottom of the bath being lined with  $\frac{1}{2}$  in. Portland cement. The edges of the platform round the bath are to be faced with stone. The general design of the bath is by Mr. W. B. Gwyther, and the contract was taken by Messrs. Mackintosh, Burn, & Co., for 35,000 rupees. The exterior design is about as ugly and devoid of architectural feeling as anything well could be, but they are used to that in India, that paradise of engineer-architects: it would appear that

practically the work has been well carried out. The proposal to empty one fifth of the water every day, so that it should be completely changed once in five days, seems most inadequate: a swimming-bath should either have a current running through it, or should be completely emptied and refilled every day, at all events if it is in full use. Possibly considerations of water supply have affected this portion of the arrangements.

THE Government, we are informed, has sanctioned the definitive adoption of the iron process, invented and patented by Mr. Conder, M. Inst. C.E., at Chichester Barracks, and the War Department has taken over the supervision of the works, which have been conducted by Mr. Conder for the last fifteen months, under the order of the Secretary of State for War. This looks as if experience had proved it to be a practical success, and we congratulate Mr. Conder thereon.

MR. ALFRED GREIG, of Leeds, has designed a new form of traction engine for tramways, which is intended to dispense with the heavy wear and tear consequent upon the working parts of such engines being close to the road surface, and, therefore, always exposed to either dust or mud, which rapidly grinds away the working surfaces. In Mr. Greig's engine the cylinders and working parts are mounted, traction engine principle, on the top of the boiler, instead of underneath, as we find it in the tramway engines now in use. The engine is 11 ft. 6 in. long, 5 ft. 8 in. wide, and 9 ft. 6 in. high, and has a boiler of the locomotive type, burning ordinary gas coke, and working at a pressure of 180 lb. per square inch. There are two cylinders, each  $5\frac{1}{2}$  in. in diameter by 10-in. stroke, and the power is transmitted through spur gearing to the driving-wheels, as in ordinary steam traction engines. It is taken from a pinion on the crank shaft to an intermediate wheel, which gears into other wheels, one on each of the driving-axes, thus dispensing with coupling rods. The engine is carried on spring wheels, which save the wear and tear of sliding axle-boxes and improve the running. The exhaust steam is conducted to an air-condenser placed above the engine, and over the tubes of which cold air is drawn by means of a Blackman air-propeller, driven by a small auxiliary engine. This fan, which is placed in the roof over the boiler-flue, for there is no chimney-stack, also creates the necessary draught for maintaining steam. The engine is fitted with all the Board of Trade requirements, including an automatic steam brake, which shuts off steam directly the engine reaches a speed of nine miles an hour. The new engine, with which a very satisfactory trial run was made recently on the West Brighton and Shoreham Tramways, about the worst road in the kingdom for locomotive work, appears to be eminently suited for working tramways by steam efficiently and economically. It has been constructed by Messrs. Aveling & Porter, Rochester.

WE have received from the publishers of *Church Bells* an "Album of Notable Midland Churches," containing illustrations and descriptions of a good many churches, some of which are not very well known. The engravings are unfortunately poor in style, but they seem to aim at correctness, and with the descriptions the Album may be regarded as a useful memorandum of some churches that are worth keeping in mind.

WE regret very much to learn that Mr. Beresford Hope is dangerously ill, at his residence at Bedgebury, in Kent.

FROM the letters of the special correspondent of the *Times* at Bolton it appears that not only is the institution of the "picket" in full operation, but that tradesmen in the neighbourhood find it, or think it, necessary to write letters to the local papers to contradict any rumour that they have supplied provisions or other necessaries for the imported workmen. It appears that numbers of non-society

workmen who would be glad of work are struggling in vain to break through the cordon of pickets to get to the work which is offered them, and those who do get in have to be provided with food and lodging, as they cannot safely go out again. There can be no two words about such a system. A man who refuses to work except under certain conditions may be right, or may be mistaken, he may even be unreasonable, but we cannot say more than that: but a man who endeavours forcibly to prevent fellow men in search of work from doing work which he himself will not do on the same terms is a selfish scoundrel, and that is the plain English of the matter.

#### THE TRAINING OF AN ARCHITECT.

On Wednesday evening Professor Roger Smith gave the introductory lecture to the architectural classes at University College, the subject being "Education, Cultivation, and Examination." After a general review of the subject, in the course of which he deprecated the frequent abuse of examination and the popular cramming system of the day, while expressing an opinion that the examinations for Association of the Institute of Architects were such as could not well be passed by mere cramming, the Professor continued—

Having now considered general education, cultivation, and examination, I propose to pass to these subjects as they specially affect ourselves as students of architecture; and in approaching this division of the subject, I desire emphatically to point out that every architect ought to be a cultivated as well as an educated man. I shall have to point out later on that not a few of the studies and pursuits which to men in other stations are simply aids to cultivation, form part of the architect's special professional training; but apart from that, if he be not a man of cultivation, he will not do his duty well, and he will not properly occupy the position which a member of so liberal and responsible a profession ought to hold in society. You may perhaps remember that I said early in this lecture that "the object of education is to equip the student for the part he has to play on the stage of the world." If I can sketch for you the part which the architect should be prepared to play you will more readily comprehend the training he requires. Let us examine "the architect's part." There are three directions in which knowledge, skill, and experience are expected of him,—(1) As to buildings and structure; (2) As to men and affairs; (3) As to drawing and art. And I propose to take these in their order.

I. An architect ought to be familiar with buildings and structure. He ought to know all sorts of buildings, their various purposes, and how those purposes are provided for,—all that makes them suitable or unsuitable for use, and for any emergencies for which they ought to be prepared. He ought to know structure also,—that is to say, all the materials of which buildings are usually made, their appearance, qualities, defects,—the marks of goodness or badness in them, and the modes in which they are wrought, the work they will have to do in the structure, and their fitness for it. He ought to understand the sites and surroundings of buildings,—drainage and sanitation, fittings and appliances, and should have mastered the scientific principles upon which such things as heating, ventilation, lightning conductors, and cooking apparatus should be arranged, as well as their practical details. He has to understand the decay and disruption of buildings, and the risks of decay and accident that beset them, and how to guard against such risks. Again, an architect ought to know something about the history of buildings, and the most important structures in the world. He ought to know the artistic principles upon which good buildings have been designed, and the forms, mouldings, enrichments, and features which have been to the great artists in architecture what the colours on his palette are to the painter. And he ought to know by personal knowledge and experience, by measuring and drawing out in some cases, and by sketching and noting in others, a considerable amount of good architecture and good ornament, some of which ought to be from other countries than our own. And with some of this architecture

he ought to be familiarly, nay, intimately, acquainted. Further, he requires to be at home upon buildings in course of construction, to foresee what is likely to be successful or otherwise, whether in arrangement, construction, or design; and to be able to correct defects and prevent mistakes, alike of design and of construction, before it is too late.

II. Again, the architect is required to know men and affairs as well as building. You will come to find, as you advance in life, that in every professional calling, as, indeed, in every important position in life, a knowledge of men is the most valuable of all acquisitions. Even the solitary student, or the lonely landscape-painter, works for others, and if he succeeds it is either because his mind is so in harmony with the thoughts of his time that he involuntarily produces what others delight in, or else because his powers of calculation and observation enable him to take the measure, so to speak, of the men of his generation, and cleverly to produce (possibly without sympathy) some work sufficiently in harmony with the time to please them. Far more is it the case with ourselves whose work is from first to last done in contact with our fellow creatures, that a knowledge of what men like and think and do is essential to success. The inception of any architectural undertaking grows out of the desire of other people to erect a building. The material carrying of it out is done by other hands than the architect's under the control of another head, often fuller of the desire to make money than to make a building; and the whole undertaking is beset by difficulties, emergencies, and varied transactions, in which the architect has to unravel one tangled skein after another with different people. In short, from that early stage in his career, when an architect has to establish his position, make a connexion, and inspire confidence sufficient to induce persons to put their work into his hands, to the close of the transaction, when the last instalment of his own fees is paid him, he has need of tact, resource, a command of temper, presence of mind, good common sense, the ability to write a clear letter, and, in short, the qualities, natural and acquired, which enable a man to get on well with his fellow-men. All this must be combined with a knowledge of affairs. All this intercourse with other people rises out of matters that have relation to the buildings, or the site for them, or the materials of them, or the uses they are to be put to, the laws affecting them, or the customs, or the prejudices, or conflicting interests of the folk who have to deal with them. Now, in every one of these things the architect or chief builder, if he is to be chief, must be sufficiently posted up to take the lead. He must be familiar with such of the forms of transacting business, correspondence, accounts, vouchers, &c., as are used in building affairs, and such laws, customs, rights, as are incidents of or affect his work, and, in addition, with an infinite number of things that bear on it only indirectly. Estimates, accounts, the value of the things that are used in making buildings, the value of buildings themselves, and of the land they stand on. Road-making, repairs, light and air, the statute and common law as affecting buildings and property,—on all these affairs he is expected to be able to give advice,—and sound advice. He ought to know something about every use that a building can be put to, and though so much is almost unattainable, yet he ought to be constantly approaching to such a state of unusual knowledge of what goes on under all roofs the longer he lives.

III. *Drawing and Art.*—We build our buildings on paper to an extent never hitherto practised, but rendered apparently necessary by the modern contract system; but more than this, we study with the pencil when we examine existing work. The pencil aids to develop and fix our ideas when we are designing; with the pencil we make our intentions clear to our clients, and at a later period to the surveyors who prepare the estimate, and the artisans who carry out the work. Drawing, then, is a most essential,—the most essential of acquisitions for an architect. The best draughtsman may possibly never make an architect, though I do not think such a result need often occur; but no architect can hope to succeed at the present time who does not draw well, and is not familiar with all that ought to be and habitually is done in drawing out architectural designs, plans, and details, from first to last. Familiarity with plans is not a substitute for

familiarity with building, but it is an admirable introduction to buildings, and the best possible aid to the mastering of them. The draughtsmanship that is necessary will extend beyond familiarity with plan-drawing. A good draughtsman must have so far mastered the use of the instruments as to be able to think through his bow pencil or his straight-edge, and he must be able to draw all the ornaments in his buildings, including representations of the human figure, that his drawings shall be serviceable guides to the workmen. He ought to have mastered perspective, and to be at home to some extent in colour. Finally, in the use of these means he should have the feeling and inspiration of the artist, and he should have sympathy with and a knowledge of other walks of art as well as his own. Art which I have named last, on the principle on which the most famous performer is placed at the foot of a play-bill ("and Adeline Patti," for example) is that which determines the level at which our architect shall work. If he can be the artist in feeling and training, and in what he designs, his work may be noble architecture, and certainly will be good. Being an artist, be it remembered, relates to everything that develops a sense of beauty in form, line, and colour, and in all the allied parts as well as in our own. I need hardly point out that this considerable range of knowledge and experience will take years to acquire,—in fact, it is the work of a lifetime; but what we are concerned with is that approach to it which justifies a beginning. This ideal portrait is not often, however,—even if time enough be taken,—carried out symmetrically and completely. Opportunity enables a man to accumulate experience, knowledge, and skill in one direction. The lack of opportunity, or of will, or taste, cramps him in another; and so it comes to pass that most men are better in one walk of this profession than in another,—fortunate if they are able to find that class of work for which they are most fit. In passing I ought to point out that more than one of the matters that figured in our enumeration of the cultivated man's acquisitions or methods are almost essential to the architect. This is especially the case with his drawing and his cultivation of the fine arts. He almost alone of all professional men should, as a matter of course, include foreign travel as a part of his training. He also, in common with all professional men, should cultivate his mind and powers by Bacon's method of reading, writing, and social intercourse. In short, he should be a cultivated man. I now turn to the standard which has been set up by the Royal Institute of British Architects as marking what they consider should be the attainments of a young architect before he is admitted as an Associate of that body. This standard we find set forth in the programme of the examination and in the specimen examination papers published, and though my statement is less detailed than the series of subjects of examination, you will find that those subjects group themselves under my broader headings perfectly well. My first heading is "Buildings." To the subjects which I embraced under this head the programme allots 400 out of the total of 700 marks, divided as follows:—History of architecture, 100; mouldings, features, and ornaments, 100; sanitary science, strength of materials, and shoring, 100; materials and construction, 100. You see that the largest demands, even when a deduction, which I shall come to directly, has been allowed, are made under this head. This is partly on account of the fundamental importance of a knowledge of buildings, and partly because fair opportunities for acquiring that knowledge are open to you in your student days. My second head was "Men and Affairs." This comprises two heads in the examination programme, between which 100 marks are allotted. They are:—Specifications and estimating, 75; professional practice, 25. The first of these two subjects most students can easily acquire, and skill in it can be readily tested by examinations; but much of the knowledge comprised under the head of professional practice cannot be acquired till later in life, so but few marks are allotted to the subject; moreover, the skill, tact, self-possession, and judgment needed for the transaction of business are not matters in which a candidate can be directly examined; though, as far as they come out in his viva voce examination, they will be sure to have a share in examining the result. My third head, "Drawing and Art," is directly

represented by one heading only, Plan, Section, and Elevation, to which 200 marks are allotted. Of course a proportion which the programme does not disclose of the marks allotted to the first group of subjects will be given to the sketches with which the answers are to be illustrated, and, as far as they go, these marks will increase the proportion devoted to drawing and art at the expense of those devoted to knowledge of buildings; but it is not likely that this could ever take place to so great an extent as to equalise the two. This examination grows, as you know, out of the voluntary examination, which acted as a pioneer to prepare the way. I had the honour of having some share in preparing the preliminaries of that examination, and am, alas! the only survivor of the five who acted as examiners and moderators on the first occasion, the others being Scott, Digby Wyatt, Aspietel, and John Papworth. Some of those who organised and subsequently recast the scheme still remain,—among them, I am happy to say, my immediate predecessor in this class, Professor Hayter Lewis, to whose initiation as honorary secretary to the Institute, more than to the action of any other person, we owe it that to-day we have an entrance examination for Associates of the Institute. The advantages which it was considered that students would obtain were, first, that the programme would make it clear what directions in the opinion of persons qualified to judge an architect's studies and his preparation for the serious work of his profession ought to take; and, secondly, that the examination itself would establish a standard of attainment which it is not unreasonable to expect that every student with the usual means of study at command shall reach before he looks upon himself as qualified to practise. The Institute by adopting this examination as the door through which every Associate must enter, had in one sense doubled the value of it, for it had added a double stimulus to work. Passing has always been a distinction; but now failure to pass entails a very serious professional disability. Of all things I should deprecate,—and I think in this I should speak the feelings of the examiners and council generally,—I should deprecate this examination being looked upon, or coming at any future day to be looked upon, as an arbitrary test. It is intended to be, and I think is so worked by the Board who undertake it, as really to be a test of qualification. That is to say, a man is not held fit to be admitted to the Institute because he has passed the examinations, but because he has fitted himself to perform the duties of an architect, and the examiners will direct their questions so as to satisfy themselves of this fact only. Whenever, or if ever, the examination fails to keep up its character in this respect, if it admits what are called catch-questions, and sinks to the level, for example, of the Civil Service examinations, where a man is passed as a consequence of his having temporarily worked up certain subjects, it will fail of its real object. Consider, then, that your duty really is to prepare yourselves for practice, and that this examination is an incident in such preparation. And do not consider that you are to prepare yourselves for examination, and that if you can worry through you are sure to be right as far as fitness for your professional life goes. If we have now arrived at some clear understanding of what you require to prepare you for practice, the only questions which it remains for me to deal with are first, the broad question of how generally you are to obtain it, and the narrower one of how much of it you can get here from me? I am not going to delay you in order at any length to examine any scheme of architectural education not at present in actual force, and within reach. Such an examination you will find in the reports in the professional papers of the conference on education held in May last. I should, however, like to refer, before I pass from the subject, to the programme of instruction in several of the American colleges, which, through the kindness of Mr. Oates, have been brought under the notice of many architects. In these programmes a course of scientific instruction is in each case provided, lasting several years, and taking in its turn history and draughtsmanship; but without enough attempt, so far as I can see, at securing for the student any familiarity with buildings. I trust that if these are seriously examined as precedents, it will be by the help of the light thrown upon them by observations from the pen of Mr. Wace appended to them.

The American schemes appear to me too theoretical, not artistic enough, and in other ways not suited as models for an English course of architecture, should such a course come to be established, as is very probable. It will be even less necessary to raise the question of technical education for artisans, which is one of the most important ones of the present day. The subject before us to-night is, it is true, to a great extent, a branch of technical education, for it relates to the education of the architect for the exercise of his art, and time will not serve us to travel outside its limits. I propose to pass at once now to the question of how, with the opportunities that London at present offers, you can be educated for your profession? Even that stage of preparation which the Institute examination marks cannot be reached without time. To become a great architect is the labour of half a lifetime. We have, however, had great architects in this country, and have them now; so it is clear that whether our appliances and methods are the very best or not, at least they can suffice. I once heard one of the greatest of modern water-colourists exclaim, before a gathering of artists, "It is not the water in the brush, but the spirit in the man that makes a painter in water-colours!" This is quite true; and if we take any great architect,—say, Sir Charles Barry,—it was the spirit in the man that made him what he was; still, the water-colourist does have water in his brush, and Barry reached his eminence by some path. Let us turn to the published memoir of him, and ask what was that path? Pupilage for a long term, travel for a long term, and then continuous effort,—first to obtain, and then to carry out, responsible practice,—is the answer that we shall obtain. Now, that simple programme will form the outline of the only course at present open to the architectural student of the present day, and I recommend both parts of it to your cordial adoption, not necessarily as the best possible programme,—on that I offer no opinion here,—but as the best possible in London in the year 1887; and I will endeavour to show how much pupilage and travel themselves can do for you, and what can be done to fill out, add to, and supplement these two cardinal elements. With or without sound preliminary training, let us suppose that the student begins his career as a pupil. The life of Barry tells us that he was articled for and worked out seven years. This is not perhaps too long for a man to work at the drawing-board, but it is too long to be in one place. The term now fashionable is three years, which is too short, and I believe that, as a rule, four years is a very useful term, and that then most men had better change, and spend two other years seeing the practice of other offices as assistants, and, as a rule, as paid assistants. I have not much to suggest to pupils; but I ought to point out that what is really intended to be done for them is not to teach them as they were taught at school, but to give them a chance. In consideration of the premium he has paid, a young man who for a long time is more of a hindrance than a help is tolerated in a place where the work would go on better without him, and it is an understood thing that he is to be allowed opportunities of learning if he will use them. This,—though it may not sound a very precious privilege,—is really of far more value than most young men have the remotest idea of, and the great danger, especially for students who come straight from school and have not had the training in self-culture which college affords is that the opportunities may not be properly made use of. Let me urge on the notice of any pupils who may hear me, half a dozen or so friendly hints:—first, to consider no trifle beneath their notice; secondly, to recognise that to acquire habits of punctuality, order, the mode of conducting simple affairs, endorsing letters, conveying messages, &c., are all essential to their success in after-life as business men; thirdly, to do everything entrusted to them as well as they can, but as far as possible to secure the difficult jobs and pass the easy ones on to some one else; fourthly, to let nothing pass that they do not understand without extorting an explanation from some one; fifthly, to visit the buildings on hand and the builders' workshops whenever there is a chance; lastly, to make sketches and notes of every possible thing, insignificant or otherwise. A pupil who will spend his four years in the practice of this line of conduct will leave the office a good deal nearer being an architect than he entered it. It

is, perhaps, right to add that though I may have given what does not seem a very brilliant account of pupilage, and though I am about to show that it must be supplemented somehow, I do not think that what it supplies can be got elsewhere. So practical a pursuit as an architect's business can, I think, only be learnt by taking part in the actual conduct of it; and though many pupils would do better had they spent some time in preparatory study before being articled, I see no reasonable prospect of any system being introduced to supersede pupilage without great disadvantage. In the pupil's career I include any subsequent time spent in somewhat similar work, though under the name of an improver or assistant. A still more useful addition to a pupil's course is a time spent in a position somewhat analogous to that of a clerk of works, or as resident assistant to a clerk of works, or as resident draughtsman on some building. Naturally, this is a rare chance. Very few pupils of five or six years' standing, if any, are really fit to be of much service as clerks of works; but if they can in any capacity spend some time on a building, they will find opportunities for acquiring practical knowledge that are invaluable. Let us now inquire what advantage the student ought to be able to reap from pupilage, and from that kind of extension of it which I have sketched. First, as to buildings, our first head. He will learn little or nothing of their history, and in the ordinary course he will see little or nothing of old buildings, but he will have opportunities in a disjointed way of acquiring familiarity with many of the features, ornaments, mouldings, decorations, and with the general design of the buildings in course of erection by the architect to whom he is articled, and not infrequently with the design of some ancient buildings, as shown in prints, books, photographs, and sketches,—Classic, Gothic, or Renaissance, according to the proclivities of his master. He ought to have the opportunity of acquiring a pretty thorough knowledge of ordinary construction, and in some cases of special construction, and of learning how to specify and how to make approximate estimates. He will be sure to have opportunities of learning something about materials; but probably most of them will be wasted unless he gains elsewhere some general systematic familiarity with the subject theoretically. He may get some acquaintance with the appearance of buildings in course of erection, and of course it may happen that he may come into contact with old buildings in course of decay; but this experience is generally reserved for later days. Passing to my second head "Familiarity with Men and Affairs." In a large office a pupil rarely has anything to do with men and not much with business. In a small office, the pupil often has to see people, and to devote part of his time to letter writing or accounts and writing out reports, and from all of which engagements he will by degrees learn that valuable familiarity with men and things which we term business habits. If he is at all observant and does his best to make himself useful, and especially if he writes a good hand,—a valuable, and, I regret to add, a rare acquisition,—ought to become perfectly familiar with all the ordinary business documents that an architect has to do with, and so when he enters upon practice this part of his office routine will be at his fingers' ends. Much of the proper dealing with men must, however, be learned from his actual responsible contact with affairs in real life. My third head was "Drawing and Art." If a pupil goes into an office properly prepared, or, at least, well up in drawing the figure, and he has fair abilities, four years ought to make him at least a fair draughtsman. If in four years he thoroughly merits the praise of being a really good draughtsman, he has done well. The routine of preparing drawings from first to last should be familiar to him, and he, generally speaking, will have had an opportunity of making himself acquainted with perspective. Making designs is another matter; it depends upon other things than office work, and will not be learned in the office. As to art, as applied to buildings, or as seen in printing and sculpture, if the student is articled to an artist, and artistic work is being done during his term, he ought to gain much artistic training from office work. If (as is often the case) there is little to teach him fine art going on, he has to look for it elsewhere, and he need not look in vain, for many of the best artists in our profession have been brought up in offices where they had little chance of learn-

ing the fine art of architecture, though fortunately for them the technical art of building was learnable thoroughly. If I am correct in the view I have taken, it seems that the student unavoidably, and in the nature of things, is to look elsewhere than to the architect to whom he is articulated and the associates with whom he will work in the office for preliminary preparation and for several important parts of his training. As for preliminary preparation, it is impossible for an architect to have too good an education, and I wish that every student were a graduate of one of our Universities; but, at any rate, I hope that most will have obtained a thorough English training, with a good knowledge of, at least, one modern language, a fair amount of mathematics, and the elements of some of the natural sciences; that is to say, physics, and, if possible, geology and chemistry; and last, but not least, that he will be well grounded in drawing. It is seldom that a youth or his friends select architecture for his profession without his having some amount of skill in drawing, but it has rarely been carried far enough. The student should be able to draw the human figure from the antique fairly well, and ought to know something of perspective and landscape. If he has not advanced at least as far as this, it is better to spend some months at a drawing-school before entering an office at all. Some actual work in a joiner's shop is not a bad preparation for pupillage. Whether any part of this, which I call preliminary work, has to be taken up in addition or not, the following portions of the equipment I sketched a short time back must, it seems, be got elsewhere than at the office: As to Buildings, their history; much of their construction and materials, and science, and the superintendence of work. The study of existing buildings. As to Drawing and Art, design and the refinements of draughtsmanship, and fine art generally. As to Men and Affairs, all those parts of the conduct of practice which lie beyond ordinary routine, including the law of buildings. The most important of these is the study of erecting buildings, and I wish with all great emphasis to lay down distinctly the truth,—sometimes I fear forgotten,—that to study the buildings you must go to them. The knowledge about buildings which lectures, books, photographs, and prints convey, is not a knowledge of buildings. You must see, study, and sketch them. There is very great advantage in a student, after a sufficient number of years have been spent in preparing himself, taking a tour, an extended tour, and a continuous tour through as many of the regions of Europe that are architecturally rich as he can, and if it can be extended into the East so much the better. This sort of tour has, I think, fallen in the estimation of students partly because the facilities for short trips are now so good, partly, I think, because many men during the last twenty-five years have practised little else than English Gothic, and such have been contented to limit their studies to this country, with perhaps a visit or two to France, Belgium, and Germany. But the star of English Gothic is setting, and the student cannot afford to neglect Classic, Renaissance, Romanesque, and Byzantine examples, such as he must cross the Channel to study: and for good reasons which I cannot stop to go into now, six separate trips of a month each do not do one half, probably less than half, the good that one tour of six months will do. Some building or buildings must at some time be examined very thoroughly. I am disposed to think that the balance of advantage is on the side of comparatively few good examples most thoroughly investigated rather than a large number less completely studied. Each building selected should be measured and drawn out in detail, so that the drawing would suffice to re-erect the building, or the parts of it which are of architectural merit, if it were burnt. It is obviously convenient in many cases to select some English building for this kind of analysis. Of course, a much larger number of buildings must in addition be less thoroughly treated. Though I have urged the long Continental tour as desirable,—and, let me add, most enjoyable,—it must not be supposed that short periods of study of buildings near home are not great helps. Never lose a chance of visiting, examining, and drawing good work, old or new. There is a certain amount of very good old Gothic, and fairly good old Renaissance, to be met with in London, and the best modern work

of both sorts here is quite as well worth study as the old, only let it be the best. London also presents opportunities of studies in museums, of which, I think, few architectural students avail themselves as they might. We have an unrivalled collection of Decorative work, and Renaissance, and Oriental specimens at the South Kensington Museum, where there is also a magnificent series of casts, including many that would form excellent studies for architects. At the Architectural Museum there is a rich collection of Mediaeval architecture; and at the Crystal Palace a series of casts and models of every age, the Renaissance, Byzantine, and Gothic being very good indeed. In all these places students who want to work can get leave to draw with very little difficulty. I now turn to the other points in which the student of architecture requires help. First, I am bound, I think, to refer to that provision which this college has made for assisting him, a provision of which I am proud to say that in the past a large number of men now successfully pursuing the practice, and in later years numbers of men whom I hope to see successful in life, have availed themselves. Those portions of your necessary studies in which you can be helped by attending classes here are,—(1) The history of buildings. This, with an examination into their features, details, and the growth and metamorphoses of architectural styles, forms the subject of the A, or art course here. I do not pretend for a moment to have time, in a session of thirty evenings, or the ability, to tell the students all they require to know; but I claim that the course here gives a systematic and connected view of this history of ancient and modern architecture. I endeavour to make the subject interesting, and prefer to content myself with only taking up as much as can be done thoroughly, rather than to attempt to get over too much ground. There is a magnificent series of diagrams, which are lent to students to work from as well as hung up in the room, and I have endeavoured, with a success of which I confess I am a little proud, to induce the students themselves to draw illustrations of the subjects of the lectures.

The Materials and the Construction of buildings from the subject of course B, and here, as in the history of architecture as an art, I am far, indeed, from attempting to cover the whole field; but the course is consecutive, systematic, and thorough; it takes up all the principal building materials, and how to use them, and I endeavour to make sure work as we go. From both these courses I believe students derive the advantage that they have planted in their minds a sufficiently connected view of the art in the one case, and of construction in the other, for them to be able to appreciate the meaning of every fact which comes under their notices either in their reading or sketching, or on buildings; in other words, that beyond direct gains they are enabled to get advantage from many other sources of information which would otherwise be of less service. I desire to state very plainly that these courses are not so much directed to enable students to pass the examination at Conduit-street as to give them a real help in their education as architects; but I believe that in this way they will more efficiently aid those who are going in for these examinations than if I attempted to shape them exactly to fit the course of the question papers. I think, too, the final examination at the end of the term, and an intermediate one, which it is usual to hold, are of great service to those who are preparing for the Institut examination, by enabling them to see how much they are able to accomplish in answering a previously unseen paper of questions on architecture within a fixed period, and quite without assistance. I am sometimes asked if these courses give enough information to enable students to pass these divisions of the examination to which they respectively relate. My answer is, that it depends upon the student. If he simply attends and takes some notes, and does nothing else,—Certainly not. If he attends, and gives time and study at home to the subject, and tries to make all that he heard in the classroom his own, and then to pursue the lines suggested for further private reading at points where want of time obliges one to curtail part of a subject,—Yes. Not, however, forgetting that personal familiarity with essential architectural buildings is absolutely essential

to success in the examination. Course C proposes to give such information on the general conduct of building operations and architectural practice, and on some of the laws respecting buildings, as is most needed by men beginning practice, including some notice of the supervision of building works, and the decay of buildings, and the measures to be taken to secure dangerous and ruinous structures. Here, again, I think that by giving what is most serviceable to the young architect, I am doing my best for him in his preparation for his examination. Here the work of this college stops; but I have little hesitation in saying that it will help you in the departments to which it is directed to master your subjects more thoroughly than by solitary study you easily can, and that what you will learn in this room is adapted to form the groundwork upon which your own further work may usefully stand. I regret that time warns me that I must condense as far as possible what remains for me to say, and give you bare references in place of stating matters at length. Before leaving this college I must point out that some of the sciences bearing upon architecture can be well studied here, and that the Slade school affords excellent means of instruction in drawing the figure, though in neither case are the courses specially arranged for architects. Some particulars of these will be found at the foot of the prospectus of my lectures. At King's College Professor Kerr gives a course of lectures on the Arts of Construction. His ability and his long experience as a public lecturer are too well known for it to be requisite that I should say more to point out the value of the course. The most important subject remaining, Architectural Design, is to be learned best at the Royal Academy. One must be a good draughtsman to get in; but here not only is good drawing made better under the eye of that accomplished architect and teacher, Mr. Philip Spier, but design is practised under the personal direction of the very first architects of the day, those I mean who have the honour of being members of the Academy. No opportunity so good as this exists, and no better opportunity well could be devised for students to acquire skill in design; and quite apart from the medals and prizes, this is enough to repay you for any trouble taken in obtaining admission. Next, I must refer to the Architectural Association and its work, a subject so considerable that I cannot do more than glance at it on general terms. A students' mutual improvement society, numbering about 1,000 members, with a library and at least a dozen classes and courses of lectures, and its own travelling studentship and series of valuable prizes, it is an organisation of great importance and with vast possibilities for good. I hope you will all belong to it, for from it individual portions of your architectural equipment can be well obtained. It is sometimes said that there are imperfections connected with the scheme of the Association, the most serious being that the work is to a certain extent fragmentary, and in the nature of things unequal, and that some of the amateur teachers are not practised instructors. Whether this be so or no, the facilities offered are very many and very great, and especially so in that all-important branch of your studies, the study of design. The elementary class of design, the class of design, and class for colour-decoration are worthy the attention of you all as open to you before you can enter the Royal Academy, and to these classes many an architect is indebted for his first opportunity of learning and practising design. The practical side of our art is studied by the members of the Association in many classes, each good in its way, and each taking up a useful portion of the work. The visits to modern buildings, which are organised by the Association, are a means of learning how the best work of the present day is being done, and in themselves would be worth joining for. In the Brown Book of the Association you will find the whole programme set forth, and there, too, you will find the regulations and programmes of all the other organisations which I have alluded to. Let me recommend to your notice the page of advice to students which that pamphlet contains, and to your practice the personal consultation with a member of the committee of advice which it suggests and recommends. Among the announcements in the Brown Book, one will appear for the first time which I should be

glad to believe will be continued for many years,— the Studio established by Messrs. Baggeally & Millard. This new and as yet untried venture, is fortunately in good hands, and if proceeded with, ought to afford admirable assistance to students in draughtsmanship and design and I hope also in construction. The Royal Institute of British Architects does not give any courses of instruction, but it possesses the best architectural library in London, and this is now accessible without charge and without more than the nominal formalities to all working students of architecture, including students at this college. The City and Guilds Institute has given in the month of July short courses of lectures on subjects, most of which are of value to architects. These, no doubt, will be repeated next summer. The establishment at this Institute of various classes bearing on our pursuits is in contemplation, meantime a class of exceptional instruction in masonry was conducted there last session by Mr. Harvey, and this subject is to be pursued together with the allied subject of descriptive geometry, under the same teachers this season. The instruction given by Mr. Harvey is spoken of by those who know most about it as exceptionally good, and there is nowhere else where the same subject, treated from an architect's point of view, is taught so thoroughly and practically. Here I might well add, were it not that I know that this address, or much of it, will, by the courtesy of the professional press, be read by students who cannot get to London, or who, being in London, cannot see their way to getting to Gower-street or Conduit-street. To any such I should like, with your permission, to address a parting word, and to say, "Courage, my friend. Remember, it is the spirit in the man, not the water in the bush"; and though I have spent the evening describing useful aids to study, there are few of them which a resolute and energetic student cannot dispense with. What I take to be absolutely essential is first work in an office, and that I take it you have; secondly, buildings to study, and there is hardly a parish in England where there is not at least a fragment of the noble Mediaeval architecture of our country within your reach; thirdly, books, and of those you must manage somehow to get hold of a few, but if your choice be not large you must be more thoroughly master of the ones you have, and lastly, instruction in drawing. That happily the schools of art have spread through the country. Read, I pray you, the "Advice to Students," issued by the Institute of Architects, and appended to the programme of the examinations, and you will notice that there is not scant reference to the London advantages which I have dwelt upon, though I have good reason to think that the Board of Examiners are not insensible to their value; but that the course pointed out is one which a student, with comparatively little aid, may fight out for himself. Still, I am quite sure that the aid offered here and elsewhere will make that course easier, shorter, and I think, surer. In taking leave of the subject and releasing you, let me revert to what was said earlier in the evening upon cultivation. I trust that each one of you will not simply learn his profession and push his way, but will cultivate his mind, and so successfully that he shall be known, not merely as a safe constructor or a brilliant designer, but as a man of taste, of judgment, of varied knowledge, of some accomplishments: in short, that he shall be an ornament to his profession.

**Class of Masonry.**—We hear that the City and Guilds of London Institute is having a class-room specially fitted for Mr. Lawrence Harvey's class of masonry. It will be lighted in such a way that the light will be thrown direct on the drawing or work of each pupil, and that all cross lights and dazzling of the eyes will be avoided. The pupils will only have to bring their drawing instruments, drawing boards being provided by the Guilds Institute. The class will begin work on the 17th inst. Intending members who have not yet applied are requested to send their names before that date to Mr. Lawrence Harvey, 10, Great Queen-street, Westminster, S.W.

**The Association of Public Sanitary Inspectors.**—At the annual general meeting of this association, held at Westminster Town-hall, on Saturday last, October 1, Mr. Hugh Alexander, Chief Sanitary Inspector, Shore-ditch, was unanimously elected Chairman of the Council, vice Mr. G. B. Jerram, C.E.

## Illustrations.

### INTERIOR OF A RENAISSANCE CHURCH.

THIS is a study exhibited a couple of years since at the exhibition of the "Manchester Academy of Fine Arts," in which it is endeavoured to adopt the Renaissance style for a modern town church, in accordance with the requirements of Anglican ritual. The chief points aimed at are, 1, Economy in the cost of fabric (the chancel only being lined with stone); 2, Clear floor space, with uninterrupted view of the altar and pulpit; and 3, Wall space for the adoption of a complete scheme of pictorial decoration.

The church is calculated to seat 1,070, exclusive of choir and clergy, the nave being 102 ft. long, divided into five bays (and having a narthex of 17 ft. more on the west end), and 39 ft. in clear width; the aisles, intended only as passage ways, 8 ft. clear; the chancel and sacristy 41 ft. long, and having on the north side a morning chapel, and on the south, organ, vestries, &c.

The triforium of the nave contains illustrations of the suffrages in the Litany: "By the Mystery of Thy Holy Incarnation," &c.; with the four major prophets and four evangelists over the chancel arch, on the jambs of which are SS. Peter and Paul, the pillars of the church.

The chancel is surmounted by a dome, proposed to contain an "Adoration of the Lamb," and the transept roofs have angel figures bearing the titles of Our Lord from Isaiah and St. John. Behind the altar (which is raised thirteen steps from the floor of the nave) are reredos, after the manner of well-known Flemish examples, and setting forth pictorially the Eucharistic mystery, extends the width of the church.

The view given shows the north-east angle of the nave, with chancel and morning chapel beyond. W. HENRY JEWITT.

### COMPETITION DESIGN OF FULHAM VESTRY HALL.

THIS is the elevation of a design which was sent in for the above-named very ill-managed competition, by Messrs. Cheston & Perkin, and the drawing was subsequently accepted for exhibition in the architectural room of the Royal Academy. The elevation is picturesque in effect, and well suited to the architectural associations of the locality. It was intended to be executed in red brick and terra-cotta.

### NEW STOCK EXCHANGE BUILDINGS.

The recent additions to the Stock Exchange on an area of 20,700 ft., between Old Broad-street and Throgmorton-street, consist chiefly of a new "House" (so-called) for markets joined to the old "House," each being about 8,000 ft. in area; also of committee-rooms and offices, with a frontage of 96 ft. in Throgmorton-street, and offices let to brokers, with a frontage, which will be 186 ft. when completed, in Old Broad-street,—through both, an entrance to the Stock Exchange. In the basement of the latter are electric lighting and heating and ventilating engine-rooms.

The new "House" has an octagonal hall and a dome, 70 ft. diameter and 100 ft. high, two arched transepts with apses, and irregular aisles.

Materials used:—Peterhead granite high plinths, dome piers in large blocks with moulded bases, frieze round, doorways and archways; half-polished Aubigny and Portland stone arches, cornices and pendentives; Pavonazetta Carrara marble walls, built with them. The dome riveted iron construction shows inside with moulded panels of Hittich's wire-work plastering; the latter also over transepts, and the same plastering in ceilings throughout the building. Entrances, lobbies, and staircases lined with Turkey red, Ippelen and Italian marble. Joiner's work: wainscot and mahogany. The dome covered with diamond-shaped leaves in copper; all other roofs with lead. The fronts in the streets are Portland stone and granite.

Below the new Stock Exchange is a settling-room, lighted by electricity, as are also the strong rooms and the buildings above. The plastering of the old "House" has been removed, the pillars covered with Korea and Giallo-Antico marble from the Roman quarries

near Carthage, with Belgian pedestals, the walls with Pavonazetta.

About 700,000 cubic feet of air, cooled or warmed as required, are driven in per hour by fans, the exhausted air also being drawn away by similar means.

The work has been carried out from the designs and under the superintendence of Mr. J. J. Cole.

### HOUSES, CHISWICK.

The drawing now published illustrates three buildings on Chiswick Mall. To the immediate right is shown old Walpole House, recently repaired for re-occupation. There is much that is interesting in its history, as it extends back to the Domesday Survey. In the Monasticum it is mentioned as in possession of the Dean and Chapter of Westminster, a prebendal house belonging to them having stood upon its site. Walford states that Barbara, Duchess of Cleveland in Charles II.'s time, died in the house, and that Dan. O'Connell later lived there some years.

Next to Walpole House are two semi-detached houses recently erected, and further to the left is Eyot Villa, the residence of Mr. John Thornycroft. Mr. John Belcher was the architect, and all the works have been executed by Messrs. Adamson. The drawing was in the recent Royal Academy exhibition.

### TOMBSTONES OF THE SEVENTEENTH AND EIGHTEENTH CENTURIES.

MANY of our country churchyards contain examples worth preserving of these interesting memorials. Frequently moss and ivy so thickly cover them, that the ornament is nearly hidden, but they have probably acted as a preservative.

The examples here given are taken from four churchyards only. The Queenington altar tomb is much injured by the roots and stems of ivy, and the turf is now above the base; but the one in Tewkesbury Abbey churchyard has been recently removed, and carefully re-set, owing, we believe, to the judicious and loving care of Mr. Collins, the builder. It is of a fine grained stone, and the carving delicately finished, but it is weather-worn in places.

Some of the designs are rude, but there is a character and feeling about many quite lacking in much of the modern machine-made work for the like purpose; and they seem to show that a certain traditional art lingered among masons in quiet country places long after it had disappeared from large towns.

The Gothic revival has caused rather a feeling of contempt for them, quite undeserved, and has led, in many instances, to their destruction. All antiquarian and artistic feeling should be opposed to this, and it is the desire to foster a better appreciation of them which induces us to give these illustrations.

**Society of Engineers.**—The Society of Engineers had its first meeting for the Session 1887-8, on Monday evening, October 3rd, at the Town-hall, Westminster, Professor H. Robinson, President, in the chair, when a paper was read on "Stability of Factory Chimneys," by Mr. R. J. Hutton. The author entered fully into the theory of stability of tall chimneys, pointing out some errors in the formulae ordinarily used, and, in connexion with stability, considered the relative effects of wind pressure on various forms, as circular, octagonal, and square, and at various angles. He then showed that the section of chimney which combined the highest theoretical stability with the least amount of material was not the same as that required by practical considerations for its greatest efficiency in producing draught, and that a compromise had to be effected between the two forms. Some examples of successful chimneys were then given, and also of some that had failed, with an examination of the causes of failure.

**New Theatre at Brighton.**—We hear that the plans for the new Eden Theatre, to be erected in the King's-road, Brighton, were passed by the Local Authorities last week, and the work will be commenced in a few days. The building will, we are informed, "be practically fireproof," and provided with ample exits. Some special features will be introduced in the construction by the architect, Mr. Frank Matcham, of London.

EAST END PANEL.

CENTRE PANEL.

WEST END PANEL.

Monument to Bishop Courtenay in Winchester Cathedral.—Designed by Mr. G. H. Kitchin.

MONUMENT TO BISHOP COURTENAY, WINCHESTER CATHEDRAL.

This monument, designed by Mr. G. H. Kitchin, architect (the son of the Dean of Winchester), has been placed on the spot where the remains of the tomb of Bishop Peter Courtenay, who died on the 22nd September, 1492, were discovered by the present Dean in December, 1885. The coffin was then discovered having on its lid a long cross, at the foot of which was a small shield with the Courtenay arms. Round the coffin-lid was the inscription "Hic recondita sunt ossa Petri Courtenay, Episcopi primo Exon, deinde Winton, qui obiit A.D. mcccxcii."

As the tomb stands close up to Fox's Screen three sides only of it are seen. Of these the long northward front has three chief panels. In the centre are the arms of the Bishop impaled with those of the See of Winchester, under the mitre; the shield has for supporters two dolphins, as we see them round the shield outside the Lady Chapel. Underneath is the Bishop's own motto, which appears also in the Lady Chapel, "In gloriam Dei." The right and left panels bear each a shield in centre, charged, the one with the Tudor rose, the other with the Portcullis, symbols which indicate the Bishop's close connexion with his friend and master, Henry VII. In the outermost small panels of the front is a symbolic ornament, which the Bishop employed elsewhere, a T cross, with the initials P.C. attached, and a bell suspended from it. This bell is an allusion to the great "Peter's Bell," which the Bishop gave to Exeter Cathedral.

The panel which fills the western end of the tomb bears the coat of the Courtenay family, with two swans as supporters on it; and over it and the corresponding panel on the east front is a scroll bearing the motto, "Honor Deo et Regi." The supporters of the eastern shield, which carries the arms of his father and mother, are two hoars.

The lesser ornaments, the T cross and bell, and the gerbs and sickles in the spandrels of the larger panels, are all taken from the splendid chimney-piece which the Bishop placed in his palace at Exeter, where it is still to be seen.

The carving has been executed by Mr. Whitley, under Mr. Kitchin's superintendence.

ON THE SIZE OF HOUSE DRAINS, AND THE USE AND MISUSE OF TRAPS.\*

RECENT investigations seem to prove that certain elements of ordinary atmospheric air,—chiefly oxygen,—acting upon aerobian microbes, destroy or attenuate their virulence, so that in either case the microbe, as a vehicle of specific disease, is annihilated. The significance of this fact, in relation to the proper ventilation of sewer and house drains, has, I think, not been generally realised. The earlier advocates of such ventilation,—among whom I venture to claim a place,—aimed rather at the dilution and rapid removal of sewage emanations than at the destruction of associated microscopic organisms; but they were not

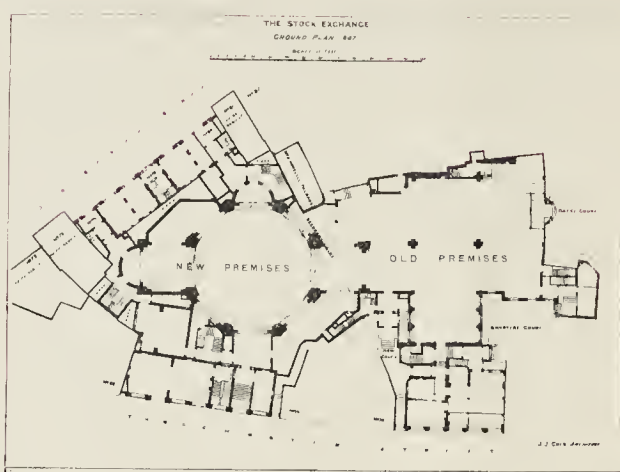

without some apprehension of the truth, since demonstrated, that such organisms are practically destroyed by the action of atmospheric oxygen. It is exactly thirty years since I myself published a paper on sewer ventilation, in which I endeavoured to arouse the better class of my fellow-citizens by pointing out the fact that while they in the most elevated and least crowded parts of the city had to submit to the frequent recurrence of epidemic disease, the people on the banks of the river (which seemed to them so pestiferous) were almost exempt from anything of the kind. And my explanation was this: I said that "the agents at work in both localities were identical, but they were differently developed." In the one case tainted air, undiluted and confined for miles in unventilated sewers, remained pestilential, whereas in the other, "mingling freely with the atmosphere, it became harmless,—as a homeopathic globule in a glass of water." I should be inclined to use very much the same language now,—and I regret to say there is almost as much need to use it,—but we have made an immense stride when we are able to plant our feet upon ascertained fact instead of reasonable but somewhat vague deduction.

We may, indeed, say that we have now a new and potent argument in favour of drain ventilation. We advise it not merely for the dilution of noxious gases, and their rapid removal, or for the relief of hydrostatic pressure, or the aeration of sewage, but also for the destruction of disease germs, or at least the attenuation of suspended virus; and it is evident that if we succeed in this we render our aerial drainage, if I may so call it, innocuous, so that even if it accidentally

STUDY FOR A MODERN RENAISSANCE CHURCH. BY MR. W. H. JEWITT.

gained admission to our houses it would do no harm. To secure this, however, even partially, it is obvious that we must allow a much larger volume of fresh air to pass through our drains than has hitherto been customary,—in short, the more nearly we can make them approach in airiness to the condition of open drains the better.

These remarks apply to drains of every size, but in this short paper I shall refer to house-drains only. One reason why I do so is that it seems almost a hopeless task to convince those who have control of the common sewers that anything in the shape of ventilation is called for. After nearly forty years of sanitarian effort, argument, entreaty, and painful and costly experiences, it is now almost as necessary as ever that those who connect their drains with common sewers should carefully protect themselves against the risks they run in doing so. In this and many other things, sanitarians have been very much like the "importunate widow," but after so many years' ineffectual reiteration of the same tale, they may almost be pardoned if they begin to despond. In the case of house-drains, however, they are able to appeal to individuals, and individuals are more amenable to reason. Now, our house-drains are under our own control; we can cut them off entirely from the common sewer and ventilate them as much as we like; and in view of the facts already referred to, this important question presents itself: Do we in practice ventilate our house-drains sufficiently to secure the best results? I think it is perfectly manifest that we do not, and that it is simply impossible to do so with drains of the size generally used.

Pipes of small diameter are recommended to facilitate rapid flow and scour; but we want rapid flow and scour of aerial as well as of liquid sewage, and we are met by this difficulty, that whereas small pipes are best for the one purpose, large pipes are absolutely necessary for the other. Now, while we admit the importance of dealing with the aerial as well as the liquid contents of drains, we have hitherto made no adequate provision for doing so. We have, no doubt, several schemes of drain ventilation which are theoretically good, and which are useful so far as they go; but they stop a very long way short of that thorough flushing of the drains with fresh air which is desirable. In order to bring out clearly the difference between what is usually done and what I think ought to be done, let us suppose that we are dealing with a house of moderate size, having, say, two baths, three water-closets, three basins, and three sinks. A 4-in. pipe would suffice to carry away the sewage from such a house, but in practice a 6-in. pipe would probably be used. Now in many,—I fear I must still say in most,—cases no attempt would be made to ventilate this drain at all, although soil-pipes connected with it would for the most part be ventilated. In some an outlet-shaft would be provided, 2 in. in diameter, in some 3 in., and, in a comparatively small number, shafts 4 in. or 4½ in. in diameter. Let us consider the state of matters in such a drain with the outlet-shaft of the largest size. If we suppose that the contents of the drain would fill a 4-in. pipe, the 4½ in. shaft would give an area almost equal to that of the remaining empty segment of the 6 in. pipe, so that, roughly, what we have to do is to ventilate a tube, say 5 in. in diameter and 100 ft. long, the greater part of which is horizontal. Even assuming that there are no restricting cowls or gratings at either end, it is manifest that in such a tube there could hardly be any appreciable current without the application of great mechanical force, even if we suppose the tube to be smooth and empty. But the tube we have to deal with is neither. It is rough, and it has for the greater part of its course an exposed surface, greater than that of a 5-in. tube, part of which is in motion in an opposite direction to that which the aerial current would naturally take. In such circumstances it is evident that the current would not only be sluggish, but variable, now in one direction, now in another, and often, when opposing forces were well balanced, stagnant. If such be the condition of a drain with a 5-in. air-outlet, I need hardly pause to consider the condition of the great majority now in use, which have nothing like so much ventilation.

Of course everything depends on what we mean by ventilation. If we mean by that term such a change of air in the pipes as is possible under the conditions just described, we may admit that some of our house drains are venti-

lated; but if we mean by it constant flushing of our drains with fresh air having something like its normal proportion of oxygen, then I fear we must say that none of our house-drains are ventilated; with such restricted sectional area and consequent friction the thing is impossible.

The question then comes to be, can we provide the air space necessary for ventilation without either extending the exposed surface of the sewage or of the contaminated periphery with which the air must come in contact? I venture to think that it is quite possible, and indeed easy, to do so by means of a simple contrivance which I now submit to you (see diagram). A drain-pipe such as this may

be made of any ordinary size, but assuming that one having the upper portion 12 in. in diameter would suffice, let us contrast it with the drain already described. In the first we had a sectional area for the transmission of air of (omitting fractions) 15 in., in the other you have 120 in.; in the first the surface of sewage exposed is 6 in., in the other 2½ in., assuming that the maximum flow would fill a 4-in. pipe; so that in this new pipe there would be fully a half less exposed surface of sewage and eight times the amount of air with increased velocity; besides which the flow of sewage would be more rapid, being more confined. In such a drain 100 ft. long, open and unobstructed at both ends, the current would not be overpowered by friction, and would hardly be affected by the comparatively trifling area of moving surface; and we by no means advise that it should be open at the two ends only, but at as many points as practicable along its course. Dealing with comparatively pure air we should be at liberty to make intermediate openings without risk,—the fresh air would thus have the upper hand and keep it. We can give air as well as water too much to do, and in fact it is more dangerous to overcharge air than water with impurity.

But while I recommend the use of large pipes immediately in connexion with the house,—that is to say, on the inlet side of the manhole and intercepting trap,—I must observe that in most cases it will be advisable to use pipes of small diameter between the intercepting trap and the outfall, especially if that outfall be a common sewer. In that case our object must be to leave no room for air in the pipe,—to use pipes large enough to hold the sewage and no more, so that when full, or nearly full, the air may be expelled from them. I speak of things as they are, not as they ought to be. Our sewers ought to be in a different condition, but while they remain a source of danger the more completely we shunt them off from our dwellings the better, and the less we allow their polluted air to remain in contact with the seal of our intercepting trap the better. Where the outfall is good and the branch may be safely ventilated the large pipe of the section shown will be best. In short, the use of the one or the other is indicated by the practicability or otherwise of thorough ventilation.

I must now make one or two remarks on the use of traps in connexion with a thoroughly ventilated house-drain. The complete isolation of a house-drain is a fundamental condition. It must not be connected aerially either with a common drain or with the drain of any other house. Having secured that condition by means familiar to you all, and having also secured the thorough flushing of the drain with fresh air and water, it follows that trapping, as a protection against foul air, is unnecessary.

We are practically safe, and the fewer traps we have either outside or inside the better. We do not require to trap soil-pipes, rain-water pipes, or gullies; and by leaving them trapless we only the better insure the purity of the air

in the drain. The truth is that by a multiplicity of traps we create a multiplicity of obstructions and deposits, and to that extent interfere with the rapid cleansing and efficient ventilation of the drain. The only excuse for using traps inside at sinks, baths, and the like, is to protect the inmates from cold draughts and smells from waste-pipes. For this purpose some obstruction is no doubt necessary, but it need not take the form of a syphon trap. If it does it is most desirable that every trap of the kind should be accessible and cleansable from the vessel with which it is connected. Scullery sinks should be provided with a grease-box, which would also serve as a trap; but it ought to be inside, easily got at, and regularly cleaned by the servant who works at the sink. By appliances at present in use it is impossible to catch the grease in close proximity to the sink, especially where much hot water is used, but I think the difficulty may be got over by a contrivance which I shall now describe. This consists of a shallow box encased with cold water, and covered with a movable grating resting about ½ in. or more, according to circumstances, below the level to which the waste water will rise. The casing or jacket is really an expansion of the cold water supply to the sink, and the water in it would therefore be frequently replaced. The contents of the sink entering this box would at once spread over the cold bottom and impinge against the cold sides and raised central division. Much of the grease would rise through the grating and congeal above it, and thence be easily removed; but a good deal would, no doubt, adhere to the bottom and sides of the box. A depression is made at the end of the box to catch sand or other solids; the size would be in proportion to the amount of work to be done in the sink. It is evident that such a box would be quite easily cleaned, and that the cleaning of it could not be neglected without interfering with the use of the sink; moreover, as it would not be enclosed in any way, it would not be out of sight and therefore out of mind.

I shall conclude with a word or two about the trapping of water-closets. The ordinary wash-out closets have necessarily traps which prevent the inconvenient or otherwise objectionable ingress of external air, but I have no doubt that a good valve closet without any trap is hygienically a greatly superior apparatus. The external air is effectually excluded in this case by the water held in the basin; but it would be sufficiently excluded by the valve itself if we assume that the air in the house-drain is innocuous; there is, therefore, no use of a trap in addition to the valve, and without that obstruction the contents of the closet are at once discharged into the drain and carried clear of the house in a few seconds. In this way you not only with certainty get quit of excrementitious matter, but also of water which has been in contact with it; whereas in trapped closets you may get rid of the former but not of the latter, and in many varieties you get rid of neither. It is about twelve years since I first ventured to use trapless closets, and I have recently had an opportunity of comparing some of these, which have been in use for more than ten years, with trapped closets of about the same age, with the following result: in no case was I able to detect the slightest smell from a trapless closet, however long I held the valve open, and in every case where the closet was trapped a most offensive smell was perceptible if the valve were kept open for a few seconds. All my experience, indeed, points to this,—that our best chance of safety lies in so contriving our house-drains and plumbing-work that there shall not be one single receptacle where stagnation is possible throughout our entire system, and that the pure air of heaven shall constantly permeate every nook and cranny of it.

Besides plenty of air, a good scour, and periodical flushing, one thing more is desirable, if not essential, if the contents of our house-drains are to be harmless, and that is that they should be regularly cleaned. I may not enter upon this subject now, but venture to say that I see no difficulty whatever in having this cleaning done periodically at less expense, and with very much less trouble to the occupants of the house, than a somewhat analogous operation to which we are quite accustomed,—the sweeping of chimneys. There is, indeed, no reason why we should not have drain-sweeps as well as chimney-sweeps.

## PUBLIC SEWERS, AND HOUSE DRAINAGE.\*

*Public Sewers.*

As the necessity for some of the requirements of house drainage depends on the sewer, the writer proposes to say a few words on this subject before dealing with house-drainage proper.

So far as the drainage of a house is concerned, it is necessary to deal with sewers as they exist, not with a theoretically perfect condition of things. Sewers, as separate pieces of construction, may be, and frequently are, admirable; but as channels for the rapid removal of all that passes into them they are faulty.

Sewers in most of our towns are designed not only for the removal of excreta and vegetable matter, but they have also to receive a large amount of storm-water, necessitating the presence of washings from roofs, street sweepings, &c., and they should therefore be constructed to provide a rate of flow in them which shall remove much heavier substances than those contained in sewage proper. If this be not done, the more ponderable matter will subside, and even if this subsidence be regular, there will be a considerably reduced rate of flow due to friction; and as the subsidence never is regular, bars will be formed in the sewer which, unless removed by flushing or excavating, will in time close the sewer altogether, or make it nothing better than a cesspool.

The necessities of practice and the configuration of the ground in almost all cases prevent the possibility of sewers, worked by gravity only, being laid to such gradients as will produce a regular rate of flow sufficiently rapid to remove the ponderable matter, or the sewage proper, in a space of time sufficiently short to prevent deposits and fermentation in the sewer; thus, as fermentation must necessarily take place, and as the householder has no power over the cleansing or ventilation of the sewer, it becomes his duty to separate the occupants of his house from the possible and probable effects of any direct connexion with a receptacle or channel which contains gases injurious to health, and may contain the germs of serious disease which have passed into it from some other habitation.

If the drainage of all houses were in such a condition as to get rid of all matter liable to decomposition at once, and it were not the fact that, owing to the faulty construction of many house-drains, decomposition has already become active before the matter to be removed has ever reached the sewer; if the sewer were self-cleansing and thoroughly ventilated, and the dangerous matter were removed before fermentation set in; if it were not the channel through which must necessarily be passed excreta carrying with them the germs of disease, there would be no necessity for the careful separation of the several systems of house-drainage from the sewer proper. But, as sewers do receive matter already decomposed, as they do not at once remove matter subject to decomposition, and as they are not thoroughly ventilated, it is necessary that each house should be disconnected as effectually as possible from any chance of contamination from this source, and the intercepting trap between the main house-drain and the sewer is a necessity.

Much exception is taken to the system at present in force for the ventilation of sewers, and it is proposed by some to put a large ventilating-shaft at the head of every sewer; but a very small amount of calculation will prove clearly that, even if the openings into the street were closed, any such system would be perfectly ineffectual, and that if the street-openings remain as they are, any such ventilation would not extend beyond the first or second of these openings. If sewers could be cut off into short lengths with an effectual seal at either end there would be no difficulty about the matter; such an arrangement is easily ventilated; but how to ventilate a large length and area of pipes, opening in many places either into the air or to other sewers, the writer knows not. The ventilation of a coal-pit will serve to illustrate the difficulty.

Street-openings are frequently offensive to the sense of smell because the sewer is foul, but this is not a reason for closing up the openings

into the streets, which would have the effect of forcing the gases into the houses by the pressure of the sewage when increased in volume during the day, or by a sudden access of storm-water, or by the expansion of the gases themselves, or by a combination of two or more of these forces; but it is a reason for increasing the number of openings, and thus reducing the temperature in the sewer as compared with the outside atmosphere in cold weather, and diluting the gases to the utmost extent possible. It is of course obvious that if fresh air be admitted foul air must be expelled.

If sewers can be efficiently ventilated there should be no delay in doing it. The proposal which seems to the writer to have the most practical value is that of carrying a pipe from the sewer to a point above the roof of every house, or of certain houses on one side of the street only, or alternately on one side and the other, but so that ventilating-pipes shall not be opposite each other on the two sides of the street. The ventilators should not be connected with the house-drain or with that part of it which is in the street (as this is liable to be flooded, and the ventilation would then be stopped), but with the highest point in the sewer. To make such a system of ventilation efficient, it would be necessary that a street-opening should be placed midway between each pair of ventilating-shafts; or if the shafts did not rise to the same elevation above the sewer, they should be so spaced that each should receive an equal amount of air in proportion to its requirements from the street-opening; and the latter should be of ample dimensions, so that the indraught should not be checked. Taking the difference of temperature between the column of air in the ventilating-pipe and that of the atmosphere at the street-opening at 5°, or assuming that the expansion of the gases produces a head equal to this difference of temperature, then a 4-in. pipe 40 ft. high might be expected to change the air in a 60 ft. length of 3 ft. sewer running one-third full, in 13.7 minutes (see Hood on "Warming and Ventilating Buildings," p. 364); or in other words, in order to change the air in 27 cubic feet capacity of sewer five times per hour, a ventilating-pipe 40 ft. high, and having a sectional area of 12.56 in. will be required, on the supposition that a difference of temperature equal to 5°, or a difference of head representing the same amount can be secured. Having made these few remarks on the condition and ventilation of sewers, the writer proposes to proceed to the consideration of house-drainage proper.

*House-Drainage.*

It is proposed to take certain propositions as axioms granted by all sanitarians, and to enlarge on these. The axioms are taken from a report prepared by a committee appointed by the Civil and Mechanical Engineers' Society. If no remark be made on any particular axiom it is considered that none is required.

(1.) Every drain, or part of a drain, inside a house, and all soil-pipes, shall be water-tight throughout. The writer believes that this requirement can be thoroughly carried out with glazed stoneware pipes, if they be thoroughly heddled in concrete, and no contact with any part of the foundation of the house be permitted. He, however, prefers to use cast-iron pipes where a drain passes through a house, and considers that with this material it is to be preferred that the supports should be at considerable intervals, that access to all the joints should be simple and easy, and that the drain should be in such a position that it will come under constant inspection. Under these conditions leakage can be quickly detected, and injuries from rusting may be reduced to a minimum.

(2.) The main drain of the house shall be ventilated at its upper extremity by means of a continuation of the soil-pipe, or by a special pipe provided for the purpose, such ventilating-pipe, whether connected with the soil-pipe or otherwise, having a clear sectional area of at least 10 square inches throughout, and being carried to such a height that its outlet shall be at least 3 ft. above the eaves of the roof, and the same distance above any window or opening in the roof not being a chimney, and not less than 6 ft. distant from any chimney or opening in the roof, whether of the house to which it belongs, or of the next adjoining house, measured in any direction. The main soil-pipe shall be similarly ventilated, and if there be more than one soil-pipe, then each such soil-

pipe which shall be longer between the basin of the closet and the main drain than 8 ft. shall be similarly ventilated. The main drain shall be disconnected from the sewer or cesspit by means of a syphon trap of approved construction, provided with means for cleaning the trap, and the portion of the drain between the trap and the sewer or cesspit, and it shall be ventilated by an inlet air-pipe or ventilated disconnecting manhole; and if there be more than one outlet ventilating-pipe connected with the house-drain, then each such portion of drain and outlet ventilating-pipe shall be provided with a suitable syphon trap and an inlet air-pipe, or disconnecting manhole, as already described; and the area of the inlet air-pipe shall in all cases be at least double that of the outlet ventilating-pipe in the clear.

It is contended by some writers that the inlet for fresh air should be at the head of the drain, and the outlet at or near the disconnecting manhole. The objection to this arrangement is that the soil-pipe will either remain unventilated, or a separate system of ventilation will have to be provided for it, thus introducing unnecessary complications. The argument in its favour, that it follows the flow of the drain, does not seem to be at all conclusive, for as no house-drain ever runs more than one-third full, unless under most exceptional circumstances, there is not much reason to fear that the air passing up the drain, which is more volatile than the water flowing down it, would have its current arrested by the water. The effect would be that the current of air would be temporarily accelerated, and especially would this be the case when, as frequently happens, the drain has a diameter of 6 in., while that of the ventilator is 4 in.; also, if the water in the drain were giving off vapour, this would rise in the drain and travel in a direction contrary to that of the water; this, therefore, seems to be the natural direction of the current.

Writers have repeatedly stated that the number of ventilating-shafts should, if possible, be increased indefinitely, and from some of the statements to this effect it may be inferred that the relative elevation of the several shafts is a matter of no importance, and that rain-water pipes may be used for this purpose. It cannot be too often or too urgently repeated that this is altogether a mistake (see Hood on "Warming and Ventilating Buildings," p. 360); that under no circumstances should rain-water pipes be used as drain ventilators; they cannot go above the eaves of the roof, and therefore the foul air from them is liable to enter the house; also, if more than one upcast shaft be used it will not, unless each shaft be of exactly the same height, heated to exactly the same extent, and affected by the wind in just the same manner, increase the ventilating efficiency, but will rather diminish it. The writer has frequently come across systems of ventilation which were faulty on this account; but when the system of ventilation is simple,—that is to say, where there is one upcast shaft for each inlet, where the inlet opening is of ample dimensions, and leads as directly into the drain as possible, with few or no angles or bends,—he has found no difficulty, and he is of opinion that coils of any kind should be avoided, and that a mica return flap on the inlet opening is unnecessary. Where the work can afford it, a ventilating disconnecting manhole should be built, as it affords easy access to the drain; but a perfectly satisfactory arrangement can be made without it so long as the drain remains in good order.

The disconnecting trap should be self-cleansing; therefore it must be of large radius, with easy curves in all directions, and there must be no projections or corners in it which will either arrest the flow through it or tend to collect deposit. These requirements condemn all forms of dip trap, and, in fact, the only trap which will satisfy them is the ordinary syphon trap, if the radii of the curves be sufficiently great, and it be of good form throughout and well glazed. No inspection pipe in the middle of the length of the trap is possible; this would seriously retard the flow and cause deposit. A cascade action is recommended by some, but consideration will, it is thought, show that this action, while it may, by the greater head obtained with a small supply of water, force an obstructed trap, does not really offer any advantage which does not exist to a greater degree in the ordinary syphon described above. If with the cascade action a greater

\* From a paper by Mr. Reginald E. Middleton, M.Inst. C.E., M.Inst. M.E., Vice-President of the Civil and Mechanical Engineers' Society. Read at the Bolton Congress of the Sanitary Institute.

local head be obtained with a reduced amount of water, it is at the sacrifice of the general gradient of the drain, and therefore of the rate of flow in it. With the cascade action the distance travelled is greater than with the other system for the same fall, and the very fact of the head being obtained proves conclusively that this trap has a retarding effect on the flow, and the conclusion arrived at by the writer is that it is far hotter to make the best of the gradient procurable, to have a length of drain next to the trap from 1 ft. 6 in. to 2 ft. long, falling at the rate of 1 in 6, than to have a local vertical fall, whether small or great, and that in this manner a far better scouring action and a cleaner trap would be secured than with a cascade action trap.

(3.) No pipe which passes through any part of a house, not being a soil-pipe or soil-drain, shall be connected directly with the main drain.

(4.) No water-closet shall be situated next to a larder or place where food is stored. No pan-closet or D-trap shall be used, and every water-closet shall be trapped, and shall be arranged so as to prevent sphygnage.

(5.) The overflows from safes of closets and of baths, and from cisterns, shall be discharged into the open air in an exposed position, and shall not be connected with the soil-drain or rain-water pipes, either directly or indirectly, but shall act as detectors.

(6.) All sinks, baths, lavatories, and urinals shall be trapped with suitable traps, and the discharges from them shall be carried outside the walls of the house, and shall not be connected directly with any soil-drain, nor shall they be introduced under the grating of any trap, but they shall terminate in the open air, and not near any window or other opening.

The writer is aware that many sanitarians prefer to introduce the pipes leading from sinks, &c., under the gratings of the yard gullies; but he thinks that this is a mistake, and that it is far preferable that the discharge should be made fully in the open air, so that there may be as little chance as possible of the collection of any matter in the pipes, than that it should be hidden out of sight and, possibly, choked. If the gratings became foul from this cause, it is better that this should be apparent than that it should be hidden; it is the object of scientific drainage to bring any collections of foul matter to light, not to hide them.

(7.) All water-closets, urinals, and slop-sinks shall be provided with suitable flushing-cisterns, and the flushing-pipe for any closet shall not have a less internal diameter than 1½ in., and the height of the flushing-cistern above any closet, urinal, or slop-sink, shall not be less than 4 ft. It shall be impossible to draw water from any cistern used for flushing purposes for any other purpose than that of flushing.

(8.) The cisterns used for general purposes shall be easily accessible, and shall be provided with covers ventilated into the open air outside the house by a rising pipe other than the overflow-pipe; and no pipe from them shall be connected in any way with any soil-pipe, drain, or with any pipe receiving the discharge from any bath, lavatory, urinal, sink, or flushing-cistern.

(9.) No rain-water pipe used to receive the waste from any bath, lavatory, sink, or urinal, shall be placed near a window or other opening; and no rain-water drain shall connect directly with a soil-drain, and no rain-water pipe shall be used as, or connected with, the soil-pipe nor as a ventilating-pipe.

Though there are many bad sanitary appliances in the market, the selection of good ones is a simple matter, requiring little more than common-sense knowledge, it being obvious that sharp bends and angles and straight vertical sides are undesirable; that all utensils should retain matter liable to decomposition for as short a time as possible, and should pass it quickly to the drain, which in its turn should pass it quickly to the sewer. Complications both in apparatus and in the drains and ventilating and inspecting chambers, are most undesirable, and economy without loss of efficiency should be studied. Finally, whatever sanitary work is done, it is of the first importance that it should be done well, that the construction should be thoroughly accurate, and carried out in a trustworthy manner.

**City of London Court.**—A new building for the City of London Court, designed by Mr. Murray, is, the *City Press* says, to be erected by the Corporation, at a cost of nearly 14,000l.

THE WALLS OF CHESTER.

Sir,—Mr. Thompson Watkin says I have not answered his question about the absence of mortar in the Chester walls, or, I suppose, in a portion of them. I have, it seems, in vain referred him to the walls of Dijon, Sens, Bordeaux, and Artois. In all of these, as in the walls of other towns, the sculptures were placed carefully without mortar, just as they were found in the Chester and London walls. The *castra* of Richborough, Reculver, and Lyme are, or should be, well known to archaeologists. Like that of Chester, the walls are upon layers of boulders without mortar, but above they are strongly cemented. It is in the absence of any underground foundation that the walls of Roman *castra* are distinguished from Mediaeval buildings.

When Mr. Watkin asserts that the origin and date of the Continental walls, mentioned above, have been disputed, he is correct; but the arguments used to prove them Mediaeval were as illogical and futile as those adduced in favour of a Jacobean theory to explain the walls of Chester. M. Schuermans, in a masterly article on the walls of Artois, has shown the utter impossibility of their being other than Roman. See the *Bulletin des Commissions Royales d'Art et d'Archéologie*, 1877.

Mr. Watkin says that the eminent gentlemen whose names he prints as converts to the theory of himself and Mr. Shrubsole still adhere to their opinion. But is it really so? We do not see them writing in support of it.

As soon as possible, I shall endeavour to give my views on what are now the important questions, namely, to what cause may we ascribe the peculiar construction of the Chester walls; and the probable period. In the meantime, I rest in perfect confidence that truth and common sense will prevail.

C. ROACH SMITH.

Temple-place, Strood, October 1st, 1887.

Sir,—I will endeavour to complete my remarks on this subject, now that I have Mr. Watkin's reply, page 476. Before doing so I will answer one of his inquiries, the remainder as we proceed. Do I know of any Roman wall in England built entirely without mortar? No. Here is, however, one of the most telling arguments in favour of the Roman theory. If the Romans did not build the wall thus, could any other people? They are, at least, likely to have done so. They would have relied upon the huge size of the stones and their Continental custom, and it would have been in harmony with other works already cited where, in part, mortar is not used. We can in these works trace their tendency to construct in this manner. On the other hand, would any builders of the seventeenth century, or of the time of Anne; or, to go back to the Edwardian period, since a part of the wall is pronounced to be of that time, have been likely to build without mortar? Can Mr. Watkin tell me of any city wall so erected? Or, can he tell me of any other important building? There are three periods for him to choose from. It must be remembered that there was artillery to be guarded against, and is there even the bare possibility of its being omitted in a work of such magnitude as the walls of Chester? I have already shown that it is the lower portion only that is so constructed. Are the builders of either of the three periods likely to have built the base without, and the upper part with, mortar?

The details of the construction now require notice, and the uniformity of design wherever opened is first in importance. At all the points observed there are the same lower courses of massive stones, much the same tool-marks, a plinth of varying size, as we find in the Roman wall of London. No mortar, except to the Roodeye wall, where it is used because it had more to do; to resist, perhaps, the wash of the tides and certainly the thrust of the bank. This mortar is as hard as flint, and Mr. Frank R. Williams has detected pounded brick in it, and has sent me specimens. The work is the same except the mortar, at the Kaleyards, called Edwardian by your correspondent, the same wherever the massive stones are visible. This uniformity of design in the lower portions proves that the latter were built at one time, and it is incredible to think that it could have been so rebuilt at any one of the three periods named, the lower part without, the upper part with, mortar. The absence of mortar to stones confessedly Roman is an item of detail of no

little value, since, even on the supposition that the stones were brought from some other Roman buildings, it proves that the Romans did actually build largely without mortar at Chester. The same remark applies equally to the moulded stones which have evidently been taken from a large number of small buildings, which were in like manner built without mortar, except to some of the upright joints. If re-used in Roman times, the absence of mortar is accounted for. If at any later time, it seems incredible. There are the stones, open to the observation of every one, and their evidence in this respect is not capable of being denied. There is, however, an important detail which must now be considered. None of the stones that I have seen have Lewis-holes of modern form. Mr. Jones has kindly measured what does appear for me. They average only 1½ in. deep, 1 in. broad, and 6 in. long, straight sides. Some are T-shaped. It seems impossible or nearly so for stones to be lifted by their means, and if so they indicate that the stones were rolled into position, that labour was cheap, and that progress was slow.

Is any builder of the seventeenth century, or later, with such a mass of work to do, likely to have undertaken it without at least some of our modern appliances? Is not this evidence fatal to any late date?

I may here note Mr. Watkin's remarks relative to the recent rebuilding of part of the wall west of the North Gate. The work he describes could hardly be Roman, except, perhaps, that what he calls the buttress wall may have been, in part, the backing of the wall of Roman date. He is speaking of the south face. Let him look at the north. Nearly all the way up to the little gate referred to, going west from the North Gate, he will see an almost continuous course of Roman stones, in some cases two, in some three, mostly of large sizes, with tool-mark patterns, which appear never to have been disturbed. How far this goes below ground I cannot say. In Mr. Hughes's shed, just east of the new opening, and ninety-four paces west from the centre of the North Gate, is a curious set-off, made up, not with the chamfered plinths as to the east of the North Gate, but with a quarter-round springing from a fillet, very like one of the coping stones we found built up in the wall. Beside this is another stone similar, but shifted in position, as some of the other Roman stones are. All above is of later date, and if opened it is very likely it would be found to resemble the bulk of the specimen I sent. Why did not your correspondent say something as to these stones? They have always been visible, they are very distinct, and tell their own tale. They can be found again west of the opening named. I am unable to divine your correspondent's objection to regard these stones as Roman work *in situ*. They clearly form part of the wall left and right of the North Gate, where we know, from Pennant's description and view, that a Roman double archway existed until the middle of last century. What more reasonable than that the wall should survive when the gate has been pulled down? In reply to his question, I cannot tell him of any cornice to any other Roman city wall, nor can he tell me of any such wall which retains its full height. We have nothing, therefore, to judge by.

But there is other evidence,—that of cost. It is a very easy thing for any one to assert any date that he considers possible; but at Chester, I believe, this can all be checked by documentary evidence. Mr. Earwaker, in his interesting discourse at the Town-hall, told us that there were hundreds of documents showing the acts of the municipality. I have not examined them, and the test I am now about to propose ought to be decisive for or against me. I therefore asked your correspondent,—p. 411,—(1) which statement as to age he considered most likely to be true, and (2) relative to the extent.

He replies (p. 477), "I believe the newly-excavated portion of the north wall to have been constructed in its present state (or mostly so) immediately after the siege; the North Gate, cornice, and walls" "during the repairs in Anne's reign."

He does not, thus, say that the whole of the city walls are of these dates, as I had understood him to do in some of his other letters. I am unable, therefore, to carry out my test to the whole of the city wall, but still to sufficient for the purpose.

I accept his answer, but it is bound to apply

equally to the small portion of the north wall from the North Gate to the Phoenix Tower, a distance of 394 ft., where the wall is only of moderate height, excepting a portion which I will not include, for it is thinner, clearly of later date than the Roman stones, which do not appear here. They go visibly from one of these points to the other, giving 50 ft. to clear the modern work at the North Gate, and also the other exception named in addition. The part of the wall above the Roman masonry we must assume for this purpose to have been erected at the same time, as I made clear in my inquiry, or later.

I have taken out the quantities of this portion, and find that, at current local prices, which I have verified, it would cost 2,560*l.* to erect the small length of wall as it now stands, the stone being supposed to be ready to hand for use from some older wall and not bought.

Let your correspondent reduce this to the currency of *temp.* Charles I. or Queen Anne, and let him, or any of his local friends, trace the records of the municipality to find entry of it. I will add to this, to make it even more certain. The Murangers of Chester have (or had) the task of the repair of the wall. Let him search through their accounts as well. If the entry had ever to be made he is sure to find some allusion to so heavy a work. Alas! for the Murangers, theirs could have been no easy office, if your correspondent is right, for this cost applies to only 394 ft. out of eight or nine thousand feet, forming the entire circuit of the city wall.

This is not all. If a careful observer examines these walls he will be able readily to find traces of repair after repair. At the North Gate he can count six such places close together. If this were a new wall at the periods named, the unhappy custodians must have had to pay for all of these since its erection! What a small outlay does the 1,000*l.* for repairs, *temp.* Queen Anne, recorded at Pemberton's Parlour appear? Yet it is spoken of as a heavy outlay (as it doubtless was). The work then done can be readily traced. It seems to be among the newest portions of the wall, done in great part with poorly selected stone, laid after the foolish local plan, any way except on its natural bed. Beside this wall, the Roman stones appear to be un injured.

The Roodey wall is referred to, and Mr. Watkin ventures upon a supposition derived from its present position, with the readiness so often met with. Conjectures in this respect are of no value. I have my own, but I do not state them for this reason. In the meantime it has to be remembered that it lines out exactly with the present western wall at Water Gate.

Finally, your correspondent refers to the ease with which Roman stones lying about Chester could have been found when wanted, and he thus accounts for their presence in the wall. Let him take a rule and measure the cubic contents of the vast mass of what he acknowledges to be Roman stones, now in the wall. He will be startled at the quantity, and be bound to abandon the supposition. In the short length of the North Wall already referred to, it amounts to about 21,840 cubic feet. This is sufficient to build a block of masonry about as lofty as the central tower of the cathedral, and about 14 ft. square, hut perfectly solid.

A still greater obstacle than the possibility of finding such a mass of stone lying about is the fact that the walls are very fairly coursed. Each is slightly different from those above and below, and there is a certain amount of variation. The builders had, therefore, not only to find Roman stones, but stones that would fit in with the courses, the facework being undisturbed. While this search was supposed to be made, the suburbs of Chester were lying in ruin after the siege, and stone, if wanted, must have been abundant. There was, therefore, no necessity to search for Roman stones.

My remarks have been demurred to on account of the few hours I spent at Chester. I found the time all too long to go through baseless theories, which ought never to have been put forward. I addressed myself to this examination unfettered by any preconceived opinion, except, perhaps, rather in favour of the non-Roman theory, from a recently published article. I am assured that the great bulk of observers will come to the conclusion that the unmortared portions of the walls of Chester are of Roman date, *in situ*, although

that Roman date may be a late one, and that the mortared parts are of varying Medieval periods down to our own day.

E. P. LOFTUS BROOK.

SIR,—Mr. Brock, in describing a section of our north wall (p. 441, *ante*), writes that "from the base the wall rises to a height of about 10 ft. without mortar, and 8 ft. with mortar. Allow me to correct this. I have visited the excavation with the City Surveyor, and on the spot ascertained that from the base the wall of massive stones rises to the height of the so-called Roman cornice 19 ft. 4 in. and is without mortar in its several courses, dry earth supplying its place. The mortar seen by Mr. Brock is a modern and superficial repair on the inner face only. This correction is material, since in judging of its age, or whether it is Roman or otherwise, it is important to know whether 19 ft. of the wall, or, according to Mr. Brock, only 10 ft. of it, is without mortar. Over the area returned by Mr. Brock as mortar, I saw a workman passing his arm between the layers of stone, first removing the dry earth, and then feeling for inscribed stones. I do not think he could have done this with Roman work. I think that most of your readers will agree with me that a wall made up of 19 ft. of loose stones without mortar, supported behind by 14 ft. of soil, has scarcely the look or characteristic features of a Roman military wall, or is likely to deceive any one familiar with such work.

GEORGE W. SHRUBSOLE.

Chester, Oct. 1st, 1887.

SIR,—Permit me to supplement my letter in last week's *Builder* [p. 476] with a few remarks, more especially on the subject of the Roodey stones, serving amongst other purposes, as the abutment of a bridge across the creek. Naturally there is much inquiry on the point of the existence of the Roodey in 1874, for a new intercepting sewer, revealed the fact that this creek at its mouth had been some 300 ft. wide. Mr. Shrubsole read a very interesting paper on it before the Chester Archaeological Society (see *Chester Courier*, March 28th, 1877), and in my "Roman Cheshire" I have gone fully into the matter. As the creek was gone, covered with silt, and above was rubbish of post-Roman and Saxon times. It existed, though almost completely choked up, till the beginning of this century, or, in fact, till some forty years since, being a large open drain. The deep depression in the field between the wall and the Militia Barracks, and the deep "dip" in the wall itself, reveal its site.

The existence of this creek explains, as I have pointed out ("Rom. Chesh.," p. 103), the passage in the "Polychronicon" that Elifeda "enclosed the city with new walls, and made it high two such as it was before, so that the castle that was sometime by the water without the walls is now in the town within the walls." Why the castle lay more than the whole of the western side of the walls should be "by the water" would be puzzling, if we had not evidence that the castle rock was more or less surrounded with water, the creek being on its north side, and the extension of the wall from Newgate round the castle, to meet the advanced Saxon wall on the Roodey side, in the vicinity of this creek explains how the castle came to be included within the walls.

But was the mouth of this creek built upon by Elifeda? I think not: but only excavation can show this. If not, a bridge would be necessary, but I do not think it would be an arched one, probably in imitation of Roman work; there would be one or two rude stone pillars and a roadway of timber.

I have always admitted that the large stones supporting the bank at this place are of Roman origin, though not *in situ*, and I should much like to see excavations in their rear. Sir James Picton, I may add, thoroughly seconds this idea, and thinks more would be learned by an excavation on the spot named than in any other.

W. THOMPSON WATKIN.

Liverpool, Oct. 3rd, 1887.

#### REFUSE DESTROYERS.

SIR,—I, with others, have reason of complaint against the general tenor of Mr. Jones's remarks upon Furnaces for the Destruction of Towns. Refuse in his paper of a few weeks ago, a reprint of which appeared in your paper of the 10th ult.

In referring to Hardie's patent, Mr. Jones says it is composed of the old saddle-shaped boiler. This is not the case. Again, he says I use forced draught somewhat like Young of Glasgow; again, he is incorrect, and does not take the least notice of the most essential part of the patent, viz.: the drying of the refuse in closed vessels or chambers, heated by the waste heat and flame given off by the burning of the refuse on the hearth of the furnace, and drawing off the noxious vapours as they arise through the fan with fresh air; the mixture is forced into the ashpit, and through the burning refuse of the hearth of furnace (which in my patent extends the whole length and width).

The bulk of the noxious vapours arise during the drying of the refuse, and up to now the drying has been carried out in open fires leading to the chimney, and from thence to the surrounding atmosphere, which it contaminates. This is the fault of furnaces

of the type of Fryer & Co., and others. I am aware that Mr. Jones says that in passing through his crematory furnace the objectionable fumes are burned and destroyed. I say, but to a very limited extent unless with very large additional cost of apparatus. It being impossible to burn them without air, or other supporter of combustion, if cold air is used, temperature is reduced, or if heated there is increased expenditure of heating it, besides requiring a separate furnace for the work. In my system the fumes of the drying-chamber are drawn off and mixed with air (required for combustion) passed through the grate-bars of the furnace in minute quantities, and with this fresh air, passing immediately through the fire, enters into combustion, along with the matter on the hearth, and becomes innocuous before going to the chimney. This is done by a single furnace.

It is evident that Mr. Jones, having omitted any remarks upon such portions of my patent as are considered points of value, had not examined the specification properly, or that his omissions are an object. He ought to have been more explicit in his remarks, or should have left out any mention of it. T. C. HARDIE.

Durley, Oct. 4, 1887.

#### BOLTON EXHIBITION.

SIR,—Thanks for your graphic notice of our patent w.c. in your Saturday's issue. May we be allowed to point out to you that you are wrong in saying we have no means of cleansing trap of w.c. If you will kindly refer to the diagram again, you will find we provide ready means of access to this trap, and with regard to the washing of the pan, we beg to inform you that in practice we find very little if any soil fouling the back or sides. The pan extends considerably towards the back to prevent its being soiled.

DUCKETT & SOX.

#### THEATRES.

SIR,—To prevent such events as that at Exeter, how would it answer to give always to every person as they pass in to any public meeting or entertainment a small plan with sections showing all the means of entrance of such buildings? Many would understand them, and thus be well acquainted with the internal arrangement of such buildings as they are with the outside streets.

It would more than pay the manager of such public buildings or hotels by the advertisements which might be printed upon the back.

R. F. CAMPBELL.

\* \* This is done, we understand, at Drury Lane, and it is a right thing to do, but it will not in itself prevent panics, though it may do something to mitigate the results.

#### PROVINCIAL NEWS.

Bury St. Edmunds.—A new lodge is about to be built at the entrance to the Bury St. Edmunds Grammar School for the Governors. Mr. Frank Whitmore, of Chelmsford, is the architect.

Gallowhill (Northumberland).—A large country mansion is in progress at Gallowhill, near Bolam, for Mr. Charles Perkins, J.P. The contractors are Messrs. Joseph Burnett & Son, of Birtley, and the architects are Messrs. Septimus Oswald & Son, of Newcastle-on-Tyne.

Liverpool.—The foundation-stone of the new engineering and technical department of the Liverpool University College was laid on the 1st inst. by the Mayor (Sir James Peole). The want of more accommodation has long been felt, and the architect, Mr. Waterhouse, has been asked to scheme out a building capable of accommodating the main departments of the college, excluding the scientific and technical; his plans have been approved by the council, and sketch plans were exhibited to the public on Saturday. The building, of which the foundation-stone was laid on Saturday, consists of a shaped block resembling the form of the letter L. The long portion of the block forms a room about 100 ft. in length, which is to be a joiner's workshop. The shorter part of the block comprises the laboratory, lecture-hall, and various class-rooms. The longer side of the block faces Brownlow Hill, and has a frontage of 170 ft. The eastern face extends 102 ft., and it is here that the main entrance will be constructed, it being an arched doorway 12 ft. in height, and opening into an entrance hall. The style of the building is Gothic. Upon the ground-floor there will be the joiner's shop. The entrance hall of the other part of the building leads into a large laboratory. Behind the eastern frontage of the building there is to be a boiler-house, in which will be placed the furnaces and boilers necessary to drive the

machinery of the shops, and to work the lift which runs from the ground floor to the top story. The boilers will also supply hot-water pipes with which the entire building is to be heated, pipes extending through all the rooms on each floor. Upon the first floor the chief room is for a museum, the entrance being to Brownlow-hill. The lecture-lecture, which is 40 ft. by 34 ft., has seat room for over a hundred students. On the same floor there is an apparatus room, small lecture hall, and rooms for the professor and assistants. A lavatory and two rooms for the accommodation of the porter complete the provision of the first floor. The main part of the second floor is occupied by a large drawing-room. An examining-room and class-room lead to the south, and upon this floor are also superintendent's room, and several small diagram rooms. The height of the main building roof is 60 ft., while a small tower, which rises beyond the rest of the building, reaches 80 ft.

**Morpeth.**—Now business premises are in course of erection in Bridge-street for Alderman F. B. Grey. Mr. James Waterston, mason, and Messrs. G. & C. Haswell, joiners, are the contractors employed. The architects are Messrs. epitimus Oswald & Son, of Newcastle-upon-Tyne.

**CHURCH-BUILDING NEWS.**

**Holme-next-Sea.**—St. Mary's Church, Holme-next-Sea, which has been closed for the last two months for the purposes of restoration, was reopened on Sunday, the 25th ult. The work of restoration was commenced about three years since, when the roof, which was in a very dilapidated state, was replaced by a new one. The old-fashioned pews, which were painted in various colours, have now been removed and new open benches substituted. Prayer desks have been placed in the chancel, and a stone pulpit has been presented to the church by Miss Myth. The works have been carried out by Mr. Southgate, of Hunstanton, under the direction of Mr. William Adams, architect, Lynn.

**London.**—A new church for the English Wesleyan Congregation was opened on Wednesday, the 5th inst., at Vanbrugh Park, Blackheath. The building consists of a nave, transepts, lecture hall, class-rooms, &c. The exterior is of Kentish Rag and Bath stone, and the whole of the roof, pews, pulpit, reredos, &c., is selected pitch-pine and the outer doors of oak. The tower and spire at the angle of the building towards towards Mycena and Vanbrugh Park roads is over 100 ft. high. The site as presented by Mr. Young, a member of the congregation. Mr. Thomas Arnold was the architect and Mr. James Morter, of Stratford, is contractor. The stained glass was executed by Messrs. Pepper & Boyes, the carving by Mr. Allen, the gas pendants by Messrs. Marshall, of Hellenham, the enclosing fencing by Messrs. Aylls, and the heating by Messrs. Haden & Son, of Trowbridge.

**Over Winchendon (Bucks).**—The interesting little church of Over Winchendon, near Aylesbury, has recently been re-opened by the Bishop of Oxford, after renovation under the direction of Mr. William White, F.S.A. The plans were prepared some fifteen years ago, but the raising of sufficient funds proved a considerable difficulty and caused much delay in carrying out the work. The chancel is of the period of transition from Norman, with two lancet windows in the east gable and a corbel between them inside, with the string course pitched round it, on which was placed, perhaps, the image of a saint, or, as is thought more likely, a rood. If circumstances should permit, it is proposed to put a large cross here, made of lead, reaching up to the roof, with a reredos beneath containing a representation of St. Mary and St. John on either side of the base, painted on caupied panels, for which the figures have been already drawn by the architect. In each side wall are three lancets, and on the south a recess, apparently of a priest's door, now blocked on the outside, and immediately westward of this is a low side window, also blocked, of later date. There is a pointed chancel arch of simple or rather of rude construction, and a screen of later date against which new oak "return stalls" have been fixed. It is within memory that the wooden steps to the rood-loft remained. The nave is of Norman date, and in its south wall is a richly-moulded

doorway, and one simple window, of Norman date, with a recessed arch inside. The timber porch has been reconstructed as before, but without the plastering. The north door has been opened out; the north aisle is of fourteenth-century date; the windows have flowing tracery. The aisle opens from the nave with two round arches, and one pointed with flat soffits and large rectangular piers evidently cut through the old wall. The chancel fittings are of oak. The old altar and altar-rails have been re-used somewhat altered. Some Medieval benches have been refixed at the west end. The other benches are made up in deal. They stand on floors of wood block. The passages and the chancel arc laid with the old slabs, one containing a good brass made up with tiles.

**Shrewsbury.**—The dedication of Holy Trinity Church, Belle Vue, Shrewsbury, which has been rebuilt, took place last week. The old church, whose foundations were begun in July, 1836, consisted of a nave 60 ft. by 46 ft., with a flat plaster ceiling 24 ft. high; at the west end was a small tower, under which was the entrance lobby, from this was a staircase leading to a large inconvenient gallery; a very small apse at the east end formed the chancel. A new chancel with side aisles was built in 1861, by the late Mr. S. Pountney Smith, and this is the only portion of the old structure at present standing. The foundation stone of the new nave was laid twelve months ago. The new nave is 87 ft. long by 25 ft. wide, and has north and south aisles 14 ft. 6 in. wide, with arcades of five spans; the nave is lighted by clerestory windows, and is 30 ft. high to the wall-plate. The roofs are all of red deal, hoarded and felted on the outside and covered with Sedan green slates. The whole of the work has been carried out in brick, the exterior and interior being faced with Rahanon red pressed bricks, relieved with dressings and hands of Grinshill stone, and the arches of arcades are formed with outer ring of brick and inner ring of stone, the columns being Forest of Dean blue stone, with caps and bases of Grinshill. The levels of the old chancel floor have been altered to suit the new nave, the altar being approached by eight steps. The nave and aisles are seated with low-framed benches of pitch-pine, chairs being placed in the chancel aisles, and also at the west end of the nave, and the north aisle of the chancel will be fitted up for daily services. The choir stalls are of oak, and will accommodate fifty persons. The flooring under all seats is laid with wood blocks, making a noiseless and dry floor; the passages and porches have been laid with plain red tiles, in herring-bone pattern, by Messrs. George Woollicroft & Son, of Hanley. The encaustic paving of the chancel is the work of Messrs. Minton, Hollins, & Co., of Stoke-on-Trent. A baptistery is formed by a semicircular projection from the west wall of the nave; the roof of this is covered with copper, the floor will be laid in mosaics, and the lower part of the wall will be adorned with fresco painting; the old font, which is of meagre proportion and design, is temporarily refixed, a new one of alabaster having been promised. The organ has been moved to a new position, and rebuilt. The glazing of the windows is in cathedral tinted glass, executed by Mr. John Davie, of Shrewsbury. Ventilation is provided by means of inlets through the aisle walls, and the church is lighted by string-courses of gas jets, both sides of the nave, 21 ft. from the floor, and brackets in the aisles. This work has been carried out by Messrs. Alltree & Lea, of Shrewsbury. The heating has been executed by Messrs. J. L. Bacon & Co., of London, by means of a 1½-in. iron piping, laid in trenches down the passages of the nave and aisles. A general scheme of subjects for filling the windows of the church with painted glass has been prepared by Messrs. Heaton, Butler, & Bayne. Two of the windows in the aisle have already been filled in by them, and also the five lights in the baptistery. The church will accommodate 822 people, being an increase over the old church of about 340 sittings. The whole of the work has been executed by Mr. Richard Price, builder, Shrewsbury, from the design and under the superintendence of the architects, Messrs. Lloyd Oswald & Pountney Smith, of Shrewsbury. Mr. H. L. Whittingham was the clerk of the works throughout.

**Sutton (Sturley).**—New Christ Church, Sutton, is designed in the Gothic style of the early part of the thirteenth century, and is intended, when complete, to accommodate 1,000 worshippers. The work in the present contract

consists of nave, 92 ft. long, 30 ft. wide, and 48 ft. in height from the floor to the semi-circular barrel vaulted ceiling; north and south aisles, of the same length as the nave; chancel; on the north side of the chancel, clergy vestry, choir vestry, organ-chamber, furnace-room, lavatories, &c. Accommodation will thus be afforded for 900 persons, inclusive of the choir. The tower and spire, which will be 160 ft. in height, the northern baptistery, south chapel, and south porch, are intended to be dealt with in a future contract. The materials employed in the construction are local stock bricks for walls, faced internally and externally with local red bricks; Monk's Park Bath stone for columns, caps, and bases of interior and for external weatherings, and Broseley pressed roofing tiles for roof coverings. Internally the floors will be paved with wood blocks, with the exception of the space within the communion-rails, where Broseley pressed tiles of ornamental pattern will be used. The warming is to be effected by means of hot water on the low-pressure system, the pipes being carried under the whole length of aisles, and ventilation is provided for by controllable air inlets through the hot-water pipes and in the sills of windows, and exhaust ventilation through the ceilings. A special feature is made of the organ, the chamber of which is on the north side of the chancel immediately over the choir vestry, with a separate chamber for bellows and blowing-engine, in the basement. The organ manual will be placed on the south side of the chancel adjoining the reading-desk, and will be connected to the organ with pneumatic tubes carried in a tunnel constructed under the floor of chancel. The seating, choir stalls, and most of the furniture and fittings, are included in the present contract, amounting to £6,788, which is being carried out by Messrs. T. Gregory & Co. under the designs of Mr. J. T. Newman, F.R.I.B.A., and Mr. William Jacques, A.R.I.B.A.

**STAINED GLASS.**

**Canterbury.**—A large painted window, with subjects of the "Ascension," "Agony in the Garden," &c., and containing the Fagge and Macefields arms, has lately been erected in the parish church, Westbere, to the memory of the late Mrs. Parker, wife of Major F. G. S. Parker. The window, which is fourteenth-century in character, has portraits of the deceased lady and her son introduced, and has been designed and executed by Messrs. Chas. Evans & Co., under the supervision of the architect, Mr. E. P. Loftus Brock, F.S.A.

**Enderby.**—This parish church has lately been further enriched by the addition of a painted Jubilee window with representations of St. George, &c., the work of Messrs. Chas. Evans & Co. An elaborately-engraved brass beneath has the following inscription:—"To the glory of God and in commemoration of the 50th year of the reign of Queen Victoria. Erected by the Congregation. June, 1887."

**Preston.**—A stained-glass window has recently been placed in St. Wilfrid's Church, Preston, representing figures of St. Elizabeth, St. Peter, and St. Agnes. The work was designed and executed by Messrs. Warrington & Co., of London.

**Southampton.**—There has recently been erected in St. Luke's Church, Newtown, Southampton, by Mr. Gamlen, of Newtown House, a two-light stained-glass window, in memory of his wife. It contains four scenes from the 10th chapter of St. Mark, relating to the healing of the blind Bartimaeus by Christ. The work has been designed and executed by Mayer & Co., of London and Munich.

**School of Art Woodcarving.**—The School of Art Woodcarving at the City and Guilds Institute, Exhibition-road, South Kensington, has re-opened after the usual summer vacation. To bring the benefits of the school more within the reach of the artisan class a remission of half fees for the evening class is made to artisan students connected with the trade. Instruction is also given by correspondence to amateurs unable to attend the school classes. During the past year the students have been engaged on various architectural and other important works. The public are permitted to visit the school and inspect the work in hand on application to the manager on any weekday except Saturday between the hours of 11 a.m. and 4 p.m.

