The PRESIDENT read two letters, one from Professor Flückiger, of the University of Strasburg, and another from the Rector of the University, stating their desire to promote a knowledge of English pharmacy, and asking for a copy of the PHARMACEUTICAL JOURNAL AND TRANSACTIONS.

Mr. GREENISH moved—

"That the request of Dr. Flückiger be complied with, and that the PHARMACEUTICAL JOURNAL be forwarded weekly to the University Library, Strasburg; all the back numbers of the third series, as far as possible, to be sent."

He said he had known Professor Flückiger, who was formerly at Berne, for some time, and had always found him ready to acknowledge and reply to any communication addressed to him on the subject of pharmacy.

Mr. SUTTON seconded the motion and it was unanimously agreed to.

PORTRAIT OF JACOB BELL.

The PRESIDENT begged leave to present to the Society a copy, by Mr. Downard, of the late Sir Edwin Landseer's portrait of Jacob Bell, and, at the same time, with an artist's proof of the engraved portrait of Sir Edwin Landseer himself. Sir Edwin, though not a pharmacist, always took great interest in pharmacy, and was a most intimate friend of the founder of the Society. He (the President) had also been honoured by his friendship, and would esteem it a privilege to be allowed to present to the Society these two memorials.

The proposition of the President was received with acclamation, and after a formal vote of thanks to him had been passed, on the motion of the Vice-President, seconded by Mr. Sandford, the President, Vice-President, and Messrs. Sandford and Williams were appointed a special committee to superintend the hanging and arrangement of these and of the other works of art belonging to the Society.

FINANCE.

The report of this Committee was read and adopted, various accounts and salaries being recommended for payment.

BENEVOLENT FUND.

The report of the Benevolent Fund Committee was read, recommending three grants of £10 each to widows of chemists and druggists. It was moved by Mr. Urwick that in the case of Mrs. Moss, widow of the late Mr. Moss, of Carlisle, a pharmaceutical chemist and local secretary, the grant should be increased to £20.

MR. BROWN said that Mrs. Moss had been an unsuccessful candidate at the late election for annuitants, and if, as some members wished, annuities had been granted out of the annual subscriptions, this lady would certainly have been one of the recipients; he therefore had much pleasure in seconding the motion.

After some conversation the motion was unanimously agreed to, as were the other grants proposed.

LIBRARY, MUSEUM, AND LABORATORY.

The report of this Committee stated that there were now 49 students at work in the Laboratory, 36 attending Professor Redwood's lectures, and 25 attending Professor Bentley's. The Professors reported that though the number of students now attending the classes was less than at the same time last year, they had every reason to be satisfied with their conduct, and were of opinion that when the new system was further known it would work advantageously, as the number of students was gradually increasing.

A letter had been received from Mr. Thompson, superintendent of the Botanical Gardens at Hobart town, offering to supply the curator with such botanical specimens as could not be obtained elsewhere. The Committee recommended that the offer be accepted with thanks. The curator had also reported that he believed persons made use of the Museum who were not entitled to do so, to the inconvenience of the students, and it was therefore suggested that all persons not connected with the Society desiring to use the Museum, should apply to the Secretary for a form of admission, without which they should not be allowed to enter. The following books were recommended for purchase, 'Markham's Memoir of the Countess of Chinchon,' 'Thorpe's Quantitative Analysis,' 'Suffolk's Spectrum Analysis,' also the latest editions of 'Hassall's Adulterations Detected,' 'Fresenius' Quantitative Analysis,' 'Roscoe's Elementary Chemistry,' 'Williamson's Chemistry for Students.' Amended regulations for the library were submitted for the approval of the Council.

Mr. GREENISH, in pursuance of notice, moved—

"That the Library be open every evening, and that publicity be given in the weekly issue of the Journal and Transactions of the Society."

He said that for some time past the library had been opened on two evenings a week, from seven to nine, and the attendance had been fairly good; since the Society had gone to considerable expense in improving the library, he would ask whether it would not be desirable to throw it open as he now suggested. Most chemists in London allowed their assistants one evening a week, but if that did not coincide with an evening on which the library was open it was of no use to them, and he had even found a difficulty himself from not always remembering what the evenings were. He saw no reason why it should not be open every evening except Saturday.

Mr. HAMPSON seconded the motion.

Mr. BROWN, in supporting the proposition, suggested that the library might be closed at five instead of six, if it were re-opened at seven.

The VICE-PRESIDENT said he hoped a record would be kept of the number making use of the library, in order that it might be seen how far the new regulations, which he had no doubt would be adopted, were appreciated.

The motion was unanimously agreed to, and the report of the committee and the following library regulations, as amended by Mr. Greenish's resolution, were unanimously adopted :—

LIBRARY REGULATIONS.

"1. The Library is open from Nine o'clock, a.m., until Five o'clock, p.m., and, in the evening, Seven to Ten o'clock. Saturdays, from Nine o'clock a.m. until Two o'clock p.m.

"2. 'Members' of the Society and 'Associates in business' only may obtain books on making personal or written application for them.

"3. 'Associates' and 'Apprentices or Students' of the Society may obtain books on presenting a recommendation from a Member or Associate in business, the person recommending being responsible for the safe keeping and return of such books. A form of recommendation may be obtained from the Librarian.

"4. No person shall have more than two volumes at a time, nor shall he be entitled to keep any book for a longer period than fourteen days, except country Members and Associates in business who shall be allowed to retain books twenty-one days. But when a book is returned it may be borrowed again, provided it has not been bespoken by any other person. Books which have been bespoken shall circulate in rotation, according to priority of application.

"5. The scientific journals shall not be circulated until the expiration of the month of publication. Works containing valuable plates, and a few standard works of reference, shall not be circulated, except by special permission of the Committee; such books shall be distinguished in the catalogue by an asterisk.

"6. The expense of carriage of books borrowed by country Members and Associates in business, will be defrayed one way by the Society.

"7. If any book be retained by a borrower for one month and be not returned after written application has been made for it, the Council may order it to be replaced, and charge the borrower in default with the amount thus incurred. If any book, when returned by a borrower, is found to have been damaged during the period he has had it, a fine equivalent to the injury shall be paid by the borrower.

"8. The Library shall be closed during the first fortnight in September, to admit of the examination of the books."

THE 'HISTORICAL SKETCH OF PHARMACY.'

The SECRETARY read a letter from Professor Redwood on the subject of the re-issue of Bell's 'Historical Sketch of Pharmacy,' with a continuation to the present time, stating that the proposed work, which the Council had about two years since requested him, in conjunction with Mr. Sandford, to undertake, would occupy a considerable amount of time, trouble, and research, but that if the Council wished it, he was ready to undertake the duty. The letter was ordered to be entered on the minutes, and after some discussion the further consideration of the matter was deferred until next month.

SPECIAL COMMITTEE ON THE PRELIMINARY EXAMINATIONS.

The Report of the proceedings of this Committee was read.

Mr. SCHACHT moved the adoption of the Report. He said the Committee had divided their labours into two evenings' work, the first of which received the approval of the Council at their last meeting, and the proceedings of their second meeting had now been read. In order, however, that members might be reminded of the whole proceedings, he would read the substance of the recommendations of the Committee.

Mr. SAVAGE was very glad that this matter had been brought forward so clearly as it had been; and the only improvement he could suggest was that instead of saying that the candidates should sit a sufficient distance apart from each other, a definite distance should be prescribed, say 4 feet, in order to prevent any possibility of contact or irregularity. He was very glad it was proposed that deputy superintendents should be appointed, because only on Monday last he was present at a Preliminary Examination where the Local Secretary, being a conscientious man, although in exceedingly ill health, was attending to his duties, when, if a deputy had been appointed, he would have been very glad to have left the work to him. He had much pleasure in supporting the adoption of the Report.

Mr. STODDART also supported the adoption of the Report.

Mr. BAYNES remarked that one objection put forward by the Board of Examiners was, that in some cases Local Secretaries or Superintendents would be supervising the examination of their own assistants. There did not seem to be any provision made for meeting this objection, to which he himself, however, attached no importance.

The VICE-PRESIDENT said in the ordinary course of things there would be three or more candidates examined at the same time, and it would be impossible for the Superintendent to give any advantage to one candidate over another without observation.

Mr. ATHERTON said the Committee had not thought it necessary to take any notice of the point mentioned.

Mr. SANDFORD also expressed his approval of the new regulations.

Mr. URWICK suggested the desirability of sending the regulations to the candidates before they came up, in order that they might make themselves acquainted with them prior to taking their places in the examination room.

Mr. BROWN was so thoroughly satisfied with the scheme as a whole, that he would waive any sentimental objection he might have to details. He must say there were some places in the kingdom where the Preliminary Examination had been so conscientiously conducted, and so admirably superintended, that he was sorry to see them omitted from the list of centres, but he could scarcely complain of this because no doubt their importance was not sufficiently great to entitle them to incorporation in the list. He was not quite certain whether it was, under all circumstances, absolutely prohibited that the Examinations should be held in the Superintendent's own house or premises; there might be objections in some cases, but he did not think they were so great as to render the prohibition absolutely essential. At the same time he should not divide the Council upon that point, though he thought in some cases there might be a difficulty in getting a suitable room, and that the examination might be conducted more satisfactorily in the Superintendent's own house.

Mr. Hampson said the Committee had very carefully considered this point, and it was thought better on the whole to insist on the examinations being always held on neutral territory, where a man would feel he was not in his own house, but was exercising a public function for the benefit of the Society.

Mr. Schacht said the point raised by Mr. Urwick with reference to the instructions to candidates was no doubt very important, but probably it would be met by this, that a certain notice had been drawn up which it was proposed to print at the heading of the papers given to the candidates on which they were to answer their questions, calling their attention to the importance and necessity of observing the regulations prescribed to them. It was supposed that this would enlist their good feeling, and at the same time excite their caution. He might add that it was proposed to prohibit the use of any scribbling paper by the candidates except the reverse side of the paper on which they answered the questions, because he understood the examiners were glad sometimes to see the scribbling of the students, in order to form an idea as to whether they understood the questions, and for that purpose it was desirable that these rough notes should be preserved.

On the motion of Mr. Schacht, seconded by Mr. Sandford, it was unanimously resolved—

"That on and after July 1st, 1874, the following be the conditions for the conduct of the Preliminary Examinations, and the Examination for the Bell Scholarships, the Pereira Medal, and the Prize of Books.

"1. That for the year ensuing from the 1st of July next the following places be taken as centres :—

ENGLAND AND WALES.

Barnstaple	Dorchester	Nottingham
Berwick-on-Tweed	Exeter	Oxford
Birmingham	Guernsey	Peterborough
Boston	Hereford	Plymouth
Brighton	Hull	Portsmouth
Bristol	Jersey	Preston
Cambridge	Leamington	Reading
Canterbury	Leeds	Salisbury
Cardiff	Leicester	Scarborough
Cardigan	Lincoln	Sheffield
Carlisle	Liverpool	Shrewsbury
Carmarthen	London	Southampton
Carnarvon	Lynn	Stafford
Cheltenham	Macclesfield	Swansea
Chester	Manchester	Taunton
Colchester	Newcastle	Truro
Darlington	Northampton	Worcester
Doncaster	Norwich	York.

SCOTLAND.

Aberdeen	Edinburgh	Inverness
Dumfries	Glasgow	Perth
Dundee		

"2. That persons be especially appointed by the Council to superintend the Preliminary examination in London and the provinces ; that they be called superintendents of examinations, and be paid fees for each examination ; such superintendents not being necessarily members of the Board of Examiners.

"3. That a deputy superintendent be also appointed by the Council in each centre.

"4. That a fee of one guinea be paid to the superintendent or deputy superintendent on the occasion of each examination.

"5. That wherever it can be so arranged, the local secretary be offered the appointment of superintendent.

"6. That the examinations be held in the months of January, April, July, and October, on the first Monday of the month, at 12 o'clock noon.

"7. That Medical Latin be discontinued in the Preliminary Examination after the end of the year 1874.

"8. That it being objectionable to hold the Examinations in the house of the superintendent, he shall be authorized to engage some other apartment suitable for the purpose, and charge a sum not exceeding ten shillings to the Society on account thereof.

"9. That the Examination for the Jacob Bell Memorial Scholarships be held annually on the first Monday in July, concurrently with the Preliminary Examination, and that on such occasions an extra fee of one guinea be paid to the Superintendent.

"10. That notice be issued in the Pharmaceutical Journal two months prior to the day of holding the Preliminary examination, that such examination will take place, and giving a list of the Centres at which it will be held.

"11. That in future the Examination for the Pereira Medal and Prize of Books be held in London and Edinburgh only.

"12. Candidates for the Preliminary Examination must give notice to the Secretary, 17, Bloomsbury Square, not less than 14 days prior to the day on which the Examination is to be held, of their intention to present themselves for examination, and state the Centre at which they desire to be examined.

"13. That the instructions to Superintendents of Examinations be as follows :—

"Pharmaceutical Society of Great Britain.
"17, Bloomsbury Square, W.C.

"Instructions to Superintendents of Examinations.

"To be read aloud to the Candidates before commencing their writing.

"The Preliminary Examination.

"The Examination Papers, with Special Sheets for the Candidates to write upon, will be forwarded from the Secretary, under cover, to the superintendents, so as to be received by them on the morning of the day fixed for the Examination.

"Writing materials for each Candidate should be provided and all arrangements for the accommodation of the Candidates completed before the hour fixed for opening the packet of questions and papers from the Secretary.

"Candidates must be in their places at the time appointed, and after this time no candidate shall be admitted.

"Candidates should be placed at sufficient distance from each other to prevent copying, and they must not be permitted to bring either books, scribbling papers, or memoranda into the examination room.

"The Examination Papers must be opened by the Superintendent at the appointed time, in the presence of the Candidates and immediately distributed by him.

"He must see that each Candidate signs his papers in the place indicated.

"No Examination Paper shall be taken from the room until the Examination is complete.

"The Superintendent must carefully watch the whole Examination to see that the Candidates do not use unfair means, either by assisting each other, or using books or notes. No person, except the superintendent, should be permitted to be present, and on no consideration shall Candidates be allowed to speak to each other after the papers are distributed.

"A Candidate wishing to ask any question must hold up his hand ; the superintendent will come to him, and satisfy any legitimate inquiry. No explanation will, however, be given on the subject matter of the questions.

"At the expiration of three hours from the time of the distribution of the questions, the written papers of the Candidates with all memoranda and scribblings thereon, must be delivered to the superintendent, who must immediately enclose all the papers in the envelope sent herewith by the Secretary, seal it with

his seal, and forward it by first post thereafter to the Secretary, enclosing the accompanying declaration duly filled in and signed."

The SECRETARY was instructed to communicate with the local secretaries in the proposed centres, asking them if they would undertake the duties of superintendents, and consulting them as to the appointment of deputy-superintendents in the respective districts.

HOUSE.

The report of this Committee was read and adopted. It recommended the payment of the surveyor's fees and the balance due to the contractor for the recent alterations and repairs; also the purchase of furniture and fittings for the Library, and the new Council Room. Ventilators were also ordered to be placed in the Examination Room.

PARLIAMENTARY.

The report of this Committee stated that certain information had been received with reference to alleged infringements of the Pharmacy Act. The Committee recommended that the particulars of one case should be forwarded to the solicitor with instructions to take proceedings in the event of his being able to obtain further and conclusive evidence. The attention of the Committee had been drawn to the prosecution of a chemist for the sale of adulterated musard; and a letter had been received from the chemist's association at Wolverhampton asking what their position was with regard to the sale of sweet spirit of nitre, milk of sulphur, sal volatile, citrate of iron and quinine, and other preparations. The letter had been forwarded to the solicitor in order that he might embody in the case he was about to lay before Counsel the points which had been raised.

Mr. HAMPSON was very glad to find the Council were moving in this matter, which very seriously affected the whole trade. He was somewhat doubtful of the value of the opinion when obtained, but he hoped the Parliamentary Committee would consider the whole subject carefully, and, if they found it necessary, would recommend the Council to go to Parliament for an alteration of the Adulteration Act.

Mr. SANDFORD said the main point, he believed, on which the Solicitor desired to have the assistance of Counsel's opinion was, whether under the Pharmacy Act certain offences were not amenable to the law on the action of the Council of the Society, and if so whether persons so offending were liable to be prosecuted in a Police Court. This was a very important question and required grave consideration, but he did not apprehend the Society was competent to expound the law, and therefore those who put such questions as those sent from Wolverhampton should be recommended to watch the cases as they occurred, and act accordingly.

Mr. HAMPSON said he was only anxious that the Parliamentary Committee should apply themselves to this question, and if they found they could recommend any amendment in the Adulteration Act, to go to the Government as speedily as possible, and, if possible, get the amendment made in the ensuing session.

Mr. WILLIAMS thought this a very good suggestion, and hoped some step would be taken to strengthen the hands of the Government in altering the Act, which he was sure they had no idea would operate as it was found to be doing. If it were to be carried out in the stringent way in which it was now attempted to administer it, it would be impossible for chemists and druggists to carry on their business.

Mr. ATHERTON suggested that a sub-committee should be appointed to wait on the Government on this matter.

The PRESIDENT thought it would be better not to take any active steps until the opinion of counsel had been received and considered.

Mr. BETTY said he believed it was generally known that the operation of the Adulteration Act was not what the Legislature intended it should be, and it was also known that the Society, as a body, was in opposition to it. It could not, therefore, be too widely known that the Council had taken that responsible position upon themselves to defend the interests of chemists and druggists in the matter. He did not think they could ever hope to abolish the Act, but he thought if they used their utmost endeavours they might so amend it that it would be fair to the public, and at the same time would not unduly press upon those who administered to the public wants.

Mr. GREENISH remarked that it had been stated once or twice by Mr. Sandford that there was an understanding with Earl Granville that the Adulteration Act should not affect chemists with respect to medicines, but, unfortunately, that understanding was in no way binding upon the magistrates.

The report of the Committee was then unanimously adopted.

REPORT OF EXAMINATIONS.

December, 1873.

ENGLAND AND WALES.

Examinations.	Candidates. Examined.	Passed.	Failed.
Major	4	4	0
Minor	96	54	42
	100	58	42

Four certificates received in lieu of the Preliminary :—

University of Durham	3
University of Oxford	1
	4

APPOINTMENT OF EXAMINERS.

The Council then proceeded to the election of two Examiners, to complete the number of fourteen, and upon a ballot being taken, Mr. George Spratt Taylor, of London, and Mr. Frederick Baden Benger, of Manchester, were declared elected. One Examiner was also required to be elected for Scotland.

The SECRETARY reported that he had received a letter from Mr. Mackay, stating that Mr. Tait, whose intended retirement caused the vacancy, was now willing to continue his services, and he was therefore unanimously re-elected.

LOCAL SECRETARIES.

Mr. WILLIAMS moved the resolution of which he had given notice that the Local Secretaries should be relieved of the duty now imposed upon them of collecting subscriptions. He said he had no wish to press this if there were the slightest idea that it would be offensive to local secretaries; his only motive was, that it was thought by the officers of the society that it would be much more convenient if subscriptions were paid direct, and not in the present round-about manner. As the collector for London had been removed, and all London members were now expected to transmit their subscriptions direct, he thought there could be no objection on the part of the country members to being placed in the same position.

Mr. SUTTON, as a Local Secretary, said he should be very happy to second the motion, because he thought it would relieve Local Secretaries of a great deal of trouble and difficulty.

Mr. ATHERTON also said he should be glad to be relieved of the duty, but at the same time he questioned the advisability of the proposal, and feared it would lead to a falling off in the number of members.

Several other members having expressed themselves to the like effect, Mr. Baynes in particular fearing prejudical consequences would arise to the Benevolent Fund,

Mr. WILLIAMS withdrew the motion for the present.

The Registrar placed upon the table a written copy of the register of Chemists and Druggists, arranged in alphabetical order according to the towns.

Provincial Transactions.

GLASGOW CHEMISTS' ASSOCIATION.

SESSION 1873-4.

The fourth general meeting of the Association was held in Anderson's University on Wednesday, the 24th December, 1873, at 9 p.m., Mr. John Currie, president, in the chair. Owing to its being Christmas Eve the attendance was not large.

The minutes of previous meeting having been confirmed, the Chairman stated that it was intended to have the annual festival a month earlier this session, and that the election of members of committee would now be proceeded with. At this point Mr. J. G. McMurdoch suggested that the festival might take the form of a *conversazione*, or of a supper and ball, instead of a *soirée* and ball as on last occasion. Mr. J. A. Clarke strongly objected to having either a *conversazione* or supper and ball, as he feared that a considerable amount of difficulty would attend the getting up of the former, while the pleasure attending the latter could, from obvious reasons, only be participated in by a limited number. He therefore proposed "that the festival take the form of a *soirée* and ball." Mr. Kinninmont seconded the motion. Mr. Murdoch, seconded by Mr. Foster, then moved as an amendment "That we have a supper and ball." On the amendment and motion being put to the vote it was found that the majority were in favour of the motion.

The following gentlemen were then elected as "Festival Committee," viz. :—Messrs. Hunter, Brodie, Fenwick, Murdoch, Fotheringham, Wallace, Galbraith, Young, McDonald, Ritchie, Clegholm, Bardsley, Paterson, Garry and Foster, with power to add to their number.

A discussion on "the Adulteration Act" then followed. Mr. Alex. Kinninmont, in an able and interesting speech, strongly condemned the Act, and said he thought its workings in connection with the drug trade had been so ridiculous and unjust that every chemist in the kingdom should do his utmost to get it repealed. Referring specially to the "citrate of magnesia" prosecution, he did not see how they as chemists had any right to alter the name of such an article as "citrate of magnesia," which had been known to the public by that name only for many years. At any rate he for one did not intend to change it, and he would further state that if any prescription for "cit. mag. eff." should chance to come to him he certainly would give the so-called article ; and that no chemist, in his opinion, would be justified in doing otherwise.

Messrs. Hunter, Brodie, and the Chairman also joined in the discussion, the Chairman remarking that it would be well for chemists to be on their guard in the meantime. He thought that for their own safety they should make some change in their cit. mag. labels in order to keep within the letter of the law.

Parliamentary and Law Proceedings.

ACTION AGAINST A CHEMIST AND DRUGGIST IN SCOTLAND.

In consequence of inquiries having been made respecting the particulars of the law suit referred to at a recent meeting of the Glasgow Chemists' and Druggists' Association (see before, p. 483), we have applied to Mr. Freeland, who has kindly placed at our disposal the following details :—

On the 26th November, 1872, a man of the name of Dawson, and his wife, went into Mr. Freeland's shop in Bathgate, whilst he was at tea, and asked for 3 oz. quicksilver and 1 oz. of nitric acid, to be put into a bottle. A lad, Paris, aged 17, an apprentice in his third year, put the chemicals into a two-ounce bottle, and placed the bottle on the counter with a cork in it ; but observing that the contents commenced to effervesce, he proceeded to ease the cork, when the mixture squirted up into his face, and at the same time a portion of the spray flew across the counter, and fell on Dawson and his wife, and on a woman named Hunter, who was in the shop making a purchase, and who was the female pursuer in the action afterwards brought. One drop fell on the latter person's head, and another on the side of her nose. All the parties immediately washed the acid off with water, a plentiful supply of which was in the back shop. The boy received nearly the whole in his face, and Dawson and his wife received a great deal more than the female pursuer (who, standing farthest off, received very little). Dawson only made a claim on Mr. Freeland for assistance to get a new coat, the one he had on being a little spotted with the acid, and was paid 22*s*., with which he was perfectly satisfied. The lad Paris was back at his work in the course of three days, and has suffered no permanent injury ; and there are no traces now of his ever having received any of the acid on his person.

The woman, Hunter, also made a claim for compensation, which was eventually pressed in the form of an action in the Court of Session, that came on for trial before Lord Mure and a jury on the 18th of November last, and occupied two whole days. The damages were laid at £350. It was alleged on behalf of the pursuer that the lad, Paris, was totally ignorant of the nature of chemicals ; that he placed considerable quantities of quicksilver and nitric acid in a bottle which he stoppered, thus causing an explosion, whereby the female pursuer was seriously burned on the face, arms, and head ; that she suffered intolerable and excruciating pain in the head for several days and nights, and still continued to suffer great pain from the effects of the explosion. Mrs. Hunter deposed that a great deal of her hair had come off, that her health had much changed, and that she was no longer able to work as she did before the accident. Dr. Kirk deposed that he was called in and found Mrs. Hunter, pillowed in bed, suffering much pain, with a good number of copper-coloured spots on the side of her head. In his opinion the symptoms were caused by a burning substance. She had never regained her former robustness.

For the defence, Dr. Longman deposed that he visited pursuer at defendant's request, when she complained of a burn on the head and in the right corner of her left eye. The only spot he observed was on the side of the nose ; and he considered she got off with almost no injury. Nitric acid produced a yellow, not a copper-coloured stain : he had experimented with nitric acid and quicksilver, which produced the same yellow colour, but was not so active as pure nitric acid. Dr. Littlejohn deposed that nitric acid, dropped on the skin and washed off directly, would not cause injury. Would ascribe the symptoms under which the pursuer was said to have laboured to a blow, a fall, or a cold. Dr. Anderson said that he saw pursuer on the 12th of March. On examination he detected a mark below the left eye. He found no trace of any marks on the head, and there was no appearance of loss of hair. She said that her health was very good, that she was well enough, and that she felt nothing permanently wrong with her. Dr. Watson deposed that spots such as described would not cause much injury. He doubted whether the copper-coloured spots had anything to do with the accident at all. If destruction of tissue had

taken place, the mark would have been permanent. No effect would be produced on the system.

After some other evidence the judge summed up, and the jury having retired, returned in fifteen minutes with a unanimous verdict for the pursuer, laying the damages at £12, with expenses. The foreman of the jury stated that they had not been guided in their decision so much by the injury sustained, as by the principle that more care should be taken in dispensing chemicals, and they intended it as a lesson to chemists to provide properly qualified assistants to take charge during their absence.

We are informed by Mr. Freeland that several attempts were made to settle the pursuer's claim without going into court, but unsuccessfully. Although the damages awarded amounted only to £12, it is estimated that the costs—in consequence of the case being carried into the Superior Court instead of being tried in the County Court—will amount to between £300 and £400. Mr. McDonald, of the Glasgow Apothecaries' Company, and other gentlemen, have kindly undertaken to receive subscriptions towards defraying these heavy expenses.

Review.

QUANTITATIVE CHEMICAL ANALYSIS: by Dr. C. REMIGIUS FRESENIUS. Sixth Edition (reprinted from the fourth). Translated from the fifth German edition by A. VACHER.

What we have been impatiently waiting for now fully four years has come at last: a new edition of the only trustworthy book in English on quantitative analysis. In 1870, when the fourth edition had been sold out, the publishers, it is true, at once re-issued the book under the editorship of Mr. Vacher; but, alas, what he gave us was not our trustworthy old friend whom we had learnt to love in spite of the pig-tail of pedantry that was dangling about the back of his head. That pig-tail we had come to consider part and parcel of the man, so that, if the editorial scissors of Mr. Vacher had cut off nothing else, we should even then have felt something like disappointment; but unfortunately, not the tail alone but a good portion of useful hair had disappeared too, and some of the head into the bargain, so that what was finally left was a Fresenius *minus* "Fresenius" *plus* Vacher; and this, both as to the negative and the positive term, was precisely what we did *not* want. We are glad to know that Mr. Vacher has seen the mistake he made at the time and now partly rectifies it. A book on quantitative analysis, if it is to be good for anything, *must* give full information regarding the *practical details* of the methods; because it is just these little things without which, in the execution of the processes, success is not certain, and it is these things which even the most talented student, in general, cannot be expected to find out for himself. And not merely the "student?" Is it not the same with professional chemists in all those cases at least in which they consult Fresenius for actual information, not for merely refreshing their memories? Smile as much as you like at Fresenius' pedantic minuteness in explaining the proper way of managing a sulphate of baryta or chloride of silver precipitate, or the true orthodox way of charging your potash bulbs or drying your combustion tube; still when, in the course of an investigation or a piece of commercial work, you come across a determination which you have never executed before, you may be very thankful to the old schoolmaster for his little bits of advice and turn them to good account. Granted that, if you are a chemist at all, you would have been able to find out all these things for yourself (and a great deal more, possibly, besides); but this is just what one would not have the time to do, and what it would be foolish to lose time over, if another man has done it for you.

To turn to the second point let us simply say, in plain English, that we did not want a book from Mr. Vacher, for the simple reason that we had no evidence of his being competent to write one. We do not wish to be rude to him; in fact, what we have to say against him is not more than what we should not hesitate to assert with regard to nine-tenths of the most eminent chemists of the country, and Mr. Vacher surely cannot feel hurt at his being condemned in such good company. A chemist may be the greatest scientific genius living and yet be utterly incompetent to write a book to supersede the one we have before us. No man should attempt to write a "Fresenius" unless he be a "Fresenius" himself, *i.e.*, unless he has made a speciality of analysis and devoted half his life to cultivating it *for its own sake.*

But stop, we are writing a critique of the fifth edition instead of attending to our immediate business and giving our opinion on the sixth. Well, in turning to the publishers, all we have to say is, that by this new edition they have rendered a great service to the chemical community; but, speaking to the editor, we are sorry to be obliged to say that he has again failed to do the right thing. Chemical science now-a-days, and its helpmate, analysis, with it, progresses with rapid strides, so that a book which was quite up to the mark in 1864, must necessarily, in many of its chapters, be antiquated in 1874. After having kept the public waiting for four years, why not have discounted their patience a little longer and brought out a translation—from the author's manuscript—of the *new* German edition now in course of publication? Or if this was not practicable, why not, by the addition of supplementary notes to the chapters that required them, bring up the book to 1873, a date which, in its present form, it has no right to bear on its title-page. We hope and trust that the publishers will lose no time in issuing a supplement to this book, to bring it up to its proper standard, or else they must not be surprised if some enterprising publisher should one day—by an obvious process—turn *their* book into so much waste-paper.

In the meantime, however, the book, even as it is, is *the* book on quantitative analysis, and none of the many chemists who are not enough of German scholars to read the original will fail to place it upon their laboratory book-shelves. The special part (pp. 541-722) alone is worth all the 18*s*. Here you find a full, accurate, critical exposition of all the best processes (or at least what, in anno so-and-so much, *were* the best processes) for the analysis of waters, silicates, ores of all sorts, manures, soda, bleach, tanning materials, sugar, etc.; and wherever you see the author recommending or condemning a method, depend upon it, his judgment is founded upon a thoroughgoing series of critical experiments, carried out either by himself, or at least under his immediate superintendence by one of his students, in his laboratory.

In fact, in its descriptions and critiques of special analytical methods, the book is simply the best that has ever been written, and it is questionable whether there ever will be a better one. The more purely scientific chapters are rather weak. The author's very lengthy explanations in chemical arithmetic especially are such that, with all our veneration for our old master, we often find it difficult to suppress a smile. *Vide*, for example, the chapter on gasometric calculations, which, without any loss of substance, might have been condensed into one-tenth of their present space, and thereby have been rendered much clearer than it is.

BOOKS RECEIVED.

YEAR BOOK OF PHARMACY, comprising Abstracts of Papers relating to Pharmacy, Materia Medica and Chemistry, contributed to British and Foreign Journals, from July 1, 1872, to June 30, 1873. With the Transactions of the British Pharmaceutical Conference at the Tenth Annual Meeting held at Bradford, September, 1873. London: J. and A. Churchill. 1873.

A CLASSIFIED AND DESCRIPTIVE CATALOGUE OF THE INDIAN DEPARTMENT OF THE VIENNA UNIVERSAL EXHIBITION, 1873. By J. FORBES WATSON, M.A., M.D., F.L.S., F.C.S., etc. London: W. H. Allen andCo. 1873.

Correspondence.

Homœopathic Concentrated Poisons.

Sir,—Allow me to remind your correspondent, "A Hater of Injustice," that the object of my recent communication to the Clinical Society was not to discuss homœopathic theories of disease and its treatment, but, by referring to three cases of alarming poisoning by concentrated solution of camphor, to show that modern homœopathic medicines are dangerously concentrated.

The printed directions on the bottles containing the preparation in question are "dose, two to five drops on lump-sugar, which may be repeated every half-hour, or oftener if necessary." So that the patient who took three drops every five minutes was strictly within the limits of the dangerously vague printed directions, while the two patients who much exceeded the prescribed dose probably did so under the erroneous impression that homœopathic medicines are weak and harmless, or they may have mistaken this saturated alcoholic solution of camphor for the much weaker spirit of camphor of the British Pharmacopœia. The mistake made by these patients is likely to be made by others, and, in fact, it has been made by others of whom I have heard. It is therefore obvious that the employment of this and similar concentrated poisonous drugs, is attended with considerable risk, and I repeat that to indicate this unquestionable fact was the sole object of my communication to the Clinical Society.

I venture now to suggest that no such dangerous concentrated preparations ought to be sold without the word "Poison" being plainly written or printed on the bottles which contain them.

George Johnson, M.D.

11, *Savile Row, Dec. 26th*, 1873.

Homœopathy and Allopathy.

Sir,—It is useless to discuss the merits of Homœopathy in the Pharmaceutical Journal, both because the minds of its readers are already settled upon that point, and because its "inappreciable" doses are not subjects for scientific investigation or logical argument. They are in every aspect "inappreciable," and must be swallowed in faith. Under these circumstances I fail to see the advantage of opening the columns of the Pharmaceutical Journal to an *anonymous* champion of an unphilosophical mysticism to attack the upholders of rational practice in such language as this:—

"I am sure no practitioner can honestly test the system without becoming a convert; and that no one could write as the Editor of the *British Medical Journal* does who had really investigated it. There is not a single dispassionate argument throughout either of these articles, which consist of nothing but distorted facts and clap-trap appeals of the most transparent kind. The Editor resorts to the last refuge of the defeated antagonist—a poor trick after all—to slander that which he cannot disprove. . . . He is bound either to establish his position by disproving the homœopathic law of similars, or to retract it, and apologise for having so grossly maligned a truth."

Now, this is simple scolding, of which we have enough at home, without this "Hater of Injustice" intruding himself into our Agapemone. But as I am equally responsible with the author of "The Dying Faith" for the statement of which he complains (See Pharmaceutical Journal for 1870, p. 823), it seems right for me to notice his attack.

He says that he is prepared to substantiate by facts and reasoning "that homœopathy never was a delusion and is not a fraud." I have done my best to extract all the pertinent facts (or opinions put forward as facts) in his letter, but of reasoning I can find none. This is of the less consequence as we none of us desire to dispute (however much we may disbelieve) the merits to which a *bonâ fide* homœopathy is pleased to lay claim: all that we care about is to expose the pseudo-homœopathy, which obtains its results by ordinary agencies, and fraudulently attributes them to veritably homœopathic treatment and infinitesimal doses.

The following assertions contain all that is pertinent to this last issue:—

1. "The dose is always infinitesimal, however concentrated the remedy, that is, it is less than sufficient to produce chemical or physiological action. . . They produce plenty of 'appreciable,' though no sensible effects."
2. "Many homœopathic dilutions do give positive results when chemically tested, but whether they do so or not is no argument against their therapeutic power. The only real test is their efficacy in combating disease, and this is being proved every day and hour."
3. "Five drops" (of Homœopathic Camphor are to be taken) "every 5, 10, or 15 minutes, according to the severity of the symptoms."

It is only necessary to state that fact No. 3 gives as the maximum "*homœopathic*" dose of *Camphor* 24 grains in the first hour (equivalent to 35 ozs. Camphor Julep*), and we cause the above facts to knock one another over like a pack of cards, carrying with them the pretended practice of infinitesimal doses! Our outraged "Hater" further informs us that until he read of it in "The Dying Faith" he had never heard of "pseudo-homœopathy," and he adds, that in his opinion "both systems have their value." Now it seems likely that a man who could swallow 24 grains of Camphor as a homœopathic dose, would scarcely be suspicious enough to discover anything not obtrusively thrust under his nose, but it does not follow that persons whose suspicions are aroused by pretensions which set all scientific conclusions at defiance should be equally obtuse. We also know that it is not uncommon for homœopathic practitioners to hold such opinions *as to the merits of both systems*, and to be willing to play on either string according to the pleasure of their patients. Can we help suspecting that they play *on both strings* for their own advantage? At all events, we know from your correspondent's admission that they give camphor in extreme doses. I have recently learned beyond all question that they give phosphorus in doses of a single drop to an extent which I confess I should be glad to be able to imitate, producing effects which are not only sensible but offensive, and there are few of us who within the limits of our own observation have not known potent remedies such as calomel given in full medicinal doses, under the guise of homœopathic treatment.

In conclusion, I will refer to one accusation brought against us by your correspondent which we often hear alleged by the devotees of homœopathy as a triumphant evidence of its superiority. It is that we have copied their remedies while we abuse their practice. While claiming our equal right to all the resources of nature, by whomsoever discovered or first applied, I would ask in return, and as an *argumentum ad absurdum*, what stock-in-trade homœopathy would have had to commence with if this exclusive rule had always prevailed. When orthodox practitioners copy the *homœopathic system* without acknowledgment they will deserve the obloquy which does somehow appear to be attaching itself to modern homœopathists.

Richard W. Giles.

Sir,—Instead of exposing, as is fashionable just now, the shortcomings of both systems of medicine, I should prefer that we should consider certain things which are common to both.

There are many diseases treated on different systems with equal success, and many cases in which diet and accessory measures are of more service than drugs.

Patients usually consider that they ought to have something administered to them, and are not satisfied without the doctor orders medicine of some kind.

The homœopaths are certainly wiser than the allopaths in not making their Pharmacopœia intelligible to the public, and I believe that more harm than is generally supposed has been done to patients, as well as medical men and chemists, by the publication of the British Pharmacopœia in English. I am very pleased to see that the proposed universal Pharmacopœia is to be printed in Latin, and should like to see the formulæ of our British Pharmacopœia in that language.

It is very desirable to educate the public in chemistry, physiology, and hygiene, so as to make them intelligent

* The equivalent of camphor julep will be found correct when allowance is made for camphor undissolved in the maceration.

patients, but I look upon it as quite another thing, and a very dangerous proceeding, to teach them how to make their own medicines. I do not mind patients reading their prescriptions, but do not think it necessary to tell them how to prepare the ingredients ordered.

From what I have seen of medical men and chemists when they have had the misfortune to become patients, I have been led to the conclusion that they would have derived more benefit from the remedies prescribed if they had not known the composition of them. In the case of unprofessionals, also, whether allopaths or homœopaths, I think this will be found applicable, and maintain, for the patients' sakes, that it is not desirable for them to prepare their own medicines, or to know the composition of them.

FRATER.

Sir,—

"Ill natur'd foes there are, and yet 'tis true
There are as senseless friendly bigots too."

I cannot let the remarks of a "Hater of Injustice," which appeared in your columns last Saturday, pass without a few comments.

The allopath will gain nothing by unfair attacks or unjust assertions, but the letter of your correspondent does not make it clear that the *British Medical Journal* has been guilty of either one or the other, beyond his own *ipse dixit* founded upon his own experience, which so far as the treatment of disease is concerned appears to be rather limited.

Now avoiding theories and disputed points as much as possible, it shall be my endeavour to state my reasons for believing that homœopathy is a delusion and a snare.

For forty years I have more or less been mixed up with the administration of medicine; part of that time in a London hospital and other institutions of a similar character.

Ten years ago, or rather more, my attention was drawn to the practice of homœopathy, and as it *appeared* to have many advantages, on account of the facility of getting fastidious patients to take small quantities of nearly tasteless medicine (the medicines themselves being comparatively without cost) I was induced to make a trial.

I procured some of the best works on the subject, Pharmacopœia, etc., and a good supply of remedies from some of the best homœopathic chemists; but after several years of study and practice, candour compels me to give it entirely up, as it uniformly failed in my hands to produce results at all equal to those obtained from allopathy.

And this has been a conclusion further confirmed by taking notice of its effects upon others wherever I have had an opportunity of judging, and which I have endeavoured to do most impartially.

The homœopath must not be too thin skinned, for the allopathic mode of treatment has received but little fairness at his hands; neither should he be surprised that until his own system is cleared from a good deal of the mysticism and empiricism which now seem to envelop it, that conscientious men who (after patient investigation) believe the definition given by the *British Medical Journal* as neither untrue nor unfair, say so, particularly on a subject of such momentous interest as the health and lives of the community.

And, in conclusion, I boldly affirm that the law of similars is not so unassailable as your correspondent seems to think.

A SEEKER AFTER TRUTH.

THE ADULTERATION ACT IN ITS RELATION TO DRUGGISTS.

Sir,—A Liverpool chemist has been convicted and fined for selling two ounces of mustard, simply because it was not pure *powdered mustard seed*. At the same time the prosecution was obliged to admit that there had been no fraud practised or intended. Does not this make the Act most unjust and oppressive in its application to the plainest comprehension? My own experience is that no one selling or purchasing the ordinary condiment called mustard understands it to be simply powdered mustard seed—this article is not liked by the public as a condiment, it is too sickening, and by no means so suitable for the purposes intended. It is plain from the evidence that the mustard was not sold as pure powdered mustard seed.

Now, as almost every chemist has possibly fifty or a hundred articles in his stock of daily sale which render him liable to the same tyrannical application of the law, is it not time to seek some common protection from proceedings which probably were never intended by the promoters of the Act, and which in the end must really defeat the object in view by bringing such proceedings into contempt? Let no chemist flatter himself that he is safe, and therefore can look with unconcern upon his unfortunate brethren who have been pounced upon. The law as it now stands can be applied in many ways not yet carried out, and certainly in one case already decided—the butter case in Liverpool—Mr. Kelly was put to more than one hundred pounds expenses to prove that his butter *was not* adulterated. I do not believe the House of Commons ever intended such an operation of the Act as this.

J. B.

Birkenhead, Jan. 3rd, 1874.

ERRATUM.—Through an erroneous transposition of words which occurred during the correction of the proofs of last week's number, the following correction is necessary in some copies:—Page 541, column 1, line 18 from bottom, for "as pure oleic acid," *read* "as well as pure oleic acid."

"*An Apprentice.*"—The contract of apprenticeship is at an end, but such a case is eminently suited for an arrangement.

J. N. Place.—Proctor's 'Practical Pharmacy' is published by Messrs. Churchill, price 12*s*.

Enitar.—There are two views entertained by botanists as regards the formation of the *pome:* one considers the fleshy portion outside the scaly or bony part in which the seeds are enclosed, as consisting of the combined epicarp and mesocarp, the former corresponding to the epidermis of the adherent calyx, and the latter to the combined cellular portion of the calyx and ovary; while the other considers this fleshy portion as the enlarged flower-stalk, as in the Rose, united to the calyx. Those who adopt the former view, regard the outer skin of the fruit as the *epicarp*, the fleshy part, which is eaten, as the *mesocarp*, and the core containing the seeds, as the endocarp (Bentley's 'Manual of Botany,' 3rd Edition, page 282); while those adopting the latter view usually regard the part within the outer fleshy portion as forming in itself the entire pericarp. These two views will explain the discrepancies referred to in the two books quoted.

W. H. W.—Please to repeat the question, as in its present form it appears to contain a mistake.

"*Hampton.*"—No; because its physical properties are entirely different.

"*Erin.*"—Professor Graham's original paper on 'The Law of the Diffusion of Gases' is printed in the *London and Edinburgh Philosophical Magazine*, vol. ii. (1833), p. 175; his paper on the 'Molecular Mobility of Gases' will be found in the PHARM. JOURNAL, second series, vol. v., p. 166.

M. P. S.—Yes.

R. J. M.—It is the albuminous seed of a palm, *Phytelephas macrocarpa*. Possibly other species also yield it.

T. A. Appleton.—We think there must have been some misunderstanding. The words of our answer last week were the actual words of the new bye-law, and admit of but one construction.

J. Smith.—At any time a candidate presenting himself must be examined according to the then existing regulations.

"*Plodding Student.*"—(1) Both are correct, one being an empirical, the other a rational formula. (2) Ammonium alum. (3) Yes, but you appear to have mistaken the formula of alumina for that of dried alum. (4) Yes.

Mr. Parkyns (Liskeard).—Your letter and enclosure have been handed to the Secretary. All orders for copies of the Journal should be forwarded to the publishers, Messrs. Churchill, 11, New Burlington Street, W.

"*Spes*" and "*Compositae*" are referred to the rule respecting anonymous communications.

W. H. Smith.—Stem bark is almost invariably present mixed with the root bark. The sample forwarded we consider to be above the average quality.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Lindsay and Blakiston (Philadelphia), Lillard (Nashville), W. M. Rogers, Spring (Brooklyn), R. Edwards, Fingland, Badcock, Gibson, "The Whole Truth," "Apis," "Erin," "Modified," J. H. R.

THE ADULTERATION OF POWDERED IPECACUANHA.

BY JOHN MERCER.

Now, when the Adulteration Act is being carried to such absurd lengths, and sometimes chemists are, without reason, dragged into police-courts, it is of the most paramount importance, if we intend to maintain that reputation for honesty and fair dealing which I believe we have justly acquired, that the greatest care should be exercised by us in taking into stock the various drugs and chemicals which crowd our shelves. None know better than we the difficulties to be encountered in pronouncing definitely upon the purity or otherwise of many substances with which we have to deal, and how absolutely we are in the hands of wholesale houses, and obliged to take their reputation as a guarantee for the genuineness of many drugs in daily use. It is true that microscopy, united with chemistry, will very much lessen the difficulty, but I am afraid the number well up in the former would be very insignificant if compared with the chemists and druggists' register.