**SETTING OUT CURVES**  
WITH THE USE OF A THEODOLITE

**NOTE**—THE THEODOLITE IS SET UP OVER THE POINT MARKED A AT THE JUNCTION OF THE CURVE WITH THE STRAIGHT LINE, AND THE VERNIER UPON THE HORIZONTAL PLATE CLAMPED TO 90° OR 180°—THE CROSS HAIRS IN THE TELESCOPE ARE THEN DIRECTED TOWARDS ANY PEG UPON THE TANGENT LINE, THE LOWER LIMB OF THE INSTRUMENT IS CLAMPED WITH THE CROSS HAIRS ACCURATELY SET ON THE TANGENT LINE, THE VERNIER PLATE UNCLAMPED, AND THE TANGENTIAL ANGLES SET OUT AS REQUIRED—

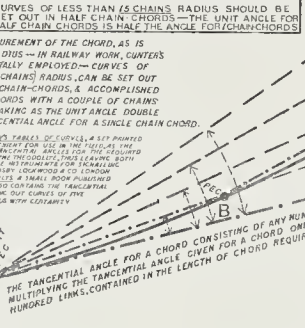

TANGENTIAL ANGLES FOR CHAIN CHORDS		TANGENTIAL ANGLES FOR CHAIN CHORDS		TANGENTIAL ANGLES FOR CHAIN CHORDS	
RAD. OF CURVE	TANGENTIAL ANGLE	RAD. OF CURVE	TANGENTIAL ANGLE	RAD. OF CURVE	TANGENTIAL ANGLE
5	5.43.8	20	1.25.9	50	3.4.4
8	3.34.8	25	1.8.7	60	28.7
9	3.11.0	30	5.7.3	70	24.6
10	2.51.9	35	4.9.1	80	21.5
12	2.23.2	40	4.2.9	1.60	1.0.7
15	1.54.6	45	3.8.2	2.40	7.2

IN THE ANNEXED TABLE, THE UNIT OF LENGTH FOR A RADIUS, IS OF THE SAME DENOMINATION AS THE UNIT OF LENGTH EMPLOYED FOR THE CHORD—SO THAT THE SAME CHAIN, MUST BE USED FOR THE RADIUS AND THE CHORD—

CURVES OF LESS THAN 5 CHAINS RADIUS SHOULD BE SET OUT IN HALF CHAIN CHORDS—THE UNIT ANGLE FOR USE IN ANY SINGLE HALF CHAIN CHORD, IS HALF THE ANGLE FOR CHAIN CHORDS—

NOTE—RANKINE'S TABLES OF CURVES, ARE SET POINT TO POINT, IN ORDER TO FACILITATE THE SETTING OUT OF CURVES, IN SINGLE CHAIN CHORDS, THE TANGENTIAL ANGLES FOR TANGENTIAL CHORDS, CAN BE SET OUT ACCURATELY BY TWO CHAIN CHORDS, & ACCOMPLISHED BY MEASURING THE CHORDS WITH A COUPLE OF CHAINS TIED TOGETHER, AND TAKING AS THE UNIT ANGLE, DOUBLE THE VALUE OF THE TANGENTIAL ANGLE FOR A SINGLE CHAIN CHORD.

NOTE—RANKINE'S TABLES OF CURVES, ARE SET POINT TO POINT, IN ORDER TO FACILITATE THE SETTING OUT OF CURVES, IN SINGLE CHAIN CHORDS, THE TANGENTIAL ANGLES FOR TANGENTIAL CHORDS, CAN BE SET OUT ACCURATELY BY TWO CHAIN CHORDS, & ACCOMPLISHED BY MEASURING THE CHORDS WITH A COUPLE OF CHAINS TIED TOGETHER, AND TAKING AS THE UNIT ANGLE, DOUBLE THE VALUE OF THE TANGENTIAL ANGLE FOR A SINGLE CHAIN CHORD.

**NOTE**—TO RETURN TO A TANGENT LINE AT THE END OF A CURVE, SET UP THE THEODOLITE OVER THE POINT OF JUNCTION D OF THE STRAIGHT LINE DH WITH THE CURVE WHICH CAN BE SEEN, AND LET THE VERNIER PLATE BE CLAMPED AT THE CALCULATED TANGENTIAL ANGLE FOR THE LENGTH OF ARC TAKEN—THEN CLAMP THE LOWER LIMB OF THE INSTRUMENT, REVERSE OF TRANSIT THE TELESCOPE—TRAVERSE AND RECLAMP THE VERNIER PLATE TO ZERO—THEN SET OUT A STRAIGHT LINE DH IN THE DIRECTION SO OBTAINED—

CASE 5—  
FIGURE I  
—RANKINE'S SYSTEM—

**NOTE**—TO CONTINUE CURVE FROM AN INTERMEDIATE PEG D—SET UP THE THEODOLITE OVER THE PEG FROM WHICH THE CURVE IS TO BE CONTINUED, PROCEED AS DESCRIBED ABOVE FOR FINDING THE DIRECTION OF THE TANGENT LINE AT THE PEG, THEN CLAMP THE VERNIER PLATE AT THE REQUIRED TANGENTIAL ANGLE DH, MARK OUT THE POINT E AT A DISTANCE FROM D EQUAL TO THE LENGTH OF CHORD TAKEN, AND CONTINUE AS MANY MULTIPLES AS REQUIRED.

**NOTE**—IN SETTING OUT A CURVE TO THE LEFT OF A TANGENT LINE, THE TANGENTIAL ANGLES GIVEN IN THE TABLE, AND THEIR MULTIPLES, MUST BE SEVERALLY SUBTRACTED FROM 90° TO OBTAIN THE ANGLES TO BE READ UPON THE VERNIER PLATE.

FIGURE I—THE LENGTH OF A CURVE IS GENERALLY ARRIVED AT, IN PRACTICE, BY MEASUREMENT WITH A CHAIN ROUND THE POINTS A-B-C-D-E SET OUT IN THE FIELD—THE LENGTH MAY BE CHECKED IF DESIRED BY THE FOLLOWING CALCULATION:  
LENGTH = R x 2 x 3.1416 x (27.28) = 1000.582 x R  
(X NO OF MINS IN TANGENTIAL ANGLE)

**The Student's Column.**

**LAND SURVEYING AND LEVELLING.**

**XV.—SETTING OUT CURVES.**

CASE 5 illustrates the best method for setting out curves of very large radii, and is based upon the fact proved in Case 1, that at any portion of a circular curve, the angle subtended by an arc of a fixed length is constantly the same, no matter in what part of the curve the arc or distance be taken, and the angle subtended by any other distance is proportional to that distance. To apply this principle in practice, the late Professor Rankine suggested the measurement of a chord line, which should be taken in comparative short lengths, so as to be practically equal to the length of the curved line adjacent to the length of chord. An accurate circle might thus be completely set out on the same as a polygon of an infinite number of sides; but in practice, so long as the length of the curve line is not more than one link greater than the length of chord, the method is accurate. Referring to fig. 1 it will be seen that the length of the chord A B is practically equal to the length of the curve A B, but the length of the chord A C is less than the length of the curve A B C, and the length of the chord A E is very much less than the length of the curve A B C D E.

The length of a chord line which subtends an angle of 60 degrees at the centre of a circle is equal to the radius; but the length of an arc or curve equal to the radius subtends an angle at the centre of the circle of 57.29 degrees. For a radius of two miles (160 chains) it will be found that the length of a chord of two chains is approximately equal to the length of the curve it connects, but that for a radius of less than one-tenth of this distance (16 chains) it is advisable to take half-chain chords. For curves of less than 5 chains (330 ft.) radius, the arc subtending an angle of 60 degrees at the centre of the circle is so soon approached, and the length of chords to be measured would be so small, that the method shown in Case 3 will furnish the best curve. On the other hand, when Case 3 is applied to curves of over 5 chains radius, the length of the tangent lines from their point of intersection to the commencement and end of the curve is so long, while the perpendicular offsets become so short, that the method explained by Case 5, with the use of a theodolite for setting out the tangential angles, is more advisable.

A very convenient list of tangential angles multiples for curves, from 5 to 200 radius, and has been compiled by Mr. Alexander Beazley, M.Inst.C.E., and is published as a set, printed on card, for use in the field. The special card, giving the required tangential angles for any required radius, can be placed on the theodolite in one of the clip spring pieces which are intended to hold the magnifying-glass for the reading of the vernier. The angles marked upon the card are calculated from the formula given in Case 1, namely, "Angle in minutes equals the chord divided by radius when the result is multiplied by 1719." This angle is set out with the use of the opposite vernier, as indicated by the small sketch of the plan of a theodolite at the top of our diagram.

We give a copy of the figures upon one of these cards as an illustration:—

Radius 20.			
1	1	26	358 34
2	2	52	357 8
3	4	17 3/4	355 42 1/2
4	5	43 3/4	354 16 1/2
5	7	9 3/4	352 50 1/2
6	8	35 3/4	351 24 1/2
7	10	1 1/2	349 58 1/2
8	11	27 3/4	348 32 1/2
9	12	53 1/2	347 6 1/2
10	14	19 1/2	345 40 1/2

Multiples for 20 Rad.	
1	85.94367
2	171.88734
3	257.83101
4	343.77468
5	429.71835
6	515.66202
7	601.60569
8	687.54936
9	773.49303

With the use of a book containing the angles required, the angle is read, and the book placed away in the pocket, so as to leave both hands free for setting the instrument; but with the use of a card temporarily fixed upon the theodolite the angles to be set out are constantly under inspection.

**Nineteenth Century Art Society.**—Monday, the 10th inst., has been appointed for the reception of works of art intended for the Autumn Exhibition of the Nineteenth Century Art Society, at the Conduit-street Galleries.

**VARIORUM.**

Messrs. Crosby, Lockwood, & Son have sent us their list of books for the forthcoming season. The list includes "A Dictionary of Terms used in the Practice of Mechanical Engineering; comprising upwards of 6,000 definitions," compiled and edited by the author of "Pattern Making"; "Practical Surveying; a Textbook for Students preparing for Examinations or the Colonies," by George W. Usil, A.M.I.C.E., author of "The Statistics of the Water-supply of Great Britain"; "Marble and Marble Workers: A Handbook for Architects, Artists, Masons, and Students," by Arthur Lee, author of "A Visit to Carrara," "The Working of Marble," &c.; "Our Granite Industries," by G. F. Harris, F.C.S.; "Tables, Memoranda, and Calculated Results for Mechanics, Engineers, Architects, Builders, Surveyors, &c.," selected and arranged by Francis Smith, fourth edition; "Lockwood's Builder's and Contractor's Price Book for 1888, containing the latest prices of materials and labour in all trades connected with building," edited by F. T. W. Miller, A.R.I.B.A.; and "Horse Painting, Graining, Marbling, and Sign Writing, with a Course of Elementary Drawing, and a Collection of useful Receipts," by Ellis A. Davidson, fifth edition, with coloured plates.—Mr. B. T. Batsford, of 52, High Holborn, has sent us his new catalogue of new and second-hand books on Civil and Mechanical Engineering, Geology, Electricity, and many other scientific subjects. The catalogue will repay perusal, as it includes a large number of standard works "without which no [technical] library is complete."—"Shortland Celebrities of the Past," by Edward Pocknell, Past-President of the Shortland Association, illustrated by twenty-two portraits drawn by Arthur Fredericks (London: James Wade, 18, Tavistock-street, Covent-garden), is an interesting and timely souvenir of the recent very successful International Shortland Congress held in London. The text consists of short biographies of twenty-eight "celebrities," from Tritheim, or Tritenheim, Abbot of Spanheim (1483-1506), down to James Henry Lewis (1786-1853). The list of short-hand worthies thus treated of includes John Jewell (1522-1571), Bishop of Salisbury; Dr. Timothy Bright, whose tercentenary was one of the events celebrated by the recent Congress; John Byrom, F.R.S. (1691-1763); and Thomas

Shorthand (1705-1770), whose history is somewhat remarkable. While shorthand now plays a very important part in the work of the world, there are many who believe that it is as yet in its infancy, though it has made great strides within the last fifty years, owing mainly to the labours of Mr. Isaac Pitman, the inventor of phonography, who has lived to see the jubilee of the introduction of his system of shorthand, an event which was marked during the Congress by the presentation to his family of a bust, an admirable portrait-bust from the chisel of Mr. Brock. It is satisfactory to see that *pari passu* with the practical use of the art, the literature and what may be called the archaeology of shorthand are not being neglected, for besides Mr. Pocknoll there are other workers in this field, most notably Dr. Vestly-Cibson, who has just published his "Biography of Shorthand."

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

**11,121, Window Fastenings. H. S. Harris.**  
At the top ledge of the lower sash of an ordinary window, a plate of brass, having two sides fixed at right angles to it, is placed; a lever is secured between these sides by means of a pin running through it and the aforesaid sides. Fastened to the plate at one end of the lever, is a spiral spring, and over the same end of the lever is a pin or small piece of metal, which keeps the lever in position, ready for use. To the lower ledge is affixed a catch. With this apparatus, the window being closed, the end of the lever and the catch meet and lock automatically, rendering it impossible for the window to be closed without being secured. It cannot, moreover, be opened from the outside. When opening the window it is only necessary to press the end of the lever, thereby depressing the spring and unlocking the casement.

**13,597, Fall Pipes, &c. J. Parsons.**  
One end of the fall-pipes or pipes used for various purposes, as soil-pipes, waste-pipes, rain-water pipes, &c., are made with one end slightly narrowed or contracted, and on the other end is a socket to correspond with the tapered end. When two pipes are connected, the jointing substance is compressed by the weight of the pipe above it, and a solid joint is effected. The method of fastening is also improved, nails or spikes being driven into the wall at an acute angle, and thus holding the pipes without the necessity of cutting plug-holes in the brickwork.

**17,119, Trapping Drains and Sewers. P. F. Richards.**  
A trap having on the intake side a floating ball of copper, supported on a curved dip, forming the trap seal, with a clear water-way round the curved dip, is the improved form. On the tide or overflow pipe rising on the outside side of the trap, the water in the trap rises and so flows the ball and blocks it against the intake of the trap, and on the falling of the ball the trap again comes into action.

**12,330, Waste-Preventing Cisterns. J. J. Tyler.**  
The improvement is in stamping the cisterns, which are known as "two-gallon waste-preventing cisterns," out of one piece, care being taken to need the iron after each different stamping operation.

**13,537, Improved Flushing Apparatus. D. Lyon.**  
The idea is to raise water by partial vacuum over and into the top of a trapped outlet, the top of which is at least 2 ft. above the standing level of water in the cistern on the discharge of the water by siphonage occurs without the employment of valves or tight-fitting parts. The specification describes the mechanism for this purpose.

**5,280, Fixing Roofing Sheets. C. J. Latta.**  
A forked piece of metal is employed in combination with the double or folded edged roll caps in securing the roll cap to the roof by sliding into the sliding-down clips before described. A saddle-piece is also fitted to the hanged end of the roll cap in such manner that when used against a drip all the same is a perfectly water-tight joint.

**9,966, Bolts for Doors. A. E. Earl.**  
The object is increased safety, and consists in passing a pin through a hole in an ordinary bolt, so that when the bolt is shot forward it cannot be pushed back without first removing the pin.

NEW APPLICATIONS FOR PATENTS.

**Sept. 23.**—12,893, S. Harrison, Testing Gas Pipes and Fittings.—12,903, T. Murphy, Compressed Air Door Regulators.—12,919, A. Wells, Revolving Food Shutters.  
**Sept. 24.**—12,935, J. Macneilkin, Wind Guards and Ventilators.—12,975, W. Horn, Door Latch.  
**Sept. 26.**—12,978, A. Knowett, Domestic Fire-

grates.—12,991, W. Murray, Gates.—13,011, W. Jones, Pipe Cutters.—13,018, R. Prowse and D. Dalg, Sliding Windows, &c.—13,022, J. Carey, Sliding Tiles, &c.—13,035, J. Fisher and L. Booth, Fireproof Curtains or Screens for Theatres and other Public Buildings.

**Sept. 27.**—13,065, E. Weldon, attaching the Blades of Saws to Handles.

**Sept. 28.**—13,110, A. Harris and J. Hannay, Fireproof Theatre Curtains.—13,111, S. Bennett, Hoists or Lifts.—13,127, A. Stephenson, Butt-hinge and Method of Fixing same to Doors.—13,161, S. Huntley, Devices for Facilitating the Cleaning of Drains, &c.

**Sept. 29.**—13,130, J. Hargreaves, Manufacture of Cement.—13,193, J. & T. Stanley, Preventing the Spread of Fire in Theatres, &c.—13,207, A. Morley and H. Wilson, Indicators for Electric Bells.

PROVISIONAL SPECIFICATIONS ACCEPTED.

**11,068, J. Speakman, Paint Restorers and Removers.**—11,334, A. and R. Knox, Wood Planing Machines.—11,434, O. Elphick, Syphon Cisterns.—11,438, J. Cante, Fireproof Holders for Joists for Party Walls.—11,527, J. Holt, Latches and Bolts for Doors, &c.—11,703, A. Rose and R. Hunter, Safety Fasteners for Window-sashes.—11,745, W. Ormrod, Self-lubricating Mould for Brickmaking Machines.—11,772, S. Spencer, Window Fastening.—11,829, W. Crozier, Locking Sash Fastener.—12,034, A. Ledger, Drawing-boards and T Squares.—12,279, E. Williams and J. Morgan, Fire-grates.—10,950, J. Bear and W. Gaines, Closing Doors and Preventing the Slamming of Same.—11,410, J. Reid, Rendering Doors, Windows, Casements, &c. Air-tight or Draught-proof.—11,833, R. Herrmann, Wall-papers, &c.—11,937, J. Homan, Fireproof Floors.—11,961, B. Turner, Door Springs.—12,014, G. Brewer, Automatic Apparatus for Closing Doors.—12,052, W. and S. Denham, "Filler" for French Polishing.

COMPLETE SPECIFICATIONS ACCEPTED.

**Open to Opposition for Two Months.**  
**12,463, P. Prouvay, Saws.**—12,374, W. Buchan, Ventilators.—15,493, J. Shanks, Lavatories or Wash-hand Basins.—16,612, C. Harris, Gas Chandeliers, Gasoliers, and Brackets.—1,463, B. Bancroft, Automatically Closing Doors, &c.—1,493, J. and J. Wilson, Curving Smoky Chimneys.—9,122, J. Lowe, White Lead.—10,236, C. Gregson, Concrete Walls, &c.—14,580, H. Perry, Machine for Sticking and Varnishing Paper-hangings.—15,336, A. Hildge, Indicator Bolts for Doors.—15,584, P. Walker, Ventilators.—3,433, S. Hill, Door-spring.—4,001, E. Ledger, Shop Window-hings.—9,187, A. Reichert and G. Yingling, Sawing Machine.

Farkes Museum (Lectures for Sanitary Inspectors).—Mr. J. Gordon, on "Scavenging, Disposal of Refuse and Sewage." 8 p.m.  
**FRIDAY, OCTOBER 14.**  
Farkes Museum (Lectures for Sanitary Inspectors).—Professor W. H. Corfield, M.A., M.D., on "Sanitary Appliances." 8 p.m.

Miscellanea.

**The Water Supply of Tottenham.**—Having regard to the very rapid development of the district under their jurisdiction, the Tottenham Local Board of Health are making important extensions to their system of water supply. The works include an artesian well at the Longwater pumping station, 12 ft. in diameter down to the chalk, and carried by a 24-in. boring in the chalk to a depth of 450 ft. from the surface; two 50-horse-power engines, pumps, boilers, water-tower, and engine-house. The scheme has been designed by Mr. W. A. H. De Pape, Chief Waterworks Engineer, and the operations are being conducted under his personal superintendence. Mr. W. Brown, of Tottenham, is the contractor for sinking the well; Messrs. Wood Bros., of Soverly Bridge, for making the engines; and Messrs. Wilkinson Bros. for erecting the buildings. The works recently constructed from Mr. De Pape's plans comprise large reservoirs and a water-tower at Mount Pleasant. The entire scheme will involve an outlay of 25,000l., and when it is completed Tottenham will occupy a very favourable position in respect to its water supply as compared with many other districts adjacent to London. As to quality, it is stated that the water, which is obtained from the chalk stands nearly equal to Kent and Colne Valley in the analytical reports of Dr. Frankland to the Registrar-General. A singular feature in connexion with the sinking of the well is the variation in actual strata from those shown by the trial boring: in one instance a layer of limestone rock, 15 ft. thick, being met with, the substance having previously been entirely unknown in the district.

**The Edinburgh Theatres.**—The Scotsman says that the Burgh Engineer and Firemaster have completed a portion of their report on the condition of the Edinburgh theatres, and the remainder, which is in progress, is expected to be ready at an early date. The part prepared deals with the Lyceum Theatre and Newsome's Circus, and bears evidence of a close examination having been made into both houses. The strictures passed on the circens are now, of course, of little account, the building having been burned to the ground, but the result of the inspection of the Lyceum will be made the subject of mature deliberation. It is understood that in respect to this theatre several recommendations with the view to further insuring the public safety are made. While on this subject, we may mention that it is said to be the intention of Mr. and Madame Newsome to rebuild their circus in Nicolson-street, Edinburgh, as soon as matters are settled with the insurance company.

**Brussels.**—A new National Theatre is being built in Brussels. When completed it will be the largest and finest theatre in the country, and is to be named the Flemish Theatre. For the ventilation Messrs. Robert Boyle & Son's system has been adopted, the extraction of the vitiated air being effected by the latest improved form of the air-pump ventilator.

**Liverpool Engineering Society.**—The usual fortnightly meetings of this Society were resumed at the Royal Institution, Colquhoun-street, on Wednesday, October 5th, Mr. John J. Webster, M.Inst. C.E., President, in the chair. A paper was read by Mr. F. Huddleston, M.Inst. C.E., on the Coal Appliances of the Port of Liverpool. The coal annually shipped at Liverpool, Birkenhead, and Garston is rather more than three million tons; from 600,000 to 650,000 tons is exported to foreign parts, most of the rest being used as bunker coal. The Liverpool High Level Coal Railway at the Wellington and Bramley-Moore Docks was opened for use in 1856, and in 1884 the accommodation was doubled. The appliances consist of nine hydraulic cranes, with powers varying from 10 to 24 tons, used to load vessels of all classes, and one balance-tip for loading flats. The traffic at the present time is carried on by means of locomotives and hydraulic capstans, but up to the year 1884 horses only were used. The level of the railway is about 21 ft. above the quay, the space beneath it being made use of as sheds, &c., and there is no interference with the ordinary traffic to and from the docks. The coal shipped is from the north-west and south-west coalfields of Lancashire, and is brought down by the Lancashire and Yorkshire Railway Company, who provide extensive sidings at Sandhills. The Birkenhead appliances consist of three hydraulic hoists and seven low-level balance-tips in the east and west floats. The hoists are used for vessels of large size, while the balance-tips put bunker coal into flats, which are afterwards taken alongside the steamships in the various docks; about 200,000 tons of South Wales coal is shipped yearly at Birkenhead for bunker use. The shunting at the tips is done by horses. The sidings for coal wagons are at the Cavendish Wharf. Liverpool and Birkenhead together ship two million tons per annum. At the North-Western Railway Company's Docks, at Garston, there are eight vertical drop-balance-tips worked from a high level and fed by hydraulic capstans. These ship annually rather over one million tons of coal from South-West Lancashire, the greater part of which probably goes coastwise.

**The German Screw Industry.**—The manufacture of screws in Germany is chiefly centred at Berlin, where screws are now made in such quantities and of such qualities that these products are esteemed not only in Germany, but in other countries. The principal manufacture is that of fine screws worked bright, from the larger sizes for machinery, down to the smaller kinds for watch-work, &c., the materials employed being iron, steel, brass, German silver, &c. Efforts are now being made to increase the production of rough black screws for ordinary wood and ironwork. This class of screws has hitherto been principally made in Westphalia, but the development of screw-making machinery which will take the place of hand labour, in Berlin will, it is considered, cause a great change. There are in the Westphalian district, near Hagen, fifteen screw manufacturing, employing in all about 3,000 workpeople. The Berlin industry comprises twenty-eight factories, with about 1,500 workpeople. As these are, however, almost exclusively engaged in the manufacture of screws, while at the various establishments near Hagen only about one-third of the workpeople are employed in this particular industry, it is claimed that Berlin is at least as important a seat of screw manufacture as the Hagen district. Berlin used at one time to draw its supplies of raw material almost entirely from Westphalia, but of late years the constantly increasing employment of ingot steel instead of finished iron, has developed the use of Brunswick raw material, from Peine, which is cheaper than the Westphalian product, owing to the shorter railway journey it has to make. Steam machinery is exclusively employed for making bright screws, one factory having lately erected a new steam-engine of 45 horse-power. The screw-making machines in use are upon a system invented by Kernall some thirty-five years ago, but which has since been much improved. The manufacture of these screw-making machines constitutes a special branch of Berlin industry. The introduction of new automatic machinery will, it is expected, lead to a further development of the manufacture of screws, more particularly in connexion with the making of nuts for the larger sizes of machine bolts. The history of the Berlin screw

manufacture is considered to disprove the assertion that an important metal article can only be made in the immediate vicinity of the works where the raw material is produced. This result is attributed to the intelligence and skill of the Berlin workmen.—*Iron.*

**Electric Wire Casings.**—Mr. Samuel Elliott, of Newbury, has sent us his book of designs and sections for moulded wood casings and covers for electric wires, many of which are of new design. Architects and others concerned for buildings in which electric lighting is used will find it worth while to obtain this catalogue.

**Sanitary Appliances.**—Messrs. Thos. Crapper & Co., of Marlborough-road, Chelsea, have sent us a copy of their illustrated catalogue of sanitary appliances, and we have recently had an opportunity of inspecting at the works some of the items shown in it. Their improved fittings for baths are very simple; each valve is separate, and can be easily disconnected. Some good closet apparatus are on the list; of these we may specially mention the "Elastic Valve-Closet," No. 2, which has a special rim to prevent the escape of water over it. A cheaper apparatus is the "Marlborough" closet, which is of the pedestal type, in one piece of earthenware. Messrs. Crapper & Co. also make a very good syphon water-waste preventer, fitted with tranquil pipe for deadening the sound of filling. We might make a long list of commendable things to be found in the catalogue, but we conclude by mentioning Messrs. Crapper's excellent air-tight frames and covers for manholes, side entrances to drains, &c. The covers are not hinged to the frames, so can readily be removed when necessary, so as to allow full access to the manhole or entrance.

**The Middlesex Hospital.**—The new buildings, which have been in course of erection for the past twelve months, were opened on Monday by the Lord Mayor. The "Trained Nurses' Institute" is a plain substantial building, erected on the lines of the adjoining Nurses' Home, and affords accommodation for twenty-four trained nurses, including sitting-room, bath-rooms, office, store and linen-rooms. A door is formed in the division wall on each floor, giving access to the home and the hospital, on the basement floor a large dining-hall has been built, and is connected to the existing refectory. The kitchen has been enlarged, and is fitted up with gas ovens, steam closet, boiling coppers, &c. The heating is by steam coils, and the ventilation is by Verity's patent waterspray tubes, with a large exhaust cowl on top. The Residential College is a large building, erected for the accommodation of the medical students practising at the hospital; it contains separate apartments for thirty-three students, with the warden's bed and sitting-room, bath-rooms, and box-room. On the ground-floor is a large dining-hall, a common room, and a study or reading-room. The entrance is from Cleveland-street, and opens into a spacious entrance-hall; another entrance is from the hospital garden. The basement contains stewards' rooms, kitchen, scullery, stores, and servants' rooms. The front is built of stock bricks, with red brick dressings, the cornices being in moulded red bricks to match. The garden front is of a more ornamental character, being built of red bricks with buff-coloured terracotta dressings. There are four tiers of bay windows, with casements and fanlights. A porch entrance is here added with ornamental iron gates, and railings on each side to match. In addition to the present medical school buildings, another large building has been added, giving a lecture theatre, physiological class-room, laboratory, library, students' and luncheon-room. These are approached by a fireproof staircase constructed in a wing adjoining, openings being made in the walls, giving access to the rooms on the several floors. The entrance is from Cleveland-street, with another entrance from the Hospital garden. The entrance-hall and corridors are paved with Elhner's polished marble concrete, Hyatt's prismatic lens lights being used to give additional light to the lavatories below. The whole of these buildings, as also the museum, is heated by hot-water pipes and coils. The library and lecture theatre are lighted by Wenham lamps, the other gasfittings being of the ordinary kind. In the hospital considerable additions and alterations have been made; the old steam boiler has been replaced by a new one of the marine multi-tubular

type; this is made of steel plates, and is worked at a pressure of 80 lb. on the square inch; a Bradford's large size hydr. extractor, and a large size washing machine have been added, also a 4-ft. Blackman's air propeller; two sets of drying hoods heated by 4-in. steam pipes were also necessary to meet the increased demands on this portion of the work. The hospital kitchen has been fitted with modern cooking appliances, all of which were supplied and fixed by Messrs. Slater & Co., of High Holborn. The terra cotta was supplied by Messrs. Wilcock & Co., of Burnantofts, Leeds, 2,097 pieces being made and delivered in seven weeks. The iron railings are by Richardson, Ellison, & Co. The stoves, chimney-pipes, and tile hearths from Thos. Blaisy, of Great Portland-street. The locks and furniture were made to master keys by Charles Smith & Sons, of Birmingham. The furnishing is by Shoelbred & Co. The fittings and sanitary appliances are from Messrs. Dent & Hellyer, of Newcastle-street Strand. Messrs. Holland & Hannen were the contractors, Mr. Beal being their foreman & works. Mr. Keith D. Young is the architect and Mr. Thomas Gamage the clerk of works.

**English Machinery for America.**—We have previously had occasion to record the manufacture of some splendid specimens of the roll casters' and roll turners' art in South Staffordshire, for use in linoleum mills. Hitherto the rolls have been mainly for Scotch mills. Now, however, the United States have come to this country for a complete machine plant for linoleum mills, weighing altogether some 30 tons. The whole work is in the hands of Gloucester millwright, and the rolls have been supplied from the West Bromwich locality. Three very fine rolls have been despatched weighing respectively about 13 tons, 20 tons, and 24 tons, and the turning of the same in the lathe has been accomplished very successfully. The work is quite a triumph of the engineer's craft, and deserves special mention. The roll are made with a hollow core through the centre through which, in operating on the linoleum manufacture, a jet of steam is constantly kept passing to keep the rolls warm. The more importance attaches to the contract since the American buyers intimate that if the plan when erected is found to work satisfactorily, a duplicate order may probably be placed.—*Engineer.*

**A Year's Building Operations in Glasgow.**—At a meeting of the Glasgow Dean of Guild Court the other day, Lord Dean of Guild Blackie submitted a summary of the year's transactions of the Court. During the twelve months ending 31st August last the number of linings granted was 238, being an excess of 38 beyond the numbers of the previous year. The excess was wholly due to an increase number applicable to churches, halls, and schools, warehouses, stores, &c., and to alterations and additions. Those applicable to shops, 39 in all were fewer by three than those of the previous year. These 39 linings comprised 1,028 houses and 79 shops, as compared with 1,262 houses and 52 shops in the previous year. The aggregate value of the property included in the 238 linings was estimated at 424,730l., as compared with 394,540l. in the preceding year. The excess was due to the increase under the four headings of "public buildings," "churches, halls, &c.," "warehouses, stores, &c.," "alterations and additions," which amounted to 250,280l., as against 183,490l. in the previous year. On the other hand, dwelling-houses amount had decreased from 208,050l. in the preceding year to 174,450l. Comparing the amount of business transacted in the Court five years ago, he said that in 1883 dwelling-houses figured to the amount of only 88,650l., and had risen in 1887 to 174,450l.; warehouses, stores, and workshops, which in 1883 stood at 291,461l. were in the past year registered at only 73,100l. Churches, halls, and schools had during the same period risen from 35,500l. to 63,200l., and alterations and additions had decreased from 71,670l. to 58,930l. These figures, he said, did not seem to indicate any marked revival in the local building trades, but possibly, looking to the fact of the area of the municipality being a fixed quantity, and now presenting a comparatively fixed space for the erection of new buildings, the figures he had quoted might be susceptible of a more encouraging interpretation than he had felt at liberty to put upon them.

**The Obelisk in Central Park, New York.**  
 Although it was stated a year ago, as recorded in the *Builder* of October 2nd, 1886, that the Egyptian obelisk in Central Park, New York, had not been so thoroughly protected by the hot asphalt treatment it received in the autumn of '85 as was expected, a second year's experience somewhat modifies that statement. The obelisk has just been examined again, and the result of the examination is to the effect that the treatment has been useful as a preventive of further scaling from the action of frost. This would seem to prove that the effects of the preservative process adopted only begin to show themselves after a lapse of time.

**Peterhead.**—Messrs. D. Macandrew & Co., Aberdeen, whose offer was accepted (in October last year) for the erection of the riotous structures comprising the prison and accessories for the accommodation of the convicts to be employed in the construction of the harbour of Refuge at Peterhead, have been pushing the work forward with great expedition. The governor's house, offices and stores, school officers' quarters, warders' quarters, kitchen, baths and washhouses, and infirmary, are all slated, and the plasterers progressing rapidly inside. The mason work of the gatehouse and refractory cell block will be completed by the end of this month (October). The cell block is 156 ft. 10 in. long by 40 ft. wide, four stories in height, and built entirely of cement concrete. A spacious corridor, 18 ft. wide, runs the entire length of the building, and extends to the full height of the block, viz., 120 ft. The cells are ranged on each side of this corridor, twenty-six on each side, fifty-two on each floor, or 208 in all. Three tiers of galleries are carried round the corridor at the levels of the first, second, and third floors respectively, being reached by one main central iron staircase. Each cell is separately ventilated. All the other buildings are of rubble granite masonry of the dull red colour of the well-known Peterhead granite. The door and window lintels, quoins, plinths, string and cornice courses, chimney copings, and other dressings are moulded of cement concrete polished by hand, giving the appearance of freestone, looking exceedingly well and in harmony with the red granite. Even in a locality where granite is so abundant and so easily obtained as at Peterhead, the Prison Commissioners have saved nearly 2,000l. by the option of concrete dressings. The whole of the cell blocks will be heated by powerful hot-water stoves. The prison will be lighted with gas supplied by the Corporation of Peterhead. The roof of the prison is on a clay bank, 40 ft. or ft. above the level of the sea just adjoining; and the whole of the buildings will be drained means of glazed tile-ware pipes discharging to the sea. The prison works are expected to be finished in May next year, and the total cost amount to 31,000l. The buildings are designed by the official architects of H.M.'s Prison Commissioners for Scotland, and are being carried out under the superintendence of Mr. McHardy, the Acting Commissioner. Mr. Alford is surveyor, and Mr. John Cockintosh the resident clerk of works.

**LEIGH (Essex).**—For alterations, additions, and improvements to the pottery buildings and managing director's house, for the Victoria Pottery Company, Limited. Mr. Alfred J. Hopkins, architect, 27, Mortimer-street, London. Quantities supplied:—  
 J. Higgs, London, £2,659 0 0  
 W. Spendlow, Southend, 2,584 10 6  
 S. Darke & Son, Southend, 2,090 0 0  
 Baker & Wiseman, Southend, 2,064 10 0  
 J. W. Steward, Southend, 1,971 0 0  
 Bullock & Woodwiss, Southend, 1,789 1 4

**LONDON.**—For erecting lecture-hall and retiring-rooms for the Directors of the Stoke Newington Assembly Rooms Company, under the superintendence of Mr. William Eve, 19, Union-court, Old Broad-street, E.C. 4.—  
 S. Page, 1,006 0 0  
 Woodward, 998 0 0  
 Brown, 948 0 0  
 Mills, 909 0 0  
 Holland, 900 0 0  
 Harris & Wardrop, 886 0 0  
 Higgs, 885 0 0  
 Godfrey, 877 0 0  
 Dabs, Amherst Park (accepted), 865 0 0

**LONDON.**—For the erection of a house in Wigmore-street. Mr. Leo W. Goodwyn, architect:—  
 Hayward & Co., Whitechapel, £2,313 0 0  
 Crossley, 2,220 0 0  
 Darvall, 2,117 0 0  
 Adamson, 2,015 0 0  
 Sabej & Son, 1,827 0 0  
 Liddart, 1,775 0 0

**LONDON.**—For building additional story to warehouse, Queen-street, Mile End, New Town, for Messrs. Burrell & Co., Mr. John Hudson, architect, 80, Leaden-street, E.C. 3.—  
 Eaton & Co., Whitechapel, £399 0 0  
 Little, Whitechapel, 383 0 0  
 W. Gladding, Mile End (accepted), 328 0 0

**LONDON.**—For alterations and repairs at 37 and 39, Cadogan-place, Port-street, S.W., for Messrs. Richards & Son:—  
 Howd & Lightfoot (accepted), £110 0 0

**LONDON.**—For alterations at the Three Colts, London-wall. Messrs. Alexander & Gibson, architects, 49, Great James-street, Bedford-row:—  
 Mattock Bros., £1,516 0 0  
 Oldie, 1,495 0 0  
 Wilkinson Bros., 1,475 14 0  
 Arley, 1,179 0 0  
 Beale, 1,168 0 0  
 Gould & Brand, 1,143 0 0

**LONDON.**—For an extension of the Wiltshire Brewery, Hackney-road, for Messrs. Chandler & Co., Mr. F. W. Steer, architect:—  
 Ashby Bros., £7,403 0 0  
 Bywater, 7,440 0 0  
 Brass, 7,363 0 0  
 J. W. Sawyer, Clapham Park-road\*, 6,892 0 0  
 \* Accepted.

**LYME REGIS.**—For four almshouses for the Jubilee Committee, Lyme Regis, Dorset. Messrs. Stokes & Homan, architects, 31, Great James-street, Bedford-row:—  

	First Tender	Amended Tender
Cooper, Lyme Regis	416 3 0	£135 0 0
Randall, Lyme Regis	470 0 0	430 0 0
Parsons & Perryman, Axminster	421 0 0	407 0 0

 \* Accepted.

**MARYLEBONE.**—For the erection of new business-premises and dwelling-house, on the site of Nos. 63 and 64, Paddington-street, Marylebone, W., for Mr. Joseph Chaplain, Mr. Thomas Durrens, architect, 44, Upper Baker-street, N.W.:—  
 Scott, £2,897 0 0  
 Foxley, 2,689 0 0  
 White, 2,573 0 0  
 Patman & Fotheringham, 2,961 0 0  
 Bishop, 2,780 0 0  
 Clifton, 2,754 0 0  
 Wall Bros., 2,732 0 0  
 Bywaters, 2,695 0 0  
 Ashwell, 2,679 0 0  
 Oldrey & Co., 2,670 0 0  
 Stanley Bird, 2,609 0 0  
 Simpson & Sons, 2,560 0 0  
 Higgs (accepted), 2,298 0 0

**SOUTHSEA.**—For the erection of a mission-hall, King-street, Southsea. Mr. James Newman, architect:—  
 Beech, £743 0 0  
 J. Croad, 656 0 0  
 R. Stokes, 570 0 0  
 H. & W. Evans (accepted), 450 0 0

**SANDOWN.**—For the erection of a purifying-house, Sandown, for the Sandown Gas and Coke Company, Limited. Mr. James Newman, engineer:—  
 H. Stay, £223 0 0  
 J. Hayden, 183 13 0  
 F. Goussot, 173 0 0  
 W. & F. Jacobs, 2,009 0 0  
 R. Grubin, 163 0 0  
 George Hayles (accepted), 136 0 0

**SANDOWN.**—For the erection of public offices, Sandown, for the Sandown Local Board. Mr. James Newman, architect. Quantities supplied:—  
 W. Jolliffe, £760 0 0  
 E. W. Daniels, 740 0 0  
 G. Thomas & Son, 740 0 0  
 I. Barton, 719 0 0  
 R. J. Sibley, 699 0 0  
 R. Griffin, 689 18 0  
 H. Attrill, 651 0 0  
 G. Hayles, 613 0 0  
 F. Colenutt, 615 0 0  
 J. Ball (accepted), 590 0 0

**TUNBRIDGE WELLS.**—Proposed new house on Meadow Hill Estate, for Mr. M. A. H. Edwards. Mr. W. B. Hughes, architect. Quantities supplied:—  
 Judd, £1,020 0 0  
 T. Hyder, 1,600 0 0  
 Charlwood & Son, 998 0 0  
 J. Jarvis, 984 0 0  
 W. H. Canty, 838 0 0

**WEST THURROCK (Essex).**—For building new club-room, stable, and other additions to the Fox and Goose public-house, West Thurrock, Essex, for Messrs. Ince, Coope, & Co., Limited. Mr. John Hudson, architect, 80, Leaden-street, E.C. 3.—  
 Hammond & Son, Romford, £569 0 0  
 Eaton & Co., Whitechapel, 569 0 0  
 W. Gladding, Mile End (accepted), 514 0 0

**WOOLWICH.**—For partly rebuilding and other repairs to No. 1, Hill-street, Woolwich, for Mr. J. J. Bothamley, Mr. A. T. H. Stoneham, architect, 67, Moorgate-street, E.C. 4.—  
 Bridel, Greenwich, £233 0 0

**\*\* SPECIAL NOTICE.**—Lists of Tenders frequently reach us too late for insertion. They should be delivered at our office, 49, Catherine-street, W.C., not later than 12 Noon on THURSDAYS.

TO CORRESPONDENTS.

Doubling Freestones.

The stone from these quarries is known as the "West Beds," and is of a crystalline nature, and is doubtfully one of the most durable stones in England. It is of the same crystalline nature as the Chiswick Stone, but finer in texture, and more suitable for architectural work.  
**HAM HILL STONE.**  
 Greater facilities have been provided for working these quarries, and the stone can be supplied in large quantities at short notice. Prices, and every information given, on application to CHARLES TRASK & SON, Norton-sub-Hamdon, near Ilminster, Somerset. London Agent—Mr. E. WILLIAMS, 16, Craven-street, Strand, W.C. [ADV]

**Doubling Free Stone.** For prices, &c., address S. & J. STAPLETON, Quarry Owners, Stone and Lime Merchants, Stoke-under-Ham, [ADV]

**Asphalte.—The Baysal and Metallic Limes Asphaltic Company (Mr. H. Glenn), Office 3, Poultry, E.C.—The best and cheapest material for damp courses, railway arches, warehouse floors, flat roofs, stables, cow-sheds, and mill rooms, granaries, tun-rooms, and terraces. [ADV]**

**Asphalte.** Baysal, Patent Metallic Lava, and White Asphaltic. M. STODART & CO. Office: No. 90, Cannon-street, E.C. [ADV]

**SPRAGUE & CO.,** PHOTOLITHOGRAPHERS, 22, Martin's-lane, Cannon-street, E.C. [ADV]

**To Builders, Builders' Supply Merchants and Others.**—WALTER'S WATER-CLOSET, for letting waste water from lavatories, sinks, roofs, &c., will be immediately after being used. Costs 50 per cent. less than ordinary water-closets. No water cistern required. No fittings. No water supply. Simplicity and effectiveness guaranteed. Being largely adopted and giving every satisfaction. Testimonials from Sanitary Engineers, Sanitary Inspectors, Medical Officers, &c. Highly spoken of by leading trade papers. Prices, drawings, and full particulars, on application to **BROOKS & PICKUP,** Towseley Colliery, Barnley. [ADV]

**Remedy for Damp Walls.**—Applied to dry weather CARSON'S ANTI-DAMP SOLUTION is an economical and effectual CURATIVE. Full particulars (post-free) WALTER CARSON & SONS, La Belle Sauvage-yard, Ludgate Hill, London. [ADV]

**Scaffold Poles,** fresh Petersburg, 35 ft., 3s. 9d. 25 ft., 2s. 12 ft., 1s. 4d. each. A prime parcel of each selected 1 by 10 and 1 by 11 Pitch-Pine, in the Surrey Docks, cheap; also a very choice parcel of 12 ft. and 13 ft. 3 by 11 dry Yellow Pine, at a very low price. J. ARCHER SMITH, Timber Merchant and Importer, No. 271, Southwark Bridge-road and Greyhound Bridge, Old Kent-road, S.E. [ADV]

**NOW READY. F. W. REYNOLDS & CO.'S ARCHITECTS' ILLUSTRATED CATALOGUE**  
 Of Contractors and Builders' Hardware, comprising Kitchens, Ranges, Tiled and other Stoves, Chimney-pieces, Tiles, Locks, Brass-foundry, Ironmongery, Sanitary Goods, &c., &c.  
 160 pages, and containing over 600 Illustrations. A copy sent post-free on receipt of Trade Card.

### The Milan Cathedral Competition.

OW far the fourteen architects\* who are to join issue in the final competition for the façade of Milan Cathedral will keep to the lines and character of their first sketches it is, of course, impossible to say; but we may presume

that the second series will not differ materially from the first, as most of the competitors will naturally reason with themselves that they were selected for certain qualities exhibited in their first designs, and that it will be, to say the least, prudent not to depart very far from these, lest in so doing they should unwittingly part with the very qualities which gained them the premium in the first instance. What it is proposed by the competitors to put in the place of the present jumble of a façade we can therefore pretty well guess; and it is of some interest to consider what has to be done, and which of several principles shown in the first designs is to be preferred.

According to the constant habit in Italy, Milan Cathedral, built late in the fourteenth and completed (except the façade) in the fifteenth century, was left without the façade in the hope that, by taking more time to think about it, something finer could eventually be achieved than was apparent at the moment. This habit of Italian architects, though it looks rather like being afraid of their job at the time, has had the advantage of leaving some splendid pieces of work to do for their successors, and providing a constant subject of architectural interest and excitement in the efforts made from time to time by this or that architect to produce a design worthy of the occasion, and to get it accepted and carried out. Florence has waited till the present day for the completion of its front; Milan is only just now in prospect of seeing the work carried out; and there are many lesser buildings in Italy still awaiting the addition of that architectural front-piece which, in all probability, they are doomed to fall into decay without ever receiving. Milan, however, has the funds, or the greater part of them, in hand, through the munificence of a late citizen, and the completion is likely to turn out a solid thing, and not a mere affair on paper; so that the result becomes a matter of, we may hope, some immediate interest.

There have been various designs made for

the façade at different times. Pellegrini had a commission to complete it in the sixteenth century, and did actually produce a Classic façade somewhat of the style of Carlo Maderno's west front of St. Peter, with an enormous order and a *fronton* in the centre of it, of which Ferguson truly observes that "it was fortunate that it was not carried out." Apparently, however, his Classic doorways were built in the middle of the blank façade, because the design of Buzzi, made early in the seventeenth century, which in its general lines is evidently designed to match the features of the Gothic edifice in the rear, nevertheless shows purely Classic doorways and windows closely resembling those actually existing. The actual façade, completed in the early part of the present century by Amati, seems to have been partly suggested by Buzzi's; at all events, it represents the same general idea, imitation Gothic details built up around Classic doors and windows, in the attempt to connect together these two incongruous elements.

In both designs, massive Gothic buttresses or piers are run up between the ranks of the Classic window openings and pediments, but Buzzi's design differs in one important respect from the existing one, in that it terminates with a large tower and spire at each extremity or flank of the façade. The existing façade has only a large pannelled pier,—architecturally speaking, a collection of buttresses and pinnacles, at the angles; massive enough, but nothing to call a tower. It is this very question, whether the new façade should or should not have flanking towers, which has been greatly debated at Milan; though this is only one of two or three crucial questions which suggest themselves in considering the subject.

It is an understood condition, specially named in the first conditions of competition, that the designs must conform to the style and the architectural arrangement of the building; and in all but one of the first designs there seems an obvious intention to do this. As to the general style of the building there is, of course, no difficulty in defining what that is, and in following it in the new design. There is of course the question, which some critics may raise, as to whether a façade may not be regarded as a separate work in itself, to be judged apart from the rest of the building, and erected in any style which the architect feels most in sympathy with, or which is the favoured style of his day. Of course this has been done in other instances, but we do not think precedent justifies it. With the exception of the front, Milan is homogeneous in style and built very nearly in one period. The addition of the façade should be the completion of the design, not a new feature, however

effective, in an incongruous style. This conclusion, we fear, condemns the design of the only English architect, Mr. Brade, who was fortunate enough to be numbered among the chosen fifteen. His design, the small illustration of which, reproduced from *L'Illustrazione Italiana*, gives a sufficient general idea of the treatment, is evidently a fine piece of modern Gothic, and it is probable that the complete drawings on a larger scale would quite justify the compliment that has been paid to his ability; but such a design is absolutely unsuited for the position, and would, in fact, be absurdly incongruous; and while we are glad that one English architect, at least, has been found worthy to be counted among the successful ones, we should be still more pleased if his design had been one which we could wish to see carried out, and which we could conscientiously support as one with a high claim to be chosen. This it is impossible, however, to do; the choice of a design in a school of Gothic so different from that of Milan would be a complete mistake, and would be felt to be so by Italian architects and critics generally, if we are not much mistaken; and Mr. Brade would do wisely, if he really wishes to have a chance of ultimate success, to modify his design in the second competition so as to harmonise with the environment.

It may be a question whether, as the general mass and proportion of the existing façade have become familiar to the eye, the new design should not more or less conform to its general outlines and proportions. Some of the competitors evidently have thought so, and have aimed at doing this, among them Signor Locati, of Milan, the small engraving of whose design we give from the Italian paper before named. The main arrangement of this has much similarity to that of the existing façade; the chief difference being that a circular window is substituted under the central gable, and that the raking lines of the front are made much lower and flatter in their slope. The slope of the existing façade follows the steep lines of Buzzi's design, and one or two other competitors also have followed this precedent, but it is not a good one. It is next to impossible to give monumental character to the front of a great cathedral with a gable termination with steeply-sloped lines. The thing becomes smaller and loses dignity at once. The design of Signor Locati avoids this defect, and is fairly monumental in style, and may be said to be one of the best and most suitable of those in which towers are not included; but one must admit that, though in good taste, it is rather mechanical in design, and does not show any stroke of genius.

The questions which concern the suitability of the new design to the architectural arrange-

\* The number is reduced to fourteen, as our readers may remember, by the lamented death of Tschagin, the Russian architect, one of the fifteen selected competitors.

ment of the present building, are principally the extent to which the sloping lines of the roofs should or should not be expressed in the lines of the front, and whether the doors should be arranged so as to indicate and form entrances to each of the five aisles. This latter point is also one which has been much discussed. The five-aisled plan is one of the prominent characteristics of the church, and should be distinctly expressed externally. A cathedral church with three aisles usually shows three doors in its façade, and on the same principle it would seem right that the five aisles should express themselves externally likewise. The selected competitors themselves show a majority in favour of this view: nine of them show five doors; MM. Hartel and Neckelmann show two centre doors and two side ones; Herr Becker, Signor Brentano, and Signor Beltrami show three; and Signor Azzolini shows an alternative elevation with three or five doors. There is something to be said in favour of the greater mass given to the outer portions of the façade by not cutting doors out of them; but the whole question depends somewhat on the general treatment of the design. The question is about the outer doors; there can be no doubt that the pair in the intermediate portion of the façade are desirable; and all the competitors are in agreement on that head. Where the outer pair are added they should at least be small ones, unless where there is a great mass of building placed at the extremity of the façade and accentuating it. Thus in M. Deperthes' design, where there are angle towers which overtop the central lantern, the large doors at the outward position are rightly placed. In such a design as that of Signor Locati it would, of course, have been a complete mistake to have placed large doors in this portion of the façade; though his range of doors, diminishing each way in a kind of arithmetical progression, has again, like the rest of his design, a somewhat mechanical appearance. Altogether, we may conclude that while most considerations are in favour of the five-door arrangement, the point must be decided with reference to the general architectural treatment of each design.

The question of towers or no towers is a more difficult one. Fergusson was of opinion "that the want of some such features is greatly felt in the building as it stands," and we are disposed to agree with him. The question is whether they should be dominate or be subordinate to the central tower. Our opinion would be that the best result would be obtained by towers on a tolerably large scale, but just sufficiently subordinate to the central tower to group as subordinate. M. Deperthes, as will be seen from the small illustration of his design (also from a cut in *L'Illustrazione Italiana*), has thought this subordination unnecessary, and has carried up his new towers to almost exactly the same height as the central one; indeed, slightly overtopping it. We cannot think this kind of three-legged composition would be satisfactory, though M. Deperthes' front is a vigorous and spirited design in itself. The late M. Tschagin, whose design we also give (from *L'Illustrazione*), has shown a better sense of proportion and subordination in his treatment of the towers, which in this case, however, are placed over the ends of the intermediate and not of the outer aisles. The effect of this is good enough in the elevation of the façade, but how would it be in the view of the building seen from the opposite direction, with the ends of the outer aisles projecting beyond the towers?

On the whole, we may divide the selected designs into (1) those which employ a central mass and no flanking towers; (2) those which employ towers over the intermediate aisles; and (3) those which employ towers over the outer aisles or at the extreme ends of the façade.

Of those which treat the building with towers over the intermediate aisles and not at the extreme angles, is that of MM. Hartel and Neckelmann, of Leipzig, of which we are enabled to give a larger-sized illustration from a photograph from their drawing, furnished by the authors. Here the western towers are

kept a little in subordination to the central tower, and the architects have been able, by keeping the towers towards the centre, to get sufficient appearance of height to harmonise with the general character of the rest of the building, without carrying their towers actually to such a height as to overpeer the central tower; and this is one of the advantages of the arrangement of keeping the towers towards the centre instead of at the extreme angles of the façade. The design by the late M. Tschagin places the towers, as we observed, in the same manner, but keeping them lower, and this appears to us to be one of the best compositions of the set. The question of indicating the rake of the roofs in the façade is very variously viewed by the competitors. In Tschagin's design, as will be seen, the centre portion is kept horizontal, and the side aisle terminations beyond the towers are shown with a slope. MM. Hartel and Neckelmann reverse this treatment, and keep the wings horizontal. Theirs is, perhaps, the preferable method, if the slope is not shown in both portions, but we do not like the strong horizontal band being left with nothing over it between the large towers and the angle turrets; it certainly wants a little filling in and connexion there; the tall angle turrets are too much cut off from the main mass of the façade. The method of keeping the large towers at the extremities of the façade is illustrated in the other lithograph, illustrating a design submitted by Messrs. Pugin & Pugin. The large drawing from which this was taken in pencil, washed with Indian ink, is very sketchy in execution, and has come out proportionately so in the lithograph, but it shows the general effect of the design. This design had the misfortune of being delayed several days on the road beyond what it should have been, and the authorities, keeping to the letter of the law, though they exhibited it with the others, refused to allow it to be included in the competition. Mr. Brade is one of those who has adopted the principle of having a very lofty and important central gable, the side towers being kept rather in subordination; the central feature is very finely treated in itself, though, as observed, quite out of keeping with the style of the main building. The design by M. Deperthes, the Parisian architect, though there is a great deal of vigour about it, strikes us as too wide; in the elevation the central tower seen in the rear fills it up, but when seen in perspective apart from this combination, it would appear rather abnormally high at the angles and wanting something in the centre of the skyline to connect the whole. In the design by Signor Moretti, of Milan, the central feature is strongly emphasised, the whole running very much on the lines of the existing façade, except that the angle portions are raised into richly-treated spires, which are, however, slightly subordinate to the central final in height. In general composition, Signor Moretti's is a very well thought out design, and entirely in keeping with the character of the building. Herr Dick, of Vienna, has had two immense spires at the extreme angles on the same kind of lines as the famous Vienna spire, and far out-topping the central spire. We prefer to leave the latter predominant, though Herr Dick's design is a very impressive if rather a sensational one; Signor Brentano, of Milan, shows something of the same character of design and composition, but on a much smaller scale, and keeping the spires in subordination to the centre. The design by Signor Beltrami, of Milan, eschews towers altogether, having a centre mass with a low-pitched pinnacled gable, and dropping the side masses successively at the ends of the intermediate and outer aisles respectively. This is a design showing much fine detail, and, thanks to the author's courtesy in sending us photographs, we shall be able to illustrate it shortly. It has the merit of precisely expressing the composition of the building in the rear of the façade. A special point in this design is the proposition to build a campanile (as mentioned by Mr. Waterhouse in a communication to the *Builder* of June 11th of

this year), not in immediate connexion with the façade, but as a central object in the square in front of the cathedral, working into it the Renaissance details of the existing façade. Signor Azzolini, of Bologna, and Signor Nordio, of Trieste, adopt much the same principle of design as Signor Beltrami, but the raking line is too marked and too prominent in both their designs, giving a triangular or gabled effect which is by no means dignified in so large a structure. The design by Signor Ferrario, of Milan, is one with lofty spires at the extremities, and a comparatively low centre; that of Signor Bianchi, of Milan, much on the same lines, but the centre is kept higher, and so far it is better; in Signor Ferrario's there would be too great a gap between the towers. In both these last two a bad effect is produced, to our thinking, by the raking lines over the intermediate aisles dropping towards and hutting against the towers; this has an awkward effect; it would have been better to connect the towers horizontally with the central mass. Herr Becker's design is another of the "triangular" fronts, the raking line being carried right down from the point of the central gable to the extreme end in a straight line, scarcely broken by the heads of buttresses running through it. That is certainly not the way to do it. Another Vienna architect, Herr Weber, adopts somewhat the same principle, only treating the outer aisles with horizontal cornices at a lower level. In both these designs the centre gable, running up to a mere point with nothing to give accentuation to it, has a poor and weak effect. In both of them, on the other hand, the principal portals are treated in a fine and bold manner.

There is none among the designs but has its fine points, and there are several among them which are unquestionably fine conceptions, and would form a not unworthy completion to the building; and nearly all of them appear to have been designed with a conscientious effort to produce something in keeping with the character of the cathedral.

#### PHOTOGRAPHY AND ART.

THE annual exhibition of the Photographic Society of Great Britain, at present open in the rooms of the Society of Water Colours, contains a good many things that are really worth looking at for their success of execution or for the beauty of the objects which they represent; and though the interest which this exhibition excites is cold indeed compared with that aroused by the class of exhibitions which we are accustomed to see in these rooms, the very contrast of feeling naturally suggests some reflections as to the contrast between these two methods of representation, the chemical and manual, and what photography can and cannot accomplish.

The days are long past when photography offered to us as representations of landscape only some half intelligible assortments of masses of dark and light. Comparatively speaking, the advance of late years is wonderful in this department of photographing; and a good many of the landscape photographs can be really enjoyed for their intrinsic beauty of representation. In almost all cases, indeed, it would seem that something is lost; one point is sacrificed to another, except where the scene offers special circumstances peculiarly suitable to be dealt with by photography. "A Frosty Walk" (31), for instance, by Mr. H. Tolley, represents a phase of nature, the ground whitened by hoar frost, which falls in admirably with the special powers and the characteristic tone of photography. In "At Ham, Derbyshire" (52), by the same exhibitor, the main point in the picture consists in the complex and delicate ramifications of the boughs and twigs of a bare tree, which form a network across nearly the whole surface of the picture, leaving the landscape to be seen through them. This anatomy of the tree, caught in every detail with the greatest sharpness, is an exquisite object in itself, and it is of real value in another sense, as a record of natural fact more elaborate than any painter

could emulate by the labour of the eye and hand. "Falcon Crag, Derwentwater" (235), again, by Mr. T. A. Green, is composed in this way of a foreground tree, a noble tree, and a distance retreating behind it; the distance is beautifully soft, but we fancy something of it has been lost and that the softness is really incompleteness; nevertheless, the result is beautiful in its way. Mr. Scamell's "Cottages at Steventon" (557), with the minute elaboration of the foliage and the broad mass of white light on the houses, is a most effective little bit, and here, it will be observed, there is no distance at all, and this is just one of the scenes in which photography succeeds best. Mr. Green's "Head of Butternere" (236) is very soft and aerial in effect, but as in many of these soft and rather misty views, the sky is lost, or only seen in faint and uncertain indications of cloud forms. One must expect also the water from the foreground of "Cottages at Steventon,"—water appears to be in every case and under all circumstances a failure in photography. We have not found one successful example in this collection. Smooth water, giving much reflected light, becomes wough in texture and loses all hint of water; rough water looks only like a dry, wrinkled surface. Instantaneous renderings of breaking waves or surf, as in "A Ground Swell" (462), by Mr. W. P. Marsh, show the sensitiveness of the modern plate, which can catch a wave actually on the curl, but as a representation of water it is valueless, almost disagreeable to look at, except solely as a business record of facts of form, which a sea-painter may perhaps find useful to refer to. Among other landscape subjects which are successful may be mentioned the two platinumotype photographs "On the Thames" (425), exhibited by the School of Military Engineering, the lower plate especially: two by Mr. F. M. Sutcliffe (548, 549), the first a fine little scene carefully chosen for effect,—two trees on a ridge of down near the foreground, and a cloudy evening sky behind, a photograph into which something like poetic feeling has been conveyed; "View of Moel Wyn from Festiniog" (535), by Mr. C. E. Nesham, in which the large extent and aerial perspective of the hills is finely reproduced, though the sky seems to have been lost; "The Lea at Ware" (552), by Mr. Edgar Clifton, a carefully-chosen subject, with an old barge in the foreground,—artistic feeling is shown here in the choice of subject and point of view, at all events; "Dunluce Castle" (219), by Mr. Vernon Heath, of which the same may be said; and "Carolling" by Mr. H. P. Robinson (40), a landscape with two figures walking through fields, in which the landscape has really the softness and distance of a water-colour painting, but we imagine this has been touched upon and is not pure photographing work.

The figures in this last, however, jar upon the sentiment of the scene; they are supposed to be two rustic women singing as they go through the field. Mr. Thorne Waite or Mr. Tom Lloyd would have made a couple of expressive figures of them, in harmony with the feeling of the landscape; here we are brought down to the plain prose of commonplace everyday life, and the result is a total failure. The study of this and of a good many other photographic subjects compiled with similar aims is very instructive. It shows what we owe to art and artists in the production of the rustic idylls which form such a prominent and such a generally beautiful portion of our water-colour exhibitions. The photographers are very fond of trying to do the same thing, and the failure in most instances, where the picture is simply a direct chemical transcript from nature, is complete and in many cases almost ludicrous. "A Pretty Hop-picker" (63) seated on a stile is not pretty a bit; her face is a dead dull blank. Mr. J. Gale shows some cottage or rural scenes with figures,—the most successful being "Saturday Afternoon" (249), where he has been rather fortunate in his figures, and the broad mass of light on the white cottage is a good piece of effect. In others, such as "Too Wet for the Woods To-day" (245), the figures of an old woman leaning over the gate and a man coming up to it are simply vulgar. We can fancy what Mrs. Allingham would have

made of them; and the same thought occurs in reference to "St. Catharine's Hill, Guildford" (61), a charming nook of landscape with a little girl seated in the midst of it just in the spot where "the figure" is wanted,—it is all right so far; but the common, inexpressive countenance of the child spoils it; the artist's hand was wanting. So again in "The Secret" (553), by Mrs. Payne, a little girl and boy; a charming expression has been caught in the former, but the boy's face looks dull and sulky. Photography, in fact, gives in general the commonest and poorest expression of the countenance; the artist seeks out and gives the best expression; and there is the gulf between photography and art,—or at least a part of it; for the still greater and essential distinction lies in the delight we all find in creating ourselves, or in studying the creations of others. Photography merely copies; the artist,—even the most nominally realistic artist,—does far more than copy; and nowhere can this distinction be more clearly seen and more strongly felt than in studying the efforts of photographers to produce pictures of human life. "Home, sweet Home" (41), an interior by Mr. Lyddell Sawyer, is another, we might almost say flagrant, example; the little bunched-up figure of the child held up in its father's arms is capital, and would be worth the attention of a painter, but the figures and physiognomies of the parents reduce the whole thing to sheer vulgarity.

Among really successful figure scenes we may, however, mention the little sleeping child, "Tired out" (482), by Mr. R. W. Robinson, a perfect little picture just as it is.

In what has been with the public the great and popular function of photography, the taking of portraits pure and simple, there are some brilliant successes. Among these the three "Studies," by Mr. McLeish (292) are admirable; the photographer has been fortunate in his subjects, but he has also known how to light the profile portrait of the beautiful young girl on the right so as to give the most brilliant and striking effect to it. A medal has been awarded to another series of large portraits by Mr. W. J. Byrne (283), but from the artist's point of view these are not so good as No. 292, and in particular in the centre figure of the girl's head, nearly life-size, the modelling of the month has been quite lost.

As on former occasions, architecture, which of all classes of subject lends itself best to photography and loses least by any defects of the process, is the least represented of any class of subject. There is a fine and remarkably sharp view of St. Paul's Cathedral (20) by Mr. J. Bracebridge Hilditch, which, considering that it is an enlargement from the original negative, is a triumph of clear definition. It has been touched upon here and there with white for high lights, but so obviously as not to constitute any deception. Mr. Richard Keene shows some "Interiors of Osmaston Manor" (4); Mr. W. Webster some interiors of "Eaton Hall" (21), Mr. Salmon has some good photographs from St. Bartholomew's and other City churches, Mr. T. M. Browning gives a good view of the Ponte Vecchio at Florence, and Mr. Bedford Lemere has been successful in producing some very elaborate interior detail from rooms in "Beau Manor" (92). Perhaps the most remarkable of all the architectural photographs for sharpness of definition are the two by Mr. Mold of interiors of St. Mary's Church, Banbury (189 and 432), a Classic interior which appears to have undergone recent decoration. Considering the difficulties in regard to light in interiors these may be called extraordinarily successful. But we should recommend the Society to pay more attention to architectural photography, especially of ancient works, in their exhibitions: there is no class of subject in which their work can show to more advantage or be of more value.

Among the curiosities of the exhibition is an architectural curiosity also, a photograph of a real contemporary series of lake dwellings, in full occupation, at Tupuselai, in New Guinea (404). Any architect visiting the exhibition would find it worth while to look at this.

There are various photographs of flashes of lightning (but these are getting common now); photomicrographs of minute objects from plant and insect life by Mr. F. H. Evans, for which the exhibitor has received a medal; the photograph of the claws of the house-spider, magnified 240 times, is one of the most remarkable and successful of these. Mr. G. W. Webster has somehow succeeded in photographing a couple of skylarks and their nest, the one bird on the ground, the other just hovering down; how he managed to get so close to the birds as to secure the photograph without frightening them away is the marvel; but the bird in flight illustrates one of the weak points of instantaneous photography; the bird's wings seem stationary, just as in the case of the instantaneous photograph of an express train which we noticed on another occasion: all idea of motion is taken away, wheels and wings alike are stopped dead. Mr. Sidney Tebbutt shows a photograph taken on a moonlight night in Saxony,—"full moon and cloudless sky, exposure three hours, from ten p.m. to one a.m.," but here again photography fails,—it conveys no idea of moonlight: the lens, in fact, sees more than the human eye can, and as we mentally refer to our experience from actual vision, the photographic result appears false, though in a scientific sense it may be true enough. On the whole, the more we study photography, the more we feel how far removed is real art from mere imitation of nature; how much of the pleasure we derive from painting springs really, unknown perhaps either to spectator or artist, from that expression of the artist's own mental mood, and that sympathetic response to it in the mind of the spectator, which mere photographic reproduction is powerless either to express for the one or to awaken in the other.

#### NOTES.

**T**HE paintings by M. Verestchagin at the Grosvenor Gallery are somewhat of a disappointment, not from any want of power, for there is plenty of that, but from the prevalence of mere big realistic war pictures, mingled with what may be called stage effects. The latter element is certainly predominant in the three big canvases grouped under the title "The Forgotten Soldier," the first showing a cold snowy mountain range with a vulture hovering; the second the vulture in progress downwards through the intermediate units; the third the dead soldier and the vultures in congress. The snow picture is fine, but there is nothing in it to compensate for the size of the canvas employed. The battle scenes are of genuine interest in their way, but it is the interest of realistic description, not of artistic treatment. Among these one of the best is "Before the Attack" on Plevna (79), with the unfortunate soldiers huddled on the ground on a wretched rainy morning, preparing to tramp through the mud and be shot on the way to the ramparts in the distance. This and various other works of the same kind give a vivid idea (or we should imagine so) of the gross realities of war with the tinsel taken off; and from M. Verestchagin's method of treating them, and from some stray remarks in the catalogue, we gather that this is his intention, and that he is in fact a kind of Ereckmann-Chatrain in painting. In a kindred spirit he places alongside each other three large paintings of executions; in the centre one of crucifixion under the Romans, on the left a scene showing English troops blowing some Indian scoundrels from the guns after the mutiny, and on the right an execution by hanging in Russia, a thick snow falling and a row of gallows dimly seen through it. This is a double cut, we presume, at English and Russian barbarity. There may be various opinions on the *moralé* of the subject, which it is not our business to go into; but it is not the kind of thing one goes to an art-gallery to see. Our remembrance of some earlier works of M. Verestchagin's led us to expect something different from this. Among the small paintings are some beautiful little things, especially some interiors of

Indian palaces, and two views of the Taj at Agra, from the gardens, in sunset and in early morning light, which are delightful. A large interior of "the private mosque of the Great Moguls at Delhi" (96), shows M. Verestchagin as an exceedingly fine draughtsman of architecture on a large scale; though here again the canvas seems on a much larger scale than the subject really requires. The exhibition is well worth seeing in its way, but one cannot help regretting that a painter of M. Verestchagin's talents should have devoted himself so much to this merely realistic illustration of painful scenes. He might have done higher things than these, with his powers.

THE interests of the Panama Canal Company will not be materially advanced by the advocacy of writers who are either hopelessly ignorant of the A B C of engineering, or presume on an equal amount of ignorance on the part of those whom they address. The well-known Paris correspondent of the *Times* leads the van of this kind of advocacy. He is good enough to explain that "what was done at Suez will be done at Panama. The canal at first will not be made either of its full depth or full width, but will be navigated by large vessels before it has been entirely completed." This sounds very plausible to those who think that one canal is as good as another. But the simplest calculation shows the absurdity of the statement. In the Suez Canal, over the course of which but one hill worth notice occurs, the excavation below the water-line, on the original section, was very nearly equal to the excavation above it. By halving the width a temporary reduction of about 32 per cent. was effected in the bulk of the excavation. The Panama Canal, according to its published section, has a bulk of 21 millions of cubic metres to be excavated below the water level, and of 110 millions of cubic metres above it. To halve the width of the canal would thus make a most insignificant reduction in its cubic contents, as the slopes must be the same whatever be the width of the water-way, and a mere vertical slice of 11 metres is all that would be for the moment left uncut. The great problems of the 360 ft. of cutting, and of the disposal of the 40 ft. floods of the Chagres, would remain unaffected by the reduction of width. The effect of leaving in one or two metres in depth at the bottom of the canal would be hardly appreciable in figures of such colossal magnitude. Matters must be in a bad way if advocacy of this kind is sanctioned by M. de Lesseps.

THE new number of the Statistical Society's *Journal* contains an excellent article on the Mortality of the Troops serving in the United Kingdom from Consumption, by Dr. Lawson, Inspector-General of Hospitals. Of course, on such a subject there is much that is retrospective; but it is very encouraging as showing us the great improvements between 1862, the date of the alteration, and now. Ventilation was at a particularly low ebb in barrack life in early days. In a report of 1861 upon 162 barracks containing in the aggregate 5,330 rooms, giving accommodation to 75,801 men, on the basis of 600 cubic feet for each man, the Commissioners recommended that the number of tenants should be reduced to 53,806 men. In 82 barracks, told off for 42,589 men, there were no means of ventilation provided; in 78 others the means were deficient, and what there were acted inefficiently; and in only one barrack was the ventilation as could be wished. Tommy Atkins, if he had known it, might well have founded a grievance, that he was not allowed that cheapest of all God's blessings, fresh air. Of course, improved ventilation was not the sole agent in lessening the mortality of phthisis, but it was a very important one, and one that was of particular interest to all those who were concerned in the erection of public buildings. The author also speaks well of what may be called rural barracks or camps, such as Aldershot, the Curragh, Shorncliffe, &c., in which the men get the advantage of country air to a much greater degree than those who are penned up in town barracks.

BY the death of Mr. Grierson, which occurred on Friday last, the Great Western Railway Company lose a most energetic officer, and the railway interest an able and powerful champion. The deceased gentleman had only been seriously ill for a very short time, and the announcement of his death caused general surprise and regret. The chief of the executive of a system which has, by the absorption of other lines, acquired a greater mileage than any other railway in this country, must necessarily be a man of varied attainments, and the late General Manager of the Great Western was eminently fitted for the position. He had, during the long period of his connexion with the Company, successfully overcome much opposition, and surmounted many obstacles; and he had no inconsiderable share in bringing the line to its present satisfactory position. His book on "Railway Rates, English and Foreign," which was published last December, is one of the most important that has appeared on this subject, and bears evidences of very careful research and far-extending inquiry. As its professed object was to refute some of the charges just then rather frequently made against railway companies, the work is naturally somewhat biased, and not altogether free from errors of detail and incorrect conclusions. At the same time the public are indebted to Mr. Grierson for a great deal of very useful information, and the railway interest for a fund of powerful and ingenious argument, and his loss will be felt on all hands.

IT is announced that an "apprentices' exhibition" will be held in the People's Palace in East London, the object being "to encourage the old apprenticeship system, which is generally admitted, to the detriment of English industry, to be gradually dying out." All boys and girls who are serving their time as bound apprentices within the metropolitan area of London will be qualified to exhibit, and the Committee will be prepared to consider any special cases of boys and girls who, though not legally indentured, are *bona fide* serving an employer for a fixed term of years, for the purpose of learning a trade, within the same area. Every exhibit must be the genuine handiwork of the exhibitor. The list of the Council includes the names of Professor Huxley, Sir Henry Roscoe, Sir W. Hart Dyke, and Sir Lyon Playfair. The exhibition will be opened on December 19th. It is an excellent move, and we hope it will be a success; it can hardly fail to be of considerable interest.

DR. ALFRED CARPENTER writes to the *Times* to call attention to the state of the River Cam. He says:—

"During the past four years it has been my privilege to assist at the examination of candidates for the diploma of public health which is now granted by the University. In each succeeding year I have seen unmistakable signs of an approaching catastrophe unless the local authorities do their manifest duty at an early date. The odours given off during the past week from the bad and borders of the stream between Trinity boathouse and Stourbridge-green, and even down to Fen Ditton, were very alarming to me, and had I sons at the University I should, for their sakes, positively prohibit boating on the river."

Dr. Carpenter goes on to warn the local authorities against trusting to disinfectants, and that the only safe course is to put the sewage on land instead of putting it into the river; but as it is supposed by the Board of Works that the sewage of London is to be successfully treated with disinfectants it is improbable that Dr. Carpenter's words will persuade the Cambridge authorities that their much smaller aggregate cannot be treated in the same manner. Dr. Carpenter assumes that the University authorities have no jurisdiction or cannot get their wishes attended to by the town authorities, and that otherwise this state of things could not possibly be allowed to continue; but he should not be too sure of that. Men may be very learned in the higher mathematics without understanding the simpler problem of sanitation, and possibly the Dons do not go on the river much. If it is in the state which Dr. Carpenter describes the rowing

men are certainly to be doubly pitied. It is bad enough to be condemned to row on a river about as wide as Bond-street and with no depth or weight of water, but if even this amount of water is largely mixed with sewage the Cambridge undergraduates might well felicitate those of Harvard on the superiority of their river accommodation, as they are reported by our friend *Punch* to have done in choice Latin: "Vos estis diabolice fortunati; noster est bestia fluminis."

THE Milan correspondent of the *Courier de l'Art*, commenting on the conditions for the second competition for the new facade to Milan Cathedral, observes that no directions have been given and no opinion expressed in the conditions as to whether the facade should have five portals or only three, or whether there should be flanking towers at each side of it, "selon le système ultramontain"; but adds that, after the result of the first competition, every one seems to be of the mind that the towers are not necessary to the success or completeness of the project. He goes on to observe that one clause in the new conditions seems to imply that the premium will be withheld from any one who sends in a design out of keeping with the style and "organism" of the existing building; that this very proper restriction was, however, laid down in the conditions of the first competition, and was practically ignored by the jury, since they selected among the fifteen a design in the style of English Gothic of the thirteenth century, and have therefore no right to take up a new position in the matter now. It is certainly the case, as we noted at the time, that the first conditions required the competitors to conform to the style of the existing building, and in that case they certainly should not have selected a design "in the English style of the thirteenth century"; but if they selected the design referred to because it evinced genius, and if they at the same time make it clear to the designer of the same that he must modify his design into conformity with the style and period of the existing building, they will place themselves in the right for declining the premium if the architect neglects their intimation.

AS a rule the *Museo Italiano di Antichita Classica* concerns itself chiefly with questions of epigraphy and the like, interesting only to the specialist. In a recent number, however (ii. 1), the editor himself, the well-known scholar and archaeologist, Sig. Compagnotti, gives us a paper of very human interest. He has collected together all the known inscriptions, six in number, of representations of Sappho in vase-painting. It is a familiar fact that vase-painters do not represent historical personages unless under very exceptional circumstances: we look in vain for Solon, or Pericles, or Demosthenes. If a historical person wants to be perpetuated on a vase he must contrive to gather round him a halo of mythological romance. So it was with Sappho. She was the tenth Muse, and as such was noised out of place in the cycle of mythology. Ovid (if the epistle be genuine), among the purely mythological heroines he addressed, included Sappho. It would be impossible here even to enumerate all the interesting points as to literary tradition, artistic treatment, and notably epigraphy, to which, in connexion with these vases, Sig. Compagnotti calls attention. He gives plates of five out of the six. Three have been published before, and are here reproduced for comparison. Two appear for the first time. They each have special interest,—one, from the little known collection of the Countess Dziahnisky, is the earliest representation of Sappho we have: the design, though red figured, is quite archaic in manner. The other is indisputably the most interesting of all the Sappho vases. Sappho is seated, surrounded by three of her women disciples. She is reading intently from a roll, on which can clearly be made out a dactylic line of halting scansion from one of her own poems:—

θεοὶ ἡρώτων ἰπῶν ἀρχοῦσι ἄλλων.  
A famous Cambridge scholar (of anti-archeo-

logical prejudice) was once heard to say he would give all the Greek pots that were ever discovered for one new fragment of Sappho." One of the despised "pots" has returned him good for evil. The existence of the vase has long been known; it is only surprising that a piece of such exceptional interest has so long escaped publication.

**M. W. THOMPSON WATKIN** writes to us that the Roman tessellated pavement at Tockington, which last week we described (p. 487) as having first been found in 1884, was discovered as far back as 1785, and that in Seyer's "History of Bristol" (vol. 1, p. 203), published in 1821, it is thus referred to:—"We have one pavement of this kind nearer to Bristol, at a place now reduced to a farm-house, now called Tockington Park, eight or nine miles distant on the right-hand as you go to Gloucester. It was discovered about A.D. 1785 in the farm-yard, not more than a foot under ground, and a large quantity of dung lay over it, on removing which some part of it, about a yard square, was laid open. The tesserae were rather larger than they are generally found, formed into a pattern as usual. Very little notice was taken of it and it was soon forgotten; the number of foundation walls around it make it highly probable that this is the site of a Roman villa as yet unexplored." The discoveries in 1884 were some more fragments of tessellated pavement and the base of a column or pedestal." We shall have further information to give on the subject next week, after visiting the site.

THE collection of Greek and Roman sculpture now arranged in the old print-room is a place quite unsuitable to and unworthy of the collection, and consisting, to a great extent, of funeral and monumental bas-reliefs and tablets, which have been long hidden out of sight in cellars, is a most interesting and valuable addition to the classic antiquities department. Among the Greek work are one or two very fine grave-reliefs, of the class to which we called some special attention a short time since; and there are some fragments in the collection which are interesting in an architectural point of view. One cannot help being struck by the remarkably "Renaissance" look of some of the Roman work, indicating that some of the early Renaissance sculptors were more direct imitators and reproducers of Roman work and Roman feeling than has been fully recognised. The reliefs of children in one or two examples are very like the work of Luca della Robbia, and the heads of Antistius and Antistia, a Consul and his wife, a high relief, beneath scalloped canopies, are things we should have expected to find in the Florentine Court at South Kensington. These heads are obviously portraits, and that of the consul, with his mean physiognomy and abnormally large ears, shows what a low type of man could succeed in securing this convenient and often lucrative post under the empire. We may have more to say about the collection.

**DR. FURTWÄNGLER** thinks that he has identified as an original work from the hand of Praxiteles a beautiful marble head now at Athens. The head was found at Eleusis, and as published in two prototype reproductions in the *Εφημερίς Αρχαιολογική* (1886, pl. 10). It will now, of course, attract a great deal of attention and controversy. It represents a youth with long heavy hair, confined by a simple band, and the expression is certainly tinged with that gentle contemplative melancholy which we are accustomed to associate with Praxiteles. If Dr. Furtwängler's surmise be correct, we have a head not only of great interest, as coming from Praxiteles, but also one of the subject of which is both novel and important. He thinks the statue, of which the head only remains, represents Eubouleus, a somewhat shadowy personality, of whom we should be glad to know more. Some mythologists make him the brother of the arch-Eleusinian ploughman, Triptolemus; others say he was the swine-herd whose swine were swallowed up in the earthquake that ac-

companied the rape of Persephone. Anyhow, he is a personality closely bound up with the worship of the two great goddesses at Eleusis. The worship is authenticated by several inscriptions. It is known from an inscription on a Roman copy that Praxiteles made a statue of Eubouleus, and presumably it was executed for Eleusis. The paper, which is of great interest, is reported in the *Philologische Wochenschrift*, Oct. 8.

THE authorities of the Berlin Museum have just issued (for sevenpence) a little book which, though it is in intent a guide-book to the Pergamene marbles, should be of much service to all students of ancient art. It gives a brief but very complete account of the whole course of the excavations, and has two plans of the city of Pergamos as it is now laid bare. As few persons ever consult and still fewer possess the magnificent illustrated work which the Prussian Government is in course of publishing on the excavations, this little book supplies a real need for the general public.

THE birthplace and early home of Dr. Johnson, which is to be put up for sale at auction in the course of next week, stands over against the place of his baptism, St. Mary's Church,—since rebuilt in memory of Bishop Lonsdale,—and has a return frontage to the Market-place, Lichfield. Facing the house is his statue, by Lucas; whereof one piece of sculpture commemorates Johnson's penance in the market of Uttoxeter. The house was built, as his own freehold, by the father, Michael Johnson, a native of Cubley, Derbyshire, who for some while of his career as a bookseller enjoyed no mean repute among his fellow citizens. But suffering reverses of fortune he had nothing to leave at his death (December, 1731), except this house to his widow, and a few pounds for his sons, Nathaniel and Samuel. Here the latter was born on September 18 (new style), 1709. It formed his home, perhaps, until his unsuccessful venture in opening a school, in 1736, at Edial Hall, near to Lichfield. Meanwhile, he had been in residence for fourteen or fifteen months at Pembroke, Oxford, had served as usher at Market Bosworth (1732), and had sojourned a few months at Birmingham. In March, 1737, Johnson came up to London, and, after a return for three months to Lichfield, brought his wife to town in that same year. Michael Johnson had added to the house; this entry is made in the civic books:—"1708, July 13. Agreed, that Mr. Michael Johnson, bookseller, have a lease of his encroachments of his house in Sadler's Street for forty years, at 2s. 6d. per an." That lease was subsequently renewed to the son by the Corporation, and without fine, in token of their respect for his character and eminence. In the codicil dated December 9, 1784, to his will, Dr. Johnson devises, in trust, to his executors for sale or disposal "my message or tenement situate at Lichfield . . . with the appurtenances in the tenure and occupation of Mrs. Bond . . . or of Mr. Hinchman, her under-tenant." Edial Hall was pulled down about eighty years since. A view of it from a sketch by J. T. Smith, together with one of the Lichfield house by E. Finden, after Clarkston Stanfield, R.A., were reproduced for Croker's work.

AT the meeting of the Metropolitan Asylums Board last week, Sir E. Galsworthy, the Chairman, criticised the requirements of the Local Government Board as to the "temporary" character of the hospital buildings to be erected at Darenth or elsewhere. If, he said, the buildings were to be of brick, and the managers had approved of brick and rejected wood, as objectionable, dangerous, and, in the long run, as very expensive, they must necessarily be of some permanence. Dr. Bridges said that with regard to the alleged ambiguity as to "temporary" buildings, he meant by this that such buildings only should be erected as might be pulled down, and suggested that the one-storied brick huts at Hampstead might serve as a model of what could be done at Darenth. But why not try Lascelles's concrete cottages? Those seem just the kind of thing

for the purpose; inexpensive, capable of being made warm enough, easily put up at short notice, and easily removed. The discussion seems to have been carried on as if there were no way of building but with bricks.

**WHETHER** the Royal Institute of Water-Colour Painters will much advance the cause of art by their Art Union is somewhat doubtful. They will distribute a certain number of good drawings and engravings, which will fall into the possession of a large number of persons who will care very little more for art in consequence. The love of speculation rather than of art is the main motive which induces most persons to subscribe to a lottery of this kind. Those who desire to beautify their homes can already do so at a low cost by the purchase of the publications of the Autotype Company, and the numerous etchings and engravings which are within the reach of any one who can afford to spend a pound or two on art. The Institute would do much more to advance the love of art by having small exhibitions of really good water-colour drawings in some of the suburbs of the metropolis, and in small towns where there are no opportunities of studying art, than by the lottery which they have just established.

A CORRESPONDENT, who signs himself "A Victim," writes to the *Times* to tell how he and other persons at Gotham,—we beg pardon, Worthing,—have been cruelly taken in. A man calls at the houses, evidently selecting the time when the nurse is out, and there is no one to take proper care of the inmates, and begs to fix gas-burners, at 2s. each, which will save 50 per cent. of the gas. He is so persevering that they cannot resist his blandishments, and allow him to fix burners all over the house, which are discovered afterwards to be another number of the same class of burner that has been removed, by the same makers, and to be purchased at 3d. each, and which consume more gas than those removed. The "Victim" adds that it would be an interesting and profitable employment for the readers of the *Times* to calculate the amount of profit made by the traveller who thus takes in the unsophisticated inhabitants of Worthing. We do not see where their interest and profit will come in; but there is a certain kind of pathetic amusement to be derived from the contemplation of a person, apparently able to read and write, and therefore with some sort of education, allowing himself to be taken in by so transparent a hoax, and then solemnly warning the public through the newspapers, as if all the rest of the world were as silly as himself. Next time the "Victim" is taken in (we can hardly suppose that so suitable a subject for simple frauds will be long overlooked), and writes his account of it to the papers, he had better sign himself "A Simpleton"; and if any more bogey men with wonderful gas-burners call, he should ask nurse before he buys them.

#### NOTES AT THE EXHIBITION OF ECCLESIASTICAL ART AT WOLVERHAMPTON.

FROM the point of view of lovers of art and history it is very much to be regretted that the annual exhibitions connected with the Church Congress are so much better supported by manufacturers of church furniture, plate, and decorations than by those who possess ancient, beautiful, or curious objects which they might lend to swell the interest and importance of the "loan collection" that always forms one feature of the show. Manufacturers cannot be blamed if, seeing that the exhibition depends almost wholly upon them, they insist upon the best light and positions for their stalls, and force the ancient church plate and rare embroideries to take refuge in dark little back rooms, as last year, or in a poorly-lighted basement, as on this occasion. Surely, among the possessions of the multitude of highly-cultivated men,—chiefly clergymen,—who take part in these Congresses, enough of interest might be found to fill a moderate-sized room, such as was this year

devoted to the collection, without including what is but very remotely, if at all, connected with ecclesiastical art, and without finding it necessary to fill up with photographs and modern manufacturers' specimens which, however beautiful, are quite out of place in such a collection. We fear that the position which the objects on loan year after year occupy, and the smallness of their number and interest, must act and re-act on one another. Few care to take the trouble and risk of lending their treasures only to find them put in a dark corner of a collar; yet, if the treasures are few and insignificant, their claims are overlooked or set aside. Who will be the first to put these loan collections on a better footing, their patrons or the management?

Among the most striking objects to be seen in the cases this year was a silver crucifix, fig. 1,

Fig. 1.

which appears to have once formed part of a processional cross. The thin silver plate which forms the background has evidently been fixed to woodwork, the holes for the nails or screws still showing. The extreme dimensions of the fragment are 11½ in. by 8 in. The figure, of rude workmanship, with long body and short legs, but expressive features, is in high relief, and has been much battered out of shape in parts,—it, with the cross on which it hangs, still bears traces of gilding. The nimbus is of cloisonné enamel, red and blue. The treatment suggests a very early origin. In the same case were a number of chalices and patens, most of them very skilful imitations of ancient originals; others, some of which appeared and were illus-

Fig. 2.

trated by us last year, were the originals themselves. Among the latter, No. 257 was an elaborate and rather large chalice, with some pretty fifteenth-century architectural detail, but poor in outline. The chalice and paten belonging to Hamstead Ridware Church, Staffordshire, figs. 2 and 3, are well-known specimens of pre-Reformation church plate, and the silver paten, No. 55, from Coton Hackett Church,

fig. 4, is one of the only two pre-Reformation patens to be found in the county of Worcester, the other being in Worcester Cathedral. It is 5½ in. across, very thin; and the workmanship, which is of the most primitive description, is beginning to be obliterated by constant polishing. In the same case was an old pewter flagon, fig. 5, formerly used in Whittington Chapel, Worcestershire; it measures exactly 8 in. in height to the lip, and is a good specimen of a number of similar vessels that once served to hold the sacramental wine in a large number

Fig. 3.

of churches, and still serve the same purpose in a few places. In another case are to be seen several ivory caskets and other objects of some interest, lent by Mr. David Jowell and other gentlemen, among which we noticed a brass Russian Icon of the ordinary design, somewhat similar to a smaller silver one which

Fig. 4.

we illustrated last year. The largest of the ivory caskets was a good specimen of fifteenth-century German workmanship carved with several series of figures of saints. In the same case we noticed a small ivory diptych of fair workmanship, and six grotesque heads carved in ivory, said to be caricatures of the Popes,

Fig. 5.

full of genial humour. Conspicuous at one end of the room hangs an old Italian church banner, elaborately embroidered in gold and colours on white silk, it is now sadly faded and torn. In the centre is an Assumption of the Virgin, and at the foot a representation of a scene which is a little inexplicable: three flames or fires seem to be rising from a lake whereat a cow on the bank sinks on her knees, while the herd falls backwards in astonishment, and a town to the right of the picture collapses into ruins. The workmanship of the banner is very beautiful, but the design is wild and

coarse. At the side of the room, and lent by the same exhibitor, the Rev. A. R. Harrison, a beautiful piece of silk embroidery worked in delicate tones, on cream-coloured silk, seems to be the centre portion of an Italian altar-cloth. The centre is occupied by a cross on a gilt ground, surrounded by an oval garland of flowers. The field is occupied by flying birds, and the upper border consists of swags of flowers supported by birds. The charm of the work lies in the delicacy of the drawing and colour. Close beside this exhibit hangs a beautiful drawing of Prior Crandon's Chapel, Ely, by Mr. W. H. Bidlake, M.A.

Mr. Cecil Harcourt Smith has lent a number of Persian and Eastern fabrics of various kinds, carpets, shawls, and cloths, some of which are very lovely; the patterns are chiefly geometrical or arrangements of conventionalised foliage and flowers; in fact, what the patterns of Persian and Eastern stuffs generally are,—exquisitely designed, drawn, and coloured, but passing describing in detail. We particularly noticed No. 25, a large banging or quilt of yellow silk embroidered with birds and flowers; Nos. 9 and 12, fabrics of cloth of gold, and No. 13, scarlet silk, with a small sprinkled flower pattern.

Messrs. Doulton have lent Mr. Tinworth's terra-cotta of "The Prodigal Son," and several smaller works by the same artist. In the former the prodigal is the centre figure, seated on a stool, his hair and beard unkempt, looking down and away from his father, who stands holding the hand on which he is about to place a ring which he is taking from a child who runs to him with it. On one side a kneeling slave places a shoe upon the foot, which he has just washed and on the other a female brings the new robe. The elder son appears through the lattice from outside, pointing to the fattened calf which is being brought in at the door. The composition is completed by the introduction of figures gathering the grapes that hang from the lattice roof, children, and musicians.

Messrs. Jones & Willis have lent some very beautiful vestments and altar frontals.

Upstairs the most beautiful exhibit is that of the "Autotype Company," consisting of exquisite reproductions by their photographic process of pictures and drawings, among which are conspicuous the Sistine "Madonna," Da Vinci's "Last Supper" (from the engraving), Rubens's "Assumption," Francia's "Pieta," Reynolds's angels' heads, Sir Frederick Leighton's S. K. frescoes of "Manufacturing Art as applied to Peace and War." Near these are Messrs. West & Collier's church chairs, a varied collection of useful specimens. The largest room is chiefly devoted to church furniture, stained glass, &c. The chief stalls are occupied by Messrs. Jones & Willis and Messrs. Benham & Frond, Limited, who both show some good metal work in lecterns, lamps, altar furniture, &c., and some beautiful embroidered altar frontals. Messrs. Jones & Willis show several specimens of church furniture in oak, notably a pulpit of better design than is generally to be found in manufacturers' pattern-books. Messrs. George M. Hammer & Co. exhibit a large quantity of cheap church and school furniture and fittings, which will meet the demands of those who have little to spend. Messrs. Mayer, of Munich, have sent several specimens of stained glass, which, though it may tend to counteract the just prejudice of many persons against Munich glass, will probably still be too opaque for modern English taste. On the staircase are some beautiful cartoons for stained glass, and one fine specimen of such work by Messrs. Ward & Hughes.

In one top room are a wrought-iron chancel screen for a Licfield church, and some wrought-iron panels, very well executed by Mr. Culwick, of Licfield. Here that doubtless useful body, the Religions Tract Society, also has a stall, and here it visibly justifies its connexion with ecclesiastical art by hanging upon the walls the most atrocious coloured prints, illustrative of the second part of the Pilgrim's Progress, that were probably ever executed. In the same room Messrs. Beal & Co. show some specimens of altar furniture, embroidery, &c. In the large room the "East Grinstead School of Embroidery" have a collection of some of the best embroidery in the exhibition. We noticed particularly a gilt stole with a figure of St. George on one end and a white damask chasuble with gold embroidery. The Decorative Needlework Society also shows some very good embroidery, and the Arndel Society some of its finest plates.

## THE CONDITION OF THE THAMES.

MR. RAMSAY, Surveyor to the Twickenham Local Board, has prepared and submitted to that authority a detailed report on the present condition of the Thames between Teddington and Richmond. The causes of that condition and the suggested remedies are dealt with at considerable length by Mr. Ramsay. The removal of Old London Bridge, with its narrow arches, is regarded as one of the chief causes of the scarcity of water in these parts of the river. It appears that before the removal of that structure in 1823 the low-water mark at Richmond was 6 ft. 3 in. below Trinity high-water mark. In 1860, however, the low-water mark at Richmond had fallen to 7 ft. 7 in. below Trinity high-water mark, while in 1887 it has fallen to about 9 ft. 6 in. Even at Teddington the low-level water-mark has fallen from 2 ft. in 1823 to nearly 7 ft. in 1887 below high water at Trinity. The old bridge acted as a dam, and between that and Blackfriars Bridge the soil was silted up to such an extent that five dredging operations had to be constantly carried on between the two bridges. Dredging operations subsequently to the erection of the new bridge have also tended to lower the water-levels of the river from Teddington Weir to Westminster. By the removal of shoals which prevented the water from flowing freely down the incline or bed of the river, the motion of the water has been quickened, and it runs away in a shorter time. It is pointed out that the low-water level at London Bridge in 1823 was 14.40 ft. below Trinity high-water mark. It was reduced by the removal of the old bridge and dredging operations to 20 ft. in 1865. Mr. Ramsay lays considerable stress on the abstraction of the large quantity of water from the river by the various water companies as a circumstance contributing greatly to the scarcity of water in the upper reaches of the Thames. It is curious to note that the maximum aggregate quantity 10,000,000 gallons daily) which the several companies are permitted by their Acts to draw on the river, is about half the quantity which issues daily over Teddington Weir during the dry period of the summer season. Mr. Ramsay naturally enough argues that a further extension of power to the water companies in the direction of enabling them to draw a larger supply of water than they can obtain at present from this source would be an unwise proceeding. He asserts that the dredging operations in the Upper Thames recommended in 1873 by Sir John Lubbock and Captain Calver, have so far not been attended with the anticipated results. The object in view then was to deepen the channel between Teddington and Richmond Bridge, so as to give a uniform depth of 3 ft. 6 in. at low water of spring tides, and a bottom width of 40 ft.; the banks to slope uniformly to the extent of 4 ft. in one, and provision was made for making an even high-level mark, by topping the irregular banks with the gravel produced in the dredging. This uniform depth was planned on the assumption that the water companies abstracted daily their maximum quantity of water, namely, 110,000,000 gallons. But it is pointed out that the effect of the dredging to make the channel the prescribed width of 40 ft. has been to lower the water level within the Richmond and Twickenham district, rendering navigation, even for pleasure-boats, almost impracticable at low tide, and exposing the river to unsightly muddy banks. It is admitted, however, that the formation of uniform slopes made from the banks of the river along the Surrey side is in itself a great improvement. They will when completed not only tend to improve the river for navigation purposes, but will materially reduce the large amount of sediment which is continually being washed from the ragged banks and deposited on the foreshores. Another cause assigned for the scarcity of water in the Upper Thames is the rapidity with which storm water, owing to the extension of modern systems of drainage, flows into and passes out of the river. In order to preserve this storm water for the benefit of the Upper Thames, Mr. Ramsay suggests that a number of reservoirs should be constructed at the mouth of the tributaries of the Thames, where the stored-up water could be let into the river when it was wanted. Mr. Ramsay is in favour of a lock and weir between Teddington and Isleworth as a means of restoring the navigable condition of the Upper Thames either for trade or pleasure. He deals at length with the

various objections, official and otherwise, which have been advanced against a lock and weir,—such as the depositing of mud in the region of the still waters created by the structure; the aggravation of this evil by the discharge of numerous sewers and drains into the river above the site of the proposed weir; the withdrawal of 15,131,000 cubic feet of tidal water, which at present operates in maintaining the channel by its scourage; and lastly, the delay to barges. The objections as to the withdrawal of the tidal water and possible flooding, can, Mr. Ramsay asserts, be met by dredging the river between Putney or Barnes and the proposed lock, where "some deposition of mud and silt would inevitably take place." As the proposed lock and weir would be half tidal, silting above the lock was not to be feared, as only a small proportion of the matter in suspension would pass over it after the waters had reached the height of half tide. Considerable scavenging powers may be arranged for and secured in the structural arrangements of the weir, by which the whole tidal column may be permitted to pass through on the ebb until it reached the half-tide level, when the weir would be closed. As to the discharge of sewers and drains into the basin above the weir, Mr. Ramsay thinks that the objection may be practically dispensed with, from the fact that the whole of the sewage in the district above the weir will, under schemes now approved or works already carried out, be intercepted from the river. The objection as to the delay which would be occasioned to the barges passing through the lock would be trifling compared to the delays which have to be undergone because of the impassable condition of the river, so far as barges are concerned, in the Richmond district. With a half-tidal lock the gates would be opened on the flood when the tide had risen 5 ft. on to the level of the top of the weir, and craft would then pass freely through the lock from that time until the tide had fallen to the corresponding level on the succeeding tide. Mr. Ramsay concludes his elaborate report by the observation that until the Metropolitan Board have fulfilled their duty as a sanitary authority, by intercepting the metropolitan sewer storm outfalls between London and other bridges, and improved the condition of their main sewer outfall at Barking, offensive sewage matter will always be deposited in the upper Thames.

ARCHITECTURAL ASSOCIATION  
CONVERSAZIONE.