I do not for a moment wish to cast any imputation upon the wholesale trade ; on the contrary, I believe the many firms noted for respectability would scorn the idea of entertaining for a moment a desire to adulterate any article ; but what I am about to state will show that, no matter how respectable or whatever reputation wholesale houses may possess, it is not simply within the range of possibilities, but a fact, that they, too, can be deceived, and consequently deceive their retail customers.

This, I believe, will be found to be the case in many instances as regards powdered ipecacuanha. During the early part of last year I bought some pulvis ipecac., but the old stock lasting until a few weeks since, the new was not required. However, the old did not last for ever, and the new was opened for the purpose of making a preparation in which it was necessary that it should be mixed with a proof spirit tincture, and afterwards dried. My surprise may be imagined when I state that in about fifteen minutes a very strong odour of essential oil of bitter almonds was given off. This fact at once aroused my suspicions, and as I was not aware of any substance containing emulsin and amygdalin in such quantities as to give off such a powerful odour of the bitter almond as was the case with the ipecacuanha in question, I concluded that "almond meal" must have been mixed with the powdered root for the sole purpose of adulteration.

My next thought was to examine the product of decomposition for hydrocyanic acid, which was done in the following manner. About 40 grains of the sophisticated powder was rubbed to a cream with water, introduced into a small retort, and digested at about 90° for half an hour. Distillation was then carried on cautiously into a small receiver kept cool, and containing about one drachm of water, into which the delivery tube dipped. This distillate gave convincing evidence of a considerable quantity of hydrocyanic acid upon the application of the "nitrate of silver," "sulphocyanide," "Prussian blue," and "guaiacum" tests.

The remainder of the "powder" was then returned, and a fresh quantity ordered from another source, in which, to my great amazement, the same adulterant was discovered, though not to the same extent.

I have not examined the powdered ipecacuanha in question for the *quantity* of prussic acid it was capable of producing, therefore I am not prepared to say what might have occurred if it had been dispensed for a child, something in this style, which I have frequently seen :—Pulv. Ipecac., 40 grains in a two-ounce mixture, dose one drachm every fifteen minutes, until sickness be produced.

With reference to the sources from which the above two samples of ipecacuanha powder were obtained, it suffices to say that they were both respectable houses, the first from a London house which would consider it an insult to be counted second to any other house in the trade. Both firms were astounded when I returned the powder as adulterated, but upon examination the fact was too clear to be disputed, and upon sifting the matter both arrived at the conclusion that part of the root had been abstracted at the mill by one of the workmen, and its weight made up with "almond meal." How long this roguish trick has been practised, or into how many establishments this rubbish, or worse than rubbish, has found its way I know not, but that the evil may be widespread is evident, and to remedy it as far as possible I have thought it only right to publish the case in this journal.

That each member of the trade may satisfy himself as to whether his pulvis ipecac. is free from "almond meal" or otherwise, it is only necessary to make into a paste with water a small quantity of the powder, and let it stand in a warm place for half-an-hour. If at the expiration of this time it retains the peculiar flavour due to ipecac., it is free from bitter almond meal, but if it has a distinct almond flavour, return it at once to the source from which it came as adulterated.

In conclusion I may add that, having retained a small quantity of both samples of adulterated powdered ipecacuanha, I shall be glad to send a little to any gentleman of microscopic ability, who might wish to examine them.

Preston, Jan. 12, 1874.

A NEW FALSIFICATION OF CINCHONA BARK.*

BY M. BERNATZIK.

The new falsification of cinchonas to which attention is drawn by the author, consists in moistening valueless barks with an alcoholic or acetic solution of quinoïdine. The chemical examination of barks thus treated leads to enormously high figures as representing the amount of alkaloids. One sample analysed gave 5·92 per cent. of bases instead of the 1·24 to 3·45 per cent., indicated by De Vrij for true bark. These cinchonas cannot be distinguished in appearance from non-treated bark of good quality. The sample examined by the author agreed with the type (*cortex chinæ fuscus*, of Java) of the collection of the Institute of Vienna. It consisted of the younger branches of *C. Calisaya*, Wedd., and of *C. officinalis*, L., and was in quills about 42 centimetres long, 1 to $2\frac{1}{2}$ centimetres in diameter, and $1\frac{1}{2}$ millimetre thick.

For the rapid and preliminary assay of these falsified barks M. Bernatzik recommends the careful examination of all suspicious points with the aid of a lens. The fracture of the long pieces and the colour of the inner surface of the small finely rolled quills are noted. The whole of the piece or pieces is then

* *Journ. de Pharm. et de Chemie*, Jan., 1874, p. 49.

reduced to fragments not more than one centimetre long, and these are well mixed. Five grammes of the fragments are introduced into a test-tube, well shaken down, covered with chloroform, and allowed to macerate for half-an-hour, with occasional agitation. The liquid is filtered away and evaporated to dryness on a watch glass. What remains is wetted with one, two, or three drops of hydrochloric acid, and then triturated at first with a little water, afterwards with a larger quantity (1 to 2 c.c.). Again filter and wash the filter with 1 c.c. of distilled water. If quinoïdine is present the liquid is more or less deeply coloured yellowish brown; if absent there is no coloration.

If half of the filtered liquid be mixed with chlorine water and ammonia added, the emerald green colour of the isomers of quinine manifests itself; sometimes a green flocculent precipitate is obtained which dissolves in excess of ammonia, producing the same emerald green. Too much chlorine gives only a yellow colouration. The addition of soda solution to the other half of the filtered liquid causes a turbidity or precipitate which dissolves on agitating with ether.

If the fragments of cinchona treated as above have yielded no quinoïdine, dry them with bibulous paper and treat with cold distilled water, which dissolves the salts of quinoïdine introduced (if they be acetates); at the end of half-an-hour, filter. The filtrate is almost void of colour if the bark be unsophisticated, but is coloured if the bark has been tampered with as above. Soda causes a precipitate in it which disappears with ether.

In those cases where the barks have been only slightly adulterated, or where part of the quinoïdine salts added has been lost by moisture, it is well to unite the products of the two modes of treatment.

Finally, in cases where the falsification has been effected with an insoluble salt, it is expedient to treat a fresh sample with water containing 1 per cent. of sulphuric or hydrochloric acid. At the end of some minutes the alkaloids adhering to the surface are dissolved. In this instance the precipitate formed by caustic soda contains some isomer of cinchonine and does not dissolve completely in ether. Chlorine and ammonia should give no green coloration; otherwise the cinchonidine will not be completely exempt from quinoïdine.

The same procedures may be employed where barks have been falsified by cinchonine or cinchonidine in alcoholic or acetic solution.

THE ALKALOIDS OF THE CINCHONA BARKS.*

BY O. HESSE.

It was in the year 1638 that the corregidor Juan Lopez di Canizares, by his celebrated cure of the Countess Chinchon, attracted the attention of the physician Juan di Vega to the bark of a tree growing in the district of Loxa, and thus became the originator of a literature which, however extensive at the present time, nevertheless, upon many points gives no certain information. This uncertainty arises from the fact that as the subject became gradually more accessible to investigators it was taken up by persons who were not in a condition to surmount the difficulties by which they were met in the investigation of the barks in question. The result was, that the confusion which was originally limited to the domain of pharmacology and botany at last extended to chemistry also. And although the discovery of the active febrifuge principles of these barks—quinine and cinchonine—provided a surer basis for future researches, nevertheless other substances were afterwards frequently confounded with these, and the longest known alkaloids were again announced as new discoveries. Yet they were found to be possessed of peculiarities which had not been noticed in the previously discovered substances, in consequence of the unsatisfactory manner in which they had been investigated.

It seemed to me, therefore, worth the trouble to take in hand a small excursion into this domain, the results of which are given in the following. But before I proceed to the subject itself it will be as well to say a few words upon the cinchona barks.

Under the cinchona barks were included, until the last twenty years, the barks of all the trees and shrubs which, in the "Species Plantarum" (1753), were included by Linnæus in the genus *Cinchona*. Later, Karsten divided this genus into three parts, namely, into *Cinchona*, *Heterasca*, and *Ladenbergia*. Then Weddell* reunited the last two—forming of them the genus *Buena*—and gave the following characters as those by which the species belonging to the genus *Cinchona* might be distinguished from allied plants:—the dehiscence of the seed capsules from the base upwards, the felted clavate hairs which cover the corolla-limb, the fragrance of the flowers, and the yield of the true alkaloids from the bark of the trunks. Relative to this latter character, which he considers of great importance in the diagnosis of cinchona bark, Weddell adds, Howard informed him in November, 1869, that experience had confirmed that the yield of the true cinchona alkaloids is restricted to the barks of the *Cinchonas;* and he is therefore of opinion that it is an axiom so surely founded that it cannot be overthrown by any objection brought against it.

The species of the genus *Buena* would therefore yield only such barks as do not contain alkaloids, or at least not the same as are contained in the true cinchona barks. As, on the other hand, the cinchona barks or true quinine barks, received by us as such from South America, present a constant similarity in their anatomical structure, wherein barks from the genus *Buena* essentially differ, there would appear to be a constant relation between the chemical and morphological properties of the plants.

Meanwhile, I have before shown that the "china cuprea," which in its physical structure differs considerably from the true cinchonas, yet contains quinine and other alkaloids which are met with in the cinchona barks. It also appears that genuineness of the cinchona bark does not altogether depend on the yield of quinine, for Karsten,† studying the cinchonas growing naturally in their native country, has demonstrated the fact, which I have also confirmed here,‡ that sometimes the bark of a *Cinchona* contains not a trace of alkaloids. He has also shown, by numerous experiments upon *C. lancifolia* and *C. corymbosa*, that the alkaloidal yield is probably not conditional upon the individual species of the plant, but that the soil and the climatic conditions upon which depend the nutrition and development of the plant call them into existence. These variations, however extend not only to the relative quantity of each alkaloid, but, as has been shown in the *C. succirubra* cultivated in the East Indies, also to their entire nature.

We may, therefore, expect to see the continued experiments made in different places upon the acclimatization of the cinchonas lead even to the production of new alkaloids.

I. Quinine.

Quinine was discovered in 1820 by Pelletier and Caventou, who especially investigated closely its combination

* Translated from the 'Vierteljahresschrift für praktische Pharmacie,' vol. xxii., p. 366.

* *Note sur les Quinquinas.*

† *Die Medicinischen Chinarinden Neu-Granada's*, s. 17 and 20.

‡ *Ber. Deutschen Chemischen Gesellschaft*, iv., 818.

with sulphuric acid, the properties of which allowed of its easy and convenient separation from other free bases occurring simultaneously in the cinchona barks. At first they employed in the preparation of this compound, bark which contained quinine principally, and only a small proportion of the other cinchona alkaloids, so that from such it was easy to obtain a pure sulphate of quinine. Even thus early, however, other amorphous cinchona alkaloids were confounded with quinine, because that portion of the alkaloids which was soluble in ether or chloroform, was, without any further attempt at separation, simply taken for quinine. But this error did not hinder the production of the sulphate of quinine, because in the preparation of that salt the foreign substances remained in the mother liquor. Only in a few cases where barks contained a considerable quantity of cinchonidine, it might, perhaps, happen that the sulphate of quinine would not be free from sulphate of cinchonidine. The statement, therefore, of Broughton and others, that before 1854 sulphate of quinine could not have been prepared in a state of purity, because it was not known how to separate quinine from quinidine, is not in accordance with fact, and requires modification.

Quinine forms with sulphuric acid three combinations : a neutral salt, which crystallizes from water with $7\frac{1}{2}H_2O$,* and from alcohol with $2H_2O$; a salt containing one equivalent of acid, and one containing two equivalents of acid. Upon quinine and its salts I have before reported at length, so that at present I will confine myself to only a few remarks respecting them.†

The sulphate of quinine with one equivalent of acid, known in commerce as bisulphate, had already been prepared by Baup. According to Gerhardt, its formula is $C_{20}H_{24}N_2O_2$, $H_2SO_4+7H_2O$; but according to Kraut‡ it would be $C_{20}H_{24}N_2O_2$, $H_2SO_4+7\frac{1}{2}H_2O$. The numbers given by Baup, however, do not agree with either of these formulæ. This salt, prepared by myself in fine crystals by dissolving sulphate of quinine in dilute sulphuric acid, was carefully freed from the adhering mother liquor, and the perfect uneffloresced crystals were analysed.

0·893 gram. of this salt lost, at the ordinary temperature, in an exsiccator, 0·177 gram H_2O, and at 100° to 115° 0·0275 gram H_2O ; the salt was then anhydrous. These figures testify to the correctness of the formula of Gerhardt, and indeed of the seven molecules of water of crystallization, six are given off in the exsiccator ; the seventh is only driven off at 110° or 115° C.

Calculated according to the formula, $C_{20}H_{24}N_2O_2$, $H_2SO_4+7H_2O$.		Found by Hesse.		Baup.
SO_3 . . .	14·59	14·57		13·70
$6H_2O$ . .	19·71 } 22·99	19·82 }	22·90	24·66
H_2O . . .	3·28 }	3·08 }		

This salt dissolves at 13° C. in 11 parts of water, as was found by Baup ; in absolute alcohol, on the contrary, it dissolves with considerable difficulty. The crystals of this salt become opaque at about 25° or 30° C., when they lose one molecule of their water of crystallization.

The sulphate with two equivalents of acid is obtained by dissolving the preceding salt in an excess of moderately dilute sulphuric acid, and concentrating the solution over sulphuric acid. At a low temperature this compound is deposited in delicate white prisms, which may be purified easily by crystallizing them from a little hot water. It is very soluble in cold water, more soluble in hot water, less soluble in alcohol, and quite insoluble in ether. Its aqueous solution shows very clearly the known fluorescence of quinine. Under the influence of light the crystals quickly become a red-brown colour. Analysis of these crystals gave the following results :—

(1). 0·973 gram, dried in the air, lost in the exsiccator 0·1715 gram H_2O ; then at 100° C. 0·0205 gram H_2O : in all, 19·63 per cent. of water, besides 0·7125 gram of sulphate of baryta.

(2). 0·875 gram lost in the exsiccator 0·147 gram, then at 130° C. 0·023 gram H_2O.

(3). 0·9745 gram lost in the exsiccator 0·1645 gram, then at 100° C. 0·023 gram H_2O.

These numbers lead to the formula, $C_{20}H_{24}N_2O_2$, $2H_2SO_4+7H_2O$, corresponding in proportion of water of crystallization with the quinine sulphate with one equivalent of acid.

Calculated.			Found. I.		II.	III.
$2SO_3$ . .	24·69		24·61		—	—
$6H_2O$.	16·67 }	19·46	16·62 }	19·72	16·80	16·88
H_2O . .	2·79 }		2·10 }		2 63	2·36

Among the remaining salts of quinine I shall only mention the hydrochlorate, which has recently, through a substitution, or as Hager* thinks, an admixture with hydrochlorate of morphine, given rise to some unfortunate accidents. But as the two salts react very differently with dilute nitric acid (1 of acid to 4 of water) it is easy to discover whether hydrochlorate of quinine is pure or not. Hydrochlorate of quinine, dissolved in that acid, has a scarcely perceptible yellow tint, which does not change when the solution is exposed for some minutes to a temperature of 50° to 60° C. But if the suspected salt contain morphine the solution takes a colouration varying from yellow to orange red, according to the quantity of morphine present. If, for example, the salt of quinine contain 5 per cent. of hydrochlorate of morphine, the solution is coloured orange red ; if it contain only 1 per cent. the colour is dark yellow, and even if it contain only 0·2 per cent. a well marked change in the colour of the solution occurs. To prevent any mistake the following method of performing this test is recommended :—

Take two test-tubes of colourless glass, and of equal diameter, and introduce into each of them about 0·05 gram of the suspected but well-mixed substance, and pour into one about $\frac{1}{2}$ c.c. of dilute sulphuric acid, and into the other the same quantity of nitric acid diluted as above. Place both the tubes in warm water (from 50° to 60° C.) contained in a white porcelain or colourless glass vessel, so that any change of colour can be well noted. If the salt be free from morphine, at the end of five minutes both solutions will still be of the same tint ; but if it contain morphine salt, the nitric acid solution will change its appearance after a few moments, while the sulphuric acid solution does not vary in that respect. When therefore hydrochlorate of quinine tested in this manner presents a difference in the colour of the two solutions it should be excluded from use. It may be remarked however that other bases beside morphine give this reaction ; several of the opium alkaloids especially react in the same or a similar manner.

(*To be continued.*)

* *Annalen der Chemie und Pharmacie*, vol. cxix., p. 361. I consider it probable that sulphate of quinine crystallized from water, and absolutely free from efflorescence, would contain eight molecules of water of crystallization. As before pointed out, the salt which appears to contain $7H_2O$ has so evidently effloresced that this can be observed by the unassisted eye. Nevertheless, the formula with $7H_2O$, which Regnault proposed for it, is still frequently used, which shows how easily an error can become established.

SIXTY-FIVE YEARS OF PHARMACEUTICAL LIFE IN FRANCE AND AMERICA.

In August last there died in Philadelphia a pharmacist, in the person of Mr. Elias Durand, who for sixty-five years had been closely connected with pharmacy, first in the eastern, and afterwards in the western hemisphere. At the last semi-annual meeting of the Philadelphia College of Pharmacy, a portrait of the deceased gentleman was presented by his son to the College, and its acceptance was made the occasion for reading a very interesting sketch of his eventful life. To this document, printed in

* *Chem. Centralblatt*, 1872, p. 727.

the *American Journal of Pharmacy*, we are indebted for the following abstract :—

ELIAS DURAND.

Elias Durand (*Elie Magloire Durand*) was born in the town of Mayenne, France, on the 25th of January, 1794, second year of the French Republic, in the midst of the most trying times of the Reign of Terror, and was the youngest of fourteen children. His father, André Durand, was Recorder of Deeds at Mayenne, a man much respected, and though a royalist in opinion, he retained his position as recorder through the varying scenes and parties of the Revolutionary struggle and the Empire till his death in 1810, being forced at times to secrete himself with the funds and records to save them from the party in temporary power.

During the period between 1794 and 1808 young Durand lived in his native town, and being placed in due course at the Collegiate school, passed through the regular studies. About this time his interest was attracted to the study of chemistry, then claiming a large share of scientific attention, which was probably the cause of his becoming a pharmaceutist, as, in October, 1808, he was entered as an apprentice to M. Chevallier, of Mayenne.

During the first winter of Durand's apprenticeship he pursued the study of natural philosophy and chemistry; in the spring he applied himself to botany. During the second winter his attention was directed to practical chemistry and the manipulations of the shop laboratory, his preceptor explaining from time to time the chemical reactions and combinations taking place during the operations carried on. The third winter was devoted to the study of materia medica and pharmacy, in connection with the collateral branches, mineralogy, geology, and entomology.

In 1812, when Napoleon was preparing the means for his invasion of Russia, young Durand, having completed his apprenticeship, and attained the age of 18 years, became eligible for the army, and, not wishing to be conscripted into the ranks, made prompt application to the Minister of War for the position of *Pharmacien* in the army, and immediately proceeded to Paris to prepare himself for examination before the Board of Examiners. There he attended the lectures of Thenard, Gay Lussac, Lefèvre, Ginault, and a course of lectures on French literature by the celebrated Andrieux. Having received notice from the Minister of War that the 10th of January, 1813, was appointed for his examination, he presented himself accordingly, and the next day was informed by M. Parmentier, the Chief of the Pharmaceutical Department of the Army, to whom all the answers of the candidates were submitted, that he had passed at the head of the list.

On the 2nd of February he received his commission as *Pharmacien sous-aide* in the 5th Corps of the Observation of the Elbe, with orders to cross the Rhine on the 15th of March. On the appointed day he presented his commission to Marshal Kellerman, commanding at Mayence, who ordered him to proceed at once to Magdeburg, the head-quarters of the 5th Corps. He joined a detachment of fifty men from the Military Hospitals at Mayence, commanded by young officers from the Military School of St. Cyr, and was eleven days *en route* to Magdeburg, chiefly on foot. On arriving, the men were nearly all entered in the 5th Corps, commanded by Prince Eugene Beauharnais, then numbering 70,000 men. Young Durand was assigned to the 3rd Division, under La Grange, near Magdeburg, and continued in the army fourteen months, till the abdication of Napoleon, having been present at the battles of Möckern, Lützen, Bautzen, Hanau, Katzbach, and Leipzic. During this brief period he experienced many severe hardships incident to a soldier's life, largely increased by the nature of the contest, which was virtually a retreat through a hostile country until they recrossed the Rhine. He was once taken prisoner at Hanau, but managed to escape.

In his capacity of pharmacien he was very little exposed to danger, unless voluntarily. His duty was to follow or precede the army, according as it advanced or retreated, and assist in the establishment of military hospitals when needed, so that when the army was in motion his duties were light, and being on horseback during battle, he was frequently an eye-witness to very important movements.

On the 3rd of April, 1814, Durand tendered his resignation as *Pharmacien aide-major* to M. Lodibert, the Pharmacien in Chief of the Corps (and afterwards President of the Société de Pharmacie), although urged by him strongly to remain in the army.

After a short visit to his home he went to the City of Nantes, and obtained the situation of head clerk in the store of M. Frétaud, one of the principal apothecaries, where he remained two years. At this time he gave his leisure to the study of botany, passing all his vacations in botanical excursions with the principal botanists of the place. During a part of this time he directed the Society's laboratory, called *Laboratoire du Jardin des Apothécaires*, and delivered a course of lectures on medical botany, during the summer months, to the apprentices in pharmacy, on the different medicinal plants cultivated in the garden. This laboratory was used in common by the principal pharmaciens of Nantes, to prepare their chemicals, and was so conducted that the management went by rotation, the materials contributed by different stores, say for calomel, nitrate of silver, ether, or other medicine needed, were made up together, and the products divided *pro rata*. In this way a great variety of costly apparatus was available to each member, quite beyond his ability to possess, and his advanced apprentices were afforded opportunities to assist and acquire practical knowledge.

On the return of Napoleon from Elba, Durand joined the National Guard against the Royalist party of La Vendée during the 100 days. After the battle of Waterloo, and Napoleon's final abdication, he returned to his duties at Nantes, but, being strongly suspected of Napoleonic proclivities, he was placed under military surveillance, and compelled to present himself every morning at the police station. This tyrannical order interfered very much with his business duties and caused great annoyance to his employer; disgust at the treatment he received determined him to abandon his country and seek beyond the Atlantic the freedom denied him at home. He reached New York on the first of July, 1816, and at once proceeded to Boston to visit Bishop Chevrus, afterwards Cardinal Chevrus, a distant relative, through whose influence he became acquainted with several scientific men of that city. Mr. Perkins, a druggist, made him an offer to establish a laboratory for medicinal chemicals, with the prospect of a partnership. He accepted the offer, started the works on the French plan, and began the manufacture of Rochelle salt, tartar emetic, spirit, water of ammonia, ether, etc., but he afterwards determined to leave Boston for Philadelphia, the city of his choice, where he took charge of the laboratory of a German, named Wesner, and manufactured chromates from the native ores of Maryland and Delaware. These salts were being successfully made, when Wesner, desiring to extend his business, engaged in the preparation of mercurial salts. This occupation occasioned Durand a spell of illness, accompanied by profuse salivation, which induced him to abandon the laboratory and return to his legitimate business, pharmacy.