THE Architectural Association commenced the session, as usual, with a *conversazione*, which was held at the Westminster Town Hall on Friday, the 7th inst.

The large hall, in which a reception was held by the President, Mr. John Slater, B.A., was devoted to an exhibition of art manufactures; and during the evening the band of the 2nd Life Guards played at intervals. Two chamber concerts were given in the Council Chamber, in which, under the direction of Mr. Malcolm Lawson, Miss Emily Lawson, Miss Isabel Tomalin, Miss Amy Hickling, Mr. D'Arcy Ferris, and Mr. Hubert Thorndike took part.

The prize drawings and the work done in the various classes were exhibited in four committee-rooms. During the evening the President announced the names of the prize-winners:—*Architectural Association Medal* (Design for College Gateway).—Mr. G. G. Woodward.

*Architectural Union Company's Prize*.—1st, Mr. W. A. Webb; 2nd, Mr. H. P. B. Downing.

*Architectural Association Travelling Studentship*.—1st, Mr. A. H. Hart; 2nd, Mr. H. P. B. Downing.

*Aldwinckle Travelling Studentship*.—Mr. W. M. Duke.

*Ernest Turner Prize*.—Mr. H. C. A. Colville.

*Blashill Prize*.—Mr. H. E. Mallet.

*Lectures on Architecture*.—1st, Not awarded; 2nd, Mr. P. L. Jones; 3rd, Mr. V. T. Jones.

*Lectures on Construction*.—1st, Mr. H. S. Wood; 2nd, Mr. H. G. Lidstone; 3rd, Mr. H. V. Lancaster.

*Honourable Mention*: Mr. A. B. Yeates, Mr. H. Ernrich, Mr. H. E. Mathews.

*Class of Colour Decoration*.—Prize, Mr. W. Doves. Honourable Mention: Mr. H. V. Lancaster.

*Class of Design*.—1st, Mr. C. E. Bateman; 2nd, Mr. H. R. Applebee; 3rd, Mr. E. W. Monro.

*Elementary Class of Design*.—Section I.: 1st,

Mr. R. D. Warry; 2nd, Mr. A. W. Jarvis; 3rd, Mr. H. Woodington. Honourable Mention: Mr. A. B. Yeates. Section II.: 1st, Mr. A. W. Cleaver; 2nd, Mr. J. Ellwood. Honourable Mention: Mr. D. J. Blow, Mr. R. A. J. Bidwell.

*Advanced Class of Construction*.—Mr. J. C. Agutter.

*Class of Construction*.—1st, Mr. W. D. Gravell; 2nd, Mr. F. R. Oglesby.

*Elementary Class of Construction*.—1st, Mr. H. Ernrich; 2nd, Mr. A. W. Jervis and Mr. L. V. Hunt.

*Quantity Class*.—1st, Mr. W. J. Bamber; 2nd, Not awarded.

*Essay Prize*.—No competition. The Prize Committee reported that the work done in the Elementary Class of Design was of unusual merit.

Amongst the exhibitors were Messrs. Holland, who exhibited an unusually massive mahogany mantel-piece designed for a house in Sydney, and an interesting oak sideboard made up of old work from the design of Mr. J. H. Rushbrook, architect. Messrs. Hindley had an inglenook complete, with fire-screens to match, in white painted woodwork, and some quietly-designed pieces of furniture. Messrs. Morris showed some of their tapestries, and Messrs. Newman had a good collection of wrought-iron work. The Coalbrookdale Company exhibited some good specimens of their cast-iron work from designs by the late Alfred Stevens and Talbot. Messrs. G. Trollope & Son exhibited some large specimens of Mexican onyx in the form of pedestals and balustrades, and also some stained wood panels in imitation of inlay work. Mr. Longden exhibited some good dog-grates and tiles, and Messrs. Jeffries some wall papers. Messrs. Walker exhibited in one of the committee-rooms the grate designed by Mr. T. Fridgin Teale, M.A., which was the subject of a paper read by Mr. Teale at the Association. The stove was fixed and alight, and seemed to give very good results. An exhibition of electric lighting for domestic purposes was made by Mr. M. J. Scott, in the form of portable lamps and fixed lights, worked from small accumulators. Messrs. Jenks & Wood exhibited some good specimens of furniture. Messrs. George Wright & Sons had on view a stately marble chimney-piece, of good design and workmanship, fitted with one of their patent "As you like it" grates.

## NEW HOSPITAL, KINGSLAND ROAD.

This hospital, the first portion of which has just been erected in Kingsland-road, was opened on October 1st. The institution was originally named the Metropolitan Free Hospital, but the title has recently been changed, and the institution is now known as the Metropolitan Provident Hospital, patients, with the exception of accident cases, which will continue to be treated free, being required to make a small weekly contribution whilst inmates. The hospital has at present a frontage to Kingsland-road of 180 ft. in length, the administrative block being carried to a height of upwards of 80 ft., whilst the ward block is limited to 60 ft. height. From Kingsland-road the return frontage extends about 130 ft. in depth, the building covering a ground area of about 23,500 ft. The administrative block is at present at the south end of the general elevation, but on the completion of the entire scheme this portion will form the central feature, whilst the block containing the patients' wards, extending to the northern boundary, and comprising about three-fourths of the entire frontage, will have, on completion, a similar block extending to the southern boundary. The administrative block is faced with red brick and Portland stone. The adjoining block northwards, containing the patients' wards, has five floors, the elevation being faced with stock brick, relieved by red brick bands and string courses. The south end portion of this part of the frontage is formed by a series of bay windows, giving an octagonal plan, and is surmounted by a turret. At the rear of the administrative block is an open area, and immediately beyond it westward is another large block running parallel with the Kingsland road blocks. The whole of the wards are connected with the administrative block by a series of covered corridors at each floor level. The administrative block contains the medical officers' apartments, clerks' and secretaries' offices, board-room, convalescent room, nurses' day-

Offices and Chambers, 3 and 4, Lincoln's Inn Fields.—Mr. J. Sawyer, Architect.

room, and also the matron's, doctors', nurses', and servants' apartments, and their bedrooms, and having on the topmost floor, in direct communication with a patients' lift, a large operating theatre, fitted with all requirements, and communicating direct with a chloroform and instrument room. The main wards are about 93 ft. in length and 24 ft. in width, each ward having accommodation for twenty-four beds. The wards are ventilated by flues and air boxes under each bed-head. The ventilating system has been carried out from the design of Mr. Collins, one of the architects of the building, the terra-cotta inlets having been supplied by Messrs. Doulton & Co. The ordinary department is in the basement, and there are patients' and food lifts from the basement to each floor supplied by Mr. Goddard. The wards and other portions of the building are heated by Calton's stoves. Hot-water is applied throughout the entire building by means of boilers and steam heaters, the arrangements having been carried out by Mr. Frazer. Protection in case of an outbreak from fire is afforded by hydrants placed on every floor, both internally and externally, in such positions as to command the entire frontages of the building, the system having been carried out by Messrs. Shand & Mason. Lightning conductors have been placed on every point likely to be in danger from lightning by Messrs. Cutting & Co. The gas-fitter's work throughout

has been executed by Mr. Cannon. The cost of the building, exclusive of the land, so far as completed, will be about 25,000*l.*, which will be increased to 40,000*l.* when the additional wing is built. Messrs. H. H. Collins and James Edmeston are the joint architects, and Mr. Shurmur is the general contractor. Mr. Hinxley has acted as clerk of the works.

#### Nos. 3 & 4, LINCOLN'S INN FIELDS.

THE accompanying cut shows the elevation of the original design of the above-named new building in Lincoln's Inn-fields, which in execution has been somewhat modified in the upper part, above the fourth story. The building, which stands on the northern side of Lincoln's Inn-fields, is used for offices and residential chambers. The front is faced with Portland stone. The work was carried out by Messrs. Chapman Bros., of Kennington, for Mr. T. Clarke. Mr. Joseph Sawyer, of London and Spalding, is the architect.

**Monument to Rossini.**—It has been decided by the inhabitants of Florence to erect a monument in honour of Rossini on his grave in the Cathedral of Santa Croce. It will be erected by the sculptor Passaglia, and will consist of a portrait statue in marble of the composer, on the base of which figures in bas relief symbolising some of his most celebrated works will be executed.

#### THE WALLS OF CHESTER.

SIR,—I will trouble you to correct a printer's error in the printing of my last letter. I did not write *Artois*, but *Arlon*. Arlon is the capital of the Duchy of Luxemburg, and is situated about fourteen miles from the town of Luxemburg. It is the modern representative of the Orolanum of the Itinerary of Antoninus. It is there called a *Vicus* and therefore it may be supposed to have been walled at a comparatively late time, probably about the close of the third century. The walls were built, in the lower parts, with dislocated sculptures of monuments, chiefly sepulchral, laid without mortar, although the portions above were cemented. In this there is a great similarity to the walls of Chester, and to others to which I propose to refer ere long.

Mr. Shrubsole having obligingly sent me a photograph of the sculptured stone he and Mr. Watkin imagine to be Mediaeval, I may remark that in no way changes my view of Mr. Brock's sketch, only that I discern in the hands of the second personage, also a girl, the foreshortened figure of an animal, probably a pet cat, such as we find on one of the stones from the walls of Bordeaux previously referred to. On this I have just received from Mr. Robert Blair, F.S.A., the following opinions:—"I have seen the photograph of the Chester so-called Mediaeval stone from the walls, at Dr. Bruce's. Both he and I agree that it is, beyond all doubt, Roman."

Temple Place, by Strood, October 10th, 1887.

SIR,—In reply to Mr. Shrubsole's letter (p. 512) permit me to say that the mortared part of the wall, with small stones, and the unmortared lower part of massive ones, are fairly of the dimension I have given, and that they were taken with the City Surveyor.

Is your correspondent referring to the same place? His mention of a cornice leads me to think that he is not doing so, for there is none at the point I named. Where the cornice does occur (it begins about 50 ft. east of the North Gate), the large Roman stones go quite from base to cornice, this being their greatest height; but this is not the point I named. At other places along the wall they are lower than the height I gave, in some cases being only one or more courses high; in others they are not visible. The height I gave refers only to the point named. At other places the wall is much higher, in others rather less.

Mr. Shrubsole saw a man thrust in his arm "between the layers of stone, first removing the dry earth," and asks if this can be Roman work. I did something of the sort myself, but it was in places where the removal of inscribed stones made it possible to do so. I can but think that your correspondent has taken some of these gaps for what he reports, although I have already called attention to the fact that there is earth in the openings. It is a peculiarity that these joints do not appear over to have been filled in either with pebbles or broken stones. I think that few antiquaries will object to the removal of Roman stones from a later Roman wall, but many gaps have been made here which have to be filled in with modern masonry.

I saw none of the unmortared part formed of "loose" stones,—all is a compact mass. It might not be incorrect to say so of some of the poorly-built mortared wall above it, particularly the inner face.

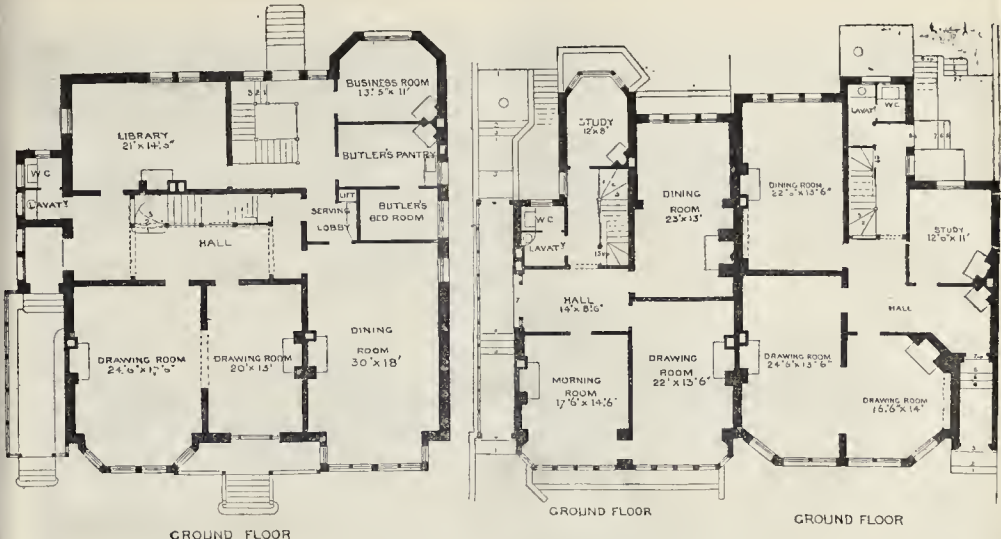

I will take this opportunity of correcting a mistake in my letter (p. 511). What I then said of North Gate applies to East Gate. There are so many diverse views of the latter that I took one to apply to the former, following the inscription on the gate itself relative to its Roman foundations, on being rebuilt in 1808. Mr. Thompson Watkin, whose "*Roman Cheshire*," I had not to hand at the moment, acknowledges, p. 106, that these foundations are of Roman date. This brings out the fact that, instead of there being but one Roman gate in line with the present walls, there were in reality two in existence until fairly recent times. Surely this must make it more difficult for Mr. Watkin to believe that the massive stones in the walls, which he acknowledges to be Roman, could ever have been shifted in position, as he asserts. There they are, in line with the gates in both cases, where Roman walls must have been.

Into his interesting conjectures relative to what Eilieda did at Chester, I need not enter, except to say that whatever was done must be regarded in relation to the Castle. There is there a grassy mound upon which the Normans did not erect their masonry keep. No one who has studied an interesting series of articles in some past volumes of *The Builder*, under initials whereby we can readily recognise the name of an esteemed antiquary, can doubt the Saxon origin of such works. I am not an advocate for theorising without certain facts, but in this case it may be a safe supposition to consider this mound as the work of Eilieda, and as the key of her fortifications, which, from analogy with other works of the kind, should be expected to have been ditched and earthen banks with stockading, and not masonry.

DESIGNS FOR MILAN CATHEDRAL FAÇADE.

We give this week a lithograph of M.M. Hartel & Neckelmann's design, accepted in the first competition for the new façade of Milan Cathedral, from a photograph of their drawing forwarded to us by the architects; and another of a design by Messrs. Pugin & Pugin, exhibited with the others, but excluded from the competition on account of delay in delivery, the fault, we understand, of one of the railway companies. Further remarks on the subject will be found on another page.

The *Illustrazione Italiana* published small woodcuts, in a recent number, of all the designs, from which we have reproduced four, which may be useful as giving a general idea of some of the designs, though, of course, they cannot represent the detail in any adequate manner.

NEW HOUSES, THE BEACH, WALMER, KENT.

The drawing from which our illustration is taken was exhibited in this year's Academy exhibition. The buildings have been erected by day work by Mr. A. Tod, from the designs and under the personal superintendence of Mr. James Neale, F.S.A. The three larger houses on the right are finished and occupied, but the other house shown on the drawing is not yet erected.

A COUNTRY HOUSE.

This house, of which we give a plan and perspective sketch, is to be built of red bricks, with stone mullioned windows and dressings; the half-timber work is in oak; tiles of an orange-red colour are to be used for the roofs and weather tiling. The estimated cost is 2,750l. Mr. Langton Dennis is the architect.

ENTRANCE LODGE, WALMER, KENT.

The illustration is taken from a drawing exhibited at the Royal Academy. The Lodge has been erected by Mr. Tod, from the designs and under the personal supervision of the architect, Mr. James Neale, F.S.A. There were no contracts excepting for the following works: Messrs. Frost Bros., of Deal, for the gas and plumbing; and Messrs. Potter & Son, of London, for the ornamental ironwork. The lower walls of the Lodge are hollow, being faced with Kentish rag, worked in courses and backed with brickwork, with quoins of red Teynham bricks. The upper story is of timber and pebble-dashing; the roofs are covered with Collier's Reading tiles. The sweep of the gates was arranged so as to preserve the two large trees, as shown on the drawing.

W. THOMPSON WATKIN.

Liverpool, October 10th, 1887.

SIR,—I asked Mr. C. Roach Smith in my last if he ever knew of the walls of a Roman *castrum* (not of buildings or aqueducts) having been built without mortar, and I added that I would not include the walls of the towns on the Continent which he named, as the date of their erection had been disputed. Mr. Smith does not answer the question; but evades it, and, while admitting that I am right in saying the date of the erection of these Continental walls has been disputed, says that it is "in vain he has referred us to them, i.e., to prove that the Chester wall is Roman. Certainly it is in vain that he has referred me to them, when the only instances he can refer to of so-called Roman walls of *castra* built without mortar are these disputed ones, and, like the portion just laid bare at Chester, they are composed of sculptured and inscribed stones. Therefore, at the outset, there is the same suspicion as to the origin of the Chester fragment, which seems more than ever confirmed by the opinions of many archaeologists concerning the walls similarly composed (though with the addition of mortar) in London.

Mr. Smith's comparison with Richborough, &c., does not hold good; for the newly-excavated portion at Chester is not, like Richborough, &c., built upon layers of boulders. In the only foundation of boulders laid bare at Chester (that of the destroyed southern wall), the boulders are set in strong Roman concrete.

With regard to Mr. Smith's statement that the arguments as to the Continental walls he named, not being Roman, are "as illogical and futile as those adduced in favour of a Jacobean theory to explain the walls of Chester," I may say that I have neither started, advocated, nor discussed any "Jacobean" theory. My views are explained at length in my reply to Mr. Brock in your issue of September 24th.

Mr. Brock candidly admits that he does not know of any *castrum* in Britain, the walls of which were built without mortar, but refers to these doubtful Continental examples, and says they are a strong argument in favour of the Chester fragment being Roman. I should opine it was just these discordant Continental examples that would help to increase the evidence against the Roman origin of the Chester fragment. He seems to be misinformed also as to the extent of the mortared portion of the latter. The only mortar is at the extreme upper part, and that is modern.

Next, Mr. Brock avers that Roman mortar has been "detected" on the Roodey stones. Certainly it has. It was "detected" during the recent excavations made in front of them three or four years since, fragments of it adhering to some of them; and this fact, with the nature of the tooling on some of the stones laid bare, helped me to see that the latter were Roman, brought from a large building. Mr. Brock will, however, find no layers of Roman mortar between the stones.

Mr. Brock states also that the evidence shows that the stones in the newly-excavated part of the north wall were not lifted into their places by means of the lewis-holes still existing in some of them, but they were rolled into position, that "labour was cheap, and that progress was slow." He asks whether any seventeenth-century builder would have done this, and if it is not fatal to any late date. Whether "any seventeenth-century builder" would have

done this is beside the question. The Parliamentarian army (whom I have put down as the builders of this fragment) could do it, and labour would consequently be "cheap." With a strong force, I see no necessity for progress being "slow."

Mr. Brock's remarks as to the number of stones from "the ruined suburbs" lying about after the siege that would be available for rebuilding the wall instead of searching for Roman stones, to my mind contradict what he has just before stated. If the stones were "rolled into position," would they be carted or rolled all the way from the suburbs? Numerous ruined Roman buildings were close at hand (and also the building of doubtful date lying parallel with the north wall, opposite the Deanery, laid bare in 1884), and there need be no "searching," unless taking up visible foundations, &c., he deemed "searching," whilst the tombstones turned up in Lady Barrow's Hay and elsewhere, when the numerous entrenchments were made, would be ready to hand. Many (or most) of the stones of the former wall (probably of Edwardian date) would be lying about also, close to their former positions, and Mr. Brock should bear this in mind, in his formidable calculation of the amount of stone required, and also in his calculation of cost.

Coming to the "butterflying wall," Mr. Brock remarks that I am speaking of the south face of the north wall. He is mistaken. The "butterflying wall" is on the northern face, whilst as to the North Gate existing as a double Roman archway until the middle of the last century, he is still more strangely mistaken. No Roman archway existed at any of the Chester gates until the last century, but it is the East Gate that Pennant describes and engraves, as mentioned by Mr. Brock, who cannot have read the singular and varied accounts of it which I have collected and given in "Roman Cheshire."

Ormerod ("Hist. of Cheshire," vol. 1, p. 281) says:—"The (North) gate at the period of its demolition, consisted of a dark, narrow, and inconvenient passage under a pointed arch, over which was a mean and ruinous gate, equally inconvenient, and varying little in appearance from the delineation of it given by Radcliffe Holme in *Hart. MSS.*, 2073."

This gate was pulled down in 1808, but, as I have said ("Rom. Chesh.," p. 106), it was probably built upon Roman foundations, which may still be detected beneath the present structure. If a Roman arch had existed here in the last century, we might, as Mr. Brock suggests, go into the question of Roman work near it. But no one has ever advanced the least claim to the old North Gate (which was remembered by many who have died within the last fifteen years) having been Roman.

Whether any further excavation is to be made near these walls (though Roman inscribed stones are in sight, and only wait to be dislodged) I cannot say. Canon Raine, in last Saturday's *Academy*, advocates every Roman inscribed stone which has been detected, being taken out, on the ground of the wall being of comparatively modern construction.

### "SHONE'S EJECTORS IN THE RECENT RAINSTORMS."

SIR.—The defenders of the Shone system of raising liquids would have a very good brief, so far as low lifts are concerned, if the assumptions on which the theoretical calculations of efficiency are based could be relied upon, viz., that the losses due to leakage and fall of temperature are practically inappreciable. The excessive value of the ratio of power to work, which Mr. Shone after about ten years' experience has found it necessary to adopt, proves conclusively that he has found from actual practical results that the losses due to these causes are very heavy. Demolition of the arguments of the "clique" will further the objects he has in view much more effectually than indications of improper motives. Statements and arguments either forced with or passed over in silence are *ipso facto* admitted to be correct.

In claiming to have discharged his duty as engineer by providing engine power capable of pumping a larger volume of sewage than the committee authorised him to provide for, Mr. Shone virtually disclaims having acted as chief engineer responsible for designing and carrying out an installation capable of dealing with the whole discharge from the Palace sewers. Who, then, was the responsible engineer? I certainly thought that Mr. Shone had designed the whole of the works as they are now carried out. What plans counter-signed by some higher authority? Mr. Shone says that he has provided pumping power capable of dealing with more than three times the volume the committee authorised him to provide for. By whose authority did he make this additional outlay? Clearly, if he was not the responsible engineer, he had no right, *proprio modo*, to deviate from the instructions of the committee.

I agree *to cetero* with Sir Robert Rawlinson in fixing upon 400 gallons a minute as the maximum volume necessary to be provided for by pumping. Provision for dealing with a larger volume by this means involves a useless waste of public money. The excess storm-water ought to be discharged through a storm-water outlet. There is in the existing installation a 12-in. pipe connecting the sump with the metropolitan sewers, provided with a reflux valve, so that whenever the surface of the sewage in the sump is higher than that of the sewage in the metropolitan sewers, the sewage will flow by gravitation from the sump to the sewer. Mr. Auld, the partner of Mr. Shone in his paper which he read at the meeting of the Society of Engineers, suggested that this outlet might be used in dry weather to let the Palace sewage flow into the city sewers by gravitation. If that plan were adopted, whenever the pipe was not full, there would be established a free communication, by which the sewer gas of the city sewers in its hot weather concentrated state, would flow back into the subway, and the main object of the huge installation would be frustrated. Mr. Shone, however, in his pamphlet, presented to the members, states that it will act automatically as a storm-water overflow, when the pumping power is overcome. Mr. Shone, therefore, or whoever may be the engineer responsible for the success of the work, has not made the mistake of supposing a storm-water outlet to be unnecessary, but the mistake of designing one of insufficient capacity.

I am quite sure that none of the "clique" have the least desire to deny Mr. Shone and Mr. Phillips the gratification due to success. Those gentlemen must, however, prove the reality of their claim. I emphatically assert that time will prove the installation to be a failure, not only as a means of discharging the sewage, but in a sanitary point of view. I am sure you will grant me space to repeat the reasons which cause me to hold these views, and to state them in such a way that silence on Mr. Shone's part must convince your readers of their truth.

Mr. Phillips has not answered either of the crucial questions I asked, viz., How did he ascertain the height of the sewage in the metropolitan sewers, and (I admit indirectly) the depth of the sewage in the subway close to the pump? The bottom is flat, 3 ft. wide, and laid at a gradient of 1 in 225, so that the depth of 12 in. above the concrete to 2,000 gallons. The 6 in. above the pipe in my last letter is a clerical error; it should be 16 in. I also ask Mr. Shone to state what is the maximum air pressure used since the commencement.

Mr. Phillips has stated that with an air pressure of 10 lb. per square inch the four gas engines were able to discharge in an hour the whole of the rainfall on ten acres at the rate of .59 in. per hour, with the exception of 2,000 gallons against a head of 20 ft. I think Mr. Phillips has overstated the acreage, but he has committed himself to the statement that the whole of the sewage discharged by the Palace sewers was dealt with in the way described. Mr. Phillips seems to think that for an interval of two minutes the rate of fall may have been double, .59 in. per hour, but I presume neither he nor Mr. Shone questions the accuracy of the Westminster gauge as to the total rainfall in the hour. In the printed report, I did not see Mr. Shone's verbal statement that the pipes are 6 in., and concluded he had found he was mistaken. I find they are 6 in. For argument, I will also take the minimum

area, viz., eight acres. This will correspond with 1,782 gallons per minute, of which, according to Mr. Phillips, 34 gallons per minute were stored, leaving 1,748 gallons per minute to be otherwise disposed of. If the whole was pumped each ejector must have discharged 583 gallons in thirty seconds, or at the rate of 194 gallons per second. The corresponding velocity in the 6-in. pipe would be 16 ft. and the theoretical head due to this velocity 4 ft., which corresponds with an air pressure of 7.4 lb. The pressure due to the dead lift of 20 ft. is 8.5 lb., so that without any allowance for friction or valve resistance, the air pressure cannot have been less than 10.6 lb. Adding, as before, 3 lb. to overcome these resistances, we get the minimum necessary pressure of 13.6 lb., without any allowance for the loss of the valve passages is rarely equal to two-thirds of the pipes. In the case of the Palace ejectors I feel sure it is not equal to this, but if equal to it, the velocity in the valve passages would be 24 times that in the pipes, or 37 ft. per second. This corresponds to a theoretical head of 20 ft., the corresponding air pressure being 8.5 lb., or the minimum total pressure 17.6 lb., without any allowance for heads due to friction and contraction. A discharge of 300 gallons per minute from each ejector would only require half the pipe velocity, and the 8.5 lb. would be reduced to 2.2, or the minimum pressure necessary to discharge 900 gallons a minute against a 20 ft. head, 11 lb. It is possible, therefore, that a pressure of 13 lb. to the square inch would be sufficient to discharge 1,000 gallons a minute. As a matter of fact, I know from actual observation that the ejectors cannot discharge 300 gallons a minute against a 20 ft. head with 10 lb. air pressure. Mr. Shone has utterly misrepresented what I said at the meeting of the Society of Engineers about the discharging capacity of the ejectors. I never stated that the ejectors could discharge 1,000 gallons a minute against a 20 ft. head with an air pressure of 10 lb., and I emphatically deny stating that the estimate I did give was based on theoretical calculations. As a matter of fact, I gave the details of the three observations of the time of discharge of the 500-gallon ejector, the times in each case being as nearly as possible equal and a little under forty-five seconds. If then the ejector discharged 500 gallons, the rate of discharge was about 330 gallons a minute. As the diameter of the pipes of the 300-gallon ejector is the same as that of the 500-gallon ejector, the discharging capacity of each ejector is the same, and I now ask Mr. Shone the question, which Mr. Phillips has declined to answer for him, Why did he specify the 500-gallon ejector? On the day that the installation there had been a little rain in the morning, sufficient to necessitate the use of two gas engines, but it had ceased about two hours before my visit, and one engine was doing the work with ease. It is therefore quite certain that the sewage in the metropolitan sewers cannot have differed much in depth from its normal eleven o'clock level, so that the maximum lift cannot have exceeded 4 ft. The engines are calculated to exert only 4-h.p. at the brake, where the air-pressure is 10 lb., and as they can exert 5-h.p. brake-power, they would be able to supply air compressed to 12 lb. per square inch, and at this pressure I estimated that the three ejectors might be able to discharge 1,000 gallons against a 20 ft. head. Mr. Shone, however, is not entitled to claim the reserve power provided to meet accidents or machinery, in estimating the discharging capacity of his installation. As there are three ejectors, he is entitled to claim two-thirds. The discharging capacity, therefore, with 10 lb. air-pressure would not exceed 500 (five hundred), and with 12 lb. air-pressure 1,000 (one thousand), gallons per minute against a 20 ft. head.

Taking 1,000 gallons as the maximum volume, which the ejectors can discharge in a minute against a 20 ft. head, with 12 lb. air-pressure, the work estimated in weight of water raised will be 6-h.p., and the necessary engine brake power 20-h.p., which is certainly equal to fully 27-h.p. indicated, or the ratio of indicated horse-power to the horse-power in work done is 1 to 1. I know that Mr. Shone bases his calculation on a discharge of once a minute; in other words, in fixing his engine-power, he estimated for a discharge of 900 gallons a minute, since the 500-gallon ejector cannot discharge more than the 300-gallon. This he thought could be raised 20 ft. high with 10 lb. air-pressure, corresponding to 16-h.p. brake horse-power of gas-engine equal to at least 21-h.p. indicated. As the work in weight of water raised is only  $\frac{1}{2}$  h.p., the ratio of horse-power indicated to horse-power in actual work estimated to be necessary by Mr. Shone himself is nearly 4:1. Experience has shown that it is not sufficient.

I do not in the least doubt Mr. Phillips's veracity, but he is labouring under a misapprehension as to the actual facts of the case, which will be effectively removed when he prepares his answers to the crucial questions I have had to ask him a second time.

That Mr. Shone should have provided, as he deliberately states that he has done, a reservoir for diluted sewage extending the whole length of the Houses of Parliament, is simply incomprehensible. Ever since he took up the sewage question his whole efforts have been directed to procure the condemnation of large sewers laid at flat gradients, whether or not intended to be used as reservoirs. He has always described them as elongated cesspools. They

are, however, cesspools which can be periodically flushed. The reservoir he has provided at the Houses of Parliament is an elongated cesspool in a much worse state than those sewers, because its contents will be stagnant and the sewage sediment spread over a flat concrete bottom 3 ft. wide. No rainfall goes directly into this "subway" reservoir. All has to pass through the 12-in. sewer so that the contents of the reservoir must necessarily be very foul. The fact that the whole of the sewage passes through this 12-in. pipe makes the flooding of the Victoria Tower quadrangle inevitable long before the sewage in the sump rises to the maximum height attained by the sewage in the city sewers, because the head necessary to force the 3,000 gallons a minute corresponding to a rainfall of 1 in. cannot be less than 12 ft. In other words, the surface of the sewage at the Victoria Tower will be 12 ft. higher than the surface at Speaker's Green.

There are several large pockets in the crown of the subway which, until recently, were simply reservoirs of foul air. In the printed report of Mr. Auld's paper it is stated that these are now ventilated by gratings. No wonder there are foul smells in the country. The remedy for these defects is, however, simple. Separate collecting sewers should be provided for the rainfall discharging directly into the subway, the brickwork block between the city and Palace sewers replaced by a reflux valve the full size of the sewer, and the communication between the sump and the subway stopped.

Mr. Shone has not challenged the accuracy of the rest of the statements I made at the meeting; his silence, therefore, must be taken as an acknowledgment of their truth.

As I have been compelled to contradict two statements made by Mr. Shone, I feel that I ought no longer to use a "non de plume." I therefore, subscribe my name and address,

WILLIAM DONALDSON.

2, Westminster Chambers.

### "NEW METHOD OF VENTILATION."

SIR.—We have read the description in your current issue [p. 480] of what the patentees, in a circular issued by them, term a "new method of ventilation"; but far from being new, it is really a very old method, having been applied to fireplaces as far back as fifteen years ago at our old offices at Mansion House Buildings. Instead of a cylinder the bottom of the shaft brought down from the ceiling level terminated at the floor-level in an air-tight casing, made of mica, enclosing the fire-place, so that the fire was made to draw its supply of air down through the ventilating tubes, and no draught was experienced by any one sitting in front of the fire, as is the case with the ordinary fire-grate.

We later on discovered that the idea of carrying a tube down from the ceiling, and connecting it with the throat of the chimney, was not original, a Mr. Hoey, of Glasgow, having used this arrangement about five years before, but without the air-tight casing.

About nine years ago we applied this principle to large sugar works at Greenock, there being six shafts employed altogether for the ventilation of the char-room, the shafts being led down from the ceiling, and communicating with the ashpits of the furnaces, which were otherwise made air-tight by the furnace-bars. Many years ago we took out a patent for the application of this principle for the ventilation of steam-ships, pipes being led from the different parts of the vessel down to the furnaces, which were made to draw their supply of air through these channels.

We are not surprised that the patentees are, as you say, in some doubt as to the function of "the cylinder." We have carefully studied this part of the arrangement, but fail to see what possible advantage can arise from its use. The inventors say that in the event of a reversal of the current in the chimney it will prevent back draught in the ventilating tube, but even allowing that it did so, which we doubt, a simple valve placed in the shaft would effect the same thing at considerably less cost and trouble. Our experience of this principle, as applied to buildings, is that there is no advantage whatever in bringing a shaft down from the ceiling and connecting it with the chimney, as an ordinary mica flap ventilator fixed in the chimney-breast at the ceiling level answers the purpose equally well, if not better, and the cost of the mica flap compared with the other is a mere trifle, amounting to only a few shillings, whilst, with regard to the trouble and labour involved in the fixing, there is no comparison. Both plans depend for their action upon whatever updraught there may exist in the flue; in many flues, even without a fire, there is to be found a strong upward updraught, which would create an exhaust through either the mica flap ventilator or the vertical tube, though in the latter there would be the increased friction to contend with and the resistance offered by drawing downwards the highly rarified air usually found at the ceiling level, especially when the gas is lighted, and the natural tendency of which is to ascend and not descend. It is simply going contrary to the laws of nature to try and ventilate a room by drawing the hot-air downwards.

We observe that the patentees recommend where there is a defective draught in the flue that a gas

et or blast fan be employed to create an exhaust. We presume they do not contend that such an application is novel, and if they consider the use of either a gas-jet or a fan as necessary before ventilation can be secured, for what are we indebted to their vertical tube and cylinder, which of themselves cannot possibly affect the draught one way or the other, they being admittedly inoperative and therefore useless unless an updraught either already exists or created in the nearest fire by other means independent of and outside their arrangement, and which must certainly be credited with whatever current that may be found in the vertical pipe?

ROBERT A. BOYLE & SON (LIMITED).  
64, Holborn Viaduct, October 11th, 1887.

SIR.—This system I have used years ago, and found it successful. It was known as Dr. Chowne's system. Dr. Chowne was also in the field before Robin, as he brought in the fresh air upon the same principle as Robin. C. B. A.

SIR.—May I be allowed to explain that as to the main function of the cylinder there can be no doubt. The cylinder or chamber, being in many cases in actual contact with the fire, becomes heated, the draught in that sense causes a rapid displacement of air without (or, better, combined with) the draught of the chimney acting on the end of the straight-pipe. It is exactly the same thing as heating a room and opening a window, the cooler air (because of its greater density) immediately displaces the warmer and rises into the room. The interposition of the cylinder is absolutely necessary as a disconnector, otherwise the downcast and upcast pipes, being continuous, are liable to become heated by conduction, and then a reverse action is at once set up, or its efficiency is greatly impaired, as we have frequently proved by experiment.

G. B. Moss.

\* \* Our correspondent, nevertheless, told us when we were examining the model that he did not know why the upcast draught should refuse to act without the cylinder, and suggested two or three theories without adopting any one of them.

ORDNANCE MAP SCALES.

SIR.—I notice that in your article on the Ordnance Survey in last week's *Builder*, one of the arguments put forth by the advocates for the  $\frac{1}{25000}$  scale is that a square inch on a map drawn to that proportion equals exactly one English acre. I beg to state that this is not quite correct, as one square inch equals only 4822.53 square yards, and I fail to see that this is an acre. Although perhaps near enough for ordinary agricultural purposes, it would not answer if applied to town work.

In the case of the  $\frac{1}{5000}$  scale, one square inch will be found to contain 192.9 square yards.

F. C. WILLIAMS.

\* \* The word "exactly" should not certainly have been employed *sans phrase*; "practically" would have been more correct; but it is "exactly" to the eye; it would require a magnifying glass to detect the difference of the square inch and the acre on the  $\frac{1}{25000}$  scale, and that was all that was intended.

FIRES IN THEATRES.

SIR.—I read Mr. Campbell's letter in your last week's issue, suggesting the engraving of the plan of every theatre on the back of the programme. Now, if everybody understood a plan the idea would be an excellent one; but my experience convinces me that not one in a hundred does.

On one occasion I was retained upon an "ancient lights" case, before a special jury, and, notwithstanding the plans, sections, and photographs which were put in, the jury could not comprehend it, and ultimately a model had to be made in cardboard.

It has struck me that if a red light were placed over every door of exit, and a finger painted on glass (with a gas-jet behind), directing the way would be quickly seen by the audience.

WILLIAM ADAMS.

COOKING STOVES.

SIR.—Can you or any of your readers inform me of a really good cooking-stove? It should be able to accomplish the following objects:—

1. Roast in front of fire as well as roast and bake in ovens.
2. Grill on top of fire as well as fry, and have a hot-plate for stews and sauces, boiling, &c.
3. Heat a boiler sufficient to give water for a bath when required.
4. Above all, it should ventilate so that the smell of the cooking should be carried away instead of permeating the kitchen, as is usual now.
5. I need hardly say it should be economical in coals.

I have had several stoves in my kitchen, and they are all faulty either in their operations, or in means that a really efficient stove ought to accomplish. I would not mind the cost if I could find a stove that would effect the above objects.

PATERFAMILIAS.

Oct. 6th, 1887.

\* I have already expressed the same opinion.—Ed.

PROVINCIAL NEWS.

**Birmingham.**—The *Birmingham Gazette* states that some Mediaeval remains have been discovered in clearing the ground for new premises in that city. A new building is about to be erected in the Priory, and in the excavations for the foundations a massive red sandstone wall has been revealed, which is supposed to be a part of the hospital or priory of St. Thomas, founded in 1285. Arrangements have been made for the remains of the wall to be photographed and sketched.

**Bournemouth.**—The new mission hall in connexion with St. Michael's Church, Bournemouth, was opened by a special service on Michaelmas Day, at which workmen employed on the building, as well as the congregation of St. Michael's Church, attended. Mr. R. Pinder was the architect of the new building, and Messrs. E. Jones & Son the contractors. The cost was about 600l.

**Bridgwater.**—On the 6th inst., the formal opening of premises for the Young Men's Christian Association, to be known as the "George Williams" Memorial Hall, took place at Bridgwater. The hall has been built to commemorate the fact of Mr. Williams being founder of the organisation. The building has frontages to Eastover of 45 ft. and 83 ft. to Salmon-parade, and is designed in the Classic style of architecture. It has been executed with local red brick, relieved with Ham Hill stone dressings and white brick in the piers, the moulded string-courses being in moulded bricks. At the front of the building, on the ground-floor, a large reading-room and library, with secretary's room attached, has been placed. Behind the reading-room there is a meeting or lecture room, with accommodation for 130 adults. Attached to this room is the junior club-room. A gymnasium has also been fitted up with gymnastic appliances. The floor has been formed with solid wood blocks to deaden the sound. The large hall is 50 ft. in length by 30 ft. in width, and has a height of 24 ft., the total accommodation being for 460 adults. Towards the front, a large room intended as a young men's parlour has been placed. On the floor above are two other commodious rooms. The sanitary appliances are said to be arranged on the most approved scientific principles. Including the furniture, the entire outlay amounted to 3,600l. Messrs. W. G. Habershon & Fawcner, of London, Newport, and Cardiff, gratuitously prepared plans and specifications. Mr. H. W. Pollard, of Eastover, whose tender amounted to 2,490l., was the builder.

**Kingston-on-Thames.**—The Corporation of Kingston-on-Thames, in a Bill which they propose to promote in Parliament next session will apply, among other privileges, for powers to provide additional wharf accommodation. The estimated expenditure of the improvement is from 1,000l. to 1,200l. This includes the cost of a concrete wall, with granite coping, necessary to give an additional frontage of 470 ft., with mooring rings or posts, and granite pitching, with stone steps 100 ft. wide for boats. The gross annual amount of tonnage unloaded at the public wharf at present is 26,000 tons, and it is estimated that about 1,500 tons more are carried by barges that are driven elsewhere to unload in consequence of the poor accommodation. Should the powers sought be granted, advertisements would probably be issued inviting tenders from contractors.

**Newcastle.**—At a meeting of the Town Council last week the Deputy Town Clerk (Mr. W. E. Cartwright) read the letter from the Lords of the Treasury, which has been already published, agreeing to a loan of 10,000l. for the purpose of executing the scheme of the public buildings, which comprises a free library, assembly room, council chamber, school of art, &c. The Public Buildings Committee recommended the Council to accept the tender sent in by Mr. John Gallimore, in April, 1886, for the erection of the buildings in accordance with the plans and specifications, at a cost of 12,000l. This was agreed to, and the Corporation seal affixed to the contract, the work to be completed by June 24th, 1889. It appears that the highest tender, by Messrs. Lucas, of London, was for 18,628l. It is to be hoped Mr. Gallimore may be able to carry out the work for less than two-thirds of that amount with satisfaction both to himself and the Corporation.

**Redcar.**—Major-General C. Phipps Carey held an inquiry at Redcar on the 6th inst. in response to an application from the Local Board to borrow

1,500l. for laying out pleasure-gardens. Mr. James Howcroft, their surveyor, presented the plans which he had prepared, and explained the mode of carrying on the proposed work.

**Royton.**—At a recent meeting of the Royton Local Board, the plans prepared by Mr. R. Vawser, C.E., Manchester, for the main drainage of the district, and the treatment of the sewage thereof at an estimated cost of about 27,000l., were unanimously adopted, and the clerk was instructed to submit the same to the Local Government Board for their approval.

CHURCH-BUILDING NEWS.

**Dewsbury.**—The consecration of the newly-built portion of Dewsbury Parish Church, took place on the 30th ult., the Bishop of Ripon officiating. The new part consists in the enlargement of the nave by 31 ft. in length and 24 ft. in width, this extension making the nave 98 ft. long. The north and south transept have been each increased 27 ft. by 30 ft., the chancel 46 ft. by 24 ft., the morning chapel 30 ft. by 19 ft., organ-chamber 30 ft. by 19 ft., clergy vestry 14 ft. by 12 ft., and choir-vestry 20 ft. by 13 ft. The length of nave and chancel together make a total length of 144 ft., the average height being 34 ft. Each transept has two three-light windows of varied designs. Several stained-glass windows have been added. The new east window, which is in seven lights, has also been filled with stained glass. On the south side of the chancel is a lofty double three-light stained-glass window, in memory of the Rev. Thomas Allbutt, M.A., for many years vicar of Dewsbury. On the same side of the chancel there are sedilia in three bays, with piscina adjoining. The screens on either side of the chancel, near the morning chapel, are of stone, with tracery heads and moulded cornices. Two porches, one on the north and one on the south side, have been added; the south porch has a stained-glass window. The walls of the new building have been built of ashlar, from Netherton quarries, Huddersfield. All the woodwork is of oak, and the roof of each transept is supported only on oak columns, from which rise circular ribs, and the roofs to the nave, chancel, and other parts of the new building, have richly-moulded principals, with elaborated oak tracery. The roofing is covered with lead and felt, on oak boards. The floors are for the most part of red wood blocks, by Messrs. Thomas Gregory & Co., of London, laid in pitch, on a bed of cement concrete. The floor of the chancel is covered with encaustic tiles, and the aisles with plain red ad black, all by Messrs. Godwin & Sons, of Hereford. The seats are of oak, as also are the choir stalls; the latter being finely moulded, and having open fronts with tracery heads. The church is ventilated by inlet tubes and grates placed at the lower part of the window and outlet siding casements fixed in the windows. The church will be warmed by hot water on the low-pressure system, the pipes running under each aisle, and covered with perforated iron grates. The ground plan of this church was left by the late G. E. Street, R.A., but the whole of the elevations, with the exception of the chancel arcade, and all the details and fittings, are by Mr. A. E. Street. Mr. A. H. Kirk, a local architect, has superintended the whole of the works; the clerk of works being Mr. W. H. Williams. The heating apparatus have been gratuitously fixed by Messrs. M. Newsome, Sons, & Spedding, and the gas supply has been undertaken by Mr. H. Blackburn. The contract for the eastward extension was taken by Messrs. J. & W. Deansland, of Bradford, for the sum of 14,000l. It is proposed to make further alterations and additions at a future date.

**Southport.**—The new church of St. Philip's, Southport, was consecrated by the Bishop of Liverpool, on the 11th inst. The church consists of nave, north and south aisles, transepts, and chancel: on the south side of the latter are the vestries for clergy and choir, with moveable screens. The total length of the church internally is 131 ft., and across the transepts 77 ft.; the width of the chancel is 23 ft. The height of the nave from floor to wall-plate is 36 ft., and to apex of ridge 61 ft. The nave is divided by stone columns into fine bays. The nave is lighted on each side with ten clearstory windows, in the west front of which is a large traceried five-light window; the transepts showing externally as

CIRCULAR CURVES

RELATIVE VALUE OF USEFUL ANGLES TO ANGLE OF INTERSECTION

FIG 2

LET X = HALF THE ANGLE OF INTERSECTION  
 THEN A = 90° - X  
 B = 90° - X  
 C = 90° + X

D = 90° + X  
 E + F = 90° - X  
 G + H = 90° - X  
 R = T · TAN X

SETTING OUT WITH TWO THEODOLITES

IF ANY TWO LINES BE SET OUT FROM THE STARTING POINTS OF THE CURVE HAVING THE SUM OF THEIR TANGENTIAL ANGLES (E + F) = 90° - X, THE INTERSECTION OF THESE TWO LINES WILL BE A POINT IN THE CURVE - BY A SERIES OF SUCH POINTS THE WHOLE CURVE MAY BE SET OUT IF THE COUNTRY BE SUFFICIENTLY OPEN TO ALLOW OF IT - WHEN THE COUNTRY IS UNEVEN, THE METHOD SHOWN IN FIG 1 BY SHIFTING AND RE-SETTING UP THE THEODOLITE WHERE NECESSARY IS MORE APPLICABLE -

FIG 4

FIG 5

MARINE SURVEYING

the instrument is numbered to read in the direction of the hands of a watch: hence when the curve is to be set out to the left-hand side of a tangent line, the column upon the card containing the differences of the tangential angles must be adopted. Thus with a radius of 20 chains, if 1° 25' 57" be the tangential angle for a chord of one chain in length, and an angle of 2° 51' 54" be the tangential angle for the intersection of a second chord of one chain's length round the arc, when the curve is to be set out to the right-hand side of the tangent line; then the tangential angles to be employed for setting out two points at the same distances for a curve to the left-hand side of the tangent line will be 358° 34' 3" and 357° 8' 6" respectively.

Fig. 2 illustrates a method of setting out curves with the use of two theodolites, each set up respectively over points at the beginning and the end of a curve, when the angle of intersection between the tangent lines which pass through those points is known.

In road work curves may be set out by offsets from lines drawn upon a plan, and afterwards be checked by means of offsets from the tangent lines. In railway work it is always well to have a length of straight line between two curves. When in road-work it is desirable to accurately set out one curve running into another, the formula given in fig. 3 may be employed. The proof is given in figs. 4 and 5.

$$CB = R \sin A - \sqrt{R^2 \sin^2 A - 4 \left( R r \sin \frac{A}{2} \right)}$$

If R = 7 and r = 5 when A = 20°

sin. A = sin. 20° = .342

R sin. A = 7 × .342 = 2.394

sin.<sup>2</sup> A = .116964

R' sin.<sup>2</sup> A = 7 × 7 × (.116964)

= 5.731376

And sin.  $\frac{A}{2}$  = sin. 10° = .173

sin.<sup>2</sup>  $\frac{A}{2}$  = .029929

4 R r (.029929) = 4.190060.

The square root of the difference between 5.731376 and 4.190060 equals 1.241.

And (2.394 - 1.241) = 1.153 = C B, the distance required.

In Marine Surveying, the use of two theodolites upon the shore can be employed for recording the position of a sounding by the intersection of lines making known angles with a given base-line. When the box sextant is used

coupled gables, with a four-light window in the centre of each gable: and the east end of the chancel has a five-light tracery window, with trefoil terminals to the main cusplings. At the west end of the south aisle rises a tower to the height of 110 ft. In the tower a bell by Messrs. John Taylor & Co., of Loughborough, is fitted, and provision is made for a peal of eight bells. The pulpit and font, in alabaster, are the work of Messrs. Norbury, Paterson, & Co., sculptors, of Liverpool, the carved oak communion-table being by the same firm. The chancel-floor has been laid with mosaic, by Messrs. Elliot, Olsten, Olney, & Co., of Manchester. The decoration of the nave and chancel with light and simple tints, with stencil patterns laid on, has been carried out by Mr. Reuben Bennett, of Manchester. The reredos is in oak, with carved panels, by a local carver, Mr. R. A. Macfoster. The church was designed by Mr. R. F. Tolson, of Manchester, the style being known as Geometrical Gothic of an Early English type. Messrs. W. Brown & Son, of Stafford, were the general contractors for the undertaking.

**Surveyorship Appointment.**—Mr. Peter Dodd, who has for six years held the post of Assistant Surveyor to the Tunbridge Wells Local Board, has been appointed to the Town Surveyorship of Southend-on-Sea.

**Tile Works.**—Messrs. Malkin, Edge, & Co., of Burslem, have opened a London House, at Sandringham-buildings, Charing Cross-road.

The Student's Column.

LAND SURVEYING AND LEVELLING.

XVI.—SETTING OUT CURVES.

THE poles shown in the direction of the chord lines A B, A C, A D, fig. 1 (Builder, Oct. 8, p. 514), are not generally necessary. The usual method is for one man to hold one end of the chain at the last point determined, taking care, if the curve be flat, to place his body upon the outside of the curve, so as not to impede the line of sight when the theodolite is set for fixing the next point in the curve. The other assistant pulls out the chain or the tape to the given length, and holds up a peg or lath, which he keeps vertical at the correct distance, moving it about as directed by the surveyor, to the right or left hand, until it accurately appears in the required direction. Should any obstacle render it necessary to remove and re-set up the theodolite over a new point in the curve, the direction of a new tangent line must be found by the method shown in fig. 1 (Case 5), and the same process of setting-out by means of tangential angles re-commenced. The use of the tangential angles, which are calculated from the formula proved by Case 1 (Builder, Sept. 17, p. 412), enables the curve to be set out to the right-hand side of the tangent line, when the theodolite is placed over the beginning of the curve, as the primary scale of divisions upon the horizontal circle of

by the surveyor out in a boat, the position is fixed by taking simultaneously the bearings of three known objects on shore, such as D, E, F, or in the case of a river section to be plotted on the line E, G, the bearings of two objects, D and F, situated respectively to the right and left of that line. The station pointer (see Builder, Sept. 3, p. 349) is used for recording upon the plan the position of the soundings has taken.

STAINED GLASS.

Horstead.—A two-light painted Jubilee window, with subjects from St. Matthew and St. Paul introduced, has recently been erected in this parish church. The artists are Messrs. Charles Evans & Co., of London.

Leeds.—A stained-glass window has been presented to the church of the Holy Trinity, Leeds. The subject is the Raising of Jairus's Daughter, and it is in memory of some of the teachers in the Sunday School. It is from the studio of Messrs. Powell Brothers, of Leeds.

Merton Abbey.—Messrs. Chas. Evans & Co. have lately erected two painted windows, with subjects taken from "The Poor are the Lord's" and "He called them unto Him," at Christ Church, Mitcham, the gifts of Mr. M. J. Harris and Mr. H. Stevens.

Wednesbury.—The painted window, with subjects taken from the texts, "I was a stranger," and "Sick and ye visited me," subscribed for by the parishioners to perpetuate the memory of the Vicar's late wife, Mrs. Fanny Haber Tnhill, has just been erected by the artists, Messrs. Chas. Evans & Co., who also supplied the ornamental brass, with inscription, it foot.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

13,616, Brickmaking Machinery. R. Scholefield.

The improvements in brickmaking machinery of the rotary type are in the direction of so regulating and adapting the apparatus that as the mould in one cylinder is being filled with clay, the contents of another mould in the same cylinder is being discharged and forced into the mould of a second cylinder; the same operation also ejecting a completely pressed form from a second or opposite mould in the same second cylinder. The cylinders, moulds, and rollers are all mounted on the same framework.

13,898, Step Ladders. J. T. Bower.

Two flaps of the ladder are connected by means of a rule or knuckle-jointed hinge, so that when the ladder is open the flaps or sides of the steps are kept apart. A self-acting catch is also affixed to the sides to keep the parts of the ladder together when closed. An additional leg is also fitted, and this, combined with the two parts of the steps, makes a kind of tripod, which gives great firmness to the ladder.

14,322, Water-closets. J. Smeaton.

Suitable improvements in the flushing apparatus and delivery ring are the subjects of this specification, which also relates to the masking of the ordinary appearance of a "rapid flush" or "flush-out closet" by a kind of vase. The distinctive name of "Amphors" is given to this description of basin in this last account.

14,448, Lock-bolt for Windows, Doors, &c. J. Johnson.

A small push bolt having an extra slit made in the catch socket so that when the bolt is pushed forward and turned a pin in the bolt engages therewith forms the lock-bolt claimed in this patent.

14,538, Circular Glass Ventilators. W. Argent.

Instead of the circular ventilator moved with a tap, a spindle is arranged to a flange with an oval cross, underneath is another movable glass with a similar oval boss upon which the circular glass cover is placed, a double stop is fixed which only allows the cover to revolve a quarter of a turn. When necessary a spiral spring is fitted so that the ventilator may be moved backward and forward with a single cord.

15,642, Safes and Strong Rooms. G. Allen.

The improvement consists in hardening the rivets which hold together the different parts of safes, &c., so as to be as impregnable to a drilling instrument as the plate itself.

8,755, Flushing and Trapping Overflows to Water-Closets. E. Emmanuel.

Four or more indentations or channels are sunk into the basin from the top flushing rim directly connecting with the overflow holes which are placed on the top side; the bottom outer edge being level with the outline of the basin. The inside

of the holes are cut away at an angle, so that the water conveyed by the indentations or channels is conveyed directly into the overflow, thus thoroughly flushing and trapping it.

NEW APPLICATIONS FOR PATENTS.

Sept. 30.—13,230, H. Marle, Drawing-boards.—13,243, W. Scott, Heating and Ventilating Public and Private Buildings.—13,258, W. Dutton, Revolving Door-post, &c., for Public Buildings and Theatres.

Oct. 1.—13,322, E. Solvay, Lime-kilns.—13,329, D. Ratcliff, Safes and Strong-rooms.

Oct. 3.—13,342, R. Platt, Window-sash Fastener.—13,376, B. Harrass, Artificial Compounds in Imitation of Wood.—13,389, D. Lang, Pipe Joint.

Oct. 4.—13,396, A. Wells, Revolving Wood Shutters.—13,421, R. Burkit and G. Green, Combined Lifting Latch and Bolt.—13,434, R. Bradshaw, Fireproof Curtains or Partitions for Theatres.—13,444, W. Webb, Sewer Ventilation.

Oct. 5.—13,467, W. Smith, Manufacture of Cement.—13,472, J. Coppard, Closing or Opening Doors, Windows, &c.—13,497, H. Smith, Swing Doors.—13,508, W. Ballantine and R. Blackie, Flushing Cisterns for Water-closets.

Oct. 6.—13,524, W. Hearn, Fastening Windows.—13,528, J. Thrush, Traps for Drains.—13,537, T. Fawcett, Brick Making and Drying Machinery.

PROVISIONAL SPECIFICATIONS ACCEPTED.

11,999, J. Pettey, Stoves and Fireplaces.—12,271, J. Davies, Brick Kilns.—12,624, 12,525, and 12,526, G. Snelus and Others, Manufacture of Cements.—11,591, R. Harrison, Flush Bolts for Doors.—11,752, J. Goodman, Bricks for the better Fixing of Wood-work and other Materials.—11,993, G. Woodcroft, Sash Fasteners.—12,133, T. Robinson, Cross-cut Saw-benches.—12,294, C. Mackey and E. Bailey, Securing Knobs to Doors.—12,771, W. Lake, Facilitating Escape from Burning Buildings.

COMPLETE SPECIFICATIONS ACCEPTED.

Open to Opposition for Two Months.

15,759, R. de Ridder and W. Bonnett, Heating Public Buildings and Houses.—3,256, G. Jeffery, Covering for Roofs.—7,846, J. Anderson, Dove-tailing Machines for Open Doretails.—11,787, E. Bailey, Cupboard Turn.—14,557, C. Friedrich, Shop Counters.—15,542, J. Fisher, Latch for Doors, Windows, Gates, &c.—12,023, G. Hayes, Bars for Glass Sashes.—12,031, H. Allison, Paints and Paint Compounds.

RECENT SALES OF PROPERTY.

ESTATE EXCHANGE REPORT.

OCTOBER 3.

Table with 2 columns: Property description and Price. Includes Wandsworth—88 and 90, Putney Bridge-road, freehold £700; Cauberswell New-road—No. 234, term 21 years, ground-rent 6l. 400; Lambeth—37 to 41, and 44, 45, and 46, King-street, 22 years, ground-rent 32l. 845; Stratford—9 and 10, Cruikshank-road, and 2, 4, and 6, Buckingham-road, 86 years, ground-rent 21l. 750; Hendon—1 and 2, Milton-road, 95 years, ground-rent 10l. 280

OCTOBER 4.

Table with 2 columns: Property description and Price. Includes Kentish Town—8 and 10, Kelly-street, 50 years, ground-rent 8l. 610; New Cross—119, Malpas-road, 78 years, ground-rent 4l. 245

By H. RUTLEY.

Table with 2 columns: Property description and Price. Includes Barnsbury—65, Bride-street, 72 years, ground-rent 6l. 300; Isleworth—3, Tolson-road, freehold 150

By BRAM, BURNETT, & ELDRIDGE.

Table with 2 columns: Property description and Price. Includes Wimbledon—The freehold residence, Ty Clyd 2,300

OCTOBER 5.

Table with 2 columns: Property description and Price. Includes Stepney—1, John-street, copyhold 107

By FARRBROTHNE, ELIAS, & CO.

Table with 2 columns: Property description and Price. Includes Little Bagnor, Sussex, the residences, Broadland and the Holts, about 6 acres, freehold 5,101

By COOPER & GOULDING.

Table with 2 columns: Property description and Price. Includes Islington—Improved ground-rents of 70l., term 32 years, ground-rent 14l. 080; A rental of 42l. a year, term 17 years, 390

By TEMPLE & MOORE.

Table with 2 columns: Property description and Price. Includes Homerton—119, 2, 224, and 226, Wick road, freehold 1,125; Forest Lane—1 and 2, Sarah's-villas, freehold 396

By DALE & SON.

Table with 2 columns: Property description and Price. Includes Bromley—95 to 101, odd, Swaton-road, 75 years, ground-rent 14l. 800; Bethnal Green—3-7, Cambridge-road, 80 years, ground-rent 10l. 450

OCTOBER 6.

Table with 2 columns: Property description and Price. Includes Islington—82, Prebend-street, 40 years, ground-rent 4l. 316; 13, Union-square, 40 years, ground-rent 6l. 5s. 400

By NEWBON & HARRING.

Table with 2 columns: Property description and Price. Includes Pentonville—53, Baker-street, 21 years, ground-rent 18l. 160; New North-road—11, Arlington-square, 40 years, ground-rent 6l. 6s. 535

By C. WILSON.

Table with 2 columns: Property description and Price. Includes Portland Estate—5 and 52, Zoley-street, 17 years, ground-rent 6l. 1,051

MEETINGS.

TUESDAY, OCTOBER 18.

Parker Museum (Lectures for Sanitary Inspectors).—Mr. C. E. Casal, F.C.S., F.I.C., on "Food (including Milk), Sale of Food and Drugs Act." 8 p.m. Glasgow Architectural Association.—Visit to the Athenaeum Buildings. 5.15 p.m. Manchester Architectural Association.—Concours. 7.30 p.m.

WEDNESDAY, OCTOBER 19.

Liverpool Engineering Society.—Mr. C. Harrison Townsend on "Ornament and Design; their Relation and Subordination in Engineering Works." Builders' Foremen and Clerks of Works' Institution.—Quarterly meeting. 8.30 p.m.

FRIDAY, OCTOBER 21.

Parker Museum (Lectures for Sanitary Inspectors).—Paper on "Infectious Diseases and Methods of Disinfection." 8 p.m.

Miscellaneous.

Money Value of Human Life.—Sir Spencer Wells writing to the Times to correct a statement about a speech at the Hygienic Congress, says his estimate of the gain to the State of the increased numbers of human lives during the last fifty years, which may fairly be calculated as the fruit of medical and sanitary work, is "at least 300,000,000. Any one who will refer to the invaluable work of the late Dr. W. Farr on 'Vital Statistics' may see the grounds upon which he has calculated that 'the minimum value of the population of the United Kingdom, men, women, and children, is 150l. a head; that is, the value inherent in them as a productive, money-earning race (page 61). Our population has increased in less than fifty years fully eight millions. Each individual of these eight millions was worth to the State 150l. It surely must be a very moderate estimate to regard two of these eight millions of increasing numbers of more healthy subjects as a clear gain due to sanitation, and the simple multiplication of two millions by 150l. gives the result 318,000,000l."

The Imperial Institute.—The Building Committee having made a selection from a list of forty-six applicants to tender for the first portion of the foundations contract, received offers from the following firms—J. & J. Greenwood, Brass & Sons, Thompson (Peterborough), Lovatt (Wolverhampton), Dvor (Birmingham) Bros., Macey & Son, Burnley (Birmingham), Kirk & Randall, Munday & Sons, Higgs & Hill, Trollope & Sons, and Mowlem & Co. The tender of Messrs. Mowlem & Co. being the lowest, and their schedule of prices for extras comparing favorably with those of the other firms, their tender has been accepted by the committee, and the works will commence very shortly. Mr. G. Wallis, who was formerly Chief Clerk of the Works in the construction of the Royal Courts of Justice, has been appointed clerk of the works for this contract.

City Commission of Sewers.—At a meeting on the 11th, Mr. Graham King presiding, the Finance and Improvement Committee brought up a report on the memorial of inhabitants and ratepayers for widening the southern end of Milk-street in Cheapside. The committee were of opinion that the proposed improvement was a very desirable one, and they recommended that notices should be served to take the necessary property to carry it out. Mr. Green, in moving the adoption of the report, said there was no street between Wood-street and King-street sufficiently wide to allow of two vehicles passing abreast. The improvement would cost about 30,000l. Mr. Treloar thought the widening of Ludgate-hill, which had been twenty years in progress, ought to be completed before any fresh scheme was undertaken, while Mr. Deputy Bedford and other members advocated the widening of Fenchurch-street in preference. Ultimately the committee's report was adopted.

Birmingham Art Work for Australia.—There is just completed at the studio of the late John Radcliffe, Aston-road, a pulpit and font for a new church at East Maitland, N.S.W. The pulpit is supported by Devonshire marble columns, resting upon polished alabaster bases and surmounted by carved capitals. Above the floor line other marble shafts carry a number of canopied niches. In the centre compartment, which is larger than the others, Our Lord is represented seated on a throne with hands lying at His feet, and His Apostles kneeling and standing around Him. In the recesses on either side are figures of Peter and Paul. Two other niches are occupied by Moses and Elias. The font is of Caen stone, with marble shafts.

**The Lancashire and Cheshire Antiquarian Society** held their first meeting of the session at Chetham College on the 7th inst. Professor Boyd-Dawkins, who presided, spoke of the important addition to archaeological knowledge that had been obtained by the researches of General Pitt-Rivers, who, during the last three years, had been working out the Roman remains in the district of Wiltshire. General Pitt-Rivers had worked out in the neighbourhood of his house in Wiltshire a very remarkable series of Roman villages. Up to the present time the great Roman palaces in this country had been traced out, but they were not absolutely certain as to the condition of the country villages. General Pitt-Rivers had, however, explored in the neighbourhood of his house a whole set of villages, the date of which went back, according to the coins that were found, as far as A.D. 252. This discovery, he maintained, was of great importance, because it threw light on a period of history of which little was known.

**Obituary.**—We regret to announce the decease, on the 5th inst., of Mr. J. S. Edmeston, the eldest son of Mr. James Edmeston. Mr. J. S. Edmeston assisted his father in the carrying out of many of his works, one of the most recent being the large building known as Olympia, adjoining Addison-road Station, Kensington, which was designed by Mr. Cole, but completed under the superintendence of Mr. Jas. Edmeston. Mr. J. S. Edmeston was appointed early this year District Surveyor for Charlton, Lec, and Kidbrook.

**Competition.**—No less than sixty sets of plans have been sent in for the Gloucester Public Baths Competition, besides two others sent too late to be admitted. It is to be hoped the Gloucester Corporation, upon whose scheme all this labour has been expended, will feel it incumbent on them to make every effort towards discovering and adopting the best plans, apart from all partial considerations, so that the great number whose labour must be thrown away may at least have the satisfaction of feeling that they have been fairly treated.

**Glasgow Artists and the International Exhibition.**—As a result of the agitation by Glasgow artists for larger representation on the Fine Arts Committee of the International Exhibition, it has been agreed that five additional artists should be invited to join the committee. Mr. James Guthrie, Mr. A. K. Brown, and Mr. P. Macgregor Wilson were chosen from among the Glasgow artists; Mr. Robert Herdman, R.S.A., as representing the Royal Scottish Academy, and Mr. Colin Hunter, A.R.A., the Royal Academy.—*Scotsman.*

**Bridge of Allan Museum.**—The new Macfarlane Museum, which has been in course of erection for about two years, has just been formally opened. The founder was the late Mr. Macfarlane, who, after a very successful career in Manchester, returned to settle down in Bridge of Allan, spending his well-earned leisure in forming a collection of natural history objects. The building is of the Early French Gothic style of the thirteenth century.

**New Art Museum at Kiel.**—The Corporation of the city of Kiel has decided on erecting a new museum of art. The German Government has promised a grant of 5,000*l.* towards this object, provided that the cost of the building does not exceed 12,000*l.* Towards the balance, 7,000*l.*, the province of Holstein will contribute 5,000*l.*, the city of Kiel 1,500*l.*, and private persons 500*l.* A free site for the building will be granted by the town.

**The New Palace of Christiansborg.**—During the last few weeks the designs submitted for the new Palace of Christiansborg at Copenhagen, which was destroyed by fire some years ago, have been exhibited in the Arts Exhibition building in that city, but as yet none has been accepted by the committee of selection. The new building will accommodate the Court as well as the Houses of Parliament, but entirely separated from each other.

**Paisley.**—A new Congregational Church, erected from designs by Mr. John B. Wilson, of Glasgow, has just been opened at Paisley. The church is in Early Gothic style and has a tower and spire 100 ft. high. Sittings are provided for about 500 persons, and there are also a hall seating 200, class-rooms, vestry, ladies' room, &c. The total cost is under 3,000*l.*

**A Correction.**—We are asked to state that the slates used for the Church of Holy Trinity, Belle Vue, Shrewsbury, were not Sedan Green, but "Ashton & Green's Permanent Green."

**Glasgow.**—The Liberal Club in Buchanan-street was formally opened last week by Mr. James Campbell, of Tullibehewan. The main entrance opens into a spacious hall with Corinthian columns and floor laid with mosaic tiles. In front is the grand staircase, lighted with large windows with stained glass. A dining-room, 60 ft. by 34 ft., the ceiling of which is treated in moulded panels, occupies the main portion of this floor. A recess at the side of the dining-room enclosed with stained glass screen forms a service-room, having a hoist, &c., in communication with the kitchen department on the basement floor. The semicircular beads of the windows and their lower portions are filled with rich-coloured stained glass, having appropriate figure subjects and ornamental designs. To the right of the entrance hall are the porter's desk and luggage-room, a writing-room with telephone, the clubmaster's business-room in communication with rooms upstairs, and a servants' stair, which extends from the basement floor to the attic, and thus isolates the servants entirely from the main portion of the house. This stair also communicates with the entrance from the court at the north end of the building for the reception of goods, and is overlooked from the clubmaster's office. Behind the stair on this floor are placed the cloak-room and spacious lavatory accommodation. On the principal floor are the reading and writing rooms, separated from each other by a glass screen; the lesser dining-room or smoking-room,—with service-room in communication with the kitchen,—adjoining; while the billiard and card rooms, having convenient lavatory accommodation attached, are placed on the mid-landing of the stair. The work has been carried out under the superintendence of Mr. Alexander Skirving. The following are the names of contractors and others employed on the building:—Messrs. A. & R. Anderson, builders; Messrs. Archibald McFarlan & Son, joiners; Mr. R. S. Bathgate, plasterer; Messrs. Fulton & Walker, plumbers; Messrs. Buchan & McIntyre, gas-fitters; Messrs. James Combie & Son, heating; Mr. John Orr & Co., painting; Messrs. McCulloch & Gow, stained glass; Mr. Mair, inspector; Messrs. Shields & Walker, measurers. The furniture is being supplied by Messrs. Alex. Cree & Co. for the reading and writing rooms; Messrs. Cumming & Smith, the dining-room; Messrs. F. & G. Smith, the members' bed-rooms; Messrs. Moir & Kemp, the ironmongery; and Messrs. Norval & Wilson, the billiard-tables.

**The Safety of Public Buildings.**—At the Leamington Petty Sessions, the other day, the Mayor announced that, in consequence of the Exeter disaster, they had had all the local licensed buildings inspected by the Borough Surveyor, with the object of ensuring the safety of the public; and the magistrates had also visited the buildings themselves. At the Theatre Royal the only change necessary to make it absolutely safe was that there should be an additional door leading into the street from the orchestra stalls and the reserve pit. At the music-hall a new stone staircase, 6 ft. wide, was to be constructed from the ante-room into the street, and an additional hydrant placed on the stage. They suggested that Local Authorities should have additional powers conferred upon them to inspect other important buildings,—such as churches, chapels, places of amusement, and schools, and to require, where necessary, any alterations to be made to ensure the public safety in case of fire or panic. The Reading magistrates decided the other day to adjourn the application for a licence for the theatre for a month to give time to provide a better exit from the gallery, and to make other structural alterations. A similar course was taken with regard to the Town-hall and another building in order to provide better exits. At the request of the Justices of the borough of Middlesbrough, Mr. G. G. Hoskins, architect, of Darlington, has during the last fortnight inspected the Theatre Royal, Prince of Wales Theatre, Oxford Music-hall, Oddfellows' Hall, Cleveland Hall, Temperance Hall, and the Music-hall at the Albert Park Hotel, and made reports on the means of egress from the several places. The licence to the Oddfellows' Hall was renewed, and, after hearing the report, the Justices granted a provisional licence for one month to the Cleveland and Temperance Halls, during which period the suggestions of Mr. Hoskins are to be carried out. The question of renewing the licences of the two theatres, music-hall, &c., has not yet been considered.

**Tree Planting and Drainage.**—It is not merely an æsthetic fancy, but equally a prudent regard for the health of the community, which has led civic authorities to plant with bordering trees many of the greater thoroughfares in towns and cities. By this arrangement the advantages of a purer air and of shade in warm weather are gained for the townsman, besides the implied increase of space and the amenity conferred by thus practically transporting a strip of country into town. It is one of the happiest features in the development of cities now so rapid, that in their outer and growing zone the hard lines of road, wall, and railing are interrupted at frequent intervals by spaces of green sward and by the luxuriant foliage of climbing shrub and spreading tree. In so far we have learnt the lesson of experience, and, in thus preserving round our homes a healthy atmosphere and some degree of rustic beauty, are wiser for ourselves than the town dwellers of a former generation. Still, we are not always duly careful even in our wisdom, as the sequel shows. This very custom of tree-planting in streets is open to a danger fortunately not common, but still grave enough to counteract, where it exists, the best effects of rural surroundings. It has happened repeatedly, as we are reminded by the letter of a recent writer on this subject, that the roots of trees in their growth have sought out the crevices of drain-pipes adjacent, and penetrating these, have grown with such vigour on the nourishment which they found there as completely to choke the pipes and prevent the exit of sewage. We have here, of course, no argument against the continuance of the boulevard system, but certainly a caution, enjoining first the more perfect adaptation of drain segments, and secondly, a kind of care not always observed in the relative arrangement of wayside shrubs and trees.—*Latent.*

**Ravenscroft Park.**—We are informed that the Metropolitan Board of Works and the Hammersmith Vestry have at last secured to the public for ever the thirty odd acres of meadow and foliage which form the beautiful demesne of Ravenscroft Park. For some considerable time it was very doubtful whether it would be given up to building purposes or devoted to public use, as, after accepting the offer of the Local Authorities, the owners placed the estate in Chancery, when a higher bid was made for it by a Nottingham gentleman, which the Court of Chancery was bound to accept; meanwhile, the Board had obtained Parliamentary powers to borrow the required purchase money. The purchaser then offered to sell the property to the Board at a profit, reserving to himself the mansion and gardens around it. This being declined, other terms were arranged, and the park and house were obtained at a cost of 58,000*l.* It is expected that the park will be thrown open early in the ensuing spring. A library and museum are proposed to be located in the house, which is a quaint old place, having many panelled rooms and a handsome old oak staircase. The acquisition of the park will manifestly be of great benefit to the surrounding neighbourhood, which will now probably come more under the attentive notice of the enterprising builder.

**A Technical School for Preston.**—The Harris Trustees, Preston, have granted out of the funds at their disposal 30,000*l.* towards the furnishing and endowing of a technical school for Preston. Of this, 10,000*l.* only can be spent upon the building and furnishing. After consulting with members of the Royal Commission and others, the Council of the Harris Institute, the present technical school, have decided to apply to the Preston Corporation for a grant of 10,000*l.* towards the erection of the new school, it being felt that 20,000*l.* will be required to build and furnish an efficient school, which will contribute largely to the improvement of the operatives and artisans and to the commercial development of the district. The Preston Corporation have already consented to provide a central site.

**New Law Court for this City.**—The works have been commenced in connexion with the new City of London Court, and the foundation-stone is very shortly to be laid by Mr. Bridgman, chairman of the Law and City Courts Committee of the Corporation. The site is in Guildhall-buildings, Basinghall-street, near the old Bankruptcy Court. The building will be erected from the design of Mr. Andrew Murray, and the contract has been taken by Mr. Morter, of Stratford, for 13,637*l.*

**LONDON.**—For the erection of vicarage for St. Thomas's, Regent-street, on site of Nos. 12 and 13, King-street, Regent-street, W. Messrs. George Lansdown & Harris, Warwick-street, Charing Cross, architects:—

### The Roman Villa at Tockington.

WE have already called attention to the Roman villa at Tockington. We are now able to render some detailed particulars of what is, in fact, a remarkable discovery. Not only does the building prove to be of large extent, but already many pavements of really great beauty and purity of design have been met with.

The site is Tockington Park Farm, a home-stead which stands back at some considerable distance from the roadway, the main Roman road from Gloucester going south-west into Somerset. It is also close to the line of the old market-street, which led westwardly to Aust, an old passage, across the Severn, thus connecting the roadway from Caerleon and Caerwent direct with the Fosseway leading to Gloucester. The villa was, therefore, in close proximity with many important centres of population in Roman times, by direct communication. The locality is also rich in other relics of the conquerors of the world, there being a great number of fortified posts on the adjacent hills, as well as sites of other villas. In fact, there is abundant evidence that the county of Gloucester must have been a very favourite portion of the country to the Romans, who were not slow to render it of easy access from end to end of Britain.

The best way of reaching Tockington is by train from Bristol to Patchway Station, on the line now connecting South Wales and Monmouthshire direct with the West of England by means of the new Severn Tunnel. A pleasant walk or drive along the course of the old roadway, still used as the main road from Bristol to Gloucester, leads past the site of the villa. The village of Almondsbury has to be passed through, and the Swan Inn will have to be noted by the traveller, for no refreshment can be had on the site. The village stands on elevated ground, and Almondsbury Green, a charming spot, of rough undulating ground, covered with a rich profusion of ferns and wild flowers, commands a magnificent panorama over the surrounding country, across the estuary of the Severn, to the high hills of Monmouthshire, and over the site of Caerwent, hidden in a valley. On the green are distinct traces of a small earthwork, showing that here, evidently, was a fortified post to guard the roadway which rises up the side of the hill. A passing glance may be given at the parish church, the quaint leaded spire of which is

lost in the foliage growing on the side of the hill, although it stands on high ground overlooking the valley of the Severn. Good scenery awaits the traveller on every side until the path to the right leading to the villa is reached, just before coming to the eighth milestone out from Bristol. "To Roman Villa," in the newest of letters, on a post, gives clear direction, and the site is accordingly reached without difficulty.

Tockington Farmhouse is a plain, comfortable home-stead, having its small piece of garden before it, a stock-yard to the left, a series of other farm-buildings in the rear, and a rick-yard nearly in front. The site, quite up to the garden, including the road to the buildings in the rear, and generally the whole of the area, is now the scene of all the confusion that excavation works bring in their train. Small trenches have been cut across and across the ground, revealing long foundations of walls, which only remain about 1 ft. 6 in. or 2 ft. high, traces of rooms, elaborate pavements, and all the outline of the villa, which is, in fact, on the site of the farmhouse itself. A cursory examination of the modern buildings shows that they are all arranged in parallel lines one to another.

They face south. This arrangement at right angles was hardly usual in the planning of such buildings, which generally grew up much as they were wanted, without regard to their relation one to another.

More careful examination shows that the somewhat modern buildings contain traces of ancient woodwork and masonry, and also the fact that some of the walls are actually on the foundations of those of the Roman villa. This explains their arrangement at right angles, for since the axis of the villa is all but exactly north and south, it follows that the ancient and the modern lines coincide. The former have regulated the latter, and this can be traced by abundant evidence, especially in relation to the continuance of occupation of the site, perhaps from very ancient times. It is certain, at any rate, that the ground has been occupied from Mediaeval times.

The plan of the villa, as far as it has been at present opened, shows some points of resemblance to similar buildings, with many others of difference. It appears to have consisted of two long lines of rooms going north and south.

The size is not small, the length being about 208 ft. from north to south, by 115 ft. from west to east; but these figures only represent the general size of the block already excavated. The buildings are arranged in a series of small rooms, which doubtless opened from a corridor 7 ft. wide, facing west. There are traces of a second line of buildings parallel with this main

wing, to the east, while a series of rooms, only partially opened, appears to have connected the two blocks on the north.

There is certainly a southern block of buildings, for many rooms have actually been opened, together with a corridor, about 9 ft. wide, which has been followed for 50 ft. without its termination being reached. At the south-west is an extension of the line, out of axis, for the rooms are brought more to the west. Such, in brief outline, is the plan of the villa. The rooms already opened are twenty-three in number, and of these no less than six have tessellated pavements, mostly of considerable beauty. Commencing at the extreme north end of the excavations, we find a room of moderate dimensions, the walls of which are about 3 ft. high. Here are traces of a masonry seat all round the room, the walls of which are covered with white plaster.

The floor is paved, as is also that of the adjacent room. Careful examination will show that these two apartments were originally one, the division wall being clearly an after insertion, since it is built up against the plastered wall surface. Still going south, the next room is one of much interest, for it contains one of the most beautiful, although not the largest, of the tessellated pavements. The room is 13 ft. 10 in. by 10 ft. 1 in. The pattern consists of a circular centre containing an arrangement of lobed leaves set diagonally. This is inclosed in a guilloche border. Beyond are some lozenge panels, set diagonally within a square, the four central triangular panels between the diagonal figures being filled in with small triangles alternately black and white. Each diagonal figure is subdivided, and nearer to the main circle than the outer lozenge panels are patterns not unlike inverted vases, the handles of which terminate in scrolls. The composition is completed to the size of the room by varying borders right and left, and finally by a large border of Greek fret forming fylfot crosses. The groundwork is white, and the colours are red and blue-black. One corner of the pavement has been repaired with coarser tesserae, evidently in Roman times, to make good some wear or accident,—the work being laid without regard to the completion of the pattern. This fine pavement is, unfortunately, in poor condition, owing to the falling in of some flues beneath it, which brought heat from a hypocaust close at hand. This room was opened about fifty-five years ago, when it was discovered by accident, and the pavement uncovered. It was subsequently filled in again, and all knowledge of its existence had passed away. After the recent discovery of the villa, the tenant, Mr. Smith, received an anonymous letter in which the writer spoke of this pavement and its

position. Search was accordingly made for it in a portion of the grounds away from the other excavations, and it was found, as were also the rooms already described, together with a fourth room to the south of it. It is of interest to note that the west wall of these four rooms forms the base of the present old building, formerly used as a granary.

At the south-east angle of the fourth room the excavators found a curious square pit-like chamber, 4 ft. 5 in. by 4 ft. 3 in., and 3 ft. 4 in. deep. It gave access by an opening 2 ft. wide, over which is a well-turned segmental arch, into the hypocaust already referred to. Entrance to this is closed by a slab of red local stone, set diagonally and mortared in at the back. It has been broken in the attempt to force an entrance, which has not yet been effected.

The continuation of these apartments, to complete the eastern wing, has not been traced further, but foundations have been met with on the other side of the Farm House as if in continuation. Proceeding along the northern buildings a small portion of one room, in front of the southern wall of the granary, has been found. It has a pavement with a simple guilloche pattern. Commencing now with the principal, or western group of buildings, we come to the most northerly room, which has a pavement formed of a large double Greek fret, much the same as has been already described, blue-black on a white ground. Next to this, going south, is a room which has had a very good pavement, now in very poor condition. One part of it is beneath a shed, the other is in the open path, and, since it is only about 8 in. beneath the modern level, it has suffered very badly. Fortunately, two of the angles remain, and part of the centre, sufficient for the whole of the pattern to be made out. It consisted of a central panel, a parallelogram filled with lobed leaves set diagonally, surrounded by a guilloche. There is then a band of plain groundwork and another guilloche. Next to this is the largest pavement, forming the floor of a room 18 ft. by 18 ft. This is still a fine work, although it is in very poor condition, owing to its small depth beneath the present surface. Its groundwork being decayed, it is bent and furrowed badly, but the colours are still bright and the pattern can be well made out. It consists of a circle surrounded by a guilloche enclosing a smaller circle containing a cross of interlaced work, with rounded ends. The main circle has a pretty pattern of leaf-like form, interlaced. The circle is enclosed by two squares of guilloches, one set diagonally and interlaced with the other, the whole being enclosed by an octagonal guilloche border, the angles of which are brought back again to the square form by continuation of the borders, there being a small square panel at each corner interlaced with the octagonal border, and having a pattern something like an inverted vase at the angles, two being of one pattern and the other two of another. The main octagon has its spaces, up to the interlaced squares first described, filled in with various lozenge panels at the angles, which contain circles of very varying design, the centres of the composition having panels filled in with involved guilloches, circles, &c. The outer square has first a pattern of small stepped triangular form, and is concluded by a border, next the walls, of enlaced guilloche ornament. The colours, as before, are red and blue-black on a white ground.

Various apartments extend southwards, where begins the corridor, and the planning of the walls to a different angle. Since these walls are not bonded into the others, it is reasonable to conclude that this portion was an addition to the main building. No pavements have been found to these rooms, although it is more than probable that they have existed. Tessellated pavement is, however, again met with in the southern corridor, where a fine, bold Greek fret can be distinctly traced. One portion has a circular piece of paving, level with the face, composed of several wedge-shaped stones, which form the circle. This was probably the base of some circular pedestal, but why it should have been formed in the

manner stated, rather than by a single circular stone, is not easy to determine.

The walls forming the apartments vary in width from 2 ft. 3 in. to 1 ft. 10 in. They are built of local stone, roughly dressed, not squared, and are put together with mortar in which no pounded brick has been used. Pounded brick is to be found in the concrete beds or backings for the pavements. No Roman tile or brick appears in the construction of the walls, although the bright red of the pavements is formed by tessere of cut brick. The white groundwork is of stone dug in the neighbourhood, while the blue-black is also local material.

The articles found in the excavations have not been of very great interest, nor have they been very numerous. A few fragments of pottery only have been met with, of varying colours, including two or three small pieces of Samian ware; a single third brass coin of Augustus; an iron strigil; while a few small oyster-shells proved that the Romans of this part of the country had the same taste for the succulent bivalve as their hrethren elsewhere. Many split bones have also been found, showing that they had been broken for the extraction of marrow. Some features, indicative of the structure of the building, were met with, and from these we learn that it was, for the most part, roofed with split Pennant stone slabs, 2 ft. long, 13 in. wide, and 1 in. thick, both ends of the slabs being cut diamond-wise. There were a few fragments of flat flanged roofing tiles, and also of the circular tiles to cover over the flanges, but since these were not very numerous, it may be supposed that stone was the principal covering. The slabs were perforated for one large nail each. These were of iron, as was sufficiently proved by a portion of one of the nails still remaining. Several pieces of hypocaust tiles were met with to convey the hot-air to various parts of the building, having patterns scored upon them. The patterns were not, however, intended as decoration, but only as a key for plastering. This was attested by the fact that their impression was actually found on the back of some of the fragments of coloured plaster found in the rooms. The base of a circular column was discovered in one of the apartments near the principal pavement, the shaft, 8 in. diameter, being broken off. It is very neatly and truly worked, very similar to an attic base, commencing with a square plinth. Examination shows that it has not been worked by hand, but turned in a lathe. The most remarkable discovery remains to be noticed. It is a stone table slab, 2 ft. 11 in. long by 1 ft. 3 in. broad, and 3½ in. thick.

The under side is slightly dished, and the upper side shows that a hack of some sort rested upon it. Three of the edges are chamfered, square stops being left in the centre of the front, at the angles, and at the ends. The chamfer is filled in with a sunk ornament, precisely like the star pattern so often found in Early Norman churches, slightly varied to the front. There is a neatly-worked cable moulding at the top edge of the chamfer, and the fillet beneath it is ornamented by a series of small sunk squares. A pattern, varied in each case, is also worked on the faces of the blocks left as stops to the chamfer. It was discovered a year ago in digging a drain in the stack-yard, not very far to the south-east of the end of the excavation of the south corridor. When found it was standing on four rough stone supports, and it was broken in removal. It is difficult to assign a use to this object, which appears to have stood as described, in the open air. It is possible that it was placed as a table to support some statues of domestic or local deities, in front of an altar. Diligent search should certainly be made for the missing supports.

The course of the excavations revealed evidences with respect to the fate of the buildings, at least to a considerable extent. Traces of conflagration were found in more than one spot. Not only was there deposit of burned wood, but several of the stones bear traces of fire.

Although there is record of a portion of the pavements having been found about 100 years

ago, as well as more recently, yet the recent discovery of these interesting remains was effected in consequence of the building of a new wall, to form a boundary to the present stock-yard, in the autumn of last year. One of the wallers cut through the largest of the pavements, to get a foundation, and not knowing the nature of the small coloured tessere, proceeded with his work, putting a few of them into his pocket. Some time afterwards he happened to show them to the steward of the estate, who at once recognised that they had formed a portion of a Roman pavement. Search was made, and the beautiful mosaic was exposed to view. It was prudently covered over again, to protect it from the frosts of winter, and, in the mean time, the nature of the discovery having been brought before the executive of the Bristol and Gloucestershire Antiquarian Society, an exhaustive exploration as far as funds might allow, was resolved upon. Sir John Maclean, F.S.A., kindly undertook the oversight and direction of the work, which is of itself sufficient to say that it has been well and efficiently done, aided by a subscription, which is, however, not yet sufficient in amount to uncover the whole of the site. Mr. Smith, the tenant, has very generously permitted his lawn and yards to be cut into and trenched, and has in every way taken the most lively interest in the works.

A meeting of the members of the Bristol and Gloucestershire Society was held on the site on the 14th inst., where a very large number of ladies and gentlemen assembled to inspect the progress of the excavations.

#### THE DICTIONARY OF ARCHITECTURE.

**T**HIS mysterious publication,\* the commencement of which dates from an unknown period, and which seems, officially at least, to belong to no one and to come from nowhere, has just evolved another instalment of itself, in the shape of what is variously called its seventh volume or its Twenty-second Part; for the Dictionary has two title-pages, which do not agree. We have adopted the simpler form, as what we suppose is intended for the real title-page. This volume completes the letters "R" and "S," leaving, we are informed, only one volume to complete the whole, so that we might hope to see the entire work within a brief period, were it not that we are told, in the same breath, so to speak, that the production of this volume has exhausted the funds in hand, and that 650*l.* will be required to complete the Dictionary. This is not a very large sum, comparatively speaking, but perhaps more than will be quite readily raised in these not very flourishing times. The size and consequent expense have been considerably increased, we are told, beyond what was originally calculated on, owing to the constant increase in the number of terms coming under notice and requiring elucidation. The number of terms in the original list for R and S, for instance, was 1,664, whereas the number of terms actually treated under these letters is 3,131. That is the way dictionaries do; they always increase as they go along, fresh subjects which ought to be treated continually presenting themselves to the memory of the compiler, or being introduced to his notice by correspondents; and the comparative increase in the number of subjects treated over those originally proposed speaks well in itself for the care of the compilers and their anxiety to include among their subjects whatever has a proper claim to be included.

It must also be noted to the credit of the compilers that they have not allowed themselves to be tempted, by the constant increase of matter, to launch out into articles or essays beyond the proper scope of a dictionary, but have kept to the real object of a dictionary, viz., to give information; instead of allowing it to grow, like another contemporary dictionary we could name, into a conglomeration of lengthy essays compiled according to the idiosyncrasies of each contributor, without any guiding principle running through it. The

\* The Dictionary of Architecture. Issued by the Architectural Publication Society. With illustrations. Vol. VII. 1887.

age is a fine bold folio, the type admirably clear, and the articles are short and practical; almost erring, perhaps, on the side of too much brevity than in the other direction. The large number of references to works on many of the subjects treated are very useful, and may often save a great deal of time and trouble to those who are anxious to know where to go for detailed information on any particular subject. A great many of these lists of books or examples are of considerable length, and though they occupy comparatively little space (sometimes half a column or more), they represent, as every one who has been unwise enough to undertake that kind of task knows very well, a good deal of tedious labour and research. In this respect, and in its general form and style, the Dictionary is a distinctly business-like publication; there is no show or literary pretence about it; the object is evidently to put the main facts about each subject in as terse a manner and in as small a space as possible.

All this is very good so far; but we regret to say that closer examination does not convince one that the work has been done as it might and should have been. There is every sign of good intentions, but there are certainly signs that the contributors and compilers are not quite up to the mark in dealing with some subjects, and especially that they are somewhat antiquated in their notions. Of all things, it is required of a dictionary that it should be up to date, and that is exactly what the Dictionary of Architecture appears not to be. There is a fine old crust of air of bygone days about it, which is picturesque, but not quite what is wanted in a dictionary which is to be useful for the future and not for the past generations. This is curiously obvious in the dates of the books and periodicals quoted. They are nearly all from publications twenty or thirty years old or more, as if the compilers were unacquainted with what was passing at the present moment. "The Builder Journal" is frequently quoted, but it is nearly always from numbers many years ago. If the compilers had looked a little more than they seem to have done at the *Builder* of the last ten years, they might have been better posted up than they are, in some matters, at all events. There is at times also a curious obscurity of diction, arising apparently from the effort to get a great deal into a few words: a most praiseworthy aim, the achievement of which, however, has not been granted to every writer.

The first article we open at is "Racquet Court," where we read, "The floor must be of hard-rubbed slabs with rubbed edges." Slabs of what? Under the heading "Slab" the dictionary gives "a large flat but not very thick portion of any material"; so that does not help us. "For ventilation, iron gratings may be built into the walls flush with the plastering, the bars should be formed diagonally at an angle of forty-five degrees upwards from the entrance [of what?], and not more than  $\frac{3}{4}$  in. apart, so as to be in a line with, and not to hinder, the flight of the balls." Will the architect who is going to build a racquet-court gain much from that? And, supposing it were intelligible, is plaster the proper internal finish for a racquet-court? We are not, at the moment, in a position to dogmatise on the subject, but we should doubt it. Under the head of "Rain-water Cistern and Tank," it is mentioned that "Buck's Patent Percolator prevents the first portion of the rainfall (which brings down impurities from the roofs) passing into the storing-tank." There is no mention of Robert's rain-water separator, the best-known and most recently improved apparatus of this kind, the latest form of which may be found illustrated, with full descriptive details, in the *Builder* for June 11th of this year; but that, of course, is much too recent for the "Dictionary of Architecture."

On the next page we read: "Rain-water pipes are often used as drain-pipes from upper water-closets"; this is seriously given as if it were an approved practice, without a hint that there is anything to disapprove of in it. It should seem from this that the compilers do not read modern books on sanitation, and do not know that the disconnection from the drain should

be by a different method for these two classes of pipes. Next page, "Random Coursed Work" is defined as "stone walling where the courses are not continued of the same sized stones," an instance of clumsiness of expression leading to ambiguity. That definition would be as applicable to rubble walling. It should have been, "where the courses are continuous, but not with the same sized stones." In the article on "Retaining Wall" the Dictionary deals only in generalities; "such a wall is battered on the outside face from 1 in. to  $1\frac{1}{2}$  in. to the foot, the greatest degree of batter (which is often curved) being given to the foot of the wall." We might have expected in a dictionary for architects to find some particulars as to the circumstances under which a retaining wall should be curved, as well as some formula for obtaining the curve. We proceed, "Counterforts are invariably carried up at the back of a retaining wall, piers are also sometimes placed on (sic) the face, which break the monotony and hide any settlements which may subsequently occur." This has nothing special to retaining walls; it might apply to any wall. The article, too, proceeds to point out as one of the best examples of a curved retaining wall in a cutting, that on the London and North-western Railway between Euston and Camden Town, "though it failed." To select as the best example an admitted failure seems in keeping with the rest of this rather singular article. It is also observed that "the soil when filled in against the wall requires great care, or a failure eventually occurs"; but what kind of "care" is required, or what kind of failure impends, is left to the imagination.

Under "S or Syphon Trap" this is all we get: "A trap formed of pipes of lead, stoneware, or other material [it should have been "a pipe" of lead, &c.], worked somewhat to the form of the letter S. It is preferable to the D-trap which has lately been improved by its being formed of one diameter." The last sentence, which stands exactly thus, with no punctuation, reaches the climax of ambiguity. Which has been improved, and which is formed of one diameter, and what does that mean? It is refreshing, however, to find the spirit of the sanitarian awake on the next page, under the heading "Safe," "a plate of lead turned up at the edges and laid on a floor, as under a bath, water-closet apparatus, washing basin, and such like, to retain any overflow of water, and by a pipe to carry it away; this pipe should not enter a soil-pipe." But, unfortunately, Homer nods on the same page over "Saint Chapelle" (sic). We might have expected under this head to find some special word about the famous Parisian building, which is the Sainte Chapelle all the (architectural) world over; but at any rate a reference to a French dictionary would have revealed the fact that Chapelle is a noun feminine, and that the corresponding adjective is "Sainte," and not "Saint."

In the note on sawdust, when saying that "in buildings it is placed in floors and in partitions, to deaden sound," it should at least have been added that it should be thoroughly stoved first; it might usefully also have been added that slag wool is preferable for this purpose. The latter material, however, is duly dealt with under its own heading. "Sculpture Gallery" is defined only as a "large apartment specially designed for the exhibition of works of sculpture." We all know that; the dictionary might have said something as to the requirements of a sculpture gallery, the best way of lighting, and the best existing examples. In the article on "Seasoning Timber" we are first told that the seasoning is "A process of preparing timber without the use of means for its preservation," a fine instance of dictionary ambiguity. Among the mechanical processes of seasoning no mention is made of "the Common Sense Drying Apparatus" fully described and illustrated in the *Builder* of October 31, 1885, and which is the latest important improvement in seasoning methods.

Under "Sheep-cot" these two apparently contradictory statements look as if an explanation was wanted:—"The front wall, 4 ft.

high to the eaves; no walls are needed." Under the heading "soil-pipe" we are advised to have soil-pipes *within* the house (in order to get a warm up-current up them), a recommendation totally at variance with most both of theory and experience; and we are told a stoneware pipe is better than metal. It might be, if we could get it in long lengths, but not with all the joints which are inevitable; and the advice is decidedly dangerous.

The definition of "Suspension Bridge" is very amusing; it is stated to be "a roadway for spanning wide valleys and rivers, suspended from inverted iron hows of chains or wire ropes"; as if the curved form assumed by the chains were an essential element in the construction, or as if the chains were intentionally made curved, and then "inverted." This is, on the whole, one of the very silliest definitions we ever saw of a piece of construction. Does not the writer suppose that engineers would be very glad to strain the chains across level, if they could get rid of the element of their weight? The sentence is really childish. Under the head of "swimming baths," it is stated dogmatically that "dressing-boxes are to open directly on the water's edge, and not on a platform." We have never been in a swimming-bath in which this arrangement was adopted, and suspect that it is only some "fad" of the writer's; it could only be done where dressing-boxes had no doors, and were pretty wide, otherwise how is a man to get his swing of body and arms preparatory to taking a header? And it would be exceedingly inconvenient to have all passage along the side of the bath stopped by boxes coming to the edge, and leaving no gaugeway. It is absurd to have such a direction inserted in a work of this kind, as if it were a *sine quâ non*. Then for scientific precision and clearness of language we may recommend the definition of syphon:—"A bent tube, having one leg shorter than the other. It acts from the pressure of the atmosphere being removed from the surface of a fluid, which enables it to rise above its common level." What rises, the fluid or the syphon? And how and for what purpose does it "act"? Possibly the writer of that sentence might have known what he meant by it, but he evidently did not intend to communicate his knowledge to the reader. Finally, we may suggest that if the writer of the article on "Stone" had paid any attention to the series of articles on "Our Building Stones" in the *Builder* of January to June, 1886 ("Students' Column"), he might have been in the way of giving some rather more scientific tests for stone, and generally giving a better account of his subject than is apparent in the short, empirical, and unsatisfactory article on so important a subject as "stone." He quotes "Building Stones used in London, *Builder* Journal, 1858, by W. Papworth," and that is just about the date the Dictionary likes to go back to; but he would have learned more on this subject, at any rate, from the *Builder* of 1886.

The Dictionary of Architecture, in short, is well-intentioned and highly respectable, but it might have been a good deal better if it had not, like some other respectable institutions, maintained a considerable leaven of what is termed by irreverent persons "old-fogeyism."

We hope the Dictionary will reach a speedy completion, and that funds will then be further raised without delay for issuing a new and thoroughly revised edition; which will certainly be necessary if it is to take a permanent place as the Standard English Dictionary of Architecture.

**Ventilating Gas Radiator.**—Mr. R. Craven sends us a description and illustration of what he calls the Clapham Ventilating Asbestos Gas Radiator. This is an asbestos gas stove in the form of a fire-grate, with a series of vertical tubes in contact with the grate both at each side and the back, which give a large heating surface, as well as inducing a current of warm-air into the room through the series of pipes. This principle has been often used, of course, but this grate seems designed to make the most of the heat generated, taking it from the back as well as from the sides of the gas fire.

## NOTES.

WE shall give an illustration of "Terry's Theatre," with a plan and section, shortly; meantime we may say that an inspection of the house justifies in the main what has been said as to the care which has been taken to render the building fire-resisting and to afford ample exit. The arrangement of the various "extra exits" is very well planned, and the push doors work most satisfactorily. There is one point, however, which requires explanation. The extra exit from the gallery is very well arranged by a straight staircase, with one landing, right down to the street; this extra exit also serves the upper circle by a door opening on to the landing through the upper circle refreshment-room. But the street door at the bottom of this long staircase is not a push-door, but a locked one, and as there is no appearance that this door is to be generally in use (it leads only to the gallery and the refreshment-room aforesaid, and past no officially guarded post), there seems the chance that it may be found shut when there is an escape made from above; and this would prove very serious; it would be a complete trap. Unless this door is to be open every evening, it ought, of all doors, to be a push door. The exit from the dress circle is very well managed, there being a curtained doorway opening on to a small landing at the end of each tier of seats, the landings kept level with the tier. There is one door on each side of the stage through the partition wall between it and the auditorium; an iron one and locked; but several persons, we are told, would have keys of it. In regard to absolute separation of the stage from the auditorium, that is a weak point, of course, the principle of the theatre being that the auditorium is fire-proof and the stage cut off and exposed to the action of sprinklers. The asbestos curtain seems likely to cut off fire sufficiently for the period necessary to allow of egress; it gives less appearance of security than the iron one, but it is more manageable; it is strained on an iron framing. The fronts of the circle seats are of fibrous plaster on an iron framing, with wired plaster behind; something of this kind was, of course, necessary here if wood were not to be used, as it is essential to have something vibratory and that will not make sharp echoes in such a situation. The rest is all iron and concrete, and looks solid, clean, but rather cold. The acoustic qualities we have not yet tested fairly at a performance; but, in any case, it must be remembered that this is a very small theatre, and would not in itself settle the acoustic question. We can hardly, we confess, imagine a theatre of the first size built in this way which would not be disagreeable and trying for the voice of the actor and the ears of the audience.

WE are indebted to the courtesy of Mr. Waterhouse, who, as will be remembered, is one of the jurors on the Milan competition, for a copy of the conditions of the second competition for the proposed new facade, which have apparently only been sent to the jurors and to the competitors. From these conditions it appears that our conclusion, embodied in a "Note" in last week's issue (p. 522) is correct, viz., that the Committee of management are in a position, on the terms of their circular to competitors, to withhold the premium from any competitor who does not conform to the conditions of the competition; and that one of these conditions, most explicitly laid down, is that the new design must be in conformity with the construction, the architectural form, and the style and decorative character of the existing edifice: we quote the precise words of the document:—"E richiesto quale condizione assoluta che la nuova facciata si accordi intimamente con la struttura organica costruttiva, con le forme architettoniche dell'edificio, e con lo stile ed il carattere decorativo delle sue parti più vecchie." There is no mistake about the wording and intention of that, and it is perfectly clear that after that the Committee have bound themselves not to select a design which does not conform to the style of the cathedral: and in this we consider they are entirely in the

right. We have never admired much the style of Milan, but it is a homogeneous whole, and it would be an artistic absurdity to complete it in a Gothic of a different manner and drawn from a different country and period.

WE print in another column a letter from the Institute of Architects, a copy of which has already appeared in the *Times* (where, by the way, the "Institute" is misprinted the "Royal Society of Architects"), expressing the official opinion of the representative body of architects in condemnation of the proposal to pull down St. Mary-le-Strand Church, and pointing out that the traffic requirements may be met by continuing the road to the north of the church. In the *Builder* for December 26, 1885, we gave a reproduction of a bird's-eye view, made by a very competent architectural artist for the Strand Improvement Association, showing how effectively this could be done so as to leave a road to the north of the two churches, up to the angle of the Law Courts, making a portion of the space between them, which would not come into the line of traffic, into a garden. This scheme if carried out would be a great public improvement, both practically and architecturally. In regard to the pulling down of old churches we are by no means bigoted conservatives, and we have before expressed our opinion that in one or two cases the practical advantages have fully compensated for the loss of churches which, though old and of some historical interest, were really of no great beauty. But the case of St. Mary-le-Strand is quite different; the steeple is one of the most graceful and original of Classical steeples in London, and is the architectural centre of the Strand vista. The wish to have such a building in such a position pulled down to gain a street accommodation which can be far better gained in another way is so stupid and senseless that it is impossible to argue seriously with those who could propose it.

LORD ROSEBERY'S speech at Keighley last week was a refreshing change among political orations, for he spoke clearly and well on the subject of technical education. The speech was well timed, for the present is the time at which public attention should be directed to this question. The Government Bill of last Session was a kind of pilot balloon, and if the people of this country are sincerely desirous of keeping abreast of other nations in commerce and manufacture they will do well to set resolutely to work to establish a sound system of technical education throughout the country. Unless general interest be shown in this question, the Government will not attempt to pass so thorough a Bill as they would if public opinion be clearly and resolutely expressed. Lord Rosebery will do much more to enlarge his reputation among his countrymen by pressing this question on the attention of the public than by following the example of other official Liberals, who can find nothing to say but that Ireland blocks the way and so that no other subject can be dealt with by Parliament. It is one thing to hold firm to an opinion, it is quite another to exclude all subjects but the one from public discussion. Mr. Morley and other eminent Liberals are wrong in thus narrowing their public efforts, and we are thankful that Lord Rosebery is more wide-minded than many of his late colleagues.

THESE are, indeed, the days of big railroads, as of everything else, and an undertaking that swallows up a whole continent is alluded to in a matter-of-fact little paragraph, although it may be pregnant with the future fate of nations. On this occasion Russia is in the field with a proposal to make a line from St. Petersburg across Siberia to Vladivostok, on the Pacific coast, and, what is more, to do it out of her own resources without asking any other country for help, guarantees, or a loan. It is to go through Ormsk, Tomsk, the Baikal region, and the Amoor goldfields, amongst other places; and although, of course, *impetris* of military and strategical importance, it will have a strong eye to developing Siberia's industrial resources. It will take five years in

building, and will cost 300,000,000 roubles (1 rouble = 9s. 2d.), which will include five large bridges at 6,000,000 roubles each. In the Crimean war, Vladivostok was not of so much note as a war station and arsenal as it is now, and in case of another dispute between the two countries, it might play a very decided part in that quarter of the Russian dominions.

OUR advertisement columns contain an announcement of an examination to be held at Manchester in February of candidates for Associateship of the Institute of Architects; an examination instituted for the convenience of provincial candidates who may not find it easy to come up to London for examination. The examining body will consist of members of the Manchester Society of Architects and a member of the London Board of Examiners, and we are given to understand that Manchester has been selected as a town which is so far central as to give, it is hoped, facilities for candidates from Liverpool, Leeds, and Sheffield to enter for examination with less inconvenience than by coming to London; and even candidates from Scotland will find Manchester nearer than London. We may point out that the examination papers of the Institute of Architects are carefully framed, and the passing of these examinations is now a real test of professional competency, the value of which is likely to increase.

WE have received the programme of an Institution to be called the London College of Architecture, established at 46, Great Ormond-street, of which Messrs. A. Hessel Tiltman and W. Henry Wood are the directors, "aided by qualified assistants." The curriculum is a very full one, including mathematics and mechanics, plane and descriptive geometry, chemistry, geology, building construction, history of architecture, drawing, designing, colour decoration, general professional practice, &c. This is an ambitious programme enough; and no doubt a College which gave satisfactory and sufficient instruction in all these varied and important subjects would have a future before it. But we have no information as to who are the professors who are to give instruction in all these subjects, and we should imagine that those who are thinking of adopting a Collegiate study of architecture and its cognate subjects would wish to have some information on that head first.

IN a recent issue (Sept. 3), when treating of the "recent excavations in the Acropolis," we were obliged regretfully to own that, spite of the extraordinary yield of statues, there had not yet been discovered "any statue inscribed with the name of a known sculptor." We had a number of bases inscribed and a number of statues baseless, but as yet no combination had been effected. Just such a combination Dr. Studniczka thinks he has achieved. He has put together a base, signed by Antenor, and a fragment of two feet, and these, united with the remarkable statue published by Rhomaidis (pl. vi.), make up, he thinks, a complete composition. If he is right the style of the great archaic master Antenor, the sculptor of the world-famed statues of Harmodios and Aristogiton, carried off by Xerxes, is no longer "matter for precarious conjecture." In a question so all-important, spite of the careful drawings and measurements given by Dr. Studniczka, we prefer reserving our judgment till we have examined the originals now in the central Museum at Athens. As far as we can judge by the drawing, there seems to be as yet a good piece wanting between the upper part of the statue and the recently-discovered feet. Dr. Studniczka gives a reconstruction of the whole composition, in which we think he clearly makes out one point, and that is that whatever the statue was that stood on the basis it was of size and weight, to our minds, disproportionate to the column that supported it. That it was the custom to set up large votive statues, and even complicated groups, which far overlapped the dimensions of the supporting column and which gave them a very unstatic effect, is known from the copies of such votive offerings which appear on vase

paintings. Dr. Stadnicka's paper, a long and complex one, appears in the last number of the *Jahrbuch* of the Prussian Institute.

THE monuments and memorial tablets at St. Olave's, Old Jewry, together with the remains of internents in that church, will shortly be removed. Failing application by the representatives of the deceased in any particular case, the monuments will be transferred to the newly-constituted parish church of St. Margaret, Lothbury, and the exhumated remains to the City of London cemetery at Little Ilford, Essex. These proceedings are authorised under the late Bishop of London's Union of Benefices Act, whereby a union has been made of the City parishes of St. Margaret, Lothbury; St. Olave; St. Martin, Pomeroy; St. Mildred, Poultry; St. Mary, Colechurch; St. Christopher-le-Stocks; and St. Bartholomew-by-the-Exchange. It is not generally known that under the Act the Ecclesiastical Commissioners are enabled to provide a sum not exceeding 10*l.* in each instance of removal under the circumstances which have arisen here.

YET another bit of "Old London" is to temporarily receive form and substance. Mr. Thomas Harris has undertaken to reproduce a portion of that once highly popular resort,—Marylebone Gardens. It will serve as the "setting" of a bazaar for liquidating a debt upon the parish church of St. Marylebone, built by Thomas Hardwicke (1813-17), whereof the interior has been entirely remodelled and decorated by Mr. Harris in 1884-5. The bazaar will be open during the last week of November, in the Portman Rooms, Baker-street, more familiarly known, perhaps, as what used to be Madame Tussaud's. We understand that Mr. Harris proposes to base his design upon a view republished in Messrs. Cassell's "Old and New London," and therein described as being taken from a print of 1780; at which time, by the way, the Gardens had been practically closed for two years and more, and their site taken for building purposes. There are extant other views showing "the grand walk and the orchestra with the music playing"—as, for instance, those by J. Donowell and R. Sayer. These are dated 1755, when the gardens had reached to the height of their fashion. Marylebone Gardens had their origin in a bowling-green attached to the Rose of Normandy Inn in the High-street. This, as Long's Bowling-green, half a mile distant from town, is cited in the *London Gazette* of January 11, 1691; and in an advertisement of nearly thirty years later is styled the Marylebone Bowling Green. John Locke in his diary (1679) writes about the several persons of quality who came hither to play at bowls. Pepys speaks of going abroad to walk in the garden at Marrowbone. The Duke of Buckinghamshire, as Lady Mary Wortley Montague's oft-quoted couplet reminds us, was its warm patron. Gay alludes to the more than questionable character of some of its frequenters. Figg's and Broughton's sparring and broadsword amphitheatres, together with other haunts of the "fancy," were not far distant. In 1739, a charge was made for admission. The silver tickets will be copied for this present occasion, and hot cakes served à la those of the noted Miss Trusler, daughter of the proprietor, circa 1760. Gaining-tables and the performance, by Arne, of Handel's music, formed a great attraction. The Mr. Fountain who is mentioned in the anecdote of Handel and his self-confessed "very poor stuff," as related by J. T. Smith, kept the school, hard by, which long enjoyed a high reputation. The main entrance stood over against the present parochial National schools in High-street. The grounds lay eastwards as far as Harley-street, covering Devonshire-place, with parts of Beaumont-street and Devonshire-street. Some relics of their trees may still be seen within the area we indicate. Rysbrach's workshop was situated here, as appears from a conveyance by Lowe, the singer, of his property in the Gardens for his creditors, in the year 1769.

WE are glad to see that practical subjects are having their full share of attention in the scheme of the Architectural Association classes and lectures for the ensuing session; not that we are by any means disposed to attach less importance to the artistic side of architecture, but that we have sometimes thought that the tendency of the Association was rather to lean towards the artistic side at the expense of the other. The practical subjects in the programme include a course of lectures on Construction, by Mr. Lovegrove; a course on Graphical Statics, by Mr. Quick; and a course on Land Surveying (including both lectures and field works), by Mr. A. T. Walmisley. The list of subjects to be treated by the Advanced Class of Design includes some which it should be interesting as well as useful to work out.

THE last number of the "Journal of the Royal Historical and Archaeological Association of Ireland," published quarterly, contains the fourth of a series of articles on the "Rude Stone Monuments of Sligo," by Mr. W. G. Wood-Martin, Fellow and General Secretary of the Society, which is largely illustrated, and goes very fully into the subject. The series of articles is still in continuation.

PRINCE PIOMBINO, the owner of the Villa Ludovisi, has allowed the publication of a monument of great interest and singular beauty, just discovered in his grounds, which occupy, it will be remembered, the site of the Gardens of Sallust. The monument consists of three slabs of marble forming three sides of a square, and all sculptured in rather high relief. Had there been four sides instead of three, we should have supposed they had formed a square puteal; as it is, it is difficult to see what purpose an enclosure of only three sides could have served, unless, as Signor Visconti conjectures, it formed the railing that enclosed a subterranean staircase. However, the chief interest lies in the sculptured reliefs. The centre relief is a group of three figures, a young girl, dressed in the thinnest possible Ionic chiton, clinging close to her figure, is just rising out of a stream, supported on either side by an attendant maiden; they also wear long full chitons with sleeves; they hold a piece of drapery,—evidently a sort of bath towel,—in front of the bathing maiden. We have no hesitation in saying that, merely considered as a composition, the relief is one of the most charming things ancient art has left us. The interest, however, of the design is doubled by the fact that obviously we have here no ordinary bathing scene. It is difficult to communicate an impression of this sort, but every archaeologist will agree with Signor Visconti that the whole pose and manner of the figures indicates a solemn rite, a baptism in honour of a god. Who the god is there can be little doubt. It is well known that at the lesser Eleusinian mysteries, celebrated in honour especially of Persephone and Dionysos bathing in the Ilissus was an important part of the ritual (*παρά τοῦ Ἰλισσοῦ οὐ τὴν καθαρῶν πλοῦται τῆς ἑσπέρου μυστηρίου*). Sufficient ordinary bathing scenes remain to us on vases to make us sure that what Sig. Visconti calls "la severa decenza" of the long Ionic robe worn by the bathing maiden is due to ritual intent. He does not point out, what seems to us manifest, that the "type" of the maiden rising from the water is the same as that of Persephone rising from Hades,—no doubt, an instructive piece of symbolism. On the other two sides are respectively a nude maiden playing on the tibia, no doubt in honour of Dionysos and a closely-draped maiden lighting a lamp, again in honour of Persephone. The monument is executed in the finest archaic style. We can only hope that Prince Piombino will allow casts to be taken. It is published in prototype in the September number of the *Bullettino della Commissione Archeol. Comunale di Roma*.

COPIES of four of Mr. G. F. Watts's paintings, executed under his superintendence,

\* Dublin: Hodges, Figgis, & Co. London: Williams & Norgate, 1887.

and which have received their finishing touches from the artist's own hands, have been presented by him to the Church of St. Jude, Whitechapel, and are now hung there as permanent additions to the decoration of the church. We have occasionally mentioned the annual loan exhibitions of paintings which the Vicar of St. Jude's, the Rev. S. A. Barnett, instituted some years ago in the schools during the Easter holidays. Mr. Watts, who believes so fervently in the moral influence of art, took a great interest in these exhibitions, and many of his finest works have been seen from time to time in St. Jude's Schoolrooms. The presentation of these copies of his paintings to the church is a farther and very practical testimony of his interest in the efforts to bring art within the knowledge and interest of those who are called "the masses." The pictures of which copies have been presented are "Love and Death" (the painter's greatest work), "The Messenger of Death," "Death crowning Innocence," and "The Good Samaritan." The moral or religious turn of the three last-named subjects is obvious enough; "Love and Death," however, we never regarded as having any moral at all, or as being anything but a grand and impressive allegory of the most tragic contrast of human life. Mr. Watts may think well to read a moral into it now, but we suspect it is a moral superimposed afterwards. However, the experiment of thus introducing modern art into the church is of much interest, and perhaps so good a precedent may be followed elsewhere.

MR. WYON sends us an impression of a Jubilee medal which was struck from his design for presentation to her Majesty. The gold medal from this die is among the presents exhibited at St. James's Palace. The obverse bears a profile portrait of the Queen, which is a very good piece of modelling,—certainly far superior to that which has recently appeared on the current coinage of the realm; the reverse represents Victoria, enthroned, attended by a rather mixed assortment of mythological personages, with a decorative Gothic background to the group. This allegorical design is not, to say truth, more interesting than such designs mostly are in modern work; but the portrait on the obverse is a success.

WE are informed that an unfortunate hitch has occurred in regard to the Eucleuch Memorial in Edinburgh which will delay its completion beyond the time contemplated. A proper understanding does not appear to have been come to between the architect of the monument and the sculptor of the statue, for when an attempt was made to place Mr. Boehm's figure of the Duke upon the summit of the column it was found that there was not sufficient standing-room, a foot projecting over in front and a mass of drapery behind. This of itself would be awkward enough, but when it is known that the capital is surrounded by a bronze cresting *within* which the figure was intended to stand, it is obvious that a new arrangement must be made.\* As formerly described in this place, the memorial is in the form of an octagonal Gothic column, ornamented with bas-reliefs, heraldic devices, &c. in bronze, all of which has been fitted into its place and found satisfactory, excepting, as above stated, the culminating feature. It seems rather odd that a sculptor and an architect should not be able to make both ends meet better than this.

THE more serious portion of Mr. Harry Furniss's collection of sketches, called "Politics and Society," to be seen at 25, Old Bond-street, is the best worth looking out. The ultra-comic outline sketches of scenes in Parliament, which often figure as the headings to *Psyché's* "Essence of Parliament," are well enough there, but not worth collecting, with two or three exceptions. It is otherwise with the single-figure sketches of Members, which have appeared as cuts in that same series of humorous summaries of Parliamentary pro-

\* Since the above Note was written the cresting has been removed.

ceedings, and which occupy the whole lowest line on the walls all round the room. Except that the heads of the figures are of exaggerated size in most cases, these can hardly be called caricatures; they only just emphasise the special character of each Member's physical composition, and in some cases (which it would be rather unkind to name specially) Mr. Furniss can hardly be said to have gone beyond nature at all. The whole of these little very personal sketches, which look a great deal better in the original drawings than in their necessarily rather reduced reproductions in *Punch*, are full of keen observation and clever satire, but we can hardly join with some of our contemporaries in calling it "good-natured" satire; at all events, we do not imagine that will be the view taken by the originals of some of the sketches. Among the perfectly serious portrait studies are some very fine ones, among which we may mention the "Earl of Iddesleigh" and the "Marquis of Salisbury" (20 and 31), done for the *English Illustrated Magazine*; "Two Lord Chancellors" (218) for the same publication; "Last Visit of Lord Beaconsfield to the House of Commons" (232), done for *Harpur's Magazine*, and "A Jubilee Council of Past Masters" (266) drawn for *Punch*, but which is serious enough, and in which Mr. Furniss has rivalled Mr. Tenniel in the latter artist's own line.

IN reference to the question of giving plans of theatres with the playbills or admission tickets, which has been recently suggested, it appears that this is the constant custom in America, and a correspondent has sent us two playbills of the Casino Theatre, New York, and another house, containing plans of the respective houses with brief descriptions of the exits and where they lead out to. As we have said, this is a good thing to do, and a practice that might very well be adopted generally, and then people with any common sense and presence of mind would know which way to turn if there were an alarm, and might, perhaps, assist in guiding others. We are still of opinion, however, that those who are able or likely to make any use of such plans form a very small proportion indeed of an average theatre audience.

#### "AT OUR COURT AT ST. JAMES'S." THE QUEEN'S JUBILEE PRESENTS.

By admission into St. James's to see the Queen's Jubilee presents the public are enabled to pass through some of the most interesting portions of the Palace. The crowd are formed into a queue in the Colour Court, wherein until of late years the Palace guard used to be relieved every morning. On the right, above the modern Ionic colonnade,\* is part of the Chapel, dating back more than 350 years ago. Here, too, may be seen some earlier portions of the main gate-house, its turrets denuded of the customary leaden "types," or cupolas, which is attributed to Holbein. It was ornamented with love-knots that commemorate a time when Anne Boleyn's star had risen. The clock was made by Clay in 1731; new dials were inserted at the repairs to the gate in 1831. Ascending the principal staircase, the public enter the suite of rooms which are now used for Leveson only, since the Drawing-rooms have been held at Buckingham Palace. At the head of the staircase is the Guard Chamber or Armoury, opening into the Tapestry, or old Presence Chamber. The tapestry was worked for King Charles II., and delineates a, to him, highly-congenial story. The Tudor chimney-piece, in stone, of this chamber bears, amongst other devices, the initials "H. A." From the bay-window, on the left, it has long been customary to proclaim the sovereign on accession to the throne. This window overlooks what used to be known as the Chair Court, and the roadway into the Mall. The roadway has been laid through the former Friary garden, appertaining to the Capuchins, who came hither in the train of Katherine of Braganza. Pepys recounts his visits to "the new buildings," whereof the chapel was, *temp.* William III., assigned to a

congregation of French refugees. It has been rebuilt as the Lutheran or German Chapel. A part of the Palace's north-eastern wing, by the chapel, was burnt in January, 1809, and not reconstructed. According to an old bird's-eye view, the road into the Mall ran a few yards to the east of its existing course.

Next come, in the order named, Queen Anne's Room, the Red Drawing-room, and the Throne Room, or Presence Chamber. Into the furthest apartment was carried Dr. Johnson, in his infancy, that he might be touched by Queen Anne. His gold touch-piece is preserved in the British Museum. This suite of rooms, facing southwards, ranges along the garden evenly with the Mall. To the left is the park gate, at which, on August 3rd, 1786, Margaret Nicholson attempted to stab George III. Beneath the garden wall is a raised mound or terrace. This may be a continuation of the raised walk which Nell Gwynne had made for her in the garden of her second house in Pall Mall, being that whereupon she would stand to talk with King Charles as he sauntered in the park. Beyond the Throne Room is an ante-chamber, at the south-western angle of the building, wherein at ten in the morning of Trinity Sunday, June 10th, 1688,—a day long kept sacred by his faithful adherents,—was born "the most unfortunate of princes, destined to seventy-seven years of exile and wandering, of vain projects, of honours more galling than insults, and of hopes such as make the heart sick."\*

Northwards from the Throne Room stands the Corridor, forming a side of the Engine Court, and bearing on its inner walls the portraits of Henry, Prince of Wales, and all our sovereigns from Henry VIII. to Queen Anne. These are by or after the old masters. The light-coloured hair of King James II. is noteworthy, as also the tall, large person of Queen Mary, his daughter, which, as contrasted with her husband's smaller frame, is strikingly emphasised by their waxen effigies at West Minister. From the corridor we pass through a lobby or ante-chamber into the Banqueting Hall, which was erected in 1822, and is lighted by gas. It contains some paintings of military scenes, including a copy of Raffaele's Battle of Constantine, in the Vatican; Lillie, Tourmay, Vittoria, the death of the Duke of Brunswick at Quatre Bras, and Sir Charles Napier's defeat of the Amerees at Meaneo, in the Scinde war of 1843. Thus we quit the Palace by the Ambassadors' staircase, having the chapel now to our right, over against the apartments of H.R.H. the Duchess of Cambridge. That block of buildings abutting against Cleveland-row occupies the site of the Guards' sutling-house, and was built for Frederick, Prince of Wales, on his marriage. The Chapel Royal stands over the site of that of the ancient hospital, whereof the precincts extended northwards to near the end of Arlington-street. In the course of enlargement by Sir Robert Smeike in the year 1836, several remains of the previous structure were discovered. The ceiling is said to have been designed and coloured by Holbein, but it has been repaired and repainted often enough since his day. The register records the marriage, on the 24th of February, 1676, of Sir Christopher Wren to his second wife, Jane Fitzwilliams (Peter Cunningham).

Situated within the ancient Manor of Eia, the site of the Palace and park forms portion of that dismal swamp which lay about the Eya hook, or Tyburn, and retained here and there traces of the dense thickets to the north and west of London which King Offa of Mercia cites in his charter to Westminster (785). In such a watery waste, itself adjoining to Pollenstock and the Bulinga Fen,† as being then sufficiently remote from town was founded,—we cannot say precisely when, but anterior to the Conquest,—an hospital, dedicated to St. James-the-Less of Jerusalem, for "fourteen poor sisters, maidens that were leprose, there to live chastely and honestly in divine service" (Stow). The pristine endowment of about 160 acres was subsequently increased by pious citizens to the extent of nearly 320 acres of fields about Westminster, together with 80 acres of land and wood in Hampstead, Hendon, and Chalcott (Chalk Farm). Meanwhile, a brotherhood of six clerks and two laymen had been set

up for the conduct of religious offices. King Edward I. not only confirmed these gifts, but, in rivalry with his subjects, granted (1290) a fair, to be celebrated in St. James's-fields, to begin on St. James's Eve, July 24th, and to continue during five days. The profits of toll, and hire of booths, &c., went to the sisterhood, and, moreover, it was decreed, in their behalf, that all shops in the City of London should remain closed for the while that this fair lasted. The fair was revived in the fields north of the present Piccadilly by King James II., who ordained that it should be open during the first fifteen days of May, thus giving a name to the quarter now known as Mayfair. In the reign of Henry III. the hospital was rebuilt by Berkyn, abbot of West Minister (1222-46). Henry VI. bestowed its perpetual custody upon Eton College, which to this day owns much of the property, locally styled South Hampstead, beyond Primrose Hill. On succeeding to Walsey at York Place, King Henry VIII. coveted the prospect that stretched westwards to the view from his new Whitehall. So in 1532 he compounded with the authorities of Eton College, and in exchange for the Leper Hospital, then valued at 100*l.* a year, gave to them Chatsworth with other property in Suffolk. In the charter of feoffment, statute 23 Henry VIII., c. 21, in conveyance from Abbot Islip (1500-1532) to Henry VIII., is mentioned an ancient landmark, Eye Cross. This stood alongside of the Eya hook, on the confines of the hospital meadow. Some would connect it with the stone cross near to which our Norman kings held their *placita* or public courts and assemblies,—a relic of the Frankish *jours de Mai*. In many records, 22 Edward I. *placita quo warranto*, for example, these are said to have been held "apud stone cross in county Middlesex." About this time, too, the king had from the monks at Westminster, in lieu of their Benedictine cell or chantry at Hurley, Berkshire, some 100 acres, part whereof he converted into the modern St. James's Park. The cell at Hurley had been dissolved by Wolsey for his project of endowing colleges at Ipswich and Oxford. On the eastern verge of his park the king set up a tennis-court, cockpit, howling-green, and tilt-yard, and, at the further corner, built himself a new house over the hospital site. He assuaged all compunctions of conscience in granting "by his especial grace and his own pleasure" an annuity of 6*l.* 13*s.* 4*d.* to one inmate of the Spital, Jane Harwood by name.\* This is the "faire mansion" cited by Holinshed,—at first known as the Manor, or St. James's, House, shown in its original shape in Wynogarde's view of London, and more clearly in his separate drawing bearing date 1558. Some hold that Holbein, who died 1543, planned the buildings, and that Cromwell, Earl of Essex, superintended the works. What the latter describes as the "sumptuous wall of brick" wherewith Henry enclosed his demesne is mentioned in the statute 25 Henry VIII., c. 12, for determining the limits of the royal palaces in Westminster. The Act releases that the sovereign "therunto adjoining has made a park, walled and environed with brick and stone, and therein has devised and ordained many and singular commodious things, pleasures and other necessities, most apt and convenient to appertain only to so noble a prince, for his singular comfort, pastime, and solace." It will be remembered that he dealt in the same princely fashion with the parks of Marylebone and Hyde. Of the necessities we will say nothing,—the other uses for which the park was devised were amply vindicated by Henry and his successors on the throne.

St. James's Palace has none other rival than Windsor in fulness of its chronicles concerning the domestic annals of our dynasties of Tudor and Stewart, Orange and Guelph. It has witnessed the deaths of Mary I.; of Henry, Prince of Wales, after two years' residence; of Anne Hyde, Duchess of York; and, under circumstances of unusual fortune, of Wilhelmina Carolina of Anspach, wife to George II. During the period 1638-41 Marie de' Medici found refuge † in the home of her daughter, the "Rose and Lily" Queen, who here gave birth to Charles II., his brother James and his sister Elizabeth. As in the case of the

\* Lord Macaulay's "History of England," chap. viii.

† This fen (Tobhill) and the Cufords (Cowford, in the Green Park) are set out in King Edward's delimitation of the Minster Manor,—A.D. 951. But Kemble dates this twenty years later.

\* Rymor's "Fœdera," xiv., fo. 563.

† There is extant a small contemporary print showing the Colour Court, and how "La Reine d'Angleterre" se jette sur pieds de la Reine sa mere's son arrivée dans les Palays de St. James."

Tower, this palace has been a prison King Charles was brought hither from Windsor (January 19th) for trial in Westminster Hall. On Monday, the 29th of January, he bade farewell to his captivo children, Henry and Elizabeth, the others being out of the country. The following day, at about ten a.m., he started to walk through the snow to the scaffold before Whitehall, stopping on the way for a cup of water at the Spring Garden by a tree he and his elder brother had planted there. The Loyalist Duke of Hamilton, Arthur, first Lord Capel, and Henry Rich, Earl Holland, underwent imprisonment in St. James's prior to execution of their sentence in New Palace-yard.

At night-time of November 4th, 1677 the Princess Mary was married, in her bed-chamber, to William of Orange. The chapel she subsequently decorated with the flags captured from her father's forces at the Boyne. Here, also, her sister espoused Prince George of Denmark, and here were married two of George II.'s daughters—Anne, Princess Royal, to William, Prince of Orange (1734), whom she determined to have, "even if he were a haubon," and Mary, to Frederick, Landgrave of Hesse Cassel (1740). Their sister, Caroline, died in the palace, comforting herself by deeds of charity, for an unfortunate attachment to Lord Hervey—"Pope's "mere white crnd of ass's milk." In this chapel, also, have been celebrated the nuptials of Frederick, Prince of Wales and Augusta of Saxe-Gotba; of George IV. and Caroline of Brunswick; and of her present Majesty, and Victoria, the Crown Princess of Germany.

Having thus recalled some of the history and associations of the building, we may proceed to some consideration of its present contents, regarded from an artistic point of view. This, to be sure, is not the point of view of most of the visitors, for among the immense crowd of persons who are daily struggling, in a quiet and good-humoured way, through the barriers in the courtyard of the Palace, up the staircase and round the rooms, there are probably very few who care one jot about the artistic qualities of what they see. Indeed, if one might judge solely from the remarks overheard, "certainly" would be a better word than "probably." Curiosity, especially about what is connected with royalty, a love of what is costly or magnificent, a loyalty none the less real because shown in a way which benefits rather themselves than the object of it, and a mere desire for something new, are the feelings which guide most of the feet that pass to St. James's Palace just now. There is, nevertheless, a good deal to be seen there that might tempt the lovers of art and beauty. Apart from the exhibition altogether, there are some good pictures on the walls of the rooms, especially portraits, some of them by artists whose names alone must attract attention, and whose work one ought to see when an opportunity like the present occurs.

The first room at the head of the staircase entering is hung round with snits of armour, in which there are three valuable presents to Her Majesty from Indian potentates. One of them is a suit of horse trappings of surpassing magnificence, and the others are trophies of enormous elephant tusks mounted upon rose-wood stands and covered with golden ornaments, very costly, carved with wonderful skill, and beauty of a sort,—but entirely barbarous in conception. These are the presents of the Maharajah of Travancore. In the second room is some old tapestry. The third is fitted with glass cases containing a variety of costly objects, among which we noticed the following as of some artistic value also: a large and beautiful embossed silver bowl, presented by Lord and Lady Rothschild; an enormous centrepiece and vase wrought in steel, with some beautifully-executed medallions containing figure subjects, and some fine damascened work in gold and silver; a tall silver and silver-gilt vase presented by the King and Queen of the Belgians, very beautifully designed and executed; and a simple but exquisitely-formed silver bowl embossed in the style of the last century, presented by the boys of the Charterhouse, perhaps the best piece of English silversmith's work in the room, as far as refinement of form and ornament are concerned. In the same room is a finely-designed and executed vase in dull silver supported by four small unde figures well worthy of their Italian origin. The vase is the present of our fellow-subject resident in Italy. Another case contains, among other things, a pair of beautiful vases from the Worcester

potteries, ornamented with a delicate foliage pattern of Persian character. The commercial element crops up in this room in the form of a case of presents from manufacturers of Turkey towels, colours, &c., consisting of samples of their wares. Near the door hangs an embroidered quilt from Macclesfield, with some beautiful work in the borders, but the centre exhibits the crown in a nimbus of rays, and tbat it was that attracted the attention of several persons as we stood by it, not the borders. In the third room the first object to attract attention is a portrait in oil of the Maharanee of Travancore, presented by herself. If it is a faithful witness she must be a very charming person. In this room are a large number of presents from India, consisting chiefly of chased silver jugs, caskets, and cups, mostly very delicately chased in the well-known patterns of which as yet, at any rate, one does not tire. Many are set with turquoise pretty thickly sprinkled, and looking very well in the silver. There are some carved ivory caskets; two of them, from the Maharajah of Kuch Behar and the inhabitants of Bombay, show distinct traces of European influence, but we could not say certainly that they are the worse artistically. One silver casket is in the form of a temple, and there is the model of a palanquin in silver, beautifully executed, and decidedly pretty enough to excuse the puerility of the design. In one case are a number of Indian inlaid and damascened boxes and vases of good shapes, and at the end of the room the Pope's present of a capital copy in mosaic of very small cubes of Raffelle's figure of Poetry in the Stanza of the Vatican, which it is unnecessary to describe.

The next room, which is the throne-room, is chiefly devoted to illuminated addresses in table cases. Most of these are of no artistic interest whatever, and one from the British Consulate at Berlin, otherwise beautiful, is spoiled by a vulgar representation of the British crown in a nimbus of gilt rays. Some ostrich feather screens from the Cape Colony, which occupy a case in the middle of this room, are marvellous in their pure feathery whiteness. In the last room but one are stacked along the wall a number of plain deal boxes containing signatures of subscribers to the Women's Jubilee Offering. The rest of the floor space is occupied by a series of screens, on which are bung collections of water-colour drawings made and presented by the members of the Royal Society of Painters in Water Colours and by the Institute of Painters in Water Colours, among which are to be seen sketches by H.R.H. the Princess of Wales and H.L.H. the Crown Princess of Germany, as hon. members of the two societies, respectively showing that these eminent ladies are at least as skilful with the brush as most good amateurs. Space fails us to mention all the well-known names of the contributors to these collections, and criticism of the few works in which the artists have failed to do themselves justice would be ungenerous. Among the best, we noticed "Roadside Pastures, Picardy," by David Murray; "A Sketch of Denn's Yard, Westminster," by Herbert Marshall; "A Surrey Cottage,"—Mrs. Allingham,—an old man sitting, with his pipe in his mouth, by the fire to have his portrait taken; "After Winter Rains," W. Eyre Walker; "Coming into Port, Venice," Clara Montalba; "A Highland Cottage," Birket Foster; two sketches by Mr. Ruskin; "Colliers Discharging," W. S. Wyllie; "Going to Church," Sir J. D. Linton; &c. In the last room is Mr. Gunter's great Jubilee cake, which looks very much as one would expect it to look, as well as some quilts and the banner used at the Children's Festival.

On the whole there, is a great deal of good work, artistically, among the many offerings by which friends, subjects, and independent admirers have testified their appreciation of a sovereign whose long reign has been productive of so much good to her people, and whose personal character has endeared her to them. English artists, too, may congratulate themselves upon the notably superior artistic character of work produced at home over that which has been sent from most other countries.

**Builders' Benevolent Institution.**—The fortieth annual dinner in aid of the funds of this excellent charity will take place on Thursday evening, Nov. 3, in the Hall of the Worshipful Company of Carpenters, London-wall, Mr. Herbert H. Bartlett, President, in the chair.

FLOOD PREVENTION WORKS AT LEICESTER.

LEICESTER has until within the last year or two suffered for very many years from the flooding of the surface of the streets in the lower portions of the town; and entire districts thickly populated (chiefly by the working classes) were, from time to time, inundated; but the several mill-owners along the line of the river Soar, and the canals passing through the town, have also been largo sufferers through their mills being flooded and by large and valuable stocks of goods being damaged or spoiled, to say nothing of the number of hands thrown out of work during the inundations, and the sickness and loss of health resulting from the occupancy of the flooded dwellings, which were for months afterwards damp and a source of danger to the inmates. The immediate danger has been met as promptly as circumstances would admit of by the cleansing of the cellars and ground-floors of the dwellings, by the removal of the mud and filth left behind on the subsidence of the waters, and by the use of disinfectants; but it is not to be wondered at that before much could be done the health of the occupants of the flooded houses should have suffered. That the constant recurrence of such inundations has given rise to loud complaints, and been followed in each case by public meetings urging the Corporation to adopt comprehensive measures of relief, is only what might naturally be expected to occur on the part of the inhabitants of any district subject to such inundations.

The Corporation have, in fact, had the subject before them from time to time for the past thirty years. The first report was made to them in November, 1853, by Messrs. Crossley & Foxton, and this report was reprinted in 1861, and again in 1867. In 1869 Messrs. Hawkshaw & Hawksley reported on the subject, and the late Borough Surveyor reported thereon in 1872.

Acts of Parliament were obtained in 1868, 1874, and 1876 for dealing with the lower reaches of the river, and the sum of about 124,400*l.* has been expended in dealing with the river from a weir constructed in 1875 at Messrs. Evans's Mill to the Belgrave Mill, a distance of 130 chains, and in dealing with the canal from the Lime Kiln Wharf, also to the Belgrave Mill, a distance of 70 chains, including the lowering of the Willow Brook from the Lime Kiln Lock to the Midland Railway, a distance of 60 chains, in connexion with which latter work a new bypass for a distance of 220 lineal yards through Wood-street, and an additional tunnel 100 yards long under the Midland Railway goods yard, had to be constructed.

The first works undertaken under the 1868 Act, namely, the widening of the Swans' Nest Grass Weir, the construction of sluice gates and cutting of a new channel from Swans' Nest Weir to the Belgrave Mill, a weir at Evans's Mill, and a new flood river channel to Hitchcock's Weir, and the widening of the river beyond, towards Thompson's Factory, have since proved inadequate, and another new weir and further widening of the river between Evans's Weir and the North Bridge have been carried out under an Act of Parliament obtained in 1881, while a new stone weir has taken the place of the Swans' Nest Grass Weir, and the river has been farther widened between it and the Belgrave Mill under the 1874 Act. Fig. 1 is a map showing the works from the North Bridge to the Freemen's Meadow.

The works executed under the 1874 and 1876 Acts are of an extensive nature, and for this account of them, and of the further works, we are indebted to Mr. Gordon, the Borough Surveyor. The works done under the two Acts named consist of a practically new river channel varying from 80 ft. to 90 ft. bottom width, with pitched slopes 2 to 1, and in the lower reach with extra flood slopes giving an increased width of 45 ft. of river in floods. From Evans's Weir to the new weir, which has been constructed at the Abbey Corner in connexion with the new park, the water has been lowered 3 ft. 6 in. From this latter weir to the Swans' Nest New Weir, constructed at Belgrave, the water has also been lowered 3 ft. 6 in. The works have been carried beyond the horongh boundary to the Belgrave Mill, where a new towing-path bridge of 100 ft. span across the river has been erected.

Starting back from the New Swans' Nest Weir, where a new lock has been constructed

at a lower level, a new channel has been cut for the canal until the old line of canal is intersected, which has been regulated, widened, and deepened, and is practically a new canal at a 3 ft. 6 in. lower level for a distance of 70 chains up to the Lime Kiln Wharf, where another new lock of 3 ft. 6 in. lift has been constructed.

In connexion with these works a new road 1,000 yards long has been constructed from what was formerly called Sidney-street (but now the Abbey Park-road), right across the Abbey Meadow, and along by the old abbey wall to the abbey lane. Two bridges have had to be constructed for this road, one across the canal, of 45 ft. span and 30 ft. between the parapets, and the other across the river, of three spans, viz., two of 30 ft. and one of 40 ft., also with 30 ft. width between the parapets.

The road along the abbey wall, and at the other end from Belgrave-road to the first bridge, is 40 ft. in width, but between the bridges along the whole length of the park it is 50 ft. in width. These works were originally designed by Mr. Stephens, the late Borough Surveyor, and the detailed plans were worked out by Mr. Hewet, C.E., under Mr. Stephens's directions. The execution of the works was eventually entrusted to Mr. Griffith, C.E., and have been carried through by him under the direction of the Flood Works Sub-Committee, with the exception of the formation of the road between the Belgrave-road and the Abbey-lane, which was carried out under the direction of the present Borough Surveyor, Mr. Gordon, C.E., by Corporation workmen. The works carried out

under the direction of Mr. Gordon by Corporation workmen, under great pressure, in order to be ready for the opening of the park by their Royal Highnesses the Prince and Princess of Wales, in May, 1882. The whole of what is called St. Margaret's Pasture, across which this road runs, has been raised to the level of the new road since, and is now used as a recreation-ground. A new bridge has also been constructed by Messrs. Shaw & Co., of London, across the canal, 40 ft. in width between the parapets, together with improved approaches from Pasture-lane and Lower Church-gate, under the direction of Mr. Gordon, the Borough Surveyor. The expenditure upon the Abbey Park-road, Slater-street extension, Pasture-lane Bridge, and approaches, not included in the previously-mentioned sum, amounted to about 6,000l.

The important works now in progress were lately visited and inspected with much interest by the members of the Association of Municipal and Sanitary Engineers and Surveyors, of which body Mr. Gordon is this year the President. An extraordinary flood having occurred in July, 1880, which flooded about 422 acres of land and streets in the upper reaches of the river above the point to which the River Improvement Works had been carried, the Highway Committee instructed Mr. Griffith to report upon the best means of preventing future flooding. He reported on 23rd August, 1880, and his report was then submitted to Mr. Hawksley, who approved it generally, with some modifications. A Bill was then deposited in Parliament under the advice of Mr. Hawksley,

ironwork of the towing-path bridge across the new weir and the entrance to Mr. Hitchcock's basin was let to the Bridge and Roofing Co., of Darlaston, for 819l. Soon after Messrs. Kellett & Bentley's contract was commenced, the two-span bridge, erected in 1875 over the flood course at Soar-lane as a roadway-bridge to the Midland Railway goods and coal wharf, was washed down, or rendered so dangerous, by the effects of a flood which occurred in 1882, that the portions of it left standing had to be taken down. Under the Act of 1881 it was intended to add another span to this bridge, but this calamity rendered it necessary to build an entirely new bridge of three spans, and the case being pressing, a separate contract was advertised, Messrs. Kellett & Bentley being again the successful contractors. In the meantime the traffic had to be carried on across the adjoining railway bridge. The addition to this latter bridge, with retaining walls and the inverting of the river bed in connexion therewith, was also let to Messrs. Kellett & Bentley.

This section of the work embraces, in addition to the bridge work mentioned, the widening of the flood course for a distance of 533 lineal yards between the Soar-lane Bridges and the North Bridge from the original width of 45 ft. to a width of 75 ft. and 95 ft., the necessary land for the purpose having been obtained from Lord Dysart on the north side, and from Mr. Hitchcock on the south side.

The slopes of the river channel are pitched with rough-dressed granite pitching, 12 in. deep, set with blue has lime to a height of

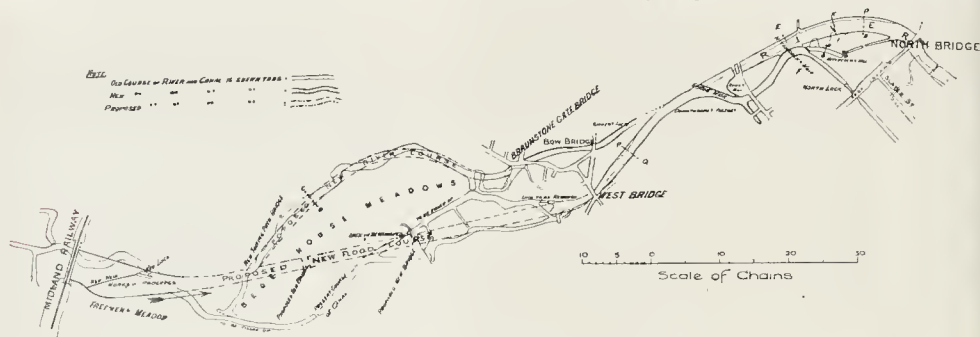

Fig. 1.—Map showing the Leicester Flood Prevention Works from the Freeman's Meadow to the North Bridge.

under the 1868 Act were executed by Messrs. Smart & Thumb, of Nottingham; and Mr. John Lea, of Leicester, carried out the new weir at Evans's Mill and the flood-channel in connexion therewith under the 1874 Act. Messrs. Benton & Woodiwiss, contractors, of Derby, executed the works on the river between the North Bridge and Belgrave Mill, including the weir in connexion with the park, the new bridges at the Abbey Corner, and across the canal, also the New Swans' Nest Weir and the canal lock in connexion therewith. The towing-path bridge at Belgrave was erected by Messrs. Richards & Sons, of Leicester. Messrs. Whitaker Bros., contractors, of Leeds, carried out the canal works, including the new lock at the Lime Kiln Wharf.

The new park has been formed upon about 68 acres of the Abbey Meadow, which was subject to constant flooding, but was drained by the lowering of the weirage, while the surplus soil arising from the river excavations was used to form embankments round the park, and also to form mounds and undulations to give artistic effect to the design of the landscape gardeners, Messrs. Barron & Sons, of Elvaston, Borrowash, near Derby, who obtained the premium awarded for the best plans of the park in a public competition, and were entrusted with the superintendence of its laying-out and construction, and with the planting of the whole. The draining, formation of the roads, and other earth works, were carried out by workmen in the employ of the Corporation, under the direction of Mr. Griffith and Messrs. Barron, and the lodges and pavilion were erected from the designs and under the direction of Mr. Tait, architect, Leicester. The total cost of the park works was about 29,340l., exclusive of land. The new road, 520 yards long, from Slater-street to the western entrance, was constructed

The Bill received the sanction of Parliament in July, 1881. Mr. Gordon had in the meantime taken office as Borough Surveyor, under the obligation to take charge of these works in addition to his other official duties; but, as nothing farther than Parliamentary plans had been prepared, nothing could be done until a complete survey on a large scale and detail plans had been made, which, owing to the greater intricacies of the work, and interests involved, was likely to occupy some time. Some of the works under the former Acts, more especially the Canal and Willow Brook Works, and the formation of the Park, were then in full swing, and great efforts were being made to get the latter ready for opening in May, 1882. Little progress was therefore made with the preparation of plans for the new flood works until the new Borough Surveyor was requested to report on the condition or state thereof, when he recommended increased assistance to push them forward. Towards the end of 1882 some time was also lost by an alternative scheme being again revived, on which Mr. Gordon was requested to report, as well as on the probable efficiency of the Parliamentary scheme generally.

A commencement was made in July, 1882, by the lowering of the North Lock, the contract for which, with towing-path wall in connexion therewith, was let to Messrs. Whitaker. The Castle Mill Lock was also lowered at the same time to enable the canal traffic to be carried on when the water was lowered in the town pond to the proposed level of the new weirs. The next contract was let to Messrs. Kellett & Bentley, in April, 1883, for 13,900l. Further works were subsequently let to them, bringing up the value of the works undertaken by them to 20,658l. In connexion with this section, the

3 ft. 6 in. above the water level, or 6 ft. 6 in. above the bed of the river, the remainder of the slope being turfed. The slope is 2 to 1 on the north side, and on the south 1 1/2 to 1 along the Midland Railway Company's wharf, varying along Mr. Hitchcock's garden from a battered wall to a slope of 1 1/2 to 1. Beyond this, along the land of the trustees of the late Mr. Ahell, the slope is 2 to 1. In Mr. Hitchcock's garden two bays or arms of the river, the one forming the overflow from the old weir, and the other from four flood-gates, widened out towards the present line of river, and were washed into deep holes, so that the intended pitched slope across these bays had, in reality, to be made more of the character of a strong retaining-wall with a stiff batter, and this had to be continued, in a modified form, all along these premises, as the intervening ground was found to be all made ground of a somewhat treacherous character. The backing up of this pitching, which, in this case, is carried up to the ground-level, consists of lias lime concrete, and is of considerable thickness.

Near to the North Bridge the whole of the works of Messrs. Thompson had to be underpinned for a depth of 5 ft. Those of Messrs. Hawley, Mr. Hollingworth, and Mr. Forsell, had also to be underpinned along the Tail Race of the North Mill, and a new retaining-wall and brick invert had to be constructed in connexion therewith, owing to the immense scour of the water in a flood over a weir which had to be constructed between the higher and lower levels of this race having undermined the foundations.

The new weir constructed at the west end of Mr. Hitchcock's garden is intended to pass the flood waters flowing past the weir higher up the river and through the bridge of the railway company along the canal towards the North

Lock, and will act as an auxiliary to the weir at Evans's Mill. It consists of four spans, each of 50 ft. in the clear, with ashlar piers to carry the wrought-iron towing-path bridge over it, and will pass 130,674 cubic foot per minute with a head of 2 ft. of water on the crest, notwithstanding that it is calculated that the latter will be drowned to the extent of about a foot in an extreme flood. The fall from the crest of the weir to the water below at summer level is 5 ft. 5 in., the depth of water on the low side being 3 ft., and on the high side 5 ft. 6 in. The foundation and body of the weir consist of cement concrete in the proportion of 9 to 1 and 6 to 1, faced with Derbyshire ashlar block-work, the crest stone being granite, hammer-dressed, 3 ft. 6 in. wide and 1 ft. 6 in. deep. The bed of the river for the whole width of 100 ft. opposite this weir from the toe stone of the weir to the opposite bank, consists of cement concrete varying in thickness from 2 ft. 6 in. to 1 ft. 6 in., and forms therefore an extended apron to the weir. This was found to be necessary owing to the bed of the river consisting of gravel at the level at which it had to be formed. (See cross section, fig. 2.)

At the east end of the weir a new loading basin has been formed for Mr. Hitchcock, of the North Mill, the old and irregular form of the basin having been abandoned at the request of that gentleman, who contributed the increased cost involved. The new walls of this basin are constructed of lias lime concrete faced with brindle brick. The entrance to it from the

pipe from the river, and the construction of a new well in the centre of big ground.

The next contract was let in September, 1883, to Messrs. Pilling & Co., of Manchester, and was for that section of the works between Soar-lane and the West Bridge on the one hand, and the Brannstone Gate Bridge on the other, amounting to 28,000*l.*, but to which other works were added under their schedule, and, including another section of the river up to what is known as the Grass Weir, bringing up the total amount of work executed by that firm to 41,473*l.*

This contract included the widening and deepening of the Leicester Navigation from Soar-lane to the West Bridge; and the widening and deepening of the river Soar from its junction with the Leicester Navigation to the Brannstone Gate Bridge, and all works in connexion therewith. It embraced the following works viz.:-

1. The underpinning of the whole of the buildings abutting on the river Soar between the Brannstone Gate Bridge and the eastern corner of Messrs. Turner's factory, together with such new retaining walls as were required along the route.

2. The providing of an additional flood arch at the Bow Bridge.

3. The diversion of the river in an oblique direction by means of two covered outlets, or tunnels, each of 22 ft. span, for a length of 220 ft., under the Midland Railway West Bridge, station yard, and sidings, in lieu of the old wooden structure, which was almost at right

near Mr. Hitchcock's basin, in time of flood discharge 260,793 cubic feet per minute without the aid of flood-gates. Four sets of flood-gates have, however, been placed in this weir, each 6 ft. broad by 5 ft. 7 in. in height. Two of them are placed in the bay next the Midland wharf, and two in the third bay from the eastern abutment. Part of the outhouses of Evans's Mill have been taken to give a better water-way for this weir, and land at the eastern end of the weir, which could not be utilised for weir purposes, has been given up in exchange. The weir and the towing-path and retaining walls are of similar construction to those previously described.

The underpinning has in all cases been done with brickwork in Portland cement, and faced with brindle bricks to the height of the water-line. The entire bed of the river between the toe of the weir to and through the Soar-lane Bridge is lined with 9 in. of brickwork in cement on a bed of 15 in. of lias lime concrete, the finishing ring of brickwork being brindle brick. There are 4,879 square yards of this class of work below this weir, forming one continuous apron through the bridges.

In widening the canal above the weir, part of the old station, and more particularly a portion of the original hoard-room and hirth-place, it may be said, of the Midland Railway Company, had to be demolished, together with stabling and storage buildings, while for the diversion of the River Soar under the railway, cottages and other stabling were acquired and removed.

Fig. 2.—Cross Section of River Soar Improvements on line EF of Map through Hitchcock's Weir. (N.B.—For "Lime Concrete" read "Cement Concrete.")

Fig. 3.—Cross Section of New Weir on the River Soar at Leicester, opposite to the Freeman's Meadow (see Map).

canal is spanned by a wrought-iron bridge of 70 ft. span in continuation of the towing-path, and giving a clear headway of 8 ft. for hosts and barges passing into the basin.

Between Soar-lane and the North Lock the canal has been widened and deepened, with the object of giving increased sectional area and lowering the water to the extent of 1 ft. 10 in. The depth of water at the lower level is 5 ft. 6 in., although the original depth was not more than 4 ft. 2 in., so that the bed of the canal has been lowered about 3 ft. 2 in. The increased sectional area thus gained and the lowered level of the water will, it is anticipated, fully prevent future overflowing of the river and flooding of the district. New towing-path walls have been constructed throughout the whole of this length, consisting of cement concrete, the length between Soar-lane and the new weir being faced with brindle brick, that between Hitchcock's basin and the North Lock being floated and rendered with cement and lined. On the opposite side, along the Midland Railway Co.'s wharf, a similar wall has been constructed, but of lias lime concrete, all these walls being coped with a heavy ashlar coping.

Heavy underpinning works and new retaining walls had to be executed in connexion with Messrs. Collier & Messrs. Bowmar's premises adjoining the North Lock. New intakes and water supply works, consisting of wells and settling-tanks, had also to be carried out in connexion with these works, and similar works have had to be executed for Mr. Hitchcock, including in this case the laying of a 12-inch

angles to the canal and railway, and which caused such serious obstruction to the flow of water in the past.

4. The widening of the river between the Bow Bridge and the above outlet on land taken from the railway company, and the construction along such length of a heavy retaining wall with a protecting railing along the top thereof.

5. The widening and deepening of the canal from the West Bridge to Soar-lane, the land required for these works being taken from the Midland Railway Co.'s West Bridge Station at great cost.

6. A new towing-path wall constructed from the West Bridge to Evans's Weir, beyond which, for a length of 110 yards to Soar-lane Bridge, the height of the retaining wall is 16 ft. above the bed of the river, protected by an iron railing.

On the opposite or east side of the river various new river walls have been constructed and a considerable amount of difficult underpinning of buildings completed. For a length of 120 ft. at the back of houses in All Saints' road and All Saints' place, it was thought advisable to take down the outhouses, in the shape of wash-houses, water-closets, and ashpits, resting on the river wall, and to rebuild them after a new retaining wall had been built, rather than attempt to underpin the old wall and buildings.

The new weir at Evans's Mill consists of six bays or spans, each 50 ft. in the clear, with ashlar piers between them to carry a wrought-iron towing-path bridge. This weir will, therefore, with a head of 2 ft. 6 in. of water on it, acting as a drowned weir, as in the case of the weir

The additional section added to this contract already referred to was a very expensive diversion of the Old Soar from the Brannstone Gate Bridge to the Grass Weir, including the bridge, which is 45 ft. span and 220 ft. in length, and the cost of which was 7,310*l.* The additional cost of this section, including the bridge, was 10,763*l.*, bringing up the expenditure under the 1881 and 1884 Acts, to 110,000*l.* This includes, however, lands purchased under compulsory powers not yet dealt with, and from the sale of which there will be a surplus which will go towards the works yet to be executed.

The extreme length and peculiar construction of the above bridge arose from the necessity of improving the flow of the river, which formerly crossed Brannstone Gate at right angles through the old Roman bridge, and also from the need of providing for a new road to open up land belonging to the Corporation, being at the same time the commencement of a much-needed means of communication between the eastern and western portions of the town.

The works of the upper reach now in progress and partly let, and for which further borrowing powers to the extent of 60,000*l.* under an Act of 1884 had to be sought, consist of making an entirely new river channel about a mile long in lieu of the present canal from the West Bridge to the viaduct of the Burton Branch of the Midland Railway, and of widening and deepening the river Soar for a length of 920 yards from the Old Grass Weir to the junction with the aforesaid new river channel at a point near the present bathing station. The present Castle Weir and lock will both be done away with

entirely, and the water above this point lowered to the extent of 4 ft. 10 in. for a distance of 483 yards up to the Swans' Mill Lock, which will also be done away with, and the level of water in the canal lowered to the extent of 7 ft. 6 in. from this point upwards for a distance of 1,000 yards to the new weir and lock, with a lift of 7 ft. 6 in., now being constructed at about 130 yards from and below the railway viaduct, opposite the Freeman's Meadow (see fig. 3). This channel, which is to answer as a navigable canal, will be in one pond or level throughout, and will be capable of carrying a maximum flood to the point at which the old Soar branches off, and two-thirds of the flood water below that point. It will have a bottom width of 60 ft. for the latter section, with slopes of 2 to 1, pitched with granite pitching 12 in. deep to a height of 4 ft. above the water-line on the one side, whilst on the other side there will be a concrete towing-path wall faced with brindle brick and provided with a Derbyshire stone coping, finished 2 ft. above the ordinary water-level. The towing-path will be 10 ft. wide, and the slope on the west side thereof also 2 to 1. The slopes on both sides of the flood course will be carried up to a height of 3 ft. 6 in. above the anticipated flood level.

The old river Soar proper will be intersected by the new flood course about 170 yards to the north-west of the present stone weir, and will be regulated and deepened with a bottom width of 30 ft. and slopes of 2 to 1 from this intersecting point down to the Old Grass Weir, which will be demolished, and the surface-water level of the river lowered to the extent of 4 ft. 10 in. for a distance of 920 yards, making one continuous pond or level of one mile and a half in length, from the Freeman's Meadow to the North Lock.

As a part of this scheme it is proposed to widen the West Bridge, to give increased waterway, effecting at the same time a much-desired street improvement by the erection of a new bridge for a greater width of roadway, at a lower level, with an improved gradient. It is also intended to provide for other bridges along the new flood course for opening up the Corporation estate lying between the canal and river, and for which, together with new roads, the Estate Committee has made a provision of 15,000*l.* In connexion with this provision, a new road, extending from Braunstone Gate across the river and new flood course into the Newark, was projected and discussed by the Council, and plans deposited with Parliament, but eventually withdrawn. In October, 1881, a plan was prepared by the Borough Surveyor, under the directions of the Estate Committee, and approved by the Council, for other new roads in connexion with the flood scheme, but these are not included in the estimates for works now authorised farther than that no doubt some of the requisite bridges will be carried out.

The new flood course forms nearly a straight line from the proposed new weir to the West Bridge, crossing both the old river and the canal, and the works yet to be completed will have to be carried on in such a manner as not to interfere with or interrupt the traffic of the Leicestershire and Northamptonshire Union Canal.

At the junction of the Old Soar with the flood course, the towing-path will be carried over the mouth of the former by a wrought-iron bridge of 90 ft. span. The weir and lock now being constructed near the railway viaduct are similar in construction to those already described, excepting that the section of the weir and lock walls are proportionately greater, and suited to the greater lift of 7 ft. 6 in., which this lock will have. (See cross section, fig. 3.) The length of the weir will be 500 ft. clear of all obstructions, as there will in this case be no piers, as with those previously described. A maximum flood of 400,000 cubic feet per minute will give a head of 2 ft. 5 in. on the crest of this weir, thus reducing the former flood level from 2 ft. to 3 ft. on the high side of the weir, and beyond the railway to a considerable extent, even if no widening and deepening of the river and canal towards St. Mary's Mills be undertaken. The contract for this weir and lock, and the flood basins of about 51 acres in extent in connexion therewith, was let to Mr. Evans, of Birmingham, in March last, for 18,000*l.*, and will be completed in March next. It is proposed to raise the whole of the land belonging to the Corporation, and called the

Bede House Meadows, 3 ft. 6 in. above the anticipated flood level, and to form an embankment on the east side of the new flood course up to the new weir, on the high side of which the embankment will be correspondingly higher. The lowered summer water level of the whole of this section, and the reduced flood level which it is anticipated will ensue from the removal of the Castle Mill and Swans' Mill locks, together with the increased sectional area given to both the new flood course and river, will have the effect of freeing from flooding the whole of the land hitherto subject to it, and afford increased facilities for drainage, the lowering of the water and flood lines being, in fact, equivalent to a raising of the entire district several feet above the river and canal,—advantages which must result in an inestimable improvement of the sanitary conditions of the whole of the districts affected.

The money spent and to be spent upon these works for the prevention of floods has been:—

Under the Acts of 1868-1874 and 1876	£124,991
Act of 1881	85,000
Works in progress and yet to be let under Act of 1884	60,000
Roads and Bridges, 1886 Act	16,000
	£284,991
Purchase of Abbey Meadow, 68 acres of which have been devoted to the formation of the Abbey Park, for	£40,258
Construction and laying-out of park	29,340
Approaches and roads	6,900
	75,698
	£360,689

We may add that the members of the Association of Municipal and Sanitary Engineers and Surveyors were much impressed with the magnitude and importance of these river works, which are such as are seldom seen in an inland town.

## Illustrations.

### EXAMPLES OF SPANISH MEDIEVAL ARCHITECTURE.

SAN JUAN DE LOS REYES, TOLEDO.

**T**HIS church was erected by Ferdinand and Isabella in 1476, noted by Street as "the only great Gothic work in Toledo besides the cathedral." Street says, "there is a nave of four bays, a cimborio or raised lantern at the crossing, roofed with an octagonal vault with groined pendentives, quasi-transapses (they are, in fact, mere shallow square recesses), and a short apsidal choir of five unequal sides." The view, from a photograph by Laurent, of Madrid, shows the choir end of the building.

SAN ESTEBAN, SEGOVIA.

This view (also from a photograph by Laurent) shows as a main object the remarkable thirteenth-century steeple, with arches slightly pointed in the lower stage, the point apparently gradually disappearing as the work ascends, till the upper stage shows a completely round-arched arcade. Street expresses great admiration for the effective manner in which the angles are treated, not with an ordinary angle shaft, but as a large splay with a shaft set in the centre of it. The illustration also affords curious evidence of the little reliance which is to be placed on engravings made from sketches even under the best superintendence. It may be supposed that no author would have been more careful than Street about the correctness of his illustrations; yet the view in his book shows two faces of the tower, one of them the same that is shown here, with the arches in the third and fourth stages decidedly, and even rather sharply pointed; the incorrectness of which will be obvious from a glance at the illustration produced from a photograph of the actual building.

### EDINBURGH MUNICIPAL BUILDINGS COMPETITION.

We publish this week the two principal elevations submitted by Mr. G. E. Corson, of Leeds, in this competition, together with a small scale-plan of the floor on the level of the entrance from High-street.

### BRADFORD NEW POST-OFFICE.

This building has been erected on a site purchased from the Corporation, and having an area of about 2,500 yards, it being part

of the arrangement that the area in front of the new building should be maintained as an open space. The building is faced with Bolton Wood stone, the rear portions having dressings of the same, the walls being from the Heaton Quarries. The roofs are covered with Bangor green slates. The public entrance has polished Shap granite architraves, and the doors are of wainscot. The lobbies are faced with Bolton Wood stone, and doorways to the public offices are of teak, with pilasters and pediments on the inner sides. The public office is 60 ft. in length by 30 ft. in width, and has a dado of Burmantofts faience, the ceiling is panelled and ribbed, and the beams are supported by pilasters. The sorting-office, in the rear of the public office, is 155 ft. in length, with an average width of 32 ft. There are also on the ground-floor registered letter, private box, and inquiry offices; also offices for the Postmaster, clerks, and medical officer, and rooms for the messengers. A roadway extends round the rear of the buildings, part being roofed over for a cart-shed and loading platform. The principal posting-boxes are under the portico at the northern end of the front, but there are also posting-boxes in the public office. The instrument-room, the dimensions of which are 86 ft. by 29 ft., is on the first floor, where are also placed the telephone and superintendent's rooms, retiring-rooms for male and female clerks, approached from the roadway at the rear by separate staircases; and on the second floor are the battery-room, the office of the telegraph inspector, rooms for the linemen and mechanics, and the caretaker's apartments. The basement is occupied by stores, kitchens for clerks, postmen, pneumatic apparatus, engine, &c. The general contractors were Messrs. Bealmond, of Bradford; the carving to the central dormer and panels over windows were executed by Mr. Frith, of London; the wrought- and cast-iron railings and gates by Mr. Tomlinson-Walker, of York; the clock was supplied by Messrs. Potts, of Leeds; the internal fittings by Mr. Elder, of Hayes; and the public and sorting offices and instrument-rooms are lighted by Founess lamps. The architect is Mr. Henry Tanner, and the clerk of works was Mr. Thomas Leake.

### COMPETITIVE DESIGN FOR WILLESDEN PUBLIC OFFICES.

This design, submitted by Messrs. Newman & Newman, was placed second in the competition for the proposed Public Offices at Willesden.

It appears that the design placed first, by Mr. Hamor, was formally accepted, subject to its being capable of being carried out at a cost of not more than 6,000*l.*, the stipulated limit. It appears that the lowest contractor's estimate is considerably above that sum, and the authors of the second-placed design ask, with some reason, whether they ought not to have the opportunity of showing whether their design comes within the stipulated cost. In strict equity they certainly have a right to make this claim, and to have it considered.

### CONGREGATIONAL CHURCH, GEORGE-STREET, CROYDON.

The total length of this church is 108 ft., and width 54 ft., providing sittings on the ground-floor for 800, and over 200 in an end gallery, the aisles being so arranged that side galleries can be added if needed. There are two main entrances to the ground-floor of the church in front, also two separate staircases to the end gallery and two back entrances, all with swing doors. The church is rapidly emptied.

Beneath the church is a large school-room, 15 ft. high, and capable of seating 600 people at a public meeting, whilst class-rooms annexed give a total capacity for Sunday-school work for 1,100 children.

Internally, the church is faced with gault bricks, and has Bath stone dressings and arcades,—the school and rooms being plastered. Externally, the front as shown is faced with Kentish rag.

The total cost of the whole was 9,700*l.* (exclusive of upper part of tower and spire, which is not yet erected), the contract being carried out by Messrs. Perry & Co. Mr. John Sulman, of London and Sydney, being the architect.

ARNOLD'S CEMENT-TESTER.

Mr. ARNOLD's method consists in making the briquette by filling the mould with a proper quantity by weight of *dry* cement, and then consolidating it under a press (see fig. 1),

FIG 1

the requisite amount of water necessary being sucked up from a bath by the cement while the briquette is under the press. The moulds (see figs. 2, 3, and 4) are made

FIG 2

FIG 3

FIG 4

deeper than required for the section of the briquette. Metal dies, which exactly fit inside the mould, are placed upon the top of the cement before it is inserted in the press, so that when the die is properly pressed down, its top is level with the top of the mould, and no further compression can take place. Thus a uniformity of pressure is insured upon each briquette moulded from the same cement. But as the moulds are filled by weight, the bulk would vary with cements of different weights per bushel, and a slight difference in the pressure would be the result, with the use of cements of various qualities, unless different thicknesses of dies were employed.

The chief advantages possessed by Arnold's machine appear to be the following:—An experienced man is not absolutely essential to form the briquette. The cement takes up the required quantity of water, and so more. Thus the sample is neither drowned nor parched. The section of the fractured area is free from air-bubbles, and the results of the tests from the same cement show a greater uniformity than can be obtained by hand-moulded briquettes.

The following advantages are also claimed by the patentee, which, if borne out, will prove of great importance to those engaged in testing cement, viz., that evidence of a blowing cement will be noticed in twenty-four hours after moulding the briquette, and that owing to the cement not being disturbed after its admixture with water, particles of free lime can be detected at the fractured area.

It may be anticipated that a greater strength will be indicated by the machine-made briquettes, while hand-made briquettes will give a result dearer than obtained in actual practice, and probably some slight modification in specifying cement would be required to obtain the ordinary quality of cement if Arnold's process were generally adopted.

While on the subject, we may observe that it would be a great advantage in the way of fairness and the avoidance of disputes between consumers and makers of cement, if one form of testing machine were universally adopted, though we cannot say that we think it at all probable that any such uniformity will be arrived at for some time to come.

**Obituary.**—We record with much regret the death of Mr. Robert Hunt, F.R.S., late Keeper of the Mining Records, which occurred on the 17th inst. Mr. Hunt, who had recently completed his eightieth year, was a voluminous writer upon scientific subjects. Besides producing several works of his own, he edited three editions of Ure's "Dictionary of Arts, Manufactures, and Mines."

Brick and Concrete Piers Designed by Mr. A. W. Blomfield.

PLAN OF COLUMN AS TESTED

PLAN OF COLUMN AS INTENDED

STRENGTH OF BRICK AND CONCRETE PIERS.

SIR.—Some time since, in designing a large brick church, I determined, for several reasons, to employ in the nave arcade circular columns 2 ft. 6 in. in diameter, constructed with an outer casing of purpose-made radiating Leicester bricks in cement, and a core of Portland cement concrete composed of fine shingle and sand and cement in the proportion of three to one. This mode of constructing the columns was objected to as unsafe, and ultimately I had to give way and substitute Bath stone, as the work could not be delayed sufficiently long to test by experiment the safety of my first intention.

No doubt it had ever occurred to my mind, and my experience of the strength of Portland cement concrete, extending now over many years, gave me such confidence in the correctness of my judgment that I determined, with an eye to the future, to make some experiments with the assistance of Messrs. Kirkaldy.

These trials have lately been carried out, and I now enclose Messrs. Kirkaldy's report. I also send drawings of the columns I intended to use, and of the short lengths submitted to the tests.

I should mention that no column of larger diameter than 2 ft. can be tested in Messrs. Kirkaldy's machine, so that I could not submit a section of the column as actually designed, nor could I use the purpose-made radiating flat bricks. I therefore caused shafts 3 ft. long and 2 ft. in diameter to be constructed with rough-cut Leicester bricks, which being frogged were less suitable for the purpose and more liable to crack under pressure; the core was filled with concrete such as I intended to use.

These shafts resisted the greatest pressure which Mr. Kirkaldy's machine could bring to bear without crushing, and with no apparent injury except to the casing of bricks. They may now be seen, exactly as they left the machine, in the yard of Mr. Woodward, 96½, Curtain-road, E.C.

Seeing that Portland cement concrete continues to increase in strength for many months (some authorities say two years) after it is made, and that these shafts had only been made four months; that they were not so perfectly constructed as the actual columns would have been; and that owing to the limited capability of the machine the pressure could

not be continued to the crushing point, the experiments were neither so exhaustive nor so satisfactory as could be wished, but the results are extremely interesting as far as they go, and sufficient to prove conclusively the ample strength of such columns as intended to use.

In this particular case the weight on each column, allowing for wind pressure, could never have exceeded fifteen tons per square foot of sectional area.

ARTHUR W. BLOMFIELD.

October 5th, 1887.

Subjoined is Messrs. Kirkaldy & Son's statement of the results of their tests:—

Report on Results of Experiments in Testing Composite-Columns, Concrete and Brick, for Mr. Arthur W. Blomfield, by Messrs. David Kirkaldy & Son, 99, Southwark-street. October 1st, 1887.

Results of Experiments to ascertain the Resistance to Thrusting Stress of four 12-in. Cubes of Concrete, mixed here by Man from Mr. J. Woodward:—

Test No.	Description.	Dimensions.	Base Area.	Cracked slightly.			Crushed, steelyard dropped.		
				Stress.	per sq. in.	per sq. ft.	Stress.	per sq. in.	per sq. ft.
V.	3 of gravel to 1 of cement. Made May 27.	12-0 12-0 x 12-0	sq. in.	lb.	lb.	tons	lb.	lb.	tons
2,252		14-0	252,970	1,757	113-0	278,240	1,932	124-2	
2,253		14-0	224,350	1,558	100-2	272,570	1,895	121-8	
2,251		14-0	219,225	1,968	107-3	269,180	1,869	120-1	
2,250		14-0	220,530	1,530	98-4	268,560	1,958	119-9	
		Mean	234,467	1,828	104-7	272,212	1,890	121-5	

Bedded between pieces of pine ½ in. thick.

Results of Experiments to ascertain the Resistance, to a gradually increased Thrusting Stress, of six Bricks, received from Mr. J. Woodward:—

Test No.	Description.	Dimensions.	Base Area.	Stress in pounds when		
				Cracked slightly.	Cracked generally.	Crushed, steelyard dropped.
V.	Red Brick, recessed both sides	3-65 8-90 x 4-25	sq. in.			
2,256		37-82	77,500	96,230	99,160	
2,255		39-68	71,700	90,100	95,820	
2,254		39-19	68,900	87,420	91,780	
2,259		38-68	62,200	84,500	89,810	
2,253		39-68	57,200	81,000	89,330	
2,257	39-68	61,900	68,600	85,260		
	Mean	39-29	64,750	84,637	93,032	
	lb. per square inch		1,648	2,154	2,342	
	Tons per square foot		105-9	138-5	150-6	

Bedded between pieces of pine ½ in. thick.

Result of Tests of two Composite Columns, composed of Bricks and Cement of the same quality, as subjected to the above Tests:—

Approximate area of Concrete, 178 square inches. Brickwork, 278 square inches.  
 V. 2,249, Brick and Concrete column, 12 courses, 38 in. high, 24 in. diameter, 452 square inches area. Cracked slightly with 505,000 lb. = 225-4 tons; cracked generally, 626,560 lb. = 279-7 tons. Per sq. in. of area, 1,336 lb.  
 V. 2,249, Brick and Concrete column, 12 courses, 36 in. high, 24 in. diameter, 452 square inches area. Cracked slightly with 522,000 lb. = 233-0 tons; cracked generally, 635,000 lb. = 283-5 tons. Per sq. in. of area, 1,404 lb.

ARTHUR W. BLOMFIELD, Esq., 6, Montagu-place, Montagu-square, London, W. DAVID KIRKALDY & SON.

THE RECENT FIRE AT WHITELEY'S.

As the adjourned inquest on the death of the persons killed in this fire is to be resumed on Monday, a short summary of the evidence already given may be of use.

The inquiry was opened on August 10th last, in the Westbourne Park Institute, by Dr. Danford Thomas, Coroner for Central Middlesex.

Four deaths resulted from the fire, the immediate cause being the fall of the external wall of the factory, a building at the back part of the premises in the Queen's-road. The said wall fell into Douglas-place. Several witnesses suggested that the wall had been blown out by an explosion, but Mr. William Penfold, Engineer of the Metropolitan Fire Brigade, who was present before the wall fell, heard no explosion.

Mr. James E. Saunders, member of the Metropolitan Board of Works, said he was the architect of the factory in Douglas-place, and of the buildings in the Queen's-road. The factory was first burnt in 1883; it was then restored, the damaged brickwork being first removed, but the remainder was utilised in position. The walls were 23 in. thick from the basement up to the first floor; 18 in. thick from the first floor up to the third floor; and 14 in. thick on the fourth floor. Each floor was formed with iron girders and wooden joists. The first floor was what is called "fireproof," being formed with iron joists resting on the iron girders.

The iron girders and joists ran into the walls, as also did the wooden joists. The walls with the iron joists and those with the wooden joists had equally given way. A large block of brickwork had been thrust outwards and then laid in Douglas-place, at a great distance from the wall. He did not think that this block of brickwork could have reached its position by the simple collapse of the wall without some force to thrust it outwards. Inside the four external walls the floors were supported on iron columns, which were carried right up to the roof. The ironwork was not encased with cement or other material. The gas pipes were all of iron.

In cross-examination, Mr. Saunders said:—The walls in the basement were built in cement, and the other portions of the factory walls were built in mortar. The large block of brickwork in Douglas-place was from the wall above the second floor, if not above the third. It was lying face upwards, about 20 ft. from the wall from which it fell. Its weight was about two tons. It had not been moved since it fell. He was of opinion that some expansive force caused the wall to fall. If the wall had simply fallen out, the large block of brickwork would have fallen with the face downwards.

Mr. Horace Gundry said he was the District Surveyor for Paddington, appointed by the Metropolitan Board of Works. He was the District Surveyor during the erection of the whole of Mr. Whiteley's premises in Douglas-place and in the Queen's-road. He had sur-

veyed the buildings since the fire in 1883, and since the last fire, and he concurred in the opinion expressed by Mr. Saunders as to the falling of the large block of brickwork in Douglas-place. Some of the bricks had fallen in blocks, and these had no appearance of having been subjected to much heat. In a firm mortar becomes pulverised, and the work disintegrated; but the large block of brickwork referred to was quite solid.

The inquiry was then adjourned to August 17th, the jury requesting the Coroner to call an expert in explosives to examine the building and report thereon.

On the second day of the inquiry, August 17th, Colonel Majendie submitted a most exhaustive report in which he said that not only could the position and appearance of the large block of brickwork in Douglas-place be quite reasonably accounted for without recourse to the explosive theory, but there were points that very strongly, if not conclusively, negatived the theory of an explosion. He was assured by Captain Shaw and Mr. Palmer that it was quite consistent with their experience that large masses of brickwork should come to rest at far greater distances than 20 ft. from the wall from which they fell. There was evidence that a fire of more or less formidable proportion existed before the walls fell. Colonel Majendie concluded his report in the following words:—

"I believe the fire to have originated from some other cause (other than explosive) which it is no part of my duty to explore; that this fire was, so to speak, 'bottled up' for a considerable time; that the fall of the building was the result of the fire, and nothing else, such fall being in all respects inconsistent with the experience of the Fire Brigade, and that the supposed 'explosions' were either the noise of the falling building, or not inconceivable some minor secondary explosion of gaseous atmosphere or steam, or noisy ignitions of inflammable substances."

A letter from Captain Shaw was read, in which he said:—

"How the idea of an explosion at Whiteley's originated I cannot say; but, so far as I am aware, it is absolutely and entirely without any shadow of foundation."

Professor Alexander Kennedy, C.E., F.R.S., said he was Professor of Engineering at University College, London. He had inspected the scene of the fire, and had heard that an explosion was suggested as the cause. He found no broken glass, and the idea that an explosive such as dynamite or gunpowder was used was negatived. He examined an iron girder 16 ft long which had fallen into Douglas-place; it was only ½ in. out of straight; for about 4 ft or 5 ft. from its blue state, it had evidently been very hot. The joint was covered with burnt paint and dust, but beyond the 4 ft. or 5 ft. there was no sign of any serious heat. The front end of the joint rested on stone. On tier of columns was left standing complete after the fire. He did not think that the expansion of the girders could have so affected the walls as to cause them to fall.

In cross-examination, Professor Kennedy said, according to the plans the girders were placed in pockets, to allow for expansion. With the exception of the external wall, the entire structure of the factory rested on iron columns. The girders resting on these columns were 80 ft long; they were bolted together at each column, but not to the walls. The bolts were loose. These details of the ironwork he gave from the plans. There was no figure showing the space for expansion. It might have been about three quarters of an inch in each wall. He thought that would be sufficient allowance for expansion. In some cases brickwork had been drawn away with the iron girders.

Mr. Samuel J. Mackie, C.E., said he had had large experience in explosives; he had examined the building, and fully concurred with Colonel Majendie's evidence. In his opinion the girder which had fallen into Douglas-place had been red-hot, and was oxidised over the surface.

In cross-examination, Mr. Mackie said the wall had been no flaking or scaling of the girder. If it had been red-hot only for a short time, it would not expect to find it scaled.

The jury then retired, and, after a consultation of half an hour, they returned, when the foreman said that they had unanimously resolved to ask the Coroner to adjourn the inquiry till Monday, October 24th, at 10 o'clock in order that further investigations might be made, which, under the circumstances, he thought should be undertaken by the Government. The inquiry was adjourned accordingly, and we understand that further evidence as to the construction of the building will be submitted to the jury on Monday next.

THE GLASGOW INTERNATIONAL EXHIBITION (1888) BUILDINGS.

THESE buildings, facing Kelvin Park and the new University, are making rapid progress. They occupy a site lying between the river Kelvin and Sandyford-street and Dumbarton-road, which but a few weeks ago formed the recreation ground for the youth of the eastern districts of Glasgow, but which is now almost covered with buildings in various stages of progress. The foundations were completed about the middle of July, and immediately thereafter the contract for the erection of the superstructure was arranged and operations commenced. The progress made since then has been very rapid, and is to the credit of all concerned. It is always well to take time by the forelock, and in no case is that more true than in such a case as the present. Exhibition buildings are proverbially behind time; and if now in progress are completely finished when they are opened they will be nearly unique in that respect. If one may judge from what has already been done, however, it will not be the fault of the architect or the contractor if the building is not finished; and if the main building is roofed before the winter weather sets in, which we understand it is meant to be, the satisfactory completion of the work in good time may be considered assured. The building, as it is being erected, is considerably larger than was at first proposed. At an early stage it was seen that the demand for space would probably exceed the original anticipations, and it was therefore determined that the building should be as large as the available site would permit. The increase is proportionately greatest in the machinery annex. This has been extended in area fully 35 per cent., and the main building 15 per cent., the total increase being about 20 per cent.

From an article which recently appeared in the *Glasgow Herald* we give a few details as to the dimensions and area covered by the buildings, which may be of interest. The extreme length of the space roofed in is about 1,450 ft., or over a quarter of a mile, and the extreme breadth 360 ft. The main building for general exhibits, &c., is 1,050 ft. in length, being rather more than the length of the main building of the Manchester Exhibition, while it is considerably wider than the latter building. The machinery annex is about 330 ft. in length by about 285 ft. in breadth. This department is somewhat smaller in area than at Manchester, but as the class of exhibits which may be expected in the Glasgow district will occupy less space per exhibit than those at Manchester (cotton-spinning machinery, &c., which requires large floor-space), the collection will, it is hoped, not be less numerous or representative of the engineering industries than that at present in the Manchester Exhibition. The general arrangement of the main building is very simple,—always an advantage in buildings of this class. A grand central avenue, 60 ft. in width, extends along the whole length of the main building, intersected at the centre by a transverse avenue of the same width. On either side of the former is a series of courts, 50 ft. in width, and varying from 100 ft. to 190 ft. in length. At the east end of the grand avenue the large concert-hall is placed. It is about 160 ft. in length by 100 ft. in width, with a large recess for the organ and a spacious platform for an orchestra and chorus. This hall will accommodate an audience of at least 3,000 persons.

The fine-art galleries are to be made a special feature of the Exhibition. They cover an area of about 3,200 square yards, divided into ten galleries, the largest of which is 150 ft. in length and 36 ft. in width. Three of the galleries measure 100 ft. by 33 ft. (about the same length as the large gallery in the Fine-Art Institute, and 3 ft. wider), and other three 65 ft. by 33 ft. These galleries are for pictures. Two galleries, 85 ft. in length by 25 ft. in width, are arranged for architectural drawings, photographs, etchings, &c., and there is a sculpture gallery, 150 ft. long by 25 ft. in width. The walls of this section of the building are of brick, and the roofs are of iron. The floor is to be laid solid on concrete; all the openings between the galleries and between them and the main building are to have iron doors, made by Messrs. Chubb & Co. (Limited), and the building will be practically fireproof.

Apart from the picture galleries, the building generally is constructed of wood (the roof being

of iron), with the exception of the kitchens and certain walls erected for fire prevention purposes, which are to be of brick. As a further protection against the spread of fire in the main building, it may be mentioned that the whole area under the building is to be divided into numerous sections by brick walls built up between the joists to the level of the floor. At various points inside the building there will be firemen's stations, and hydrants will be placed at short intervals along the main avenue and in the courts. The chief dining and refreshment rooms are at the west end of the main building, and as several spacious apartments, besides kitchens, stoves, are provided, ample accommodation is being reserved for this important department. Like the fine-art galleries, this section is to a large extent isolated from the main building and separated from it by brick walls.

The great central dome, constructed of wrought iron, will be the chief feature. It will rise to a height of about 140 ft., and there are four octagonal minarets or towers grouped round it. Besides these towers, the long line of the roof is broken up by other towers of varied design.

Any notice of the Exhibition would be incomplete without a reference to the work being done and to be done outside the main buildings. A large part of the park on both sides of the Kelvin is to be enclosed, to form the Exhibition grounds. In these grounds a number of buildings have to be erected,—dining-rooms, tea-rooms, refreshment-rooms of various kinds, and for other purposes. All these are being arranged for, and will necessarily be commenced very soon.

To provide facilities for exhibiting working models in the naval engineering and ship-building section, it has been agreed to deepen the river Kelvin, between the weir and the Prince of Wales Bridge, and that work is now being carried out. It has also been resolved to erect a new bridge, close to the present iron bridge, to meet the requirements of the enormous traffic between the two sides of the river. A great attraction in the grounds will be the "fairy fountain." A similar fountain was shown at the Colonial Exhibition in London, and may now be seen at Manchester.

For the accommodation of the archaeological section of the fine arts department, and for exhibits of stained glass, tapestry, ancient furniture work, ironwork, &c., a building which will be a reproduction of the Bishop's Palace of Glasgow has been proposed, and if it is erected it will probably occupy a site on the slope below the University buildings.

ST. MARY-LE-STRAND CHURCH.

STR.—We are directed by the Council of the Royal Institute of British Architects to address you in reference to the Church of St. Mary-le-Strand. They consider that in a matter of such public importance they need offer no apology for troubling you with an expression of their opinion to the effect that the obstruction to the traffic in the Strand, stated to be due to the existence of this church, can be most effectually remedied not by its removal, as has been suggested, but by the construction of an improved roadway on its northern side, as contemplated in a plan which, we are informed, was approved by the Metropolitan Board of Works some years ago.

The Council are further of opinion that, though obviously most desirable to put the church into thorough structural repair, any reparations to a building possessing such great artistic value as this should be carried out in strict accordance with the original design, departure from which is earnestly to be deprecated.

J. MACVICAR ANDERSON, Hon. Secretary.  
WILLIAM H. WHITE, Secretary.  
Royal Institute of British Architects,  
9, Conduit-street, Hanover-square, London, W.  
October 17th, 1887.

THE WALLS OF CHESTER.

STR.—Mr. Thompson Watkin's letter, p. 527, calls for some reply from me. His letter is in no way an answer to my challenge. I have proposed to him a test which is a practical and a crucial one, to prove the accuracy, or otherwise, of his assertion that entire portions (from base to summit) of these walls are of the time of the Commonwealth or of the reign of Queen Anne. If the bill has ever been

paid it must be in existence, or, at any rate, there must be reference to the spending of so large a sum for so large a work. I have told him what the amount was likely to be for a specified portion only, and where the bill or reference to it is likely to be found (if the work were ever done as he says it was). I call upon him to prove his repeated assertions by producing this bill, or your readers and myself will know that he cannot do so. If he cannot, it will show that the work was never done at either of the times he names, and that the architectural evidences of the work itself, which show a Roman origin, so far as the unmortared parts and the Roodeye wall are concerned, may be taken as certain evidences of date by those who will read them aright. But then the dates named by your correspondent must be dismissed as the crudest of fancies.

To make matters worse for himself, he speaks, p. 527, of the work having been done by the "Parliamentary Army." Can he bring forward any record? Surely, if an army was set to carry out such a heavy mass of masonry as this, there must be some notice of it. Without such evidence being adduced, is your correspondent justified in making such a suggestion, especially since there is no record of any other Parliamentary army having erected any wall to any other city?

Mr. Watkin may accept as fairly as I intended my remarks to be, that the Roodeye wall is built with mortar. It had, as I expressed myself, more to do. This is not mortar adhering to the stones from some previous use, as he suggests, but the mass of the wall is constructed with mortar, in which Mr. Williams has detected pounded brick. The word "detected" he will notice, if he reads carefully, is used by me not for the detection of mortar, but of pounded brick in it. The lower courses do not show any such cementing, I am told, as if it had been washed out from the face, perhaps, by the action of tide; and where the wall clears the bank, the mortar is, at any rate, not apparent, resembling, in this respect, the other Roman walling elsewhere.

In my calculations, which your correspondent calls "formidable,"—and they are so for his hypothesis,—I have allowed nothing for the value of the stone used, and have said so, p. 512.

E. P. LOFTUS BROCK.  
London, October 18th, 1887.

STR.—Of the opening in our north wall, Mr. Brock wrote recently in your columns, "that from the rise to the height of about 10 ft. without mortar, and 8 ft. with mortar." After visiting the spot in question, I was able to inform him, as I did in your columns [see p. 512, ante], that there was at the spot mentioned 19 ft., and not 10 ft. of wall without mortar. Since then, I have seen a drawing of the wall at the Towhall, showing nearly 20 ft. of mortarless wall. Such being the fact, it is neither correct nor generous of Mr. Brock to say [p. 523, ante] that the "parts of the wall are fairly of the dimensions he has given." I do not see it; and I invite Mr. Brock to get the correct height of the unmortared part of the wall, and publish the result in your columns.

Mr. Brock says of the unmortared walls, "all is a compact mass." That your readers may be in a position to form an opinion of the wall in question, let me give a description of its interior composition, from the published account of the visit of Sir Henry Dryden:—"Nearly the whole of the material of the part taken out and rebuilt consisted of sculptured stones,—plinths, cornices, copings, sepulchral slabs, bas-reliefs of figures about 2 ft. high, and other moulded stones,—evidently the remains of large, ornate, solid buildings."

Given the above material, with dry earth as the bonding element, to form a wall, would it be possible to do so—and worthy of being called a "compact mass?" Some, I have no doubt, will ask, how a wall of this kind manages to hold together. The answer is, that it is backed up by 14 ft. of earth.

The composition of the whole being as I have stated above, with earth only between the stones, there was no difficulty in putting the arm between the various courses.

CHESTER, Oct. 17th. GEORGE W. SHURBOLE.

STR.—Mr. Brock, in the last number of the *Builder* [p. 526] says that the "existence" of the foundations of the Roman North Gate, or, in fact, of two Roman gates, until "fairly recent times, must make it more difficult for Mr. Watkin to believe that the massive stones in the walls, which he acknowledges to be Roman, could have ever been shifted in position, as he asserts. There they are in line with the gates, in both cases where Roman walls must have been."

He will see by my letter in the same number that neither of the gates was Roman "until fairly recent times," though I think the later gates (Medieval) were probably built upon their foundations; but with regard to the "massive stones" in the walls, especially near the North Gate, as Mr. Brock admits they have been brought from Roman buildings they must have been "shifted in position" by somebody. Mr. Brock says by the Romans themselves. Who ever placed them in their present position was almost bound to do so if the Roman line of wall was to be kept; and as Mr. Brock is aware that I hold that the present north and east walls, from New

Gate to Morgan's Mount, are more or less on the site of their Roman predecessors, it is merely the question of who moved them.

With regard to the views of Dr. Bruce and Mr. Blair on the "ecclesiastical" stone, I may say that the Rev. H. C. Scarth, and many antiquaries and architects, hold that the stone is ecclesiastical. Mr. R. S. Ferguson, without speaking absolutely, thinks it more like a Medieval ecclesiastical stone than otherwise.

W. THOMPSON WATKIN.

Liverpool, Oct. 17th, 1887.

#### "SHONE'S EJECTORS IN THE RECENT RAINSTORMS."

SIR,—It is really unprofitable labour to attempt to answer Mr. Donaldson's long inconsequent letter at p. 546 in this week's *Builder*. But as he seems very desirous of having a further answer from me, I will indulge him so far.

As to his first and second paragraphs, the sentences therein are mere assumptions, without any facts to uphold them, and therefore are not worthy of argument or consideration.

As to his third paragraph, I have nothing to say against his gathering himself among others under the wings of the gentleman he has named. He says, "the excess fifth-water ought to be discharged through a storm-water outlet," and refers to "a 12 in. pipe connecting the sump with the metropolitan sewer." These observations prove that he is unacquainted with the real facts of the matters he questions. If he wishes to learn what the facts are, let him explore the places, and there ascertain them for himself. Then he may be able to discover in what he is wrong in his deductions.

As to his fourth paragraph, in which he says "that time will prove the installation to be a failure, not only as a means of discharging the sewage, but in a sanitary point of view," time and circumstances have already incontestably proved that he and the clique he represents are false prophets. The ejectors and the gas engines have effectually done their work under varying circumstances since Christmas last, and will, I am certain, continue to do so. If the installation should ever fail or get out of order, it will be through the neglect, inattention, or wilful damage to it of those having charge of it.

As to his fifth paragraph, that I have not answered his "crucial questions," viz., how I ascertained the height of the sewage in the metropolitan sewers, and the depth of the sewage in the subway reservoir,—I may state that I have had special experience in ascertaining these matters, and therefore no one is better acquainted with the various depths of altitudes of the sewage and rainfall flow, in the metropolitan sewers in Westminster and elsewhere both in dry and wet weather than I am. I also am as well acquainted with the depth of the sewage in the subway reservoir when 2,000 gallons, or any other quantity, overflows into it. I may add that the air pressure used since the commencement has been 10 lb. per square inch; that no more pressure has been, or ever will be, required under any circumstances; that the lift has never exceeded, and will never exceed, 20 ft.; and that there never will be any flooding of the basements.

As to his sixth, seventh, eighth, and remaining paragraphs, I may dispose of them by again stating the facts of the case, which he has not and cannot divulge, namely, (1) that the rain-fall at Westminster, on August 17th last, was 0.53 in. per hour; (2) that the area draining to the ejectors is 10 acres; (3) that the quantity of water draining from this area to the ejectors was 357 cubic feet, or 2,227 gallons per minute; (4) that this quantity of water (except 2,000 gallons which overflowed for two minutes into the subway reservoir), Shone's three ejectors of 1,100 gallons aggregate capacity, and Atkinson's four gas engines of 4-h.p. each, all working together, successfully discharged at the rate of 1,134 gallons per half-minute, without any flooding whatever of the basements; and (5) that the lift was 20 ft. to the head of water in the main low-level sewer outside. These are "the actual facts of the case." It is, therefore, not I who am "labouring under a misapprehension," but Mr. Donaldson himself, who will not accept the facts, and imagines and argues on all sorts of things which are beside the question. If he wants to know what the heads of water were on the 17th of August, on the receiving and discharging sides of the ejectors, let him go to the places, and ascertain, if he can, the particulars for himself. I very much doubt, however, his capability to do this.

The hydro-pneumatic system of drainage, as invented by Mr. Shone, and carried out at Eastbourne, at the Houses of Parliament, at Henley-on-Thames, at Warrington, at Southampton, and elsewhere, is now so well understood and appreciated by scientists, sanitary engineers, and the intelligent rate-paying public, that nothing Mr. Donaldson, or the clique he represents, may say in depreciation of it will have the slightest effect in retarding its adoption. Let all who are interested in sanitary drainage go to the authorities at the places I have named, and learn from them as to the actual working of the system.

I beg to say, in conclusion, that I shall not waste my time by again answering Mr. Donaldson's October 15th, 1887.

JOHN PHILLIPS.

\* \* \* Mr. Phillips will not be placed under any necessity to answer further letters from Mr. Donaldson,—in our columns, at all events. We have received a copy of a reprint of a letter addressed to the editor of the *New York Sanitary Engineer*, signed by Mr. Donaldson, and dated December 17, 1884, consisting entirely of a strong recommendation of Mr. Shone's system, and observing, among other things, that "the safeguards used under the ordinary system, namely, storm-water overflows, can be used with equal care to relieve the ejectors when the Shone system of sewage is adopted." Mr. Donaldson describes himself in this letter as "a personal friend of Mr. Shone, engaged with him in promoting drainage schemes on his system." The reprint of this letter bears on the cover a second letter, dated ten days later, and signed jointly by "William Donaldson" and "Shone and Ault," addressed to the Improvement Commissioners of Cambridge, and inviting their attention to the recommendation of the Shone system contained in Mr. Donaldson's letter to the *Sanitary Engineer*. It appears, therefore, that Mr. Donaldson was very recently doing all he could to recommend the system which he is now doing all he can to disparage. After that, the least we can expect, is that Mr. Donaldson's value to Mr. Donaldson's opinions or statements on the subject as to waste any more space upon them. If Mr. Shone thinks it worth while to reply categorically to the statements in Mr. Donaldson's last letter, he can have space to do so in our next, and then the correspondence must close.

#### A DECIMAL SYSTEM.

SIR,—In your recent article (see p. 483, ante) on "Our National Maps," you allude to "our tedious and troublesome duodecimal subdivision of the lineal foot," and to the great advantage of substituting a decimal subdivision. This subject is of such great importance that I hope you will not allow it to drop; for there is nothing by which you could do a greater service, both to architects and to the nation at large than by setting on foot such a reform. One great defect of our present system is that it utterly fails in the essential point of facilitating accuracy, by the want of minute and regular subdivisions of the inch. Our eighths and sixteenths are always awkward, and for accurate calculation quite useless; hence, whenever scientific men have to use careful and minute measurements, they are obliged to discard English measures altogether, and to use not only French measures, but French terms, which are so gaining ground that we shall have to adopt them bodily unless we speedily render our own system convenient and adapted to scientific necessities. For larger measures we are overburdened with useless and cumbersome cross divisions, and a simplification of these is urgently needed. The random use of yards and feet in linear measure is had enough; but our square measures, in which some things are reckoned by the square foot, others by the square yard, some by the "square" of 100 square feet, and others by the "rod" of 272, and where no number of linear yards makes up the side of a square acre, would strike a stranger as an absurdity, apparently designed to cause waste of labour and facilitate confusion.

It would be hard, but would it be impossible, to divide the foot into tenths, hundredths, and thousandths, to abolish the yard, and make all larger measures multiples of a fourth, to abolish thus at once a simple and logical system, still retaining a link by which all measures could be easily converted from the old to the new; and we should save ourselves from the much harder alternative of embracing the entirely different system of France, with its long, ugly names, which otherwise appears to be inevitable. Shall it be reform or revolution? None would benefit by the former more than architects; will not they lead the way?