Mr. Durand next went to Baltimore, and applied to Mr. E. Ducatel, a prominent pharmaceutist of that city, who would have engaged him but for his inability to speak the English language, and who advised him to devote himself to the study of that language, which he did for three months, at Belair, with considerable success. Returning to Baltimore, he hoped to enter Mr. Ducatel's store, but was disappointed. Not discouraged, however, our young adventurer set out on foot to find Dr. Gerard Troost, of Cape Sable, Maryland (afterwards the first Professor of Chemistry in the Philadelphia College of Pharmacy in

1821), who was engaged in making iron salts. It was in the midst of winter, the ground covered with snow, and the road unfrequented and difficult to find, owing to dense forests intervening, with only two houses on the road after leaving the vicinity of Baltimore. Having reached the first house noted on his paper about one o'clock, he applied for dinner. The appearance of the inmates was anything but favourable, and the wall of the room was hung with coloured pictures of Indian massacres, which impressed his imagination strongly. After paying for the ill-relished meal of pork and beans, he continued his forest journey about two miles, when he saw coming towards him some ten or twelve persons, strangely attired, quite different from anything he had seen before. As they came near it became apparent that they were wrapped in blankets, had painted faces, carried bows and arrows, and, in fact, were the counterpart of the pictures, being the first live Indians he had seen. With his ideas excited by the pictures he had just examined, aided by the uncouth character of the people at the house, he had some doubts of his personal security when thus brought face to face with the red skins in the forest, and for a moment felt undecided whether to advance or retreat, but, going towards them, one of the chiefs came forward and presented a paper for his perusal, which proved to be a recommendation from the President of the United States, stating that the chief and his warriors had been faithful to the country during the war of 1812 on the frontier. Our traveller, greatly relieved from his embarassment, gave the chief some money, shook hands with each of the troop, gave a hearty hurrah ! with his hat off, to which the Indians responded and passed on their way. Continuing his journey, the snow increased, night set in before attaining his destination, and seeing a light in the distance, he went towards it for shelter until morning. He was kindly received, and, on inquiry for Dr. Troost, was informed that he was four miles out of his way, and was invited to remain. A death had occurred in the family, many relatives had gathered to attend the funeral on the morrow, and no other place could be offered him for lodging than the room where the dead man was laid out. Having attended the funeral, the first country burial he had seen in America, he was greatly surprised to find the dinner feast which followed on the return of the guests to the house, and of which he partook, reminding him more of a marriage occasion. His host kindly sent him to Dr. Troost's, with a negro guide.

Mr. Durand was kindly received by the Doctor, who, however, did not need his services, as the rough processes of the copperas manufacture were chiefly conducted by negroes, but invited him to remain and keep him company as his guest, being much in need of social intercourse in his isolated home. He found Dr. Troost a learned chemist, mineralogist, and geologist, with a general acquaintance with the sciences, and when urged, accepted the hospitable invitation to remain until the end of winter.

About this time he received proposals from Mr. Ducatel to take charge of the pharmaceutical part of his business, and on the 5th of April, 1817, he entered on the duties of his new position. His professional knowledge was appreciated, business flourished, his employer was well satisfied, and extended towards his new clerk many acts of kindness as well as his love and affection. Mr. Durand often spoke of the social advantages he received whilst resident with Mr. Ducatel, among which was meeting with eminent Frenchmen in exile. It was during his stay in Baltimore that he began to study American botany, and to form the nucleus of the great herbarium which he afterwards acquired.

On the 20th of November, 1820, he married the daughter of his friend and employer, Miss Polymnia Rose Ducatel, who died on the 18th of February, 1822, leaving an infant daughter, who lived to the age of fourteen years.

In May, 1823, E. Ducatel retired from business, leaving his establishment to his son, Jules Ducatel (afterwards Professor of Chemistry in the University of Maryland), and his son-in-law, E. Durand, who entered co-partnership as E. Ducatel and Sons, which continued only a year, Durand retiring, with the view of establishing himself in Philadelphia. He also determined to visit France, to procure his *matériel*, and in July, 1824, he left New York for Havre in the ship "Sylvie de Grace," arriving on the 14th of August. His time was employed in selecting stock, apparatus, and bottles (which were duly labelled for use and of the heavy French pattern), together with everything needful for a first-class French "officine," and returned in the same vessel to New York on April 22nd, 1825.

The house then existing at the south-west corner of Sixth and Chesnut Streets, where the "Ledger" office now stands, was for a consideration of 500 dols. ceded to Durand for a ten year's lease. On the reception of his goods he fitted up the store at considerable expense, using French glass ware, porcelain jars, mahogany drawers and marble counter, in a style unique and attractive in that day. But the most important part was the stock of drugs and chemicals he had selected, including many novelties, and the apparatus for making and vending carbonic acid water. Coming well recommended from Baltimore, as well as from abroad, the principal physicians, Physic, La Roche, Monges, Bache, Jackson, Griffith, Dewees, and others, were prompt in patronizing the store, and its enterprising proprietor soon had a flourishing business.

In 1825, Mr. Durand married a second time, Miss Marie Antoinette Berauld, daughter of a merchant of Norfolk, Va., one of the French refugees from the St. Domingo Insurrection. (He had four children by this marriage, all of whom died young, except his son, Alfred B. Durand, who survives him.)

In 1825 he was elected a member of the Academy of Natural Sciences of Philadelphia. This brought him into contact with men of science and opened a field of usefulness for his botanical talents, which he cultivated with great zeal and success, and corresponded with many botanists in Europe, by which his collection of plants was greatly extended. In the same year he became a member of the Philadelphia College of Pharmacy, and in 1832 was elected a corresponding member of the Société de Pharmacie of Paris, and contributed valuable original articles to the journals of both Societies. In fact, he wrote the first article of the first regular series of the *American Journal of Pharmacy*, and others are scattered through the following ten volumes. In 1829, in connection with Dr. Togno, he translated and published Edwards and Vavasseur's 'Manual of Materia Medica and Pharmacy,' to which he made many additions of a pharmaceutical character, before the publication of the 'United States' Dispensatory.'

At the period when Durand opened his store, French pharmacy stood confessedly far in advance of that of all other countries, whilst his thorough education and recent visit to France for stock, etc., gave him such great advantages that his store became an important centre of pharmaceutical information, which directly and indirectly had much to do with the introduction of scientific pharmacy into Philadelphia. Many of the finer medicinal chemicals were made first by Durand, which gave him a prestige in the United States, and his great skill as a pharmaceutist, his untiring industry, close attention to business, and social and scientific qualities attracted the most eminent physicians to his store, which became the daily resort of such men as Drs. Horner, McClellan, Mitchell, Meigs, Mütter, Bache, and Goddard. The possession of a good library, and the monthly reception of important foreign journals, enabled him to study new medicines promptly; and many new preparations, as solution of iodide of iron, kermes mineral as now made, iodide of arsenic, iron by hydrogen, etc., were first introduced through his store. This devotion to his profession soon rendered "Durand's drug store" well known to the general public, and gave a great impetus tohis prescription business.

Durand took pains in training his apprentices; and some of the best American pharmaceutists emanated from his counter. He required of them daily study of articles in the Dispensatory, and it was his custom to examine the packages of drugs for stock when received, making it the occasion to point out to his boys and assistants the faults and merits of the articles. Looking at pharmacy as a profession, requiring education and training for its success, he taught them to respect their business, and always manifested a warm interest in their progress. One of his *élèves* has said "he never required those in his employ to do that which he would not willingly do himself, and his intercourse with them was not that of master, but of a genial friend." The writer (Professor Procter) remembers gratefully when, in early life, he was engaged in investigations under great disadvantages for want of accurate instruments, his friend Durand imported a set of French metrical weights, and presented them to him with a word of encouragement.

In 1835 Durand was the first to introduce the bottling of mineral waters in the United States, and opened a large establishment in Sixth Street above Arch. The apparatus for manufacturing the waters, and especially that part of it for bottling under pressure, was of his own invention and superior to any then in use in France. He afterwards sent the apparatus to the Société de Pharmacie, and it was adopted into use in Paris. He also at this time extensively manufactured vinegar from cider by a quick process, by which air was forced through the cider and rapidly acetified it. This business was in full and successful operation when the money crisis of 1837 prostrated the commercial community, and with it this branch of his business, with great loss to the manufacturer, who afterwards adhered closely to his legitimate profession until his retirement.

About this period, and for many years after, various valuable contributions to American pharmacy came from Durand's store, through the late Augustine Duhamel, who was a *protégé* of Durand and identified with his store, having been for many years his chief clerk. The *process of displacement*, now called percolation, was there first introduced to America by Duhamel, and his active pen placed on record, in the *American Journal of Pharmacy*, from vol. vi. to vol. xviii, many valuable evidences of his industry and research.

A peculiarity of Durand's business was the number of specialties he introduced, original or of foreign origin, partially growing out of the patronage of particular physicians. His long experience had given him considerable knowledge in therapeutics, and his medical friends willingly availed themselves of his hints in his efforts to render their prescriptions elegant and acceptable as well as efficient compounds.

Through all the varied engagements, disappointments and losses of Durand, his interest in botany never wavered, and it appears to have been a source of great pleasure and satisfaction. In 1837 he made an expedition to the Great Dismal Swamp of Virginia, where he acquired many interesting specimens. His friendly relations with Joseph Bonaparte (Count Souvilliers) caused him often to visit the fine country seat of the latter, at Bordentown, famous for its botanical treasures, where he met and was useful to many of his countrymen in exile in their inquiries regarding American institutions. He spoke of the Count as a man of mild and polished manners, unaffected, and gifted with a most agreeable flow of language. Possessing great erudition, he yet suited his conversation to the person conversing with him, making intercourse with him pleasant and agreeable, and he seemed to be perfectly familiar with all the natural sciences.

In 1840, when the Philadelphia College of Pharmacy was invited to assist in the revision of the U. S. Pharmacopœia, Durand was one of the committee appointed to that service, in which he took part and contributed valuable suggestions to the work, several of which yet remain after three successive revisions. The writer served with him on this committee, and well remembers his valuable labours and counsel given on that occasion.

In 1844 Durand was elected Vice-President of the College of Pharmacy. In 1851 Mrs. Durand, who during twenty-six years had been his companion and friend, died at their home in Ninth street, which event induced him to retire from business in favour of his son, and devote his leisure time entirely to botanical studies. Though so long a resident of the United States, and possessing an excellent command of the English language so as to write it fluently and correctly, his conversation was always marked with a French accent, and sometimes with French idiom. He was a good Latin scholar, wrote with great facility in a close set handwriting, and was the author of several biographical and scientific memoirs. In 1854 he was elected a member of the American Philosophical Society, and was subsequently one of its curators.

In 1855 he published, in connection with Dr. Hilgard, a memoir on the plants collected in the expedition of Lieut. R. Williamson, U. S. Engineer, to California, and another called 'Plantæ Prattenense' on an extensive collection of plants made by Mr. Pratten in Nevada and adjacent territory. In 1856 he published an enumeration of the plants collected in Dr. Kane's first expedition to the Arctic regions, in the Journal of the Academy. About this time he wrote and read before the Philosophical Society a biographical memoir of the late François André Michaux, the author of the 'Sylva Americana,' who willed a sum of money for the establishment of a park of American forest trees, which is now existing in Fairmount Park, and known as the "Michaux Grove." In 1857 he commenced the work of separating the North American plants in the herbarium of the Academy of Natural Sciences, and forming them into a distinct collection, which occupied him several years, often working four hours daily in the botanical room of the Academy. His labours in connection with this valued institution will, however, be more fittingly enlarged upon by a special memorialist appointed by the Academy. In this year he was elected an honorary member of the American Pharmaceutical Association. In 1859 he published a memoir entitled, 'A Sketch of the Botany of the Basin of the Great Salt Lake of Utah.'

In 1859 his friend, Dr. Thomas Nuttall, author of the three volumes in continuation of Michaux's 'Sylva' and other works, and so many years the botanist in chief of the Academy of Natural Sciences at Philadelphia, died in England. The memoir written of him by Durand is said to be one of the best notices of that distinguished botanist and ornithologist, of whom he was the successor in the botanical department of the Academy.

In 1860 Durand visited France a second time, and derived great pleasure from intercourse with his relatives, and many friends who had been with him in "*The Grand Army.*" He also for the first time visited England, and was greatly pleased with the gardens and museums of London and vicinity. Whilst in Paris he had occasion to examine the herbarium of the "Garden of Plants," and finding the collection of North American plants very incomplete, he determined to remedy the deficiency by sending over his own fine collection. Ascertaining, however, on his return, that he could yet make valuable additions to his collection, rendering it more complete, he subscribed to all the botanical expeditions, and set to work himself to collect, making excursions every summer, returning always with rich harvests of plants. Finally, in 1868, after putting his herbarium in order by arranging the new specimens in proper position, he packed the whole carefully and shipped it to France, following it on the 26th of June, in company with his son and daughter-in-law, in the "Ville de Paris." Durand's collection, the work of many years, contained over 10,000 species and over 100,000 specimens from all parts of North America. This munificent gift to his native country was fully appreciated, especially by the professors at the Garden of Plants

Museum, where it has been arranged in a special gallery, and labelled "*Herbia Durand.*"

About the year 1858 Mr. Durand presented to the Philadelphia College of Pharmacy a general herbarium of about 12,000 specimens, which forms the nucleus of the present collection in its museum.

After his return from France in 1869, he wrote an elaborate article on the genus *Vitis*, of North America, and the relation of the cultivated varieties of the grape to the natural species, together with remarks on the wines made in the United States, and sent it as a contribution to the proceedings of the Linnean Society of Bordeaux, France. This essay attracted considerable attention abroad, and was reprinted by the Société d'Acclimatation, of Paris. He subsequently was elected to membership by both societies.

As a citizen, Durand took but little part in political or municipal affairs. His social and scientific qualities endeared him to all who came in close contact with him. One who knew him intimately says "he was a man of generous impulses, and his private charities were numerous." He was an active member of the French Benevolent Society, Philadelphia, took an interest in rendering it available to his needy countrymen in this city, and remembered it in his will.

After his last return from Europe he continued his interest in botany in favour of his collection at Paris, but feeling that age was advancing, and that he had worked industriously and effectively during his long life, he gradually relinquished his scientific engagements. Finding his bodily powers and faculties depreciating, he quietly retired from his usual walks, and after a season of depressed intellectual vigour, he slowly faded away in the eightieth year of his age, and died on the 14th of August, 1873, at his residence in Broad Street, Philadelphia, honoured and respected by all who knew him.

PREPARATION AND COATING OF IODIDE OF IRON PILLS.

In an article in the *Journ. de Pharm. et de Chimie*, (vol. xviii., p. 328) M. Magnes-Lahens discusses the conditions most favourably for the preparation of iodide of iron pills. Some of the variations from the Codex recommended are already adopted in the B. P. The operation, he thinks, should be conducted at a temperature of 50° to 60° C. (122° to 140° F.) slight excess of iron should be present, and an iron dish should be used in preference to glass or porcelain vessels. His formula is as follows :—

Pure iodine	4·10	grams.
Powdered iron	1·90	,,
Powdered sugar . . .	2·50	,,
Powdered gum arabic .	2·50	,,
Distilled water. . . .	2·50	,,

Put the water and the powdered iron into an iron dish, add the iodine gradually, and assist the reaction by stirring with an iron spatula and gentle heat; when the reaction is complete, add the gum and the sugar, then heat to about 50° C., stirring continually, until the mass ceases to drop when a little is taken up with the end of the spatula. The mass may then be readily converted into pills or dragées.

To obtain the pills, incorporate into the mass 5 grams of powdered liquorice root, and if the consistence require it, heat it for some minutes; divide into one hundred pills, roll them in powdered gum, and, if desired, coat with mastic and tolu.

For sugar-coated pills (dragées), incorporate with the mass 7·50 grams of powdered gum arabic, then heat very slightly to soften it. The hundred pills obtained are rolled in powdered gum arabic, heated, and agitated with a circular motion in a suitable vessel, until of the proper hardness, after which they may be sugar-coated.

Each pill and each dragée contains about 5 centigrams of iodide of iron and one centigram of powdered iron.

The pills contain iodide of iron in a state of perfect purity. Put into cold water some months after their preparation, they will dissolve, save the excess of iron, without colouring it.

The following is the mode of coating proposed by M. Magnes-Lahens: Roll the pills quickly, about fifty at a time, with the hand in a clear mucilage of gum arabic spread thinly in a saucer; when they are completely moistened throw them into a basin containing a mixture of sugar, 9 parts, with gum arabic one part; agitate them until they are covered with a layer of the powder, heat them for about eight or ten minutes, at first very slightly, and afterwards increase the heat, rotating the pills continually. After cooling, coat them a second and then a third time, following the process just described. These pills may thus be prepared in small or large quantities; in the latter case they should be put in the drying closet after each coating. Made with this precaution they will keep a long time in a good condition.

SALT TRADE IN INDIA.

In the 'East India Progress and Condition Report' we find some interesting notes on this subject. The consumption of salt in India is given as 9½ lbs. per head in Bengal, and as high as 12 lbs. in Madras. In Bengal for a long period salt was obtained by an expensive process of evaporation, conducted along the coast of the Bay of Bengal. The Government bought all the salt so manufactured, and stored it up in warehouses, and thus had the monopoly of sale. This system, however, was found to be a bad and expensive one, and was abandoned in 1863, when the price fell 50 per cent. Last year 5,765,177 cwt. was imported, chiefly from England, but some also came from France, Bombay, Sind, and the Persian Gulf. The total revenue from salt for the same year in Bengal amounted to £2,578,134. Recently some of the richer inhabitants suggested the raising of the tax, but the Lieutenant-Governor "declared he would rather cut off his right hand than be a party to increase the tax on a first necessity of the poor, which is already enormously high."

Throughout India the feeling is that the tax is as high as it safely can be, and a desire is spreading to equalize the tax throughout India, since it varies much in different parts. In the North West Provinces the salt is obtained from "salt lakes," which during the rainy season overflow, and leave behind, when they recede, a thick incrustation of salt. The revenue for the year was £803,285, and the expenses £88,562. In the Panjab salt is obtained from mines and salt lakes, and yielded a revenue during the year of £800,236, with expenses of £78,490. The Salt Range in the Panjab is practically inexhaustible, the principal beds being 150 to 200 feet thick. The mines are worked by galleries and excavations, or, when the salt is near the surface, by quarrying, Dr. Oldham states, that nowhere else in the world are salt deposits known of such vast extent and purity. In Bombay the revenue for the year was £657,289, from the Government monopoly and import duty. Much, however, is smuggled.

In British Burma the net revenue was £11,477. In Madras the net income amounted to £1,153,425. There, too, the Government has a monopoly; they contract with the manufacturers at the different salt works, store up the salt, and fix the price at which it shall be sold. The sum of £40,000 is paid annually to the French Government at Pondicherry not to manufacture salt, but to buy its supplies from Madras, and sell the salt at the same price as it is sold at in Madras. The abolishment of this monopoly does not, however, appear to be contemplated.

THE PHYSIOLOGICAL AND THERAPEUTIC ACTION OF EMETINE.

BY DR. A. E. D'ORNELLAS.

Under the above title the author has written a lengthy memoir; the following are some of the conclusions which he has formulated :—

1. Emetine is the active principle of ipecacuanha, to which its powerful physiological and therapeutic action is due.

2. The fat odorous nauseous principle is but an accessory.

3. In medical practice emetine should not be substituted for ipecacuanha, as it is not so perfect a medicament.

4. Emetine has an irritating topical action upon the mucous membrane, and upon denuded flesh, but not upon the intact skin.

5. Emetine injected hypodermically into animals or human subjects induces vomiting, as when administered by the stomach, but more slowly and in larger doses.

6. Emetine introduced into the circulation is always eliminated by the gastro-intestinal mucous and liver, and it causes vomiting up to the moment of its elimination.

7. Emetine during its elimination by the intestinal mucous causes stools more numerous in proportion as its emetic action has been less energetic.

8. In moderate doses, emetine diminishes the respiration and, slightly, the circulation; it lowers the animal temperature, but does not change directly the vascular tension. In emetic or nauseating doses the action is the same but more energetic.

9. Emetine has an anticonvulsivant action, and by the relaxation it produces in the voluntary muscles combats effectively the convulsions caused by carbolic acid or strychnia.

INFLUENCE EXERTED BY CERTAIN GASES AND OTHER BODIES UPON THE PRESERVATION OF EGGS.*

BY F. CRACE-CALVERT.

Some time since, the late Dr. Crace-Calvert forwarded to a friend, for the purpose of being communicated to the French Academy, two papers giving the results of experiments made relative to the influences of various gases and other bodies upon the preservation of eggs. Circumstances delayed the accomplishment of the author's wish, and it was not until the occasion of the announcement of Dr. Calvert's death to the Academy by the Perpetual Secretary that these papers were read. The principal points contained in them were as follows :—

Oxygen acts very differently, according to whether it is dry or humid. An entire egg placed in dry oxygen is not altered; but placed in humid oxygen it is after three or four weeks covered with a white mould, composed of filaments about one centimetre long, supposed to be the *Penicillium glaucum* or a mycelium. When broken, the egg shows no sign of decomposition, although an examination of the gas in the apparatus reveals the presence of a considerable quantity of carbonic acid and a little nitrogen. If a hole be made in the extremity with a fine needle, the egg then undergoes decomposition in dry oxygen, and gives a large quantity of nitrogen and carbonic acid; a little mycelium appears on the surface of the egg, and the contents, which have become putrid, contain a large quantity of vibrios and microzymes. In humid oxygen the decomposition is still more complete, as shown upon the analysis of the resulting gaseous mixture; the *Penicillium* penetrates to the interior and gives to the albumen a creamy appearance. In the yolk microzymes are found, but no vibrios; and from this and other experiments the author concludes that the *Penicillium* prevents the development of vibrios, either simply by its presence or by the carbonic acid that it produces.

In humid *Nitrogen*, both pierced and intact eggs were preserved three months. The contents of the former were a little decomposed; under the microscope no filaments of *Penicillium* could be seen, but vibrios were present; no foreign gas was produced. The intact eggs were covered with a slight down of *Penicillium*, but the interior remained sound.

In *Hydrogen*, the eggs, both pierced and whole, became covered with a slight down, but the contents remained sound.

In *Carbonic Acid*, both dry and humid, pierced and whole eggs were perfectly preserved, no trace of *Penicillium* appearing upon the surface. Common *Coal Gas* gave the same results as carbonic acid.

Chlorine.—Eggs kept in a 5 per cent. solution of chlorine in a stoppered bottle during eight months underwent no visible alteration; but being replaced in the same solution, and the bottle left unstoppered, seven days afterwards they were covered with *Penicillium glaucum*.

Hypochlorite of Lime.—Eggs placed in a 5 per cent. solution of hypochlorite of lime on the 18th April were covered with *Penicillium* by the 28th; on the 8th May this was considerably augmented, and on the 8th June, when the experiment was concluded, the yolk could be seen through the shell to be displaced, and the microscope showed the presence in the interior of numerous filaments of *Penicillium*.

Lime Water.—These eggs were examined at the same dates as the preceding. On the 28th April no change was observed; on the 8th May they were covered with *Penicillium*; and on the 8th June there were present besides in the interior other moulds. The contents were decomposed; in the white much *Penicillium* was present, and in the yellow a great quantity of microzymes. Solution of *Sulphite of Lime* (5 per cent.) gave the same results.

Carbolic Acid.—Eggs immersed in a 5 per cent. solution of carbolic acid on the 18th April presented no change up to the 8th June. At that time they were slightly covered with *Penicillium*, but the interior was perfectly sound.

FERRIC CARBONATE.*

BY R. ROTHER.

Chemists at the present day conclusively accept the non existence of ferric carbonate. But the writer has succeeded by means of a peculiar manipulation in producing a ferric compound which contains the veritable body, although not in an absolutely definite condition.

The process under consideration admits the generation of this exceedingly useful compound in any desirable quantity with comparatively equal convenience and despatch.

The method of preparing the iron combination containing the ferric carbonate is so remarkably simple and expeditious that the writer believes henceforth the troublesome ferric hydrate will be, at least for most all pharmaceutical purposes, for ever superseded by the admirably adapted ferric oxycarbonate.

This new combination differs chemically, physically, and technically from the ordinary ferric hydrate in the following particulars: It is, firstly, although but partially a real carbonate, and therefore probably not susceptible of conversion into medicinally unavailable and pharmaceutically inapplicable inert allotropic modifications.

The adverse property which imparts the peculiar tendency to abandon water of hydration and assume inactive forms, and therefore so seriously detracts from the efficiency and general utility of the gelatinous ferric hydrate precipitated by ammonia, does not seem to be possessed by this carbonated ferric base.

Ferric oxycarbonate (an expression which the writer merely employs as a distinguishing term) when yet moist, differs characteristically from the hydrate by the copious effervescence of carbon dioxide when treated with acids. Furthermore, its solution in acids is immediate and perfect, definite and exact saturation being a predominant feature.

Normal salts are thereby only permissible, as basic compounds are wholly precluded, since an excess seems to remain undissolved, and therefore the point of saturation is attained without loss of time.

* From the *Pharmacist*, vol. vi, p. 353.

Another point of distinction is found in the remarkable fact that certain organic acids, as citric, for example, do not act energetically on it in the cold, shown by the feeble effervescence, but that the application of a moderate heat determines a combination almost instantaneously attended with a profuse evolution of carbon dioxide, and the production of a perfect solution at once.

Secondly, ferric oxycarbonate differs diametrically from the hydrate in form. It is not gelatinous, but compact, yet not granular, and not exceedingly heavy. It possesses a remarkable evenness of structure and aggregation, being miscible with water to the production of a uniform fluid, holding the precipitate regularly suspended during the course of its deposition when placed at rest.

It differs from the hydrate decidedly in colour; whilst the hydrate is brownish-red this is bright red when moist, approaching to scarlet when dry.

In its practical bearing ferric oxycarbonate, owing to its compact form, readily subside sand deposits rather firmly, rapidly, and closely. This presents the incalculable advantage possessed by such precipitates in being readily washed by decantation; the most perfect method of washing precipitates at present known. After perfect washing by this method, the precipitate separated from water as nearly as practicable by decantation, is poured upon a filter and allowed to drain. This removes all the water except that confined within the interstices of the particles, a quantity which is surprisingly small. The washing is completed in 4 to 6 hours, during which time the water can be renewed 4 or 5 times; after the last decantation the washings drained from the filter do not react with barium chloride.

The precipitate, when removed from the filter and dissolved with the aid of gentle heat in citric acid, for example, forms a solution stronger than the officinal solution of ferric citrate, and therefore requires dilution instead of considerable evaporation, as is usually required by the ordinary method.

The writer having found a decided advantage to accrue from the application of concentrated solutions which were mixed by pouring the iron solution as neutral as possible into an excess of concentrated ammonia, concluded that perhaps the ammonia could well be replaced by sodium carbonate.

Thereupon the writer employed crystallized disodic carbonate in small fragments and in slight excess, and treated this directly and by the aid of heat with the undiluted solution of ferric sulphate. The resulting precipitate was the ferric oxycarbonate.

The writer's process for preparing ferric oxycarbonate is as follows:—

Take of Ferrous sulphate cryst. .	24 troy ounces.
Sulphuric acid	4¼ „
Potassium chlorate . . .	848 grains.
Disodic carbonate. cryst. .	44 troy ounces.
Water sufficient.	

Pour the sulphuric acid into two pints of water with constant stirring, and add the ferrous sulphate; with continued stirring now add the potassium chlorate, a little at a time at first, but more rapidly in proportion as the ferrous sulphate dissolves. Then place the sodic carbonate into a capacious vessel and add about one-fourth of the solution of ferric sulphate; or better, use first a similar volume of water, apply heat immediately, and when nearly all the carbonate is dissolved add the remainder of the solution, one-fourth at a time, with constant stirring. Dilute the mixture with six to eight times its volume of water, let the precipitate subside, and remove the supernatant liquid by means of a syphon, mix the residue again with water as before, and repeat the washing as at first, three or four times, or until the washings give no precipitate with barium chloride. If large vessels for this purpose are not convenient the precipitate may be divided among a number of smaller vessels and thus washed with equal rapidity and perhaps greater facility in the manipulation. Lastly, pour the precipitate after the final decantation, upon a filter, drain off the surplus water, and spread the residue out to dry in the open air.

The writer now prepares solution of ferric citrate as follows:—

Take the washed and drained precipitate of ferric carbonate obtained from 24 troy ounces of ferrous sulphate as above.

Citric Acid, Cryst.	18 troy ounces.
Water, if required, sufficient.	

Place the citric acid into a capacious capsule, add the precipitate gradually and heat the mixture; after solution is complete add water, if necessary, to the measure of three pints and strain through muslin.

The moist ferric oxycarbonate is most conveniently dried by the method used for the production of drop chalk and other material exhibited in that peculiar form. It dries without shrinking unevenly, and therefore presents no fissures in the dried mass. When dried between folds of paper it does not adhere, but drops off readily in friable fragments which crumble under mild pressure to an almost impalpable powder. It is therefore most easily powdered by rubbing in a mortar. The powder retains the original bright colour. The fine appearance readily distinguishes it from the dried hydrate, as the latter is nearly black in the unbroken fragments, which are exceedingly hard, gritty, and difficult of pulverization.

The writer believes that this oxycarbonate is a great improvement over the officinal subcarbonate of iron in many respects.

For the preparation of ferric acetate solutions, it is particularly adapted, firstly, since it can be so perfectly washed; secondly, so rapidly and thoroughly freed from most of the adhering moisture, which is an especial point of importance, because the solutions should be from the first at their utmost concentration, as heat is not admissible in connection with an absolutely pure ferric acetate; thirdly, that definite and exact saturation can be speedily attained; and fourthly, that absolutely pure ferric acetate can thus be produced from a ferric compound which presents the iron in its normal and active state, and consequently the resulting salt will not be so prone to generation of insoluble basic acetates.

The approximate composition of ferric oxycarbonate was determined as follows:—

The precipitate was thoroughly dried between folds of bibulous paper, then powdered, and finally exposed for several days in the dry open air.

One hundred grains of the powder was now weighed off and allowed to remain on the balance: after twenty-four hours it was observed that the weight was regularly and constantly diminishing. The original weight was then restored by a further addition of the powder, but after six or eight hours another addition was required to restore the equilibrium.

In the course of three days, the powder having constantly decreased in weight, it was found that between 2 and 3 grains of the powder had been successively added to counterbalance the original weight.

At this juncture 50 grains of the powder was treated with chlorhydric acid in an apparatus for the estimation of carbonic acid; when it was found that only 3·4 grains of carbon dioxide was present in the combination; 100 grains, therefore, contained 6·8 grains carbon dioxide.

Twenty-five grains of the powder was then heated to redness for a short time in a platinum crucible, weighed, again heated to redness for a short time, and re-weighed. The first and second weighings were identical in result. A dark brown residue of 16·25 grains remained, leaving 8·75 grains for carbon dioxide and water. However, on cooling, the weight of the residue increased ·2 of a grain, which must therefore be deducted as hygroscopic moisture in the original substance, yet this inference is only approximative, as the altered body may possess a different disposition in this regard when compared with the first substance and its relative quantity. The brown residue

remaining after ignition of the oxycarbonate is utterly insoluble in chlorhydric acid, and the non-appearance of effervescence now conclusively shows that the precipitate was free from any adhering sodium carbonate.

One hundred grains of the powder therefore contains 65 grains ferric oxide, and 35 grains carbon dioxide, water of hydration and hygroscopic moisture. Deducting the 6·8 grains carbon dioxide and 28·2 grains remain for water of hydration and hygroscopic moisture, subtracting ·8 grains as atmospheric humidity absorbed by the powder, and 27·4 grains is left as water in actual combination. Hence 99·2 grains of the absolutely dry iron compound contains 65 grains ferric oxide, 6·8 grains carbon dioxide and 27·4 grains water of hydration.

Now dividing the number indicating the weight of the ferric oxide 65, by its equivalent number 160, and ·40625 results as a quotient.

Dividing 6·8 the number denoting the weight of the carbon dioxide by its equivalent 44, and ·15454 is obtained as a quotient. Likewise dividing 27·4, the weight of the water, by 18 its equivalent, and 1·52222 results.

Now dividing each of these numbers by the first quotient and we have in succession 1, ·38 and 3·75, or approximately 1, ·4 and 4.

But in consideration of the constant dissipation of carbon dioxide during the drying of the powder, we can safely write 1, ·5 and 4, which may then be formulated thus :—

$$Fe'''_2\,3(CO_3)\ .\ 4(Fe'''_2\,6(OH))\ .\ Fe'''_2O_3.$$

This formula assumes the presence of normal ferric carbonate and normal ferric hydrate in combination with anhydrous oxide.

The proportion of carbon dioxide actually present is, however, only one-sixth of what would be needed to form normal ferric carbonate with all the iron contained in the compound. It is, however, highly probable that twice the indicated amount of carbon dioxide exists in the freshly precipitated carbonate, since during the process of washing bubbles of gas continually rise, and moreover the copious effervescence of the moist fresh precipitate when heated with citric acid goes far to aid that supposition.

The moist precipitate could also be determined with great accuracy, comparatively, by operating upon a definite weight of pure ferrous sulphate and estimating the carbon dioxide in the moist magma immediately after thorough washing. The result would, however, be only interesting in so far as to how much more firmly the moist body retains the acid than the dry.

By changing the order of mixing the solutions, and otherwise altering the method of manipulation, distinctly characteristic products are obtained. If, for instance, the whole of the ferric solution is poured upon the carbonate in the cold, a deep red solution will result at first, even after much effervescence has occurred and a large quantity of the carbonate has dissolved ; if now heat is applied to the mixture, precipitation takes place, and although the resulting compound contains ferric carbonate, it nevertheless is more bulky, much darker coloured, and generally inferior to the bright coloured oxycarbonate.

If the solution of ferric sulphate is first heated and then treated with sodium carbonate by gradual addition, a deep ruby red liquid results, which on the further increase of heat sets to a stiff transparent ruby red jelly, which when further treated with alkaline carbonate forms a bulky gelatinous precipitate, probably containing alkali. Much carbonate can be thus added to the iron liquid, and if the heat is timely removed the solution will remain intact, and perhaps a tolerably pure and concentrated solution of a highly basic oxysulphate could be prepared from it by dialysis.

THE DILUTION OF ALCOHOL.

The following table, showing the proportion of distilled water required to reduce alcohol of certain degrees of strength to those of greater dilution, has been compiled by M. Berquier, and is published in the *Répertoire de Pharmacie* (vol. i., p. 628). Opposite to the figure representing the degree of strength of the alcohol which is to be diluted will be found the proportion of alcohol and water to be used to reduce it to the strength at the top of the respective columns. Thus if it be desired to prepare alcohol of 80° from that of 94°, the figure 94 is sought for under the heading "Strength of Alcohol employed," then to the right under the head, "Strength required, 80°," will be found the figures 808 and 192, indicating that 808 parts of the said 94° alcohol and 192 parts of distilled water are required to prepare 1000 parts of alcohol of 80°. For the convenience of English pharmacists the specific gravities corresponding to the different percentages of alcohol have been added.

TABLE INDICATING THE PROPORTIONS BY WEIGHT OF ALCOHOL OF DIFFERENT STRENGTHS AND OF DISTILLED WATER REQUIRED TO PRODUCE 1000 PARTS OF ALCOHOL OF LOWER STRENGTH.

The Pharmaceutical Journal.

SATURDAY, JANUARY 17, 1874.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square,*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ.'*

PUBLIC ANALYSTS.

LONG before the existing Adulteration Act was introduced into Parliament, and when the appointment of public analysts was first mooted in the bills brought before the House of Commons in reference to sanitary legislation, we gladly took the opportunity of expressing the opinion that much good might result from the institution of a department of State Chemistry. The cultivation of sanitary science naturally inaugurated from a medical point of view, and carried forward with so much benefit to the country under the direction of Mr. SIMON and his colleagues, had indeed demonstrated the necessity for a constant and systematic exercise of chemical skill in regard to many matters affecting the health and well-being of individuals as well as of communities. The analysis of water supplied for domestic use, the investigation of chemical points involved in various questions affecting the health of towns or districts, the examination of articles supposed to be adulterated, had each and all of them come to be evidently services which were indispensable throughout the country. It was not, in our opinion, to be expected that medical officers of health should perform the duties of analyst, even if they possessed the technical competence to enable them to do so, for they would require an amount of time and attention inconsistent with the performance of the other duties of medical officers of health.

Apart also from the chemical work required in connection with public health affairs, there were many other cases, such as the testing of gas, in which the services of the chemist would be useful in every town, and we hoped that the appointment of a staff of public analysts would tend at once to benefit the public, and to promote the more general cultivation of a science which receives far too little attention in this country, notwithstanding its importance.

But we must confess to looking with great regret at the mode in which the appointment of public analysts has generally been carried out in connection with the Adulteration Act. By a strange confusion of ideas the requirement of medical knowledge in the analyst, according to the terms of the Act, has led to the appointment, in most instances, of medical men to the office; very frequently indeed the office has been combined with that of medical officer of health, and in such instances the natural result has been either an absence of any real work of a chemical nature or the work has been done by deputy. An advertisement that appeared last week in our own advertising columns was very suggestive as to the amount of chemical knowledge that might sometimes be possessed by the deputy in such cases.

Even in those cases where chemists have been appointed the action they have taken has been singularly unfortunate, as we have had occasion from time to time to record in these pages. That this has been in no small part due to the vagueness and uncertainty of the Act and its provisions we readily admit, but though we make full allowance for such difficulties, we cannot avoid the conclusion that those chemists who have accepted appointments under the Act are themselves mainly to blame for the complications in which they have been involved in the discharge of their official functions.

Under the circumstances therefore, though we do not think it wise, it is not surprising to find a public analyst coming forward to call attention to the difficulties experienced in the discharge of the official duties connected with his post, "hoping by this means to enlist some sympathy for the analyst." It is with this object that Dr. THOMAS STEVENSON appears as the writer of an article in the current number of the *Practitioner*, contending that the merits of public analysts are too little appreciated, their difficulties too little weighed, and their failures too highly magnified. Considering the large number of examinations made by public analysts, Dr. STEVENSON thinks "these gentlemen may be congratulated on the fewness of the instances in which their certificates have not stood the test of a second analysis." We do not know how far Dr. STEVENSON is entitled to speak as the representative of the class to which he belongs, but we cannot help thinking he suggests the application of the proverb, "*qui s'excuse s'accuse.*"

Dr. STEVENSON first draws attention to the obscurity involving the term "adulteration," and to the difficulties resulting from the absence of any established standards of purity. No doubt these difficulties have been serious; but we think that as regards the analysts they have been self-imposed, and do not in any way call for sympathy with those who have been entangled in them. They seem to result from that confusion of ideas we have already referred to, by which medical qualifications, properly speaking, were required of analysts in addition to that special qualification which they ought to possess for performing the work of chemical analysis. To decide whether or not an admixture of any material with articles of food, drink, or drugs is prejudicial to health, or even whether it is a fraudulent increase of weight or bulk, is no doubt a very important duty, but we cannot perceive that it is any part of the analyst's function to perform that duty. Whether the use of alum in making bread is objectionable as regards the health of consumers of such bread is a question which no amount of analytical skill or

chemical knowledge could decide. Such questions, we conceive, are purely for the medical officers to deal with, and it is by such co-operation between those officers and competent chemical analysts that the interests of the public can best be secured without prejudice to the trading community. In like manner the questions whether the admixture of flour with mustard or sugar with cocoa, are adulterations or fraudulent, require no chemical knowledge to decide them. In these cases, and in many others it seems more a matter of evidence whether in regard to general usage, and the prices of the articles in question, the presence of the admixtures certified by the analyst should be deemed adulterations.

Dr. STEVENSON refers to the "citrate of magnesia" case in terms which would seem to indicate a belief on his part that citrate of magnesia was really an article used in this country, for in terms it a case of the sophistication of effervescing citrate of magnesia, though we should imagine he ought to know perfectly well that the preparation generally known by this name consists essentially of tartaric and citric acids, carbonate of soda and sugar. He objects to the opinion of Mr. ARNOLD that sweet spirit of nitre is not a drug, and to the distinction drawn between drugs and medicinal compounds. As regards this point, it is unnecessary to enter into any philological discussion, and we will simply refer Dr. STEVENSON to the price-list of any wholesale druggist to ascertain what distinction is customarily made between drugs and pharmaceutical preparations.

As regards the conduct of Dr. DUPRÉ in the witness-box at the Westminster Police Court, Dr. STEVENSON somewhat patronizingly expresses the opinion that it did him infinite credit. We cannot share that opinion, and though we unhesitatingly confess our belief that, in giving evidence, Dr. DUPRE said nothing which was not prompted by honest conviction, we cannot, now that this subject has been raised, refrain from expressing our regret that so able a chemist should have placed himself in such a false position as he did on that occasion. Dr. STEVENSON feelingly and even plaintively laments that "the exemplary costs awarded to the defendant in this case will, alas, deter other local boards from taking any proceedings for the adulteration of drugs," and he erroneously jumps to the conclusion that in future "the sale of medicines and medicinal compounds will be subject to no adulteration law." He seems to think "Othello's occupation's gone!" We need not remind our readers that there is no foundation for his statement, though we congratulate them on the probability that the acknowledged impropriety of the "Citrate of Magnesia" case, and the unwarrantable nature of the prosecution for the sale of Sweet Spirit of Nitre, will operate as a bar to interferences with legitimate trade which have no kind of justification.

Among his other lamentations, Dr. STEVENSON refers to what he terms "the shameful practice of selling citrate of iron and quinine containing 7 instead of 16 per cent. of quinine." Far be it from us to object to the application of Dr. STEVENSON's adjective to the substitution of the inferior article and its sale as the other; but with all due respect for his righteous indignation, we venture to suggest that he should abstain from such abusive declamation against the vendors of drugs and pharmaceutical preparations until he has certified himself that the "shameful practice" is not a creation of his own fancy, or that if it does prevail he should take the trouble to ascertain the conditions under which it occurs. We feel sure that in any earnest endeavour to detect and repress practices of such a nature Dr. STEVENSON or anyone else will always command the sympathies and support of the Pharmaceutical Society and of the general body of pharmacists throughout the country, but we hope they will never lend themselves to the promotion of mere sensational outcry which can be of no real service to anyone.

Finally, as regards public analysts, we estimate too highly the possible services they might render, to suggest any disparagement of them individually, or as a body. We hope, however, that in the interests of the public, as well as of chemists, that the functions of those officials will be properly restricted. We desire to see these important appointments filled by chemists competent to make trustworthy analyses, to see that those who undertake the duties of the office are adequately remunerated for their services and that they are relieved from the necessity of submitting to the vulgar badgering of witness-box examination in regard to matters of opinion with which the chemist has properly no concern.

THE CHEMISTS' BALL.

THE annual Chemists' Ball has now become so firmly established as one of the events of the Pharmaceutical Year, and has been so highly enjoyed by those who have attended it in former years, that probably it will be lost labour to remind many of our readers that the Chemists' Ball for this year will take place next Wednesday. Doubtless the date of this gathering was "made a note of" in numerous diaries as soon as announced. Still, some may be so bound up in the cares of business that there is a danger of their missing, through oversight, this opportunity of relaxation, and for their benefit we repeat here, what has been stated in our advertising columns for some weeks past, that the Annual Ball will be held at Willis's Rooms, King Street, St. James's Street, on Wednesday next, the 21st inst. For a list of the Stewards, and particulars as to where tickets may be had we must refer to the advertisement.

BY a decree of the French Minister of Public Instruction, M. CHATIN, member of the Academy of Medicine and Professor at the Paris School of Pharmacy, has been named director of that School, in the place of M. BUSSY, who had retired. The chair of chemistry in the same institution has also been declared vacant.

Proceedings of Scientific Societies.

PHILADELPHIA COLLEGE OF PHARMACY.

The usual monthly pharmaceutical meeting of this College was held on Tuesday afternoon, November 18th, 1873. Mr. Peter Williamson in the chair.

Prof. Maisch presented to the College cabinet a beautiful specimen of the leaves and fruit of *Chondodendron tomentosum*, which had been sent by Mr. Daniel Hanbury, of London.

Mr. Richard V. Mattison read a paper on Pancreatin, in which he detailed a process of preparation analagous to that of E. Scheffer's for making Pepsin. The solution of Pancreatin was found to possess the property of emulsifying cod liver oil readily. The paper will be published in a future number.

Prof. Maisch read the following paper on Emulsifying Cod Liver Oil, by W. M. Rice. A sample was exhibited made by this process, in which the taste of the oil was thoroughly disguised.

Emulsion of Cod Liver Oil.

BY WILLARD M. RICE, JUN.

The high and important position occupied by cod liver oil in the lists of the materia medica, has induced many pharmacists and others to turn their attention to perfecting some mode by which this nauseous remedy may be rendered palatable and acceptable. Many of the formulæ so elaborated have been published in this and other pharmaceutical journals, while it is to be regretted that others have been withheld, thus placing their authors in the constantly increasing lists of nostrum venders. But none of the efforts thus far made have succeeded in *completely* masking the unpleasant fishy taste and smell of cod liver oil, although some approach very nearly to this "consummation devoutly to be wished."