A. S. FLOWER.

#### A NEW METHOD OF VENTILATION.

SIR,—Messrs. Boyle's letter in the *Builder* of the 15th inst. (which must not be too severely criticised, as their monopoly is being attacked) may be condensed thus:—"Your system of ventilating from above downwards is not new, has been tried before, and is contrary to the laws of nature." Messrs. Boyle recommend their own system of a mica flap (outlet) ventilator as answering every purpose which ours professes to do. Our own experience, and that, we venture to think, of most people who have had to do with the system they advocate, is that it is not satisfactory. These ventilators are noisy, and we have heard of one instance at least in which they had to be blocked up from this cause alone.

Our letter in yours of the 15th inst. [p. 547, ante] will have explained the reason for the interposition of the cylinder in our system of ventilation, viz., as a device, which, without the heating of the downcast pipe, which, without some such mode of isolating it, would be liable to become heated in the same manner as the upcast pipe, and thus probably cause a reverse action. It has other functions, one of which we suspect to be additional motive power due to the rarefaction and expansion of the air within by reason

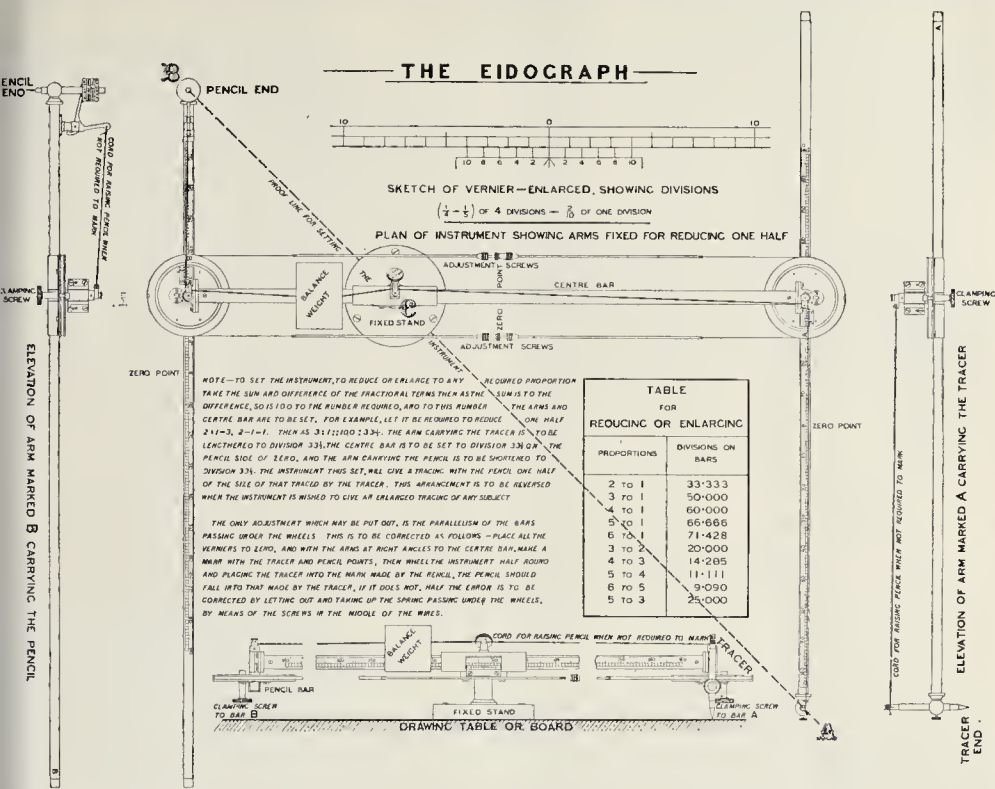

of the heat; but this is a point on which we do not at the present moment feel justified on enlarging until further investigations enable us to speak with more certainty. It is to be inferred that Messrs. Boyle's experiment in a somewhat similar direction to ours in ventilating the sugar mills at Greenock failed in a more or less degree, but this is easily explained to us by two facts,—first that the place of exit of the conducting shaft employed by them was not the point of maximum draught in the flue, as in our system; and secondly, that the shafts, not being disconnected at intervals in their course (for which purpose we insert cylinders with a siphon), were liable to become heated throughout, and so gradually lose their efficacy as air conductors, and possibly even cause a reverse action to be set up. It is true that hot air naturally rises, but this tendency can be modified by superior attraction, and this is what we claim for our invention. We have not in actual practice had to employ artificial means of creating a draught, but in certain cases in summing this may be necessary, or where the flue is defective and to provide for such contingencies we suggest that a gas jet may be used with advantage in the cylinder, and a blast fan can be applied to the flue by us in large halls, but in any case we do not refer to our comprehensive scheme for ventilating large buildings. Lastly, we would invite Messrs. Boyle, or any of your readers who take an interest in this important problem of sanitary science, to inspect our system, which we feel sure will carry conviction to the most sceptical.

YOUNG & MOSS.

**Aberdeen New Public Baths.**—The ceremony of opening the newly-finished Public Baths at Aberdeen took place on the 12th inst. Lord Provost Henderson presided. The buildings (which cost 6,000*l.*) belong to a limited liability company, who have secured a site at the east end of Constitution-street, abutting on the Links, and measuring nearly an acre, so that there is space to enlarge the buildings if the venture proves a great success. The front buildings, two stories in height, face the Queen's Links, from which place of recreation they are well seen, and present a pleasing contrast to the rather plain buildings in the neighbourhood. The front elevation is 90 ft. in length, the materials used being white Aberdeenshire granite, hammer-blocked ashlar, relieved with dressings of string courses and pediments, &c. In the front block there are on the ground-floor the entrance lobby, staircase, ticket office, superintendent's rooms, cloak-room, and refreshment-room; and on the first floor a spacious billiard-room, directors' room, and first and second class slippers' baths, Russian bath, dressing-rooms, &c. At the west end of the front block are situated the steam-boiler house and engine and pump rooms. The principal feature of the buildings, however, is the swimming-bath lying at the rear. This bath is 75 ft. long by 30 ft. wide with a depth of 3 ft. 6 in. at one end, gradually increasing to 7 ft. at the other, and is lined with white enameled tiles. Along the sides of the bath are ranged dressing-boxes and also fresh-water foot-baths, lavatories, &c. In the hall containing the swimming-bath is a promenade gallery to accommodate about 500 spectators. At one end there is a commodious gymnasium. The upper part of the roof is glass, and ventilation is provided by means of moveable louvre boards in the roof. The buildings are heated throughout by steam pipes. The water for the baths is pumped from the sea, about 600 yards distant, through 9-in. cast-iron pipes laid across the Queen's Links. The water is drawn from the sea by a 25-h.p. engine and centrifugal pump, capable of filling the swimming-bath in two hours, thus admitting of the water being changed once a day or oftener if required. Before being used in the baths the salt water will be filtered through beds of sand and gravel and perforated pipes. The equipments of the baths are on the best modern models, and have been erected from designs by Messrs. Jenkin & Marr, civil engineers and architects, Aberdeen.

**The Swinton Local Board and the Pollution of the Irwell.**—The Swinton Local Board, who have been served with notices by both Captain Dauntsey, of Agercroft Hall, and the Salford Rivers Conservancy Committee, to cease polluting Slack Brook, Pendlebury, and the river Irwell, have invited Mr. Vawser, C.E. of Manchester, to visit Pendlebury and report upon the scheme prepared by the Board's surveyors for dealing with the sewage of the above district. The Board have purchased several acres of land for erecting precipitators and other works.—*Manchester Guardian*.

**The Student's Column.**

**LAND SURVEYING AND LEVELLING.**  
 XVII.—ENLARGING AND REDUCING PLANS.

THE enlargement of plans by the aid of either the pentagraph or the eidograph can never be recommended where great accuracy is of importance. Where possible, the best way is to replot the whole survey from the field-book to the enlarged scale required. But may be well, nevertheless, to describe these instruments, as they are of use under some circumstances.

The pentagraph is usually made of brass, and consists of four flat bars, so fixed as always to form a parallelogram in all positions of the instrument. The two longer bars shown in the figure are united by a double pivot, which is fixed to the end of one of the bars, and works in two holes placed at the end of the other. The pencil point is attached to one of these bars, and the tracer point to the other bar. The two shorter bars are fixed by pivots to the longer bars, and are also joined at their opposite ends in a similar manner to the joint uniting the longer bars. The position of either the pencil or of the tracing-point is a fixture, while the position of the fulcrum attached to one of the shorter bars and the position of either the pencil or of the pencil point which is attached to the adjacent longer bar can be shifted to suit the proportion required for reduction. This adjustment is effected by means of sliding milled axles, which can be fixed at any part of the longest long and short bars by turning milled-headed clamp screws. The fulcrum contains a lead weight, to which is fixed a bright iron or steel pin, over which the whole instrument travels when in use, being halanced by the six ivory wheels, which rest upon the drawing paper or table upon which the instrument is working. It is important that the drawing paper should be perfectly flat upon a level table, otherwise the wheels upon which the instrument is mounted will sustain frequent shocks, which will lead to inaccuracy in the drawing.

In the eidograph, consisting mainly of three brass bars, these supporting wheels are dispensed with, and the whole instrument is solely supported by the central fixed stand over which it works. The bar marked A carries the tracer and the bar marked B carries the pencil. The central bar is clamped at C. When employed for reduction, as shown in the detail plan, the portion of the central bar carrying the bar marked A is heavier than the portion of the central bar carrying the bar marked B. Hence the balance-weight is placed upon the short end of the central bar to steady the instrument in such a position that the whole is balanced over the fulcrum under C.

The geometrical construction of these instruments is based upon the principle involved in

the construction of similar triangles. In both the pentagraph and the eidograph the pencil-holder, the tracer, and the fulcrum should under all circumstances be in a right line when set up ready for use, so that a fine string stretched from the pencil-holder to the tracer-holder should pass over the fulcrum as indicated by the dotted line shown in the diagram which illustrates the eidograph. Otherwise the instrument is not correctly set.

The pencil-holder is made to slide easily up and down the cylinder in which it rests, and the draughtsman is enabled to raise it off the paper when not required to mark by gently pulling the silk cord attached to the lever arm, which cord passes over the bars of the instrument to the tracer point to which it can be

## PROPORTIONAL COMPASSES

ELLIOTT PATTERN

fastened if desired, so that the draughtsman can prevent false or unnecessary marks being made upon the paper by passing over the cord at the tracer end two fingers of the same hand that moves the tracer. Additional small weights are provided to rest upon the top of the pencil-holder when the pencil is required to make strong marks upon the paper.

When the plan to be reduced contains numerous buildings, the use of the proportional compass will be found advisable. Those fitted with a rack gearing for the movement of the slider are the best, as they can be most accurately set by means of the milled-headed adjusting screw shown in the diagram, and when clamped by the opposite milled-headed screw, are not liable to slip. To move the adjusting screw, the clamp screw must be first loosened, and the instrument is then so set that when the arms are opened, the distance between the points marked A and C bears the required proportion to the distance between the points marked B and D. The plan to be reduced, and the paper upon which the reduced plan is to be plotted, are covered with squares drawn to their correct scales respectively, and the intersection of the lines are indexed for reference by numbers in the one direction, and by letters in the other direction.

## Books.

*Sanitary Engineering for India.* By B. R. HARRINGTON, C.E. Calcutta: W. Newman & Co. 1887.

"Sanitary Engineering," the title of a work lately published in Calcutta, has been written, the author states, with a view to affording instructions "to municipal officials and others not specially informed on the subject." Sanitation, though sorely needed, cannot be said to have yet obtained a firm footing in India, and Mr. Harrington may be right when he observes that the methods and works which are needed by, and adapted to, European conditions are not applicable as yet to Eastern countries. In his remarks, however, on the disposal of sewage, he seems to have overlooked the fact that their prejudices must, at all events for a long time to come, prevent the Hindoo portion of the agricultural community being reconciled to the idea of sewage farms.

The second division of Mr. Harrington's treatise is devoted to the kindred subject of the water-supply of towns, which is perhaps of greater importance than that of drainage in a climate which during nine months of the year is perfectly dry. It is undoubtedly true that the health of the native population is more dependent on, and is more affected by, the quality of the water-supply than by the condition of the drainage, and is therefore deserving of prior attention. The author states that "the pressure system" is not adapted to Indian towns generally, and the statistics of comparative cost per head of population, if correct, go to prove his assertion. Without accepting his views altogether, it may be admitted that, as a general rule, there is no need to adopt the European system for the supply of towns, and that the wants of the population generally may be sufficiently met by a simple gravitation system. But Mr. Harrington argues too exclusively from the situation of the great cities of Upper India, and the existing sources of supply from snow-fed rivers. In the peninsula different conditions prevail, and it is only from a few rivers that a perennial supply of water can be depended upon; hence a system of storage is absolutely necessary, and where such a system has to be resorted to, the supply under pressure necessarily follows both on the score of economy in distribution and prevention of waste, as well as security from pollution. In no other way could the cities of Madras and Bombay have been supplied. There are many other cities in Mysore, the Deccan, and Rajputana similarly situated. Where, however, it is possible to draw direct from snow-fed rivers, as in Upper India, undoubtedly water may be supplied by simple gravitation so as to meet all the requirements of a town or village community, but it is questionable whether Mr. Harrington has realised all the difficulties of securing the permanency of the off-take in rivers whose beds are constantly shifting and whose level varies so much in the season of flood and low water. His plan of distribution, however, as illustrated in his diagrams, certainly seems to combine practical effectiveness as well as simplicity; and if there are no local objections thereto, it undoubtedly is deserving of consideration on the score of economy, and may, it is to be hoped, if it has not already done so, attract the attention of the authorities in India.

*A Treatise upon Cable or Rope Traction as applied to the Working of Street and other Railways.* By J. BUCKNALL SMITH. London: Offices of Engineering. 1887.

This book consists of a reprint of a series of articles which have lately appeared in the pages of our contemporary *Engineering*. The author has been engaged for some time past in carrying out the practical work connected with the subject of which he treats, and his work has a real and living interest for those who may be engaged in working out problems of a like nature. This is a point that will not be unappreciated by practical working engineers in the present day, when the schoolman and theorist occupy so much of the technical book-producing field.

In his preface Mr. Smith tells us that upwards of twelve and a half millions sterling have been expended upon tramways in this kingdom alone, and three per cent. of the entire population is carried daily by this means of transport, and in some cities one person in five, 20 per cent. of the population, travels daily on street railroads. This being the case, it is evident that tramway should have a literature, and Mr. Bucknall Smith supplies the most important contribution yet issued of a no inconsiderable branch of the subject, and one, if the author is right in his opinions, that will take a far more prominent position in the near future.

The modern tramway,—a term, by the way, against which the author exclaims,—was first employed in the United States as early as 1832, but it was not until 1852 that the first successful line was laid down. The first type of street railway was introduced in this country at Birkenhead in 1860, and the next year obtained temporary footing in London. The "Endless Cable Haulage System," the chief subject of the book, was introduced during the year 1873 at San Francisco, and had the important merit of achieving a marked financial success. Since then it has been adopted in other cities of the United States and has crossed the ocean to Australia and New Zealand, besides being tried in other countries. In England we first had practical experience of the system on our suburban height of Highgate Hill, where a cable line was built in the year 1883, and similar works are described as being in course of construction in other parts of London and Edinburgh and Birmingham.

In his introductory chapter the author gives further particulars relating to the introduction of tramways in general. In 1875 powers were granted by Act of Parliament authorising steam traction, and, as our readers are aware, electricity and compressed air have both been used for supplying motive power. We can hardly expect to see the other fast rising sources of motive power, gas, used for locomotive purposes, although even that is possible if startling improvements in gas producers and means of refrigeration are in store; but the petroleum engine may yet propel the street cars of our cities, although here again we want vast strides of improvement to bring such a motive power within the range of practical problems.

These speculations are, however, beside the mark, and we must return to our author at his cable haulage, which is very much within the field of engineering practice. Sir Frederick Bramwell told the members of the British Association at Manchester, a few weeks ago, that rope haulage was first introduced by a less person than the great Brunel (we do not know whether Sir Frederick meant to include mining operations) in the construction of the Thames Tunnel; and some of our readers, alas! too few now, for time passes,—remember when the trains on the Blackwall Railway were hauled from Poplar by rope worked by stationary engines. This, however, was a very different system to that which Mr. Smith has been instrumental in introducing into this country from across the Atlantic.

It will be as well, however, to let our author enumerate the merits of his system in his own words. It offers important advantages, by reducing the working and maintenance expenses by avoiding dirt, smoke, sparks, and steam, and by obviating cruelty to horses. On the last point Mr. Smith lays considerable stress and not without reason. The working life of a tram horse averages  $\frac{1}{2}$  years, and annually about 5,000 horses are crippled, used up, or destroyed by the tramways of this country alone. In other words, the existence and even of a tram horse might be described without exaggeration as death by slow torture, and

rust that there are few, even in this age of practical considerations, who would not welcome any system that would put an end to so much misery to the most faithful and uncomplaining of our dumb servants. But even for the hard-headed "practical" man the mechanical haulage should have attractions. With one or more traction, 77 per cent. of the weight of a tramway are absorbed by hauling. There can be little doubt that a mechanical system can be devised that will save tonnage at a less costly rate than this, and we may hope, therefore, that steam locomotives, cables, or electricity may come more and more into use, even if Mr. Smith is right in his somewhat typical if over-true remark that, "in practice, we may rest assured that the public and companies, however professedly humane, will still continue to use animal power so long as it fits their convenience or their pockets."

Leaving, however, what Mr. Smith refers to as "ethical recommendations," we may give a brief glance at the contents of the book. We had first mention made of the application of rope haulage to mining purposes, and the author then goes on to give some particulars of the old Blackwall Railway, to which we have already made reference. Other early cable railways are also referred to, covering a geographical range from Canterbury to Hong Kong. In 1844 there were thirty-seven miles of wire rope used for hauling on the Durham and Sunderland Railway.

To work the system of endless cable traction here are, of course, required powerful stationary hauling engines. At Highgate, where the line is about a mile in length and of unusual difficulty to work, there are two twenty-five horsepower engines situated in one house at the top of the hill. The cable passes from the winding drums round guide pulleys into the trench which runs beneath the rails wherever the cars have to be pulled. From beneath the cars there descends a gripping arrangement by which the car can be attached to or released from the rope at will, as it may be necessary to stop or go on. The continuous slot, through which the gripper descends, is  $\frac{3}{8}$  in. wide. The cable is made of cranicle steel wire. It is 3 in. in circumference and weighs about five tons.

The various devices by which difficulties inherent to such a means of locomotion are got over are explained in the book. The author gives, in clear and simple language, descriptions of most of the important features; and the illustrations with which the work abounds are admirably suited for conveying a sufficient idea of the mechanical problems dealt with. A chapter is devoted to the explanation of the process of wire-rope manufacture, and the work concludes with a well-written description of the City and Southwark subway scheme.

*Steam Heating Problems; or, Questions, Answers, and Descriptions relating to Steam Heating and Steam Fitting.* From the Sanitary Engineer. New York: The Sanitary Engineer.

This is, in fact, a kind of reprint of "Answers to Correspondents" given in the *Sanitary Engineer*, and it contains a good deal of valuable information, even to experts in steam heating. Many of the replies are small essays, taking the questions submitted for their text. The answers and questions were apparently given as they appeared in the pages of our contemporary, the labour of the editor or compiler having only been that of classifying them into sections.

The various heads under which the subject is treated are as follows:—Boilers, Value of Heating Surfaces, Radiators and Heaters, Piping and Fitting, Ventilation, Steam, Cutting Nipples and Bending Pipes, Raising Water Automatically, Moisture on Walls, and Miscellaneous Questions. The reader will not, of course, expect to find all these subjects exhaustively treated, for it could hardly be hoped that correspondents would be so complaisant as to frame their questions to this effect,—indeed, their chief characteristic appears to be to ask the same question over and over again. There is, however, a great deal of information packed away in these answers, although some of them appear to be of not very recent date, and the numerous illustrations are well calculated to help the text.

Taken in the way we have indicated, we have no hesitation in recommending the book to the notice of English practitioners.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

11,889, Improvements in the Manufacture of Pigments. F. W. Lyte.

This invention refers to an improvement on a previous specification in which the process of producing the pigment from basic salts is described. The principal difference is in the drying, grinding, and subjecting the material previously named to great pressure.

14,206, Improvements in Window Fastenings. R. A. Lee.

The object of this invention is to secure the window-sashes in any desired position for ventilation, &c., and to prevent the window-sash being opened above a fixed distance from the inside. The apparatus consists of a wedge-shaped box with a foot or flange at its base, the box being open at the front, and made with a slot at the back and top to allow of a T-piece sliding in it. A T-shaped stud of metal is also made so that its stem will slide through the wedge-shaped box. Two pieces of india-rubber are placed round these, and the action is that the T-piece is allowed to rest on the top of the slot, and takes its own position, with the india-rubber resting against the sash; but as soon as it is attempted to raise the bottom or lower the top sash, the T-piece, with the rubber, moves down towards the thin end of the wedge-shaped facing, and prevents the window from being opened.

13,983, Improved Boss Valve. J. Creighton.

This valve is designed to obviate the inconvenience of cutting off the supply from a number when one of the series is out of order, or during the temporary removal of one or more of the taps. The invention relates to the class of valves known as regulator valves, and by means of it the supply of water from the main is regulated or entirely shut off. The valve being placed in the box, the action of unscrewing the tap checks, or stops the supply, whereas when the tap is screwed home, the valve opens, and the flow is continuous.

14,674, Portland Cement. W. Scott and Others.

According to this invention, Portland, Roman, or hydraulic cement is mixed with flints, gravel, or flint sand, and slaked lime. These materials are put into a suitable reducing apparatus whereby the mixture is reduced to a very fine powder, and with a certain proportion of ingredients a quick-setting cement is produced.

14,848, Ventilating Buildings. G. Barker.

The system of ventilation which is the subject of this patent is particularly designed for dwelling-rooms, and consists in admitting air through a double door, which appears to the eye as an ordinary door only. The current of air is guided in any way desired, but preferably brought in at the outside side near the lower panels of the door, and admitted into the apartment as near the ceiling as possible.

9,783, Flooring Cramp. A. S. Bayer and C. F. Mott.

The bed plate of this cramp has rearwardly projecting spurs on its under face, which bed themselves in the joints or beam, with a notch at the rear end for engagement with a fixed abutment. A cross-headed pusher is fitted to slide in guides on the upper face of the bed-plate, and is operated by a cam formed on a hand-lever pivoted in rear of the push-head between a pair of upright plates rising from the bed-plate, one of the uprights being formed with rack-teeth, with which a point on the lever engages to hold the lever and push-head up to work. The cam is connected with the push-head by a slotted link to facilitate the withdrawal,

NEW APPLICATIONS FOR PATENTS.

Oct. 7.—13,576, W. Aubin, Fastenings for Window-sashes, &c.

Oct. 8.—13,634, W. Day and G. Dinamor, Water-waste Preventer Syphon Flushing Cistern.—13,656, W. Rickwood, Plates and Buttons for Fixing and Securing Roof Coverings, &c.

Oct. 10.—13,675, T. Potter, Door Checks and Closures.—13,676, H. Harris, Flushing Cisterns.—13,678, F. Poler, Turbine Ventilator.—13,680, J. Sisson, Construction of Roofs.—13,688, H. Gross, Brick and Tile Kilns, &c.—13,705, C. Stewart, Machine for Making Dowel Pins.

Oct. 11.—13,740, C. Duplany, Fireproof Curtains for Theatres and Construction of such Buildings.—13,782, G. Willmor, Dustbins.

Oct. 12.—13,798, W. Hopkins, Hanging or Poising Doors.—13,826, C. Smith, Flush Cistern and Appliances for Closets.—13,828, G. Humblet, Hollow Fireproof Partitions.

Oct. 13.—13,856, A. Heath, Securing [Knobs to Spindles.—13,859, H. Steven, Fastenings for Rain-water Pipes, &c.—13,869, C. Evans, Painters' Brushes.—13,902, R. Punshon, Paving, Flooring, and Roofing Material.—13,912, A. Osterberg.—Fastening or Fixing Window-sashes, &c.—13,920, J. and B. Craven, Machines for Making Sanitary and Drain Pipes.

PROVISIONAL SPECIFICATIONS ACCEPTED.

10,675, J. Rickerby, Combined Compasses, Callipers, T and Set Square, &c.—11,221, J. Sington,

Screws and Screw-drivers.—12,116, E. Johnson, Attaching Door-knobs to Spindles.—12,304, W. Bath and W. Geddes, Fireproof Curtains for Theatres, &c.—12,325, A. Melville, Fireproof Curtains for Theatres and other Buildings.—12,362, P. Barrett, Counterbalancing Window-sashes.—12,434, F. Alford, Ventilator.—12,893, S. Harrison, Testing Gas Pipes and Fittings.—9,384, J. Miller, Ventilators.—12,239, R. Johnson and T. Benton, Hand-saws.—12,341, E. Kirby, Window-fastenings, &c.—12,437, A. Winrow and H. Trundy, Brick-making Machines.—12,747, C. Peak, Metal Door and Window Plates.—19,955, J. Mameikan, Wind-guards and Ventilators.—13,001, J. Hudson, Automatic Fire Sprinklers.

COMPLETE SPECIFICATIONS ACCEPTED.

Open to Opposition for Two Months.

14,136, D. Wilkie, Chimney and Ventilating Shaft tops.—12,213, W. Murray, Window Sashes and Frames.—257, J. Gamble, Warming and Ventilating Houses, &c.—366, T. Storme, Ventilating Rooms or Buildings.—12,948, J. Lowe, Machine for Cutting the Edges of Wall-paper.—16,293, J. Ickringill, Securing and Ornamenting Parquetry.—16,390, L. Oppenheimer, Wood-block Flooring.—1,664, W. Farrell, Gauge for obtaining Lines, Angles, &c., in Working Mouldings on Stone.—11,109, J. Carrett, Chimney-top.

MEETINGS.

FRIDAY, OCTOBER 21.

Architectural Association.—Opening Meeting of the Session. Address by the President, Mr. John Slater, B.A. 7.30 p.m.  
Society of Antiquaries of Scotland (Rhind Lectures in Archaeology).—Mr. Alexander S. Murray, LL.D., on "The Archaeology of Greece." I. 4 p.m.

MONDAY, OCTOBER 24.

Society of Antiquaries of Scotland (Rhind Lectures in Archaeology).—Mr. Alexander S. Murray, LL.D., on "The Archaeology of Greece." II. 4 p.m.

TUESDAY, OCTOBER 25.

Parkes Museum (Lectures for Sanitary Inspectors).—Mr. J. F. J. Sykes, B. Sc., M.R.C.S., on "General Powers and Duties of Inspectors of Nuisances; Method of Inspection." 8 p.m.  
Glasgow Architectural Association.—Mr. J. J. Burnet, F.S.A., on "The Architect's Assistant."

WEDNESDAY, OCTOBER 28.

Society of Antiquaries of Scotland (Rhind Lectures in Archaeology).—Mr. Alexander S. Murray, LL.D., on "The Archaeology of Greece." III. 4 p.m.

FRIDAY, OCTOBER 29.

Parkes Museum (Lectures for Sanitary Inspectors).—Mr. J. F. J. Sykes, B. Sc., M.R.C.S., on "Nature of Nuisances, including Nuisances the abatement of which is difficult." 8 p.m.

Society of Antiquaries of Scotland (Rhind Lectures in Archaeology).—Mr. Alexander S. Murray, LL.D., on "The Archaeology of Greece." IV. 4 p.m.  
Archæological Benevolent Fund.—Annual Meeting. 3 p.m.

SATURDAY, OCTOBER 22.

Altenham Institute (Goldington Crescent, N.W.).—Professor Silvanus P. Thompson, D. Sc., on "Technical Education." 8 p.m.

## Miscellaneous.

**Fireproof Paints.**—A Danish manufacturer, Herr H. Dirichsen, of Copenhagen, has produced some fireproof paints with which experiments have just been made. Two little wooden buildings were erected, furnished with curtains, &c., one building being painted with the new paint and the other not. The latter was consumed in nine minutes, whilst the former was at the end of a quarter of an hour not warmer than the walls could be touched, although only  $\frac{1}{2}$  in. in thickness. Other experiments were also made with thatched roofs, those coated with the paint not burning, but only becoming charred; whilst gaseous, such as is used for theatrical dresses, showed an equal resistance to burn. Even when petroleum was poured on wood thus impregnated the fire made but little progress. M. Dirichsen has patented his invention.

**The Theatres of Brussels.**—The grand opera in Brussels, the Théâtre de la Monnaie, which was opened a few weeks ago, has been greatly improved. The passages have been widened, and the number of exits increased in all parts of the house, whilst the orchestra has been so constructed as to be raised and lowered in order to make the performers invisible when Wagner's operas are being played, according to the composer's favourite arrangement. The house is still lighted with gas, but in the course of the present month it will be replaced by the electric light. In Belgium, by the bye, all theatres are under the supervision of the local authorities; thus in the smaller towns the Commissioner of Police is responsible for all safety arrangements in case of fire. During the last few months nearly all Belgian theatres have, in consequence of the fires in Paris and at Exeter, been greatly improved, whilst one, the Théâtre des Galeries, in Brussels, has been condemned. The new Flemish theatre opened in that city a couple of weeks ago is fitted with iron galleries with numerous exits, whence iron ladders lead down to the floor of the house.

**Barwash, Sussex.**—The new (R.C.) Church of St. Joseph, built by Madame de los Heros, of Southover Hall and Carlton House-terrace, has been opened. The church is built of local bricks with Bath stone dressings, is cruciform on plan, and consists of nave, chancel, and side chapels, these latter forming the transepts. The chapels and chancel have circular apsidal ends and a delicate arcading runs round each. The nave has wagon vaulting in brick in pointed form, carried on stone transverse ribs, and terminating against the chancel arch. The side chapels are domed in brick and stone. The chancel is elaborately groined, the filling in being of fine brick. The carving has been executed by Mr. A. Stevens; the hot-water heating by Mr. F. W. Gritten; the marble mosaic by Mr. R. Davison; the glazing by Messrs. Bell & Co. The presbytery adjoining the church is also near completion. The contract has been satisfactorily carried out, under the architect, by Mr. E. Thurton, of Tunbridge Wells.

**Window-Cleaning Accidents.**—Attention has been repeatedly called to the extreme risk to which servants are exposed when standing or sitting on the outside ledges of windows for the purpose of cleaning them. It should go without saying that such work is wholly unfit for female servants, and they ought never to be permitted to clean the outside of windows at all. Even for men, unless they are steady, careful, and "strong"-headed, there is much danger. Yet what is to be done? The professed window-cleaners are generally reckless of carpets and paint, and the percentage of panes of glass they break, while repudiating all liability for damages on frivolous pretences, is very large; moreover, they are so arbitrary in their practices and aberrant in their arithmetic, that it is a misery to employ them. Windows ought to be so constructed as regards sashes that they could be cleaned from the inside. Where this is not practicable, it is better to use long-handled pads, which do not necessitate either standing or sitting on the ledges, or leaning against the too often broken or insecure frames themselves. It is lamentable that limbs and lives should be imperilled and occasionally sacrificed in the performance of a simple and quite ordinary domestic function which ought to be wholly free from risk.—*Lancet.*

**Manchester Architectural Association.**

The annual *conversations* of the Manchester Architectural Association was held on Tuesday, October 18, in the lecture-hall of the Athenaeum, Princess-street. There was a large attendance of members and their friends, who were received by the President of the Association, Mr. A. H. Davies-Colley, A.R.I.B.A., who also delivered a short address, in which he reviewed the work of the year, and welcomed the members and guests. Mr. Davies-Colley was supported by Mr. Lawrence Booth, Past-President; Mr. A. E. Murray, Honorary Secretary of the Royal Institute of Architects of Ireland; Mr. G. G. Hoskins, President of the Northern Architectural Association; Mr. J. Murgatroyd, Mr. Medland Taylor, and other gentlemen. There were also present, Mr. E. Kirby, President of the Liverpool Architectural Society; Mr. J. Ely, Honorary Secretary of the Manchester Society of Architects; Mr. Alderman Bennett, &c. Letters of apology for absence had been received from Mr. E. I'Anson, President of the Royal Institute of British Architects; Mr. W. H. White, the Secretary of the Royal Institute; and Mr. A. McGibbon, Hon. Secretary of the Glasgow Architectural Association. An attractive exhibition of architectural drawings and models, decorative art and furniture, and specimens of building materials and construction, were inspected by the guests during the evening; and selections of vocal and instrumental music were given at intervals, the latter by the band of the Aegercroft Rowing Club.

**Stanningley, Leeds.**—Mr. Briggs Priestley, M.P., laid the memorial stone of a new Congregational Sunday School at Stanningley on Saturday, the 8th inst. The portion of the building of which the memorial stone was laid is part of a larger scheme which it is intended to carry out, which will consist of an extension of the chapel adjoining, with new rostrum, communion screen, choir seats, &c., and which is being built by Messrs. Wordsworth & Maskell, of Leeds. At the rear of the chapel it is intended to erect four new class-rooms, averaging 15 ft. by 14 ft., and an infants' room, 24 ft. by 22 ft., with gallery. The communication with the chapel is to be by a covered corridor and vestibule from the outside. On the basement will be a beating-chamber and kitchen. The communication with the upper floor will be obtained by means of a hoist. The warming will be by hot water, on the low-pressure principle. The chapel extension will add 100 sittings to the present seat accommodation, and the estimated cost is 7500. Mr. S. Robinson, Bradford, is the architect.

**Election of Water Engineer of Nottingham.**—Out of over ninety applicants for the post of Water Engineer to the Nottingham Corporation, nine were invited to appear before the committee on Friday, the 14th inst. The following were the selected gentlemen:—Mr. H. J. Clarson, Surveyor and Manager, Tamworth Waterworks; Mr. L. T. Godfrey Evans, M.E., Liverpool Corporation Waterworks; Mr. J. E. Hughes, London; Mr. W. A. H. De Pape, M.I.M.E., Tottenham Local Board of Health; Mr. C. H. Priestley, Assoc.-Mem. Inst. C.E.B., Cardiff Waterworks; Mr. H. Preston, Grantham Waterworks Company; Mr. Whitton, Nottingham Corporation Waterworks; Mr. Willink, Vyrnwy Water Scheme of the Liverpool Corporation Waterworks. The committee decided by nine to four in favour of Mr. W. A. H. De Pape, M.I.M.E., subject to the confirmation by the Nottingham Council.

**Cemetery Chapels, South Shields.**—In a competition limited to the architects of South Shields, the Burial Board of that town have selected the following designs submitted for their proposed new cemetery chapels and superintendent's house:—1, "Respite Finem," by Mr. Henry Grieves, A.R.I.B.A.; 2, "Accipe Homo," by Messrs. Stout & Dockray. Six designs were sent in. The Board have given instructions to the author of the first to carry out the works, and have awarded a premium of ten guineas to the authors of the second design.

**Marble Mosaic Hearths.**—Messrs. W. & M. Mainzer send us a sheet of chromolithographed examples of their marble mosaic hearths. The designs in themselves are of no great interest, but they serve to indicate what class of work can be executed for hearths in this material, the effect of which in such a position, and with a good design, is a very agreeable change from tiles.

**Glasgow.**—The Stockwell Free Church erected in Pollokshields, for the Stockwell Free Church Congregation, was opened on Sunday last. The buildings, which are very extensive, comprising a church seating 1,000 people, church hall seating 480, large class-rooms, session house, ladies' room, vestry, &c., have been designed by Mr. John I. Wilson, of Glasgow, his scheme having been selected by the Committee from those submitted in competition. The style of architecture is a free treatment of Italian Renaissance, with a massive tower rising to a height of 140 ft., and containing a fine bronze ball of nearly two tons weight. The entrance vestibule which is semi-octagonal in form, and unusual spacious, has a mosaic floor, laid by Mr. E. Main, of Glasgow. The interior of the church is somewhat novel in treatment, and being free from columns supporting the roof has a very light and open effect. The area, 52 ft. wide, is roofed over in a single span with a double coved ceiling, across which the roof principals are partly shown. The following are the contractors for the various departments of the work, mainly of Glasgow:—Mason, Mr. I. Shannon; Wright, Mr. D. Buchanan; Plumber, Mr. W. Anderson; Slater, Mr. A. Sinclair; plasterer, Mr. A. Brown; glazier, Messrs. Melkic & Sons; painter, Mr. W. Stevenson; gasfitters, Mr. I. Buchanan, Glasgow, and Mr. T. Brown, of Birmingham. Heating, Messrs. Cook & Co., Edinburgh; upholsterer and carpets, Messrs. F. & J. Smith; tiles and mosaic, Mr. T. Main; wrought-iron gates and railings, Mr. George Adam, Purbeck. Mr. George Banks was clerk of works.

**The Keighley Technical Institute.**—The new wing of this Institute was formally opened by the Master of the Clothworkers Company of London (Dr. James Self) on the 14th inst. The whole building forms three sides of a square, with a large open court in the centre. The style of the new wing is in harmony with that of the main structure, and the entrance is formed by a spacious vestibule approached under moulded arches, surmounted by a balcony. Surrounding the vestibule is a stone arcade, which on one side gives access to the hall of the new school, and on the other a cloak and crush room. The chemical lecture theatre, which is 52 ft. long, 30 ft. wide, and 23 ft. high, is entered from the level of the balcony and the vestibule. Adjoining the theatre is a lecture-room, and in close proximity to a wide corridor a spacious apartment is situated, which will be utilised as a workshop and weaving room. This apartment is 70 ft. long and 30 ft. wide. The upper floors are reached by a broad staircase leading from the hall. Several class-rooms occupy the first floor, and on the second floor a museum, 90 ft. long by 28 ft. wide, is placed. On this floor also is the chemical laboratory, which measures 70 ft. long by 30 ft. wide. The entire cost of the building, including the fitting and furnishing, is estimated at 12,000. The architects are Messrs. W. & Mawson, Bradford.

**The Munich Exhibition of 1888.**—The Bavarian Association of Industrial Art (according to the *Sprechsaal*) organised an Exhibition to be held at Munich from May 3 to October, 1888; the principal object of which is to display the progress made during the last twelve years by German industrial art. The development of art in Germany will be represented from an historical point of view by the fitting up of a series of rooms in the styles of the principal artistic epochs; these apartments being fitly devoted to the reception of specimens of the older styles of German industrial art. Modern works are to be grouped according to national and corporate associations, German, Austrian, and Swiss artists being invited to exhibit, and the necessary supervision being exercised by local and central committees. Arrangements are being made for the decorative treatment of the rooms at the cost of the exhibitors, but where collective exhibits are organised the exhibitors will be allowed to carry out the decorative work in conjunction with the directors of the enterprise. The question of awards and distinctions will be treated by a commission representing various countries taking part in the display. The official circular refers to the previous Exhibition of 1876 as having given a marked impetus to artistic progress, and urges upon the exhibitors the duty of making the forthcoming display in every respect successful.

**The Water Supply of Italian Towns.**—In the inquiry on the sanitary condition of all the Italian towns and villages instituted in 1885, the following data, according to the *Reichsanzeiger* (Berlin), were obtained with regard to the supply of drinking water. In 2,491 communes, with 6,196,584 inhabitants, only spring-water was consumed; 1,583 communes, with 5,267,741 inhabitants, had only well water; 1,732 (5,965,703 inhabitants) spring and well-water, and 130 (721,893 inhabitants) only water collected in cisterns for consumption. In 1,321 communes, with 7,026,229 inhabitants, cistern-water in combination with spring and well water was drunk, whilst 946 communes, with 3,201,803 inhabitants drew their drinking water exclusively or chiefly from rivers, and 55 communes with 79,154 inhabitants from lakes. Spring-water is consumed chiefly by the populations of Liguria, Latium, the Abruzzi, the Basilicata, Calabria, Sicily, and Sardinia; well-water preponderates in Piedmont, Lombardy, and Emilia; cisterns are found most frequently in Tuscany, the Mark, Emilia, Campania, Apulia, and Sicily; river-water meets with the largest consumption in Venetia and by the population living near to the mountains of Lombardy, Piedmont, Liguria, and Tuscany; lake-water is drunk near the large lakes of North Italy. In 2,720 communes drinking water is brought longer or shorter distances in metal or wooden pipes, or in conduits constructed of masonry, stone, or clay; in 447 communes the supply is simply through open channels. In 614 communes lead pipes are used in taking drinking-water to towns and houses. In 6,763 Italian communes, with a population of 22,434,735 persons, the required drinking-water is supplied in sufficient quantities; in 1,495 communes, with 6,024,375 inhabitants, the quantity furnished is insufficient. Regarding quality, it is stated that, with a sufficient supply of drinking-water, 81.8 per cent. of the communes have good, 13.1 per cent. medium, and 5.1 per cent. bad water; in the case of the communes with insufficient supply, the proportions are 56.3, 25.5, and 18.2 per cent.

Estate Agency Office,  
 No. 10, Union-court, Old Broad-street, London, E.C., Tuesday, Oct. 18, 1887.

Dear Sir.—Referring to your article in the "Standard Column," during the last few weeks, on "Setting-Curves," it occurs to me to offer to any of your readers who wish further to pursue the subject, a copy or copy of my complete work thereon, with full tables of angles, distances, and offsets required in practice (of which the publishing price is half a guinea) at 3s. 6d. a copy, applied for at my above address, previously to the 31st proximo. The book, I believe, was reviewed in the columns at the time of publication, but I herewith give you a copy for immediate reference. It is now a work proved utility.  
 As a constant subscriber of nineteen years' standing to your journal,

I remain, dear sir, yours faithfully,  
**DAVID LIVINGSTON, C.E.**

To the Editor of the Builder,

### The Late Mr. Beresford Hope.

THE death of Mr. Beresford Hope calls for something more than a passing notice in the pages of a journal devoted to architecture, if only on account of the fact that he was the only amateur since Earl de Grey, the first President, who was ever considered worthy to fill the office of President of the Institute of British Architects. But apart from this claim to commemoration, the active part which Mr. Hope took in promoting church building, his great munificence in aid of such work, his knowledge of and enthusiasm for Mediaeval architecture and art, his loyalty towards all that was best in the architectural profession, and his interest in their work, render his name of which all English architects will think with regard and gratitude. There is something beyond this, too, which the death of Mr. Hope suggests. For he may be said to have been one of the most prominent representatives of a great movement which has run its course and passed away. His name is indissolubly connected with the Gothic revival and with the great modern church building age of the England of this century. Many of us can remember well how great was the zeal, how fervent the hope and enthusiasm for the future, which characterised the writings and speakings and the whole course of action of the leading architects and ecclesiologists who were associated with that movement; how certain they all were about it, how fully persuaded in their own minds that there was a glorious future for English Mediaeval architecture, starting on the basis of the great works of the fourteenth or the thirteenth century (for in this matter there were fluctuations of faith) and going on continually to greater and nobler developments. And of this faith Mr. Hope was no wavering or backsliding disciple. He stuck to his guns to the last, and, with a persistence which had its pathetic aspect, he, at the last meeting of the Architectural Museum at which he presided, went through the same profession of love for and belief in Mediaeval art as the starting-point of modern architecture, before an audience which gave him its applause and respect, but not its credence. The movement with which he was so closely associated died, in fact, before him. And now his own death seems to remove one of the most noteworthy links between us and a past period of architectural history, which, so fast do things move in these latter days, seems

already far behind and forgotten, hidden away, as it were, behind the balustrades and flower-pots of the new Renaissance. Let us think kindly, however, of the Gothic revival and its champions. All revivals are in their nature doomed to be transitory; but at least the Gothic revivalists worshipped a noble and pure phase of the art, which stooped not to such gauds as pots and balustrades.

Mr. Hope was born in 1820, the son of the Mr. Thomas Hope who distinguished himself as the author of a kind of modern Greek novel or romance under the title of "Anastasius," from which he got the sobriquet of "Anastasius Hope," by which he has been sometimes referred to in print as if it were his real name. Mr. Hope the elder had, however, other claims to remembrance besides this work, which have been overlooked in the notices which have appeared in the daily papers. He was the author of a book of illustrations of "Household Furniture and Interior Decorations," executed from his own designs, which was published in 1807, and consists of a number of finely-executed outline plates of rooms and furniture designed on severe antique models; and he also wrote a "History of Architecture," in two volumes, published in 1834, which is, of course, out of date in the light of recent archaeological knowledge, but which is a well-written and comprehensive treatise from the point of view of the author's day, and deserves not to be forgotten. Both the wealth and tastes of the son may be said to have been hereditary, for Thomas Hope was an enthusiast about Greek art and architecture, which was the taste of his day, and the son's architectural proclivities turned in the same manner towards Gothic, as the taste of his own day; the general interest in art and architecture was inherited; the particular form it took in father and son respectively was merely an example of harmonising with the environment. Mr. Beresford Hope's architectural leanings were probably influenced by,—at least, they were closely connected with,—his ecclesiastical creed: he was throughout his life an earnest and devoted adherent of the moderate High Church party, and was one of the first and most important members of the Ecclesiological Society, in which sound Church views and correct Gothic detail went hand in hand.

The election of Mr. Beresford Hope to the office of President of the Institute of Architects, to which we have already referred, did not take place without considerable opposition and paper warfare, as our own columns of the early part of the year 1865 bear witness; and we then expressed our decided opinion, with the greatest respect and friendly feeling to Mr. Hope, that the election of an amateur President as the head of an

essentially professional body was a mistake, especially in regard to the discussion in Council of the many purely professional questions which must inevitably come before such a body. This opinion no one at the present moment will be likely to dissent from; but it must be added that in the address which Mr. Hope delivered from the presidential chair at the opening of the Session 1865-6 of the Institute, he did much to justify, so far, the choice of the majority who voted his election. Instead of giving, as might have been expected, an address from his own special point of view as an ecclesiologist, Mr. Hope adopted the broadest view possible of the profession of architecture; and his address (which will be found in the *Builder* of November 11, 1865, under the heading "Architects, Engineers, and the Coming Season") was in the main a most sensible and well-written appeal in favour of doing away with the strong but, as he considered, arbitrary and unnecessary line of demarcation which in modern times has been drawn between the profession of architect and engineer. He wished to see engineers included in the ranks of the Institute of Architects, that so each branch of the profession, now too much separated, might be drawn into closer union, and each might learn something from the other. "The world should not," he urged, "continue to deceive itself with the belief that Stephenson and Brunel were not architects,—self-made architects, it may be, just as the mathematician Wren and the physician Perrault were self-made architects, but, like those worthies of the seventeenth century, great architects. The notion that because to them architecture came without its usual training, therefore the engineer is for the future to dispense with the trained and learned architect for the construction of buildings whose monumental elevation gives its colour to our age, is a wrong on our whole craft of architecture." The idea which Mr. Hope proceeded to enlarge upon was that all works were not engineering, in the true sense of the term, because they were executed by engineers; that great railway stations and viaducts were really works of architecture; those who erected them were in reality doing, well or ill, architectural work; that in order to do it well they required architectural training and study, the study of the past, as much as those who undertook any other class of building; whereas pure engineering practically repudiates the past, or uses it only to point a self-exalting contrast. "I do not say," he added, "that engineers themselves do so; but this repudiation of the past is the necessary price at which the constructive part of the engineer's business can any longer be formally divided from architecture." In the

same address Mr. Hope took a very high view of the part which ought to be played by the Institute of Architects.

"The Institute ought to be, without rival and without demur, the central regulating Areopagus of Architecture,—of architecture as a science and architecture as an art; of architecture as practised by its professional votaries, and as studied by the amateur,—as loved by both,—throughout this imperial realm. The time should come when the absence of those letters which denote some grade in the Institute from the name of any one who practices architecture should be as much cause for inquiry, as the absence of academic distinction from that of the clergyman who has the misfortune to be a 'literate.'"

Thus the amateur president sketched out a position for the Institute which it has certainly of late been doing its best to fulfil, and which it may entirely fulfil if the best members of the architectural profession will be true to it and to the highest interests of their profession: for that is where the rub really lies.

Among Mr. Hope's various essays and addresses on architectural subjects are some which will repay perusal, even from the standpoint of the present moment. Some of the best of these were addresses delivered at the Architectural Museum, and published afterwards as pamphlets. In one entitled "The Common Sense of Art," delivered in 1858, he gave a fairly comprehensive view of what he thought might be evolved in the way of architectural novelty and originality, from an eclectic study of the whole field of Gothic architecture, answering at some length the question he quaintly propounded at the outset, "What are we to select?" Eclecticism has run wild since then, but Mr. Hope's view was a broad one for the time, and would have been thought by many conservative Gothicists of that day a great deal too broad. Thus it is, in architecture as well as in politics; the liberalism of one generation is the conservatism of the next. In another address, given at the same place in 1864, on the "Art Workman's Position," he made one claim for the art-workman which is only now beginning to meet with any response, viz., that the name of the actual maker and designer should be connected with a piece of art-work, and not only the name of the people who sell it; and he urged this not only on behalf of the art-workman in order that he might have the credit of his work, but on behalf of art and of the public, in order that the actual executor of the work might have the stimulus to do his best which can only exist along with public reputation for his work, coupled as it must be also with liability to wholesome public criticism.

Mr. Hope's most important contribution to the literature of architecture was, however, his book, published by Mr. Murray in 1861, on the "English Cathedral of the Nineteenth Century." This is, of course, in one sense, purely a Churchman's book, and some portions of its contents deal rather with what may be called ecclesiastical polity than architecture; but, so far as it deals with the architectural question from the writer's point of view, it is admirably done, clearly and eloquently written, and very carefully illustrated. A great point in the book is the stress which he laid on the desirability of large-scale churches, churches of cathedral type, in fact, if not quite of cathedral size. He wanted a small number of impressive and spacious buildings rather than a greater number of small parish churches of the average scale and pattern; and if the most is to be made out of the picturesque and artistically elevating side of church worship, there can be no doubt that he was in the right. The whole book is, of course, based on the assumption that Gothic is the only style to be taken into consideration for churches,—it could hardly have been otherwise at that period,—but it contains a great deal of excellent criticism and suggestion, which might be applicable to church building independently of style.

Personally, Mr. Beresford Hope was a man with many friends; possibly he had some enemies, as no one is without; but we cannot say we ever heard of them. He was a genial, courteous, kindly man, with a kindly manner. In public speaking, of which he did a good

deal in his lifetime, his manner was what might be called a little pompous, only that the word rather implies something sour and ill-tempered, which he certainly was not; and he generally managed to make some good hit in his speeches, whether on architecture or any other subject, and enjoyed his joke quite as much as his audience did; and if his friends smiled at his little peculiarities of this kind, they did not like him the less. He was, to sum up, a typical and withal very favourable example of the wealthy amateur and patron of art, with much more knowledge of one branch of art, at all events, than wealthy patrons usually possess; one who used his wealth in this direction both with judgment and liberality, and did his best to encourage what he believed to be the best.

In the *Builder* for March 12, 1870, we gave a portrait of Mr. Hope, which is a very good likeness of him as he then was.

The funeral at Kildown, on Wednesday, was attended by a great number of relatives and friends of the deceased, and the coffin was almost hidden from view beneath the offerings of wreaths and flowers heaped upon it. The monumental tomb in Kildown Churchyard was erected some years ago, from the designs of Messrs. Carpenter & Ingelow, at the time of Lady Mildred Hope's death. It is a monument of some elaboration, in the Gothic style which Mr. Hope so loved, and an illustration of it will be found in the *Builder* of May 6, 1882.

#### BRITISH MUSEUM.

ROOM OF GREEK AND ROMAN SCULPTURE IN RELIEF.

We have already (p. 523) called attention to the new room in which some of the Greek and Roman reliefs so long buried in the dark basements have now been restored to exhibition and a certain amount of daylight. It would be premature at present to criticise the arrangement of these sculptures, as the deficiencies under which they are now seen are due to temporary circumstances for which the niggardliness of the Treasury is responsible, and which, it is to be hoped, may soon be remedied.

These sculptures, it will be remembered, are mainly sepulchral reliefs of Greek and Roman workmanship, dating roughly from about the fourth century B.C. down to the third century A.D.; many of them came to the Museum with the Townley Collection, others from the Earl of Aberdeen, Lord Elgin, Lord Stratford de Redcliffe, and Colonel Leake. In 1852 they were crowded out for want of space and withdrawn from exhibition, and from that period till now their place has known them no more. They have practically ceased to exist for the general public, except in Corbould's fine drawings in the "Museum Marbles."

About eighteen months ago the removal of the Department of Prints to new buildings left a room vacant, and amongst the many clamorous applications for this vacant space it was considered that the "buried sculptures," with their record of thirty-five years in disgrace, had a prior claim. This room had been used as a study by the previous occupants, and obviously a good deal of alteration was necessary in order to prepare it for the new tenants. When, however, the question came forward of granting the funds for this purpose, the Treasury absolutely declined; thirty-five years were in their sight but as yesterday, and their Lordships were of opinion that the alteration proposed was not of urgent necessity and should be postponed for the present. The sum set apart for this purpose out of Museum funds reverted to the Exchequer as savings. Fortunately, in England it sometimes happens that when public spirit fails private munificence comes to the rescue. A small balance remaining from the White bequest has been available for the little that was required to render the room at least presentable. But the whole story is an interesting evidence of British bureaucracy.

If funds should ever be forthcoming, the room will assume a very different aspect. The

sculptures now fixed in the walls will remain, but the windows in the west wall will be built up, and large skylights will take their place. By this means the whole space of an additional wall will be gained, and the present unsuitable side light will be done away with. The present wooden floor will be removed entirely, and a stronger one built on the level of the Elgin Room; and as a small flight of steps will lead from the Mausoleum Room passage direct into the reconstructed room, the whole floor space will in future be available for exhibition of sculptures. The floor space thus provided will be occupied with the fine series of large sarcophagi, with subjects in relief, which are still waiting in the basement round the walls will be placed the sculpture in low relief, which are now temporarily ranged in rows across the room; while the sculptures in high relief, built in the wall, will be seen at a more convenient height than they are from the present floor. Furthermore, the new level of the floor will allow for a basement, corresponding in height to that of the present Græco-Roman basement, which will admit of the exhibition of those objects for which there is no space above; for it must not be supposed that one, or even two, new rooms would exhaust the wealth which the cellars are ready to disgorge. Besides the large sarcophagi, already mentioned, there are a host of sculptures still awaiting release; upwards of forty more reliefs, a set of casts illustrating the development of the Akroterion on Athenian stele; a large series of capitals and other members architecturally most interesting; and a complete columbarium, fitted up with all the various forms of marble sepulchral urn in use in Roman times, some of which are of extremely beautiful work in alabaster.

To turn from what is still unseen to that which is visible, it must be confessed that at present the first sight of the new room will appear somewhat bewildering, especially to those who have not even by lantern-light seen these treasures during their incarceration. Until the room is finally arranged, it is only possible here briefly to point out some of the leading features of interest.

In the collection now on view, we have represented all the different forms of Greek and Roman sepulchral monument. The earliest type of tomb found in Greece is probably the so-called "cypolla" grave, which consisted of a subterranean domed chamber, covered with a heap of earth, *χώρα*. After the cypolla form had disappeared the *χώρα* was sometimes raised to an enormous size, as we know from a law of Solon restricting a work of this kind to the labour of five men for five days. Gradually this gave way to the simple grave, marked by a slender shaft, on which a more or less elaborate design came to be either carved or painted. We know that both forms of burial existed in the time of Plato, who distinguishes between the *χώρα* and *λίθια ἐπιτάφια*. The Egyptians, on the other hand, from the earliest times, buried their dead in a wooden sarcophagus, the sides of which were painted with subjects and inscriptions; and probably about the time when the Greek traders were imitating Egyptian wares at Naukratis on the Delta, this custom was conveyed to Greece. In the First Vase Room is a terra-cotta sarcophagus, painted with Greek designs of the sixth century, from Rhodes. A further stage is represented by the beautiful sarcophagus at Florence (*Hellenic Journal*, vol. iv., p. 354, pl. xxxvi-viii.), painted with a battle of Greeks and Amazons, of about the beginning of the third century B.C., and the analogous example found at Kertch. But, beyond a few isolated instances, which, however, are sufficient to show us the continuous stages of evolution, the Greeks do not seem to have much affected the decorated sarcophagus. How prevalent it was among the Romans we may judge from the large series of small chests arranged on the southernmost shelf across the new room. The lid of the Egyptian prototype took a form which was intended to represent the likeness of the deceased; and so it follows that in Etruscan, and often in Roman imitations, the marble figure of the dead person reclines on the cover, while the paint-

ings on the sides are here replaced by sculpture in relief. Sometimes the sarcophagus was taken to represent, in miniature, the actual house, and the lid is then carved in imitation of a tiled roof, with the edge finished off as imbrices; one example here exhibited has the front carved in the form of the façade of a Roman house, with columns and pilasters, and four doorways. In the same row are two reliefs of special interest: the one represents two gladiators in combat, inscribed with the names probably of the schools,—*familie*,—to which they belonged, with the single word *πρωθιμας*, signifying that Death had presented them with the foil of dismissal; on the other is the very rare representation of a skeleton, with a somewhat cynical reference to Death the leveller, "When only this is left, who is to tell whether I have been a Hylas or a Theseites?"

In the next row (No. 2 from the south side) is a set of banquet scenes, which furnish a rich illustration of the Greek ideas of a future state dealt with in our previous article (p. 383). One of these, marking probably the tomb of some bold sea captain, has in low relief beside his inscription the effigy of the galley in which he served.

In the third row are principally low reliefs of a better period, where the figures are freer and the composition, as a rule, quite simple; graceful figures of ladies at their toilet, or in their earthly home, friends meeting or parting with a friendly grasp of the hand; here is Athene, personifying perhaps the Athenian demos, crowning the citizen who has deserved well of her. One very fine relief from Athens commemorates three ladies of Sestos who died far from their native town; on another, which marked the tomb of fallen warriors, a female figure pours wine for a snake who twines around the trophy which they, perhaps, had helped to win, while a mourning comrade stands beside his horse looking on. The snake is frequently employed, specially in early art, as the symbolic watchfulness which guards the tomb, perhaps also not without some reference to its Chthonian character. A similar relief in the Louvre is explained as the thanksgiving sacrifice of a general for a victory. In that instance, the snake is probably the attribute of Athene Polias.

The next row (No. 4) contains a beautiful series of stele illustrating the slender shafts of the best period, crowned with the graceful akroterion in the form of a palmette; it is instructive to note how the ornament, beginning as the simple finish to the angle of the pediment, grows into the main feature of the monument, covering, as it were, with its luxuriant beauty the shaft which gave it birth. One stele in this row deserves special attention; the main relief is in the form of the special funeral amphora, on which are carved the figures of two warriors, Archiades and Polimonikos. This amphora is supported by a sphinx, who faces the spectator, but whose body, on an heraldic principle common in early art, but very rare in this good period, is flattened out as it were on both sides of the head. This stele formerly belonged to Lord Guilford, owner of the famous Corinthian puteal, which has long since disappeared. The stele was obtained at a London sale by Mr. George Plucknett, who recently presented it to the Museum. May we not hope that its long-lost companion, the puteal, which must be somewhere in England, may also one day find its way here?

The vase which is depicted on the Guilford stele has a peculiar significance in connexion with many other marble vases here exhibited. From the earliest times vases are an indispensable accompaniment of Greek funeral rites; they were employed for the funeral ceremonies, for furnishing the tomb, and sometimes for holding the ashes of the dead. Made of earth, they represented, perhaps, indistinctly the element into which human life must resolve itself: an epitaph of Zonas in the Anthol. Pal. xi., 43, says,—

Δός μοι τοῖς γαίῃς πεπονήμην ἀδὲ κίπτελλον  
ἀς γεινῶν, καὶ ἴψ' ἂ κίσσῃ ἀποθνήσκω.  
And so it came that a special fabric grew up intended solely for this purpose, and the

beautiful series of polychrome lekythi of the fourth century show us the shape most in vogue: probably from this period date the large marble lekythi here exhibited, in which the vase takes the place of the stele, and the painted scenes are replaced by an inscription on sculpture. In another passage of the Anthology, Erinna says,—

"My funeral shaft, and marble shapes that dwell  
Beside it, and sad urn, receptacle  
Of all I am, salute who seek my tomb,  
If from my own, or other cities come,"  
(Garnett's translation.)

Of course, the form of the vase, imitated from terra cotta into marble, undergoes in the new material certain modifications. As a direct development of the idea, we have in Roman times the marble and alabaster actually intended for the ashes, to be placed in columbaria.

On the north wall of the room are fixed some of the most beautiful of the later reliefs; on one of these, on the left, is a pastoral scene, with a pair of goats butting, bulls, and cows; at each end is a shepherd with his dog, the one asleep in the noonday heat, while his companion breathes upon his pipes; the whole is an idyll instinct with the spirit of Theokritus. On the right is a charming decorative design of a frieze of Amazons half reclining, each holding up her crescent shield. In the centre is the head of a sleeping baby, which looks as if it had come direct from a canvas of Raffaele. On the same wall is a curious late design of the carceres of the circus, out of which issue two Erotes driving chariots, to which are harnessed pairs of greyhounds, a scene which one would expect on late Roman gems, and which is probably of the same period as the gems of this class.

On the south wall are two long slabs sculptured with similar subjects, but which show interesting differences of treatment. The one on the right has the Nine Muses, each with a feather in her hair, plucked from the vanquished sirens, and with her distinguishing attribute: in the centre are Apollo striking the lyre, and Athene. It is curious to note that the lyre of Apollo and one Muse rests on a column, as if these reliefs had been copied from statues in the round. A similar group occurs on a sarcophagus in Berlin representing the contest of Apollo and Marsyas. In the group on the left the Nine Muses meet us again, but here they are divided off into pairs, each pair standing within a richly-sculptured niche between two columns: the treatment of this composition is strikingly like some of the early ecclesiastical sculpture of the Renaissance: a likeness which is further suggested by the style of another group on the same wall; it is a very late relief, representing boys at play, which, an inscription informs us, was dedicated by a father to his son, "Filio super omni caritate dilectissimo." The wealth of new material here offered for the study of Greek and Roman sculpture and thought in their latest phase will probably prove the most attractive feature of the new room; the interest of these sculptures will have a special claim on all students of Mediæval art.

NOTES.

**I**N spite of the long and elaborate evidence given by Mr. Walker at the inquest in connexion with the fire at Whiteley's (printed in another column), we are not inclined to accept the theory that the wall was pushed out by the expansion of the girders. Theoretically, no doubt, a length of butted girders such as existed there would expand to the extent of 6 in. or 8 in., if the fire had no action upon the iron except in the direction of its length, but the probability is that before that degree of expansion in length was reached, the iron would have buckled and twisted so much in various directions that the expansion in length would be nullified, or the actual result might even be a contraction so far as the action of the beams on the walls was concerned. The conclusion arrived at by Mr. Walker is perfectly logical if the iron did exactly what it is assumed it would do; but the

fact is, no one can say what iron will do in a fire. Our opinion is that the wall fell from the action of heat upon it, assisted by the disturbing action of the girders under the influence of heat; but we do not think there is anything to prove that this disturbing action was a pushing-out one arising from direct expansion of the iron-work; and it may just as likely have been a dragging weight and leverage exerted by iron which had twisted and lost its bearing power, and was hanging and dragging on the walls. Of course the iron does expand with the heat of a fire, but it may and probably will have become distorted in so many other ways by the time it comes to that point, that it cannot be regarded as a matter of simple linear expansion in length. The real moral is,—protect your iron with a heat-resisting coating, which will give time to put the fire out before the iron can feel it to any serious extent.

**L**ORD RANDOLPH CHURCHILL has been enlightening the public on art at the Science and Art Schools at Newcastle. Lord Randolph seems to have had a misgiving that he was not much of an authority on such subjects, and in regard to the arts of painting, sculpture, and music he confined himself to the comfortable generalisation that these three arts "are holding their own not only amongst certain classes of this country, but over the whole mass of the population of this country." What Lord Randolph means by that he best knows. Probably it was intended as the kind of pleasant generality which would draw applause and might mean anything or nothing. But there is another art about which Lord Randolph is compelled to speak more plainly, that of architecture. He does not find it progressing. He was recently appointed (as, indeed, we observed with some amusement) on a Special Committee on the War Office sites question, and is therefore, no doubt, constituted *ipso facto* an authority on architecture. The War Office designs were all very bad, Lord Randolph thinks, and so English architecture is in a bad way. Now, as a matter of fact, one of the designs was much better than Lord Randolph knows of; but the generally unsatisfactory character of the selected designs was due in great measure first to the fact that the Government conditions were such that many of the first architects of the day would have nothing to do with the competition, and secondly to the fact that one meddling and pragmatical amateur on the first committee of selection managed the rejection of some much better designs because they did not agree with his preconceived notions. The Law Courts is a failure, no doubt; not, however, because it is Gothic, but because it is badly planned, and in this case again the failure is due to the fact that the authorities weakly allowed the best plan, which they had premiated as such, to be pushed on one side. The most audacious statement of this amateur exponent of architecture is that there is no trace of architectural excellence in the residential architecture of to-day. It is a fact that there are a larger number of picturesque houses, houses in which artistic effect, externally and internally, is carefully studied, being built during the present generation than for many generations previous; and it may be useful to Lord Randolph (or, at any rate, to those who listened to his clap-trap) to know that one of the most gifted of the younger architects of France, M. Paul Sédille, in some recent articles on English architecture contributed to a French periodical, has expressed his special admiration of the English Domestic architecture in the warmest terms; and Frenchmen are not by any means given to praising English art. But then M. Sédille knows something about architectural design and Lord Randolph knows nothing, and that makes all the difference.

**T**HE *Transactions* of the Institute of Architects become more and more interesting and valuable in regard to their illustrative contents. The third volume of the *New Series*, which is just in the hands of members, is full of architectural illustrations, many of them of great beauty and interest. The Institute

acted well in giving a large series of Mr. A. B. Mitchell's drawings as Soane Medallist: these are admirable in their combination of freedom of effect with architectural accuracy, and are beautifully reproduced by the phototype process. Mr. Bidlake's drawings as Pugin Travelling Student include very careful measured illustrations of the north porch at Spalding Church; and two pencil drawings by Mr. Oakeshott (Aldwinckle Student), are also given. There is a whole series of illustrations to Mr. Brindley's paper on the use of marble, showing a number of examples of the decorative use of this material. Mr. T. G. Jackson's drawing of the remarkable doorway at Traù is also reproduced as a double-page plate by the phototype process. There are a considerable number of illustrations of Japanese domestic architecture appended to Mr. Conder's paper on that subject, including some reproductions from photographs of interiors by the phototype process. Some sketches in Shropshire and Worcestershire, by Mr. H. D. Walton, are also of considerable interest, and very well executed. In fact, from being what it once was, a mere collection of papers, the *Transactions of the Institute of Architects* has become a volume of things full of artistic beauty and interest, and we heartily congratulate the Institute on their new volume, and hope it may have many equally worthy successors. Among special points in the literary portion of the present volume may be mentioned the reprint of Mr. Wyatt Papworth's paper on "English Buildings in the Middle Ages," which contains a great deal of curious information on prices and the mode of conducting building operations at that period, and in a historical point of view is of permanent value.

CONSIDERABLE interest is being taken in this country in a railway case now proceeding in America involving the question of "undue preference." The suit is against the Cincinnati and New Orleans and the Texas Pacific lines for "discriminating" in freight rates in favour of the Standard Oil Company. This latter concern is a tremendous monopoly, and has been able to apply such pressure to the Railway Companies as to compel them to refuse to convey the oil of its competitors. Whatever may be said as to the adequacy of our laws relating to railways, those relating to undue preference are clear enough to make it impossible for such arbitrary proceedings to be taken with us, and the injustice involved in the case in question is so glaring that it is probable that Mr. Rice, the complainant, will win his suit. He claims that the offending companies should forfeit their charters,—a very heavy penalty,—for their abuse of privilege, so that a verdict in his favour would place them in a most peculiar position. Some years ago a verdict was given against another railway company for "discriminating" in favour of the very same concern, and the present complainant appears to have been far more hardly used than were the firm (Messrs. Scofield & Co.) who instituted the proceedings alluded to. That case was fully argued at Cleveland before a jury composed of men selected especially for the case, and, although the damages awarded were considerably below the amount claimed, the principle of the right of the State to interfere in such matters was clearly affirmed.

A MOTIONLESS GRINDER at first sight seems an impossibility, but nevertheless such an instrument has been produced. When, however, we learn that the motion is contained in the particles to be operated on themselves, the mystery is explained. The pneumatic pulveriser, now being introduced by the British Pneumatic Pulveriser Co., works on this principle. The material to be operated upon is fed into a couple of receptacles or boppers placed side by side a short distance apart. Close to the bottom of each of the hoppers there is a small pipe-like opening, the mouths of these openings pointing towards each other. A jet of superheated steam or compressed air is introduced into each opening, and in this way the particles of the material to be pul-

verised are thrown violently against each other, and the result is a powder of any required degree of fineness ranging between a coarse sand and an impalpable powder. The company have issued an ecstatic circular as full of italics and superlatives as a young lady's letter, in which they set forth the virtues of the apparatus. From this we learn that some of the most difficult substances, such as chrome iron ore, quartz, corundum, cast-iron chips and turnings, granite, French chalk, soap-stone, &c., have been successfully treated. The possibility of an improved grinder for cement-making is a point that more nearly interests us, and we are pleased to learn that the pneumatic pulveriser has been used for this purpose with most gratifying results. When used for reducing clinker cement to powder, a fineness corresponding to a mesh of 200 holes to the inch has been readily obtained. "Diamond cut diamond" has always been recognised as the leading canon of pulverisation, and the apparatus in question appears admirably adapted for extending the principle.

THE relation between science and nature has received a fresh exemplification in the newly-discovered connexion between agriculture and the iron trade. Everybody nowadays has heard of the Thomas & Gilchrist process, by which the phosphorus, which is so bad for steel-making purposes, is eliminated cleanly and quickly from the iron, where it is often very abundant. The resulting rubbish is known as "slag," which hitherto was deemed waste material and which contains an immense deal of phosphoric lime. Any stray iron in it is first separated, and the slag, which in the early days of the iron trade grew into perfect mountains of hideous blackness around the site of the works, is ground into a fine powder, when it forms an admirable fertiliser, far exceeding the capabilities of guano, coprolite, or bonedust. The quality of the powder depends on the fineness of the grinding; it contains as much phosphoric acid as superphosphate, while the price is only one third.

DR. DÜMMLER, in a recent paper, tries to rescue from the reproach of being "Etruscan" a small but important class of Greek vases which have not hitherto received the attention they deserve. As six out of the twenty specimens he enumerates belong to the British Museum, his theory will be weighed with interest in England. All of the vases that we have seen (the five at Würzburg we take on trust from Dr. Dümmeler's account) certainly bear an unmistakable stamp of identity of *fabricque*. They also have a puzzling barbaric air, which, of course, is the reason that they have so long been shelved as Etruscan. Dr. Dümmeler thinks they are Greek work under the influence of Scythian surroundings; in fact, that they were made at some colony in the Pontus, exported probably to Corinth, thence re-exported to Italy. He bases this opinion, which he frankly acknowledges is only opinion, on one of the series, an amphora in the Museo Gregoriano at Rome, on the shoulder-piece of which a combat is depicted in thoroughly Scythian fashion; three horsemen in peaked Scythian caps turn round in rapid flight to shoot at their pursuers. Herodotus (vii. 64) describes the Scythians as wearing sharp-pointed caps, to which he gives the Eastern name "kurbasia." Their custom of fighting in feigned retreat was well known, not only Herodotus but Plato refers to it, in the *Laches*; he uses the Scythians as stock example of men who fight flying as well as pursuing (*ὄπισθεν τῶν καὶ Σκύθαι λίγονται οὐκ ἔτιον περὶ αὐτοὺς ἢ ἑσκόροντες μάχεσθαι*). Dr. Dümmeler rightly says that a number of questions must await the complete and accurate publication of the whole series. He gives five instances in plates viii. and ix. of the last issue of the *Bulletino* of the German Institute in which his paper appears.

IN the same number (II. Heft., 3, 1887) Dr. Hartwig gives two autotype plates of a head of Parian marble, in the possession of Mr. E. Haug, once American Consul at Rome. The head is in itself of fine work and considerable

interest, but Dr. Hartwig's paper seems to us little more than a string of precarious conjectures. From some marks in the head it is conjectured that it was provided with a coronal of rays, and hence was intended to represent the sun-god Helios. It is compared with a rayed terra-cotta head, also in the possession of Mr. E. Haug, and with the well-known coins of Rhodes with the Helios type. The marble head seems to have been attached to a body, and, from the turn of the neck, it is possible that the complete statue stood in a quadriga. From this it is, of course, only a step to think of the Helios, by Lysippos, the work for which the artist was most highly celebrated in antiquity. In fact, Dr. Hartwig thinks that we have here a marble copy of early date of the original bronze. We feel inclined to say with the Scotchman: "Mehbel yes, and mehhe na."

THE last vacant site in Chambers-street, Edinburgh, has been disposed of by the Improvement Trust. By an arrangement between the trustees and the gentleman to whom the site has been disposed of, a memorial tablet is to be placed in the building which is in course of erection, bearing the inscription:—"Near this spot stood the house in which Sir Walter Scott was born, August 15, 1771. Erected by the Magistrates and Town Council: Sir Thomas Clark, Lord Provost; James Lessels, Architect."

THE President of the Royal Scottish Academy, Sir William Fettes Douglas, has represented to the Merchant Company of Edinburgh that it would be a graceful act were the Company to provide a statue of Adam Smith, to be erected in the new National Portrait Gallery now approaching completion. This appeal has been unavailing, as it appears the Company are fettered by their rules as to the disposal of the funds under their management. An effort is, however, being made to procure the money required for the statue by public subscription.

THE *Indian Engineer* of October 1st contains an interesting account, with illustrations, of the process of "launching" the Torkham Bridge girders over the Mehelcoo river. The river is in a deep ravine, and subject to sudden and violent floods, so that building the girders below and hoisting them vertically was out of the question, and they were built on the cliff side and hoisted or landed forward into position by the aid of a steel rope stretched across the ravine, the trailing end of the girder being taken by a roller working on rolled beams laid as rails. The details of the attachment and method of working are given in the diagrams.

THE collection of drawings by the members of the Dutch Watercolour Society now on view at the Gonpil Gallery in New Bond-street includes some fine things, but also shows that the Society is entirely devoted to a mannerism of the "Bottesque" type. There can hardly be said to be a finished drawing in the room, though there are some very fine and powerful sketches of landscape, nearly all of a murky and desolate type, melancholy having apparently marked the modern Dutch School for its own. Among the best of these cold pastorals are Bakhuyzen's "Spring Evening" (22), Du Chattel's "Winter" (30), and Bastert's "Winter Evening" (39), Bakhuyzen's "Wood, Winter" (60), and Poggenbeck's "Winter's Evening" (95). Mauve's "Across the Village" (95), with a back view of a flock of sheep, shows a remarkable power of indicating forms of animals in the middle distance without giving a single detail,—a power which means, of course, very careful study, though it looks careless; but the same artist's "Return of the Flock" (56), where the sheep come up nearer to the foreground, might be entitled "Return of the Snuggles," and shows a tone and colour in landscape which we are thankful to think exists nowhere on this earth. In Gabriel's "Landscape" (2) it is impossible to make out whether the middle portion represents a river or a wet road after rain; after

trying some time we gave it up. Among the architectural subjects are two large interiors by Bosboom (11, 18), executed on a thin paper, which is pasted on a mount so as to leave ridges and wrinkles over the surface; as this occurs in both drawings, it is evidently by design, and is about as shallow a piece of trickery as could be. If the painter had given the same trouble to getting his architectural lines perpendicular it would have been better for his work. There are two or three little bits of Israels; among others, one, "Reading the Bible" (102), which is interesting as showing what the artist's style was in his early days; the others appear to be recent works. Van Essen's "Heads of Lion and Lioness" (28) is an admirable piece of animal painting. In another room is to be seen a large "Pastorale" by Henner, a nude figure relieved against a background of sombre trees, under an evening sky, piping to another who listens; the scale is larger than necessary for the subject; it would have done as well or better half the size; but it is a pure poetic fancy expressed in rich colour, which is worth all the dingy achievements of the Dutch water-colour artists.

A COLLECTION of drawings, under the title of "The Sunny South," by Mr. G. Q. B. Talbot, is on view at the gallery of the Fine Art Society. The landscapes show what may be called good painting, but no great force or originality; the artist has been successful, however, in representing a curious and striking effect of "Morning Mist from Montreux" (39). The drawings dealing with architectural subjects are very good; we may notice particularly the little drawing of "A Marabout's Tomb, Algiers" (31), which is very bright and sparkling in effect. Architectural subjects seem to be Mr. Talbot's hest point, though there are out a small proportion of them in the collection.

SIR WILLIAM MUIR, Principal of the Edinburgh University, in his opening address for the winter session, delivered last week, referred to the outward aspect of the University, and to the additional embellishments it had recently received, specialising the dome over the entrance to the quadrangle of the old college buildings. These buildings, he said, had been hopelessly closed in by the noisy bustle of crowded streets, but now the building, as befitting one of the great edifices of their beautiful city, could be discerned from afar. He also alluded to the handsome fountain erected in the quadrangle by Dr. Cunningham,—a touching monument of the affection,—*patris hanc peritura* of the octogenarian founder toward his *Alma Mater*. He intimated that arrangements were in train for the erection of the academic hall to be attached to the new buildings. He alluded to the progress made in regard to the building for the Students' Union, and to the efforts being made to provide university houses or hotels for the accommodation of the students,—a movement which he wished would meet with every success, and he felt that success was certain if they were carefully planned and arranged, and well regulated.

It appears that a proposal to build a hotel on Shepperton Eyot, near Shepperton Lock, has excited the reasonable apprehension of the West Surrey Water Company, whose intake is a short distance below the Eyot, and who apprehend that their water supply must inevitably be contaminated by the drainage from the proposed hotel. Their secretary has addressed a letter to the Rural Sanitary Board, pointing out that if such a building were erected "it might become a serious matter to the district supplied by this Company," as it unquestionably might, and probably would. Plans of the hotel would have to be submitted to the Board for approval: so the architect and proprietors of the same would do wisely to consider in the meantime what can be done to provide for the drainage of the hotel otherwise than by sending it into the river. They will probably find it difficult to get permission to do the latter from any Sanitary Authority properly alive to its responsibilities.

THE special number of the *Art Annual*, forming what used to be called the Christmas number of the *Art Journal*, is already out; we suppose before long Christmas numbers will be published at Midsummer. As before noted, it consists of a sketch of the life and work of Meissonier, by Mr. Lionel Robinson, with a number of illustrations from the painter's works. These include an admirable photogravure of "La Rixe," as a frontispiece, and a very successful engraving by Mr. Carey after "Waiting for an Audience"; there are also engravings of the brothers Van de Velde, and of the celebrated picture of the retreat from Russia. The smaller illustrations go to prove that Meissonier is a very difficult artist to reproduce, and that much of the painter's delicate art evaporates in the process; few of the cuts gave any just idea of the delicacy of the originals. Some reproductions of original studies by Meissonier are of considerable interest, and will be new to most readers. The study of horses on page 24 shows the care which Meissonier gave to the representation of the animal which he has rendered so splendidly in many of his small masterpieces. The view of the painter's house in Paris is a very poor specimen of architectural sketching. Mr. Robinson's biographical essay contains a good deal that is of interest as to the painter's method of working, &c.

HOW many of our readers are aware that there is a journal devoted especially to bookbinding, under the title of *The Bookbinder*? It is published monthly,\* and the number dated October 25th contains three interesting illustrations of the bookbinder's craft, one by Dupin (1498), and another of a quarto bound by Francis Bedford, and another of the "Hortus Sanitatis," a book bound at Strasburg in 1536, but in the quasi-Oriental style derived from Venice, the first Paradise of bookbinders. There is something else in *The Bookbinder* which interests us more, however, namely, a suggestion that "finishers" who are readers of the journal should, from time to time, send designs to its Editor worked out in printers' ink on white paper, and that any that seemed worthy of it should be published. That is a direct and practical encouragement to artistic effort on the part of working bookbinders, and we should be interested to see what it results in.

#### "OLD BRICKS FOR SALE,"—BOW-STREET AND COVENT GARDEN.

The best known, perhaps, though by no means the most popular house in London, will very soon have been razed to the ground. An important scheme for improvements on the Duke of Bedford's estate, at the north-eastern side of Covent Garden, involves the destruction of the old Bedford Hotel, in the East, or Little, Piazza,—its back premises and the kitchen extending far behind Russell-street; and of the former Bow-street Police-court. This latter is Nos. 4 and 4A, and with it will fall the adjoining premises, Nos. 3 and 5, in that same street. Since the removal of the criminal business to the new Courts on the opposite side of the way these premises have hitherto been occupied by various theatrical agents, hosiers, and costumiers. For the new buildings, erected in 1879,† were demolished all the premises which lay within the area bounded by Broad-court, Cross-court, and Duke's-court, and the last-named alley, a turning out of Bow-street, was abolished.

In Sir Patrick Colquhoun's work‡ we read that a police-court with three magistrates was first established at Bow-street in the year 1749, and that seven other metropolitan courts were subsequently opened in terms of the Statute 32 Geo. III., c. 53. At Bow-street presided the celebrated Sir John Fielding, a descendant of Sir William Fielding, first Earl of Denbigh, and younger half-brother to Henry Fielding, the novelist. Despite the affliction of blindness, Sir John Fielding composed numerous didactic works, amongst them being a description of the

\* William Clowes & Sons.

† For view and plans of the new courts and police offices (Mr. John Taylor, architect) see *Builder* for June 21, 1879.

‡ A Treatise on the Police of the Metropolis, &c. By a Magistrate. Third edition. 1786.

cities of London and Westminster, 1776, 12mo. His ability and rectitude elevated the character of the office of a metropolitan Justice, which in those days had sunk to very low repute. Having succeeded to his brother, whose efforts for the Hanoverian cause were, in December, 1748, rewarded by the then paltry place of Acting Justice for Middlesex and Westminster, he removed to Bow-street. His house there, occupying the site under review, was destroyed, with all its contents, by the No Popery rioters on Tuesday, June 6th, 1780. He died at Brompton, four months afterwards, in September of that year. That house, moreover, had another claim to fame, for it was thence, on February 28th, 1749, that Henry Fielding gave forth to the world his labour of some years, "A History of Tom Jones, a Foundling." Its successor, built of red brick, may yet be distinguished by a stuccoed front, rising one story above its neighbours, by the railing before Nos. 3 and 4 and 4A having terminals in shape of Roman fasces whereof all but two of the axes are broken off, and by its high-pitched gable at the rear. The police-court and cells to the south were on the ground-floor at the hack, and had a large apartment in the basement. But these features are now in ruins; all movable fittings have been carted away; and an extensive clearance is being made, preparatory, as we gather, to the opening out of a wide thoroughfare from Bow-street in alignment with the Northern or Great Piazza, and King-street beyond. These changes, combined with others of recent date, quite alter the aspect of this familiar street.

At daybreak on the morning of Wednesday, March 5th, 1856, Covent-garden Theatre, which Sir Robert Smirke had rebuilt in 1808-9, was totally consumed by a fire that broke out towards the close of a masquerade ball given by Anderson, the *soi-disant* "Wizard of the North." Of that house the pit and box entrances were in Bow-street. The theatre was reconstructed by the Messrs. Lucas, after the late E. M. Barry's designs, and at a total cost exceeding 70,000*l*. Then followed the ridiculous and for many years useless Floral Hall, which was opened on March 7th, 1860, by a ball to celebrate the constitution of our Volunteer Rifle Corps. For its southern entrance the continuity of Inigo Jones's Piazza was ruthlessly broken, and arches of cast-iron substituted for the arcade. Gye's project for a large central flower-market is at length, however, partially realised, since within the past few weeks the Floral Hall has been adapted for service as a fruit depot in connexion with the market in Covent-garden.

"I've had to-day a Dozen Billet Doux  
From Fops and Wits, and Gits, and Bow Street Beaux."

Thus did Mrs. Bracegirdle begin an epilogue, by Dryden, on the boards of Drury-lane. Sir Walter Scott comments on the passage by observing that a billet-doux from Bow-street would now be less flattering than alarming. But in Dryden's time Bow-street was eminently the Bond-street of the town. It was originally laid out in the year 1687, being more curved in shape than it is at present, and terminated towards the upper end, beyond Hart-street, in a *cul-de-sac* that abutted against the hack of Long-acre at a spot a few yards east of Phoenix-alley, since Hanover-court, the last home of John Taylor, the Water Poet. Hutton, in his "New View of London" (1708) calls it "a spacious Str. betw. Russell Str., Covent Garden, S.E., and near Long Acre;" Strype, writing in 1730, describes it as being "open and large with very good houses, well inhabited, and resorted unto by gentry for lodgings, as are most of the other houses in this parish" [St. Paul's]. But within four or five years it rapidly declined in favour; a downfall to which the Police-court, with its inevitable surroundings, in all likelihood largely contributed. Amongst its inhabitants during the decadence were Edmund Curll, at No. 1; Spranger Barry, over what is now Mrs. Edwards's ham and beef shop; and was formerly Will's Coffee-house; \* and Dr. Johnson, who came hither from the "Black Boy" in the Strand, and quitted his lodgings for others in Holborn. For Rich's theatre was pulled down the house which Dr. Radcliffe had occupied during the interval 1687-1714. It was whilst residing here that he had the famous passage of arms about the garden door with

\* This shop, with a private door opening out of Bow-street, is now 21, Russell-street. First known as the Red Cow, and then as The Rose.

Sir Codfrey Kneller, who lived in the Eastern Piazza (Bedford Hotel). Three doors from Radcliffe, at the widow Hilton's, opposite to the "Cock," lived Wycherley, with his wife, the Lady Letitia, widow to Charles, second Earl of Drogheda; and it is in the "Cock" tavern, on the eastern side of Bow-street, that he lays two of the best scenes of his "Plain Dealer," wherein, as elsewhere, he excels all our comic dramatists for his truth of detection of what is cant, and in exposing hypocrisy: the play is worth volumes of sermons. Tonson, too, had his private house and printing-office in Bow-street. At No. 3 lived Marcellus Laroono (1680-1702), who drew the figures for Tempest's "Cries of London." The house which Grinling Gibbons occupied for many years was, if we mistake not, over against the present Strand Union Relief and Register offices. On the eastern side, too, once lived Major Mohun, the actor, and William Longueville, friend to the author of "Hindibraa." In this street was born (1661) Robert Harley, Earl of Oxford; and Waller for two years was tenant of the house on the site of the old Police-court. Here Waller composed his famous Panegyric upon Cromwell, for whose superiority as compared with his subsequent Congratulation he excused himself to the King in saying that poets succeed better in fiction than in truth. In his rooms at the northern end of the street, Bonnell Thornton held (1762) an exhibition of paintings in ridicule of the Society of Arts,—for as yet the Royal Academy was not,—which we have seen imitated in our own day by Mr. Furness's humorous set of drawings recently collected at the Grosvenor Gallery. To finish, though not to complete our list of worthies, we must cite one other name,—as immortal, indeed, as any we have mentioned. Snayk receives a letter, gives it to Will Honeycomb, and Sir Andrew Freeport reads it to the club, which concludes:—"If you would go down to the country, and leave off all your vanities but your singing, let me know at my lodgings in Bow-street, Covent-garden, and you shall be encouraged by your humble servant, Roger de Coverley."

#### THE ARCHITECTURAL ASSOCIATION: THE PRESIDENT'S ADDRESS.

The first meeting of this Association for the present session took place on the 21st inst. in the meeting-room of the Royal Institute of British Architects, which has been kindly placed at the disposal of the Architectural Association for its meetings. Mr. John Slater, B.A. (President), occupied the chair, and there was a very large attendance.

Seventy gentlemen were nominated for membership, and Mr. William Emerson was elected a member by acclamation.

The Chairman announced that Mr. P. J. Marvin had been nominated to serve on the Committee in place of Mr. E. Guy Dawher, resigned. The name of Mr. W. J. H. Leverton also being proposed, it was decided to take the vote on a later occasion.

Votes of thanks were passed to those gentlemen who had afforded facilities for the interesting visits made during the vacation. Votes of thanks were also passed to the Entertainments Committee, to Mr. Briggs, and to the various exhibitors at the recent *conversations*, a special vote being awarded to the Manager of the Hotel Windsor for kindly lending a pianoforte in an emergency without remuneration.

The Chairman then distributed the prizes, of which we published a list in the *Builder* for Oct. 13, p. 525, to which we may now add that the Sketch Book Prize was awarded to Mr. A. B. Pite.

The annual report of the Committee, and the Treasurer's account, were adopted by the meeting, and a special vote of thanks passed to the hon. auditors, Mr. A. C. Bulmer Booth and F. E. Eales.

Mr. Slater, who was very cordially received, then delivered his Presidential address, which was as follows:—

Gentlemen,—My first duty in rising to address you this evening is to express my warmest acknowledgments to the members of this Association, both those who are present and many who are absent, for the honour you have done me in electing me to this position. The feelings of the occupant of this chair on the threshold of his year of office must necessarily

be of somewhat complex character, as mingled with the pride and satisfaction one experiences at having been thought worthy of filling the position of President of the Architectural Association, there must be considerable anxiety as to one's ability to perform its duties in such a way as to maintain the prestige of the Association at the high level which it has attained.

When an association or society is approaching the fiftieth year of its existence, and numbers on its roll nearly 1,000 members, no one can for a moment call in question its complete success, for its position speaks for itself and is beyond cavil. But it appears to me that in this very success lurks an element of danger which, unless it be carefully guarded against by those who have the conduct of the affairs of the society, may at no very distant time threaten the stability of the fabric which has been so carefully reared. This danger is twofold: on the one hand, there is the tendency to point to what has been done and to ignore the ever-changing conditions of the times, and consequently to crystallise; on the other hand is the tendency to ignore the past and to rush eagerly and impetuously along new paths without carefully studying the direction which those paths take. We shall best guard against this double danger in the case of such an Association as our own by occasionally reviewing its history and ascertaining what were the aims and objects of its founders, by seeing how these aims have been varied with the growing requirements of the times and how in the present day they still demand modification. It seems to be the fate of all great undertakings to have their origin wrapped in a certain amount of obscurity, and this Association is no exception to the general rule, as the records of its early years are most meagre; but I believe it to be a well-authenticated fact that it developed from the Society of Architectural Draughtsmen, which was founded in 1842 by a small band of earnest workers. The objects of this Society were threefold.

1. To assist the members in obtaining employment.
2. To foster good draughtsmanship, by making it a rule that every member should furnish quarterly a drawing of some executed architectural subject.
3. The establishment of a benefit fund upon which the members could draw in the event of sickness. I may say in passing that I think it would have been a wise thing if the Association could have retained as part of its functions this last object in some form or other.

The society had some difficulty in getting a firm footing; but in July, 1845, the *Builder* had a short notice of it, stating that "the association seems now to be very satisfactorily organised, and promises to be useful in facilitating communications between its members and the profession generally." The works contributed by the members turned out to be of such excellence and of so much general interest that in September, 1845, the first public exhibition of drawings was held in rooms in Southampton-street, Strand. This attracted general attention, and was of great use in increasing the number of members. On February 3rd, 1847, a most important and, as the Germans would say, epoch-making, paper was read by Professor (then Mr.) Kerr, in which he sketched the outline of an architectural association of students for mutual instruction and improvement. The opening sentences of that paper were as follow:—"When I say that the present system of architectural education is extremely defective, I may appeal for confirmation to the experience of every one of you, and this is so much the case that the architect is perfectly anomalous among professionals." That, gentlemen, was over forty years ago. Looking at the experience that has been gained since then, and making every allowance for the improved opportunities of study which now exist, should we be far wrong in using precisely the same language in this year of grace, 1887? Can we say now that the present system of architectural education is other than extremely defective, or that the architect's position, as compared with that of other professional men, is other than absurdly,—I might almost say disgracefully,—anomalous? The result of this paper was the establishment of the Architectural Association, which held its first *conversations* in Lyon's Inn Hall on October 8th, 1847, the report of which says that "it was held under very promising circumstances, more than 100 gentlemen being present." Compare that meeting with our *con-*

*versations* a fortnight ago, and you will have some notion of the progress which the Association has made. In November, 1847, it numbered eighty members. The objects of the Association were stated to be,—(1) the development of true principles of criticism in architecture; (2) the advancement of the study of design; (3) the provision of means whereby the student may acquire an aptitude for applying and extending the present materials of the art. The new society soon gave evidence of its vitality by appointing a committee to investigate the question of competitions, which, even then, was a burning one, and in 1849 a very able report was issued. Matters seem to have gone on more or less successfully for the next few years until we come to 1856, which was a stormy year in the annals of the Association. On May 2nd in that year a series of resolutions were moved, the last of which affirmed "that the Architectural Association having been virtually renounced by both the elder and the younger members of the profession, there are sufficient reasons for taking the requisite measures for dissolving the society." I am unable to trace the causes which led to this resolution being proposed,—fortunately it was not carried,—but there had evidently been considerable differences of opinion among the members, much friction between the Association and the Institute, and some very outspoken criticism of the latter's proceedings. The discussion which ensued on the moving of this resolution led the Institute to take what I believe was its first formal recognition of the Association by addressing to its officers a very dignified letter, which contained suggestions for a much closer union between the two bodies, and which finished with these weighty words which I would urge every architect of to-day to take to heart, for they are as true now as ever they were:—"The Council desire to record their opinion that every alienation among its members tends to a lowering of the social weight and position of the profession as a body, and that a policy of affiliation is infinitely to be preferred to one of repulsion and isolation." Unfortunately, the only idea of union which the Institute seemed able to grasp at that time was that of complete fusion, and after a certain amount of discussion, a resolution was passed that this was not expedient. It was evidently felt that the Charter was not liberal enough for the Association. Notwithstanding the internal condition of the Architectural Association in this year, it had just previously done one of the most important services ever rendered to the profession, as, in November, 1855, it memorialised the Institute on the subject of examinations, and begged that body to frame some kind of examination for students, the passing of which should be the outward and visible sign of honest study, hard work, or intrinsic ability. The Association was very urgent in this matter, as although the idea of holding examinations did not find favour with the Royal Institute of British Architects at the time, it was pressed again and again, until at last,—not, however, till six years had passed,—the Voluntary Examination was instituted. It is both curious and interesting at this time to see what matters the Association turned its attention to; for instance, in the next year, 1857, a formal resolution was passed expressing the opinion of the Association "that the privilege of the Saturday half-holiday should be accorded to the pupils and assistants of architects in London and the United Kingdom." You see the immense vitality of the young body: the vexed subject of competitions was not too high for it, nor the Saturday half-holiday too low. An important event occurred in 1859, namely, the removal of the Association from Lyon's Inn Hall to Conduit-street, the first *conversations* being held there on April 2nd, 1859. It is very interesting to notice that, even at that time, there were such strong sticklers for independence as to oppose this move, on the ground that it must bring the Association too much under the influence of the Royal Institute of British Architects. Notwithstanding all its vitality, however, it is clear that the Association had not yet got into its proper groove, as we find that again in 1860 a resolution was proposed and carried to this effect: "That the members of the Architectural Association have not afforded and do not afford that practical support in its working which is necessary for carrying out its objects, and that it is, therefore, desirable that the committee should further consider and report whether there is any course short of closing its oper-

ations which they can recommend for the adoption of the Association." A special committee was appointed, and they reported the condition of the Association to be critical, but as its usefulness had been very great they were unwilling to recommend that it be broken up until every means had been tried to restore its efficiency. Most fortunately for us, and for many hundreds of others who have passed through the ranks of the Association, means were found to restore its efficiency; new classes were formed, and a lending library was established, the value of which cannot be overstated; and from that time to the present, with slight and inevitable vicissitudes, it has gone on increasing its numbers and widening its sphere of action until it has become the large and powerful body which it now is. Now, gentlemen, I have compiled this hasty sketch of the early history of the Association because I think it both interesting and instructive. We are now able to take a judicial view of those years. What is the reason that after completing its tenth year, on two occasions within five years thoughts of closing its operations were seriously entertained? Forty years ago design and draughtsmanship were considered almost the sole essentials for an architect,—the nucleus of the Association, as we have seen, was the Society of Architectural Draughtsmen. Design was its main object. For the first twelve years after its formation the Class of Design was the only class in existence; then in 1859 a class of modelling was formed, which had but a languid existence and finally expired in 1863. The whole scope and objects of the Association were too narrow and were kept too rigidly to the original lines. New ideas as to the necessity of an architect's acquiring some practical and scientific knowledge were gaining ground, and it was by conforming to these ideas, by widening the whole range of mutual study, by the institution of such classes as those for preparation for the Voluntary Examination of the Royal Institute of British Architects, which have gradually developed into the various classes which we now have, by leaving the old tracks and by entering upon new courses, that failure was averted and success assured. May I venture, most respectfully but most earnestly, to beg some of those old and honored members of this Architectural Association who have done and are still doing yeoman service for it, and who sometimes think that we are venturing upon somewhat risky experiments, to look back on those years, 1856 to 1860, and to hear in mind the words of the American poet, who says:—

"New occasions bring new duties,  
Time makes old things seem uncouth;  
They must ave by pressing onward,  
Who would keep abreast of truth."

and by truth I mean the growing requirements of the times.

I do not ignore the opposite danger which I alluded to, that of going too fast and too far in new directions, but you must remember that, although the individual constituents of the committee are constantly changing, it always contains more old than new members, so that there will always be a preponderating inclination towards following precedent rather than towards departing from it; and when any terribly novel course is suggested, as occurred for instance when the daring iconoclastic proposal to raise the subscription was mooted, the conservatism of the general body can always be successfully appealed to to resist innovation.