After a series of experiments, at the request of, and assisted by, a medical friend, the writer of this has perfected the following formula, which he offers to his professional brethren, hoping that it may prove useful :—

Oleum morrhuæ	fl. ℥viij.
Tragacanth	℥j.
Sacchar. alb.	℥iv.
Ol. gaultheriæ	gtt. lx.
„ sassafras	gtt. l.
„ amygd. amar.	gtt. x.
Aquæ	fl. ℥viij.

The tragacanth and sugar are to be dissolved in the water and the mucilage strained. In this is to be incorporated first the essential oils and then the cod liver oil. This makes an elegant-looking emulsion, not too thick, containing fifty per cent. of the oil, and of a rather pleasant taste and smell.

Many manufacturers combine the lacto-phosphate of lime, etc., with the cod liver oil mixture, but as physicians often consider this decidedly objectionable in a medicine intended, as this is, in most cases, for continued use for a considerably protracted length of time, the author has been induced to omit it. It can be added, however, by a slight modification of the above formula.

A discussion arose as to what, in the opinion of the members present, constituted a good emulsion.

Mr. Jas. T. Shinn advocated thin emulsions, and did not favour the dispensing of thick emulsions, for he thought that the patient could readily incorporate the water and oil that had partially separated by standing, and would prefer to do it rather than take a thick emulsion.

Mr. Jos. P. Remington stated that he had made and dispensed a cod liver oil jelly, made on the same principle as the emulsion of Mr. Rice's, from the formula given by Mr. Rogerson in the London Pharmaceutical Journal of March 8th, 1873. This jelly eemed to give satisfaction wherever it was used ; but it was necessary to use only the finest and freshest oil.

Prof. Maisch spoke of the use of alkaline solutions in emulsions, and of the tendency of such to spoil, if kept too long, and become disagreeable to the taste.

A Member wished to know of Mr. Rice whether a smaller quantity of tragacanth could not be used in the formula.

To this Mr. F. Stryker Boisnot replied that both Mr. Rice and himself had tried various proportions, and found that they could not use less.

Mr. R. V. Mattison said that gum arabic and sugar had proved to be the best in his experience for thick emulsions, and solution of pancreatin for thin ones.

Dr. A. W. Miller read an interesting paper on Cosmolin, and exhibited a number of specimens :—

Cosmolin and Paraffin Ointment.

BY A. W. MILLER, M.D.

This preparation is by its manufacturers explained as being purified and concentrated petroleum. According to the most trustworthy information which we were able to obtain, it is made by distilling crude petroleum so as to remove successively the gasolin, benzin, burning oils and the lighter machine oils. The residuum is then subjected to still greater heat, and its vapour is brought into contact with a jet of superheated steam, for the purpose of expelling the last traces of light hydrocarbon. After this it is still further purified and deodorized by the action of hot animal charcoal. We are consequently forced to conclude that cosmolin is simply impure paraffin, or a mixture of paraffin with varying proportions of the heavy oils which are nearest allied to it. These oils are known to the trade as paraffin oil, neutral oil, lubricating oil, spindle oil, etc. Although the manufacturers claim cosmolin to be a simple body, this is refuted by their own statement, namely, that they furnish this one simple body in the form of cerate, which remains firm at 95°, as a jelly which is fluid at 85°, and also as a liquid which is still fluid at 32°.

Taking advantage of the fact that paraffin is only very sparingly soluble in alcohol, we dissolved cosmolin in ether and in benzin, from both of which solutions the paraffin was readily precipitated by the addition of alcohol. Cosmolin is turned dark brown, like caramel, by sulphuric acid, but this is no doubt due to its impurities. Nitric acid produces no reaction in the cold, but when heated turns it yellow, and finally orange colour. Muriatic acid and liquor potassæ have no effect upon it, either cold or hot. All of these tests point to the presence of paraffin.

As cosmolin appears to possess some merits, and is certainly gaining favour with physicians, it would be desirable to contrive a formula for its preparation.

With this object in view a number of experiments were instituted for the purpose of obtaining a combination having similar physical and chemical properties. The substances which seemed most suitable were pure paraffin, and the so-called neutral oil, of the best quality, which possesses less of the peculiar coal oil smell than any other kind examined. The gravity of this oil is 869 to 864, and its boiling point is somewhere about 500°. Coal oil dealers claim that this oil is free from odour, though this statement is only relatively true. In order to deodorize it still more, it was percolated through hot animal charcoal.

One part of paraffin was melted and three parts of the oil, prepared in the manner described, were added to it. This compound, has the same behaviour towards reagents as cosmolin. Like that substance it melts at about 95°, does not evaporate below 400°, and of course will not turn rancid. Its odour is rather stronger than cosmolin ; the colour is somewhat different, though this is most probably due to using pure paraffin, as some of the impure grades have the same peculiar amber colour as cosmolin. Both preparations when burned emit the characteristic smell of coal oil, and give off a copious black smoke ; ignited drops of both fall

down with a peculiar hissing sound. The chief difference appears to be in the mode of preparation, as the manufacturers of cosmolin claim to use no chemicals, while it is well-known that both paraffin and the heavy oils are purified by sulphuric acid and soda. Still, as the compound, which may be appropriately called "paraffin ointment," was boiled in distilled water without making it either acid or alkaline, the much dreaded chemicals have evidently been completely removed.

Cosmolin is vended at the somewhat exorbitant price of 1 dol. per lb., while paraffin ointment can be sold at a very fair profit for one fourth of that price.

The above formula for this substitute for cosmolin is not offered as the best that may be devised, but only for the purpose of directing inquiry to this subject. The varieties of heavy coal oils in the market are so numerous that it becomes a tedious task to examine them all. We were, in fact, promised a sample of a purified paraffin oil made in Boston, which was represented as being almost identical with cosmolin, but it has not yet arrived.

In conclusion we would state that cosmolin does not appear to be so entirely free from all irritating properties as it is claimed to be. A case has been communicated to us by Dr. Louis G. Bauer, one of our members, in which he applied it for an aggravated and obstinate form of eczema, occurring on the upper lip. It was productive of a high degree of inflammation and considerable tumefaction, although citrine ointment and similar preparations had been previously employed without such results.

President Williamson remarked that petroleum, paraffin, cosmolin, etc., etc., had all come up since his day; but even in old times they had petroleum. An article called Seneca oil used to sell freely for 11*d.* per ounce, which was petroleum collected by the Indians. It was found floating on the water in certain parts of Pennsylvania, and by absorbing it by a blanket and wringing it out, it was collected in small quantities and commanded a good price. It was used for linimcnts, etc.

Mr. J. P. Remington read a note on Aromatized Waters, advocating the use of the compound waters in preparing elixirs, etc.

Prof. Maish spoke of a process for preparing distilled water which had been communicated to him over a year ago by Mr. George G. Percival, of Waterville, Me., but, at the author's request, was not published then. Mr. Percival found that volatile oils are very freely soluble in boiling water, so that he has taken a patent for obtaining volatile oils on a large scale by a process based thereon. He suggests to dissolve the volatile oils in hot distilled water; on cooling, a turbid solution results, showing that the water is a saturated solution. By filtering, as perfect an aromatized water as can be made from volatile oils is obtained.

Mr. Jas. T. Shinn preferred distillation, and said that he made an imitation of Curacoa cordial by distilling the oils with water and then mixing with sugar, and colouring.

On the motion of S. M. McCollin, the above papers were referred to the Publication Committee.

The meeting then adjourned.

SOCIETY OF ARTS.

On the Energies of the Imponderables, with especial reference to the Measurement and Utilization of them.

BY THE REV. ARTHUR RIGG, M.A.

Lecture VII.

*On the Energy of Heat, with especial reference to the Measurement and Utilization of it.**

The energy of heat has, in one form or other, attracted more notice than that of any of the other imponderables with which this course of Cantor Lectures has to deal. Various explanations of the cause of heat being possessed of energy have been given, but it was not until the closing years of the last century that views on this question were first enunciated, which have since borne such good fruit. Count Rumford, in 1798, by an experiment in the boring of cannon in the arsenal at Munich, and Sir Humphrey Davy, in 1799, by the liquefaction of two pieces of ice by the friction of each on the other, laid the foundation of that explanation which has been so successfully generalized, and which even now is hopefully pursued.

The first question that presents itself to us is, "What is heat?" And in order to present the modes suggested for measuring it which are diagramically expressed on the wall, it will be needful to make some preliminary statements. In the general table of energies the sources of heat are represented as the sun and fuel. That term fuel might with very good reason have been omitted, for the one source of heat is the sun; fuel is a secondary source, having its primary in the sun. Heat is obtained from the sun, and the circumstances under which it is obtained, are foreign to the subject of this lecture. Heat obtained from fuel, and also from the sun, is kinetic, or capable of producing motion when it is radiant, or passing from place to place; and it is potential, or stored up, when it is absorbed. Now it was absorbed in those primeval times when there was an immense mass of vegetation on the face of the globe; that vegetation absorbed the heat. In these primeval forests it has been preserved, and in such fuel as coal it is restored. In being so restored or returned, that is given back to the earth which was absorbed perhaps before the creation of man. These buried forests are now a-glow with light, and heat, and vigour—unmistakable types of resurrection from a grave. Let us turn to that received from the sun. Refer to the diagram of the spectrum and consider how it aids in illustrating the question of heat. In the last lecture an endeavour was made to explain how it was related to the phenomena and energies of light, and incidentally to the phenomena and energies of chemical affinity. One portion is related to the energy of light, properly so-called; another portion is related to the energy of affinity, properly so-called; and in this portion, which is perfectly obscure, and which escaped notice until recent years,—in this which is invisible to the human eye, although it may be visible to the eyes of other animals, lies that which we call solar heat. You observe that to the spectators' left-hand of the portion marked with the usual prismatic colours, there is a shade of red extended to a length equal at least to that marked with such decided colouring. It is not far from the truth to say that in this lies all the heat from which we obtain our stock of motion. It may be desirable to explain how we know that the heat lies there, and why the diagram is there drawn, and extending to such a distance from the visible portion of the spectrum, and that in such portion lies the greatest amount of heat. It is done in this way. We take a little instrument called a line thermopile, composed of a number of strips of metal laid edge to edge, and soldered at the alternate ends. The two metals are usually antimony and bismuth. The pile is in the form of a straight line, because it is to be used for determining the heat at a particular portion or line across the spectrum.

Thermometers for heat purposes may be said to be use less, and, perhaps, before going further, it may be well to state why they are so. A thermometer is an instrument which, by the expansion of a fluid, as air, or a liquid, as alcohol, mercury, etc., or by any other means, tells us the difference in temperature between two bodies. If a thermometer be placed in water, it would tell us how much the temperature of the water is above the freezing point, or how much below the boiling point. But freezing and boiling points are neither of them standard

* Cantor Lecture, delivered March 17, 1873; reprinted from the *Journal of the Society of Arts.*

points. There is heat far below the freezing point, and there is heat still higher than the boiling point; and indeed there is no approachable zero from which to commence the graduations of a thermometer. We want, too, another thing, not relative heat but absolute heat. Another means for obtaining records of heat is by the use of the thermopile and the galvanometer. This galvanometer is connected with the thermopile, and the speck upon the screen is that to which we have to look. If two short thin wires, one silver and the other copper, be taken, one wire attached to one end of that round the galvanometer, and the other to the other end, questions in relation to heat and electrical phenomena in connection with it may be made clear. If the free ends of the silver and copper wire be placed in contact and held between a finger and thumb, or placed near a lamp-flame, the speck immediately moves, and travels over a large space. No thermometer is so delicate or sensitive to heat as this combination of instruments. The heat which in a thermometer would be employed in expanding the liquid, is in this case converted into an electrical current which affects the galvanometer. Heat in the one case is measured by the expansion of a liquid, in the other by being converted into electricity, and the electricity is measured, as explained in a previous lecture, by the galvanometer. The speck is now steady, but on taking hold of the junction of the wires the speck moves in consequence of the simple touch of a finger. If the junction be once waved near the flame of a lamp, the speck moves directly—evidently there is a real and measurable energy in the heat which has passed. It should be remembered that this galvanometer requires quantity of electricity, and not what is called intensity. That motion, therefore, by being properly measured, enables us to get, inferentially, at the quantity of heat. The measurement of heat by differences of temperature is called "thermometry." The measuring of an absolute quantity of heat is called "calorimetry."

These metals thus indicating heat by the conversion of it into electricity are applied here in a line, and if this apparatus is placed in front of a real spectrum, of which that on the wall is a pictorial diagram, and moved gradually along by means of a fine-threaded screw, the line thermopile passes into successive portions of the spectrum, and according to the amount of heat in each portion, so the galvanometer deviates. If, therefore, the galvanometer at one portion is sent further aside than at another, we know it is owing to a larger quantity of heat being converted into electricity. Such an arrangement was carried out, and the largest amount of heat was found to be where that high mountain is marked on the drawing. This much must at present suffice for showing how to determine and measure the quantity of heat.

Now let the consideration be how this heat is converted into motion. Motion, we know, produces heat, but here the converse question is presented—heat producing motion. If we can show that heat produces motion, and if we know that motion produces heat, those two are mutually interchangeable. That no motion can take place without the development or absorption of heat may be made manifest by an experiment. Here is a thermopile, rather more delicate than the one hitherto used. Here is an air-pump, connected with which are two copper vessels separable by a tap. If, now the air be exhausted from one of these vessels, the one nearest to the air-pump, it then becomes empty, and if the thermopile be caused to touch the other vessel, or to touch this one, which is empty, and the speck of the galvanometer is stationary; then, when the tap that separates the two is opened, air rushes from one into the other, and the galvanometer speck indicates a change in the heat relationships of the two vessels. These changing heat relationships result whenever action takes place. If a thermopile having a larger surface, intended for the purpose of investigating very delicate changes of temperature, be attached to a condenser which serves to increase the surface and so to magnify the result, it would be found that by merely touching one portion the speck of the galvanometer moves. Now, if a fan be caused to act in front of and upon the thermopile, the impression would be that we should withdraw heat. The withdrawal of heat may be produced by the blast of air, but this air, striking on the thermopile causes the spot of the galvanometer to move in the direction indicating an increase of heat. The question is, whence comes that increase of heat? The answer is, that heat comes from my arm, and is produced by muscular energy being converted into mechanical power, which is then transformed to heat, which is changed into electricity. In this case the energy passes direct from my arm through the fan, and propels a current of air against the thermopile. If, however, the draught of air upon the thermophile, instead of being direct from my hand had been treated in this way—If a close vessel had been taken, and by means of a condensing syringe, air had been forced into it, and allowed to remain for a few minutes, and then jetted against the thermopile in the same way as the air from the fan, we should find, after the first impact of air, that cold, and not heat, had been produced. Therefore, the one blast blows hot, and the other blast blows cold. Thus, Æsops's fable of the man and the satyr appears to be realised. Much confusion has arisen from the use of the word cold, as though it was something distinct from heat. "Cold" is only a condensation of the phrase, "decrease of heat." Conflicting views would sometimes be harmonized were this word disused, and the word "heat" employed with a proper prefix.

There is a very good reason to be given for these results. The case of a blast producing decrease of heat may be illustrated thus:—In this iron bottle there is some condensed carbonic acid gas, which is under a pressure of about 700 lbs. on the square-inch. Now, it might be expected that as the blast from the fan produced heat, so the blast from this bottle of condensed gas would also. A jet of this condensed gas is now directed to the thermopile; the reflected light of the galvanometer by its motion indicates that the current has produced cold. It certainly appears remarkable that in the case of one blast heat is manifested, and in the other cold is produced. The explanation is this:—In neither case can the air be put into motion, except by the expenditure of heat. In the case of a fan the heat is at once expended in causing a blast of air, but in the other case the heat is expended in the previous act of condensation. When this condensing syringe has been used for two or three strokes, the cylinder of the syringe has become hot. The process of heat radiation is continuous. As soon as that bottle was filled, the heat accumulated in the work of condensation began to radiate. In other words, the muscular energy which condensed the gas into the bottle was dissipated in the form of heat. The contents of the bottle require an expenditure of that which may be represented by as much heat to get out of the bottle as they required to put them in; therefore, this heat must be drawn from some source or other, and the first supplies are drawn from the contents of that which was in the bottle. The paradoxical and apparently contradictory phenomena are, however, reconcilable in a most instructive manner. In the case of the fan the blast carries the muscular energy converted into heat direct to the thermopile. In the case of the bottle this heat has been dissipated by radiation.

Let us now consider and describe how Mr. Joule obtained that which has become the basis of our calculations, and the arithmetical measurement of heat, namely, 772 foot-pounds as the mechanical equivalent of the amount of heat required to raise one lb. of water through one degree Fahrenheit, or 1390 foot-pounds for raising the same quantity of water through one degree Centigrade.

His experiments extended over about seven years, and

the first apparatus used was the one shown in this diagram. There is a small vertical shaft, capable of being rapidly turned by a handle, across or through the shaft is a short glass tube, in which were introduced a number of bars of wrought iron. These were covered with oiled paper, so separating them electrically one from the other. The bundle was wrapped round with copper wire and then inserted into the glass tube, which was closed at one end with a cork, and capable of being closed at the other. That glass tube was coated with tin-foil, so that, in fact, the tube was very like what is called a Leyden jar. It had an electrical coating inside and out, the only peculiarity being that a slit was cut along the coating on the outside of the vessel to prevent electrical induction. The tinfoil was then covered by strips of wood parallel to the tube, and bound all over with silk. The ends were corked, and also covered with oiled silk, so as to close it thoroughly. From the inside of the tube two wires passed down and dipped into two mercury cups, which were connected with a galvanometer, so that currents of electricity, if any were produced in the interior metal bars, would be manifested by the galvanometer. On each side of this short glass tube were fixed two arms of wrought iron, bent in the form of a horse-shoe, and as nearly in contact with the ends of the glass as possible. This wrought-iron horse-shoe had a coil of copper wire round it, and by the usual means it could be converted into an electro-magnet. A certain weight of water was put into the short glass tube along with the bars, and having rotated the instrument for a quarter of an hour, the temperature of the water when examined was found to be hotter than before. The galvanometer being observed it was known what electricity had passed, and this, combined with the change that had taken place in the temperature of the water after fifteen minutes' rotation of the shaft, at the rate of six hundred rotations per minute, sufficed for determining the amount of electricity converted into heat. Thus, approximate data were obtained on which to found other experiments. Such experiments were made and remade, they failed, and were again renewed; and to note how Mr. Joule overcame one difficulty after another until he succeeded, furnishes a beautiful example of perseverance. Sometimes where he expected to find a substance had gained heat, he found, on the contrary, it had lost. Such anomalies, however, were afterwards completely accounted for.

Research in science claims the exercise of much ingenuity under unexpected and baffling conditions. The perplexity just described became an element in success. Mr. Joule availed himself of the process of "interpolation," and so adopted what proved of great assistance in future experiments. What has been described was the earlier of many processes. Next, he found it needful to measure the energy exerted upon the handles, because if in this vessel a quantity of heat had been generated which produced an observed increase of temperature in the water, it was desirable to know what was the value of the mechanical energy which had caused that heat to be so generated. If motion be given by the hand only, there is no means of measuring that value. The earlier object was to see if heat could be obtained; then the next object was to measure the heat obtained, and also to measure the mechanical energy by which it had been obtained. The apparatus now assumed this form. He gave up the electrical process, and began to take a vessel, similar to the one shown in this diagram, which had brass plates in it, and brass bars fixed to the inside of the vessel, and running across, so that paddles could rotate between the bars. The vessel was filled with water, and therefore when the paddles rotated the fixed bars stopped the whirl of the water, and heat was developed. The sea, as those who are accustomed to bathe know very well, is warmer on a windy day than on a calm day, simply because the motion of the water caused by the wind is converted into that motion of the molecules of the water which we call heat. So in the experiments with this apparatus the motion of the water in the vessel is converted into the motion called heat. Of course all possible means were adopted to prevent heat passing by radiation from the exterior of the vessel. Hence the vessel was enclosed in another, and that again in another. The contrivances for ascertaining a measure of the mechanical effort made to keep the paddles rotating at a uniform rate were very simple.

The little vertical shaft on which the paddles were fixed was prolonged upwards, being divided across and reconnected in line by a piece of vulcanite, which, in common phraseology, would be called a non-conductor of heat. Wound round the upper part of this shaft were two cords, the ends of which passed over two pulleys on opposite sides. To these cords were fixed weights, by the descent of which motion could be given to the paddles. The cords were two in number, and on opposite sides, in order to obviate as far as possible the heating effect of rubbing friction on the shaft journals. With this apparatus, and others constructed upon similar principles, a series of experiments enabled him to arrive at certain definite conclusions.

(*To be continued.*)

Parliamentary and Law Proceedings.

Alleged Poisoning by Morphia and Suicide by Strychnia.

On Thursday, January 8th, Mr. W. Tomalin, the deputy coroner for the county of Northampton, held an adjourned inquest at West Haddon, on the body of Mrs. Alice Gulliver, late of Creek, who died on the 23rd of November last, and whose body was subsequently disinterred.

The inquest was opened by the Coroner on the 23rd ult., and, some evidence having been taken, was adjourned till Thursday in order to give time for an analysis of the contents of the stomach.

Mr. J. Becke, of Northampton, solicitor, attended on behalf of the relatives of Mrs. Gulliver; and Mr. R. T. Rea, solicitor, Worcester, appeared in the interest of Mr. Waters, surgeon, of Worcester, whose wife was visiting the deceased at the time of her death. Mr. Waters was also present.

The deceased, it appeared, lived alone, and was supposed to be possessed of a large property. In the middle of November last Mrs. Gulliver wrote to Mrs. Waters, wife of a medical practitioner living at Worcester, and a relative of the deceased, asking her to pay her a visit, and on the 20th of that month Mrs. Waters arrived. On Saturday morning, the 22nd, two days afterwards, Mrs. Gulliver was seized with sudden illness, and Mrs. Waters called upon Mr. Walker, surgeon, of Creek, and asked him to visit her aunt in the evening. Mr. Walker offered to see her at once, but she begged him not to go then as her aunt was asleep. He accordingly went about five o'clock in the evening, and found the deceased very ill—much worse than he expected to find her. He had paid her a friendly visit on the Friday evening, and had then found her unusually well. He prescribed for her, and saw her again on Sunday morning, when he found her much better. Soon after he had left, however, she was again taken very ill, and a servant deposed that she heard Mrs. Waters open the windows, and, as she thought, shut the door. On going upstairs she found her mistress was dead. Mrs. Waters sent for Mr. Walker, who found the bedroom door and window and staircase window open, and there was a "tremendous current and draught." Mrs. Waters said to him, "Oh, I am so sorry now I was here." He asked her why, to which she replied, "Oh, Mrs. Gulliver made a will in favour of my husband, and the other family know nothing about it." She afterwards said, "I

suppose there will be a 'rumpus,'" or "a row." Mr. Walker gave a certificate of the death. He believed at the time that death resulted from valvular heart disease.