To turn now from the historic to the more immediate past, it is my pleasant lot to congratulate the members upon a most prosperous session; the meetings have been well attended, the classes have been more numerous than ever before, and the work done has been of a very high order of merit. I cannot refrain from making special mention of the Masonry Class, which Mr. Lawrence Harvey kindly conducted gratuitously, and I feel confident that every member of that class will appreciate the advantages of joining it increasingly as his professional practice enlarges, for nothing gives a man greater facility in designing than a thorough knowledge of form, and I can conceive of no better way of gaining this knowledge than by acquiring practical experience in the various problems of stone-cutting. I trust that this class will not be allowed to lapse, but that many members will avail themselves of Mr. Harvey's instruction at the City Guilds Institution. Mr. Quick's lectures on "Graphic

Statics" also deserve a word of mention, and I would strongly recommend them to the more advanced students. It is much to be regretted that the Class of Colour Decoration has not been better supported, and I cannot help thinking that there are many students whose tastes lie in that direction who would derive great benefit from joining this class; and as an inducement to the study of this branch of our art, I would remind you of the valuable Owen Jones Studentship at the Institute, which is now given for the best design in colour decoration, for which this class would form an admirable practising ground. The lectures will be continued on slightly different lines from those of the past session. Mr. Tarver gives up the History lectures, and the best thanks of the Association are due to him for the immense amount of time and trouble which he has given to these lectures. Other short courses will be given by Mr. Sedding and Mr. Stannus, the latter gentleman taking the Classic and Continental styles, and Mr. Sedding confining himself to English architecture. Mr. Lovegrove, who always gives his time and labours ungrudgingly to the Association, will continue his excellent course of lectures on Construction. In connexion with these classes and lectures, it is worth noting that by the liberality of extraneous donors the list of prizes that can be obtained by students has been much enlarged. This I think a matter for congratulation. Possibly in an ideal community work would always be pursued for its own sake, but I am quite sure ninety-nine persons out of a hundred work better if they have a goal to aim for, and the healthy stimulus of friendly rivalry for a prize is, in my opinion, productive of great good. But this friendly emulation is a very different thing from pot-bunting, which should be guarded against most rigidly, and I believe it is effectually guarded against by our rules. With reference to these prizes, I would specially call your attention to the foreign travelling studentship which Mr. Aldwinckle's liberality has thrown open to the members of the Association, the regulations for which have been slightly modified. It would be telling a three-fold tale were I to attempt to describe the manifold advantages which foreign travel affords to an architect: it is, in fact, absolutely indispensable. I feel confident many students would be glad of this assistance which this prize would afford them, and I do most earnestly hope that at the close of the current session the Committee will not have the thankless task of informing Mr. Aldwinckle that there has been no worthy candidate for his prize. It is a matter of great regret to the Committee that one prize has not been awarded, owing to the fact that there has not been a single competitor for it: I allude to the Essay Prize. Now this is not as it should be. However clever an architect may be, a little literary grace will never come amiss to him, and the information gained in reading up for the Essay Prize, combined with the practice in putting down the result of your reading in good, nervous, idiomatic English, will be of great value to every student. I do beg of you to bear this in mind, and I hope we shall have good competition for this prize next year. The vacation visits instituted last year have more than kept up their popularity, and serve an important educational purpose, affording students an opportunity of inspecting both old historical specimens of English architecture, like Loseley and Sutton Place, and the new methods of the most able modern practitioners. The annual excursion, which was first set on foot by the late Mr. Sharpe, is still most attractive. In reviewing the past session I must not overlook one very pleasing event, viz., the appointment of an old President of the Association, Mr. Blashill, who has shown the great interest which he still retains in its work in the most practical way by founding a studentship, to the important post of Superintendent Architect of the Metropolitan Board of Works. To another member of the Association, Mr. Collett, has been awarded the high honour and the difficult task of carrying out the important buildings of the Imperial Institute, and it is worthy of remark that of the six gentlemen who were selected to compete for this work four are members of this Association.

A word of notice is due to the establishment of the "A. A. Notes," under the editorship of one of the most hardworking, versatile, and efficient officers the Association has ever had, Mr. H. D. Appleton. The work of the

Association is now so extensive and of so varied a nature that some such publication was most wanted in order to keep members *au courant* with what is being done. It offers an admirable medium for suggestions of improvement and for friendly criticism of the action of the executive, and as the subscription is very low, I hope this next session its circulation will largely increase.

One of the salient features of the last few years' history of the Association has been the increase of the *entente cordiale* between us and the Royal Institute of British Architects, the outward and visible sign of which is that we are holding our meeting in this room, and I heartily congratulate the members upon the fact, as I feel sure you will all be much more comfortable than downstairs. I propose to examine this closer connexion between these two bodies somewhat in detail, because I am most anxious that there should be no misunderstanding among the members of this Association as to its meaning. I pointed out to you that when we first moved to Conduit-street some members objected, on the ground that we were getting too close to the Institute, and some may hold the same opinion as to this latest move. Now, gentlemen, I believe I am only stating the literal fact when I say that there is not a single member of your committee who is not thoroughly convinced that anything tending to diminish the independence and freedom of action of this body, anything likely to make the Association an appanage or dependency upon any larger body, whatever it may be called, would be to sign the death-warrant of the Architectural Association. I am one of the strongest advocates for making the connexion between the two bodies as close and intimate as possible, but I am a stronger opponent of anything approaching amalgamation. Each body has work to do which cannot be done by the other, but each can give the other material and valuable assistance. At one time, as I mentioned in the brief *résumé* of the history of the Association, there was a feeling of jealousy and coldness between the two bodies which was most prejudicial to the interests of each, which lost this Association the services of some of its ablest and most hardworking members, and which, if persisted in, would, I verily believe, have wrecked the Association. It would be useless to inquire now as to where the fault lay, but probably it would be found to be on both sides; but those feelings have now gone, never, I trust, to return, and it should be and I believe will be the earnest endeavour of the two bodies to work together for the advancement of education, the furtherance of art, and the general well-being of our noble profession. The proud motto of the Institute, "*Unum civium doceri urimum*," can only be realised by following the motto of this Association, "Design with beauty, build in truth." That there is ample work connected with the architectural profession wanting doing that would tax the energies of any Society or combination of Societies, however powerful, must be patent to any one who has given the slightest attention to the position of architecture and architects at the present time in this country; and this work can only be done, not by frittering away energies in isolated attempts at improvement, not by blaming the executive of this or that institution for not doing more and yet moving never a finger to help them, not by opposing endeavours to obtain increased powers and enlarged means of usefulness, but by uniting hand to hand and shoulder to shoulder, and making the most urgent endeavours to attack the problem as a whole. What the precise form of relationship between this Association and the Institute will be when the latter gets into full work under its new Charter and By-laws is not yet quite clear, but it seems to me that it should be something like that existing between the University and its colleges. These all manage their own affairs entirely and provide for their students the means of obtaining instruction; but the University, by the establishment of degrees and shaping the examinations, and by grants for lectureships, exercises considerable influence upon the curriculum and always avails itself of the advice and co-operation of the executive of the colleges. Of course, the analogy is not complete, as a University has to do exclusively with teaching, whereas a society like the Institute has much to do with practice as well as with education. But the examination which was set on foot by the Institute has shown most clearly that architectural training and education

are the subjects which most emphatically require urgent attention. This examination seems to me to be somewhat like an advanced guard sent forward to examine an enemy's country, and the chief thing that has been discovered is the nakedness of the land. The difficulty of providing adequate means of acquiring professional knowledge for the young men who are coming into the profession every year in shoals is almost appalling in its magnitude. I do not ignore the existing means, rather would I call special attention to them, such as the two colleges in London whose architectural students are presided over by two eminent professors, both of whom are past-Presidents of this Association, and where, as I can testify from personal experience, excellent work is done; and I fully acknowledge the efforts which are being made by Sir Philip Magnus at the City Guilds Institute, and by other technical colleges and schools in the country, and latest of all by the plucky action of two members of this body in establishing a studio; but when you take the average yearly number of students at all these institutions for the past few years and compare it with the number who enter this Association, it is perfectly evident that the institutions I have named do not reach one-tenth of those who are preparing themselves for architectural practice. In this matter of education the Association has for some time been well in the van. Since I became acquainted with the inner working of the Association I have been perfectly amazed at the amount of voluntary work which it does, which is most honourable to the Association and the members. But the question arises whether this voluntary work is adequate and whether it is the best. Many of the older members of the body tell us that the voluntary system is the essence of the Association. By all means let it remain so, and there can be no question that there will be ample room for all the voluntary work that can be obtained. But is there any reason why this should not be supplemented by more extended educational work of a higher kind, and which cannot be obtained gratis? There is many an able man perfectly competent to conduct classes, or to give lectures, who simply cannot afford to give his time for nothing, or even for the ludicrously small sum which the Association pays its lecturers, and I confess I can see nothing derogatory to this Association in accepting grants for lectureships, as shadowed forth in the opening address of the President of the Institute last year, snatching funds were available from the Institute; for I really believe that the limit has been very nearly reached of the voluntary work of the Association.

A writer in the "A. A. Notes" has pertinently asked what provision the Association makes for preparing its members for the Institute Examination, and has suggested sweeping reforms in the methods of imparting instruction. It is not a complicated arithmetical problem to ascertain what 1,000 half-guineas amount to, and a glance at the revenue account will show what balance the Association has, after paying the absolutely necessary outgoings, for increasing its usefulness in this way; and for my part I think the suggestions to which I have alluded worthy of the most serious attention. In this connection may I venture to make an appeal to members of the Association? I believe some old members hold the opinion that after a time they should resign membership of the Association, and leave the work to younger men. As far as the work is concerned, this may be so; but I would remind them that very little can be done without the sinews of war, and I would beg of them to leave their names on the books, and give us their small contributions yearly, upon which so much depends. The committee would willingly do more to assist with the preparation of candidates for the Institute Examination if they could, but I very much fear they have got to the end of their tether. And after all, gentlemen, the question does force itself upon my mind very frequently,—Do we get the best work of one individual in a thousand if it is given voluntarily?

The Institute Examination is so intimately connected with our work that no excuses are needed for referring to it again, although it has been dealt with by every President of the last three or four years. Some people consider the examination a success; those are those who look at it from the outside, and see that a fair number of candidates present themselves;

others, who look at it more from the inside, and have opportunities for judging of the nature of the work done, are sometimes disposed to be despondent and vote it a failure. But I do not think two opinions exist as to the immense amount of good which has been already done by its establishment. *Credo experto.* Ask every candidate who has presented himself, whether he passed the first time, whether he failed at the first attempt and has subsequently succeeded in passing, or even if he has as yet only made the attempt to pass, and I believe every one will tell you that the mere preparation for the Examination has done much to widen his horizon and to increase his interest in everything connected with his professional work. I am not saying that either the general scheme or the details of the Examination are perfect, because I believe both require modification, and I quite hope to see improvements made in it before another year has expired, but what I want to impress upon all members of this Association, whether students or masters, and if by chance any faint echo of these words of mine may reach them, others who are not members of this Association, is this: that passing the Institute Examination, and the subsequent if not consequent Associateship, should be considered as essential a part of the training of an architect as being drilled or learning to design. I do not believe it possible to overrate the value of such an examination if it be made the goal of our early studies in methodising and focussing, so to speak, those studies. I know from personal experience how difficult it used to be twenty years ago, yet how difficult it is for every one of us as we grow older, to avoid being *dilettanti* or sciolists, and how apt we are to consider superficial knowledge sound knowledge, simply from the lack of some means of putting it to the test. This test the Examination supplies, and I want every student of the Association to make up his mind that it will be in some degree a disgrace not to pass it, and every master to feel it a duty to assist his pupil to pass it, with advice and instruction on the one hand, and by allowing him time to prepare for it on the other. I should like to endorse, as strongly as I possibly can, the recommendation of Mr. F. Anson that the Examination should be recognised by a clause in the indentures of every articulated pupil. And this applies not only to London, but to the provinces also. There are differences in the mode of carrying on practice in the provinces and in London, which prove almost insuperable obstacles to framing rules of practice which should be equally applicable in all circumstances and in all parts of the country; but the necessity of recognising this Examination is equally binding upon all members of the profession wherever they may be established. It is a gratifying fact that although it has only been established five years the Examination has been already held at three provincial centres, and I should strongly advocate increasing the number of centres, even though the candidates were very few at first, because I believe it would awaken an interest in the subject, and open new ground. I see no reason why, supposing funds were available, the Association should not assist in this work. We have for a long time had one country branch affiliated to ourselves, and I do not think it would be difficult to devise a scheme whereby other provincial societies might enter into relations with us, somewhat on the lines of affiliation, with mutual advantage both of them and of ourselves; in fact, I think it quite possible that this Association may turn out to be the medium for bringing about that consolidation of all branches of the profession which is aimed at by the various suggestions for federation which have been so much discussed during the last twelve months. Instruction by correspondence cannot, of course, be so efficient as by word of mouth, but still it is largely adopted by the Universities, and in our own case I believe the Birmingham members attach great value to the papers which are sent down from London for perusal by the country members of the Construction Class; and this class teaching might be supplemented by occasional visits from the London members, or by lectures on the Institute Examination, or in other ways. These are only suggestions which I throw out as instances of what might be done in the way of additional work. There is, however, one warning which the student should ever bear in mind in reference to the Examination. Look at it not as an end, but as a means; not as the climax of your studies, but as an incentive to

fresh ones; not, as the logicians would say, as a *terminus ad quem*, but a *terminus a quo*; and if you take this view of it, there will be no fear of its becoming anything but an unmixed good. In commenting upon the state of architectural education before an assembly like this, I always have an uncomfortable feeling that I am open to the criticism of carrying coals to Newcastle. I am sure that every one here would endorse my words, but the people who want condoning are the outside public,—the parents and guardians of the youths who are soon to be sent out in a plastic state to be moulded into more or less capable architects. Until the general public are convinced that architecture is a liberal profession, and must be treated liberally, we shall not see the improvement which is so desirable. It is useless to rear a substantial building upon a rotten foundation, and we may go on improving the facilities for architectural education in vain unless the absolute necessity of a thorough and first-rate general education for an architect is fully recognised. It is thought quite natural that before studying Law or Medicine a boy should go through a college course, and after that he would not be expected to earn anything worth speaking of for some years; but many lads are articulated to an architect at the age say of sixteen or less, and are expected after three years to be able to earn their own living. What is wanted to be known is that such a system as this is not only unwise and ineffective, but that it is extravagant, and that in the long run it will pay better in actual pounds, shillings, and pence, to keep a boy at school for another two years and then give him a course at a technical college or at one of the Universities before he is articulated to an architect. Just look at what is required of an architect nowadays. Not only must he be able to design anything, from a stable to a church, and be fully acquainted with the nature and properties of the materials which he uses, but he must be a bit of a geologist in order to distinguish between alternative sites for a house that are submitted to his decision; he must know enough chemistry to be able to advise on the prevention or cure of decay in timber or in stone; he must be a mathematician and competent to calculate the strains on the various parts of the buildings which he erects; he must have sufficient knowledge of electrical science to be able to exercise a certain amount of individual judgment as to the merits of rival schemes of electric lighting; while as to sanitation, if he is not able to give a good account of his drains, and to justify his scheme of traps, disconnecting chambers, &c., he will be held up to obloquy by some candid critic in the press as being very nearly guilty of manslaughter. In fact, so multifarious are the duties that an architect is called upon to perform that his client seems sometimes to expect him to have a mechanical engineer up his sleeve and a specialist in each of his pockets. You may employ specialists for these various works if you like, but depend upon it if anything goes wrong, you the architect would be the first person called over the coals by your client. And yet, though all these things are required of him by the public, will any one say that in very many cases the public recognition of an architect's services and position is at all what he ought to expect if he be a capable man? And that is a condition which we all should do our best to see fulfilled as far as training can fulfil it.

The practice of architecture used not always to be held in low esteem. Cicero classes the architect as next in importance to the physician, and the Romans generally accounted architecture the most respectable, as it was then the most lucrative, of all the arts. The same views obtained during the later years of the Roman Empire. In the latter part of the fifth century, A.D., the Emperor Theodoric issued a document which appears to be a sort of general instruction to his Government architects, and which proceeds thus:—"It is no slight business which is entrusted to you, since by the practice of your art you have to carry out the ardent desire which possesses us of erecting new buildings. Whether it be a question of beautifying a city or of creating a pratorium for ourselves, we look to you to give practical embodiment to the schemes which we have in our mind. We wish to have expression given to our ideas in so appropriate and so stable a fashion that the only difference between our buildings and those of the ancients should be their newness. What can be a more honourable employment! what a more glorious function!

than that of bequeathing to the remotest ages monuments which will assure for you the admiration and the plaudits of posterity. For it is your task to direct the mason, the sculptor, the bronze worker, the plaster modeller, and the artist in mosaic. You have to teach them what they are ignorant of and to solve the difficulties brought to you by this host of artificers who work under your guidance and who must have recourse to your better judgment. See, then, what resources he should have who has so many to instruct. But you will enjoy the reward of your labours, and the success of the operations which you direct will form your eulogy. Observe the distinction which you enjoy. You walk immediately in front of ourselves surrounded by a numerous *cortège* with the gold wand in your hand, a prerogative which, as it brings you near our person, announces that to you we have entrusted the care of our palaces."\* This was the recognition given to the art of architecture by the rude king of the Ostrogoths, and I fear we shall look long and look in vain for such appreciation now. But, gentlemen, let us bear this in mind, that the recognition of our profession depends upon each individual one of us. The outward display which is so striking a feature of our times and under the influence of which the speculating builder runs up elegant villas with elaborate stone dressings outside and enriched plaster cornices inside, while he builds his walls with bats and shafts and forgets to purge his fines and to connect his drain-pipes,—this same display has affected the architect, and is seen not only in the palatial exteriors which mark some of our now buildings, but also, I venture to think, in the excessive modern elaboration of draughtsmanship. You must remember that it is not so much elegance of drawing as knowledge of details that is required in practical work; that comfort and substantiality in the erected building will be more appreciated by the client than the appearance of the plan and elevations on paper; so that while not neglecting draughtsmanship,—don't imagine I am disparaging that,—try and make it only a means of assuring more accurate knowledge. Our profession is really a noble one, and it behoves us all never to lose sight of this fact. We have a responsibility not only to our clients, but to ourselves and our colleagues. We should each of us consider that in us as individuals is deposited the honour of the whole body; that a delinquency on our part, a lapse from the high standard which we should set up for ourselves, or even only a manifest display of incompetency in work which is entrusted to us, may do far-reaching harm and is a slight upon the other members of our profession. We should bear in mind, as Bacon says, that we have "as well to create good precedents as to follow them," and although we cannot all be a Michelangelo or a Brunelleschi and hand our names down to posterity "in records that defy the tooth of time," we can all earnestly endeavour to do thoroughly and well the work that comes immediately to our hand, and if this spirit animates us, whether as students in our preparation or as principals in our practice, we shall do what lies in our power to uphold the dignity of our art and to hand on the Lamp of Architecture with its lustre undimmed to those who are to come after us.

[A report of the discussion which followed is in type, but for want of space we are obliged to hold it over until next week.]

**The Surveyors' Institution.**—The first ordinary general meeting of this Institution for the present session will be held on Monday, November 14th, 1887, when the President, Mr. W. J. Beadel, M.P., will open the session with an address. Chair to be taken at eight o'clock.

**Hospitals Association.**—The second evening meeting of the fifth session of the Hospitals Association will be held (by kind permission of the Middlesex Hospital, Berners-street, Oxford-street, on Wednesday, the 9th of November, at 8 p.m., Sir Douglas Galton, K.C.B., in the chair. A paper will be read by Mr. Keith D. Young, F.R.I.B.A., on "Hospital Construction," to be followed by a discussion. Cards of admission can be obtained, on application, from Mr. Howard J. Collins, secretary, the Hospitals Association, Norfolk House, Norfolk-street, W.C.

The Screen, St. Alban's: as Engraved by Le Keux after a Drawing by J. P. Neale.

**Illustrations.**

**THE SCREEN AT ST. ALBAN'S.**

**W**E give a view in the present number of the celebrated screen at St. Alban's Cathedral, as it has now been restored.

The condition of the screen when it was proposed to restore it is well exhibited in Nash's picture (engraved in Clutterbuck's "History of Herts"), except that the unsightly and incongruous plaster work there shown as covering the place of the cross and the six central niches was removed by the late rector, Dr. Nicholson.

The bases of the four upper niches and the canopies and bases of the lower ones had been shaved off flat to enable the plaster-work to be put on. Its removal showed the original face of the stone on the blank space where the cross had been. The top of the screen had served as a thoroughfare from one side of the triforium to the other, and, as a natural consequence, the whole of the cresting, except one small fragment, had been knocked off. All the pinnacles of the tabernacle work had been knocked off, and almost in every case not broken but removed from the leaded sockets. The only part wantonly damaged, if we except the crucifix, was the tabernacle work over the altar, its cresting and the ornamental filling-in of the hollow above the pinnacles having been destroyed, and the pinnacles themselves and the ornamental work of the bases unchamfered.

The central portion of the tabernacle work above the cross,—that which corresponds to the "spire" in the Winchester screen,—was apparently an ancient reparation, made by putting together pieces which were not meant to be together. Apparently they were ill-put together, and the whole thing was, in fact, askew and unsafe, and had been supported at some later time by a classical bracket of rather bad workmanship. In this no other alteration has been made than to reset it and make it straight and safe, and to substitute a canopy for the bracket.

The two or three fragments of pinnacles which had not given way at the headings, but had remained fast, though broken, gave an indication for the restoration of the others, and in this the tabernacle work of the smaller niches,

fortunately quite uninjured, afforded great help. The new pinnacles were not servilely copied but independently designed.

The scheme of the screen was evidently a group of the Crucifixion in the centre, over the altar, and at the two sides figures of saints, witnesses in later times to the faith in the religion of Christ, of which His Crucifixion was the crowning act. The group consisted of the crucified Saviour and the witnesses then present, namely, His Mother and St. John, four angels above, and four more adorning, in the smaller niches. These ten figures are completed and in their places, but the central figure is not yet put in hand. It is to be hoped, as the work has gone so far, that it will be completed ere long.

The scheme for filling the other niches was this. As the chroniclers had left no record of what figures filled them it was necessary to choose those who were most appropriate, viz., English Saints who bore some relation to the Abbey, foreign Saints who have the same qualification, and Saints in the English Calendar.

In these two classes may be mentioned the Ven. Bede, the historiographer of St. Alban; St. Hugh of Lincoln, in whose Diocese the Abbey was; St. Benedict, whose rule the Abbey followed; and (among the small statues) St. Osyth, who with others here represented had an altar in the Abbey.

There are also included two who were not Saints, King Offa II, who founded the Abbey, and Pope Adrian, the only English Pope, who was born close to St. Alban's.

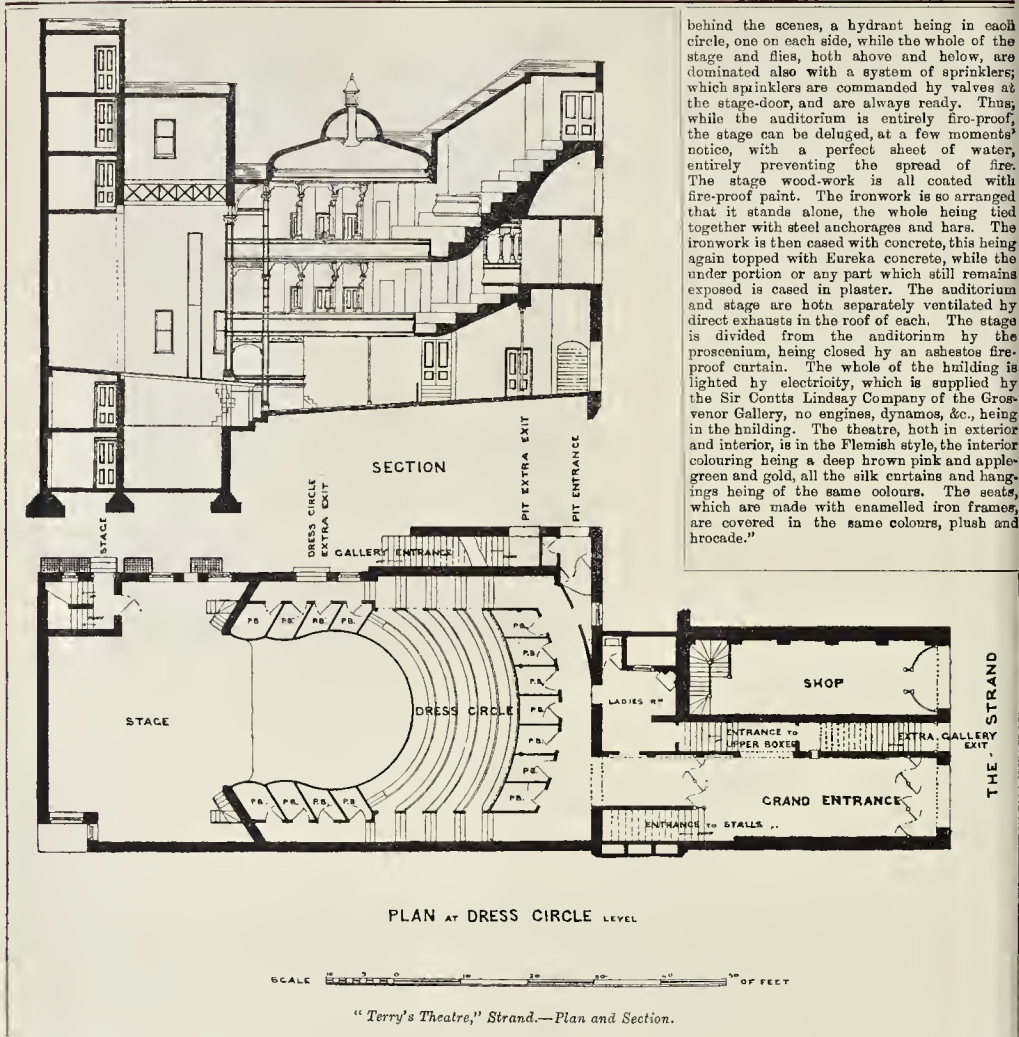

The only statues now remaining to be done are Saints Augustine, Alban, Amphibalus, and Erkenwald (all nearly completed), and the figures of the Annunciation, which will occupy the two canted niches north and south. There are also two of the small niches unfilled.

The material of the screen is clunch, and of the statues Mansfield Woodhouse stone.

The thirteen niches over the altar will contain alabaster statues, about 15 in. high, of Our Lord (in majesty) and Twelve Apostles. Two only are yet in place.

There are twenty full-sized statues, four smaller, and twenty-eight still smaller; the height of the large niches to the soffit being about 6 ft. 6 in., the second size 4 ft. 3 in., the third 3 ft. 3 in., and those for the two kneeling angels 2 ft. 9 in.

behind the scenes, a hydrant being in each circle, one on each side, while the whole of the stage and flies, both above and below, are dominated also with a system of sprinklers; which sprinklers are commanded by valves at the stage-door, and are always ready. Thus, while the auditorium is entirely fire-proof, the stage can be deluged, at a few moments' notice, with a perfect sheet of water, entirely preventing the spread of fire. The stage wood-work is all coated with fire-proof paint. The ironwork is so arranged that it stands alone, the whole being tied together with steel anchorages and bars. The ironwork is then cased with concrete, this being again topped with Eureka concrete, while the under portion or any part which still remains exposed is cased in plaster. The auditorium and stage are both separately ventilated by direct exhausts in the roof of each. The stage is divided from the auditorium by the proscenium, being closed by an asbestos fire-proof curtain. The whole of the building is lighted by electricity, which is supplied by the Sir Conitts Lindsay Company of the Grosvenor Gallery, no engines, dynamos, &c., being in the building. The theatre, both in exterior and interior, is in the Flemish style, the interior colouring being a deep brown pink and apple-green and gold, all the silk curtains and hangings being of the same colours. The seats, which are made with enamelled iron frames, are covered in the same colours, plush and brocade."

The small priest by Le Keux, of which we give a reproduction, is of some interest as showing a former restoration (on paper), without the figures. In it will be seen the classical bracket before referred to, supporting the central pinnacle.

The restoration has been carried out at the cost of Mr. H. Hicks Gibbs, and under his direction, but with the assistance and advice of an eminent architect.\* The carving and sculpture has been executed by Mr. Harry Hems.

Four of the figures are shown to a larger scale at the sides of the plate; on the left, the Virgin and St. Boniface; on the right, the Apostle St. John, and St. Richard.

#### ST. ALBAN'S SHRINE.

The shrine, of fourteenth-century date, which now stands in the centre of the Saint's Chapel, at St. Alban's Abbey, was found in fragments during the restoration in February, 1872,—some portions having been previously found in 1847. The whole of the main structure is of Purbeck marble, the vaulting and tracery panels inside being of clunch, and still retaining considerable traces of gold and colour. A notice of the shrine will be found in the *Builder* for May 4, 1872. The drawing here given was exhibited in the Royal Academy this year.

R. W. PAUL.

\* The architect does not wish his name to appear, for reasons which it is not our business to inquire into.

#### TERRY'S THEATRE, STRAND.

We give a view of this new theatre, together with a plan and section which will better explain the special arrangements which have been made for exits, and to which we have already referred.

The architect sends us the following description of the arrangement and construction of the house, which has already appeared in nearly the same words in some of the daily papers, but which we may usefully repeat here in immediate connexion with the illustrations—

"The main entrances to the dress circle, stalls, and boxes are in the Strand, the extra exit to the dress circle is in Savoy-buildings, as are both the pit entrances, extra exit, and the gallery entrance. There are three tiers, pit and stalls, balcony and dress circle, and gallery and upper boxes. Each part of the house has two or more exits. The total exit accommodation is, according to the regulations of the Board of Works, equal to 3,500 people, while, as before stated, the holding capacity of the theatre is only 800 persons. The whole, including the roof, is constructed of concrete and iron, no wood being used in the auditorium, except for doors and windows, while all the necessary woodwork before and behind the curtain is coated with Sir Seymour Blane's fireproof paint. A thorough system of hydrants in the best available positions is placed both before and

The architect is Mr. Walter Emden, assisted by Mr. George Harrison, C.E., as to the hydrant and water arrangements. The contractors are Messrs. Holliday & Greenwood. The iron-work is by Messrs. M. T. Shaw & Co.; and the water apparatus by Messrs. Rose. The carton-pierre has been executed by Messrs. Battiscombe & Harris, and the furnishing by Messrs. Atkinson; while the tile decorations have been executed by Messrs. Donlon. Mr. E. Bell has executed the painted decorations; Mr. Rust is doing the mosaic paving; Messrs. Vaughan & Brown have executed the gas-fittings, and Messrs. Verity Bros. the electric light fittings. Mr. S. M. Egan has acted as clerk of works.

#### THE NEW UNION CLUB-HOUSE, NEWCASTLE-UPON-TYNE.

This building, of which we publish an illustration, stands upon a plot of ground extending 130 ft. in Rosemary-lane, by 71 ft. in Westgate-road. It adjoins the neighbouring buildings in Westgate-road, and is bounded by Rosemary-lane and St. John's Church on the west, and by new premises on the north. The principal façades are in Westgate-road and Rosemary-lane. These fronts of the building are enriched with oriels thrown out on the first floor, and with balconies and other highly effective ornamental features. The building is constructed

Prudham stone, and stands upon a plinth of grey Aburdene granite.

The ground-plan shows the arrangement of the building. On the first floor are the drawing-room, smoking-room, and other principal rooms of the club-house. On the second floor a few bedrooms; with the necessary dressing and bath rooms, and above, the usual domestic offices and servants' apartments.

The kitchen, with its offices and accessories, are in the upper story of the wing extending down Rosemary-lane.

The work throughout has been executed by Messrs. Shaftoe & Barry, of York, who were the contractors for the building. The warming and ventilating arrangements are by Mr. W. W. Phipson, the ornamental plastering by Messrs. Jackson & Son, the kitchen fittings by Messrs. Clements, Leakes, & Co., the stained glass and ornamental glazing by Messrs. Powell & Son, the marble mosaic pavements by Messrs. Burke & Co., and be gas service and fittings by Messrs. Stevens & Co., and Messrs. Barkentin & Krall, all of London. The marble chimney-pieces were supplied by Messrs. Walker & Emley, and the stoves and grates by Messrs. Mather & Armstrong, of Newcastle, who also fitted up the system of pneumatic bells. The contract for the whole of the furniture, which has been designed in harmony with the building, has been executed by Messrs. Robson & Son, of Newcastle. Mr. G. C. Davies acted throughout as the architect's clerk of works.

**NEWPORT-ROAD SCHOOLS, LEYTON.**

These schools, affording accommodation for 1,040 children, in three departments, have been erected at Leyton, Essex, for the Leyton School Board, from the designs of Mr. J. T. Newman, architect, at a cost, inclusive of caretaker's house, boundary-wall, &c., of 7,910l. The works have been carried out by Mr. James Porter, builder, of Stratford, E.

**PRINCIPAL ENTRANCE, "EDDESBUURY."**

The illustration is the principal entrance of "Eddesbury," the residence of Mr. James Asham, situate in "West Derby," near Liverpool. The house is built of red Harbom brick and red Rancom stone. The roof is covered with red slates from the Tilbertswate quarries. A considerable part of the internal fittings and nichings is of oak. The architect is Mr. J. Francis Doyle, of Liverpool.

**HOLY TRINITY CHURCH, GATESHEAD.**

The design illustrated this week, by Messrs. Dept. Oswald & Son, architects, of Newcastle-on-Tyne, was selected in limited competition. The design is really for the enlargement of

the existing church, which will be utilised as the south aisle of the new edifice. Its west front, shown on the exterior view, is ancient, dating from 1248, and will be preserved absolutely intact. The remainder of the present church, which was restored and re-roofed about fifty years ago, will be interfered with as little as possible, an arcade being substituted for its north wall. The pillars and arches of this arcade are spaced so as to leave the old roof, with its wall posts and corbels, exactly as at present. This roof, although of a different style from the rest of the building, is internally of graceful form, and its retention seems desirable for many reasons. The western gallery will be taken away, displaying internally the full proportions of the window, now partly hidden. With these exceptions, the present edifice will be left practically unaltered.

The walls of the church will be built of local stone, plastered internally, unless (as is hoped) funds are forthcoming to line the interior with stone, which is very desirable, especially in the chancel and nave. The roof timbers will be of pitch pine, left the natural colour, without stain or varnish. The church will be seated with chairs for about 600 persons. The furnishings of the chancel may have to be temporary in the first instance, but will be added gradually as adequate funds become available for permanent reredos, choir-stalls, chancel-screen and gates, lectern, pulpit, &c., of suitable architectural character.

It may be noted that tradition affirms the site of this church to be that of a Saxon monastery, of which records prove the existence prior to A.D. 653.

**THE FIRE AT WHITELEY'S.\***

The inquest as to the death of the four persons killed by the fall of the wall at the time of the fire at Whiteley's in August last was resumed and concluded on Monday, before Dr. Danford Thomas, Coroner for Central Middlesex.

Mr. Charles Robert Walker, C.E., of Great Queen-street, Westminster, said that on the 26th of August he received instructions from the Coroner to examine Mr. Whiteley's premises, with a view to ascertain the construction of the ironwork, the relation of the ironwork to the brickwork, and the expansion of the iron under great heat. He had to report that the factory in Douglas-place was a building about 80 ft. from east to west, and 72 ft. from north to south (or facing Douglas-place). It consisted of four floors and a ground-floor,—five in all. The height from the ground to the upper ceiling was about 55 ft. The first floor was said to be a "fire-proof" floor, and all the others were strong wooden floors supported on iron girders. The ceilings were of match-boarding, and the joists appeared to be very strong, and closely laid together, so that the girders were thoroughly sandwiched between timber, which at the time of the fire would be very dry. The iron girders were supported by columns extending from the basement to the roof, except in one case, where a partition wall was carried to the first-floor level, and columns were carried from the level of that wall to the roof. There were three tiers of girders and columns extending from the basement to the roof, and one tier extending from the first floor to the roof. In the provision-shop in Douglas-place, a building of four stories and ground-floor, about 150 ft. long, and varying from 30 ft. to 40 ft. in width, the floors were carried in a similar way; the ground floor was a "fire-proof" floor. Girders were largely used in other portions of the building in connexion with wood-work, and in some cases in connexion with "fire-proof" flooring, but the girders generally were isolated, and ran parallel to the street. With regard to the construction of the ironwork, in the factory in Douglas-place the girders carrying the floors were rolled iron joists, 12 in. by 6 in., weighing about 56 lb. per foot. They were in lengths of about 16 ft., and were carried on four cast-iron columns. The ends of the girders were bolted to the columns, different methods of connexion being adopted,—one on the ground-floor, another on the first floor, another on the second floor, another on the third and fourth floors. All those methods of connexion had the same effect, namely, that of securely bolting the girders through the column to each other, or making one continuous girder of the whole length, the ends of which con-

tinuous girder were in the wall. The columns varied in diameter (the stronger being at the bottom), and were bolted together vertically, so that the girders with the columns formed three frames about 76 ft. long by 66 ft. high. The fourth frame rested upon the partition wall carried to the first-floor level, and was therefore about 76 ft. long by 46 ft. high. The first or "fire-proof" floor consisted of rolled iron joists, 8 in. by 4 in., laid at right-angles to the large girders, and the ends of those joists rested on the wall before mentioned. That wall also supported one end of the short joists carrying the other portion of the first floor. In this floor there were two main girders side by side instead of one, as in the other floors, in order to obtain additional strength for the heavy floor. At the time of his inspection, none of the girders remained fixed to the columns, so that his examination did not show whether they were closely bolted together or not, but he had every reason to believe that they were closely bolted together. The girders in the provision-shop in Douglas-place remained intact at the time of his inspection: they were securely bolted to the columns. There was no allowance whatever for expansion or lateral play; in fact, it might be said in both cases that the walls were tied together by means of girders. With regard to the relation of the ironwork to the brickwork, at the time he made his examination one girder only remained in the western wall of the factory; that girder was bent at right angles about 3 ft. from the wall, and stood in that position. There were five holes in the brickwork from which the girders had fallen. In one of those holes, where the first-floor girder had been, there was a clear impression of the girder on the brickwork at the back of the hole. The hole was about 6 in. deep. Two other holes on the first-floor level were of about the same depth, and the two holes at the level of the second-floor girders were about 7 in. or 8 in. deep. In the western wall seven girders remained fixed, two of which, however, were supported by columns, and five hung from the wall, one girder standing out horizontally from the wall. He could see three holes from which the girders had fallen; these appeared to be about 14 in. deep, and judging from the appearance of one he should think that there was a pocket or space at the back of the end of that girder. As both the girders in the east and west wall remained standing firmly in the wall, he concluded that they were closely and firmly built in, or they could not possibly have remained in such a position. It was not possible for him to have any of the brickwork round these girders cut away at the time when he made his first examination. He endeavoured to arrange to see the girders when the men were pulling down the wall; he was unable to do so, but from his examination of the girders after they were taken down they appeared to have been firmly built into the brickwork. He also found that one of the girders on the ground-floor level in the east wall was firmly built in the brickwork, and that the bricks actually touched the back of the girder. In the provision-shop in Douglas-place he was able to examine a number of girders when the wall was being pulled down, and they were built into the brickwork. He had an interview with Mr. Saunders, the architect, who kindly afforded him full information, and went through the detail drawings of the destroyed building with him. Mr. Saunders informed him that "pockets" were not mentioned in the specification, but that instructions were generally given to keep the ends of the girders clear. Mr. Saunders also showed him details of the ironwork, from which he was able to distinctly state that there was no allowance or provision for expansion at the connexion between the girders and columns, except such small play as there might be between a 3/4 in. bolt passing through an inch hole in the leg on the column and through a 3/4 in. hole in the girder, and that was assuming that the ends of the girders did not butt against the column. On the 30th of September, having arranged with Mr. Saunders to meet his assistant, Mr. Point, he had two holes cut in the brickwork at the back of two of the girders. He found in one case the brickwork built close up to the back of the girder; in the other case a very small space was left, but not a "pocket." In the case of two heavy girders in other parts of the building he found that there was a pocket at the back of the girder, but in all cases the girders were built around and securely to the wall at the face. He felt bound to say, how-

\* See Builder, p. 580, ante.

ever, that Mr. Point, Mr. Saunders's assistant, told him that if any "pockets" were left it was by accident and not by design. With regard to the question of the expansion of iron under heat, in ordinary temperature the expansion was so slight that in building little heed need be paid to it. But the expansion increased in direct ratio to the temperature, and up to 200° Fahr it was about one eight-hundredth of the length. It was, therefore, necessary to endeavour to ascertain the temperature of the girders during the fire. A great quantity of melted lead was found in the factory, and he had also seen a piece of metal consisting of part of a girder, part of a column, part of a steam-pipe, and other pieces of iron, partially melted and fused together, so that the temperature must have been very great. Many of the girders must have been red-hot, as was, indeed, quite clear from the red scales upon them. In such a case the expansion would be  $\frac{1}{2}$  in. or even  $\frac{1}{4}$  in. per foot of girder. In the case, therefore, of what was practically a continuous girder 80 ft. long, the expansion would be 6 in. or 8 in. over all. It was then necessary to consider how much of that expansion would be communicated direct to the ends of the girders. Rolled iron joists were not very stiff laterally, and in expanding they would probably huckle and arch somewhat, especially as the girders were fixed at the ends. On the other hand, the fact that the columns were bolted together, and that the floors would rest on the girders during the early part of the fire, would help to keep the girders from buckling. He did not think that the whole of the expansion could have gone to the walls, but he believed that about 2 in. of that expansion would be communicated to each end of the girders and against the walls. Though the resistance offered by the ends of the girders being firmly built into the walls might tend to increase the buckling, buckling so caused would not lessen the strain upon the walls. In his opinion the expansion of the girders caused considerable outward thrust upon the walls, and as the ends of the girders were not absolutely free, that expansion would tend to push the walls over. In a small building near the factory, called the "stables," he noticed two rolled iron joists about 30 ft. long had thrust and bulged outwards the brickwork near their ends. He believed that was due to the expansion of those girders under great heat. The bolts which he produced would show that there had been very great expansion in the girders. A short bolt which must have connected a third or fourth floor girder to a column had been bent as with a hydraulic press, the depth from the head to the head exactly corresponding with the thickness of the lug on the column and from the nut to the head with the thickness of the web of the girder. In his opinion, that bolt had not been bent by the fall of the girder, like another bolt produced, which showed the manner in which it had been wrenched by the falling of the girders. Two long bolts (produced), which had come from a second floor girder, also showed evidence of expansion in the girders. In addition to the iron girders in the factory, there was a considerable amount of shafting running both parallel to and at right angles to Douglas-place. It was urged that the north wall of the factory also fell into what is called "Whiteley's-mews," and that there were no girders in that wall. The ends of the short rolled iron joists which carried the fireproof floor were said to be in the north wall, and those joists might have communicated the expansion of the longer cross-joists to the wall. The ends of the strong wooden joists carrying all the floors were also in that wall, and when the main girders carrying the joists fell, the joists falling might have overthrown the wall. Iron, when used in a building, could only expand to the extent stated when submitted to great heat, as in a fire. The ends of the girders being firmly built into the walls, the expansion of the girders would cause an outward thrust upon the walls,—already weakened by the heat of the fire; and such thrust did, in his opinion, afford a reasonable explanation of the falling of the walls. The walls were well built, and the brickwork was very good indeed. He had no desire to find fault with the building. He believed the ordinary method of construction had been observed, and that there were many buildings similarly constructed.

In answer to questions put by the Foreman

of the Jury (Mr. Mark H. Judge), Mr. Walker said that before he had seen the results of this fire, he should probably have built the warehouse in the same way. He could not give any other explanation of the fall of the wall except that it was due to the pushing force exerted by the expansion of the girders. Asked whether the walls of a building ought to be tied together by iron girders, and whether iron girders ought to be built tight into the walls, Mr. Walker said where the girders were meant to carry wood floors he would make special provision for the expansion of the girders, but in fireproof floors he did not think that would be necessary.

Mr. W. B. Lewis, M.Inst. C.E., was the next witness. He said he had had experience in iron and brick construction, and that the building which was the subject of inquiry was constructed in the manner usually adopted for such buildings. He could not agree with Mr. Walker in thinking that the expansion of the girders had much to do with the falling down of the wall. The wall was, no doubt, subjected to very great heat. He thought that the tendency of the girders would be to pull the walls in rather than to push them out, but he should attribute the weakening of the walls to the heat to which they were exposed, apart from the girders altogether. In common structures like the one under inquiry it was not usual to make any allowance for the contraction or expansion of the ironwork.

By the Foreman of the Jury.—The expansion and contraction of iron under ordinary temperatures was so slight that it was not necessary to make any special provision for it. In other words, it was only usual to provide for safety in such structures under ordinary circumstances. This was not a "fireproof" building, and therefore no special means would be taken to protect the ironwork, notwithstanding that ironwork in the presence of fire was an element of danger rather than of security.

By Mr. Roche (representing Mr. Whiteley).—His belief was that a girder 12 in. by 6 in. would huckle and twist by the heat long before it could exert any effect upon the wall.

Mr. F. W. Shields, M.Inst. C.E., said he had had considerable experience in iron construction, and his opinion was that the iron girders had practically no effect upon the falling of the wall. He thought that the wall fell owing to the operation of an ordinary law of nature. The heat inside the building expanded the wall, which was cool on the outside, and this difference of external and internal temperature caused the wall to buckle, without any pull or thrust from the girders.

By the Foreman of the Jury.—He should, if this had been his own building, have built the girders solidly into the brickwork, for the reason that the girders supporting the various floors of a building were needed for use also as ties from wall to wall. He did not think that the wall could have fallen from the thrust of the continuous length of girder through the application of heat at a distance from the interior face of the wall. Did not know that the wall fell within a very few minutes of the alarm of the fire having been given, and before the fire had itself reached the inner face of the wall. Did not know that immediately the wall fell upon the people whose lives were lost, the firemen who set to work in removing the debris found that the bricks were not too hot to handle, as they would have been had the wall fallen owing to the direct action of heat.

By the Coroner.—The brickwork was very good.

Mr. T. Chatfield Clarke, F.R.I.B.A., said that as surveyor to a large fire office he had had considerable experience of the behaviour of buildings under fire. He had looked at the drawings, plans, sections, &c. of the destroyed warehouse, as erected from the plans of the architect, Mr. J. E. Saunders, and as the result of the examination he was prepared to say that if he (the witness) had had to construct the building, with its particular requirements, he should have constructed it in exactly the same manner as that adopted by Mr. Saunders. As to the strength of walls, that was a matter which was regulated by the Metropolitan Building Act. It was the universal practice to make use of cross girders as ties from wall to wall.

In answer to a question by the Foreman of the Jury, Mr. Chatfield Clarke said he did not consider that the expansion of the girders was an appreciable factor in the destruction of the

wall, and therefore he should not be disposed to alter the construction on that score.

Mr. J. Tavenor Perry, A.R.I.B.A., said that as surveyor to a fire insurance office, and as architect to the Alhambra in Leicester-square, he had had much experience in connexion with the effects of fire upon iron construction, and he had found, in buildings erected as the one under inquiry was, with the iron girders built in as ties, that the tendency of the ironwork was not to expand and force the walls out, but rather, by the sagging of the girders under the action of heat, to drag the walls inwards, the girders sometimes falling inwards from that cause without pulling the walls with them. A case of that kind happened at the hurrying of the Alhambra, when a large built-up girder, about 50 ft. long by 4 ft. 6 in. deep, which had been put in about twelve months before to carry a considerable part of the weight of the dome, fell inside the building, leaving the walls which carried it intact. That girder rested on stone templates. In his experience, when iron subjected to the action of heat began to expand appreciably, the tendency was to sag immediately.

Mr. J. Howard Colls, President of the Institute of Builders, was next called. He said that as a builder of much experience in the erection of such buildings as the one which was the subject of inquiry, he had never seen it specified that the ends of the girders were to rest free in pockets with room for expansion. It was the usual practice to build in the ends of the girders most carefully, and where that was not done the work would be regarded as having been "scamped." It was most necessary to make use of the girders as ties. If they had not been built in in this particular building, he did not believe it would have stood to be burnt down: it would have fallen down.

The next witness was Mr. E. H. Wallis, M.Inst. C.E. Examined by the Coroner, he said that he could not but conclude, from his examination of the plans, that primarily the girders, from their construction and disposition, had, when expanded by heat, exercised considerable effect in pushing out the walls.

In the total length of 80 ft. the expansion would not have been less than 3 in. or 4 in., say,  $\frac{1}{4}$  in. or 2 in. at each end. That might not seem much, but acting on a wall possibly already weakened by the action of fire, it might easily be sufficient to push a wall over.

Captain Shaw, the Chief of the Metropolitan Fire Brigade, was the last witness called. In answer to questions put by the Coroner, he said that while his experience showed that many walls were crippled and weakened by heat, irrespective of the disturbing element of iron construction, there could be no doubt that the expansion and perhaps the contraction of iron was a frequent source of the collapse of buildings attacked by fire. What might have been the precise sequence of causes in regard to the fall of this building he could not say; but it was his experience that, as a rule, the walls of buildings in which the floors, &c., were of wood, stood longer under fire, and more often survived fire, than the walls of buildings in which iron construction was used.

The Coroner having summed up the evidence, the jury retired to consider their verdict. After being absent for about half an hour, they returned the following verdict:—

"That the four deceased persons were found dead and did die from the mortal effects of fractures of the skull and other injuries, arising from the falling of a wall at a time when there was a fire at Mr. William Whiteley's. Although there is not sufficient evidence to show how the fire originated, yet we are of opinion that it was the work of an incendiary or incendiaries."

To this verdict they desired to append the following rider:—

"First, that the present state of the law in regard to fires is most unsatisfactory, inasmuch as it would have allowed the fire by Mr. Whiteley to have passed without any official inquiry but for the deaths resulting therefrom.

Secondly, that provision should be made by law for an official inquiry into the origin and circumstances of all fires.

Thirdly, that such an inquiry would tend to diminish the frequency of fires, by making felony more easy of detection and by bringing public reprobation, if not punishment, on persons responsible for fires arising from carelessness or want of precaution.

Fourthly, that the information and statistics which would result from fire inquiries would expose faulty and inferior work and thus lead to improvements in building constructions.

Fifthly, that the serious danger which may result from defective construction where ironwork is largely used calls for immediate attention, with a view to such an amendment in the Building Act as will secure the requisite supervision."

CASE UNDER THE METROPOLITAN BUILDING ACT. NEGLECT TO GIVE NOTICE TO DISTRICT SURVEYOR.

at the Worship-street Police-court a few days before Mr. Baskin, the District Surveyor of East Hackney North (Mr. Mason) summoned Messrs. Brooke, Simpson, & Spiller (Limited), for neglect for having executed works to four buildings without notice.

Defendants' counsel objected that the summons addressed to the old firm instead of the present company, but the District Surveyor produced a plan from the company on the subject of the summons, and the summons was amended by the addition of the word "limited." The defendants demanded exemption under section 6, contending that clause was to be construed as "60 ft. from the best buildings (and ground) of an adjoining lot."

included in one alleged offence was the repair of external wall, in which about 100 new bricks were on the face of the wall, and the District Surveyor considered this was a repair affecting the structure of the wall, because if the new work had been taken away the brickwork over it would have fallen.

The magistrate decided that the context of the Act of the exempting clause referred to, as well as the general policy of the Act, shut out the construction put upon it by the defendants; and as the buildings to which the works were done were within 60 ft. of other buildings belonging to the defendants, the District Surveyor was entitled to notices.

The case was not to be considered a work requiring notice, because old bricks were simply replaced by new, and there was no alteration as if stone had been substituted for bricks, or the wall had been made thicker.

The defendants were fined 4l. and 12s. 6d. costs.

THE WALLS OF CHESTER.

SIR,—I have to ask you of your favour to correct me a slight error in one of my letters, in which I copied the name of Mr. Shrubsole with that of Mr. Simpson Watkin, as believing in the Mediaeval age the Roman sculpture of two figures.

Mr. Shrubsole assures me that he has expressed such opinion. C. ROACH SMITH. Stood, Oct. 24.

SIR,—Permit me, in a few lines, to reply to Mr. Brock's last letter. I am told that if the walls of Chester at the two points I have indicated were built, one in the time of the Commonwealth, and the other in the reign of Anne, the latter must be built, that if I cannot induce them, "it will show that the work was not done at either of the times" I name.

As we know from Randle Holme and others that the breaches were made at different times in the last during the siege, it follows that they must have been at some time repaired. As the great wall of the town has been a little to the west of the Phoenix Tower, the Parliamentarians, when they obtained possession of the city, did, as I have before said, rebuild not only this wall, but the others, to mitigate the danger of an attack by the Royalists, by whom they might at any moment be besieged.

Finally, he alludes to my use of the word "formidable" with reference to his calculation for labour, and the quantity of stone, &c. My contention was, and is, that if the Parliamentarians repaired the large breach, as I believe they did, the cost, even including that of "the stone," which Mr. Brock says he has omitted, would be comparatively nil. With stone at hand from the old ruined wall, Roman ruins, and tombstones close at hand, forced work for the army, and impressed work from the citizens, the wall could be rebuilt both very cheaply and very rapidly.

W. THOMPSON WATKIN. P.S.—It is, of course, quite possible that in the archives of the Chester Corporation some accounts constituting a "bill" may be found, for the repairs effected in 1708, and also some papers (though I doubt it) referring to the reparations by the Parliamentarian army. But as this would involve a long search, perhaps some of the Chester authorities will try it. As it is certain that repairs did take place at these periods, it is Mr. Brock's place to procure these "bills," if extant, and disprove the views I have argued by them.

SIR,—I will cheerfully reply to any inquiries of your correspondents relative to the interesting subject of the age of the walls of Chester; but is not Mr. Watkin making needless comments as to whether or not I am correct in calling the mass of the last and the heightening of this century, "fairly recent times"? I think I am right in doing so, but the point to be kept in mind is that two Roman gades did actually stand in the line of two of the present walls, and thus proving their course. He says [p. 552] that there is between him and me "merely the question as to whether the stones of the last and the heightening of this century, 'fairly recent times'?" I think I am right in doing so, but the point to be kept in mind is that two Roman gades did actually stand in the line of two of the present walls, and thus proving their course.

He says [p. 552] that there is between him and me "merely the question as to whether the stones of the last and the heightening of this century, 'fairly recent times'?" I think I am right in doing so, but the point to be kept in mind is that two Roman gades did actually stand in the line of two of the present walls, and thus proving their course. He says [p. 552] that there is between him and me "merely the question as to whether the stones of the last and the heightening of this century, 'fairly recent times'?" I think I am right in doing so, but the point to be kept in mind is that two Roman gades did actually stand in the line of two of the present walls, and thus proving their course.

The mere fact, however, of the absence of mortar is, of itself, evidence of high antiquity, and it is surprising that it is not so accepted by your two correspondents. The whole mass of the walling of ancient British hill forts, from Cornwall to Northumberland, from the borders to the extreme end of Scotland, from end to end of Wales, in Ireland, and the Continent, in all these the absence of mortar where walling occurs is universal.

These walls are built of stones far smaller than anything I have seen at Chester, and they still stand in many examples. I have already referred to the feeling for the use of unmortared masonry by the Romans, and your correspondent's rejection of the evidence of Continental examples will not be followed, I feel sure, by the majority of your readers.

Mr. Shrubsole, p. 551, still doubts my measurement. This can readily be determined. I hope to be at Chester shortly, and shall be very happy to meet him, if he will let me, and have a pleasant visit to the spot. We can then measure it together. His belief as to the goodness of the erection of the unmortared part of the wall, I think, carries its own refutation with it, for if erected as he states, it would certainly not stand. But it does stand. It must be remembered that the archon supporting bank does not exist along a large portion of the wall, and where it is highest.

The height I have given for the Roman work is a good working average, at the point named. It would not have been fair to have overstated it, since

it would have increased by so much the already heavy mass of Roman walling I have specified, all of which Mr. Watkin has to account for from his Roman foundations. The discussion of the measurement hardly affects any principle, and I have already acknowledged that in other places the Roman part is higher, at others lower. E. P. LOFTUS BROOK.

\*.\* We have not space to continue the correspondence on this interesting subject further at present.

PUBLIC APPOINTMENTS.

SIR,—The Shirley and Freemantle Local Board recently advertised for a Surveyor. From a Southampton paper I have just noticed that that body met the same evening on which the applications had to be sent in, and there and then made the final selection out of sixty-six applicants. Does not this look as if the affair had been "cut and dried" and settled beforehand?

I do not complain of the successful candidate (who is no doubt perfectly competent) obtaining what influence he could; but I do think the Board are greatly to blame in advertising and putting so many persons to trouble and expense if they had no intention of fairly considering all the applications sent in. O. E. H. T.

COMPETITIVE DESIGNS

FOR WILLESDEN PUBLIC OFFICES.

SIR,—In your issue of last week, under the above heading, the following statement was made, viz. :—"It appears that the design placed first by Mr. Harnor was formally accepted, subject to its being capable of being carried out at a cost of not more than 6,000*l.*—the stipulated limit. It appears that the lowest contractor's estimate is considerably above that sum," &c.

As this matter is still before the Board, and is being considered by them, I do not feel myself at liberty to enter into the question beyond saying that the design has undergone certain modifications, which therefore render any comparison with the original sum named misleading. I can, however, say that, allowance being made for these, the lowest tender is as near the stipulated sum as can reasonably be expected.

EDWARD HARNOR.

October 22nd, 1887.

\*.\* We wrote on the basis of a newspaper report of the proceedings at the Willesden Local Board, which, as Mr. Harnor's letter seems to imply, may not have given a correct idea of the whole case. Of course, we have no wish to prejudice Mr. Harnor in any way, but we have a strong opinion that the conditions under which a competition design has been accepted ought, in fairness to all concerned, to be strictly observed.

TERRY'S THEATRE.

SIR,—I note, in your description of the above, in this week's Builder, that you mention the gallery extra exit door on to the street. This door will never be locked at night at all until after the performance is over. The only reason it has been kept locked during the day time is because the rooms in the Strand block are not quite finished yet.

I may say, with regard to the oddness of the appearance, that this is not a necessary adjunct to a fireproof building; the walls could be papered or coloured as warmly as desired. The reason for this cold colour is that it shall not absorb the light or detract from the stage or dresses of the audience at the same time, as the effect that is given of air makes the audience feel more satisfied as to ventilation. WALTER EMDEN.

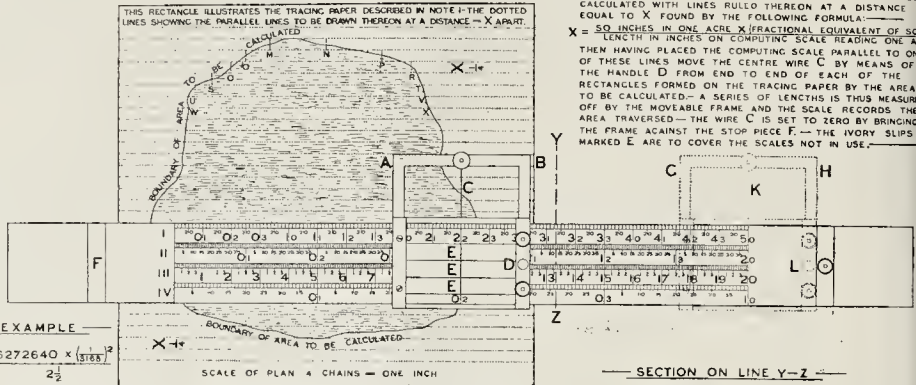

Extensions at the Royal College of Surgeons.

The Royal College of Surgeons, in Lincoln's Inn-fields, is at present undergoing a considerable enlargement by the addition of two floors, which increase the height of the structure by from 20 ft. to 30 ft., the building having now an elevation of about 80 ft. from the ground level. Each of the new floors has nine windows carried cross the frontage, the lower floor windows being circular in form. A main cornice and balustrade are surmounted by vases. The new floors cover the entire ground space occupied by the building, extending in depth to the rear in Portugal-street. They are intended for professional workrooms and scientific laboratories in connexion with the college. The library of the college is also about to be extended, and one of the houses in Lincoln's Inn-fields, on the east side of the college, has been purchased, and is now undergoing alterations for the purpose of adapting it to library purposes. Mr. Salter, of Woburn-place, is the architect; and Messrs. Higgs & Hill are the contractors.

COMPUTING SCALE

THIS RECTANGLE ILLUSTRATES THE TRACING PAPER DESCRIBED IN NOTE 1—THE DOTTED LINES SHOWING THE PARALLEL LINES TO BE DRAWN THEREON AT A DISTANCE X APART.

NOTE 1—PLACE A PIECE OF TRACING PAPER OVER THE AREA TO BE CALCULATED WITH LINES RULLED THEREON AT A DISTANCE EQUAL TO X FOUND BY THE FOLLOWING FORMULA—  
 $X = \frac{50 \text{ INCHES IN ONE ACRE}}{\text{FRACTIONAL EQUIVALENT OF SCALE}}$   
 X = LENGTH IN INCHES ON COMPUTING SCALE READING ONE ACRE THEN HAVING PLACED THE COMPUTING SCALE PARALLEL TO ONE OF THESE LINES MOVE THE CENTRE WIRE C BY MEANS OF THE HANDLE D FROM END TO END OF EACH OF THE RECTANGLES FORMED ON THE TRACING PAPER BY THE AREA TO BE CALCULATED—A SERIES OF LENGTHS IS THUS MEASURED OFF BY THE MOVEABLE FRAME AND THE SCALE RECORDS THE AREA TRAVERSED—THE WIRE C IS SET TO ZERO BY BRINGING THE FRAME AGAINST THE STOP PIECE F—THE IVORY SLIPS MARKED E ARE TO COVER THE SCALES NOT IN USE.

EXAMPLE  
 $X = \frac{6272640 \times \frac{1}{2}}{2} = 1568160$   
 $X = \frac{6272640 \times \frac{1}{10036224}}{2} = 1568160$   
 $X = \frac{6272640 \times \frac{1}{10036224} \times \frac{2}{3}}{2} = 1045440$   
 6272640 50 INCHES = ONE ACRE  
 4 CHAINS = 3168 INCHES

LENGTH IN INCHES ON COMPUTING SCALE READING ONE ACRE

I	2 1/2	INCHES
II	6 1/2	DO
III	3	DO
IV	12 1/2	DO

NOTE 2—THE SELECTION OF EITHER SCALE I—II—III—IV WILL DEPEND UPON THE SCALE OF THE PLAN AND THE SURVEYOR MUST EMPLOY WHICHEVER WILL GIVE THE BEST VALUE FOR X TO ENSURE ACCURACY.

THE PLANIMETER

AN ENGLISH ACRE CONTAINS 6272640 SQUARE INCHES.  
 A SQUARE METRE CONTAINS 1550 SQUARE INCHES.

VERNIER  
 ENLARGED SCALE OF DIVISIONS READING HUNDRETHS.

The Student's Column.

LAND SURVEYING AND LEVELLING.  
 XVIII.—INSTRUMENTS FOR THE CALCULATION OF AREA.

THE annexed illustration shows a portion of a computing scale usually made to 3 chains to 1 inch. The large figures denote acres, and the subdivisions numbered 1, 2, 3 indicate rods. The perches are engraved upon the ivory scale attached to a movable metal frame, the use of which will be understood upon reference to the drawing of a complete instrument, as shown above, which illustrates the type of computing scale used at the Tithe Commission Office. The application to a plan is explained in note 1. Four scales are shown upon this instrument (see note 2). The example given apposes the plan to be drawn to a scale of 4 chains to 1 in., in which case the calculated distance between the parallel lines upon the tracing-paper is seen to be 1 in.,

when the upper scale marked I is to be employed, and a length of 2 1/2 in. is seen to measure an acre. The wire line C in the frame A B is first so set that the frame rests against the stop-piece F. It is then placed upon the tracing-paper over the area to be calculated so as to start from zero at the line M, with the edge of the scale parallel to the lines upon the tracing-paper, and after carefully moving the frame so that the line C traverses from M to N the instrument is then lifted up and replaced with its edge parallel to the lower lines upon the tracing-paper, so that the wire C starts from O at the same position on the scale as it indicated when at N. The frame is traversed over each rectangle successively from M to N, O to P, Q to R, S to T, &c., by means of the handle D (see section upon the line Y Z), and thus by a series of mechanical additions the area can be read off the scale in acres, rods, and poles. With the use of the upper scale, as it shows, when the frame reaches the stop-piece L it indicates that five acres have been traversed.

In Merrett's improved computing scale the screw in the metal frame is made to act as a clamp, and different scales are applied to the same metal frame, instead of the ivory pieces employed to cover the scales which are not required for use in the instrument adopted by the Tithe Commission Office. The ready edge is also bevelled off against the scale. In the Planimeter the bar E F can be made either to slide in the box to which the other is attached (see fig. 1) or can be permanently fixed to this box. In the latter case it is constructed to record square inches only. In former case it will record square inches with the mark upon the sliding box is made to coincide immediately under the mark upon the bar E F which is situated near the figures 22-174 fig. 4. The sliding box is fixed to the sliding arm E F by the clamp screw H, and the marks above alluded to are made to coincide the movement of the slow-motion screw F. The horizontal wheel M records the square units one revolution, the wheel L records square units and tenth parts of a square unit, and the vernier attached outside the wheel L enables

hundreds of a square unit to be read. When needle-point D is placed outside the area to be calculated no account is taken of the figures on the sliding bar E F, but when the needle-point D is placed inside the area to be calculated, the number engraved upon the bar is added to the reading of the instrument after a boundary of the area has been completely traversed by the pointer S, before the first digit of the instrument is deducted. We give an example in a future article to show its application.

IR.—In the "Student's Column" in the Builder October 15th, you give a formula for ranging trees which you illustrate by diagram, merely stating that the proof is contained in the figs. 4 and 5. I have taken the trouble to work out the solution from the said figs., and I obtain the following relation, which you will see differs very much in form from that which you give:—

$$R = R' \cos A - \sqrt{(R-r)^2 - \{ (R-r) - R \sin A \}^2}$$

Would you kindly say if this is not correct, or if you give the detailed analysis of your own relation, and oblige,

RAILWAY ASSISTANT?

\* The geometrical proof is shown in fig. 4. The algebraical proof is illustrated by fig. 5.

Fig. 4.—In order that the circle with the centre in fig. 3, should touch the tangent line E A, its radius must be in a line parallel to it, at a distance equal to its radius (see fig. 4), and in order that it should touch the circle having its centre at K, its radius must be in a circle having a radius equal to the difference of the two given radii, concentric with the circle D C, which touches the tangent line E A (fig. 4). Therefore it lies in the intersection of a parallel line and the circle with a radius equal to the difference of the two given radii. This intersection comes in the point G (fig. 4). The problem, therefore, algebraically resolves itself into the following:—

f A = the angle F C E = A C H = N C K (fig. 5),  
R = radius of original curve,  
r = radius of new curve,  
M C = r,  
M G = N K - G P,  
N K = R sin A,  
M G =  $\sqrt{R^2 \cos^2 A - K P^2}$   
K G^2 = (R-r)^2  
K P^2 = (N C - M C)^2 = (R cos A - r)^2  
G P =  $\sqrt{(R-r)^2 - (R cos A - r)^2}$   
=  $\sqrt{R^2 - 2 R r \cos A + R^2 \cos^2 A + 2 R r \cos A - r^2}$   
=  $\sqrt{R^2 (1 - \cos^2 A) + 2 R r (\cos A - 1)}$   
=  $\sqrt{R^2 \sin^2 A + 2 R r (1 - 2 \sin^2 \frac{A}{2} - 1)}$   
=  $\sqrt{R^2 \sin^2 A - 4 R r \sin^2 \frac{A}{2}}$   
M G = R sin A -  $\sqrt{R^2 \sin^2 A - (4 R r \sin^2 \frac{A}{2})}$   
Q. E. D. (see Builder, Oct. 15, p. 548).

N.B.—The "Railway Assistant" has since then to say that he has found the right solution, which agrees with ours! It is a pity he did not do so before giving all this trouble, but as the answer may be useful to others, we leave it to you.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

3,419, Panelling, &c. W. H. Carmont.  
In order to prevent the warping of wood, and for other convenience, the panelling is, according to invention, made up of different thicknesses of lead glued or cemented closely together, with the iron or fibre placed crosswise. The wood is pressed into moulds, and the process may be applied to a variety of purposes where combined strength and lightness are required, such as in the manufacture of lift furniture, &c., and is especially suitable in cases where the wood is exposed to the weather, for instance in the bodies of vehicles.

15,223, Concrete Wall Construction. J. Tall.  
According to this invention, in order to effect an inter connexion and disconnexion of the panels or segments used in concrete building a rotatable bolt is used, which by a half turn in one direction secures panels, and by a half-round turn in the other direction allows them to be detached.

15,038, Rain-water, Stove, and other Pipes. Gregson.  
By this invention, the nails or holdfasts are permanently fixed in the wall, and on the spigot or

faucet, which is made much longer than usual, ears are cast, having holes so made that while the ear is passed over the nail by the lower hole, the weight of the pipe causes it to pass to a second one, where it may be fixed by wedges. The projections are also thicker than ordinary to allow the pipe to stand away from the walls.

15,184, Fanlights, Windows, &c. G. Stierlin.  
The fanlight made in accordance with this invention is mounted on spring hinges. The spring catch is pulled, which unlocks the fanlight, at the same time it falls open. It is kept in any position by fastening a link of the chain on a peg at the side of the door.

15,546, Syphon Trap Closet-pans. A. C. Henderson.  
The apparatus which is the subject of this invention is inodorous, and is designed to prevent sewer gas entering the house. The trap is in the form of an S, and is connected with the basin. Arrangements are made for flushing both basin and trap, and the form is designed to seal the trap against the inflow of sewer gas.

16,708, Syphon Cisterns. M. Syer.  
According to this invention, the tube is flushed with water, and has the confined air acting as a valve to keep back the water and close the water-way; then a small heat tube attached to the syphon cover, charged with water by means of a hole in this small tube, in its turn acts as a valve to keep back the confined air under cover. To this heat tube is connected a small blow or suction pipe, used in conjunction with a "push" arrangement or lever, with sucker or plunger attached. Air is blown into the heat tube, and the trapping water therein is blown or sucked out, thus releasing the confined air, and allowing the water to flow down the syphon tube when all the water in the cistern is syphoned out.

NEW APPLICATIONS FOR PATENTS.

Oct. 14.—13,928, J. Hind and F. Sharp, Automatically Opening Doors from the Interior of Buildings in Cases of Emergency.—13,946, H. Whiteley, Opening and Closing Fanlights and Casements.—13,951, W. Howitt, Fixing Glass and other Roofing.—13,973, Sir G. Chubb and Others, Strong Rooms and Safes.—13,975, W. Moore, Preventing the Bursting of Water Pipes by Frost.  
Oct. 15.—13,979, W. Taylor and G. Holley, Windguards for Chimneys and Ventilators.—14,025, Sir G. Chubb and G. Exton, Unfastening and Fastening Doors, &c.—14,041, E. Holt, Automatic Drain Cocks or Valves.—14,045, S. Tudenham, Metal Bars and Frames for Windows, Doors, Panels, &c.—14,056, J. Beauland, Hinge for Doors, Gates, or Windows.—14,078, H. Elliott, Glazing Greenhouses, &c.  
Oct. 18.—14,101, C. Gardner, Waterfall Fireproof partition and Drop Screen.—14,113, E. Tarvor, Construction of Theatres.—14,167, J. Greenslade, Window Frames and Sashes.  
Oct. 19.—14,184, J. Fairhair and R. Jones, Door and Window Fasteners.—14,206, D. Sorfield, Automatic Draught, Dust, and Rain Excluder for Doors.—14,229, H. Lake, Wood Paving.  
Oct. 20.—14,243, J. Dowman, Keeping Window or Door Sashes Raised or Open at any required Height.—14,262, J. Potter, Fireplaces.—14,267, F. Keegan, Fastening Show Case Doors or Window Casement.—14,284, W. Wubli, Sewer Sanitation.

PROVISIONAL SPECIFICATIONS ACCEPTED.

Table with columns for location, agent, and price. Includes entries for Stepney, Clapham, Blackfriars, Bankside, Bermondsey, Ealing, Kingsland, Stoke Newington, Brighton, and Ponders' End Station.

MEETINGS.

Table with columns for date, time, and location. Includes meetings for Saturday, October 29; Monday, October 31; Tuesday, November 1; Wednesday, November 2; Thursday, November 3; Friday, November 4; and Saturday, November 5.

Miscellaneous.

**The Leland Club.**—The four days' proceedings of this wandering body of antiquaries came to a pleasant and successful termination on Tuesday last week, at Mayfield Palace, which interesting old building, said to have been founded by St. Dunstan, was courteously shown to the party by one of the holy mothers of the sisterhood now occupying the historical edifice, which they have converted, with great care of the early work, to their religious uses, and generally repaired and restored throughout. Bayham Abbey, some ten miles distant, had been visited in the first part of the day, when the remains were described and commented on by Mr. John Reynolds, of Bristol, who, throughout the excursion, gave additional interest to the various castles, churches, and monastic buildings visited by the Lelanders by his lucid explanations of their architectural features and history generally. Mr. George Patrick, of Wandsworth, at Maplestead "Round Church," where he read an excellent paper on its history and foundation by the Knights Hospitalers, and at Rochester Cathedral, which he described in a short and telling address, added much to the instruction and interest of his listeners, as also by his paper on Heddingham Castle, and the doings of the great De Vere family, who, as Earls of Oxford, resided in that Norman stronghold in an uninterrupted succession for some 500 years. A word of praise must also be gratefully awarded to Mr. Rendle, who, on the first day of the meeting (Friday, the 14th inst.), gave the above society an admirable paper "On the History of Southwark," in the Church of St. Mary Overy, followed by Mr. Thomas Morgan, F.S.A., and Mr. R. E. Way, with a description of Gover's and other famous tombs therein, and the Roman antiquities still constantly discovered in digging foundations in various parts of the old Borough; many curious objects and several rare Roman coins of his own collecting the latter gentleman exhibited on the occasion. At the Armourers' and Braziers' Hall, which, by the kindly invitation of that ancient and honorable Company, the Lelanders visited the same afternoon, Mr. Charles J. Shoppee, a past-master, gave them a short but comprehensive history of the guild, accompanied by an exhibition of the arms, consisting of valuable suits of armour, rare old swords and other weapons of war, as well as pointing out the many fine old pictures, portraits, and rare engravings, and also exhibiting the rich and curious plate belonging to the Company. In the evening of this day, the members of the above club closed their interesting doings by paying a visit to the French (Huguenot) Hospital, near Dalston, of which Mr. A. Girard Browning, the Secretary, afterwards gave an account, as he led the members of the club through the passages and chambers of the "Hospice." At Rochester, on Monday, Mr. C. Roach Smith, F.S.A., as an honorary member of the Leland Club, met the party at the railway station, conducting them through the cathedral and the remains of the fine old Norman castle afterwards, at each of which he kindly gave short descriptions of their origin and history, and also of the Roman foundation of Durobrose (Rochester) itself. At "Kit's Coty House," which was visited later in the day, he delivered a comprehensive address upon the nature of such pre-historic monuments.

**A New Cathedral Cloister at Exeter.**—A few days ago Lord Clinton laid the cornerstone of a new cloister, at the south side of Exeter Cathedral. The scheme is to restore the old cloister, with a library, and the former foundation has been traced and the building will be erected according to the original form. The library will be over the cloister, extending from east to west. The total cost has not been estimated, but that of the portion in hand will be 4,000l. The 4,000l. will provide five bays of the cloister, with library, staircases, and lavatories. The architect is Mr. John L. Pearson, R.A., of London, and the builders, Messrs. Luscombe & Son, of Exeter.

**The Society of Engineers' Visit to Acton and Ealing.**—Our account of the Society of Engineers' visit to the sewage works at Acton and Ealing, the refuse destructor at Ealing, and the new storage reservoir at North Ealing for the Grand Junction Water Company, is unavoidably held over this week, for want of space.

**The Office of City Architect.**—At the meeting of the Court of Common Council last week, the Officers and Clerks' Committee brought up a report on the reference to consider the nature, duties, and emoluments of the office of City Architect, which has recently become vacant by the death of Sir Horace Jones. They submitted information as to the extent of the duties which devolved upon the department of the City Architect during the tenure of office by Sir H. Jones from 1864 to 1887. They considered that, looking to the extent and character of the new works executed under Sir H. Jones's direction, it was improbable that for some time to come the necessity for the employment of a gentleman of such acquirements would arise. The committee had, therefore, after very careful consideration, decided to recommend the appointment, at a salary of 800l. a year, of a gentleman of ability and capacity as the head of the department, to be called the City Surveyor, who should be competent, in ordinary circumstances, to undertake the discharge of the duties of an architect, except such as required the highest professional services. Mr. Sly, the Chairman, then moved the adoption of the committee's report, and stated that since the death of the City Architect the work of the department had been carried on most satisfactorily, and plans and specifications of the new City of London Court had been prepared and approved. Major Joseph, as an amendment, proposed that the appointment of an Architect and Surveyor should be continued. The subject gave rise to a long discussion. On a division, the amendment was lost by 79 votes to 71. Mr. Deputy Ashby moved the adjournment of the debate, which was lost, and the report was ultimately adopted by a majority of 11, though Mr. George Shaw at once gave notice of a motion to rescind the resolution.

**The Glasgow Institute of Architects.**—The twentieth annual general meeting of the Glasgow Institute of Architects (Incorporated) was held in the Religious Institution Rooms, Glasgow, on the 18th inst. Mr. David Thomson, President, in the chair. The report of the Council, which was read by Mr. William MacLean, the secretary, gave an account of the work of the Institute during the year. The financial statement, submitted by Mr. T. L. Watson, showed a balance in favour of the Institute of 289l. 1s. 5d. In moving the adoption of the reports, the Chairman congratulated the members on the flourishing state of the society. As to the proposed Registration Bill, he had attended a conference in London, and had expressed the opinion, on behalf of the Council, that they would oppose the formation of a central association in London for the regulation of all professional matters in the provinces.

**Employes' Supper.**—A very pleasant gathering of the employes of the firm of Messrs. Banning & Sons, contractors, London, who are engaged in the work of restoring the parish church of Frolesworth, took place at the residence of Mr. Hoggin, farmer, on Monday evening last. The work of restoration being near to completion, Mr. H. Banning, junior member of the firm, took the opportunity of complimenting their employes for the assiduity and workmanlike manner which has marked their conduct during the somewhat short and forced period (owing to the approach of winter) that the work has been in progress by entertaining them to a substantial supper.

**The Late Lord Iddeleigh.**—A statue to the memory of the late Lord Iddeleigh was unveiled at Exeter on Wednesday, the 19th inst., by the Lord-Lieutenant of Devon (Lord Clinton). It has been executed in Sicilian marble by Mr. J. E. Boehm, Esq., A.R.A., and is described as a most faithful likeness. It stands on a pedestal of polished grey Haytor (Devonshire) granite, which has been executed for the sculptor by Messrs. J. Easton & Son, of Exeter.

**Royal Institute of British Architects.**—The opening meeting of this Institute for the present session will take place on Monday evening, November 7th, when there will be a ballot for new members, and the President (Mr. Edward T. Anson, F.G.S.) will deliver his opening address.

**Bradford Post-Office.**—We are asked to mention that the wood block-flooring at the Bradford post-office (illustrated in our last) was laid by Messrs. M. C. Duffy & Son, Limited, of Bernondsey.

**Mr. Conder's Sewage Purification Process.**—The Rural Sanitary Authority for Surrey has recommended the adoption of this system in connexion with the drainage into Beomond's Watercourse, Chertsey. At the meeting of the Board last week Mr. Durran presented to the Board a report on the question, in the course of which he said, as reported in the *Surrey Advertiser*:—"I have again visited the Chichester outfall, and from what I saw and the sample of effluent water obtained, I am of opinion that the scheme without proper settling tanks being provided would be of little or no use for the purpose required for Chertsey; or any of our villages in the valley of the Thames. Mr. Conder, who himself visited Chertsey last Saturday, also pointed out another grave difficulty, namely, the uncertain flow of the refuse from the brewery, but this he informed me could be got over by the Sanitary Authority requiring that the brewery refuse should be so purified by the brewers themselves, before entering the main drain, as to be harmless to the scheme. From these facts I would beg to suggest that Mr. Conder be asked to put up his apparatus, and that temporary tanks be provided, so that the scheme can be tested before any other steps are taken." The Board then gave their assent to try the scheme.

**Association of Municipal and Sanitary Engineers and Surveyors.**—The fourth examination of candidates for the offices of Municipal Engineer and Local Board Surveyor, carried out under the auspices of this association, was held at the Town-hall, Manchester, on Friday and Saturday, the 7th and 8th of October, 1887. The examiners in the several subjects were:—1, Engineering as applied to Municipal Works, Mr. E. B. Ellice Clark, M.I.C.E., County Surveyor, Sussex (West), late Surveyor to the Commissioners, Hove; 2, Building Construction, Mr. W. G. Laws, City Engineer, Newcastle-on-Tyne; 3, Sanitary Science, Mr. J. Gordon, M.I.C.E., Borough Engineer, Leicester, President of the Association; 4, Public Health Law, Mr. H. P. Boulnois, M.I.C.E., Borough Engineer, Portsmouth. The following gentlemen, having satisfied the examiners, were granted their certificates of competency by the Council: Messrs. J. Cook, T. E. W. Mellor, J. W. Metcalf, W. Parker, R. W. Smith-Saville, F. D. Ward.

**Appointment.**—Out of 100 applications for the appointment of clerk of works for the outfall sewerage works at Burnham, Mr. A. E. White, of Westminster, has been elected. Mr. Henry Hill, of High Wycombe, is the contractor.

**Cremation in Sweden.**—The first crematorium in Sweden was finished at Stockholm a few weeks ago, and the first cremation in that country was carried out on Saturday last.

**\*\* SPECIAL NOTICE.**—Lists of Tenders frequently reach us too late for insertion. They should be delivered at our office, 49, Catherine-street, W.C., not later than 12 Noon on THURSDAYS.

**TO CORRESPONDENTS.**

Registered Telegraphic Address, "THE BUILDER, LONDON."

M. & Sons (your letter seems to be practically an advertisement of a special form of fire extinguisher. For that our advertising columns are used.—H. T. G. (Banks)—G. F.—W. B.—E. G. (Bion) your letter to the Builder to very little purpose.—W. S. C.—E. B. & Sons (your letter is not one that we can print a great deal of it being entirely uncalculated for by anything in the letter to which it professes to be a reply).—T. S. M'C.—U. E.—W. W. (we do not think the architectural profession will accept you as their champion).

All statements of facts, lists of tenders, &c., must be accompanied by the name and address of the sender, not necessarily for publication. We are compelled to decline pointing out books and giving addresses.

Note.—The responsibility of signed articles, and papers read at public meetings, rests, of course, with the authors.

We cannot undertake to return rejected communications. Letters or communications (beyond mere news items) which have been duplicated for other journals, are NOT DESIRED. All communications regarding literary and artistic matters should be addressed to THE EDITOR; all communications relating to advertisements and other exclusively business matters should be addressed to THE PUBLISHER, and not to the Editor.

### Christian Symbolism in Great Britain and Ireland.

HERE has been for a long time a want of a work treating on the Early Christian symbolism of the British Islands, and antiquaries were therefore much gratified when it was known

that the subject had been selected for the Rhind Lectures in Archeology for 1885, and entrusted to the pen of Mr. J. Romilly Allen, F.S.A. Scot., who had already given proof of his ability to deal with the subject in a manner befitting the needs of the work. These lectures have just been published,\* with numerous illustrations from the author's own drawings, and the work appears before the public with the merit of being unique, concise, and comprehensive. In his first lecture, Mr. Allen treats of the Christian symbolism in foreign countries, by way of clearing the ground for the introduction of the true scope of the design. He defines symbolism as a means of conveying ideas and facts to the mind by representations which are, in the first place, merely pictorial, but by frequent repetition, gradually assume certain stereotyped or conventional forms. Hence it is a system whereby pictures of natural objects, or scenes of which the historical aspect is well known, are made to express allegorically something beyond the apparent fact, and thus set in motion a train of thought which leads us on to the contemplation of those abstract ideas associated more or less directly with the thing depicted. In this way, every religious representation may, in fact, be symbolically treated.

In the early days of art, however, the subjects selected for symbolical reference by the primitive art-workers were naturally limited, and perhaps there were hardly more than a dozen scenes in the life of Christ which found favour in their eyes. If these early and prominent subjects were classified, they would properly fall into several divisions, such as the Historical (chiefly Old Testament history), which symbolise events in the life of Christ, as the sacrifice of Isaac or Moses striking the rock; the Parabolic, already in their very essence used figuratively, and hence merely a transference from literature to art, as the allegorical story of Dives and Lazarus; and so forth.

\* Early Christian Symbolism in Great Britain and Ireland before the Thirteenth Century. "The Rhind Lectures in Archeology for 1885." By J. Romilly Allen, F.S.A. Scot. London: Whiting & Co., 30, 32, Sardinia-street. 1887.

The Mystic and Supernatural subjects depict, for example, the Day of Judgment, the Binding of Satan, and the Jaws of Hell. Rites and Ceremonies, the Church and her Officers, form another class. The moral and spiritual life of man, the virtues and vices, the conflicts between Good and Evil, the Deadly Sins, and Death itself, comprise another section. Then follow the subjects suggested by the properties of the animal, vegetable, and mineral world, such as the qualities of birds, beasts, fishes, gold, &c., applied in a spiritual manner to Christian doctrines. To these follow the subjects connected with the universe, and with the progress of nature, as the seasons, the Zodiac, the heavenly bodies, and other personifications. Human pursuits, and subordinate objects taken in lieu of the subjects to which they belong,—as the key for St. Peter and the sword for St. Paul,—and monograms, close the list.

If we arrange these things according to their literary sources they fall into the following divisions:—Pagan prototypes adapted to Christian teaching, as the myth of Orpheus applied to Jesus Christ, or the ancient gems engraved with portraits of deities and emperors set in Medieval rings with Christian inscriptions; Scriptural subjects, which are usually selected from the most prominent features of the faith; Apocryphal subjects, derived from the uncanonical books, which, on account of the attractive philosophical and moral apophthegms they contained, were, nevertheless, greatly admired and frequently quoted in the early Medieval period; subjects from the lives of the saints, which are, however, rare at the early periods; and, lastly, the scientific subjects, such as those found in the "Bestiaries," or illustrated works of emblematic zoology, so favourite and yet so grossly misunderstood a science in the days of which Mr. Allen takes cognisance.

There are numerous contemporary remains, one might almost say an inexhaustible field, capable of supplying examples to the student of Early Christian symbolism, and, indeed, the only profitable way to understand this symbolism is to examine the literature of the period, and to search contemporary illustrated manuscripts, which alone give the clue to the conventional method of treating particular subjects, and alone enable us to divine the actual ideas of the artists who designed them. The rudeness of the execution of some of the earliest Christian sculptures is shown by Mr. Allen to have been a stumbling-block to many inquirers, who have failed to interpret accurately (as well they might) the meaning of some subjects, by not making sufficient allowance for the want of art-training in remote places and distant times. These

sculptures, like the debased designs on ancient British and Gaulish coins, were copied, barbarously enough, from well-executed classical models, and are often quite as unintelligible as the coins themselves are, until placed side by side with the originals, when the meaning is quite apparent.

The sources of chief importance for the general study of Christian art are, first of all, the paintings on the walls and roofs of sepulchral chambers in the catacombs at Rome; the sepulchral tablets bearing Christian symbols, the sculptured sarcophagi, and the minor objects found in the catacombs. These, which are of paramount importance in this behalf, range in date from A.D. 50 to 400. The peculiarities of Christian art which these catacombs enshrine have frequently been treated of in illustrated works. One of the best and latest is perhaps the new edition of Mr. William Palmer's work on the subject. But we are inclined to believe that as yet sufficient attention to these splendid remains has not been given by those who seek to explain our own earliest national phases of sculpture and illustration. Mr. Allen gives, under this branch of his work, a capital and lucid description of the catacombs and their contents, and here it may be said that we hardly yet properly value the labours of Bosio, Fahrenli, Seroux d'Agincourt, and De Rossi, who indefatigably devoted their time and attention to the exploration and explanation of what was in their day a new and unknown branch of archeology.

From A.D. 400 to 700 we must rely on the second source,—that, namely, of paintings and mosaic work employed in the decoration of the internal surfaces of ecclesiastical buildings in Italy and the Eastern Empire,—the sarcophagi deposited in the basilicas at Rome, Ravenna, Milan, Arles, and elsewhere,—the early ivories, the miniatures in the Latin, Greek, and other manuscripts, engraved gems, coins, crystal objects, and other minor relics. A third period, 700 to 1050, is illustrated by the decorations of churches as before, added to which must be mentioned the pre-Norman sculptured crosses in Great Britain, miniatures in contemporary manuscripts, and some objects, such as belt clasps, which the Burgundian graves have yielded up to reward the patience of the explorer. The last period of which Mr. Allen takes notice, A.D. 1050 to 1200, when the Byzantine style finally retires before the Gothic advance, is more richly endowed with greater variety of objects. Subsidiary portions of churches, as fountains, pavements, capitals of columns, friezes, sculptured slabs, stained-glass windows, ornamented doors, pulpits, screens, shrines, and a vast number of relics, all intimately connected with the church

lend their aid to the student; but almost all of these betray the manifest stamp of imitation of older examples by reason of the conventionalism with which they are replete.

One of the many interesting phases of catacomb art is the admixture of Pagan idea and treatment with the Christian element or motive. This Mr. Allen accounts for in two ways: firstly, the necessity of disguising Christian doctrines during the times of persecution; and, secondly, the difficulty of creating a new system of symbolism without founding it, to a certain extent, on what had gone before. To the former fact it is owing that the elegant and attractive subject of Orpheus charming the beasts with his lyre occurs three times under circumstances which point to its symbolical application to the Saviour's word softening the hardness of Pagan hearts. The representation of the Good Shepherd has, again, been compared by some to the statues of Hermes Kriophorus. Of Old Testament types the most striking and the most tragic are alone selected.—The Temptation of Adam and Eve; Noah and his Ark; the Sacrifice of Isaac; Moses striking the Rock; Moses and the Burning Bush, typical of the Christ delivering sinners; Daniel in the Lions' Den; the three Children in the Fiery Furnace; Jonah (in four scenes); and David with a sling. Similarly, too, the New Testament subjects are by no means numerous. Those most frequently occurring are the Raising of Lazarus, who is generally upright and swathed with bandages, in a niche, with pediment and side columns, almost reminding us of the conventional appearance of the mummified Osiris (typical of the defunct person to whom he is likened) in Egyptian art, whose myth, indeed, has some points in common with the symbolical aspect of Lazarus: the miracles of Changing the Water into Wine, the Loaves and Fishes, Healing the Blind, the Paralytic carrying his Bed, the Feast of the Seven Disciples by the Sea of Tiberias, and St. Peter saved from Drowning. Other subjects, not so frequently found, include the Virgin and Child, the Adoration of the Magi, Herod, St. John baptising Christ, the Wise and Foolish Virgins, and some others.

Of early Christian gilded glass, the British Museum contains several specimens, which will be seen to the best advantage when Mr. Franks opens to the public,—as we hope he will before long,—the new Gallery of Glass and Fictilia, which will prove to be one of the most attractive fine-art additions to that institution. Several inscriptions occur on these relics, one of the most common being "Pie Zeses," a Græco-Latin salutation of "Drink, and long life to thee." Some, at least, of these are said to have served as ministerial chalices, and the inscriptions would then refer to the Eucharist. Those with stains of blood on them are believed to have contained the blood of the early martyrs scooped up at the scene of execution, and piously deposited in the catacombs by their friends; at the same time, it must be borne in mind, although Mr. Allen does not appear to allude to it, that very similar inscriptions are found on Romano-British pottery used for purely convivial purposes; as "Bibe," "Bibamus pie," "vive," "vivas," "sese," "vita," and so on.

The sculptured sarcophagi in the Lateran Museum have contributed many valuable scenes from the Old and New Testaments. It is curious that while the miracle of the Loaves and Fishes occurs twenty times on these sculptures, and the apprehension of Peter as often, there are only single examples of the Cross. The Temptation of Adam and Eve, and Daniel in the Lions' Den, occur each fourteen times; Jonah's story, twenty-three times; Moses striking the Rock, twenty-one times; but the Passage of the Red Sea,—no doubt a difficult subject to represent,—only once. The ancient Christian ivories, in like manner, contribute other scenes to make up the tale of Biblical allegories. The best known is probably the

"Franks Casket" in the British Museum, of Scandinavian art, bearing Runic inscriptions, and representations of the Adoration of the Magi, and the Flight of the Jews from Jerusalem.

Manuscripts are so rare at this early period, and the material of which they consist so frail compared with stone, gems, metals, or ivory, that it is not to be wondered at that this class of relics does not contribute so rich a harvest of early Christian pictures to the consideration of the inquirer. There are two Greek MSS. of Genesis, one at Vienna, and the other, much injured by fire, at the British Museum, which between them originally contained nearly 300 miniatures, whereas the Greek Gospels seldom contain any pictures beyond portraits of the Four Evangelists. The Alecuine Bible of the ninth century; the Bible and Psalter of Charles the Bald, of the ninth century, at Paris; the "Codex Aureus" of the same date in the British Museum; the Oxford Cadmon; the Book of Kells; the Duke of Devonshire's Æthelwold, and a few others, belong to this class; but Mr. Allen has curiously enough omitted to cite in this part of his work the Utrecht Psalter, which some have attributed to the sixth century, a literary connecting-link between England and the Continent of high antiquity and remarkable interest, not only for its history and palæographical value, but for its profuse illustrations which bear upon early Christian symbolism.

Mr. Allen's second lecture treats of the symbolism of the Romano-British period and of the Celtic sepulchral monuments, between A.D. 50 and 400. Of the few Christian relics of this period Mr. Allen gives good notices. The cross on the lid of a sarcophagus, found in 1869 during excavations on the north side of

Fig. 1.

Westminster Abbey (fig. 1), with inscription in memory of Valerius Amantinus, is, by some, conjectured to belong to this period; but Mr. Allen inclines to believe that the sarcophagus and its cover, which seems not to fit in every respect, were appropriated by an unknown Christian, perhaps in the fifth or sixth century, at which time the cross was cut. Few, however, will deny the close similarity of the cross with those found, incised or in low relief, on tomb slabs of six hundred years later than the suggested date, and we fear that the evidence for early Christianity in England resting on this relic must be received with very great hesitation. The number of sepulchral remains belonging to the period of Roman occupation which show any Christian traces is, as the author declares, infinitesimally

small; a silver bowl, two pewter cakes, a piece of Samian ware, a terra-cotta lamp, and a few similar objects, make up the total on which the whole argument for Roman Christianity in England rests. Christianity, if indeed it were introduced in Roman times among us, must have made little or no progress in those times. Celtic sepulchral monuments, on the other hand, abound with Christian evidences, chiefly the *Chi-rho*, or sacred monogram of the name

Fig. 2.

of Our Lord, fig. 2, as on the tombstone of Carausius, at Penmachno, co. Carnarvon, measuring 1 ft. 10 in. by 11 in. No one can doubt the remote antiquity of this stone. Many others could be cited, and the author has gathered up numerous examples of early ornamental crosses on sepulchral stones of the Celtic age, as, for example, the six kinds figured by him from slabs at Clonmacnoise; the latter illustration shows what is known as the "window-frame" pattern. Among other conventional remains of the period none yield in interest to the so-called "hog-backed recumbent monuments," found in Scotland and northern England, but not elsewhere. The precise symbolism of these does not appear to be yet clearly ascertained. It may, indeed, be questioned whether they are to be classed with Christian symbolical remains, seeing that they carry no determinative emblems, although they undoubtedly belong to a Christian period, for their ornamental features correspond with those of the sculptured crosses of the pre-Norman period. They are generally about 6 ft. long and 1 ft. 6 in. wide and high; those at Brompton, co. York (fig. 3), are good examples. There are some also, not mentioned by Mr. Allen, at Durham. The conventional form consists of a central ridge running the whole length of the stone, from which the sides slope away. It is highest in the middle, and so possess a "hog-backed" appearance, and the sides are ornamented with marks like scales or tiles. The most remarkable feature is that of the end, which takes the form of the huge head of an animal, or a muzzled bear's head and head. As there is no evidence of a strictly Christian character on them, as we have already said, may they not be a survival of a Pagan form of burial, existent archaically in early Christian times, but before the use of Christian symbolism on sepulchral stones had become universally imperative?

The third and fourth lectures discuss the High Crosses of Ireland and their subjects on shaft and base. These two essays occupy a large portion of the book, and form the best critical account extant on the subject. The richness of the design and work, the strict

Fig. 3.

Fig. 4.

Fig. 5.

conventionality they exhibit, the peculiar feeling which they indicate, may be well gathered from two corresponding designs of the Sacrifice of Isaac (fig. 4); the first on the arm of the Cross of St. Patrick and St. Columba at Kells; the latter on the shaft of the Great Cross at Monasterboice. This type, with but little alteration, lingered on as late as the eighteenth century in some parts of Scotland, and Mr. Allen figures a stone dated 1774, in Logierait churchyard, co. Perth, the sculptor of which has evidently drawn inspiration from, but not improved upon, the first ideas of the Celtic designs. As other examples of this class of art we may mention Daniel in the Lions' Den, the Flight into Egypt, and the Miracle of the Loaves and Fishes on the base of the Moonee Abbey Cross, as characteristic of Early Christian symbolism as taught by the Irish Church in the early period under review. There is one subject which Mr. Allen has not clearly explained. It is a bird holding a circular disc in its beak coming down between two persons holding crooked staves, which occurs twice at Kells and once at Nigg, Ross-shire, where the staves are exchanged for open books. The author thinks that this refers to St. Paul and St. Anthony breaking bread in the desert; but the idea is obscure and too far-fetched. It is probably representative of an episode in the life of a Celtic saint. It is not unlikely that this refers to St. Hilda, of Whitby, and St. Aidan. In the seal of Whitby Abbey, in the British Museum, St. Hilda, with staff and hook, stands between two tonsured priests, each celebrating the Eucharist with a chalice on an altar. Over each cup is a bird flying down, and holding a round disc, intended for the wafer, in its beak. Examination of the life and miracles of St. Hilda would no doubt throw light on this subject.

Passing over much that is worthy of notice among these Irish symbolics, we find the fifth lecture devoted to the consideration of Norman sculpture, chiefly in the architectural details of churches, from A.D. 1066 to 1200. This is a truly vast field, and really deserved a separate treatment in another volume. It is here introduced with a prefatory examination of Saxon architecture and details of sculpture, and, of course, can only deal with a limited number of the extant specimens. How striking some of them are may be gathered from one example here given, the Baptism of Our Lord, on the font at Bridekirk, Cumberland. There is a Runic inscription on the font, and the peculiar treatment of the foliage points to the eleventh century for the time of its execution (see fig. 5). Of a later date, but of equal interest, is the Norman leaden font with zodiacal signs and monthly employments in Brookland Church, Kent. These subjects should be compared with those found so frequently in manuscript calendars.

The concluding lecture deals with the Medieval *Bestiary*, or Book of Emblematical Animals, so favourite a work in the libraries of old. There are several specimens in the British Museum, nine among them illustrated, as we gather from Mr. Birch's and Mr. Jenner's "Catalogue," and Mr. Allen's list of all the extant MSS. will be of great use to future inquirers. The texts of many have been published, and probably the "*Bestiaire Divin*," by Hippeau, Caen, 1852, is the most comprehensive work on the subject, but the whole subject awaits comparative and classified treatment. The symbolism which encircles most of the animals in the somewhat limited and fanciful list of Medieval fauna, is not difficult to be conjectured; but there are some more abstruse subjects, as the *terrobolem*, or *turrobolem*, two stones which emit fire, that are found in the East on a mountain, one male, one female, and of human semblance, which almost savour of the marvels told by Mandeville and his precursors. These two stones typify firstly the love between the opposite sexes, but metaphorically, those who wish to lead a life of chastity, are hereby enjoined in the accompanying descriptive text to avoid the society of women, and thus escape the temptations which ensnared Adam, Samson, David, and Solomon. These curious subjects occur also on a font at Alne, in Northumberland. The work closes with full

indexes. It fills a want in our antiquarian art literature in a very praiseworthy way, and Mr. Allen will no doubt receive what he really deserves, much credit and advanced reputation for this his latest contribution to archaeological literature.

## NOTES.

**T**HE last number of the *Journal of Proceedings of the Institute of Architects* contains an appeal, signed by Mr. Richards Julian, on behalf of the "Dictionary of Architecture," recalling the circumstances of its foundation, and mentioning that it is necessary to appeal to the old members as well as to new subscribers for funds to complete the work. The unsatisfactory nature of the last volume we have already referred to, and it now appears from Mr. Julian's letter that the whole of the literary matter is at present furnished by Mr. Wyatt Papworth, who was always editor, and appears now to be the sole survivor of those who originally contributed to the Dictionary. Now, with no possible unkindness or disrespect to Mr. Papworth, it is surely only reasonable to point out that no one man can write a dictionary of such a subject as Architecture; and that this is not the method on which an adequate dictionary could possibly be produced. A first-class dictionary of this kind can only be produced by the co-operation of many writers, each treating of the subjects he knows most of, and controlled by a competent and far-seeing editor, who knows what men to go to for each class of subject, and has sufficient general knowledge both of architecture and literature to control and keep up to the mark the whole form of the Dictionary, and to see that scientific and other definitions are given in logical and intelligible language. To suppose that any one man can be editor and all the contributors rolled into one is to suppose what is absurd, and what can only lead to such unfortunate results as those we pointed out in reviewing the new volume of the Dictionary two or three weeks ago. A certain class of articles, such as that on Serlio (which is reprinted, as a "specimen," we presume, in the *Institute Journal*), have been done by Mr. Papworth as well as they could be done; we must be grateful for them; they are a class of articles which require a great deal of laborious research; but if Mr. Papworth is wise he will on his own account decline for the future to represent the whole staff of the Dictionary: the position is neither fair to himself nor to the Dictionary. Then we are told in said paragraph in the *Journal* that this state of things was rendered necessary by the decease of the old contributors (a brilliant staff undoubtedly), and that it was found "impossible to replace them." Has any effort been made to do so? We very much doubt it. And does Mr. Julian really expect us to believe that it would not be easy to find men who could furnish better articles than those on Suspension Bridge, Syphon, and others, the absurdity and even absolute incorrectness of which we pointed out the other day? If an appeal is to be made for fresh subscriptions to complete the Dictionary, we hope that the appeal will be met by a refusal of any further aid until the working out of the Dictionary is placed on such a footing as to ensure a very different result from that presented to us in the volume just completed.

**I**T is gratifying to find that the strike at Bolton has terminated in an agreement on the part of masters and men to refer their dispute to a "Board of Conciliation," who are to take evidence upon the rates paid in other towns, and draw up a scale for the Bolton men; but it is a sad reflection that both sides could not agree to a measure of that kind before costing each other this loss of time and work and money, and on one side distress and poverty, which in the ease of many will not terminate with the strike. We read in the daily papers that "in consequence of the employers importing men during the struggle, not more than half of the strike hands can find work"—a bitter lesson which, however, to judge by the past, we fear will be read in vain.

**D**R. SCHLIEMANN has obtained from the Greek Government permission to make excavations in the island of Cerigo, the ancient Cythera. It would be too much to hope that he will discover the ancient wooden statue of the goddess Aphrodite in complete armour which Pausanias saw when he visited the island, but unless time has dealt very unkindly with the remains of the temple he will surely be able to restore to us some notion of the plan of this the most ancient precinct of the goddess on Hellenic ground. This temple of "the Heavenly Aphrodite" was, Pausanias says, at once the most ancient and the most holy of the Greek temples to Aphrodite. Further, we may hope at Cythera to come upon many a missing link between East and West. It was an early Phœnician settlement. "The temple of Cythera," says Herodotus (i., 105), "was built by the Phœnicians who belong to this part of Syria,"—i.e., to the part about Ascalon, "where was the earliest of all the temples to the Heavenly Aphrodite." The excavations are to be begun at once.

**O**N the agenda paper for this week's meeting of the Metropolitan Board of Works we see that Mr. F. H. Fowler has given notice of his intention to move:—

"That it be referred to the Works and General Purposes Committee to consider and report on the desirability of the Board proposing the following amendments of the law relating to buildings and streets:—

"That the open space now required by law to be left at the rear of dwelling-houses should be increased, so far as regards suburban districts.

"That a greater width than 40 ft. should be required for new streets in suburban districts.

"That owners of land, when laying the same out for building on a large scale, should be required so to arrange as that a suitable proportion of the land may be left open and unbuild upon in the interest of the public health and comfort."

There is very much to be said in favour of these proposals, as thoughtful people who have witnessed the "development" of suburban building estates must have been long ago convinced. Particularly is this so with regard to the melancholy fragments of ground which, when attached to suburban houses, are called "gardens," albeit they are gardens in which, for want of sun and air, nothing will grow. The way in which what are called the "back-additions" to houses are often made to jut out over the greater part of the so-called "gardens," throwing each other into the shade, and preventing the free access of sunshine and wind to the windows of dwelling-rooms, is something like a satire on our much-vaunted sanitary knowledge. Such houses may comply with the letter of the law, but they evade its spirit.

**T**HANKS to Mr. Ellis Lever's impotunity, the miners of Great Britain appear likely to be provided at last with a safer light than they have had all these many years. Although the coal-owner of old times would have been horrified to find that the Davy lamp, by which he set such store, was now condemned as useless, together with several others, such as the Clanny and the Museler, none of these in point of fact gave enough light, and were not safe in meeting an explosive current with a velocity of 6 ft. per second. The new Act, which has been framed with great care, forbids the use of any lamp which will not meet this not uncommon emergency; and this difficulty is claimed to be solved by the Edison Company, which has produced a miner's portable electric lamp, giving comparative safety, and a great increase of light. It must not, however, be expected to insure complete immunity, for the circumstances of each mine differ so much in themselves,—for while naked lights may be used in one without danger, another is so fiery that it is impossible to enter it without safety lamps. Nor must we overlook the tendency of many colliers to unlock the old lamps for the purpose of getting more light. So reckless were some of the men, that false keys made of hard cheese-rind have been found in the pockets of the dead after an explosion. Against such rashness there was no remedy, except the invention of a new lamp which should not offer any temptations for tampering with it.

**T**HE Cambridge Senate has entered into a contract with Messrs. Luscombe for the proposed new buildings of the University Library. The contract price is 13,685*l.*, of which amount 400*l.* is to be expended upon sculpture. The existing library is stored in the upper floors of two quadrangles on Senat-House-hill, between Gains and King's, and close to the ancient sites of Milne-street (now represented by the Trinity Hall and Queens-lanes), the church of St. John the Baptist, and the hostels of St. Edmund, St. Austel, and St. Nicholas. The fabric dates from the middle of the fifteenth century. There is extant a highly-interesting list, drawn up in the year 1473, which gives the then classification of the books, and shows the positions of the stalls and desks along the first floor of the southern side of the older quadrangle that overlooked the already-appropriated site of King's Chapel. Thomas Rotherham, Archbishop of York, a bountiful benefactor in kind to the library, erected circa 1475, the Gothic front which appears in the print by Loggan. That frontage was replaced with a Classical order about 170 years ago, but its central gateway was preserved and reconstructed for the stable at Madingley Hall, near to Cambridge. This alteration, together with others, was effected to make room for King George I.'s gift to the University of the 30,000 volumes which he had bought for 6,000*l.*—the library of Dr. Moore, Bishop of Ely. The sovereign's donation evoked the well-known epigram in connexion with Oxford and the troop of horse together with Sir Thomas Browne's equally famous rejoinder. Under the catalogue room were held the Divinity Schools, removed, in 1879, to the Selwyn Divinity School building over against St. John's, and designed by Basil Champneys. The library was enlarged twenty-one years ago, at a cost of nearly 15,000*l.*

**F**OLLOWING the example of the manager who collaborate with authors in the production of dramatic pieces, Mr. Henry Irving has collaborated with Mr. Alfred Darbyshire of Manchester, and designed, in conjunction with him, what is, if we may believe the *Daily Telegraph* (which is absurdly effusive on the subject), an absolutely safe theatre. There is very little that is novel in Mr. Irving's theatre, a ground-plan and section of which, to a scale of 32 ft. to an inch, is given in the *Daily Telegraph* for October 29th. The only noticeable novelty is the abolition of the gallery, the audience usually occupying that part of the house being placed on the ground-floor in the rear of the pit. There is only one tier or horizontal division for the accommodation of the public above the pit level, and this is divided into an upper circle and a lower circle. There are two means of exit from every part of the house, and these exits, with the exception of the exits from the upper and lower circle, are arranged on opposite sides. The theatre is detached upon all four sides, which may perhaps represent an ideal theatre, but it is one that is difficult of realisation in London, and, indeed, in most cities, and by imagining the site to be entirely disengaged from the adjacent buildings, many of the difficulties which beset an architect in designing a theatre are evaded, but not successfully overcome. There is a general deficiency of lofty accommodation, which would render the exits, especially from the dearer portions of the house, liable to be obstructed on the audience leaving the theatre.

**I**N connexion with the consecration of Truro Cathedral, which took place on Thursday, the 3rd inst., we have received a small sheet of diagrams forming a key to the scheme of subjects represented in the coloured windows executed by Messrs. Clayton & Bell. The diagram gives the outlines of the great east window, consisting of three long lancets with three shorter ones beneath, the two rose-windows in the transepts, the little lancet lights under the south transept rose, the single lights in the east of the two choir aisles, the four lancets in the baptistery, and of one of

the double two-light late windows in the old church, now called the old choir aisle. The subjects of the east window are "The Church Triumphant" in the upper division, and the life of Our Lord in the lower one. The former is represented by Our Lord in majesty, with the seven gifts of the spirit over his head, and beneath and around him are grouped archangels, the Blessed Virgin, the Holy Innocents, patriarchs, apostles, martyrs, prophets, and The Church. The Gospel story is told in the time-honoured and obvious way by representations of the chief incidents, among which the Nativity, the Crucifixion, and the Resurrection of course have the chief places. The north transept window is called the "Root of Jesse," and is genealogical. The Virgin and Child occupy the centre, round which twenty-four of the earthly ancestors of the Messiah are grouped. The chief places are given to Jesse, David, Solomon, and Rehoboam, the older patriarchs coming next. The south rose window is called "Pentecost," and represents the Holy Spirit in the form of a dove, surrounded by Cherubim and Seraphim, and by the twelve Apostles. The three lancets under it present incidents in the early history of the Church, commencing with the stoning of St. Stephen and ending with the entry of St. Augustine into Canterbury. In the baptistery windows St. Paul, St. Cyri, St. Constantine, and St. Winnow represent respectively the Church, the Priest, the King, and the Ascetic, the lower divisions of the same windows being devoted to scenes from the life of St. Martin. The two single lights at the ends of the choir aisles are devoted to St. Stephen and St. John the Evangelist respectively.

THE Society of "Painter-Etchers" (a foolish title, the real meaning of which is merely that they are etchers of original subjects and not of other people's pictures) opened their sixth annual Exhibition at 160, New Bond-street, this week. The Exhibition is rather smaller numerically than in some previous years. In other respects it is fully up to its usual level. As usual, there are a good many works which seem to outstep the true province of etching, and show efforts to work up etching after the semblance of engraving; which is only doing what engraving can do with more force, brilliancy, and permanence. The essential powers of etching lie in the great freedom for which it affords scope, and in contrasts,—broad contrasts,—of light and shadow, not weakened by over-working; and though many of the elaborated works show great diligence and delicacy, we confess that we have more pleasure in etchings pure and simple, according to the old creed, where a few free lines and touches are made to mean a great deal. The elaborated etching appeals to the eye; the pure line etching to the mind. As examples of the latter kind of work we may mention Mr. Short's "Shore Entrances, Bosham" (28); Mr. F. Slocombe's "Pastoral Farm" (67); Mr. Short's "Staithes" (133); and Mr. Pen-nell's "Chelsea" (153). The last-named artist gets a brilliant and powerful effect, in the true spirit of etching, in his "Trafalgar Square" (95), in which the opposition of light and shadow is very strikingly arranged, and the column and statue become little more than a dark silhouette against the sky; the only way perhaps, artistically, to remove it from vulgarity. There are a considerable number of architectural drawings, to which class of subjects Mr. C. O. Murray is a large and laborious contributor; and though his numerous works,—the "Prentice Pillar, Roslin" (73), "Edinburgh Castle from Grass Market" (79), "Durham Cathedral" (87), &c.,—hardly exhibit genius, they show artistic feeling, an eye for effect, and conscientious workmanship; the Edinburgh Castle, with the castle showing light above the dark old houses of the Grass Market, is the finest. Mr. A. H. Haig's "Return from the Fair" (48), a very large etching, showing a scene in an ancient town with an old Gothic bridge making a great mass of light in the middle of the picture, is a very powerful thing; Mr. C. J. Watson's "Whitefriars Bridge, Norwich" (50),

and Mr. J. Watkins's "Ponte de Canareggio, Venice" (53), are also fine works of similar type. Mrs. Harry Hime's "Durham" (33) should be looked at. There are a certain number of wonderfully soft-looking pictures which get much of their half-light from dirty stains over the ground, which we do not call true etching, though this is what at once takes the fancy of the uninitiated. Mr. Strang's portraits (20, 22, 23) are good examples of true etching portraiture, the modelling being obtained almost entirely by lines in one direction without cross hatching, a method of representing modelling of surfaces which is admirably adapted to give freedom of effect and retain the appearance of light, and which seems peculiarly adapted to etching; in engraving it would have a somewhat hard and unfinished effect. The President, Mr. Seymour Haden, does not exhibit this year.

WE have received an announcement of an intended exhibition, to be held in London next year (date and place not yet given), of appliances for safety against fire, water, and burglars, or, as it is rather ungrammatically headed in the circular, a "Fire, Water, and Burglar Proof Exhibition." The architects of the country, and especially those devoting their attention to the construction of theatres, will be invited to exhibit their models, "for which substantial awards will be given." The architects of the country, if they are wise, will probably wait to see under what kind of auspices the exhibition is to be carried out, and who are to make the "substantial awards." The thing appears to us rather like an attempt to make capital out of the recent frights people have had about fires. The addition of the contrivances for safety against burglars is an attraction of a separate nature, certainly. It will probably furnish an interesting and useful study to the gentlemen of that profession, and enable them to prepare fresh appliances to overcome the difficulties which an unsympathetic public is disposed to place in their way.

ALARMED by the deplorable loss of life at the Opéra Comique Theatre, Paris, the Italian Government has recently issued a circular to the various Prefects calling their attention to the urgent necessity of protecting the public from the risk of fire in theatres, and promulgating a new and much more stringent series of regulations with regard to the construction of such buildings. These regulations are simple, but effective, and go far beyond any rules that have hitherto been framed for that purpose. Theatre buildings must be entirely isolated on all sides, and have exits on every side opening into a public street. The pit must have at least three principal exits, one at the back and one at each of the sides delivering directly into the street. There must not be more than three tiers of boxes, exclusive of the pit tier, as a general rule, but if a fourth tier be constructed it must be provided with two staircases and two separate exits. A separate exit must be provided at the back of the stage leading directly into the street for the use of the performers. Two staircases and two separate exits must be provided for the three tiers of boxes, distinct from the other staircases and exits. The staircases and exits should be wide and commodious, as well as the corridors, and all doors should open outwards. These regulations are to apply to all new theatres, as well as to those which are substantially rebuilt. The ends aimed at are excellent, but are they always possible? and will not the requirement of isolation of the site prove in some cases practically prohibitory?

THE exhibition of drawings and sketches at 160, New Bond-street, under the title, "Summer Time on the South Coast from Rye to Penzance," by Mr. C. Gregory, contains some pretty drawings, but is hardly of that amount of interest to justify a special and separate exhibition. The fashion for "one-man" exhibitions is developing, but it ought to be understood that rather high powers are required for an artist to render a gallery attractive by an exhibition of his own sketches

only, and that it is not given to every one to achieve this.

THERE is another exhibition of Mr. Ernest George's water-colour sketches of architectural subjects at the Fine Art Society's Gallery, which is, if anything, better than the last one (from an architectural subject point of view, *bien entendu*); more equable in style. This artist has acquired great freedom and facility in the representation of architectural scenes in water-colour, in a manner which is sketchy, but with sufficient indication of detail, and in which a complete balance of effect is preserved, which we thought was not always the case in the former exhibition of his drawings in the same room. It is hardly necessary to pick out any drawings for special mention; the interest of the subject and the merit of execution is so very equable: Mr. George never rises above what may be called architectural sketching, and never falls below a high point of excellence in that. The collection makes, independently of its artistic merit, a very good comparative collection of picturesque architecture, worth the study of all who are interested in the subject.

TERRIBLE things seem to have been happening at the Grosvenor Gallery, as shadowed forth in a correspondence printed in the *Times* of Wednesday, between Mr. Alma Tadema, Mr. Burne Jones, Mr. Conyns Carr, and Mr. C. E. Hallé. The latter two gentlemen, as every one knows, have been for a long time officially connected with the Gallery, but it appears from the correspondence that Sir Coutts Lindsay has been pursuing, or has shown an intention to pursue, a course which is "at variance with the dignity of art," and Mr. Hallé and Mr. Carr will have none of it, and print letters from Mr. Tadema and Mr. Burne Jones to say that they are quite right. This is followed in *Thursday's Times* by a lofty rebuke in the "Grand Seigneur" style from Sir Coutts Lindsay, who implies that his "salaried assistants" have been endeavouring repeatedly to make demands on him to which he could not accede, "accompanied by threats of resignation," and to his regret he has been "obliged to sever the connexion." All this is mysterious and puzzling to the outsider. According to Messrs. Carr and Hallé, they have left Sir Coutts; according to the latter, he has left them; but neither of them gives any hint of the nature of the artistic heresies which have led to this melancholy disruption of ancient ties. Is it Verestchaguin that has vexed the souls of the believers? We are not told. The result will probably be a gain to the Royal Academy exhibitions, as far as Mr. Burne Jones and Mr. Tadema are concerned. But where will Mr. Hallé get his pictures hung?

#### LETTER FROM PARIS.

THE rules which govern the Corps des Ponts et Chaussées in France are as those of the Medes and Persians, and no engineer, whatever his standing and position, can override them. Consequently it comes to pass that M. Alphonse, who has for some time held the position of Inspecteur-Général of the First Class, having on the 27th of October attained the age of seventy, was the same day placed "en retraite," in virtue of the rule to that effect. But inasmuch as this indefatigable worker is still, in spite of his age, full of energy and activity, the Government has departed from its rule so far as to retain him in an irregular fashion, "hors cadre," as "Directeur des Travaux," and General Director of the Exhibition works, and a unity of administration is thus assured for the present, in municipal operations.

At the Exhibition, the foundations of the Galerie des Machines are completed, and the piers for the Palais des Beaux-Arts and of the "Arts Libéraux" are to be commenced almost immediately. The domes of these two palaces have been commissioned from the "Société des Ponts et Travaux en Fer." In the "Palais des Groupes diverses" designed by M. Bonvard, the covering in and glazing are complete, and the complicated work of the Dome is being proceeded with. This will run to a height of 60 mètres.

The levelling up of the Champs de Mars is in progress, and the planting of trees has been commenced, in order that they may have time to grow and develop into a thick foliage by the year of the Exhibition.

The Eiffel Tower has been in check for a time, whilst the carpenters were getting up the scaffolding, of 42 metres in height, which was to serve for the building of the arched supports. The base of each pier will shortly be surrounded with a facing of masonry, and the erection is now near the point when the metal bearers for the first platform can be riveted on. After that the scaffolding can be dispensed with, as there will then be the central *point d'appui* necessary for the erection of the main body of the tower.

The Ministry of Commerce has decided to institute a retrospective exhibition of labour and of anthropological science, which is to present a kind of complete tableau of the history of labour in all times and countries. An exhibition of this kind was vainly attempted in 1867 and in 1878; and it will certainly prove one of the curiosities of the Exhibition of 1889. It will comprise five divisions: anthropological and ethnographical science; liberal arts; art-work and handicrafts; methods of transport; and military art. A committee presided over by M. Jules Simon, and assisted by M. Ernest Reuau, has been charged with the preparation and classification of this portion of the Exhibition; among the members of the committee is M. Charles Yriarte.

It had been intended to utilise as a "Salle de Spectacle" the space included between the four great piers of the Eiffel tower, but as this would shut out the vista of the central pavilion the idea has been abandoned, and it is now intended to erect a decorative fountain there, a model for which has been executed by M. de Saint-Vidal, a pupil of Carpeaux. This fountain will stand within a basin of 20 metres diameter, with five faces accentuated by pedestals bearing statues symbolical of the five continents of the globe. In the centre will be a sphere around which will be grouped statues personifying "History," "Commerce," "Sleep," and "Love." What is the connexion of ideas in this oddly assorted group, it is not easy to understand; one thing is pretty evident, that by the year 1889 Paris will have become a kind of museum of allegorical and symbolical figures. On the sphere will be another figure representing "Night," reclining, and supporting on her right hand a genius who will carry a torch which will be lighted with electric light. The water will flow from among the rocks supporting the sphere, and fall in successive cascades to the basin below. The whole erection will be about 30 ft. high, and will be lighted up at night by variously-coloured electric lights.

Paris has now one more educational building, in the new college of "Lyceé" for young girls, opened a few days ago in the Rue de Rochechouart, and called the "Lyceé Racine." It has been built after the design and under the direction of M. Gout, who has produced a façade in the Roman style, sober enough in aspect, but not without elegance. The interior, which has accommodation for 300 pupils, has a fine principal staircase; the planning is good, and there is a successful application of enamelled brick for the decoration of the walls and ceilings of the schoolrooms.

The works in connexion with the Bourse de Commerce are now in active progress, especially the removal of the buildings adjoining the old Halle aux Blés, which is at present standing completely isolated. Amid the ruins of the streets demolished for the construction of the Rue du Louvre, the iron cupola of Legrand and Molinos rears conspicuously its great metallic structure, looking orionally like an enormous pigeon-house. New building is going on at a little distance from it; and, besides the Bourse itself, there are being erected, at each side of its main entrance, two large hotels, adorned with colonnades and galleries, giving accommodation which is much wanted in this crowded and central business quarter. These buildings have been designed so as to harmonise with the design of M. Blondel's central building; not like the new hotel at the Gare St. Lazare, about which we have already complained, and which has ruined the effect of M. Lisch's façade of the railway station, and blocked up a new open space almost before it can be said to have existed.

The Metropolitan Railway, which was believed to be dead, has arisen from its ashes.

M. Hérédia, returned from England, is hastening to submit to the Council a new scheme, very doubtful in point of economy, as its cost will exceed by ten million francs that of the scheme already blackballed. As the new project is for an entirely subterranean railway, there will probably be a strong Parliamentary opposition to it, without counting the popular opposition of the Parisian public, who like light and air, and have no love for travelling through sulphur-laden tunnels like those in the neighbourhood of Baker-street and Portland-road.

Among works of smaller size, but not of less interest, we may notice the rebuilding of the fine stone staircase leading to the Chapel of the Cluny Museum. It is sufficient to add that this restoration has been confided to M. Bœswilwald to assure every one that it will be carried out with the greatest care and in a conservative spirit.

Among the many measures taken during the recess to protect the Paris theatres from a calamity like that at the Opéra Comique, may be mentioned the clever manner in which one of the most dangerous theatres in Paris has been transformed. We refer to the Palais Royal Theatre, which is now hardly recognisable. We are not speaking of all the compulsory modifications—electric lighting, iron curtain, hydrants, &c. We refer to what has been done externally. In place of the old sombre and mean-looking wall lining the Rue de Valois, and presenting no outlet, there is a brick façade adorned with mosaics, with two galleries on each story communicating with each other by permanent staircases from the roof to the first-floor level, whence a movable stair can be let down to the street level when needed. These stairs and balconies are treated in such a manner as to complete the general design, producing an effect certainly original and not unpleasing. M. Paul Sédille was the architect for the alterations.

The crematorium erected in Père la Chaise, from the designs of M. Formigé, has excited a good deal of public curiosity. Until some special legislation authorises the process the crematorium will only be used for the destruction of hospital *débris*. The Fours-Gorini system is employed; a corpse can be burned in two hours, leaving 4 kilogrammes (nearly 9 lb.) of ashes. As to the structure itself, the inauguration of which will take place shortly, the exterior decoration of it is hardly completed; and there is to be added to it a grand vestibule with a room for the reception of families. It has the form of a parallelogram in three stages, and is surmounted by two extract chimneys in white stone. At the back are three domes, each covering a crematory chamber; these rise above an entablature with a sculptured frieze. Bands of red stone are alternated with the white, and the principal façade is to be further decorated with black and white marble.

At Père la Chaise also, a monument is being erected to the caricaturist André Gill, who died some years ago, having enjoyed, in the days of the Empire, a reputation much beyond what his real talent justified. The monument is a very simple one, surmounted by a bronze bust of the artist, executed by Madame Laure Martin Coutan.

We have already mentioned that the Union Centrale des Arts Décoratifs have instituted three competitions, the first for painters, the second for sculptors, and the third for architects. The decision on these was given last month; the architectural competition has had the best results, and the Judges have asked that the premium of 2,000 francs, awarded to M. Hourlier, should be raised to 3,000, and that the third premium, awarded to M. Maucout, should be raised from 1,000 to 2,000 francs. As to the painters' competition, the best design, that of M. Mazerolles, did not fulfil the conditions of the programme. In the section of sculpture, the jury premiated the designs of MM. Deloye, Faivre Lindeneher, and Cordonnier.

In the past month there have been two competitions at the Ecole des Beaux Arts, of which the most important, founded by the mother of the eminent landscape-painter Troyon, takes place every two years. On this occasion the prize has been carried off by M. Raymond Moisson, pupil of M. Paul Sédille.

Though writing of Paris we may mention here the competition concluded at Rouen a few days ago, for the erection of a monument commemorative of the Franco-German war. The first premium was awarded to M. Georges Chédanne

architect, and M. Benêt, sculptor; other premiums were also given.

The changes which we announced in the administration of the Beaux Arts have been effected. M. Castagnary has replaced M. Kaempfen at the head of this important "Service," and the latter has succeeded M. Ronchand as Director-General of National Museums. If one may believe the current reports, M. Castagnary has come into office with his hands full of reforms. One does not think much of these "new broom" professions; we shall be content if he will only carry out the little reform of having explanatory notices affixed to the paintings and statues in the national museums; a little improvement which has been demanded for twenty years, to relieve visitors from the necessity of purchasing a costly and unwieldy catalogue.

The mention of this reminds us that the Municipal Administration of Paris have determined to place on the façades of public buildings, in a conspicuous manner, the names of the architects who have designed them, with the dates of their foundation and completion; a regulation which may prove in the end very useful in regard to the history of the public buildings of Paris.

An exhibition of modern engravings lately opened in the Georges Petit Gallery brings out the curious contrast between the works of the old French masters of the burin, such as Mantuelli, Dupont, and others, and the engravers of the new school, in which "l'eau forte" predominates, and which has replaced the old mathematical regularity of hatching by a bold sparkle and play of light and shade of which the old Classic school never dreamed. Among the works of the older school that are exhibited may be mentioned some splendid plates by Pollet, who was also a master of water-colour and miniature; various engravings by Martinet after the pictures of Delacroix; the famous Hemicycle des Beaux-Arts, engraved by Dupont after Delaroche; views of Paris by Méryon, the lithographs of military scenes by Charlet and Raffet, and the humorous subjects of Gavarni and Danmier. Among the works of the new school are those of Charles Jacques, mostly animal subjects full of truth and life; the peasant scenes of Millet, the masterly works of F. Gaillard and Waltner, the etchings of Bracquemond, and those of Lhermitte, who is as powerful with the needle as he is with the pencil. This collection is of real interest in its bearing on the history of the art of the last fifty years.

During the month two well-known painters have died. Hippolyte Lazerger had been producing for a long period an extraordinary amount of work. A great many of the provincial museums and art galleries possess pictures by him, among which we may cite especially the "St. Pierre" (Montpellier Museum), the "Chemin de Calvaire" (Orléans Museum), the "Vierge Intercédant" (Limoges Museum). He executed also some important religious paintings at Narbonne, Orléans, Nantes, Rouen, and Fontainebleau; and in Paris he decorated a chapel in St. Eustache Church, as well as a portion of the chancel of the Sorbonne. Lazerger was also a composer of music. As a painter he studied under David D'Angers. He received medals in the *Salons* of 1843, '48, and '57.

The painter James Bertrand, whose decease we have also to record, was better known in England than Lazerger. He had very fine talent, with a rather mannered style, and painted elegiac subjects of a pleasing but somewhat melancholy turn, and with a certain monotony of style and subject which ended in rather wearying the public of his works. He had received many medals in various *Salons*, and exhibited two pictures this year, "Mignon" and "Ste. Cecile."

We hear also of the death of M. Charles Léon Delalande, an architect of talent, designer of the Theatre of Courbevoie, and who built the Théâtre de la Renaissance at Paris in 1874, and that of the Nouveautés in 1879. The "Service de Architecture" of the city of Paris has also lost one of its best members, Julien Hénard, formerly *conseiller* of the Société Centrale, who has died after a long and lingering illness, leaving behind him the reputation of an able designer and a conscientious artist. He was a pupil of Hippolyte Lebas, and obtained the Prix de Rome in 1837, and received medals in various *Salons* at later dates. The Commission des Monuments Historiques possesses a large

collection of his drawings and studies. His last executed work was the new Mairie of the Twelfth Arrondissement (Bercy), of which, however, he had not the satisfaction of completing the Salle des Fêtes, which MM. Auguste Cain, Barrias, and Delaplanche are to decorate. This indefatigable worker died at the age of seventy-six, poor, but universally respected, and leaving to his son, M. Gaston Hénaud (also an architect) the example of a blameless life, and an absolute disinterestedness which placed the objects of his art before all material considerations: one of the highest eulogies we can give to any artist.

#### LONDON WATER-SUPPLY AND REMOVAL.

The seventh annual number of Mr. Alfred Lees's analyses of the accounts of the metropolitan water companies fully keeps up the high character of that excellent summary. It is instructive to be shown at a glance, by comparison with former numbers, the movement of this great industry. Comparing this, the number for 1886, with that for 1882, which we happen to have at hand, we obtain the following measure of the progress in four years,—a period of sufficient length to be significant:—

The average number of houses supplied monthly during the year with water has increased from 633,102 in 1882 to 713,147 in 1886; or by 12.6 per cent. in the four years. The average daily supply per house was the same in the two years, viz., 131 gallons, or between 24 and 24½ gallons per head of the population for domestic consumption only. The number of houses under constant supply rose from 202,443 in 1882, to 345,048 in 1886; or from 31.4 per cent. to 48.4 per cent. of the whole number. It is to be noted that this improvement does not appear, as far as these figures go, to have affected the supply per head.

The total capital employed has diminished from 61,726d. to 57,493d. per 1,000 gallons supplied, or by nearly 7 per cent.; the total amounts being 13,192,713s. and 14,480,687s. respectively, or an increase of 7.6 per cent. These figures show a marked increase in the economy of the capital outlay. The total cost of maintenance and management in 1882 was 2,656d., and in 1886, 2,564d. per 1,000 gallons; showing an economy of 4 per cent. in working cost. The net water-rates were 7-307d. per 1,000 gallons in 1882; 6,842d. in 1886; the profit on trading, 4,689d. in the former year, 4,345d. in the latter. The net dividend per cent. on stock and share capital is not stated for 1882, but was 9.20 per cent. in 1886. Thus the consumers paid, in 1886, 6.3 per cent. less than they did in 1882. The net profit appears to have been 7.3 per cent. less, but it will be remembered that the capital was nearly 7 per cent. less, taking the 1,000 gallons of supply as the unit of comparison. And as the supply of water per individual was substantially the same in both years, the companies may be congratulated on having benefited their customers to the extent of 6 per cent. in the period under review, without any appreciable loss to their shareholders. The cost per million gallons cannot be considered high for so great a city. It is kept down, as an average, by the extraordinary cheapness of the supply of the 155,291 houses of East London, which is at the rate of 4-123d. per 1,000 gallons.

It is instructive to compare the results of the concurrent, if not competitive, working of the water supply, divided as it is into eight independent districts, with those of the enormous concentration of the operations for the removal of this supply from the metropolis when its functions have been discharged. The working expenses of the main drainage system were stated by Sir J. W. Bazalgette, in February, 1884, at 6d. per inhabitant per annum. This was probably for 1882, as there had not been time to work out the figures for 1883 when the paper was drawn up. For 1885 the cost rose to 7-3d. per unit; and for 1886 it was no less than 10-45d. per unit, with the certain prospect of a considerable rise, from the operations contemplated at Barking and at Crossness. Taking the allowance of the Metropolitan Board of Works of 5 per cent. on capital for interest and sinking fund, the total cost of the drainage, and the very imperfect disinfection attempted during last year, came to 2s. 4½d. per unit of the population, as stated by Sir

J. W. Bazalgette in 1884, with an allowance of 2½ per cent. per annum of increment. What will be the cost for 1887 and for 1888 it is not for us to predict, but the matter is one as to the full elucidation of which the ratepayers will do well to alive. The cleansing of the main and intercepting sewers, which is done by hand, cost 13,000l. in 1880; pumping cost 47,886l.; and "sewerage experiments and deodorising sewers and at outfalls," cost 107,063l. And the Thames is said by those who know it well to have been worse than ever, the water being this year as foul at Woolwich as it was in former years at Greenwich.

The actual quantity of water supplied by the eight companies has risen from 140 millions of gallons per day, in 1882, to 162 million gallons in 1886. The average daily supply during the year, for all purposes, was 30-13 gallons, and for domestic use alone 24-10 gallons per head in 1882; 30-49 gallons for all purposes, and 24-39 gallons for domestic use, in 1886, showing a very slight proportionate increase both in the trade supply and in the domestic supply, in the period compared. The increase has thus been at the rate of 5½ millions of daily gallons per year. The total population supplied by the eight companies amounted to the large number of 4,748,265 in 1882, and 5,348,601 in 1886, showing an increase of 12.6 per cent. in the four years. This number, however, includes the inhabitants of a larger area than comes under the government of the Metropolitan Board of Works. It is thus not easy to obtain that comparison between the water supplied and the sewage removed, which it would be of some value to establish. Rain and subsoil water may be expected to make the outgoing volume considerably more than that supplied by the water companies. But 156,800,000 daily gallons is the quantity of sewage on which Mr. Dibdin's calculations as to the cost of treatment, brought before the Institute of Civil Engineers in January, 1887, are based. Taking this as the outflow for 1885, it is almost identical with the volume of supply, and must, therefore, apparently have been estimated on that basis. Sir Joseph Bazalgette gives a population of 4,000,000, and a water supply of 133,500,000 gallons daily for 1884.

#### THE SOCIETY OF ENGINEERS:

VISIT TO ACTON AND EALING.

On Wednesday, the 19th ult., some fifty or sixty members of the Society of Engineers, headed by Professor Henry Robinson, President; Mr. A. T. Walmisley, Vice-President; Mr. Perry F. Nursey and Mr. Jabez Church, past-Presidents; Messrs. Henry Adams, W. A. Valon, and W. N. Colman, members of Council; and Mr. C. J. Light, Secretary, visited the new sewage works at Acton, where they were received by Mr. W. Roebuck, C.E., Chairman of the Acton Local Board, Mr. C. Nicholson Lailey, Engineer to the Board, and other gentlemen.

Acton, as many of our readers will know, is a large and growing suburban neighbourhood bordering on the metropolitan boundary to the west, and like other neighbourhoods similarly situated, it has been obliged to form a drainage system of its own, quite independent of the metropolitan main drainage system. After consideration of other similar works, the Local Board has adopted the system introduced by the International Water and Sewage Purification Company, which, it is stated, has been successful at several places in France, but which is now being used at Acton for the first time in England on a large scale. The results of full experience in this case will be awaited with great interest, the more so that the whole question is in so unsettled a state at present. We gave a tolerably full description of these works at Acton in the *Builder* for Sept. 3 last, p. 326; but we may here mention that the sewage is treated by a combined process of precipitation and filtration. The precipitant used is magnetic ferrous carbon mixed with compound sewage salts, viz., sulphates of alumina, iron, calcium, and magnesia. This precipitant is gradually supplied to the sewage as it flows in a channel running along one side of the three precipitating tanks, which have a total capacity of 416,500 gallons. After precipitation is completed, the first effluent is drawn off by a floating suction and passed through a filter-bed consisting of 4 in. of ordinary drainage-pipes closely laid in single, 4 in. of fine gravel, 6 in. of sand, and 10 in. of magnetic spongy carbon, well mixed

with an equal quantity of sand and gravel. Then comes a layer of sand, 9 in. thick, and on top a layer of 1 in. of coarse magnetic spongy carbon. The second effluent is drawn off from this filter-bed and discharged by an outfall-sewer into the Thames. No lime being used in the treatment of the sludge, it is considered to be of high value for manorial purposes. It is prepared for sale by means of Drake & Mairhead's patent filter-presses, into which it is forced by specially designed duplex steam pumps. The works, as now constructed, can, it is calculated, deal with the sewage of a population of 20,000, but the machinery is capable of dealing with a largely-increased population. The works were designed by and carried out under the superintendence of Mr. C. Nicholson Lailey, the Engineer to the Acton Local Board, upon whom they reflect much credit, the buildings being pleasing in character. The works, as a whole, are entirely devoid of the unpleasant odours which so commonly pertain to sewage works. Dr. Angell, F.I.C., and Mr. Frank Candy, gave some explanation of the chemical aspect of the process, regarding the efficiency of which Professor Robinson spoke in very high terms. He congratulated the Local Board and the ratepayers of the district upon the successful result of what he knew had been a very long and uphill fight. From an engineering point of view, he said, the works commended themselves to all the visitors, for they had been constructed on economical principles, though with an amount of taste in the buildings which the members of the profession might take example by. The working of the particular system of sewage treatment which had been adopted here was in its infancy, but considered in their sanitary aspect, he was of opinion that so far as could be judged at present the works were a complete success. They were being conducted without the slightest smell,—without a trace of the odour which had been hitherto regarded as inseparable from sewage works. From what he had seen of it he thought that this process of treatment was one which had a very great future. This he said as an old sewage "expert," but without entering into details of cost, &c., which were not yet before them, though they hoped shortly to have a paper on the subject, giving full particulars, by Mr. Lailey, the Engineer of the works.

The visitors then proceeded in carriages to visit the refuse-destroyer and sewage works at Ealing, where they were received by Mr. Charles Jones, the Engineer to the Ealing Local Board. The refuse-destroyer, while generally based on the plan of Fryer's destructor, has some distinctive points, by virtue of which Mr. Jones claims to have attained unusually satisfactory results. The chief of these is the addition of a muffle furnace to the main shaft, by means of which combustion is rendered more complete. No fuel except the ordinary house refuse is used, and no objectionable fumes are given off. At this depot the sewage sludge of 13,000 people, and the house refuse of 22,000, are being dealt with. It must in candour be said that these works presented a somewhat painful contrast to those just previously visited by the members, both to the senses of sight and smell; but then, as Mr. Jones pointed out, they were never meant for "show" works, and have been in constant operation for twenty-five years. It was admitted by the visitors that to Mr. Jones was due the merit of having been the first to deal practically and effectually, and at the same time economically, with the sewage and refuse of a hitherto unsewered district in the Thames valley; but it was hinted that perhaps the works were now conducted in a somewhat too conservative spirit. The sewage is treated by the lime process of precipitation, and the effluent is stated to satisfy the Thames Conservators, though (judging by the odour which it emits as it falls over the weir at the works) it does not seem to be an altogether desirable liquid to enter the Thames at Kew. The sludge is disposed of in this wise:—The dry-house refuse, contents of dust-hins, street-sweepings, &c., are carted to the depot and tipped into very large compartments or bins. This dry refuse is spread in layers of about 12 in. thick, then some of the sewage sludge from the tanks is pumped on to it, then another layer of dry stuff is spread, followed by another moistening with sludge, and so on, until the bin is full. The whole is then allowed to stand for from six or seven to ten days, according to the

season, and what is not carted away by the farmers or market gardeners for use as manure (they are at liberty to come and take away as much as they want, without charge) is burnt in the destructor. In connexion with the destructor, Mr. Jones's muffle furnace, through which all the fumes from the destructor have to pass, was examined by the visitors. It is said to maintain a temperature of 1,500 degrees, and appeared to be doing its work very efficiently. Mr. Jones stated that all the refuse brought to the depot was dealt with at a cost of 9½d. per ton. The visitors cordially thanked Mr. Jones for his explanations.

The visitors were next driven to see the work now in progress for the construction of the new water-storage reservoir of the Grand Junction Water Company at Ealing. This reservoir is a very fine piece of earthwork, involving both excavation and embanking. The visitors were received by Mr. Alex. Fraser, the Engineer to the Company, and by Mr. B. P. Ellis, of the firm of Aird & Sons, the contractors for the work. The reservoir is situated near Hanger Hill, to the north of Ealing, and occupies ten acres of land. The water surface, when the reservoir is full, will be about six acres; the depth of water will be from 35 ft. to 40 ft., and the reservoir will contain about 51,000,000 gallons. The level of the top of this water will be 193 ft. 6 in. above Ordnance datum. The reservoir will be used for the storage of filtered water, filled from the pumping station at Kew Bridge, through a line of 30-in. pipes, which are connected with the principal mains leading to the West End portion of the company's district. At the reservoir this line of pipes will terminate in a well, in which there will be an inlet into the reservoir, and a branch outlet from it, the passage of the water being governed by 30-in. hanging valves and 30-in. sluice valves. The outlet branch is carried under the bottom of the reservoir, and leads from the lower part of a filter or strainer, the water passing in at the top of the filtering material on its way to the district. The filter will prevent leaves or other extraneous matter from passing into the mains. The reservoir will provide for the great increase in the demand for water during the hot weather in the London season, and will at all times prove a great convenience in case of accident to the machinery at the pumping stations, as from its elevation it will command the greater part of the West End district. The ground occupied by the reservoir is on the slope of a hill, the south or upper end being at about the level of top water, while the ground at the north or lower end is at the level of the bottom of the reservoir; the excavated material (about 150,000 cubic yards) is used for the formation of the banks, and there will be no surplus to remove. The banks have been formed with slopes of  $\frac{1}{2}$  to 1, except that at the north end, where the bank will be 65 ft. high, the outer slope will be  $\frac{2}{3}$  to 1. The whole of the ground consists of clay, and the banks are formed of this material; the bottom and internal slopes are puddled and panned, and covered with concrete 12 in. in thickness, composed of Thames ballast and Portland cement in the proportion of 6 to 1. The internal slope will be paved with Candy's vitrified bricks on edge in cement, and will be surmounted by a vertical wall 5 ft. 6 in. high, having a coping of hollow terra-cotta blocks. The filter before referred to is circular on plan, 65 ft. internal diameter, and constructed of brickwork in cement, faced with vitrified bricks, and coped in a similar manner to the reservoir. The filtering material will be fine gravel, laid on perforated iron plates. There will be a handrail round the reservoir and filter (from the top of which, it may be mentioned, there is a fine view of the surrounding country, including Harrow and neighbourhood). On the top of the hill a somewhat remarkable geological formation, which has been the cause of considerable trouble and expense, was met with. The ground at this part was full of pot-holes of gravel, resting on sand and silt, into which the gravel appears to have been pressed, possibly, it is thought, by the action of ice. This sand, on being exposed, particularly in wet weather, cannot be made to stand at any slope, and it has been found necessary to construct a heavy wall of concrete at the base of the south slope of the reservoir, to prevent the falling of the surface ground and avoid damage to the public road and the adjoining reservoir. The work is being carried out, under con-

tract, by Messrs. Aird & Sons, the total cost being about 36,000l., including pipes, sluices, and other ironwork. The Portland cement is supplied by the Burnham Company, near Maidstone. The ballast is obtained from the Thames, and is landed at Kew Bridge. The vitrified bricks and terra-cotta coping are manufactured at the Great Western Potteries, Torrington, North Devon. The valves are from Messrs. Laidlaw & Sons, of Glasgow, and the hanging valves by Messrs. Oakes & Co., Alport, Derby.

The day being fine and bright, the work was seen under very advantageous circumstances, and the excellence and completeness of the contractors' arrangements and plant, as well as the remarkable dexterity and strength of some of the navvies and the no less remarkable docility and intelligence of the horses employed on the work, called forth much admiration from the visitors, who for the most part, after thanking Mr. Fraser and Mr. Ellis for their courtesy, returned by train to the City and dined together at the Guildhall Tavern, thus bringing a pleasant and instructive day's proceedings to a close.

#### THE ARCHITECTURAL ASSOCIATION.

The following is a report of the discussion which followed the delivery of Mr. Slater's presidential address\* at the opening meeting of this Association:—

Professor Kerr said:—I have been asked to move a vote of thanks to the President for his address. It is very pleasing to me to see so many young men here to-night, exhibiting so much enthusiasm; and I trust that the applause which has been so thoroughly indulged in will be absorbed into the walls of this room and come out again upon occasions when this room is otherwise occupied (laughter). Mr. President, you have awakened in my mind very pleasing recollections of forty years ago, and perhaps the gentlemen present will excuse me if I say a few words on the subject. The origin of this Association was a demand for education, and for education only. The previously existing Society of Architectural Draughtsmen had no such object in view, and it had become quite effete as regarded its own objects. The offices in Southampton-street, Strand, were the offices of Mr. Jayne, who was Secretary to the Association of Architectural Draughtsmen. The President of that Society, Mr. James Wyllson, an exceedingly worthy man, who had for many years, I believe, been at the head of Sydney Smirke's office, went to Glasgow to establish himself there, where he died a few years afterwards without having been very successful. When I occupied the chair, which my friend occupies so much more worthily, forty years ago, you must not suppose that I was of his age, because I was one of the younger and more enthusiastic spirits. At that time the old gentlemen who belonged to the Society of Architectural Draughtsmen came in very handy in order to supply that little wisdom of which necessarily we stood in need. We, like yourselves, were looking forward, and not backward, and the "old fogies," as we then considered them, supplied the element of wisdom. The address from which my friend has quoted a few words was an address I delivered to that Society of Architectural Draughtsmen, and we, the younger men, filled the room. Shortly afterwards this Association was founded, not in 1842, but in 1847. We then got a *locus* in Lyon's Inn Hall, where the Globe Theatre now stands, and the first meeting to which reference has been made was a very interesting one. Although a very young man, I had succeeded somehow or other in making a good deal of fuss, and I was bold enough to ask two very distinguished men, as they then were, one of whom is still distinguished amongst us, viz., Professor Donaldson and Mr. George Godwin, to come down and give us a lift. They did so in a kindly way, and it was those two gentlemen who helped to start the Association, because they immediately lifted us up to the level of something like practical connexion with the world of professional business. A short time afterwards I read a paper; I forget what it was about, but I suppose it was something very pretentious, and I was then bold enough to ask, whom do you think? to come down and bear it? Why, Professor Cockerell, the prince of

European architects, and Mr. Beresford-Hope, deceased yesterday. Those two gentlemen came in the kindest way. The older men of those days were, as the older men are now, simply delighted to help forward youth in its enterprise in the direction of education and professional advancement. Professor Cockerell in all his dignity, delivered a fine classical speech to your predecessors. Mr. Beresford-Hope, then only twenty-seven years of age, characteristically contradicted Professor Cockerell. Cockerell's speech was a Classic one, and Mr. Beresford-Hope's was necessarily Gobbic, and I well remember the calm Olympian indignation of Cockerell as he said,—"I knew the gentleman's father; he did not hold such opinions." Now, sir, I am obliged to you for allowing me to be a little garrulous upon old times. What you have said about education commends itself particularly to my mind, and stimulates me to impress it upon those gentlemen present, because from that day in February, 1847, up to the present time, this Association has never swerved from its one purpose, viz., to advance the education of the architectural student. That is the one purpose above all others which you are safe in still following, and it is the one purpose beyond which I hope you will not allow yourselves to go very far. The President has mentioned the time when the proposition was made by some one to abandon the Association altogether in 1856. My friend Mr. Rickman was the proposer, and all of you who know him will not doubt that there was very good reason for the motion he made. The reason was this. The young men of that time had not the pluck to go forward, and the same state of things occurred at the other critical period the President has mentioned; but there is no want of pluck now; sometimes there is too much of it, and if there has been a good deal too much of it on various occasions since then, put it to the credit of the Association. Because when they tell me that young men are conceited, I say, "Of course they are, and so let them be encouraged. What is the use of starting life at all if they do not start full of hope and determination?" There is an old Scotch saying that "If you bode for a silk gown you will get the sleeve o't," and why should we grudge you, who are full of animal spirits, and all sorts of exultation and delight, that motive power which lies at the very root of success? Now, gentlemen, I hope you will go forward in this enterprise of encouraging the education of the architectural profession, which is a large one, and one in which great honour is to be gained. I am glad, for my own part, to find from the President, who is one of the Examiners, that there is a little hesitation as to whether the Institute Examination is a success or not, and for this reason, that I am very much afraid of the tendency in any examination of the sort [to go a little beyond the necessities of the case (applause)]. I am happy to find that the young men, in their own way, are indicating a little dissatisfaction in that precise view of the case. Let me tell you what the Examination of the Institute ought to be. It ought to be the simplest and plainest test to draw the line between the young man who is educated sufficiently and the young man who is not educated sufficiently (applause). Nothing further than that; it ought to be nothing else and nothing more. The Institute has no right to establish an academical standard that is in the least degree above the requirements of the profession, or more than is necessary for the drawing of that line of demarcation (applause). It seems to me, in taking that view of the case, that one of the next steps the Institute must take is to establish examinations in such a way that they may be conducted in writing and drawing in all parts of the country without involving the necessity for the examinee to come up to London or to any other centre of civilisation in the land. I may tell you that I have a peculiar mode of examining my class in King's College, which I find to be exceedingly successful. I never charge the memory with anything, and I never set a catch question (applause). I never suppose it possible that any student can in any way compromise his honour (renewed applause). I say, "You may bring your notes and the library of the British Museum, if you like." I give them so many questions periodically; they take the questions home with them, and in the course of ten days they return the answers, and I seldom have had

\* Printed in extenso in the Builder for last week (see p. 594).

any opportunity of complaining of the quality or of any suspicion of collusion as regards the production of them. Why, then, should the Institute,—and I do not say it is so,—why should the Institute have any suspicion of the honour of the Architectural students throughout the country? I would send the Institute Examination paper all over the country to whomsoever I desired it, and if he duly answered the questions on his Examination paper, certified by some proper authority, I should give him his degree upon it. I see no reason whatever for young men to be expected to come to the large centres. It may be a little before my time, but it seems to me it must come to that in the end. From what I read in the journals, and from the illustrations more particularly, it has become apparent to me of late years that the quality of the architects who are working in the recesses of the kingdom,—not in the centres of industry, but in the smaller country towns,—is vastly superior to anything that any class of architect possessed in my day. The draughtsmanship, for instance, seems to me wonderful. I do not know where the young men acquire such accomplishments. In my day there was no such draughtsmanship possible; and so it is in the papers we read, and in the questions and answers we read in some of the journals. It is evident that the standard of education has risen vastly within the last few years, and that not alone in London, Liverpool, Manchester, and Glasgow, but all over the country (applause).

Professor T. Roger Smith.—I ask permission to rise for the purpose of seconding the vote of thanks which has been proposed in so able and interesting a speech by my old friend and colleague in this Association, and in many other works,—Professor Kerr. And, in doing so, I am placing myself in a very difficult position, because, having listened to the brilliant address which he has given us, I am asking you to hear me or two words which I know will not possess anything of the same brilliancy, though they will be uttered with equal goodwill. I have much pleasure, Sir, in congratulating you upon occupying the very important position you occupy as President of this Association. We have been associated together in various ways for a considerable number of years, and it is a great pleasure to me to see you in that position. I am equally glad to be able to congratulate the members on having secured you as their President (applause). As I have just said, I have known Mr. Slater in various capacities for a good many years, and I am quite sure that there is no man among those who could aspire to the position of President of the Association who is, in my judgment, more likely to be useful to you, and to acquit himself better in the duties he is called upon to fulfil (applause). I am not about to go back over old ground, though I feel very much tempted to do so, but I should like to say that I was one of those who had something to do with the Association at and after the period of the second idea of giving up, but went on through a stroke of good fortune, and that we did go on successfully. I think was very much due to the kindness of several of the elder members of the profession, who, at my request,—I being President at the time,—came and gave us a series of excellent papers on subjects of great interest. Sir Gilbert Scott, Mr. Ashpitel, and others, came among us, and the mere effect of what they put before us was an immense stimulus and attraction, and was one of the most important agencies which helped to re-start the Association on the course which has culminated in so large a meeting to-night. But I should like to say one word with regard to the future, which is impressed upon me by the fact that there is, if I may use the phrase, "something in the air." The time seems to have come, or to be coming, when a very considerable change ought to be made, and, I believe, will be made,—some change which one can hardly quite grasp,—in the professional education of men training for our profession. I feel perfectly sure that if the Examination goes on,—and go on it must,—there will very soon be a feeling that systematic preparation for it is essential. It strikes me that it is for you, as members of the Association, and for those directing your affairs, to look to this fact in the face; to find if it be a fact, and to do the best you can to make such changes, such advances, and such reorganisation of methods as may fairly secure to yourselves a large share in any change in the system of education which we in the Association are fairly

entitled to expect. This Association has been the educating body of the profession for many years, and I should be sorry to think that if any change took place it would be in the direction of taking away from the interest and value of its work. I do not think it need be: I do not think it ought to be; but I do think it will be right for you during the next few years to look the necessities of the case very fully in the face, and to do your best to systematise and render more thorough and complete the system of education given here. I do not mean to say that individual things are to be better taught, because I believe that many individual things are as well taught as they could possibly be in an organisation of the sort; but I do think it is possible that the whole scheme could be more complete, and I really think such greater completeness is wanted in order that a larger number of men should feel themselves fit year by year to present themselves for examination with courage and with the confidence of securing success. I have no doubt that in the future an increasing number of the members of the Association will present themselves for examination, and will secure success, and reflect credit both upon themselves and upon the society. I will not detain you longer; I wish you a very prosperous session, and every possible success in the educating work of the Association during the year (applause).

Mr. T. M. Rickman, F.S.A., said that his name had been mentioned as having proposed a resolution, many years ago, for winding up the Association, and he would therefore like to explain the circumstances of the case. Mr. Cates and he, finding the Association to be in a bad way, and that no interest was being taken in the papers read, proposed a series of ten or twelve resolutions. That had precisely the effect he had expected. The whole of the resolutions up to the last one were passed unanimously, as no one could doubt the statements brought forward, but when they reached the last resolution the answer was, "No, we won't." That was just the answer Mr. Cates and he had anticipated. The members then put their shoulders to the wheel, and the result was, as the President had explained, that the Institute shortly afterwards began to take an interest in the Association, which progressed better from that time onwards. The members of the Association since he had had to do with it had been devoted to self-help and helping one another. Several views might be taken of architectural education, but, so far as his experience went, the greatest assistance that the young architect could receive was from his fellows in the office. Those therefore who studied in connexion with the Association had the advantage of meeting others who had things fresh in their minds, and he hoped that state of things would always continue (applause).

Mr. E. C. Robins, F.S.A., said he wished to note the fact that the future Examinations would be carefully looked after, in the interest of the members, because their President was one of the examiners. The suggestions made by Professor Kerr would also receive most careful attention. He did not believe that they, the examiners, got the credit they deserved, and he, for one, would be willing to make the Examination as easy as would be wise in proving those who passed to be worthy of the confidence of the public generally. With that reservation, which was of the utmost importance, he was delighted to hear the true and liberal expressions of opinion which had been given that evening. He also wished to say a word in regard to the elder members of the profession, who still maintained their connexion with the Association. He felt considerable pride in being one of them, because he always took great interest not only in young architects, but in rising men generally. Those who had had to make their own way must know that the difficulties of doing so were nowadays, perhaps, rather increased than diminished by the large demands made by the public, and by the enormous number of persons who were ready to answer those demands. He did think, therefore, that the elder members of the profession might do something more than pay their ordinary half-guinea with the rest of the younger men. As had been shadowed forth from the chair, there was a hope that some means would be forthcoming for establishing paid professorships, and he trusted the elder members of the profession would come forward and aid in the work; for himself he would be most

happy to help (applause). Perhaps the reason that had not been done before was because the question had never been mooted. There was a feeling that the work had been well done in the narrow way in which it had been carried out, but, under the advice of such a man as Mr. Slater, any educational scheme would necessarily be a well-considered one. It would be all the better if it made them quite free from the necessity of appealing to the Institute, which had a large work of its own that it ought to be doing. The members of the Association had the means of teaching themselves and their fellows, as well as of extending that education by finding proper teachers of a higher quality than they had yet been able to acquire.

Mr. J. Douglass Mathews said that he joined the Association when it was just emerging from the shadow of darkness into the light which had continued increasing year by year, each year being a greater success than the one preceding. To his mind the great advantage of the Association had been the elastic way in which it had been ruled and the manner in which it had afforded to all its members the opportunity of improving themselves by establishing those classes which were necessary to that improvement. During the twenty-eight years in which he had known the Association there had never been anything that might be termed a drastic alteration; things seemed to have gone on one after another, and necessities were met as they presented themselves. He could not help thinking that if the same policy were still adhered to the Association could be as useful in the future as it had been in the past. They had never sat down and said,—“We will simply do what we have been in the habit of doing, and we won't move”; but they had moved with the times, though not, perhaps, so fast as Professor Kerr would have liked. At the same time they had always been on the look out to provide for the things that were wanted. Those who were as old or older than himself would admit that the present was very different to the past. Complaint had been made by many that they were very much behind the age, and that they required many things they had not got. The Examination was the result of combined perseverance on the part of the Association, and would never have been brought into existence but for that body. If, then, the Examination had necessitated other requirements which the Association did not possess, they would doubtless be provided. At the same time he should look with a great amount of jealousy upon the original scheme of the Association being lost. They had hitherto been working almost wholly from a voluntary point of view, and when they looked at the great success that had been attained, they might take pride in the amount of voluntary work done. He dissented from the President's remark that the limit of voluntary work had now almost been reached. On the contrary, the work was increasing, and with the increase men were ready and willing to help it forward. Therefore, if they once gave the “cold shoulder” to voluntary work, the doom of the Association would be sealed. With respect to the Examination, he was sorry to hear it implied that it was not so successful as might have been anticipated. He could not help thinking, considering the short time that had elapsed, and the great amount of opposition to it in the first instance, that the result had been fairly satisfactory. When the matter was first proposed it was an understood thing that the Examination should increase in stiffness as time went on. He might say that never had a catch question been set, nor had there been any desire on the part of the examiners to prevent the passing of any man. Their desire had always been to assist young men in every shape and way, and if, as constantly happened, little slips occurred, opportunities were given for correction in the course of the Examination. At the same time, as Mr. Robins had said, the standard of the Examination must be kept up if it was to be of any good at all (hear, hear).

The vote of thanks was then put, and carried by acclamation.

The Chairman, in replying, said that Mr. Mathews had misunderstood him in supposing that he did not think the Examination a success. What he had meant to convey was that some people thought so, but he agreed with Mr. Mathews that, considering the number

of men who had come up during the short time that had elapsed since it was established, they had every reason to be satisfied. Prof. Kerr appeared to be somewhat in advance of the times. He (the speaker) had had some little experience of the kind of examination referred to by the Professor, because in certain classes of the Association questions were set which the candidates had time to answer to the best of their ability. No doubt some of his hearers had read Mark Twain's book describing a journey to the Holy Land with a number of people, who, whenever they saw a veiled female, invariably exclaimed, "What a Madonna-like form!" At last, Mark Twain said,—"I know what's coming; I know where they get their sentiments from"; and he (Mr. Slater) was bound to say that the answer to the queries, in too many instances, showed where they were obtained. Such a system would not do for the Examination, but he could endorse what Mr. Mathews had said, that there were no catch questions, and that the desire of the examiners throughout was very much greater to pass the candidate than to "pluck" him (applause).

The proceedings then terminated.

#### ARCHITECTURAL SOCIETIES.

**Leeds and Yorkshire Architectural Society.**—The twelfth session of the Leeds and Yorkshire Architectural Society was commenced on Monday evening at the rooms in Infirmary-street, Leeds, when there was an exhibition of prize drawings, and a *soirée* in connexion with the Sketching Club. The President (Mr. C. R. Chorley) occupied the chair. The following prizes, gained during the last session, were distributed by the President:—A. E. Dixon, 3l. 3s., for the prize for design of monument to a statesman; H. 1s. 6d., being half the amount of prize, for drawings illustrating construction of church roofs; 2l. 2s., for best set of drawings executed for the Associated Sketching Club. F. W. Bedford, prize of 1l. 1s., for designs executed for the winter session of the Associated Sketching Club. F. Mitchell, prize of 1l. 1s., for essays during winter session of Sketching Club. The President then proceeded to give his inaugural address. After referring to the prosperous condition of the Society, he said that among the discouraging circumstances attending the work of the Society was one which, he regretted to say, formed an ever-insoluble problem to those who were interested in the rising generation of architects. He referred to the apathy of architectural students respecting the serious responsibility of their future, and their great disregard for the demands which their profession makes on them for continuous and systematic study of the information required in acquiring a mastery of their calling. The instances of this culpable neglect to avail themselves of the opportunities afforded them for improvement had been more than usually noticeable of late. The courses of lectures on construction, to be given at the Yorkshire College by Professor Barr, which were supported by the Society, and which had the widest publicity given them amongst architectural students throughout the county, had failed to elicit anything like the response that might have been expected. On the motion of Mr. J. B. Fraser, seconded by Mr. H. Perkin, a vote of thanks was given to the President for his address.

**Liverpool Architectural Society.**—The first meeting of this Society for the present session was held at the Royal Institution, Colquhoun-street, on Monday evening last, when the opening address was delivered by Mr. Edmund Kirby, A.R.I.B.A., the President. In the course of his address Mr. Kirby referred at some length to the important question of the safety of theatres, which, he said, deserved the earliest attention of Parliament, and he trusted it would not be long before we had compulsory and comprehensive legislation passed to incorporate the rules of the construction not only of theatres but of every public assembly room within the scope of the ordinary Municipal Buildings Laws throughout the country. In the discussion which followed, Mr. G. E. Grayson, Mr. Thomas Cook, Mr. J. M. Hay, Mr. H. B. Bare, Mr. Alex. White, and Mr. C. Aldridge took part, and a vote of thanks was given to the President for his address.

**Manchester Architectural Association.**—The Manchester Architectural Association held its

first meeting of the session 1887-8 on Tuesday last, when there was a large attendance. There were several new members nominated, and the secretary handed in a large number of books which had been received for the library. The President (Mr. Davies-Colley) presented the prizes to the successful students in the Classes of Design and Construction (Messrs. Ernest Farrar, A. S. Chadwick, and R. Booth). Mr. Mould, the hon. secretary, announced that Mr. John Slater, B.A., the president of the London Architectural Association, had consented to read a paper on November 29th, on "Modern Architectural Education." The hon. secretary also read a number of communications, among them being one from the Royal Institute of British Architects, dated October 12th (which was received with applause), thanking the Association "for the excellent step taken" of forming a reading-class for the examination in architecture, and stating that in consequence the Royal Institute had decided to hold the examination in Manchester next February. The preliminaries disposed of, the President delivered the opening address of the session.

##### CHURCH OF ST. ANNE, ROATH, CARDIFF.

**T**HIS Church, which was partially opened for service on the Eve of St. Michael and All Angels' day, when completed, consist of a nave, with north and south aisles, a choir of considerable dimensions, shallow transepts on either side of the western portion of the choir, a morning chapel on the southern side of the sacristy, and a clergy vestry on the northern side of the same. The choir vestry will occupy the lower part of the north transept, while the upper part will contain the organ. The total length of the church internally will be 99 ft., and the total width across the nave and aisles will be 45 ft., while the height from the nave-floor to the underside of the curved ribs forming the internal roof-line will be 41 ft. 6 in.

As will be seen by reference to the plan, the site for which the church had to be designed was very confined, and the only means of obtaining sufficient length between the street to the east and the already-existing school to the west, was to start the east wall right against the pavement at the one end, and to allow the west wall to stand as close as possible to the school building at the other. This shortness of the site will also force the morning chapel and the clergy vestry up to the pavement line, and it will make it necessary to shorten the north aisle at the west end.

In order to give due prominence to the western entrance, which otherwise would be entirely hidden behind the school, a narthex will be added whenever the completion of the church may be taken in hand; at present only the choir, including the *Alche*, together with the lower portion of three bays of the nave, are finished permanently; but the nave has been extended to the west wall in a temporary manner, and the whole has been covered with a temporary roof at the level of the string-course below the clearstorey windows.

The church will be seated with chairs, and will accommodate upwards of 400 people.

As far as possible a dark-grey local stone has been used for the exterior of the building, but where freestone was necessary, Box Ground Bath stone has been employed. Internally, the dressings are of Corsham Down stone, and the remainder of the wall-surfaces are plastered.

The choir will eventually have a curved boarded ceiling underneath the rafters; the chancel arch, and the arch at the steps leading up to the sacristy, are composed of double wooden ribs, with panelled soffits between. The nave-roof will be of the same form, but open, and it will be divided into bays by single ribs over each pier. From the nave-piers to the aisle walls will occur stone arches springing from a lower level than the nave arcade; these transverse arches will support the clearstorey buttresses, which further east are taken by the walls of the transepts.

The executed work has been efficiently carried out by Messrs. Shepton & Son, of Cardiff.

The drawing from which the illustration is taken, was in the last exhibition at the Royal Academy.

J. ARTHUR REEVE.

##### ST. CECILIA WINDOW, CHRIST CHURCH, OXFORD.

**T**HIS is, perhaps, the best known of the Burne Jones windows in Christ Church, Oxford. White glass is largely employed, the draperies of the three large figures being entirely white, and very delicately shaded. There is a certain sculpturesque simplicity about the design very suitable to the material it is wrought in. The drapery is everywhere carefully thought out, and not a series of folds put in mechanically to fill up the design, as is frequently the case in glass painting. The flesh is mottled over with red, and tells warm against the drapery. The wings of the angels are pale blue. The lead lines are used as far as possible to emphasise the design, but where they are introduced to meet the exigencies of the leading, no attempt at concealment is made, which is as it should be, a glass-painting being a glass-painting without attempting or pretending to be anything else.

The three small compartments below, representing episodes in the life of St. Cecilia, are richer in colour than the upper portions of the lights, a greater variety of tints being introduced, and yet so delicate are the colours, and so skilfully are they blended, that they present no harsh contrast to the more important portions of the window.

##### PALACE COURT, BAYSWATER.

**T**HIS residence is now being erected on the site of the old Shaftesbury House in the Bayswater-road, for Mr. J. J. Fellows, the Agent-General for New Brunswick. The designs of the architects, Messrs. W. Harvey & Bernard Smith, were selected in a limited competition, and immediately put into execution.

The building is faced with dark red Rowland Castle bricks 1½ in. in thickness, the cornices and dressings being in stone from the Synope Quarry, Matlock Bridge.

The contract for the carcass is being carried out by Mr. Bush, of Gower-street, at a cost of about 10,000l.

The drawing from which the illustration is taken was exhibited in the Royal Academy of this year, but has been slightly modified for publication, and the plans added.

##### SEDLIA, HECKINGTON CHURCH, LINCOLNSHIRE.

**T**HE beautiful sedilia in the chancel of this church, of which we give an illustration in this number, have undergone and mutilation in bygone times. Many of the figures are either broken or entirely gone, but the grandly designed foliage is almost perfect. The crockets are extremely rich and diversified, and are boldly carved. The caps to columns are, both in their foliage and moulding, somewhat different, giving indications of a Transitional spirit.

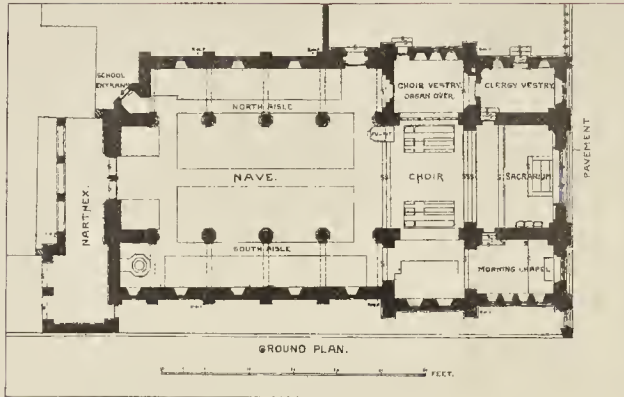

The illustrations are from drawings by Mr. Lionel Littlewood.

##### Liverpool Engineering Society.

**T**HE usual fortnightly meeting of this Society was held at the Royal Institution, Colquhoun-street, Liverpool, on Wednesday last, November 2nd, Mr. John J. Webster, M. Inst. C.E., President, in the chair. A paper was read by Mr. Henry Pooley, jun., entitled "Automatic Weighing Machines." The author commenced by giving a short account of the earliest form of compound lever weighing machine, and its subsequent improvement by the addition of steelyard and weights. The further introduction of the steelyard without loose weights was then dealt with, together with the circumstances which led to the adoption of self-indicating machines. The attempts to make self-indicating machines of high capacity on the spring-balance principle were referred to, and the reasons for their failure given. The invention by Messrs. Roberts & Sturdeley of the combined lever and spring indicator was then described, and an account was given of the experiments with the machine and the further invention of the hydrostatic indicator. Automatic weighing apparatus for dealing with grain in bulk, rice, seed, &c., were then dealt with, and the author concluded by describing the arrangement and working of the equal-beam weighing machine and bopper.

**HEATH'S FIREPROOF CURTAIN FOR THEATRES.**

We have had two opportunities of witnessing trials of Heath's patent fireproof curtain for theatres. Although, for obvious reasons, the trials had not been conducted on other than "model" scale, except as to the thickness of the curtain itself (which in the experiments has been of the same substance,—something less than  $\frac{1}{2}$  in. thick,—as would be used for a full-sized theatre curtain), the details to which the curtain has been subjected, as detailed hereafter, have been very severe.

The curtain is made of canvas on the auditorium side, lined with Bell's spongy asbestos cloth on the side next the stage, both fabrics being quilted together. The roller on which the curtain is rolled is placed in the cellar of the theatre at the back of and close to the footings of the proscenium wall, and below any opening in the wall.

**LEVEL OF STAGE**

The upper edge of the curtain is fastened to a light iron lattice girder, extending about 4 ft. beyond the proscenium opening on either side, the ends of which slide in grooves and are mounted with friction wheels; from these ends chains or wire ropes pass upwards and over pulley wheels, and at their extremities are attached counterbalance weights exceeding the combined weight of the girder and curtain. In the cellar, and below the roller in which the curtain is rolled, is situate a tank in a trough of water the length of the roller, and containing another roller (see diagram); and the curtain is carried under and round this roller and through the water, so that on rising the whole of the curtain is wet. Longitudinal traps are formed in the mezzanine and stage floors immediately over the curtain girder. The curtain is wound round the roller by simple inch and gearing, and kept in its place by a fall dropping into the gear-wheel. At the ends of the proscenium iron flanges extend the whole height of the curtain, and when the

curtain has risen, these instantly and automatically pivot and close the edges of the curtain, clamping the sides and preventing the escape of smoke or flame (see lower part of diagram, which is a plan showing one side of the proscenium opening and one edge of the curtain clamped or pressed against the wall). At the same time the girder engages a lever which opens a sluice-cock in a water-main, which extends along the inside of the top of the proscenium opening, and is perforated with jet-holes, so that the curtain is kept wet all the time that it is up. This water can, of course, be supplied from a main or cistern.

The action of the whole apparatus is as follows:—On an alarm of fire being given, by merely touching with the finger a trigger which moves the pawl, the counterbalance weight descends instantly, and the girder and curtain rapidly rise from the trough of water through the traps in the mezzanine and stage floors to the top of the proscenium opening, the iron pivoted flanges on either side clip its edges, and the water main is turned on.

The model by which the apparatus was tested is, we were informed, one-eighth the size of Drury-lane Theatre, and the curtain is raised in one second and a half. In the actual theatre it would rise 40 ft. in about four seconds, with scarcely any noise or vibration, and could be returned to its normal position in about three minutes. The model is made of strong plate iron, strengthened by angle and tee iron so far as the stage is concerned; and of thin wood, painted, for the proscenium and front part of the stage. Between the stage and the front there is only the curtain. On the occasions of the experiments the iron stage part of the model has been filled with wood and shavings, sprinkled with petroleum, and when lighted an intense fire has been burning for more than half an hour at each trial, making the iron structure in parts red hot, while the temperature in front within 1 in. of the curtain has not exceeded 90°. After the trials the curtain remained intact.

We may add that it is proposed to paint the canvas or auditorium side of the curtain in oils, so that it may be made to look like a pictorial drop scene. But it appears to us that the tendency to shrinkage on the part of the constantly wetted canvas, tethered to its unshrinkable lining of asbestos cloth, will somewhat interfere with this proposal. It is further proposed, and rightly so, that the curtain shall be raised and lowered at least once or twice in the presence of the audience during every performance, to the end that it may be kept in proper working order, and become familiar to the audience. A question that occurs to our mind, however, is whether a large expanse of wet canvas (whether painted or not) would not have a decided tendency, if left exposed to the auditorium for any appreciable interval of time, to chill the house and to induce colds?

So far as could be judged from witnessing the trials referred to, the invention is one of much practical value. It appears to be only a question of mechanical arrangement to cause the curtain when drawn up to be closely clipped to or pressed against the proscenium wall. Daily use of the curtain, and frequent inspection of the water supply arrangements,\* should go far to ensure the safety of an audience, by preventing unreasoning panic in the event of a fire breaking out on the stage of a theatre. The new curtain, as it seems to us, will resist fire for a much longer time than would be necessary for the orderly and even leisurely clearance of the auditorium; but we are not so sanguine as its inventor when he confidently said that where his curtain is used insurance companies will be able to insure the auditorium of a theatre at 1s. 6d. per cent. They would probably be unwilling to do so, for, although the curtain might for an indefinite period, so long as it remained intact, resist the spread of fire to the auditorium, there is a possibility that a falling beam or girder would rend or tear the curtain, and thus impair or destroy its effectiveness. But this consideration notwithstanding, the invention is one well deserving attention by architects of theatres, theatrical managers, and authorities and officials more or less responsible for the safety of theatres.

\* It should be mentioned that the jets of water arranged as described to pour down the inside of the curtain would not come into play every time the curtain is raised, but only in case of fire. The water would be turned on simply by pulling the lever further over than would be required merely to raise the curtain.

**CASE UNDER THE METROPOLITAN BUILDING ACT.**

NEGLECTING TO GIVE NOTICE.

At the Marylebone Police Court on October 26th, Messrs. Dixon & Dowse, of 31, Westbourne-terrace North, Builders, were summoned by Mr. H. Gundry, the District Surveyor of Paddington, for neglecting to give him notice of a building in the rear of 36, Hatherley-grove, for Mr. W. Owen, of Westbourne-grove. The defendants pleaded forgetfulness.

The District Surveyor said that he pressed this case from no motive of pique or profit, but to perform his duty. The defendants had in previous cases neglected giving notice of buildings, and he read copies of letters of complaint he had addressed to them on those occasions. In reply to the magistrate, the District Surveyor said he had not prosecuted the defendants in those cases. He further said that several of the works done for Mr. Owen in the conversion of private houses into business premises required great care and attention, as no other professional surveyor was employed. In one case the first information conveyed to the District Surveyor of works to the foundations of two of these houses was the news that they had fallen into the street. The defendants were not the builders employed on that occasion.

Mr. Mansfield imposed a fine of 3*l.*, and 23*s.* costs.

**"SHONE'S EJECTORS IN THE RECENT RAINSTORMS."**

The following letter was sent to us too late for publication last week:—

SIR,—I avail myself of your kind offer to accord me space in this week's issue of your paper, to reply to Mr. Donaldson's letter which appeared in the *Builder* on the 15th of October.

1. The ratio of power to work is strictly according to the theoretical calculations, and is very moderate for low lifts, but somewhat greater than for direct pumping for lifts above 45 ft.

This ratio is greater than is shown by calculations which were made public by Mr. Donaldson some time ago. He did not then, however, take into consideration that air compressed adiabatically cannot be credited with a larger volume than air compressed isothermally, because the larger volume is entirely due to the higher temperature, which, in cases where the air compressors and the ejector stations are widely apart, disappears before the air gets into and out of the pneumatic ejectors.

So far as my experience goes,—and I may say that Mr. Donaldson has never had any practical experience of my system,—it entirely confirms theoretical calculations as to all possible losses. Where these losses exceed the calculated losses, they must be due solely to bad workmanship and materials, as every practical engineer will be aware.

2. Mr. Donaldson's statement, therefore, that "the excessive value of the ratio of power to work which Mr. Shone, after about ten years' experience, has found it necessary to adopt, proves conclusively, &c.," is the creation of his own imagination. It has no foundation in fact.

3. Mr. Donaldson's statement as to whether or not I was the responsible engineer, requires no answer.

4. It is not stated in the pamphlet presented to the Members of the Imperial Legislature that the 12-in. pipe connecting the manhole with the metropolitan sewer would "act automatically as a storm-water overflow when the pumping-power is overcome."

There is both a reflux valve and a sluice valve on this pipe, which are kept shut, and the 12-in. pipe is also syphoned, so that it is not possible for the "sewer gas of the city sewers" to flow back into the palace sewers, neither is there any free communication between the palace sewers and the metropolitan sewer, by means of this 12-in. pipe.

5. The height of the sewage in the metropolitan sewer and in the subway close to the ejectors can be distinctly seen by the water-marks left behind. Even comparatively clear river or sea water will leave a distinct high-water mark; and sewage-marks are quite unmistakable. But independently of such marks, the height in both cases can be correctly ascertained by the special apparatus provided for the purpose,—*vide* my pamphlet just issued.

*Appropos* of this aspect of Mr. Donaldson's criticism, let me quote what he himself wrote to the late Lower Thames Valley Main Drainage Board when he was urging the adoption of my system for the whole of the Lower Thames Valley drainage district.

He wrote as follows:—"By the use of the ejectors the two following most important advantages are gained."

(a). "No reservoirs for the temporary storage of the sewage will be required either within the limits of the drainage area, or at any point between those limits and Bixey Moor."

(b). "Directly the sewage reaches the ejector stations it flows into the ejectors, which discharge it, whilst quite fresh, into the sealed iron mains, so that, in a sanitary point of view, the system we shall recommend will be absolutely perfect."

E. & F. N. Spon.

5. The maximum air-pressure used, so far, is about 11 lb. per square inch.

6. Mr. Phillips stated the acreage correctly; and I believe that he is right, too, in putting the maximum rainfall of the 17th of August last at the rate of over 1 in. per hour. This is the rainfall, as observed, which Mr. Donaldson stated at the meeting of the Society of Engineers on April 3rd last would yield 9,000 gallons per minute for the ejectors to deal with; and this is the rainfall which he prophesied would disable the Shone installation, submerge the subway, and inundate the basement of the palace. And, Noah-like, in his letter to you, he warns the officials to be on the look out, lest any valuables should be damaged when the deluge does come. But, unlike Noah, his prophesy as to what would follow the deluge proved to be false.

The facts as regards the rainfall of the 17th of August last are briefly these—Mr. Symons, in his instructive monthly *Meteorological Magazine* for October, says, "As mentioned in our last issue, the thunderstorm which occurred over the metropolis on the evening of August 17th was one of exceptional intensity, and the most severe for several years. . . . At Camden-square rain commenced at 6.50 p.m. and ceased at 9.15 p.m."

In 1 hour, from 7 p.m. to 8 p.m.,	1.24 in. fell.
In 30 mins. "	7.30 " 45 "
In 30 " "	7.30 " 45 "
In 30 " "	7.30 " 45 "
In 22 " "	7.42 " 56 "
In 10 " "	7.45 " 50 "

According to the above record, in 30 minutes .79 in. of rain fell; or, at the rate of 1.58 in. per hour, or 37.92 in. per day of 24 hours; and in 10 minutes .50 in. fell, at the rate of 3 in. per hour, or 72 in. per day of 24 hours. If this is not phenomenal and tropical for England, as stated by Mr. Phillips, I should like to know what is.

If we only add the 1.58 in. per hour, as above, to the .59 in. per hour recorded by the Meteorological Office in Victoria-street (whose facilities for gauging are not, I understand, as complete as Mr. Symons's are), and take the mean of the two quantities, we have a rainfall of 1.08 in. per hour; and yet the Shone installation did not fail. The subway was not submerged, nor did a drop of rain find its way on to the basements of the palace. These are hard facts which Mr. Donaldson cannot, and will never be able to, calculate away.

Mr. Donaldson is now compelled, reluctantly, to admit that the inlet-pipes to, and the outlet-pipes from, the ejector are 6 in. and not 5 in. in diameter, as persistently stated by him, and upon which latter size his conclusions as to the capacity of the installation, viz. 1,000 gallons per minute, as given to the Society of Engineers, was based.

His assumption that the area of the valve passages of the ejectors is not equal to two-thirds of the area of the 6-in. pipe is quite erroneous. It is, in fact, 2½ times greater than the area of this pipe.

He also over-estimates the friction in the pipes. It is quite certain that the co-efficient of friction diminishes very sensibly as the velocity increases, which hydraulic fact, apparently, Mr. Donaldson ignores.

Moreover, Mr. Donaldson seems to be ignorant of the fact that the gas engine is, as a rule, worked at half power.

The turning of a handle makes the air-compressing cylinder single-acting, and even this single end is only compressing air half the time, as the action of the inlet valves is stopped automatically as soon as the standard pressure is reached.

When, therefore, Mr. Donaldson states that he observed that the 500 gallon ejector occupied about forty-five seconds in discharging its contents, it must be understood that owing to this mode of working, the air pressure sinks quickly when the 500 gallon ejector discharges; and when two ejectors discharge together or immediately after one another, the pressure goes down to about 5 lb., and then the sewage is not discharged any quicker than the compressed air is supplied, i.e., at the rate of from 150 to 200 gallons per minute. The power exerted by the gas engines is not constant, but varies according to the work done. No wonder, therefore, Mr. Donaldson's calculations should give erroneous results when they are based on erroneous data.

7. I specified a 500-gallon ejector because I felt sure that the head of water available during a thunderstorm would be sufficient to force sewage through 12 ft. of 6-in. pipe at the rate of 1,000 gallons per minute, and a pressure of 11 lb. per square inch, steadily maintained, is sufficient to force it out at the same rate. I deny that the 500-gallon ejector will discharge no more than the 350-gallon ejector.\*

8. The power of a gas engine is, as already stated, not constant, but varies according to the number of explosions in the gas cylinder. Anyone familiar with steam engine trials will know the difficulty of obtaining correct results with one single motor, working continuously, and will understand the extreme difficulty of obtaining trustworthy results with a plant of gas-engines, air-compressors, and ejectors, each of which is working intermittently.

The volumine Hitts are not exactly alike in both ejectors, and, owing to the shape of the larger one, a greater volume of sewage is ejected with the same pressure than is the case with the smaller one; and, as it is absurd to say that the discharging capacity of the larger is only equal to that of the smaller ejector.

As near as I have been able to ascertain, it takes sixteen indicated horse-power to lift 1,200 gallons of water 25 ft. high, which is equal to doing 9-h.p. actual work.

The question is, where is the pump that will give better results at one pumping station? To set aside for the moment the sanitary aspect of the question, so admirably explained by Mr. Donaldson in (4) herein, I may state that I have never yet seen a pump that will take 10 gallons or 1,000 gallons per minute of raw unscrubbed sewage automatically at one pumping station on the old lines, and certainly I have never yet seen or heard of any apparatus which can be actuated as my ejectors can be at a dozen, more or less, stations one mile or more apart, without necessitating the erection of more than one pumping station, the work being done with a degree of economy almost equal to that which is obtainable at one pumping station on the old lines.

9. With regard to storing rain-water in the old sewer: the 12-inch sewer is laid at an average gradient of 1 in 179. It is also well ventilated and flushed, and is not, and never will be, foul.

The contamination of the rain-water flowing through it is inappreciable, and the subway or old sewer is only used for storage when the rainfall is enormously excessive.

The ordinary flow of sewage is only 50 gallons per minute, and 1,200 gallons of raw water mixed with it would, therefore, dilute the sewage twenty-four times. Sanitary engineers consider that sewage when mixed with four times its volume of clean water is practically harmless and fit to turn into rivers, &c.

If the sewers were filled with such water, it would only take the ejectors about one hour and a half to empty, so that there would be no danger of such waters to become offensive. But, before the old Palace sewer was altered by me, this subway formed the major part of the sewer, which was always more or less submerged with foul sewage waters flowing back from the metropolitan sewers in periods of heavy rainfall, and especially so in periods of moderately heavy rain, when the sewage was not so much diluted.

(10). With regard to the ventilation of the subway, I must repeat what I told Mr. Donaldson at the meeting of the Society of Engineers, viz., that the air in it is as sweet as in any ordinary room. The gratings in the courtyards are not air outlets, but air inlets, and fresh atmospheric air is drawn through them into the subway, and is carried away by the upcast shaft in the Clock Tower.

Nothing but a radical reversal of the law of gravitation (or some malicious act) can alter this state of things. I say, therefore, it is absolutely untrue that foul air proceeds from the ventilating holes in the gratings on the manhole cover over the pockets of the subway.

The Office of Works are now busily engaged in altering and building anew a number of the old drain connections, with the new 12 in. main sewer, and possibly smells may have proceeded from some of these, with which I did not interfere, and with the condition of which I am consequently in no way responsible. But to state that the smells, if any, proceed from the subway, and from the new 12-in. sewer, is to state that which is absolutely false.

In conclusion, I desire to say that if this correspondence should happen to be seen by any one really and honestly interested in my hydro-pneumatic system, I wish he or they would put my veracity, as set forth in the letter, to the test. My firm (Shone & Ault) is prepared to undertake the designing and carrying out of engineering works on the Shone system, on the distinct understanding that they shall not be paid their commission until the results calculated by us in the first instance have been verified by actual work done. More I cannot do in support of what I have advanced in this letter against Mr. Donaldson's subtle and uncalled for criticisms of me and my hydro-pneumatic system of house and town drainage.

ISAAC SHONE.

#### 4, Westminster Chambers.

### ON THE SIZE OF HOUSE DRAINS, AND THE USE AND MISUSE OF TRAPS.

SIR,—Anything coming from Mr. Honeyman is bound to command attention, and so will the paper I read to the British Congress of the Sanitary Institute, as published in the above-mentioned pp. 492 and 509 of the *Builder* (October 24). I am sorry to find, however, that I cannot agree with much that he says. He seems to me to sacrifice the practical to the theoretical.

Mr. Honeyman says that thirty years ago he blamed the sewers for the frequent recurrence of epidemic disease in the dwellings of the West-End better-class citizens of Glasgow that were highly elevated. It so happened that about ten years ago a cry was got up against the sewers here from the same quarter, and I am not sure but damages against the city were called for. I thereupon published in one of the Glasgow papers that there was no use of these highly-elevated West-End rich people blaming the public sewers for bad smells in their houses, as these, in my opinion, arose from defective or no own drains. Most or all of the houses have had their drainage improved since, and I think it was found that if there were faults connected with the sewers, the private bad drainage was, perhaps, the

chief cause of the evils complained of. It was generally easy to lock off the air of the public sewer from the house by means of a good disconnecting-trap, but it often cost a good deal to sort the leaking drains and soil-pipes, &c., on the house side of the said trap.

It is not ventilation of the public sewers, as Mr. Honeyman's words seem to imply, that has made our high West-End houses healthier now than they were ten years ago: so I think Mr. Honeyman's deductions here are fallacious.

As to what is said on p. 492 about the oxygen in the atmosphere destroying microbes, we must take this *own ground*, as we elsewhere read lately that the spores or eggs of some would come to life after passing through strong acids and hot or boiling water. I therefore think it is a mistake to suppose that by merely enlarging the house-drain in the manner Mr. Honeyman shows on p. 509, any escape of air from it into our houses would do no harm. In my opinion, the stinking air and particles from and off his lower 4-in. pipe would, in the course of time, foul the whole inner surface of his upper 12-in. drain, and so, in the long run, matters would be worse instead of better, while the expense of this extra large and peculiarly-shaped pipe would be enormous.

If an alteration is wanted in the present round drain pipe, I think 6 in. Craig's 6-in.,—less or more,—egg-shaped pipe with a cast-iron surface to the fowling than the style shown by Mr. Honeyman, and could be nearly as easily used as the ordinary drain-pipes.

On p. 509, Mr. Honeyman asks a very important question in saying, "Do we in practice ventilate our drains sufficiently to secure the best results?" He thinks not, because the fresh air does not come in enough. Now the great point here is, what are the "best results"? In reply, I say what is safest for the inmates and best for the general health of the community. In this view, making the drains larger would do more harm than good. The extra ventilation Mr. Honeyman desires would contaminate the general atmosphere of our towns all the more (and it is bad enough already) without doing a particle of good to the safety of our houses. Those are best protected by keeping the drain air out of them, and the experiments made by Dr. Carmichael, of Glasgow, clearly proved that one good water-trap is worth all the ventilation in the world that can practically be given. Even when fully exposed in the open air, the water-trap does not admit a particle: so when this is the case, how, in the name of common-sense, could the confined air in a 12-in. pipe prevent it?

Further, in the case of soil-pipes I should like Mr. Honeyman to explain how he imagines that these would be or could be any better aerated by the air from the 12-in. drain-pipe already partly contaminated, than by fresh air direct from the atmosphere, as is being done at present by himself, and by me and others.

He might as well tell us that it would be an improvement to add a teaspoonful of ink to the clean water we wash our faces in.

I consider that to go to the great expense of laying down drains 16 in. by 12 in., as illustrated by Mr. Honeyman on page 509, in place of ordinary 6-in. drain-pipes merely for the purpose of greater aeration to the drain would be a great mistake and a pure waste of money,—the game is not worth the candle.

The sectional system of house-drainage, when properly done, is an ordinary-sized pipe and no more inlet ventilation than really necessary, is much safer and better than the plan proposed now by Mr. Honeyman. To make the fresh-air inlet of the drain "twice the size of the outlet" as proposed by Mr. Middleton, on page 510, is absurd, especially when the inlet is on the ground level, as the wind there sometimes sucks the air out. Instead of being larger I assert that the fresh-air inlet might, with advantage, be only a quarter, or less, the area of the outlet, provided the outlet is not less than 4 in. in diameter.

Experimenting with a 6-in. drain lately which had a 4-in. iron blow-off pipe carried up to above the chimney, and with one of my fixed exhaust ventilators on top, I found the air entering the 6-in. eyelet ventilation than really necessary, is much safer and better than the plan proposed now by Mr. Honeyman. I then contracted for the inlet area to only 2½ in. diameter, when the air rushed in at the rate of 400 ft. per minute through the 2½ in. inlet.

Mr. Honeyman is not very logical when he upholds the virtue of the water-trap for locking off the sewer air, but condemns it as useless for locking off drain air from either soil-pipes, rain-water pipes, or gullies, and wants all these used so as to better "purify" or ventilate the drain. He forgets that by his plan he is sacrificing the people for the sake of an imaginary benefit to the drain.

I deny Mr. Honeyman's assertion that "by a multiplicity of traps we create a multiplicity of obstructions and deposits"; that is, if the traps are properly used. In practice, and in or at many houses I find to the opposite the case, and the plumber has more opportunities of doing as to this, after the work is done, than the architect.

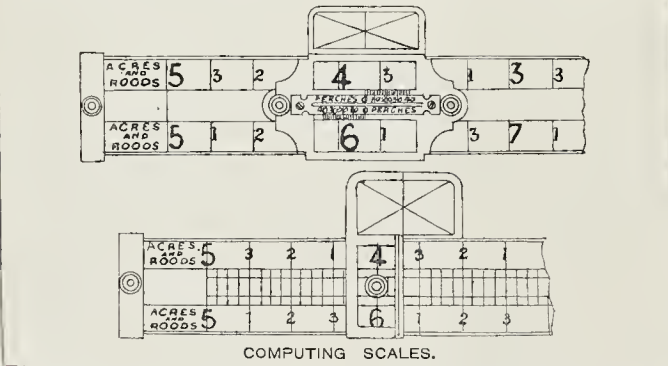

I do not agree with Mr. Honeyman that the grease-trap of the sink should be inside. I consider it should be outside, and especially if the sink be next an outer wall. A grease-trap inside generally

DIACRAM ILLUSTRATING THE READINGS UPON A LEVEL STAFF

use of a positive eye-piece an inverted image at the common focus of the object-glass and eye-piece is formed within the diaphragm plate, and the staff is read upon the horizontal line in which this focus appears.

COMPUTING SCALES.

\*\* One of the two annexed illustrations shows a form of computing scale with one set of divisions thereon indicating acres and roods, the perches being read upon the attached ivory scale as explained in the *Builder*, October 29th, p. 618. The second illustration shows Merrett's computing scale, in which one metal frame can be applied to various scales. In the instrument used by the Tithe Commission office these scales were seen in our illustration (*Builder*, October 29th, p. 618) to be engraved one under the other upon the same scale and upon the same side of it. In our description of the Planimeter

last week the word "the" should be "ten" upon line 4 from the end of column 3, so that the whole line reads "horizontal wheel M records ten square units in," &c.

**Terry's Theatre.**—We are asked to say that the electric light fittings in this theatre were carried out by Messrs. Vaughan & Brown, not by Messrs. Verity. We took the name from the account originally furnished by the architect.

**Restoration of Capesthorpe Hall Chapel, Cheshire.**—The chapel attached to Capesthorpe Hall, the seat of Mr. W. Bromley-Davenport, M.P., has just been re-opened by the Bishop of Chester, after a thorough restoration. The cost has been about 5,000l. Messrs. H. & F. Lea, of London, were the contractors, and the stonework has been entrusted to Mr. Leadbeater, of Alderley Edge.

CHURCH-BUILDING NEWS.

**Cleckheaton (Yorkshire).**—The foundation stone of the Church of St. Luke, Cleckheaton, Yorkshire, has just been laid by the Bishop of Ripon (Dr. Boyd Carpenter). The church, which is being erected from the designs and under the superintendence of Mr. Medland Taylor, architect, of Manchester, is in the Geometrical Decorative Gothic style, and consists of a nave, north and south aisle, and chancel. The aisles are carried round the western end of the nave, which terminates in a semi-hexagonal apse, at the extremity of which is the baptistery, an unusual and picturesque arrangement. The chancel well raised, seven steps leading up to the altar. The windows are mostly traceried, those in the clearstory being square-headed and simpler in character than in other parts of the building. The floor is of wood blocks, with tiles in the chancel and passages. The principal entrance to the church is by a south-western porch and tower. There are other doors at north-west and south-east, making in all three exits. Advantage has been taken of the natural slope of the ground to form a parish room and choir vestry, which extend under the whole of the chancel, and from which a spacious staircase leads up into the church. Accommodation is provided for 650 persons, the seating being all free and unappropriated. The church will be built entirely of stone, both inside and out. There will be no plaster. The contract for the church, with tower, spire, parish room, and all fittings complete, has been taken by Messrs. J. & W. Beanland, builders, Bradford, for the sum of 5,000l.

**Exeter.**—There has just been added to St. Sidwell's Church, Exeter, some new stalls of English oak. The new stalls stand upon platforms, and each seat measures 12 ft. 6 in. long. The fronts are of open tracery work, divided by uprights, upon which occur crockets and pinnacles. The seats have their backs curved.

traceroed. The stalls have been designed by Mr. R. Modley Fulford, F.R.I.B.A., of Exeter, and have been made by Mr. Harry Mams, also of Exeter.

Macclesfield.—The Bishop of Chester consecrated, a few days ago, the Church of St. John, Macclesfield. The foundation-stone of the edifice was laid in September, 1884, but the lands only permitted of the erection of half of a nave, and for three years service has been conducted there, it having been licensed for that purpose by the Bishop. Congregations came so overcrowded, however, as to render the completion of the plan imperative, and Mr. Tomley-Davenport, M.P., laid the foundation stone of the extension. The style of building is of the thirteenth-century. The nave has four bays, with two side aisles, and is 50 ft. in height; there is an apsidal chancel, 31 ft. by 14 ft., with an organ-chamber on the north side, and two vestries for clergy and choirs on the south side. The chancel is seated for 300. A leaded-glass two-light window, of which the subjects are the "Crucifixion" and "Moses leading the Brazen Serpent," has been placed in the east-end window. The cost of the building will be about 6,000l. Messrs. Valmister & Co., of Macclesfield, were the architects, and Mr. Haywood, of Alderley Edge, the contractor.

Plymouth.—The consecration of St. Matthias's church, Plymouth, took place on the 25th ult. The building is in the Perpendicular style, and consists of nave, north and south aisles and chancel, with vestry on the north side and organ-chamber on the south, and tower at the west end of the nave. The tower is about 60 ft. high, and is of the Somersetshire type, with bell-towers filled with open tracery. The tower is terminated by an embattled parapet with corner pinnacles. The nave from the tower-arch to the chancel is divided into four aisles by five bays of four-centred arches. Bath stone springing from moulded piers, and columns with red Mansfield stone shafts and Bath stone moulded caps and bases, and is lighted by three-light tracery square-headed arched windows, with stone relieving arches. The side aisles are lighted by three-light arched windows. The chancel, divided from the nave by a moulded two-centred arch, having relieving arch over of green polyphant and Mansfield stone, is separated from the organ-chamber by a four-centred arch, and has the east end a tracery window of seven lights. On the north side are three two-light windows above the vestry roof. The roofs of the nave and of the chancel are of oak and pitch pine, and are of hammer-beam construction, the main portions having moulded with tracery and panels and moulded and carved cornices, the chancel the trusses are borne by angels, and the organ-chamber roof is of similar form to that of the chancel. The piers and chancel-stalls are of oak. The font is of Beer stone and Devon marble, and the pulpit is of oak, on a base of marble and freestone. The glazing has been executed by Messrs. Fournace & Watson, of Stonehouse. The chancel pavement is from the Worcester series, and the other pavements of tiles have been obtained of Messrs. Woolecroft.

The church is warmed by Porritt's underground air-warming apparatus. The building is erected of Plymouth limestone, lined with Horrabridge brick, the dressings and moulded and tracery being chiefly of Box Ground and Sumner's pink Park stone, Portland stone being employed for the more exposed parts. The vestry and aisle roofs are covered with lead, the other roofs with Delabole slate. The wood and stone having been executed by Mr. Hems, of Exeter. The church will accommodate about 1,000 people. The architects were Messrs. Hine & Odgers, the contractors being Messrs. Finch & Son, Plymouth. Mr. Waymouth has been clerk of works.