Professor Rodgers, of the London Hospital, said :—On the 24th of December last he received three jars from Inspector Bailey, containing the viscera of a human subject—stomach, with the œsophagus attached, liver and kidneys. In the œsophagus he found a quantity of the same material as that found in the stomach, proving that immediately before death there must have been an effort to vomit. On opening the stomach he found no appearance of irritation, and he found, on analysis, that there was no mineral poison in the contents of the stomach. He had the means of detecting the presence of alkaloids, and he found the presence of an alkaloid in the stomach, liver, and æsophagus. He had not quite finished the analysis of the kidneys. He found that that alkaloid was morphia ; he had no doubt of it. He found morphia in the stomach and its contents. In the liver and the blood he found the presence of an alkaloid, but there was not sufficient to enable him to determine its character. The alkaloid in the liver might be harmless, but that in the stomach might cause death, according to the dose that was given. Having heard the statements made by Mr. Walker, the surgeon, as to the state in which the deceased was during the Saturday—a state of stupor approaching to coma—and also the evidence as to the appearances presented on the *post mortem* examination, he would say that in his judgment the condition in which the deceased was on the Saturday could not be attributed to the disease which was apparent in the *post mortem* examination. Those appearances were consistent with the supposition that a narcotic poison, such as morphia, had been administered. Taking into consideration the fact that morphia was found in the body, and the condition of the deceased on the Saturday, that would account for her condition. The vomiting would account for so small a quantity of morphia being found, if there had been a larger quantity administered. The facts would tend to show that the deceased was recovering from the effects of this narcotic poison. The circumstances actually attendant on death were not such as would lead him to form an opinion as to the immediate cause of death. He was not prepared to say whether death arose from natural causes or not, but, in his judgment, a dose of morphia producing such effects as were observed in the deceased must necessarily tend to hasten death. Death was not the result of a narcotic poison administered on Saturday ; but, from the appearances observed, he was equally positive that death did not arise from the state of the heart. The statements of the medical and other witnesses as to the condition of the deceased, with the result of the *post mortem* examination and his own analysis, justified him in coming to that conclusion. The high temperature of the body negatived that idea, but something such as prussic acid, and which now could not be detected, would cause death. Death must have been accelerated by the administration of morphia, but the actual cause of death was the administration of some other volatile noxious substance which could not be detected after so long a period.

Dr. Buzzard was next examined. Having heard the evidence of Professor Rodgers and the result of his analysis, and taking that in connection with the state of the deceased on the day before her death, as detailed by Dr. Walker and the other witnesses, he considered it highly probable that the state of the diseased was attributable to a dose of morphia. He would not state it with absolute certainty. He could suggest another cause producing the effects described. A dose of morphia sufficiently strong to produce such effects would accelerate death, especially in a person with a heart like that of the deceased. He believed that death was accelerated by a dose of morphia, but he could not state that with absolute certainty. She did not die from the direct effects of morphia though it was possible she died from its indirect effects.

Mr. Walker was also recalled, and said that, having heard the result of the analysis, it appeared to him that the state of his patient on the Saturday was the result of morphia. Morphia administered to his patient in her condition of a diseased heart would, when administered in such quantities as had been detected, be injurious, and would accelerate death. He was not at all aware that the deceased was in the habit of taking morphia.

After some further evidence, the Coroner briefly addressed the jury, and after a short retirement, they returned a unanimous verdict that the deceased did not die a natural death, but that her death was caused by poison, but by whom administered there was not sufficient evidence for them to determine.

An information having been sworn, a warrant was afterwards issued by the magistrates to take Mrs. Waters into custody.

Meanwhile, Mrs. Waters had been taken very ill, and shortly afterwards the doctors in attendance pronounced her dead. On being communicated with by Mr. Waters and his attorney in another room during the inquiry, she became much excited, and was seized with what appeared to be an epileptic attack, to which she succumbed in less than an hour.

On Friday an inquest on the body of Mrs. Waters was held at the Crown Inn, West Haddon. Mr. Alfred J. Gulliver Waters deposed that he was a surgeon, practising at Worcester, and husband of the deceased. He accompanied his wife and his solicitor, Mr. Rea, from Worcester to West Haddon, and attended the inquest on Mrs. Gulliver. The deceased was in another room. The witnesses having given their evidence, he and Mr. Rea went to Mrs. Waters. Mr. Waters told his wife what had been proved by Professor Rodgers—the detection of morphia in the body of Mrs. Gulliver. She replied, "I never gave her anything, that I am sure." They had scarcely been two minutes in the room before she suddenly caught hold of witness's hand and said—"I shall have a fit. I know I shall ; I told you so this morning ; I feel it coming. It is paralysis—just like I had before, only not so violent." Witness asked her if he should send for one of the medical men, but she replied, "No, no ; it's only a slight shock—slight, slight ; there, it's going." Witness could scarcely release his hand from her grasp. With the other hand he was feeling her pulse, the state of which alarmed him. The deceased then released her hold, and in about a minute threw herself back in the chair. He noticed that there were violent tetanic spasms, and every indication of poisoning by some means. Another medical man was fetched, and shortly afterwards deceased said to Mr. Waters, "Alfred, I have taken ——" but before she could finish the sentence, another spasm came on and she died. Before this, Professor Rodgers asked for the keys of a little black bag which she had brought with her. Witness gave them to him from her pocket. In the bag were found two small bottles ; one was empty, and the other, a very small one with a glass stopper, contained about two teaspoonfuls of some fluid. Professor Rodgers smelt it, and said, "I fancy she has taken brucia" (or brucine) or some preparation of nux vomica milder than strychnine.

Mr. Dicks, surgeon, of Long Buckley, described the symptoms as those resulting from having taken some preparation of nux vomica.

At this point the Coroner requested Mr. Dicks to make a *post mortem* examination. In the meantime evidence was given by the people in the house which showed that the poison could only have been taken at the time when some tea was given to Mrs. Waters, after the adjournment for lunch, and before the Coroner addressed the jury.

Mr. R. T. Rea, solicitor, and Coroner and clerk of the peace for the City of Worcester, was then examined. He described the interview with Mrs. Waters, when the Coroner was about to address the jury in the inquest-room downstairs. He informed Mrs. Waters, at her husband's desire, of the effect of Professor Rogers' evi-

dence, and asked her what became of the morphia which Dr. Walker said she obtained from him for a poor woman three months ago. She answered, "I took it myself; I can't live without it, I have some here to-day. I always have had some with me since that attack." She alluded to a paralytic stroke which she had about three years before. Witness said it was at least very unfortunate that she should always have had of late the very poison in her possession which the analysis indicated. She replied, "I never gave any of it to her, that I am sure." Immediately afterwards she was seized with the symptoms described by Mr. Waters, which ended in her death.

The *post mortem* examination having been completed, Mr. Dicks handed in his report to the Coroner. There was no natural cause of death, and he expressed his belief that the deceased had died from poison, and that that poison was strychnine.

Mr. Waters being questioned as to the state of his wife's mind, said she had been very desponding for the last three years, and that some of her relatives had been confined in a lunatic asylum. The jury found a verdict of "Felo de se," and the Coroner ordered the body to be buried without the rites of the Church between 9 and 12 p.m., and within 24 hours from that time. The body was therefore interred on the same night in West Haddon, a few hours after the close of the inquest.

Adulteration of Bread.

In a case which was decided at Uxbridge on Monday, the 12th inst., a baker was accused of adulterating bread with alum, to the extent of 45 grains to a 4lb. loaf. Evidence was produced by the defendant to show that that quantity of alum was not present, and the magistrates in giving their decision said they did not feel called upon to say whether the alum was there or not, as the evidence on that point was conflicting, and they considered that the prosecution had failed on another point, namely, the form of the summons, which was taken out under the third section of the Act, relating to the admixture of "any other substance with intent fraudulently to increase its weight or bulk." It had been assumed by the prosecutors that the addition of alum to bread caused it to retain an increased quantity of water and thus to become heavier, but the scientific evidence of Dr. Redwood and Mr. Wanklyn tended to negative this assumption. The summons was therefore dismissed.

Reviews.

Year Book of Pharmacy, comprising Abstracts of Papers relating to Pharmacy, Materia Medica and Chemistry, contributed to British and Foreign Journals, from July 1, 1872, to June 30, 1873. With the Transactions of the British Pharmaceutical Conference at the Tenth Annual Meeting held at Bradford, September, 1873. London: J. and A. Churchill. 1873.

A little later than has been usual with its predecessors the 'Year Book of Pharmacy' has made its appearance, and it will soon be under the inspection of some thousands of pharmacists throughout the country, from whom it will doubtless meet with the welcome accorded to an established favourite. For although about two-thirds of the articles quoted in the 'Year Book' proper have already appeared more or less fully in the pages of this Journal, as well as the whole of the Transactions of the Conference at Bradford, and they will therefore be familiar to our readers, many of them, as well as others whom our pages do not yet reach, will be glad to see these papers brought together in such a compact form.

The new 'Year Book' fairly represents the literature of pharmacy during the twelve months mentioned on the title-page, and although many of its articles partake rather of the nature of excerpts than that of the abstracts of the German Jahresbericht, yet as this has also been the case in former years it may reasonably be supposed to represent the instructions under which the editor compiled the book. We are at a loss, however, to guess why in some cases a foot-note is appended stating the article is printed entire, since the remark would equally well apply to many others in the volume. For instance Mr. Hanbury's article on African Ammoniacum, so noted is preceded by one of Mr. Pocklington's, from which only two introductory lines are necessarily omitted, and it is followed by Mr. Moss's paper on Ammoniacum, minus only about a dozen lines,—in which however happen to be included the fusing point and one of the operations of washing the resin,—and this is succeeded at an interval of a page by M. Planchon's paper on Striated Ipecacuanhas *in extenso*. We would only further remark of this portion of the book,—which numbers about forty pages less than that of last year,—that if some of the subjects are rather far removed from pharmacy, they are unfortunately not beyond pharmacist's requirements, a fact of which we have daily experience.

Of the editor's introduction, however, we cannot speak so favourably. Probably this must be ascribed to the fact that last summer Mr. Wood received the appointment of quinologist to the Indian Government, and was called upon to leave England at an unexpectedly short notice, before even the MS. of the book was placed in the printer's hands. In the words of Ovid he might have said—

"Sine me, liber, ibis in urbem."

And the result has been a summary much wanting in the precision and accuracy which made that of last year so valuable. For a justification of this assertion we proceed to make the following notes, and their confirmation may generally be found in the book itself. The first hundred lines contain so many inaccuracies that it is difficult to point them all out without incurring suspicion of hypercriticism. To commence, we question the propriety, in the face of what appears in another part of the book, of such a sentence as "propylamine, or as it has also been called trimethylamine." Nearly twenty years ago Hofmann stated that the base found in herring brine was trimethylamine, and not propylamine, and this has been fully borne out by recent investigations. The adoption of this misnomer leads further on to the use of "hydrochlorate of this base" (*i.e.*, propylamine) being attributed to Dr. Beaumetz, a statement that would surprise that gentleman. Again, 'Nouvelles Recherches sur la Triméthylamine' was not the title of the report of the Commission appointed in France to investigate the subject, but of a brochure by Dr. Beaumetz, published by Masson, dealing with the medical aspect of the question. Moreover, neither from this treatise, nor from the report of the Commission, did it become "apparent that there were three substances having the same ultimate composition (C_3H_9N), and consequently isomeric," since this was known long before, and the Commission only professed to collate such information as already existed. Further, it is incorrect to say that Rabuteau "has found as the result of experiment that one, two, or even three of the atoms of hydrogen in ammonia may be replaced by compound alcohol radicles," etc., that fact having been discovered, and several salts of these compound ammonias prepared, by Adolphe Wurtz in 1849 (*Comptes Rendus*, vol. xxviii. p. 223), and the subject was followed up by Hofmann; indeed, there is nothing to indicate that Rabuteau himself even prepared the chemicals for his experiments, which were purely physiological, and Rabuteau states in his original paper that they were supplied to him by F. Wurtz. So much for the subject of the compound ammonias!

A few lines further on, departing from the accuracy of M. Jungfleisch—as shown in the abstract of his paper—the statement is made that Pasteur prepared racemic acid from [ordinary] tartaric acid, by the action of heat upon "tartrate of cinchonine." In his original paper (*Comptes Rendus*, vol. xxxvii. p. 162), Pasteur says he prepared it from tartrate of cinchonicine—which, as D. Howard has

shown (PHARM. JOURN. [3] vol. ii., p. 765), can also be prepared from cinchonidine—the point being that in this modification of these alkaloids the one dextro and the other lævogyrous, their optical properties appear to undergo a change analogous to that which probably takes place in the formation of racemic acid. With the same absence of accuracy Mr. Umney is made to suggest that "the chlorinated lime of commerce should be guaranteed to contain 33 per cent. of available chlorine;" the result of such researches as Dr. Wright's is that "the chemist is at last enabled to prepare the alkaloids themselves synthetically;" Mr. Allen's recent experiments have "led him to conclude that exhausted tea-leaves . . . had been added to genuine tea, in confirmation of which," etc. (then Mr. Allen must have been very late in making up his mind); Carles's experiments on cinchona barks are described as "chemical and microscopical."

Finally, in respect to Mr. Howie's test for turmeric in rhubarb, it is stated that "the colouring matter obtained [by chloroform] from turmeric is imperceptibly different in tint from that of rhubarb." What Mr. Howie does say (p. 563) is that "with really fine, bright-coloured East Indian rhubarb this stain is scarcely perceptible;" while the brilliant yellow stain, akin to that of turmeric, is yielded by the inferior East Indian and English rhubarbs.

Some of these misstatements may be due only to a want of precision in the language used, and may not have been intended by the writer to bear the construction now put upon them. But they can only be taken as they appear; and judged by Mr. Wood's own standard of last year, we think they are blemishes. Moreover, the fact that so many occur in sixteen pages is calculated to raise doubts as to the abstracts and translations, where so much depends upon an author's meaning being clearly grasped and precisely stated; doubts, however, that in this case, so far as we are able to judge, would have no foundation.

GEOLOGICAL STORIES: a Series of Autobiographies in Chronological Order. By J. E. TAYLOR, F.G.S. 12mo. Hardwicke, London, 1873.

In his 'Geological Stories' Mr. Taylor has endeavoured to strike into a new line of teaching so far as science is concerned, and on the whole, we think, with considerable success. Most of our readers must be familiar with certain children's books in which a pin, or a needle, or a fragment of old timber is made to relate the incidents of its existence from the first extraction of the metal from the mine, or the first shooting of the acorn, to the final catastrophe of whatever kind that has brought its useful days to a close. Mr. Taylor has applied this same method to the teaching of the first outlines of geology. In successive chapters fragments of granite, quartz, slate, limestone, sandstone, coal, salt, jet, Purbeck marble, chalk, clay, and lignite are made to tell their own stories, and these with one or two other chapters relating to the crag of the eastern counties, to boulders and gravel-pits, furnish an excellent sketch of the principles of stratigraphical geology. Of course there is a little absurdity involved in this mode of treatment, arising principally from the circumstance that the typical fragments, if we may call them so, selected by the author, are made to talk about general phenomena, of which, granting their consciousness, they could know no more than a private soldier does of the great movements of the army of which he forms a part; but this is a consideration which is not likely to occur to those young minds for whose instruction and delectation the little book is particularly intended.

Apart from this Mr. Taylor seems to have done his work conscientiously and well. His book is throughout in accordance with the most modern views of the different subjects of which it treats: it is pleasantly and very clearly written, and will certainly escape the charge of dryness which is the most fatal of all to a popular scientific treatise. With the help of the appendix, which contains a table of British formations and an illustrated explanation of some of the common technical terms, the young reader of 'Geological Stories' may easily gain not merely a general notion, but a very precise knowledge of the principal geological facts and theories. The woodcut illustrations, which are numerous, are for the most part very good.

BOOK RECEIVED.

THE HALF-YEARLY ABSTRACT OF THE MEDICAL SCIENCES: being a Digest of British and Continental Medicine, and of the Progress of Medicine and the Collateral Sciences. Edited by WILLIAM DOMETT STONE, M.D., F.R.C.S. Vol. lviii. July to December, 1873. London: J. and A. Churchill.

Obituary.

Notice has been received of the death of the following:—

On the 25th September, 1873, Mr. Henry Bloye, Pharmaceutical Chemist, of High Wycombe.

On the 30th December, 1873, Mr. William Charles Targett, Chemist and Druggist, of Leicester.

Notes and Queries.

[377.] OBSCURE FORMULÆ.—In answer to Notes and Queries No. 377, I think I can solve two out of the four difficulties mentioned.

1. "Tinct. Testæ."—A West End Physician used to order the shell of a species of Tortoise, the *Emys Guttata*, macerated for three months in rectified spirit. The formula was, I am almost positive, ℥ij of the shell to Oj of S.V.R., and ℥iv of this tincture (?) with ℥iijss of Aq. Dest. was prescribed. The dose of this potent mixture was one teaspoonful, given in cases of consumption, and, it is almost needless to add, with no very marked effect. About three years ago I frequently made up the above prescription.

2. "Pil Aloes Glacial."—These pills are prepared by Corbyn and Co. I have had occasion to procure them once or twice for a prescription.—JOHN N. PLACE.

---

[383]. CHILLI PASTE.—*D. B.* asks for a recipe for making Chilli paste.

---

[384]. COLOURS FOR CARBOYS.—Will any reader oblige me with a couple of good receipts (royal blue and green) for show carboys?—*J. R. H.*

SYRUP OF THE BROMIDE OF IRON.—Take of bromine three troy ounces; iron (in the form of wire) 350 grains; distilled water, three fluid ounces; citrate of potash, six troy ounces or q. s.; syrup, a sufficient quantity. Put the iron, with the distilled water, in a flask, and add of the bromine two troy ounces in small portions at a time, allowing the mixture to cool, if necessary, before the addition of each fresh portion. When the odour of bromine has disappeared, warm the mixture gently, until it assumes a green colour; filter and add the remainder of the bromine. Transfer the resulting solution of ferric bromide to a porcelain mortar, and add gradually, with constant trituration, citrate of potash, until the colour of the mixture changes from brown to green; finally, add simple syrup to make up thirty fluid ounces. The syrup thus prepared corresponds nearly in strength with the syrup of the iodide of iron, and may be administered in doses from twenty to thirty drops. It is elegant in appearance, not disagreeable in taste, and is not incompatible with alkalies, or with tannic acid.—*Med. and Surg. Reporter and Canadian Pharm. Journ.*

PALATABLE DRINK OF CASTOR OIL.—Dr. H. Trevcrton Bond, writing to the *Druggists' Circular*, recommends the following plan of dispensing castor oil and converting it into a palatable drink. Pour into a tumbler about six drachms of syrup of sarsaparilla, add a small quantity (about 20 grains) of bicarbonate of soda, stir with a spatula, add about a tea-spoonful of a saturated solution of tartaric acid, and again stir well; this produces a heavy viscid froth. Pour down the side of the tumbler, so as to sink to the bottom and not mix with the froth, about an ounce of water; then add the oil. The whole is to be drank without agitation. The water is at the bottom, the oil in the centre, and the froth on the top. The drink so prepared is said to be tasteless, and the oil is all taken, as after dispensing the glass can be washed clean with water, showing that no grease adheres to its sides.

IMPURITY IN TARTARIC ACID.—In the United States tartaric acid has been found by two observers to be sometimes contaminated with sulphuric acid. The consequence was that seidlitz powders prepared with such acid were unsatisfactory, the rochelle salt being decomposed, and sulphate of soda and cream of tartar formed. The deposit of the latter towards the conclusion of the effervescence was the occasion of the detection of the impurity.

Fresenius's Quantitative Analysis.

Sir,—We observe in the Pharmaceutical Journal of Jan. 10th, a review of the edition just issued by us of 'Fresenius' Quantitative Analysis,' and as there are one or two statements made which might give your readers a wrong impression, we, as proprietors of the English copyright of the work, must ask you to allow us to make the following explanation.

You ask why we, as publishers, have not brought out a translation from the author's manuscript of the new German edition now in course of publication. Our answer is, that Dr. Fresenius, as far as we can learn, has no such manuscript yet ready, and that the fact of the German edition being delayed is exactly the reason why we considered it would be a boon to those who wanted the book, if we were to publish a reprint of the fourth edition. It is quite true, as you say, that a book which was up to the mark in 1864, must necessarily in some of its chapters be somewhat antiquated in 1874. In the present instance, however, this is a matter over which we have no control, and our apology (if any be needed) for reprinting the fourth English edition must be, that for some time past second-hand copies have been in demand at an advance on the published price.

When Dr. Fresenius shall have completed his work of revision we shall be in a position to bring out a translation, with the latest additions and improvements.

We should like to add, that advertisements of the work distinctly state that the sixth edition is merely a reprint of the fourth.

J. and A. Churchill.

11, *New Burlington Street, London, W.*,
Jan. 12th, 1874.

[*** We give insertion to the foregoing letter simply because its tone seems to convey the impression that the writers consider they have a right to be heard, and because we are willing to meet their wishes, though we do not agree with their opinions.

As regards the question put to Messrs. Churchill in the review, we regret they have not furnished a more satisfactory reply. From their point of view we can understand their publishing a reprint of an old edition of a work that was in demand at a premium. From the editor's point of view and from our own we still cannot understand why that portion at least of the new German edition, published as long since as March, 1873, should not have been reproduced, even if it was not possible to obtain the subsequent half of the work, and we can only express our regret that Messrs. Churchill have been unable to obtain the manuscript of the second portion of that edition, which we should imagine from the lapse of time must be now far advanced towards completion, if not already fit for the press.—Ed. Ph. Journ.]

Chemists' Assistants' Salaries.

Sir,—On this subject an assistant who signs himself "Truth" addresses you in terms of complaint, and says "our positions are no better than the common labouring man or policeman." Will you allow me to say to him that assistants are more likely to get better paid when they are better educated; and that one of the best tests of education is the ability to write English without falling into the blunders of a "common labouring man." I presume your correspondent means that the position of assistants is no better than *that of* a labouring man. In instituting a comparison as to their remuneration "Truth" does not tell the whole truth. For instance, last winter I had an assistant to whom I was paying a salary of nearly £100 a year. He was taken ill and laid up at home for six weeks, during the whole of which time he received his full salary. In addition to this, during the six years he has been with me he has had a fortnight's holiday each year, for which also he always received his salary in advance. In addition to this he has had many and many a day and half-day to himself. Now a labouring man, such as a joiner or mason, would not have been paid for a single hour of the time during which he had thus been absent from his employment. In this respect I doubt not that I describe the conduct of druggists in general towards their assistants. If so, then it is not true "that the position of the chemist's assistant is no better than (that of) a common labourer."