Shustoke.—The parish church of Shustoke, which was partly destroyed by fire through lightning in June of last year, was re-opened by the Bishop of Worcester on the 25th ult. The fire penetrated the walls of the nave to the extent of five or six inches, and these have been put up with red and grey sandstone from St. Green, and surmounted by a cornice of Hinton stone, with carved corbels under the principals. Above is a carved wooden cornice connecting them with the roof. A later, which is of pitch pine, is of wide span. It is divided into five large bays with principals arched up to the tie-beams, and

ornamented with a carved floral design. The new seats are of English oak, and the floor beneath is laid with oak blocks. The aisles are floored with Portland and York stone and slate squares. A new font has been added in place of the old Norman one. A new pulpit of tracery design, in oak, with a stone base, has also been added. The upper part of the chancel arch has been entirely rebuilt, with carved corbels on each side. On the outside of the east bell-tower window the mitred head of St. Cuthbert has been reproduced. A new east window of three lights, with tracery head, deeply-cut mouldings with shafts and caps to jambs, and mullions and carved flowers round the head outside, has been inserted, and is being filled with stained glass by Messrs. Burlison & Grylls. The choir seats are of oak, and an oak lectern has been added. The roof has been covered with Broseley tiles, the battlements of the tower have been rebuilt with Hollington stone of red and light grey, with new gurgoyles, together with new pinnacles at each of the angles. The top of the spire has been repaired with a new finial. Messrs. Bodley & Garner, of London, are the architects, and the contract was taken by Messrs. Stephens & Bastow, while Mr. David Knight has officiated as clerk of works. The church has been fitted with hot-water heating apparatus by Messrs. Fox of London.

Stone (Staffordshire).—The Church of St. Michael, Stone, having had recently added to it a chancel, organ-chamber, and vestries, the same were consecrated by the Bishop of the Diocese a short time ago. The style of architecture adopted for the new portions is Late Perpendicular, the material used being Weston stone. The chancel is connected with the nave by a hold arch, and in the south wall is an arch opening into the organ-chamber. At the east-end is a large stained-glass window of six lights. The subjects represented in the window are "The Last Supper," "The Crucifixion," and "The Adoration of the Lamb." The floor is laid with encaustic tiles. The roof is open framed, of pitch pine, and the choir-stalls and altar are of oak. The plaster ceiling of the nave has been replaced by a wood-panelled ceiling, and the west gallery has been removed, thus disconnecting the north and south galleries. The work has been carried out by Mr. N. Barlow, of Stoke-on-Trent, from plans prepared by Messrs. Scrivener & Sons, of Hanley, the total cost of the improvements being 3,500l.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

14,580, Sizing and Varnishing Paper-hangings H. A. Perry. This invention relates to a machine with two rollers placed one above the other, so that when the lower one is turned by a handle the upper one revolves in the opposite direction. Above and parallel with the rollers is a metal rod which holds the paper, and below the lower roller a tray is placed to hold the size or varnish. A scraper is kept close to the lower roller by springs. The upper roller is covered with waterproof material, and the lower one with flannel.

15,374, Ventilators. W. P. Buchan. This invention is claimed as an improvement on a previous specification, and has for its object the better adaptation of valve-boxes for the purposes of exhaust ventilation without the use or aid of external exhaust induced current ventilators. The self-acting valve-box is fitted in any suitable position, and it will thoroughly ventilate the apartment by its own action.

15,493, Lavatories or Washhand Basins. J. Shanks.

According to this invention, the basin is made with its deepest part near the front, so that a person washing his hands does not require to lean over so far as when the deepest part is at the middle or near the back. The form of the basin is like a pie-dish, and the waste pipe is fitted to an outlet at an incline at the bottom of the basin. The taps and fittings are preferably protected by the porcelain.

15,584, Ventilators. P. M. Walker.

According to this invention, a double plate is employed, each side perforated; but the perforations are in no case opposite each other; this prevents draught. Sometimes the perforations are oblique or radial to the surfaces of the plate.

633, Improved Clamp for Picture-frames. G. Jackson.

By this invention, instead of causing the jaw or gripping portion to move in a horizontal direction,

the moulding is held vertically and gripped while in that position. Frames may be made much more quickly by one operator instead of two. A wing nut with long lugs or ears is used, and a smaller nut clamps the moulding to the table, the vertical position being the chief improvement claimed.

1,463, Spring Door-closer. B. Bancroft.

The torsional strain of a spiral spring is, by this invention, made the motive power. When the door is opened, the spring (which is enclosed in a shoe or casing in the door) is slightly twisted, but when the door is released, it will in returning its straight position close the door.

1,493, Chimney Cowl. J. S. and J. T. Wilson.

The top of the cowl which is the subject of this patent is open, with a vane just above it governing a shield or protection three-quarters round the cowl. The action prevents draught, gives free sensitive motion round, and is a guard against different eddies of wind.

NEW APPLICATIONS FOR PATENTS.

Oct. 21.—14,313, F. Curtis, Wrought-Iron Door Latches.

Oct. 22.—14,381, B. Banks, Flushing Cisterns or Water-waste Preventers.—14,384, R. Hoeking, Water-closets.—14,387, S. Hellyer, Water-closets and Urinals, and Flushing same.—14,389, S. Rhodes, Brick Machinery.—14,392, 14,393, and 14,394, G. Snelus and Others, Manufacture of Cements.—14,405, J. Cathie, Domestic or Open Fire Grates.

Oct. 24.—14,421, E. & J. Verity and B. Banks, Automatic Casement Slay.—14,422, G. Newman, Door Springs and Checks.—14,442, G. Farraj, Fireproof Curtains for Theatres, &c.—14,456, G. Maltster, Ventilators.—14,460, P. Davies, Sink Cones and Stink Traps and Casting them with Lead.

Oct. 25.—14,507, C. Watts, Balancing Elbow Levers for opening Ventilators, Windows, &c.—14,545, M. Frankenberg, Parquetry Wood Flooring.

Oct. 26.—14,554, R. Lee, Concrete and Cement Fireproof Building Materials, Bridges, &c.—14,556, J. Stones, Fireproof Curtains or Screens for Theatres and Large Openings.

Oct. 27.—14,630, W. Ihne, Ladders.—14,639, H. Alexander, Ventilator for Roofs, Shafts, Pipes, &c.

PROVISIONAL SPECIFICATIONS ACCEPTED.

10,142, J. Mason, Hinged or Pivoted Skylights, Ventilators, Doors, &c.—12,207, J. Cartland, Door Bolts, &c.—12,640, F. Barnett, Self-lowering and Adjusting Metallic or other Fireproof Material Shutters for Theatres, &c.—12,919, A. Wells, Revolving Wood Shutters.—12,975, W. Horn, Door Latch.—12,991, W. Murray, Gates.—13,065, E. Weldon, Attaching Blades of Saws to Handles.—13,150, J. Hargreaves, Manufacture of Cements.—13,424, H. Snell, Glazing Windows, &c.—13,110, A. Harris and J. Hannay, Fireproof Theatre Curtains.—13,161, S. Huntley, Devices for Cleansing Drains.—13,193, J. & S. Henley, Building Hollow Walls.—9,099, T. Weston, Wood Screw.—16,945, C. Swindell, Stove Grates and Fireplaces.—78, J. Gray, Automatic Door-holder.—11,912, A. Boulton, Door Fasteners.—12,534, W. Ducker, Portable Buildings.—12,710, D. Grove, Portable Buildings.

A Jubilee Calamity.—We are asked to draw attention to the sad case of Mr. James Lees, late manager for the Goolo Gas and Water Company, and formerly in business in Carlisle as an iron-founder and contractor for ironwork used in buildings, in piers, and in roofing. At a public display of fireworks on Jubilee Day, a portion of the fireworks, which ought to have been harmless, exploded. Mr. Lees was much injured, and has lost his sight, so that, at forty-eight, he is blind for life, with a wife, and two daughters too young to earn anything. The town of Goolo is raising a fund, vested in trustees, to whom Mr. G. W. Cutts, solicitor, is secretary; but the sum required is larger than can be raised in Goolo, and an appeal is therefore made to the public, and especially to those connected with gas and water undertakings, and with building and engineering.

Table listing property sales with columns for address, type, and price. Includes entries like 'Mile End-22 and 23, King-street, freehold' and 'Mile End-12 to 22, Bakers-road, 47 years, ground-rent 77s.'

Table listing property sales with columns for address, type, and price. Includes entries like 'Mile End-22 and 23, King-street, freehold' and 'Mile End-12 to 22, Bakers-road, 47 years, ground-rent 77s.'

The New Cathedral at Truro was consecrated on Thursday last, Nov. 3. It had been in course of erection since 1879, from the designs of Mr. John L. Pearson, R.A. The nave has yet to be completed. When complete the total length of the cathedral will be 300 ft. and the height of the central spire 250 ft. The width of the nave and choir is 29 ft., and the height to the vanities 70 ft. The plan of the church as a whole comprises a nave and aisles of nine bays, with two western towers and spires, a large western porch, and a south porch the great transept with its aisles and a baptistry in the angle between the south transept aisle and the nave aisle; a large tower and spire over the crossing; the choir, with an eastern transept opposite the altar and one bay behind the altar forming a retrochoir; one choir aisle on the north side, and three on the south side, of which the outermost is part of the old parish church; a small tower and spire at the west end of this aisle abutting upon the main south transept; and the vestries, which are obtained in a crypt below the choir. The design comprises, besides, a cloister court to the north of the nave, and an octagonal chapter house on the east side of the court. Of this ambitious scheme the eastern part of the church is alone at present completed. The choir with all its aisles, the eastern transept, the great transept with its aisles, the baptistry, and the lower part of two nave bays,—these are all finished, and the central tower just shows above the roof. One aisle of the old church has been retained and incorporated in the new building. In round figures the cost of the fabric so far has been 71,000*l.*, the ultimate cost being estimated at 95,000*l.* The builders employed are Messrs. J. Shillitoe & Son, of Bury St. Edmunds. The clerk of works originally engaged was Mr. Tubb, and since his death Mr. R. Swain has taken his place. The altar has been painted by Mr. J. R. Clayton, and the stained-glass windows are by Messrs. Clayton & Bell. A great deal of the sculpture and carving has been done by Mr. Hitch & Messrs. Lascombe & Son, of Exeter, and by Mr. T. Nicholls. The stones selected for external use were granite from Perryn for the ashlar face, and Bath stone for the dressings. The whole of the dressings, indeed, inside and out, including the massive columns, are of Bath stone, and we are informed that nearly the whole of it has been supplied from the quarries of Messrs. Randall, Saunders, & Co. (Limited), of Corsham. Internally the ashling is of St. Stephen's granite. For thin shafts among the clustered columns a slaty blue stone from Polytham has been largely used. Another stone of a brownish-grey hue from Duporth has been less freely introduced, and in other cases the shafts have been formed of the brown Ham Hill stone, or the strong yellow stone of Northampton, and in one place of porphyry.

The Russian Naphtha Industry.—According to the *Novoye Vremya*, a Russian entrepreneur and engineer has submitted a plan to the Russian Government for the development of the naphtha industry of Russia, which will most likely be accepted. M. J. P. Kinnor, the gentleman referred to, proposes the laying down on the peninsula of Apscheron, famous for its naphtha wells, a network of pipes with a main pipe to the port of Batoum or Poti, where the oil is to be refined. The network will be of such dimensions as to be capable of conveying, by means of hydraulic pumping machinery, 200,000 pood of naphtha in every twenty-four hours to either port. The company formed to carry out the scheme will have a capital of fourteen million roubles, and has deposited 100,000 roubles with the Government, to revert to the latter in case of non-performance of the undertaking.

The International Exhibition in Barcelona.—Great activity prevails at Barcelona with the erection of the buildings for the International Exhibition to be opened in that city early next year. They are already far advanced, and will, in connexion with extensive gardens now being laid out, be very imposing. From England many applications for space have been received, particularly as regards machinery and engineering, whilst several foreign Governments give official adhesion to the Exhibition.

New Museum at Antwerp.—A new museum has just been opened at Antwerp, called the Museum of Industry and Commerce. It contains samples of Belgian industry and foreign produce.

MEETINGS.

- SATURDAY, NOVEMBER 5. Association of Public Sanitary Inspectors.—Address by the Chairman of Council, Mr. Hugh Alexander. 8 p.m. MONDAY, NOVEMBER 7. Royal Institute of British Architects.—The President (Mr. Edward Hanson, F.R.S.), will deliver the Opening Address of the Session, 8 p.m. Society of Engineers.—Mr. Perry F. Nurse on "Primary Batteries for Illuminating Purposes." 7-9 p.m. Royal Institution.—General Monthly meeting. 5 p.m. Clerks of Works' Association (Carpenters' Hall).—Monthly Meeting. 8 p.m. TUESDAY, NOVEMBER 8. Institution of Civil Engineers.—(1) Address by the President, Mr. George B. Bruce. (2) Presentation of Medals, Premiums, and Prizes awarded during last Session. 8 p.m. WEDNESDAY, NOVEMBER 9. Hospitals Association.—Paper by Mr. Keith D. Young on "Hospital Construction." Sir Douglas Galton in the chair. (Board Room, Midway Hospital.) 8 p.m. THURSDAY, NOVEMBER 10. Society of Telegraph Engineers and Electricians.—Mr. E. Stallibrass, F.R.G.S., on "Deep-Sea Sounding in connexion with Submarine Telegraphy." 8 p.m.

Miscellaneous.

The Institution of Civil Engineers.—The ordinary meetings will be resumed on Tuesday, the 8th of November, and be continued weekly till the end of May. At the opening of the Session, Mr. Geo. B. Bruce (President) will deliver his Address. On subsequent occasions, the following papers are to be read with a view to discussion:—"Accidents in Mines." Part II, by Sir Frederick Abel, C.B., F.R.S.; "Electrical Tramways: the Bessbrook and Newry Tramway," by Dr. Edw. Hopkinson, M.S.A.; "The 'Jubilee' Bridge over the river Hooghly on the line of the East Indian Railway," by Sir Bradford Leslie, K.C.I.E.; and "The Alexandra Dock, Hull," by A. C. Hurtzig. The Supplemental Meetings of Students have been appointed to commence on Friday, November 18th, and to take place at nearly fortnightly intervals. Among the subjects which will engage attention during the early part of the Session are:—"The Classification of Continuous Railway Brakes," by A. Wharton Metcalfe; and "Railway Engineering in British North America," by Robert J. Money. Leland Club.—In our notice of the proceedings of this society (p. 620, ante) we read "Durobrive" (ancient name of Rochester) read "Durobriva."

**Enlargement of the Memorial Hall, Farringdon-street.**—The Memorial Hall in Farringdon-street is at present being considerably enlarged by the extension of the building northward. The Farringdon-street frontage is being lengthened in the direction of Fleet-lane to the extent of about 30 ft., and when the works are completed the Farringdon-street elevation of the building will be nearly 120 ft. long. The return frontage of the enlarged structure is carried in an eastward direction along Fleet-lane to the extent of about 90 ft. Including the basement, it will contain five floors, and will in every respect be uniform in architectural character with the present building. The height of the building to the main cornice will be 60 ft., and to an ornamental iron cresting surmounting the roof about 80 ft. The basement will be occupied by stores, and ground and all the upper floors containing offices, of which there will be five on each floor, together with large warehouses in the rear of each floor which are intended to be let off. The building, which was commenced in March last, was already being carried up to the third floor, but during the last ten or twelve weeks the works have been suspended in consequence of a dispute between the trustees of the hall and the owner of some property on the north side of Fleet-lane, respecting a claim made by the latter on account of ancient lights. The property in question is at the corner of Farringdon-street and Fleet-lane, and it is stated that the owner asks 2,000*l.* as compensation, which claim the trustees consider excessive. Mr. W. D. Church, of South-place, Finsbury, is the architect, and the contractor is Mr. Holloway, of Lavender Hill, Battersea.

**Progress of the Dock and River Works at Preston.**—Mr. Walker, the contractor for the large new dock of forty acres on the site of the Marsh, at Preston, adjoining the Ribbles, is making rapid progress with the undertaking, and it is expected that it will be ready for the admission of water early in the coming year. During the necessary excavations an interesting discovery has been made, amongst several historical relics which have from time to time been met with during the progress of the works. It consists of an ancient canoe, about 9 ft. in length, and something like 20 ft. in width, "midships" its depth being little more than a foot. It is composed of oak, and appears to have been formed out of the trunk of a tree, in one solid block. The belief is that it has been embedded in the earth several centuries, as it is in a state of decay, and falls to pieces when touched. It may be added that the dredging and deepening of the channel of the river is being actively pushed forward simultaneously with the construction of the dock, several steam dredgers being at work.

**Luton Sewage Works.**—A Home Counties District Meeting of the Association of Municipal and Sanitary Engineers and Surveyors was held at Luton on Saturday last, when Mr. W. Leete, the Borough Surveyor, read a paper on the new sewage works recently carried out by him. The works possess some points of special novelty and interest. A résumé of the paper is in type, but it is necessarily held over this week for want of space. We hope to give next week.

**Status of the Late Mr. Samuel Morley.**—On a Saturday, the 22nd ult., a statue of the late Mr. Samuel Morley was unveiled at Bristol by Sir Joseph Weston, in the presence of 1,000 spectators. The statue is of Sicilian marble, and is 8 ft. in height. It is the work of Mr. Havard Thomas, of Chelsea. It stands on a polished granite pedestal, 11 ft. in height. The pedestal was provided and erected by Messrs. Arthur Lee Bros., of Bristol.

**Commercial Failures.**—According to *Emps' Mercantile Gazette*, the number of failures in England and Wales gazetted during the week ending Saturday, October 29th, was 11. The number in the corresponding week of last year was 96, showing a decrease of 10, being a net decrease in 1887, to date, of 18, the failures in the building trades during the week ending October 29th were 6, as against 8 and 10 in the corresponding weeks of 1886 and 1885 respectively.

**Removal.**—Messrs. George Waller & Co., owing to the expiration of the lease of their premises at Holland-street (where they have an established over fifty years), have removed to 57, Park-street and Bear Gardens, Southwark, E. (near the dry arch of Southwark bridge, Surrey side).

**The County Surveyorship of Hertfordshire.**—We note that the Hertfordshire Michaelmas Court of Quarter Sessions, held on the 20th of October, decided to increase the salary of the County Surveyor, Mr. Urban Smith, C.E., of Westminster, from 400*l.* to 500*l.* per annum.

**Sewage Treatment.**—A lecture on the "Treatment of Sewage by the Iron Process, as used at Chichester Barracks and Windsor Castle," will be delivered by Mr. Conder, M. Inst. C.E., at the Royal Engineers' Institute, School of Military Engineering, Chatham, on Thursday, the 17th inst., at 5.30 p.m.

**The New City of London Court.**—At the invitation of Mr. Bridgman (Chairman of the Law and City Courts Committee), the Lord Chancellor has consented to lay the foundation stone of the new City of London Court on Wednesday, November 23rd.—*City Press.*

### Truro Cathedral.

THE opening of this cathedral, the first entirely new cathedral consecrated in England since St. Paul's, is an incident of considerable interest, architecturally as well as from other points of view.

The circumstances

are different, certainly. St. Paul's was built at a time when Church feeling, as now understood, was at a very low ebb, and when architecture spurned all reminiscence of Medieval barbarism as a thing almost beneath its notice. Truro Cathedral is the offspring of a revival, or so we are assured, of the Medieval church in her earnestness and her aspirations, and is built by an architect who has studied Medieval architecture in preference to any other style, and whose evident object it is to restore the Medieval cathedral as fully as possible.

We fear it cannot be hoped that Truro will ever reach the reputation enjoyed by St. Paul's as a powerful and original architectural design; the detail is even more conservative and more of a reproduction than the Renaissance detail of Wren; and the general design, if one may compare buildings so different in their style, is certainly far inferior to Wren's in dignity, power, and unity of conception. It has its points of special interest, however, beyond those of mere Gothic correctness.

The cathedral, as most of our readers are aware, is nothing like complete, and we fear it is somewhat doubtful whether the funds will ever be raised to complete it. The fact is, the position is unfortunate for those who take an ecclesiastical view of things. The whole of that part of England is very much permeated by "the demon of Dissent," and we heard it roundly asserted by influential people in the neighbourhood that Truro did not want a cathedral, and that it was a foolish expenditure of money. Many of those who hold this view have, nevertheless, from what may be called an *esprit de county*, and from a hatred of being thought illiberal, subscribed pretty largely to the new cathedral; but it is more than hinted that this flow of liberality is now run out. With the wisdom or unwisdom, the necessity or otherwise, of dividing the Exeter diocese and founding a separate bishopric at Truro we have nothing to do; but since it is founded, we certainly desire that the new bishop should have a cathedral, and as fine a cathedral as circumstances will admit of, just because a cathedral is a beautiful thing, and forms a centre for the artistic and musical

life of the district; a place where people may see something grander and nobler than they can see in their ordinary parish church (or chapel); and we should imagine that even Dissenters of the more cultured order would like a cathedral as a place to see and go into, even if they declined on conscientious grounds to join in the service. For these reasons, and apart from any questions of religious sect, we very much desire to see Truro Cathedral completed, and we think it will be for the general good and happiness of the greatest number that it should be completed.

The complete plan of Truro, as proposed, includes a nave and choir; principal transepts at the crossing and subsidiary eastern transepts; a cloister and an octagonal chapter-house on the northern side of the cathedral; a centre tower with spire; two smaller western towers; and a campanile or small tower at the eastern side of the south transept. Of this there is now built the choir and both transepts, and two bays of the nave, on plan; the central tower is carried up to such a height that it just clears the nave roof, and the small tower or campanile adjoining the transept is completed.

The first glimpse of the cathedral on going up the narrow street facing the south transept is decidedly disappointing. The design and detail of the aforesaid campanile is prominent, and it is not happy. It produces the impression of a rather hard, thin, straight-lined structure, with a square-sided pyramidal copper-covered roof (a very ugly form) rising from a very slight corbel table or eaves moulding; the clock, projecting at right angles to the wall, is a miserable little affair; the whole thing looks poor and hard, and (which is a very serious defect) it looks out of scale; it looks like a tower of small size built on the scale and lines of a larger one, and we are at once convinced that if we saw it in a drawing with no figures to give scale to it, we should take it for larger than it is. The sense of thinness is increased by the fact that the upper portion, in which is hung the old peal of bells formerly belonging to the Church of St. Mary which stood on this site, is cut up into long narrow openings with neither glass nor lucarnes in them,—simply bare slits; and we are told it is not intended to put lucarnes: if so, this is a great mistake, the tower would look twice as well with something to fill up these blank openings. It is a very unfortunate feature to have standing as the prominent one on the approach to what is at present the main entrance; but it must be added that this tower is decidedly the weakest portion of the exterior design. The adjoining transept has a front much more effective than the campanile seems to promise. There is a cleverly-contrived and

richly-decorated porch (the carved decoration being, however, not all completed yet), of three arches, and with the side arches and their superstructure eanted back at an obtuse angle with the centre portion; above the balustrade of the porch rises a large recessed arch, with a drop moulding in the archivolt, giving a deep shadow, and including under that a large circular window: the gable of the transept is covered with a hatched wall diaper. To the left is the baptistery, which is fitted in at the angle of nave and transept, and shows a segment of a circle externally. The style of the building is Early English, of somewhat the type of the portions of the same date at Lincoln, mingled with a certain character which belongs to Mr. Pearson's church buildings, and is more easily recognised than described. There is the solidity (on a smaller scale) of Lincoln, but not the grace and refinement; but there is, at all events, no gimcrack, no "pretty Gothic" about it.

Eastward of the transept occurs one of the most interesting features, both externally and internally,—the old aisle of St. Mary's church, the only portion of the older edifice which was thought worth preserving, but which certainly was, and it has repaid the modern architect's care and reverence for it by leading him to what is, in fact, the most interesting portion of his design, to be described further when we speak of the interior. The aisle is an example of very good late work of very marked characteristics. It stands, or is left, just outside of the south aisle of the choir, and nearly flush with the south wall of the transept, thus filling up an angle of the site at this part. The wide windows are segmental-headed, divided into two main lights by very thick mullions branching each way at the top, and subdivided further by mullions of a subordinate order. Above the windows runs a string-course, and over it a line of flatly-cut quatrefoil panels, and then a battlemented finish. Above this rather rich-looking piece of late work we see the more solid-looking and rather Lincoln-like clear-story of the new building, with its flying buttresses coming down and losing themselves to the eye behind the interesting battlements of the old aisle; and what the flying buttresses abut upon we will see when we come inside; for that is the pith of the matter. The eastern transept is not defined on the ground plan externally, but rises above the aisle roofs; the main feature in it is a group of four large separate lancet windows, regularly spaced. In the opposite or north-east transept there are also four windows, but they are in two couplets separated by a central pier, and are further divided vertically into two stories by a cross row of large quatre-

foil lights. This slight variation of corresponding portions of the building is a characteristic feature of it, and is illustrated in various other ways. The east end is a fine and hold piece of design, though here we think that the representation of it in drawing would convey the impression of larger scale than it actually is; in other words, that the design is of that plain and monumental kind which would be more suitable, and would tell better, on a building of the largest scale than in this comparatively small one. The windows are plain lancets, in two stories, the lower ones with small buttresses between them, and with very deep jambs and archivolts mouldings, producing a deep and effective shadow; the upper tier of windows are loftier in proportion, and treated in a rather lighter manner. The main buttresses here and elsewhere are of the type of design which we are accustomed to in Mr. Pearson's churches, running up with very straight unbroken lines for a great part of their height, before any set-off is made. It is a form of buttress which conduces very much to a generally solid and monumental appearance, which the eastern portion of the Cathedral certainly possesses. The walling, which is externally of Penryn granite with Bath stone dressings, has been admirably executed; no better work could be seen.

On entering by the south transept door we find ourselves in a modern Gothic interior, which is a more complete combination of new workmanship and Medieval forms than anything since Street's nave of Bristol Cathedral; only that was a modern completion of a Medieval design, this is a modern Medieval design entirely. The impression of a certain want of solidity, and deficiency in scale, which we noticed in the exterior, is not characteristic of the interior. The whole is in keeping, as an example of a well-built and carefully-designed cathedral, of the second order of size, a cathedral to be classed, when completed, with such buildings as Norwich and Wells in regard to scale and dimension. The interior is consistently carried out in Early English style, of rather early than late type; there are hardly any carved capitals, almost the entire decorative expression depending on severely-designed mouldings of the orthodox Early English type, and at this part of the church almost the only ornament visible is a couple of "dog-tooth" enrichments in the crossing arches. The crossing piers consist of a cluster of larger and smaller shafts, unbroken by bands, except on the shafts next the abutting wall planes, where the string-courses at the base of the triforium, and the upper members of the caps of the transept arcade, just clip the adjacent shaft, so as to give a connexion between the piers and the adjoining work. The crossing arches are scored with a deep shadow on either side of the central moulding, outside of which again come the dog-tooth members aforesaid; it makes a fine and effective arch, but to all appearance a little too flat in section to be entirely in keeping with the style selected; at least, it has that effect from below, so far as the central portion of the arch mould is concerned. The outer members of the arch do not descend to the impost, but meet on a small angle-shaft standing on the main caps; pretty, but a little at variance with the effect of solidity which one demands in such a situation. Above the crossing arches there is a massive and heavy corbelled cornice supporting a gallery with a balustrade pierced with quatrefoil openings, and above this is a lantern-stage with an arched gallery round. The corbelling under the gallery is curiously irregular in the spacing and size of the corbels, a fancy of which we fail to see the advantage, unless they are old details worked up.

The main composition of the lower portion shows the orthodox arrangement of arcade, triforium, and clearstory. The transepts have two narrow bays on either side of the crossing, except on the south-west side, where the baptistery is fitted into the angle between transept and nave, and opens by a large arch to the transept with two sub-arches carried on a slender pier with four shafts of the grey Polyphant stone which has been used for thus giving play of colour and accentuation

to the lines of piers and vaulting shafts. This stone is introduced in thin shafts, in the crossing piers, the vaulting shafts, and elsewhere; its tone is a very agreeable light grey, with a slight mottle on it, just sufficient to give a little surface and texture. The triforium is very boldly treated in the transepts, with two orders of shafts carrying arch-moulds over the whole bay, the outer one (carried by a grey shaft) moulded, the inner one simply chamfered; a third order of shafts fills up the space with a sub-arcade, carrying a spandrel wall pierced with one or more quatrefoil openings, with a small dog-tooth on the edge, the effect of which is not happy; it gives the openings a ragged look. The clearstory is a large one, of two-light windows, with a long detached shaft on the inner wall plane, leaving a gallery passage between it and the window. The vault is a simple quadripartite with cross-ribs dividing the bays, lined out with an effective section giving a couple of thin dark lines on either side of the central roll.

The north transept design, which faces one on entering the door, shows a gallery carried on two arches on the ground story, the impost ranging with those of the transept arcade, but the arches kept lower. As we have before observed, there is a constant variation of treatment about the interior, another of the points in which it so strongly resembles a Medieval cathedral. Above the gallery, which has a balustrade pierced in quatrefoils, is a range of three two-light windows, with cinquefoil lights in the heads (plate-tracery); and above these the whole of the transept wall is filled up by a very large circular window, treated not exactly "wheelwise," but with four large circles filled up by smaller ones, and subsidiary tracery forms, and filled with stained glass.\* This glass is most happily designed for the situation. It is true that the subjects cannot be made out from below, at least without a lorgnette; but, for ourselves, we opine that the spectator need not afflict himself about that. One sees the very best stained-glass windows rather by faith than by sight. It is satisfactory to the intellect to know that it is not designed by accident, and does mean something; but the main point is that it should produce a fine and rich effect in the ensemble of the interior; and Messrs. Clayton & Bell have succeeded in that. There is a rich, uncertain, jewelled effect in the north transept window which is very satisfactory to one's sense of the picturesque: we care not for more, having no kind of doubt that the legends embodied in it are perfectly orthodox and appropriate, and perhaps their very uncertainty to the eye allows one to give a wide range to their meaning. Viollet-le-Duc has related how, when he was first taken into Notre Dame as a child, he thought the sounds of the organ proceeded from the colours of the great rose-window; and that is not a bad way to think of a stained window,—as a kind of coloured music.

The design of the south transept wall (it will be understood that we have been standing with our back to it all this time) shows a circular window also, and beneath it a range of three windows treated differently from those of the north transept; single lights, deep-set in the wall, with a massive pier between them, pierced through for the triforium passage. These have been filled with stained glass, which the corresponding range of lights in the north transept very much require, for at present their mass of light beneath the coloured circular window has a very harsh effect. The circular window in the south transept is designed more on the radiating or wheel fashion. We approve of the variation, but prefer the design of the north window; the south is somewhat mechanical, and does not lend itself to stained glass effect so well.

The baptistery, to which we have already referred, is a very pretty architectural incident of the church. A square-vaulted bay, making a kind of ante-chapel to it, intervenes between it and the west wall of the transept; then comes

the actual baptistery, a circular-vaulted compartment with one-quarter of the circle defined by the outer wall, the remainder by piers and arches which are ingeniously and picturesquely connected with the main work around them. The floor is raised on two circular steps of marble, which are again raised on a single marble step following the square outline, and also faced with dark polished marble. The floor is laid with a geometrical design in coloured marbles, looking well enough, but not Medieval in character, nor in fact with very much character about it at all. It would have cost no more in the working to have made it of a more thoughtful and characteristic design. The font, again, is raised on three circular polished marble steps, two of dark grey and one of an amber-toned veined marble. The base and bowl of the font are of a dark red marble, with shafts of very dark green veined with a lighter colour. The carved caps of the shafts come out badly in this dark material; the modelling does not define clearly, and they look like irregular spongy masses; a point to be remembered in treating material of this kind: it will not repay elaborate carving. The font-cover is of wood of the miniature tracery and buttress work of which there are so many examples, ancient and modern: it is well enough done, but it is like a great many other things of the same kind, and is almost ostentatiously devoid of originality or novelty. The outer wall of the baptistery is decorated with a wall-arcade of trefoiled arches with dark marble shafts. The baptistery is lighted by narrow lancet windows, filled with stained glass, with small pictorial subjects divided by stages of diaper work; the general effect is good.

The choir is raised, between the main arcades, on a flight of three steps in the first instance, bottom and upper ones of grey mottled marble, the middle one of nearly black marble; \* these project out into the crossing, leaving a small platform on the upper step; and a fourth marble-faced step rises flush with the inner order of the crossing arch. In the choir the same general architectural ordinance is repeated as in the transepts, but with some variation and enrichment of detail. The arches are enriched with dog-tooth ornaments; those of the triforium also with these and other enrichments; and one or two of the triforium caps on the south side are carved with the usual form of Early English foliage, rather capriciously used, as if by accident or by an inspiration of the workman. Whether the intention was to give this kind of idea we know not. The vault is of the same simple character as in the transepts. The vaulting surfaces in both are left perfectly plain, of unadorned courses of stone, but in the choir the transverse vaulting ribs are enriched. The plan of the choir piers is very effective, consisting of two large cylindrical members, columns one quarter engaged to each other in fact, coupled in the transverse direction of the building, and with a much smaller shaft in the nook formed by their junction on the east and west side of each pier. This is a most effective pier, and its breadth and massiveness of appearance give additional effect by contrast to the rather delicate lines and shadows of the arch mouldings. The choir arcade is very lofty in its proportions; perhaps it would be more correct to say that the arches are very narrow, for the scale of the architecture is

\* We give, from the authorised handbook to the Cathedral (which, by the way, is illustrated by most wretched illustrations) the following particulars as to marbles used in the choir floor. The steps are of Frosterly marble and serpentine alternately. The mosaic panel between the two highest of these first steps is formed of varied Devonshire marbles with the exception of the small green squares, which are of Vert Antique. The pavement in the centre of the choir is formed of various designs in dark red (St. Laurent's) dark green (Vert des Alpes), with large red squares (Rouge Royal), the cream-coloured bordering being of Jura marble. Between the next steps are two long panels on the north side, with light red slabs (Rouge de Vermeil), dark red (Rouge Royal), dark green (Vert des Alpes); on the south side, light green alaba (Cippolino), and dark red (Rouge Royal). The next level is laid with red marble (Grestenstein), green (Cippolino), and cream coloured (Hauterive). The raised steps of the Sanctuary are of Pavonazza marble, and the mosaic of dark red (Rosso Antico), light red (Rouge Jasper), dark green (Vert Antique), and light green (Alaba). In the panel, between steps 1 and 2, is the bright blue circle in the centre, of Lapis Lazuli. These marbles are gifts from various individuals.

\* We gave a brief summary of the subjects of the stained glass windows in the cathedral in our last issue, pp. 626-7 ante.

small, and the whole effect is that of elegance rather than power. The choir floor is raised a step at the middle of the third bay from the crossing, and another step at the eastern pier of the fourth bay: at the eastern pier of the fifth bay is another step with the altar-rail. The vaulting shafts are stopped on corbels on three of the piers; the two easternmost ones descend to (or rather rise from) the floor; we wish they all did; the springing of them from a corbel half-way up the pier has the sanction of precedent, of course, but it has an unsatisfactory effect, and injures the constructive unity of plan and superstructure. At the eastern end of the choir is the second transept already alluded to, flanking the sanctuary with two lofty arches, from which a flood of light descends at this point, with very fine effect. The altar-space is flanked by a richly-designed screen with sedilia at each side, and at the back the lofty and very richly-carved reredos, forming a very effective termination to the vista of the lower portion of the building. An ambulatory is carried round behind this screen, and above it are seen the three large lancet windows, a little too wide in proportion to their height, or our thinking; they would have done with a little more jamb and little less glass, but they nevertheless make a fine termination to the architectural vista, and the stained glass here also is very rich and jewelled in effect. The vault cuts rather awkwardly down upon the windows: not more so than in many Mediaeval cathedrals, but it is a defect nevertheless, which it would have been much better to have amended than to have copied; but, of course, we do not expect to persuade modern Gothic architects of that. The general appearance of the chancel is very rich; the steps around the space and around the altar are of Pavonazza marble; the altar frontal is a fine piece of textile design; the rail is a good piece of brass work. The floor here, as in the baptistery, is the weak point. It is sumptuous enough in its material,—an inlay of various polished marbles; but, in the first place, the designs themselves are commonplace, and present little or no thought or invention, relying apparently only on the beauty of the material (which is the most vulgar source of effect); and, secondly, what design there is is distinctly classical in character and out of keeping with the ruling architectural style of the building. Of course something is to be said for convenience of treating the material; circular centres and various colours are a feature to which marble lends itself very well; but more thought might have produced a more artistic and original floor, in keeping with Mediaeval feeling, without much more expenditure of work in cutting out the marble; and we do not think that in this portion of the building (the marbled floor, by the way, extends over the greater part of the choir, though very much concealed under matting) the effect produced is by no means proportionate to the value of the materials and the work, and a little more care in design bestowed on it would have made a great difference in this respect. How far the architect is responsible for all these details we know not.

The choir aisles follow the lower level of the nave, and would seem to be designed to be simply ambulatories, but the southern one is finished with seats. Adjoining this southern aisle is the old aisle of old St. Mary's Church, which reference has already been made, and there is certainly the most interesting and original portion of the interior of the cathedral, which presents at this point an appearance as picturesque as it is unique. The care to preserve the whole aisle, the only portion of the old church, we are told, which is worth preserving, was encumbered by the practical difficulty of finding abutment for the air-vault of the cathedral. The manner in which this has been done constitutes, to an architect at any rate, the most interesting point of the cathedral. What would under ordinary circumstances have been the outer wall of the southern aisle becomes an arcade, three or four feet distant from this is

another arcade, supporting what is really the north wall of St. Mary's aisle. On the other side of this arcade is the aisle itself of the old church. Between the two arcades are solid walls carried by cross arches, on which are seated the buttresses against which, above the roof, abut the flying buttresses which cross the cathedral aisle and take the thrust of the central vault of the choir. These cross walls, where visible internally, are panelled in the manner of late Gothic work, thus making an architectural transition from the early Gothic style of the new building to the late style of St. Mary's aisle. The latter is divided from the cathedral by an arcade of segmental arches, making another of the varied incidents of the interior. A more happy instance of making an architectural beauty out of a constructive difficulty has seldom been seen; it is a thing done in a true architectural spirit, and Mr. Pearson may well be proud of it.

On either side of the choir, towards the east end, are the steps leading down to the crypt, which is a very extensive one, with all the characteristics of an ancient crypt; in particular, the pretence is kept up of its being of an earlier date than the work above it, and the capitals and vaulting ribs are of distinctly Transitional character: a little architectural joke which may be pardoned. It is quite in keeping with constructive requirements that the crypt should be of a more solid and massive architecture than the superstructure; and as we are dealing at Truro Cathedral entirely with reproductions of old styles, it seems quite in keeping to choose an older and more massive one for the architectural treatment of the crypt: if we are doing archaeological architecture let us be quite consistent, and do it thoroughly. The architectural effect of the crypt is marred by its being cut up into vestries, &c., so that the vista through it is destroyed. In the crypt is kept the church plate, which has been mostly specially designed, with the exception of an alms plate of Renaissance design (not of Renaissance date), presented by a well-wisher; the chalices, patens, and crosses are all of the established Mediaeval pattern, and call for no special remark, with the exception of one presented by the bishop. This represents the value of many rings and jewels, which were presentations to the bishop at different times, and which he wished to consecrate to church use; and a large number of these have been worked into the design; set in the body of the chalice according to a symmetrical scheme. The effect is very good and original. The chalice follows also the usual lines of a Mediaeval chalice, and none could be better, either practically or artistically; but there is a good deal of originality of detail, especially in the manner in which the jewels on the base are set in the middle of a delicate meandering pattern of conventional foliage lines relieved on the surface of the metal.

The reredos, which is crowded with sculpture, is rather injured in architectural effect by a want of duly emphasised architectural lines of construction; it is a mass of carving, rich in effect, but somewhat over-elaborated; there are no plain surfaces or sufficiently prominent mouldings to architecturalise it, so to speak, and the consequence is a somewhat pie-crust effect, taken as a whole; the top line of it is too level and unbroken, it wants outline. The central portion of the sculpture represents the Crucifixion, with our Lord in Majesty above; the side portions are occupied with sculptures of typical events in Old Testament history, and figures of prophets and apostles. The work was executed by Mr. N. Hitch, of Kennington; and in detail there is much fine work in it.

The Bishop's Throne, on the south side of the choir, is a fine piece of woodwork, executed in Burmese teak, by Messrs. Luscombe & Son, of Exeter. Over the seat is a spire of open work and pinnacles, which is very well executed, but seems rather cut short in proportion; it has not the soaring effect which might have been obtained by loftier proportions. The whole of this, however, is excellent carved work of its kind, crisp and effective, and not over-finished; and the poppy-heads to the

divisions between the bishop's and the chaplain's seats are vigorous and original both in design and execution. Two of them contain figures, back to back, so as to face each way, representing St. Gregory, St. Jerome, St. Augustine, and St. Ambrose; the two outer ones are original designs of dragons grappling in combat, their serrated wings extending upwards, and forming the upper surface of the carving.

The grille which encloses the choir, and shuts it out from the side aisles, is a piece of wrought ironwork, consisting of delicate scroll-work between solid uprights. The general effect is very good, but the design does not present any striking originality, and, considering that it is, of course, all wrought work and each portion worked separately, we should have expected to find more variety in the detail, which is, in fact, little more than a repetition of the same forms over and over again. It appears to us that this kind of repetition is exactly what, though inevitable in cast ironwork, we ought to escape from in wrought work. A general similarity with variation in detail is what should be aimed at in such work. The brass lectern, with buttresses surmounted by figures of the four Evangelists, is sound and solid work, but of rather the regulation "ecclesiastical brass-work" type.

The pulpit, which is of polished Hopton wood stone from the Wirksworth quarries, in Nottinghamshire, is designed with plain moulded arches and capitals in the lower portion, supporting a richly-carved upper stage, with panels in which are carved figures of Noah, Moses, Elijah, St. John the Baptist, Christ, and St. Paul. These are well executed, but the grouping of the figure of Christ in a series along with the others, and in no distinctive or prominent situation, seems a little out of keeping. The polished stone has an admirable surface and lustre, having almost the appearance of alabaster.

The Renaissance monuments from old St. Mary's Church have been preserved and set up in different situations in the choir ambulatory and elsewhere; and the principal of these, to the memory of one "Richard Roharts, of Truro," which is placed in the centre of the north transept wall, is a fine example of a well-known type of Renaissance monument of the earlier part of the seventeenth century. It includes two reposing figures of the deceased and his wife, which were originally coloured, and the colouring has been restored from indications which remained. It is probable that the restoration represents very much what was there, but the effect is what might be called rather "gingerbread"; the different portions of the costume are realistically coloured, and it may be doubted whether such a mistake in taste as this was worth restoring and perpetuating. Over the figures is a circular-arched recess carried on coupled marble columns, the space under the arch being occupied by an inscription tablet of dark marble (the inscription cut in English, which is not usual at this date), surrounded by hold strap and scroll ornament filling up the rest of the space. This part of the work is remarkably similar to that on the same portion of the Paston monument in North Walsham Church, Norfolk, to which we referred recently; so like as to suggest the idea of its having been by the same hand, in spite of the distance in locality; but the figures are by no means equal in delicacy of execution to that at North Walsham, and the colouring makes them appear more commonplace in style, perhaps, than they really are.

A word must be added as to the organ. This has been placed in the two north-west bays of the choir triforium,—not the best place for an organ, as it is too high up, both for effect and for the practical purpose of supporting the choir; but we must admit that it is difficult to see where else it could have well been placed without interfering with the architectural effect of the building. The old position of the cathedral organ on a screen across the front of the choir was in itself a very fine and effective one architecturally, but then the old English cathedral organs were much smaller than our

In fact, the character of the work is very similar to that of the floor of the Lateran Church at Rome, of which it is given in page 666 of the present issue.

great modern instruments: the whole organ could hardly be placed there now, and the division of the instrument by placing parts of it below is had for its effect. The organ is a large one by Mr. Willis, and one of the finest of his instruments that we have ever heard; the cathedral may certainly be congratulated on the possession of it. It has at present no case beyond a mere base or corbel of wood-work. In the position in which it is placed there is scope for doing something very beautiful and effective with the case, whenever funds can be spared for this purpose.

The fittings of the cathedral, it will be perceived, are of a sumptuous character as far as they have been carried out, and if there is a little too much of the "ecclesiastical art-furniture shop" about some of them, this is not the case with all, and there seems to have been a serious endeavour to carry out this portion of the work in a manner worthy of the occasion.

As we have before said, we should have very much wished to have seen the new cathedral made an opportunity for attempting what might have been called a nineteenth-century cathedral in an architectural sense, rather than a mere repetition of the Mediaeval cathedral. In the present condition of clerical leanings on such subjects, it would, we suppose, be hopeless to expect such a thing, even if the architect wished to make so difficult an experiment. If, however, it was a *sine qua non* that we were to have a modern Mediaeval cathedral, it was at least desirable that we should have as good a one as possible; and with the exception of one or two portions of the exterior of the building, to which we have referred, it may be said that this has been done, and that as far as the interior, at any rate, is concerned, Truro has a Gothic cathedral that is as good as a Mediaeval one. In fact, but for the general look of new work everywhere, it would have been difficult to believe sometimes that we were not actually in a cathedral of the thirteenth century, so completely has Mr. Pearson mastered and assimilated the spirit and character of Mediaeval work. In this respect he is without a rival among the architects of the day.

## NOTES.

**T**HE last number of the *Journal of Proceedings of the Institute of Architects* contains a communication signed by Mr. Cates concerning the question of the "Registration of Architects," in which it is urged that any such step as a Government Registration of Architects would probably be injurious to the character of the profession rather than otherwise, as the limits would almost necessarily have to be so wide that it would certainly take in many who, though they might pass in practical subjects sufficiently, would be no credit to the profession and no advancement to the art of architecture. How far this is likely to be the case has been already pretty well indicated in the nature and methods of the agitation about it which has been attempted by a small knot of persons who are trying to advertise themselves as reformers of the profession. Mr. Cates's suggestion on the matter (which we gather represents the feeling of the Institute Council, though it is not officially so stated) is that if it is considered desirable that the public should have some definite evidence that an architect is a competent and trustworthy member of his profession, that evidence can be most properly as well as effectually furnished by the examination for membership of the Institute of Architects; in fact, that in future, now that the passing of a by no means easy or superficial examination is a *sine qua non* for becoming an Associate of the Institute, membership of the Institute would be in itself a testimonial of qualification as an architect. This has been our opinion all along. The machinery for an examination test is all prepared and complete, by the body which is the proper representative of the profession; and if Government intervention is thought

desirable, nothing is required but that Government should officially recognise the Institute Examination.

**T**HE meeting of the Court of Common Council, which was held on Thursday last week, was mainly occupied in a discussion of the question whether the office of City Architect should be continued, a discussion which ended in a resolution that it should be continued, and in the rescinding of the determination come to at a previous meeting to abolish the office of Architect and appoint a Surveyor only. We could not have desired a more complete endorsement of the views which we have already expressed on the subject. It was urged that it would be a great mistake for the Common Council to endeavour to "economise in brain power" which was the worst sort of economy in the present day, and that "the primary consideration with the Corporation must be to secure the services of an officer not only competent to discharge with the greatest possible efficiency the duties of the allied professions of an architect and surveyor, but who shall also be possessed of such professional and social status as to justify the Court in entrusting him with the large expenditure and numerous responsibilities which do, and must always, attach to the supervision and control of the City buildings, and the professional management (under the direction of the Court) of the Corporation property in the City." In all which we entirely concur, and congratulate the Court on their decision. It only remains to hope that a really first-class man may be appointed.

**T**HE Government are about to do what a Parliamentary Committee recommended more than fifty years ago, viz., to publish the Acts of each Session in a portable volume at a cheap rate. But this is not sufficient. Each Act of Parliament should be published in a handy form as well as in the large size as at present, so that a person who may not desire all the Acts of each Session may be able to have one or more which are useful to him in a compact form. Thus many who might like to have the Trustee Savings Bank Act of last Session as a convenient leaflet might wish to have the Technical Schools (Scotland) Act. We have more than once pointed out that sufficient facilities are not given to the public for obtaining Government publications in a convenient form. We hope this intention of publishing the Statutes at a low price will be followed in regard to many other publications.

**I**N reference to the Statutes of last session, it may be advisable to point out that a measure dealing with technical education in Scotland now forms Chapter 64 of the Session. The subjects to be taught in the technical schools must be approved from time to time by the Scotch Education Department, a School Board having previously provided the school, and having fixed the fees. In order, however, to obtain a grant from the Department of Science and Art for a subject, every school provided under the Act must be conducted, so far as the subject is concerned, in accordance with the conditions specified by that body. Yet, in respect of subjects other than these last, the school is to be conducted in accordance with the conditions of the Scotch Education Code, under the heading of "Technical Schools." This seems an absurd division. Clearly the Scotch Education Department is the proper body to have control over all the subjects, and we can see no reason why a grant from the Department of Science and Art should not be made on the application of the Scotch Education Department. But it would be far better to allow grants to the latter from the Consolidated Fund rather than from the Department of Science and Art. We do not propose to go into the further details to be found in this Act, baving stated its most prominent features. It shows, at any rate, one thing, that for all practical purposes the Scotch manage their own affairs, for as their Parliamentary representatives agreed to the Bill it became law. Irish representatives, if they were as business-like as the Scotch

members, would get all the Acts they wanted passed in the Parliament of Westminster, and so would England, if her representatives would think more of the business of the nation than of advertising themselves by much speaking.

**F**OR some time scaffolding has been up before the old houses forming the Holborn front of Staple Inn, and of course the "Anti-Scrape Society" have been wanting to know what was going on, and meddling and dictating as usual. The building is in the hands of Mr. Waterhouse, and what is being done is simply this: it is necessary to repair the upper stories (the ground floor is let as shops which will remain *in statu quo*, or mostly so), to render them habitable for tenants; and the cement on the front being very much damaged in places, had to be removed. It was then found that there was a nearly complete "post-and-pan" design under the cement. Now Mr. Waterhouse (who we believe is quite as much interested in preserving ancient work where possible as the "Anti-Scrape Society") argued that, as the cement must, at any rate, be removed and renewed, the new coat of cement would be no part of the old work, and that it would be much better not to re-cement, but to show the old woodwork underneath. In a few places the old timbers would require renewing, but the greater part of it is old work in fairly good condition, and to cement it up again merely because some other people cemented it up a good while ago, and because we have got accustomed to seeing it as a cemented front (for those are the arguments of the "Anti-Scrape Society"), would be a perfectly absurd proceeding. In our opinion Mr. Waterhouse has decided on the only course consistent with common sense. Bay windows are to be thrown out on the first floor (another sinful act, of course), but bay windows were there before; and the traces of them are evident, and the reinstating of them is not a merely archaeological point; it is an important addition to the comfort and cheerfulness of the rooms. The old woodwork, when it is exposed, will be oiled and new stained and varnished, so that even in this respect there will be "no deception whatever."

**I**N regard to the recent fire at Whiteley's and the question of the influence of the expansion of the iron girders in throwing down the walls, Mr. S. Griffith writes to us from "Railway Foundry, Reading":—

"The expansion of the girders in a building where a fire occurs appears to me to occur thus:—

At the commencement of the fire the girder would expand 0.00006 times their length for each degree of temperature, and this would continue until the iron became so weakened by the heat that the girders would yield to their own weight and drop, so shortening their length. I presume that we may take it that the girders would retain the rigidity until they were at least 600° of temperature, or, say, an increase of more than 500°; this he so, the expansion would be 500 × 0.00006 length of girder, and assuming the length to be 80 ft., we get the total expansion to be 0.03 × 80 ft. = 3.168 in.; the movement would therefore probably be some 3 in. to 4 in. on the two walls, or 1½ in. on each if both were free to move.

After this the shortening action would probably commence. The power of heat is practically irresistible, and these movements would certainly occur.

I think the above will show clearly what occurred at Messrs. Whiteley's."

Of course no one doubts that the girders expanded with the heat; but there are the questions left in doubt:—1st. Is it certain, even probable, that the series of short girders end to end, as described to have been the construction at Whiteley's, all expanded regular and equally, under a fire which cannot but attacked all of them from the same moment so as just to get their maximum expansion altogether at the same moment, which is necessary supposition so as to get a correspondent's "3.168 in."? It must be remembered that it was not a single girder, but length of short girders shutting on each other. 2nd. Is it probable that one wall would remain rigid while the other moved? 3rd. Having regard to our first query, and that it is ve-

little probable that the extreme expansion of the girders was exerted all at the same moment, is it certain, or even quite probable, that a push of 2 in. or 2½ in., let us say, applied very gradually, should overthrow entirely a well-built wall? Did Mr. Griffith ever see a wall that was out of the perpendicular pushed up into its place hoidly by hydraulic presses? The operation is the reverse, no doubt, of the supposed one at Whiteley's; but the success with which it has been done in several cases argues that walls are not so easily broken up by a steady push, even of much more than two or three inches.

IN the case of Bird v. Andrew, the Court of Appeal have recently thrown some light on the legal meaning of the words "plentiful supply of good water" to a house in a contract of sale. The judgment would seem equally to apply to a lease or any other form of demise. The house in question had a supply from an adjoining farm; but that, it was held on it. This farm was the property of another person, who had not granted an easement to the purchaser of the house. The easement was afterwards granted, but it only comprised a right to use the water in common with the owner of the farm. It might, therefore, be that the owner of the farm would, acting quite reasonably, take so much water as could leave the house-owner short of this necessary element. The Court, therefore, decided that there was not a supply sufficient to fulfil the meaning of the contract, and therefore the purchase of the estate need not be carried out. The case seems to show that a supply of water from a spring on another person's land will never be regarded as a sufficient supply unless the owner of the house has a priority in its user to all other persons.

Sir Spencer Wells does not succeed, even during his lifetime, in converting a great many people to cremation, it will not be for want of earnest pleading and common-sense. His recent speech before the Medicohygiene Society at Nottingham was full of facts and figures which even a child could understand; and if English society was not so impregnated with sentimentality, that bane of the nineteenth century, English people would see how much cremation would be to their advantage. Sir Spencer shows how urban burial gave place to suburban, which is now described as highly dangerous,—many cemeteries being overcrowded and surrounded by houses,—though when they were made they were isolated in the country. During the last three months we have added to our London cemeteries no less than 476 bodies of epidemic patients,—added, it must be remembered, to ground already seething with myriads of germs and evolving subtle effluvia to the ready overlaid atmosphere. Putting aside such a trifle as health for the living, it is noteworthy what expense would be saved by cremation. As there are no coffins or caskets required, two items of considerable cost are at once struck out. For a humble funeral the fees are very small, and even a good middle-class funeral, 10*l.* would cover the whole thing; and when one thinks of the small fortunes of which those harpies, the undertakers, fleece the public, by parading the word "sentiment," cremation appears to offer advantages which only want to be better known to be appreciated.

THE reported state of the Rochdale Town-hall, which was only built about twenty years ago, shows how necessary it is not only to design work well, but to see that it is carried out well. It appears that the building has been surveyed, and that it requires immediate re-roofing, besides other repairs which should have been necessary at this date. At a recent meeting of the Town Council, one of the councillors stated that the contractor formerly employed on the building had admitted to him that he "scampered" the work systematically. If, so, why did neither architect nor clerk work find him out? The result seems to argue a great want of proper supervision during the construction of the building. The Town-

hall was erected from the designs of Mr. W. H. Crossland, architect. A view and plan of the building, with description, will be found in the *Builder* for November 24, 1866; and a view of the interior of the hall was published by us in our number for February 12, 1876.

MR. S. LEE BAPTY, the present Manager of the Manchester Exhibition, has been appointed Commissioner-General for the British Empire Section of the Belgian International Exhibition, which is to be held at Brussels from May to October, 1888. In the list of classes of exhibits it does not appear that the higher branches of the Fine Arts are included; at least, the only direct mention of art is in the heading "Decorative Art," which, as generally used in this country, does not include high-class sculpture and painting. It would be well that this point should be made clear. Among the classes of exhibits in the list which may be of interest to our readers are "Scientific Instruments," "Furniture," "Ornamental Metal Work," "Heating and Ventilation," "Lighting," "Mining," "Metallurgy," "Machinery and Machine Tools," &c.

THE two new pictures by Sir John Millais at Mr. McLean's Gallery, though entitled "La Penserosa" and "L'Allegro," are not allegorical figures of Siveness and Mirth, but portraits, or so we may presume, of young ladies in modern costume. The titles should have been "La Penserosa" and "L'Allegro"; the titles of Milton's two poems, which are adopted here, refer, of course, to the men who are supposed to be the speakers, not to the nymphs who are invoked. "La Penserosa," then (for we prefer to be grammatical), is a portrait of a noble-looking young woman, a brunette, in a dark dress, with a thoughtful expression of countenance, framed in a scene where a mass of foliage on one side, and rather faint indications of distance and sky behind, are blended with the figure into a most delicate harmony of colour, illustrating how much art there is in Sir John Millais's making up of backgrounds for his figures, even when the work seems very slight. One sad defect, however, mars the picture; the waist of the figure is painfully contracted. It is almost impossible that it could have been so in his model, for no young woman could have such a general look of healthy physique with such a waist as that. If it were so, an abnormal phenomenon, the painter had surely better have corrected it; as it is, it is a blot on a beautiful work, and will be so generally felt to be so that we suspect this portion of the work will have to be ultimately repainted. "L'Allegro" is a brilliant and strong painting of a blonde young woman, with her back nearly to the spectator, and her face turned so as to show in profile. The flesh is painted with great delicacy. The rest of the picture is rather *criardi*, a confusion of bright points and frillery. Between these hangs a grand painting of the head and chest of a lioness, by Mdlle. Rosa Bonheur, remarkable for breadth of style, truth of texture, and the expression of immense muscular power conveyed in it,—a wonderful piece of work for a woman to have produced. Among the other paintings in the same gallery is a remarkably good example of Miss Clara Montalba's work (46), "Amsterdam," a painting of powerful effect, and less mannered than many of hers that we have seen; and a very sweet little figure by Mr. Fildes, entitled "An English Maiden" (63). Some landscapes by Neuhert have a certain picturesqueness of composition, but are very hard and mannered in execution.

WE cannot say that the winter exhibition at Messrs. Tooth & Son's Gallery is a very interesting one. It contains, however, a beautiful work by Mr. H. W. B. Davis "On the Coast of Bretagne" (51), an effective Cairo scene by Mr. Logsdail" (25), totally destitute, however, of artistic finish or refinement; and some good smaller works, especially two small Venetian pictures by M. Gallegos (113 and 120), on either side of a picture by M. Lhermitte, "Poil and Thrift" (117), which should be looked at, though we do not consider M. Lhermitte by any means as great a

master in colour as in black and white. The central picture of the collection, "A Court Matinée" (91), by M. Barboud, an interior crowded with figures, is supremely clever in the brilliant painting of glittering dresses and details and in the amount of character in the faces of the fashionable mob; but it is disagreeable and staring in colour, and almost revoltingly cynical in feeling. There is a good landscape by Mr. Keeley Halswelle (95), in which he may be congratulated on at last having got a new sky in exchange for his old steely-grey one; another good little Venice picture by M. Sent (99), and one or two figure pictures by M. de Blas, very good work, but only of moderate interest.

WE have been sent an interesting little paper on the process of mezzotint engraving, read by Mr. Wilfrid Ball at the little literary and archaeological society which meets under the title of the "Sette of Odde Volumes." It gives a brief account of the process, and the principal difficulties attendant upon it, with an *In memoriam* note at the end on the recent death of "one of the most promising workers in pure mezzotint," the late Mr. C. W. Campbell. Mr. Ball complains that Watt, the inventor of the steam-engine, caused indirectly the decline of mezzotint in England, by suggesting the use of steel instead of copper for engravers. As soon as it became known that 1,000 impressions could be taken from a steel plate, while only eighty could be taken from a copper plate, the latter were driven out of the market, and the depth of tone obtainable from copper gave way to comparative crudity when steel was employed. We have no doubt, however, that Watt thought he was doing the world a service in introducing steel. It is not given to engineers to comprehend these things.

#### ROYAL INSTITUTE OF BRITISH ARCHITECTS:

##### THE PRESIDENT'S ADDRESS.

The first meeting of this Institute for the present Session was held on Monday evening last, Mr. Edward P'Anson, F.G.S. (President), in the chair.

The Secretary (Mr. W. H. White) announced a large number of donations to the library, specially mentioning a sketch-book which had belonged to the late Mr. George Devey, and was now presented by the executors.

The ballot for new members was next taken, when the following gentlemen were elected, viz.:

*As Fellows.*—Mr. J. C. Madison, of Christchurch, Canterbury, N.Z.; Mr. W. H. Powell (Associate), Southampton-street, Bloomsbury; Mr. J. Jorman (Associate), Paul-street, Exeter; Mr. T. M. Lockwood, Foregate-street, Chester; and Mr. A. Hill (Associate), Georges-street, Cork.

*As Associates.*—Mr. H. T. Cradon, Saddler-street, Durham; Mr. R. M. D. Fell, Bernard-street, Russell-square; Mr. H. H. Fox, H.M. Indian Public Works Department, Burnah; Mr. G. C. Smith, Gosforth, Newcastle-on-Tyne; Mr. C. J. Marshall, Ebury-street, S.W.; Mr. E. H. Selby, Craven-street, Charing Cross; Mr. W. H. White, Lawford-road, Camden-road; Mr. R. Williams, Holly Bank, Haslemere; Mr. E. J. Bennet, Harmer-street, Gravesend; Mr. J. W. Brooker, Railway Approach, London Bridge; Mr. H. R. Lloyd, Moseley, Birmingham; Mr. F. W. Marks, Harrington-gardens; Mr. J. W. Stonhold, Stanhope-street, Regent's Park; Mr. H. A. Gregg, St. Helen's-place, E.C.; Mr. F. B. L. Harris, Lawford-road, Camden-road; Mr. A. E. Worsley, Stanhope-street, Regent's Park; Mr. T. Moore, Whip's Cross, Walthamstow; and Mr. H. L. Paterson, Wilberforce-road, Finsbury Park.

*As Hon. Associates.*—Sir John Coode, K.C.M.G., Westminster-chambers, Victoria-street.

Mr. Ralph Nevill, while the ballot was proceeding, called attention to the lighting of the library after dark. It was effected by means of argand burners, which, he said, experience had shown were perhaps the greatest consumers of gas and givers-out of heat and bad products of any forms of lighting. Failing the electric light, he suggested the adoption of the Welsh

light, which was economical, and throw out little heat or noxious products.

The President said that if Mr. Nevill would write to the Secretaries the question would receive due consideration.

The President next delivered the opening address of the session, which we print nearly *in extenso*. Mr. P'Anson said,—

“ Gentlemen,—Entering as we now are on another session, and looking back, as is the custom, on the work of the past, I cannot refrain from alluding to the fact that we are passing through, in one great respect, an exceptional year,—the year of the Queen's Jubilee, which has brought to this capital so many of our fellow subjects from all parts of the empire, and also so many illustrious and distinguished visitors, who came to share and enhance our rejoicings.

One of the outcomes of this memorable Jubilee has been the foundation of an Imperial Institute, and the commencement of a new and great building, designed by one of our Fellows, Mr. Colcutt (applause), and obtained by him in a competition limited to a few members of the architectural profession. For the purpose of founding and erecting this Imperial Institute subscriptions have been solicited, and in many cases the invitation has been liberally responded to. We amongst others were invited to take our part in the foundation, but unfortunately architects sadly lack the power to afford that material assistance which their feelings naturally prompt them to give. The larger number of the members of this body who are in a position to subscribe are members of other bodies which have contributed to that fund, and they cannot be expected to send double subscriptions; while, in our corporate capacity, the sum we might be prepared to send, even if we had the power under our constitution,—which I doubt,—would be relatively so small that we could hardly venture to offer it (hear, hear). Nevertheless, I am afraid that this enforced abstinence has been detrimental to architecture, for we live in an age when the *de ut des* of diplomacy, and the *quid pro quo* of commerce, are often too rigorously exacted. In the composition of the Executive Council for the Imperial Institute, the representation of architecture is, I regret to say, conspicuously absent, unless, indeed, it is considered that Sir Frederic Leighton, as the President of the Royal Academy, represents Architecture as well as Painting and Sculpture. We are, however, none the less loyal to the principles involved in the foundation and objects of the Imperial Institute; it is only that our pecuniary resources are inadequate,—disproportioned to our good will,—and, this being once understood by the authorities concerned, we may rest quietly assured that a fuller representation of Architecture than now exists on their Council will be deemed not only wise, but essential.

Whilst on this subject, it occurs to me to remark that one most fitting work for the Imperial Institute would be the production of a thorough and complete record,—perfect in all its details,—of the more important architectural monuments contained in India, and the many historical sites and ruined cities to be found within the various dependencies of Great Britain and Ireland. This, no doubt, has already been accomplished to a slight extent by private enterprise and liberality, but there is no complete or national work of the kind; and I venture to hope that there may soon be found means, by the agency of the now Imperial Institute, to furnish the world with at least a catalogue of the Historical Monuments extant within the confines of the British Empire (applause).

In the remarks just made, I have spoken with full cognisance of the responsible position I hold, and I have now to add that, as your President, I have recently fulfilled the sad duty of attending the funeral of the late Mr. Beresford-Hope, one of the most eminent of my predecessors in this chair (applause). Among other professional men who accompanied me on this mournful occasion were Mr. Brooks, Mr. Carpenter, and Mr. Cates. The funeral service was solemnised in Kildown Church, which, with St. Augustine's College at Canterbury and Ely Cathedral, forms one of the chief memorials of his munificence. Although not a member of the profession, Mr. Beresford-Hope always took a lively interest in the promotion of Architecture, and whether in his place in Parliament, or when engaged in the many other duties he undertook, was ever ready to assist

professional architects by his counsel and active support. He was an enthusiastic and a staunch admirer of the works of the Middle Ages in England; and with the movement known as the Gothic Revival his name will always be associated. As President of this Body, President of the Architectural Museum, and, at an earlier period, as President of the Cambridge Camden Society (afterwards called the Ecclesiological Society), he will be remembered among us and our successors. But this is not the time to do more than refer generally to his varied artistic and literary occupations, and to his numerous contributions to the cause of art. His death is a loss to the Institute, both as regards the brilliant *Review* of which he was the proprietor, and as regards the House of Commons, in which his authority on architectural questions was undeniable.

Mr. Beresford Hope was the only Honorary Fellow who, since the death of the first President, Earl de Grey, K.G., has occupied the chair of the Institute, and it is, I believe, a source of satisfaction to many members that, by the terms of the Supplemental Charter granted to the Institute in the Spring of the current year, Honorary Fellows are still eligible for election as President. It is also agreeable to reflect that, in asking for fresh powers and privileges,—some of which involved the repeal of the larger portion of the original Charter,—we have been permitted to retain any benefits accruing from the relative antiquity of our incorporation. What are these new powers, these new privileges? I doubt, gentlemen, whether you have quite realised the character of them, and so, with your permission, I will recapitulate their principal points. We humbly asked, taking into consideration the importance of this body and the necessity of maintaining a high standard of architectural knowledge in the country, for power to hold Examinations and to grant certificates or diplomas in connexion therewith; and we have obtained the right to hold and establish Examinations not only within the United Kingdom, but also in any Colony or dependency thereof, and in India. We have obtained the right to use distinguishing affixes; and also power to declare, in the year 1892, that every person desiring to be admitted a Fellow must have passed an Examination. In five years' time we shall have the right to say to outsiders, who may wish to become Fellows,—

“ You shall not enter the corporation of British Architects except through the ranks of the Associate class”; or we may say,—“ You shall not enter the ranks of the Fellows until you have passed a special Examination.” Moreover, the Examination test which we ventured, in 1882, to impose upon all candidates for the Associateship is now a right which we are empowered to exercise. These, in my opinion, are powers and privileges the possession of which entails responsibility of a very high character towards the public and towards ourselves; and they form a basis upon which all minor professional questions must rest, if any superstructure is to rise out of them. As for the changes in the constitution of our internal affairs, they are equally important in their character, but to ourselves principally. The property of the Institute, which was originally vested solely and absolutely in the Class of Fellows, is to be vested in the corporate body; the Associates, who by the original Charter could not vote or interfere in the affairs of the Institute, will have the right, with certain exceptions, to vote at the general meetings. The Honorary Associates, who by the original Charter did not exist, are recognised, and will have the right, with certain exceptions and under other limitations, to vote at the general meetings. Moreover, the mode of voting and the number of votes which shall form an effective majority at such meetings are to be decided by By-laws. All these modifications and developments of our original powers and privileges have been obtained not without some difficulty,—not without even some division amongst ourselves,—but I think that we may congratulate the Institute upon the result; nor must we forget the warm and efficient support we obtained in this matter from the non-Metropolitan societies, who shared in our discussions on the subject, and loyally assisted us throughout (applause).

The triennial Conference\* held in May brought us into most agreeable contact with our provincial brethren; indeed, it is a gratifying fact

\* Full reports of the papers and discussions were given in special Supplements to the *Builder* at the time.

that,—owing to the importance of the questions affecting our profession with which we have lately had to deal,—we have been so frequently in close relationship with them; and it is in the highest degree satisfactory to find that, whatever our individual opinions may be on these subjects, when we are brought closely together we act better, understand each other better, and promote better what we may mutually feel to be for the best interests of the important profession to which we belong.

One meeting was profitably occupied in considering the subject of professional education, introduced by an important contribution from the Rev. Professor Babcock, of Cornell University, New York State; and amongst the valuable papers which followed was one by Mr. Lawrence Booth, then President of the Manchester Architectural Association. This gentleman, a Fellow of our body, attempted to show how the authority and usefulness of the Institute could be increased by the adoption of an educational scheme which, if successful in its working, would within a few years lay a solid foundation whereon an appeal to Parliament might be based for stringent powers of repression against unqualified practitioners of architecture. Other papers,—including one by Mr. J. A. Gatch, who was then the President of the Architectural Association,—offered suggestions of like importance, and the whole resulted in a series of resolutions being adopted by the meeting, embodying a practical scheme for organising a complete system of progressive Examinations. These resolutions were:—

“ 1. That it is desirable that the guidance and direction of the education of those entering the architectural profession should be undertaken by the Royal Institute of British Architects.

“ 2. That to realise this and the Royal Institute of British Architects should prepare a scheme of a complete system of Examinations.

“ 3. That such a system should comprise 1st, *Preliminary Examination* for pupils entering the profession as a test of general knowledge, those passing this to be Probationers R.I.B.A.; 2nd, *Intermediate Examination* for pupils in their third year or earlier, for the general principles of art and construction, those passing this to be students R.I.B.A.; 3rd, *Final and Pass Examination* to qualify for A.R.I.B.A., at twenty-three years of age or earlier; and that no subscription be required from Probationers or from Students.

“ 4. That this system should be arranged with the co-operation of the local societies by whose agency the details of the Examinations could be carried out.”

At that meeting, Liverpool, Birmingham, Leeds, Bristol, Glasgow, and Dublin were represented, and your Council, feeling that suggestions from so representative a gathering should be duly respected, referred the resolutions to the special Education Committee, for the purpose of considering the manner in which they should be realised.

There are, possibly, difficulties as yet unforeseen, which may impede the carrying out of any complete scheme, but the idea expressed in these resolutions is so good, and so likely to benefit the profession, that I do not hesitate to enlarge upon it. The new Charter having conferred on the Institute the power to hold Examinations, and ultimately to make such Examinations the only means of entrance, it is most desirable that immediately on a young man entering the profession he should be started in a course of study which will ultimately lead him up to the desired end.

The *Preliminary Examination* will test the general knowledge and lead schoolmasters to systematise the studies of the pupil and to direct his attention in particular to those essential branches of knowledge which the Examination will indicate.

The *Intermediate* will be for the probationer a stage at which he will test his elementary architectural knowledge, and in the preparation of which he will lay a solid foundation for his future studies.

The *Final* will give him a standard for the development of his studies so as to place him in a position to enter on the active practice of his profession, ready to apply the principles and details he has acquired, and to further pursue his work until fully prepared to enter on that ultimate Examination which in a few years may be established as a preliminary qualification for the Fellowship.

I hope that when the scheme thus set forth is matured, it may formulate such modes of procedure as may lead to our entrusting the preliminary Examinations to local societies in the manner so well indicated in the paper I have mentioned by Mr. Lawrence Booth. Meanwhile, in the Spring of 1888, an Examination will be held under the auspices of the Manchester Architectural Society, this centre

having been selected as likely to be convenient to candidates from the great towns in the vicinity, and even to those who may come from further north, and from Scotland. The Examination will be conducted on the same lines as those to be held in London this month and in March. The Chairman of the London Board of Examiners will probably attend, and, as at former provincial Examinations, assist the Board, selected by the local society, but composed entirely of Fellows of the Institute. In thus endeavouring to bring examination closer home to non-metropolitan architects and students, the Institute is, I am sure you will feel, studying the best interests of the profession, and doing much to weld the whole profession into one united body.

It has been sought, moreover, to direct the attention of young architects in practice to the obligatory Examination, which now forms the only entrance to the degree of Associate of this Institute. The number of such architects who would be worthy members of this body, but who have not yet joined its ranks, will, I am convinced, continue to increase, because undoubtedly the preparation for and passing through the Examination, respecting the advantages of which those architects who have assessed express themselves warmly, are commendable; and it cannot be too widely known that this Examination is framed so as to have regard to the position of architects in actual practice. Indeed, I know that the Examiners are in the habit of giving the fullest consideration to the professional status of such candidates. I therefore most cordially invite all those younger members of our profession who, though not Fellows or Associates of the Institute, are already in practice, to prepare for examination, and thus qualify themselves for admission into our ranks.

To another of the meetings of the General Conference your Council referred the report of the special Federation Committee, in order to elicit an opinion as to the feasibility or desirability of carrying into effect any or all of the proposals made in that report. The meeting was a thoroughly representative one, and the report was returned, after a few slight modifications, with a request that it might be taken into consideration. This has been partly done, and the matter is now in the hands of a special committee engaged in the preparation of draft bye-laws according to the terms of the Supplemental Charter granted to the Institute in the spring of the current year; and I have every reason to believe that before many weeks are over it will be possible to convene a special general meeting for the purpose of considering the same. Meanwhile, without pledging myself to agree with all the provisions of the report, I may perhaps be allowed to express satisfaction with their general tenor. The Conference of 1887 has resolved that the centre of any federation of the members of the profession within the Empire is and shall be the Royal Institute of British Architects, and the expressed object view is to establish a closer connexion than now exists between British architects generally, and to promote the advancement of our art, harmony of practice, and intercommunication. To this purpose, roughly speaking, the Institute is to organise periodical conferences in the provinces as well as in London; the local societies, which are to retain their identity and name, and the management of their internal affairs, are to adopt the "Schedule of Professional Practice and Charges" sanctioned by the Institute, with a proviso that, so far as may not be inconsistent with the spirit of such Schedule, they may arrange terms for the guidance of their own members in circumstances not covered by the Schedule; they are also to afford every practicable assistance to students in preparing for the Examination in Architecture; and, further, local examinations are to be held by a society or group of societies, of persons desirous of qualifying for candidature as Associates of the Institute. In return, the Institute is to send over to the local societies a proportion of the amount received by the Institute in annual subscriptions from their members. These are the main points of the report of our special Federation Committee, and they seem to me to have seemed to the Conference meeting which discussed them, quite feasible,—indeed, eminently desirable. There are, of course, details, especially of professional practice, which will require care and time to work out and assimilate; but I trust that both in London and in the Provinces the leading men will

exercise mutual forbearance while completing the minor arrangements of a scheme likely to benefit the whole profession, and to the success of which I wish a hearty God-speed.

The consideration of a very important subject,—the proposed "Registration" of architects,—also took place at the Conference, when, after a lengthy discussion, it was resolved to recommend this question to the careful consideration of your Council. The matter is now before a special committee, composed of members whose names are given in the Calendar just issued, and who are fairly representative of both town and country. Mr. Connon, of Leeds, has accepted the post of Hon. Secretary to the Committee; and those who know the energy and ability of that gentleman will not fail to conclude that the work will not be allowed to flag.

Gentlemen, this is a very important question. It has been strongly pressed upon us from without. It is also clear that many amongst us think it a right step to take. But the critics will ask,—Is it for the good of the public? Is this movement a disinterested one (hear, hear) or is it not? Is it to make a trade-union of the profession (No, no),—to exclude all those who have not been admitted within the inner circle from sharing in the emoluments of those who are within? Will it really protect and guard the public from incompetent men? ("Yes" and "No"). For my part, before venturing upon any conclusion as to the desirability or the reverse of "Registration," whatever that term may imply,—I think that we may ask ourselves two very apt and pertinent questions.—First, as to the form in which the registration of architects may be best effected; and, secondly, whether the fact of having passed these Examinations for admission to the Institute, now sanctioned by Royal Charter, and to which I have just referred, will not accomplish,—to all intents and purposes, and sufficient for the present time,—the main object of registration as contemplated by the Conference of May last (loud applause).

Considering that the Institute has now been established for more than fifty years, the passing away of those who in their youth and vigour were among the earliest members of the body must be looked for, and indeed is inevitable. The first of our losses during the past session is that of Mr. George Devey, a Fellow since 1856, who of late years was but little amongst us; he was an able artist in every way, an accomplished architect, and those who knew him personally speak of him as kindly and fascinating in his manners (hear, hear). George Vulliamy, a past Vice-President, who was well known to all of us, was a man of courteous and obliging manner, which engaged our cordial esteem. A devoted lover of art, he delighted in discoursing on the great works of the Renaissance. He was, however, comparatively early in life, appointed to the honourable and responsible position of Superintending Architect to the Metropolitan Board of Works, and he had little opportunity of doing any purely architectural work. George Bell, Fellow, of Glasgow, J. R. Botham, Fellow, of Birmingham, and Thomas Henry Sapsford, City Architect at Sydney, are also among our losses; the latter gentleman's decease was announced at the meeting following his election. The next to mention is Sir Horace Jones, and I think I may emphatically say no one was on more friendly terms with the vast majority of the members, or better known amongst us, than he, for he was a truly genial and kindly man (applause); his active career has so recently closed,—the man and his works are so well remembered,—that it is unnecessary for me to enlarge on his personal qualities, or his ability as a professional man. I knew him from the commencement of his professional career, when he went to the same office in the City as I for a time did; and I observe in a memoir of him that he esteemed his position here as your President, as I do, as the crowning honour of his life (applause). Ambrose Poynter, one of the Founders of this Institute, and in the earliest years a very active member, was joint Honorary Secretary, and contributed several Papers to the "Transactions" between the years 1839 and 1848; he had a considerable professional practice many years ago, and his name is worthily continued in the person of his son, Mr. E. J. Poynter, a distinguished Painter and Royal Academician. Robert Parris, Fellow, a member of the firm of

Wiltshire & Parris, was a gentleman who practised honourably and successfully as an architect and surveyor in Lambeth; the firm of which he was a member was originally styled Bailey & Wiltshire, and it was to that office, I believe, the late Sir Charles Barry was apprenticed. George Barnes Williams, Fellow, was the successor to Mr. George Smith, whose architectural practice in the early part of this century was very extensive, and who also had a large business as a surveyor, which class of business was, in my early professional recollections, so almost entirely in the hands of George Smith, David Riddell Roper, James White Higgins, and my late father, that I recollect our much valued Fellow, Mr. George Pownall (who, with Sir Henry Arthur Hunt, is amongst the few of my early contemporaries now living), observing to me, we being then young and ardent aspirants for professional work, that until these men had passed away there could be no work for us (laughter). Mr. Williams was Mr. George Smith's assistant, and succeeded to the Surveyorship of the Mercers' Company, to that of the Morden College Estates, and of others. His principal architectural work, in my recollection, is the rebuilding of the Mercers' Hall, and he also restored the hall of the Vintners' Company. George Goldie, Associate, whose practice was chiefly in ecclesiastical buildings,—his principal works being the Pro-Cathedral at Kensington, and the Church of St. John of Jerusalem in Great Ormond-street,—was an architect of talent, well known and justly much appreciated (hear, hear). Among the Associates I regret to have to mention the loss of Oswald Adhead, Thomas Farrer, Harry Saxon Snell, Robert A. Frazier, Andrew Edwards, and Vincent Wing; also J. Stanning Edmeston and Arthur Harland, whose deaths at an early age have just occurred; and among the Hon. Associates that of Major-General Moody, late of the Royal Engineers. In Mosses, Ruprich-Robert and Olivier Rayet, the world of art and archaeology has lost much, and Professor von Neureuther, another Hon. Corresponding Member, and an architect of distinction, who resided at Munich, is also deceased.

Amongst the events which have occurred since I last had the honour of addressing you is the election of our esteemed Fellow, Mr. Blashill (applause) to the post of Superintending Architect to the Metropolitan Board of Works, which is a position of much importance. When it is considered that the formation of new streets; the compensation to be paid on the removal of buildings necessary for the formation of these streets; the checking and examination of the returns of the District Surveyors, which are made every month; the sometimes difficult task of regulating new lines of frontage, and advising the Board generally on all building questions arising out of the Building Acts, affecting the interests of some four millions of people, devolve upon this functionary,—you will admit that it is no light or irresponsible work which is placed in the hands of the Superintending Architect. Another noteworthy and to us most interesting event, which has only just been announced, is that the Corporation of the City of London, after having decided to elect a Surveyor to carry on part of the work so ably conducted by our late Past-President, Sir Horace Jones,—a decision which from the first was, I believe, by many members of the Corporation, considered a retrograde movement,—have reconsidered the matter, and have felt it desirable not to depart from the ancient custom of placing an architect on the list of their high officials (applause). They thus recognise, it seems to me, the dignity of our profession, and the strength which the old and powerful Corporation of the City of London feel is thus added to their administrative power by the existence of such an officer (applause). Appointments of this kind are amongst the few advantages incident to our profession; they are posts of high honour, and although the emoluments are not perhaps equal to those which exist in the higher branches of the legal profession, they cannot be said to be other than liberal. Indeed, the office is such as any amongst us might be proud to hold; and I recollect when Mr. Banning was elected, that Sir William Tite, who was afterwards one of our most distinguished, and certainly one of our most able, Presidents, was a candidate for the post (hear, hear).

It has been my most pleasing privilege to place in the hands of our respected Past-Pres-

sident, Mr. Ewan Christian, the Royal Gold Medal; and looking to the importance of some of Mr. Christian's very numerous works, the conscientious care with which he has dealt with those to us most precious national monuments which we have inherited, with which he has to deal,—these considerations, together with the universal esteem and respect in which he is held, induced us to recommend him to Her Majesty as a fit recipient of this honour.

The Exhibition of the Students' work, held in the Conduit-street Galleries last January, was one of the best, if not the best, we have ever had. There can be no doubt whatever that the number of young men who can now produce sketches and measured drawings of the highest quality, both as regards accuracy and artistic power, has largely increased.

The Committee of the new British School at Athens, who report that there is every cause for satisfaction in the progress already made, and that it is intended to provide board and lodging at a moderate rate in the school building for a limited number of students, have just made a proposal to us of some importance and interest. They are prepared to contribute the sum of 50*l.* towards the expenses of any duly qualified architectural student whom your Council may select to send out to Athens during the session now opened (applause). The conditions attached to the grant are,—(1) That the said student shall reside at least four months in Greece; (2) That he shall hold himself at the disposal of the Director of the school to assist in excavations if required (laughter).

I am glad to be able to remind you that the Institute now fosters to the best of its ability the Architects' Benevolent Society, which is administered partly under our care, and within this building. It has an accumulated fund of over 7,000*l.*, which, considering the long time the Society has been established, is but a moderate, I ought rather to say, a very small capital. I fear it must be taken as another illustration of the fact that architects' coffers are not as a rule overflowing with riches. It was proposed to endeavour to increase the fund in the truly British fashion of dining together, and thereby stimulating the charitable sentiments which we all entertain at heart, especially in a cause in which we are so closely interested as the relief of distressed brethren, their widows and orphans. Through the kindness of our Fellow, Mr. Banister Fletcher, one of the Court of the Carpenters' Company, it was hoped that this suggested dinner might take place,—and at Carpenters' Hall, which would have been gladly lent,—but at present it has been found impracticable to make any definite arrangements for the purpose.

There is another subject I cannot leave unnoticed,—that is the issue of a further volume of the "Dictionary of Architecture." It is most gratifying to see this work progressing so satisfactorily, as regards the matter it contains. But when will it be completed? Some of us who saw its commencement may not live to see its completion. Nevertheless, let us help as best we may towards this much-to-be-desired result. If, after all, it is too ambitious a work for this Institute, or any Committee of the Institute, to have taken in hand, what honour, what gratitude is due to the devoted few who, as a labour, and a very heavy labour, too,—of love, are bringing this important work to an end! I need but point to the volume just issued to induce you to examine it carefully. I am told by those who know most about the Institute library that very few books in it are more often consulted than the "Dictionary of Architecture," by foreign as well as home readers, and none, I am convinced, afford more information on matters of fact than does this durable monument of Mr. Wyatt Papworth's learning and research.\*

Nothing that has transpired during the past year has induced a belief that the Institute may be brought more closely into relationship with the Royal Academy. Although, in the early part of the year, it was stated that proposals involving serious modifications in the constitution of that body were being considered

\* We quite concur with the President that there is a mine of information of a certain kind in the "Dictionary," but we must repeat, and with emphasis, that there are articles in it which are utterly unworthy of such a dictionary, either from being out of date in information or essentially inaccurate in their statements and their literary expression; and we think it is much to be regretted that the President should have publicly given the sanction and approval of the Institute to a dictionary which contains articles that would render it a subject of ridicule to any scientific man or sanitary engineer who took it up.—Ed.

by its members, no communication on the subject has been received, and any action that may have been taken by the Academy has been without results as regards ourselves.

On the other hand, an arrangement of some significance has been made between the Architectural Association and the Institute (applause). Before separating for the recess we received a communication from the Committee of the junior body, asking for permission to use our rooms for their ordinary Friday evening meetings, as, in consequence of the present number of classes and an increase of work generally, the Association found the accommodation at their disposal too limited. Since then, your Council, having left the matter to be settled by the Secretaries of the Association and a small Sub-Committee of the Association, have willingly consented to an arrangement whereby, during this session, our meeting-room will be occupied once a fortnight by the Association, and I have every reason to believe, with the entire concurrence of the members of both bodies (applause). It is a source of extreme gratification to me to know that the mutual assistance long rendered is thus appreciated by both Societies in a manner so cordial, and, as the excellent President of the Architectural Association showed, in his recent Address delivered from this chair,\* so sincere. The aims of both are identical; we exist for a like purpose. In the Supplemental Charter and its Examination classes, the objects for which both are working have been defined. The Institute, while urging the members of the younger Society to maintain their absolute independence, will, in my opinion, further the interests of the profession by endeavouring to enlarge the capacities of the Architectural Association as an educational body (applause).

And now, gentlemen, having reviewed the prominent events of the period which has passed since I first had the honour to read a Presidential Address to you,—and this is the last time it will be my privilege to do so,—I commend to your attention some of the important questions which will come before you this session, namely, the settling of the By-laws to be made under our Supplemental Charter; the development of our scheme of Federation; and the consideration of the very important subject of "Registration" (hear, hear). There is also a very difficult and certainly important subject,—initiated here some years ago,—on which we have gathered the opinion of some of our most able and experienced members. I refer to the vexed question of "Light and Air." I have not ventured, although much engaged with the subject, to give an opinion on it myself, but I know that a mass of evidence has been collected by a special Committee of the Institute, the work of which has been transferred to the Standing Committee for Science,—work which well merits further consideration, with a view to the framing of some practical suggestions in regard to this matter.

Gentlemen, a great deal has been written and said of late about the progress of the last fifty years. To many of you I have no doubt that such a period seems a long time, but, believe me, it is barely anything at all in the life of a corporation; and to every one, whether he be an old man or a young man, I would say,—Do not be in a hurry. It was only last year that the London Colleges of Physicians and of Surgeons combined for educational purposes, and for the furtherance of professional education; yet the College of Physicians was founded early in the sixteenth century, and the surgeons can trace their existence back to the reign of Edward II., and even earlier. The position of the English surgeons is now as eminent as that of any other of the learned or scientific professions; but less than a hundred years ago, in 1790, one of the Masters of the College of Surgeons, on retiring from office, wrote to his subordinates an extraordinary letter. "Your theatre," said he, "is without lectures; your library room, without books, is converted into an office for your clerk; and your committee-room has become an eating parlour." Again, in 1844, only forty-three years ago, a Charter granted to the Surgeons constituted a new order of Fellows,—a grade higher than members,—who were to qualify for the distinction by strict examination, or by selection from among deserving members. It is unnecessary to tell you the results of that great step; you will draw your own inferences from the parallel I have ventured to place before you. No class

of men have been reviled, even for centuries, with more bitterness, and with more wit, than the physicians and surgeons. They have been assailed with clamour inside and outside their ranks; they have met with every kind of opposition. Such things, however, do no harm, for, when the cause is good, opposition to it creates no new enemies; on the contrary, it consolidates old friendships, brings back waverers, and strengthens the ties of interest and duty which unite the members of a sound and flourishing Society like that to which you, gentlemen, and I have the advantage to belong (applause).

Mr. A. W. Blomfield, M.A., Vice-President, said.—In the interesting and exhaustive address to which we have just listened, you made a suggestion to which I should like to give practical effect at once, by proposing that a vote of condolence be passed with the family of our former distinguished President, Mr. Beresford Hope, and that our Secretary be instructed to convey it in the usual manner to the proper quarter (hear, hear).

Mr. Ewan Christian seconded the motion, which was carried.

Mr. Blomfield.—It now becomes my pleasing duty to propose a vote of thanks to the President for the very interesting address to which we have just listened. As far as I can judge he has touched upon every point of interest that might have been expected to be alluded to in an address of the kind. I am sure you will all feel with me considerable regret that this is the last time we shall have the pleasure of hearing such an address from him from the Presidential chair. I think, gentlemen, it is hardly necessary for me formally to propose a vote of thanks to the President for his address, for I am sure it will be carried by acclamation (applause).

Mr. John Slater, B.A.—Gentlemen, as representing the Architectural Association, I have been requested to-night to second the vote of thanks to the President of this Institute, which has been proposed by Mr. Blomfield. I esteem it an honour to the Architectural Association, and as it is a personal honour to myself, to have had this duty placed in my hands. You, Sir, have alluded to the new arrangement which has been made between this Institute and the Architectural Association, with regard to the use of this room by the younger body, and I am glad to take this opportunity to thank you, and the members of the Institute, for the cordial and ready manner in which they acceded to our request. The gain on our part is undoubted. We shall be very much more comfortable in this room than in the room downstairs, where we were both hot and stuffy. However, I hope the advantage may not be entirely one-sided. A wish was thrown out a fortnight ago that some of the exuberant vitality of the younger body, some of the enthusiasm with which its meetings are conducted, might permeate these walls, and be reproduced at the meetings of the Institute. Whether this be so or not, whether it be wanted or not,—for I am not quite sure that there have not been meetings of the Institute during the past two or three years at which there has been no lack of exuberance or enthusiasm,—I think that anything which makes this Institute and this room the recognised centre of the architectural life and work of the day, whether as regards the metropolis or the provinces, must be an undoubted good (applause). So, Sir, while thoroughly appreciating and strongly advocating a close connexion of this kind between the two bodies, I am very pleased indeed to find you approving and endorsing the views which I put forward as to the work which has to be done, with reference to the profession being better done by the two bodies independently and under separate executives (applause). To use an illustration from chemistry, I cannot help thinking that the mutual reactions between two independent bodies will prevent the stagnation which would certainly ensue from a complete amalgamation. You have alluded to the probable extension and furtherance of the excellent scheme of Examination. I cannot help thinking it a striking feature of the times that, so far as I am aware, this proposal of extending the Examinations is not met, and is not likely to meet, with anything like the same amount of opposition with which the original institution of the Obligatory Examination was received. I think, Sir, that is most encourag-

ing. I believe nearly every one is beginning to feel that Examinations, if properly conducted,—and I would like to underline these words as strongly as I can,—that Examinations, if properly conducted, are invaluable in fostering and improving architectural education. And that is the sole reason for the existence of the Examination at all. The Examination here must certainly not be framed on any rigid lines. It must not be an Examination the passing of which by students will be dependent upon those students attiring the shibboleth of this or that examiner. They must be widely framed, giving free scope to individual genius,—if you like, to individual eccentricity,—but they must be thorough, and they must be such Examinations that a preparation for them will constitute a real education in the fullest and widest sense of the term (applause). I wish every member of the Institute, and every member of our body, would make himself acquainted with, and try to appreciate, the significance of the work that is now being done for and by what are called the lower classes,—I mean the skilled artisans and workmen in and about London and other large cities. On Saturday last I had the pleasure of going over the Finsbury Technical College, and of hearing a most able and interesting address from its Principal. I believe I am not stating more than the exact truth when I say that a young man of ordinary intelligence, who has passed through two years class work in that institution, would be better suited for an architect even than a man who had gone through three, four, or five years of ordinary articles. It would be purporting the subject too far to point out where this leads to; I will only commend the thought to you, because if I am correct in this belief, and if it is a fact, it becomes a serious question as to what is to become of the class of men who are mere architectural draughtsmen, and nothing else (hear, hear). You have alluded, Sir, and I was pleased you did so, to the cordial relations which subsist between this Institute and our provincial brethren. There used to be a time when the idea was held that possibly this Institute considered itself as representing too exclusively the metropolitan members of the body. I am quite sure that even if any idea or wish existed now to continue that state of things,—and I am quite sure no such wish does exist,—the energy of many of the provincial bodies, and the success to which they have attained, would compel their recognition by this Institute, and would ensure their views and feelings being thoroughly considered in any work which was undertaken. The question of federation is a most difficult one, and I cannot help thinking that we should all do well to lay to heart the wise and weighty words of the concluding sentences of your address; for I am very sure of this, that any attempt to rush through an ill-considered and immature scheme, either of Federation, registration, or any other action you like, would be the most fatal mistake which could be possibly made by any one who has at heart the real interests of the profession at large. We must not be in a hurry, but must look at the matter in all its details and bearings, and if we do that I venture to think that the day is not far distant when we shall be really able to mature a lasting federation,—a federation of aims, a federation of interests, a federation of responsibilities, and a federation of honours. That, I believe, is the kind of federation which many of the country members have been looking for, and have come to think is perhaps only a poet's dream to hope for. But if we carry out the suggestions you have made, and seriously consider all the points which bear upon the subject, I think that the members of the Committee who have the subject in charge will be able to do a good deal to speed that long-looked-for day (applause).

Professor Kerr—I should like to add a few words to the very able speech of my friend who seconded the vote of thanks to our respected and excellent President. Sir, you have to-night, in the course of your remarks, although they were eminently of a practical character, done, in my opinion, a great deal to inculcate that form of exertion for the advancement of the dignity of the profession which I think has always characterised our Presidential addresses here. You have referred to the advancement of that excellent end by education, and by the Examinations which are proposed to be instituted and consolidated for the admission of members into this body. With regard to the

Registration and Federation schemes, you have also said many wise things. I am sure you will all remember what you have said, and act upon what you have advised. But there is another subject to which you have alluded, which my friend, Mr. Slater, has not adverted to, and that is the loss we have sustained by the decease of Mr. Beresford Hope. The motion made for the vote of condolence will stand by itself, and will not prevent my saying a very few words upon the subject of that loss. It has always seemed to me that during the last forty years, the tendency of this profession has been a little downward. You and I, Sir, and some who are of our age, can remember the time when meetings of the Institute were addressed by men who had, as we thought then, very much more exalted aims than we have been accustomed to in public since. Three movements seem to me to have taken place, all under the guidance of exceedingly able amateurs, during the last forty years. There has been the movement identified with the name of Ferguson, which had for its end the advancement of the dignity of the profession by means of learning. Mr. Ferguson's learning was of the most extraordinary kind. There was another movement, the leader of which is still with us,—the movement for the advancement of architecture amongst the other arts by means of emotion,—I refer to Mr. Ruskin. But the principal movement of the three is that which is identified with the leadership of Mr. Beresford Hope, which was the advancement of the profession by means of the influence of tradition. Mr. Beresford Hope was the representative of tradition, and principally of our own tradition, although our differences of opinion on the subject may be of a very lively character. I am pleased to find that some one is to read a biographical notice of Mr. Beresford Hope in the course of the session, and I trust the opportunity will be taken of dealing with that very distinguished man, not as a mere individual unit of a group, but as the representative of a very large aim, and of a very great and considerable movement. I have always thought that, apart from all differences of opinion amongst ourselves on questions of taste, the Mediaeval renaissance of the last generation is one of the most marvellous movements of ability and enthusiasm in art which the history of the world's art can show. It was peculiar to England, and it was peculiarly creditable to England, and it is that movement that I identify with the name of Mr. Beresford Hope. I trust, therefore, when the time comes, we shall be able to enter more fully into the consideration of his career, and that the very distinguished attitude which he assumed and so successfully maintained will not be forgotten (applause).

The vote of thanks was then carried by acclamation, and the President said a few words in reply.

#### ARCHITECTURAL MODELLING.\*

I HAVE been asked to say a few words on a subject not usually regarded as one of the first importance in the education of the young architect, but it is one which, I venture to think, is of the deepest interest to him and his future clients. It is the light and shade of his building; and in assuming that the practice or the art of modelling can help forward this important section of the great art, I must say that it enters into the consideration that should be given to every touch on a building that involves light and shade, which is no less than every particle of relief that is used to ornament the structure. Now the modelled decoration of a single abstract panel is simple enough, and we see in many competitions that are annually held, that it is a question that deals with the systematic, orderly, and pleasant distribution of various details, natural or conventional, in high, or low, or flattest possible relief, but who can say more than that, in itself, the panel, as such, is a pleasant object, not offensive by any disproportion of form, light, and shade or half tone?

But the problem is a very different thing when a panel has to be so made as to take its place among an already distributed arrangement of mouldings or other projections; whether these are the proper attributes of any particular style or the accidental results of peculiar lighting.

Then the panel has to fit its proscribed place, and the prescription of colour that surrounds it must be thoughtfully consulted and studied, that the designer may forward the harmony of the whole mass.

This involves a very subtle question, namely, that of the colour of a building. Of course, I do not mean anything that relates to pigment, but to the general tone that the light and shade of the plastic mass produces on the artistic observer.

Equally the colour of a statue is, of course, not any pigment with which it may have been tinted, but the value in grey that it presents, and a capable sculptor uses his colour with all the taste with which he is gifted to convey his sense of breadth or complexity, light or dark, whichever quality may best explain his meaning.

The colour of the hair of a sitter may be represented approximately, the depth of the colour of the eye, or the over-balance of some too heavy shadow may be made right by the proper understanding of this vital principle.