The Whole Truth.

January 5, 1874.

The Sale of Poisons.

Sir,—I desire to call the attention of the pharmaceutical authorities to the fact that hawkers go about the country selling "white precipitate," thus infringing the Pharmacy Act of 1868. Now that the law compels examinations which involve expense and study I think it nothing but right that this hawking of poison should be stopped.

"Modified."

Grantham, Jan. 5th, 1874.

Date's Ointment.

Sir,—I observe in your Correspondence column that a writer wants the form for preparing Date's Ointment. I cannot help thinking that the query is nothing less than a snare to induce some unwary but confiding former assistant to divulge a previous employer's secret, and the sooner such practices are nipped in the bud, the better for the *bona fides* which should, "but too often do not exist," between master and servant. The ointment in question is prepared from a private form attached to an old-established business in Bristol, the proprietor of which has been a member of the Pharmaceutical Society from its foundation.

R. Edwards.

January 3rd, 1874.

[*** We should be sorry to conduce in any way to such a practice as our correspondent mentions, and in this case if he refers to p. 547, he will find that the formula has been given with every appearance of *bona fides*.—Ed. Ph. Journ.]

R. H. Swinburn.—Yes, it is, no doubt, a ferruginous concretion of the kind you imagine.

A. A., A. P. S.—The immature fruit of the orange; used as issue peas.

W. H. W.—You will find numerous formulæ for cements in vol. iii. of this Journal, p. 607. The difficulty in understanding your question arose from the fact that you had plainly written "grass," and not "glass."

G. Foster.—The fee for the Minor Examination is £3 3*s*.

"*Alpha*" is referred to the rule respecting anonymous communications.

Communications, Letters, etc., have been received from Messrs. W. Tearle, J. Mackay, "Plodding Student," "Cruciferæ," C. A. B.

THE AMORPHOUS ALKALOID IN CINCHONA BARKS.

BY DR. J. E. DE VRIJ.

Every chemist who has analysed cinchona bark will agree with me that a smaller or a greater part of the mixed alkaloids obtained from them is not only amorphous, but also its compounds with acids cannot be crystallized. Whilst the quinologists agree on the existence of this amorphous substance, they differ widely in their opinion on its real nature. Dr. O. Hesse, for instance, whose opinion deserves every consideration in this matter, contends in his remarkable paper, "Studies on the Alkaloids of the Cinchona Barks,"* that the amorphous substance in question is either cinchonicine or quinicine. Mr. D. Howard, in his very interesting paper on "Quinicine and Cinchonicine, and their Salts,"† says about this subject the following:—"The question now arises—Is the uncrystallizable alkaloid obtained from cinchona bark quinicine, or is it yet another alkaloid really uncrystallizable? Hitherto the most careful purification has failed to obtain crystalline salts from it such as have been described.‡ When quinicine is present it will, as has been stated, crystallize out of the mixture, but the bulk of the quinoidine, however carefully purified, refuses to crystallize, even after many months' standing. It seems highly improbable, though of course it is possible, that this is owing to some impurity which hinders the crystallization, for we find that quinicine salts prepared from crystallizable alkaloid crystallize entirely with comparative freedom, even when the heat used in its formation has been considerably above the point needed, and sufficient to decompose a portion, and there is no sign of any amorphous modification being formed."

For myself, I have already, twenty years ago, when Pasteur described his quinicine and cinchonicine, been convinced that the amorphous alkaline substance obtained from cinchona barks is not identical with these products of the modification of quinine, quinidine, cinchonine and cinchonidine, called quinicine and cinchonicine by Pasteur, though I was unable to prove satisfactorily that my opinion was right. After the publication of Mr. Howard's paper, however, I was still more confirmed in my opinion, for although I succeeded in obtaining the amorphous substance almost colourless, I was unable to obtain any crystallized compound from it, whilst the oxalate, hyposulphite, and bitartrate of quinicine, or cinchonicine, may easily be obtained crystallized. I considered, therefore, the amorphous substance to be an alkaloid or a mixture of alkaloids *sui generis*, which requires still further investigation. My investigations of this subject are still far from being complete, and although they can not therefore yet be published, I recently met with a fact which seems to me to prove indubitably the non-identity of the amorphous substance with quinicine or cinchonicine. I am indebted for this fact to a paper recently published by Dr. O. Hesse, on "The Action of Chloroform on the Sulphates of Quinine, Quinidine, Cinchonine, and Cinchonidine."§ Being struck by the great solubility of the sulphate of quinidine in this solvent, which Hesse had observed, I was led to try the action of chloroform on the oxalates of quinicine and of cinchonicine, for which preparations I was indebted to the kindness of Mr. D. Howard, and on the oxalate prepared by me from an amorphous alkaloid soluble in ether, obtained from Indian red bark. These preparations were dried on a water-bath before subjecting them to the action of chloroform. The results were very striking, as the action of chloroform on these three oxalates proved to be very different.

The oxalate of quinicine was sparingly soluble at the ordinary temperature, but dissolved freely at a temperature of 61° C. The solution in cooling deposited the greater part of the oxalate in crystals. It would be interesting to investigate whether these crystals contain chloroform in chemical combination, as I suppose they do.

The oxalate of cinchonicine dissolved freely at the ordinary temperature. By adding a few drops of water on the surface, the solution was transformed within a few minutes into a solid mass.

The oxalate of the amorphous alkaloid dissolved in the largest quantity at the ordinary temperature. By adding a few drops of water on the surface, the solution remained limpid, but the water attracted a part of the oxalate from the chloroformic solution.

Besides these facts, the dried oxalates behave quite differently on exposure to the air. Those of quinicine and of cinchonicine remain unaltered, but the other oxalate attracts moisture. This hygroscopic character is a property of all the compounds of the amorphous alkaloid which I have hitherto investigated, viz., the sulphate, hydrochlorate, acetate, oxalate and sulphocyanate. All these compounds, with the exception of the sulphocyanate, are soluble in all proportions of water, and, if they are as pure as possible, these very concentrated solutions, which have an alkaline reaction on red litmus paper, retain their limpidity even if they are mixed with a large quantity of distilled water.* These facts confirm my old conviction, and I remain therefore still of opinion that the discoverer of morphia, Dr. Sertürner, was right when about half a century ago he described, under the name of *Chinioïdine*, an amorphous alkaloid *sui generis* discovered by him in the bark of *C. Calisaya*. If this and other cinchona barks contain an amorphous alkaloid, of which the compounds with acids are equally amorphous, it is clear that it must accumulate in the mother-liquors of the quinine manufactures, so that the quinoïdine precipitated from these mother-liquors by an alkali must contain Sertürner's amorphous alkaloid, contaminated with other substances whose real nature is still unknown. I have some reason to suppose that the amorphous alkaloid in question is easily decomposed, so that it is very possible that the substances by which it is accompanied in the quinoïdine of commerce are partially the products of this decomposition.

CHINESE CAMPHOR.

According to a report issued upon this subject, the trees which produce "Chinese camphor" are not found within the district marked on maps of Formosa as Chinese territory. They occur only within the country of the aborigines, or upon the immediate border.

* If a concentrated aqueous solution of sulphate or another compound of the ordinary quinoidine of commerce, having a slight alkaline reaction, is mixed with a large bulk of water, a dark coloured resinous matter is precipitated.

The destruction of the trees is rendered necessary by the manufacture of camphor, and the trees are never replanted. Consequently, as the country becomes denuded the aborigines gradually recede, a corresponding encroachment being effected by the Chinese. The result of this state of affairs is that the border-country is the scene of continual disturbances, and fearful outrages, it is said, are committed by both sides, on every possible opportunity. A gentleman who recently penetrated into the interior states that, on entering the hut of one of the aborigines, he was proudly shown no less than six Chinese queues, or tails hanging behind the door, the possession of each queue indicating the capture of a head, and the scalping process. When they have been visited by foreigners, however, the aborigines show a desire to be friendly, but they seem to heartily abhor the Chinese, the hatred between the parties being a veritable war to the knife. The following incident is related in explanation of this unsatisfactory state of things. A member of a local foreign hong recently paid a visit to the camphor district, near San-Koh-ying, and on entering a hut belonging to one of the large dealers he found two aborigines confined in the interior. In answer to inquiries he was informed that the captives had been induced to meet a body of camphor dealers with the object of coming to an agreement about the purchase of certain trees, but as they had declined to agree to the precise terms proposed by the Chinese, they had been plied with sam-shu, and then seized and bound. If they did not yield, death was their only fate, but it was expected that they would think better of it, and come to terms. Under these adverse circumstances the production of camphor succeeds in maintaining itself at about the same annual rate without showing any very great progress or retrogression, but it may be noticed that the year 1872 showed a slight advance as compared with 1871. The production in the San-Koh-ying district, owing to the frequent attacks of the aborigines on the distillers, has slightly decreased of late, but not materially; while few districts show any augmentation of production. The country round Kiam-chai-ang has furnished an irregular supply of from 200 to 300 piculs per month. A very large proportion of the total production is, of course, exported in foreign vessels to other countries, where the article is in great demand. The price realized of late has shown a profit of two or three dollars per picul to the producers. A rather new feature is described as being a great increase at the dirtricts of production in the number of the buyers for the Hong Kong market, this being attributed to the increased facilities for transport afforded by regular steamers. It is stated that foreign buyers, not being able to compete with these Chinese dealers, who can live and work much more cheaply, have not bought so much of late as they used to do in former years. It is further mentioned that no attempt has been made to renew the monopoly of former years, and that the trade has lost much of the danger which its pursuit once involved.

MEDICATED WATERS.*

BY F. W. REINHOLD, JUNR.

THE notion that medicated waters should be made by distillation has still a strong hold in the views of many pharmacists. Recently a modification of the distillatory process has been advanced, and that is, to distil the volatile oils with water, instead of the herbs, barks, etc If the volatile oil be pure there is certainly an advantage in this change. Defenders of the methods by distillation would lead us to believe that medicated waters, particularly those made from fresh herbs, are very superior in the characteristic flavour, strength, and general permanence. But the best authorities on this question rather confirm the popular supposition that such distilled products, on the contrary, possess a very disagreeable herbaceous rankness, the peculiar leaf-odour and taste which is anything but desirable. Waters of this kind must always have age, during which time the rankness disappears, leaving them a natural and pleasant fragrance. Medicated waters prepared from dried but not too old herbs, yield pleasanter products than the fresh. Many volatile oils, when freshly distilled, have the same peculiar rankness, which disappears after some time. But the same volatile oil may later again become rank through oxidation, if not properly protected against atmospheric action. Pharmacists generally are not so much in love with the retort business as to extend its utility to the medication of waters. Medicated waters are prescribed so largely and so indiscriminately, that many pharmacists would have to keep a special medicating laboratory of stills in constant action for their required supply. Besides, waters thus prepared would entail extra and unnecessary expense on the consumer, without a really intrinsic value in return. The plea that the distilled waters are far the strongest is vain. Water will only dissolve a certain amount of volatile oil to become saturated, and therefore no manipulation will impregnate or supercharge it with more. Water can be easily saturated with any particular volatile oil without taking refuge in the retort.

So-called concentrated waters are also used, especially in England. These waters are said to be stronger than the officinal. They are sold to retail pharmacists for the purpose of making the ordinary medicated waters. But such traffic, in its very nature, is fraudulent in the last degree. When the officinal waters are already assumed to be saturated, how, in the name of reason, can simple water then dissolve sixteen times its saturating proportion of volatile oil? But the case is made plain when we know that diluted alcohol will just do this very thing. Most volatile oils will form a perfect or nearly perfect solution with diluted alcohol, or a mixture of equal parts of the strongest alcohol and water, in the proportion of four minims, or eight drops, to the fluid ounce. This solution, when poured into about 15 fluid ounces of water, will form a clear solution in most cases. A pint of this kind of medicated water will then contain additionally half a fluid ounce of alcohol, equal to about three per cent.

The best way to make these concentrated waters is to dissolve the oil in half the alcohol and mix the remainder of the alcohol with twice its volume of water, and then pour into this the first solution, with constant stirring. After standing a few hours the solution is filtered, if desirable, through magnesia alba.

To make concentrated camphor water, 16 grains of camphor are dissolved in 2 drachms of alcohol, and poured with rapid stirring into a mixture of 2 fluid drachms of strongest alcohol and half an ounce of water. This makes a clear solution. On pouring this into 15 fluid ounces of water it also makes a clear solution on shaking. The water then contains one grain of camphor to the fluid ounce, which makes it rather stronger in camphor than usual. The reason is, that water containing even so little as three per cent. of alcohol is a better solvent than pure water. This also holds good in regard to volatile oils. Medicated waters containing a trace of alcohol are not so apt to become turbid, in contact with saline substances, which is a very annoying feature, particularly with camphor water, which throws out abundance of camphor and assumes an unpleasant appearance when certain salts are dissolved in it. For the prevention of this precipitation the presence of a little alcohol is especially good.

* From the *Pharmacist*.

I believe, however, that the best way after all to make the medicated waters is to prepare them by simple maceration. That is, to shake the volatile oil with the water, then set it aside for a day or two, and shake the mixture occasionally and finally filter. I find that this saturates the water completely, and avoids the presence of magnesia and alcohol. The results I deem superior to the distilled waters, if care is taken to use pure and good oils. I find that the solubility of oils of bitter almond and gaultheria is far greater than that of the other volatile oils proper. The act of solution is almost instantaneous in each case, so that no time is required to arrive at complete saturation of the water. The oil of bitter almond seems to be the most soluble of the two.

One minim of volatile oil of bitter almond will dissolve perfectly and instantly in 6 fluid drachms of water, without the addition of alcohol or magnesia alba. According to this, the originator of the U. S. P. officinal aqua amygdalæ amaræ did not immortalize himself much when he concocted a formula which employed a quantity of magnesia alba for no purpose at all, and then used only 6 minims of oil to 12 fluid ounces of water, when the same quantity of water would have completely dissolved 16 minims of oil without the aid of magnesia alba.

In making camphor water the camphor is first pulverized and then shaken with the water, similar to the manner of making the other waters. The camphor can be powdered, with the addition of a few drops of alcohol, but even this alcohol is not required, because the addition of the same amount of water will accomplish the purpose equally well.

THE ALKALOIDS OF THE CINCHONA BARKS.*

BY O. HESSE.

(*Continued from p. 571*).

Quinine possesses the power, as was shown by Bouchardat, of deviating to the left the plane of polarized light. Bouchardat† found that at 22·5° C., $\alpha r = -121{\cdot}5°$, and at 16° C., $\alpha r = -129{\cdot}59°$. It appears therefore that the specific rotatory power of quinine is diminished by an elevation of temperature. De Vrij and Alluard,‡ being of opinion that Bouchardat, like themselves, had operated upon impure quinine, repeated his experiments. Both chemists therefore prepared absolutely pure quinine from herapathite, and they then found that at 25° C., $\alpha r = -141{\cdot}33°$, consequently a considerably higher figure than Bouchardat's. If the corresponding numbers for the yellow ray be taken, the values given by Bouchardat will be respectively $\alpha j = -158{\cdot}5°$ and $\alpha j = -169°$; for the number given by De Vrij and Alluard $\alpha j = -184{\cdot}35°$.

In order to be able to form a surer judgment upon these ratios, as well as those of the other important cinchona alkaloids, I have made numerous experiments with the aid of a remarkably large Wild's polarimeter. The whole of the experiments, except where the contrary is stated, were made at a temperature of 15° C. The source of the light used was the monochromatic sodium flame, and as solvents for the respective substances, such liquids were always used as did not themselves exercise any action upon polarized light. In that which follows l represents the length of the liquid column expressed in millimetres; p the proportion in volume of the substance contained in 100 volumes of the solution; and by α the angle of rotation observed, deduced from the mean of eight to twenty observations. Experiments were made with quinine prepared in various ways.

(I.) Sulphate of quinine, possessing the properties required by the German Pharmacopœia, was dissolved in dilute sulphuric acid and the base precipitated from the very dilute aqueous solution by excess of ammonia. When the precipitate had become crystalline, it was collected upon a filter, well washed and dried, first in the air and then in the exsiccator.

For $p = 2{\cdot}054$ (the substance being anhydrous*) and $l = 200$, $\alpha = -6{\cdot}70°$.

(II.) As in the commercial preparation of sulphate of quinine it is difficult to prevent the adherence of traces of foreign matters present in the mother liquors, which could only be removed by repeated crystallizations, it was interesting to ascertain what influence a single crystallization of the quinine of experiment (I.) would have, especially as De Vrij and Alluard had stated that absolutely pure quinine could only be obtained from herapathite. Some of the sulphate of experiment (I.) was therefore crystallized from boiling water, and the quinine precipitated as before described.

For $p = 3{\cdot}874$ (anhydrous and in alcoholic solution) and $l = 200$, $\alpha = -12{\cdot}86°$.

(III.) Finally, after converting the same kind of sulphate into herapathite, it was placed in water treated by H_2S, the deposited sulphur removed, excess of sulphuretted hydrogen driven off, and the acid liquor so obtained precipitated with ammonia. As the precipitate was slightly grey it was redissolved in dilute sulphuric acid, the solution decolorized by animal black, and the base precipitated afresh.

a. For $p = 4{\cdot}269$ (anhydrous and in alcoholic solution) and $l = 100$, $\alpha = -7{\cdot}07°$.

b. At a temperature of 25° C., for $p = 1{\cdot}0341$ (anhydrous and in alcoholic solution) and $l = 200$, $\alpha = -3{\cdot}36°$.

Calculated according to these figures, the results are :—

	Experiment.			
	I.	II.	III*a*.	III*b*.
$\alpha j =$	$-163{\cdot}09°$	$-165{\cdot}97°$	$-165{\cdot}61°$	$-162{\cdot}46°$

It appears from this that in order to prepare absolutely pure quinine it is by no means necessary first to convert the sulphate into herapathite, if the quinine sulphate will pass Kerner's† test, since in this case a single crystallization of the salt from boiling water was sufficient to reduce the traces of foreign matter which adhered to it upon the drying of the mother liquor to so small a quantity that the quinine so obtained differed in no way from absolutely pure quinine. We have, therefore, the following results from absolutely pure quinine, prepared by either of these two methods :—

At 15° C. $\alpha j = -165{\cdot}79°$ (mean of experiment II. and III*a*.)

At 25° C. $\alpha j = -162{\cdot}46°$.

The specific rotatory power of quinine in alcoholic solutions diminishes, therefore, in proportion as the temperature is raised, but this diminution is not so great as that stated by Bouchardat. Otherwise these results accord satisfactorily with Bourchadat's, but differ notably from those of De Vrij and Alluard. Probably the latter chemists had left a point somewhere unconsidered and were thus conducted to erroneous conclusions.

The rotatory power of the salts of quinine depends upon the nature of the salt and the proportion of acid that it contains, as is shown in the following examples :—

The sulphate of experiment (II.) was dissolved in concentrated alcohol : $p = 1{\cdot}9181$ (anhydrous) and $l = 220$, $\alpha = -8{\cdot}08°$, which gives for the anhydrous sulphate $\alpha j = -191{\cdot}47°$.

The same salt was dissolved in water and 6 equivalents of SO_3‡ added : $p = 2{\cdot}6662$, l 220, and $\alpha = -13{\cdot}42°$; calculated $\alpha j = -228{\cdot}78°$.

Thus when anhydrous sulphate of quinine is dissolved

* Translated from the 'Vierteljahresschrift für praktische Pharmacie,' vol. xxii., p. 366.

† Gmelin, organische Chemie, vol. iv., p. 1692.

‡ Chem. Centralblatt (1864), p. 1116.

* The determination of the water of crystallization was always made by a special experiment, in order to avoid the possibility of operating upon a substance that had acquired altered molecular conditions.

† 'Annalen der Chemie und Pharmacie,' vol. cxxxv., 327.

‡ The prepared acid contained 4 per cent. by volume of SO_3.

in the same liquid with six equivalents of SO_3 under the form of a dilute acid the specific rotatory power of the salt is augmented 37·31° ; or, the rotatory power of quinine in combination as a neutral sulphate is $\alpha j = -220·43°$, and in acid solution containing for each molecule of quinine $3\frac{1}{2}$ molecules of SO_3, $\alpha j = -264·66°$. De Vrij and Alluard found for the sulphate of quinine, which they termed "trois cachets," and which they dissolved in sulphuric acid (but how much ?) $\alpha j = -255·6°$, which gives for quinine $\alpha j = -293·1°$. On the other hand, for pure quinine, which they dissolved in an also unrecorded quantity of sulphuric acid, they found $\alpha j = -273·03°$. Obviously these differences were occasioned solely by the quantity of acid employed.

It may be mentioned that Bouchardat likewise determined the rotation of the neutral sulphate of quinine, and found that in a feebly acid solution, $\alpha r = -147·7°$. or $\alpha j = -192·5°$, figures very near to those I have obtained.

Another important specific rotatory power belongs to the quinine sulphate with one equivalent of acid.

With this it was found:—

(I.) $p = 1·7671$ (crystallized salt in alcoholic solution), $l = 200$, $\alpha = -5·54°$.

(II.) $p = 6·6869$ (another specimen of crystallized salt in aqueous solution), $l = 200$, $\alpha = -20·96°$.

It appears consequently from this experiment—

	I.	II.	Mean.
For $C_{20}H_{24}N_2O_2$, $H_2SO_4+7H_2O$ $\alpha j =$	$-156·75°$	$-156·72°$	$-156·73°$
For Quinine ... ... $\alpha j =$	.....	.....	$-264·30°$

From these experiments this interesting fact appears : that quinine in its combination with sulphuric acid in the proportion of one molecule of base to one of acid, possesses the same rotatory power as in a solution of the neutral sulphate in concentrated sulphuric acid. When, therefore, this latter is dissolved in dilute sulphuric acid, it only passes into the state of acid sulphate. But the rotatory power of quinine in the crystallized monacid salt can be augmented by a further addition of sulphuric acid. From this crystallized sulphate with one equivalent of acid were obtained :—

(*a*) $p = 4·054$, $l = 200$, $SO_3 = 1$ molecule, in aqueous solution ; $\alpha = -13·33°$.

(*b*) $p = 4·054$, $l = 200$, $SO_3 = 3$ molecules, also in aqueous solution ; $\alpha = -13·50°$.

Calculated from this experiment :—

	a.	b.
For the crystallized salt $\alpha j =$	$-164·40°$	$-166·5°$.
For quinine ... ... $\alpha j =$	$-277·23°$	$-280·77°$.

Finally, the sulphate with two equivalents of acid, in alcoholic solution, gave when $p = 4·9896$, and l 200 ; $\alpha = -14·40$ therefore :—

For $C_{20}H_{24}N_2O_2$, $2H_2SO_4+7H_2O$ $\alpha j = -144·30°$.
For quinine ... ... $\alpha j = -287·62°$.

When this salt was treated with dilute sulphuric acid, no considerable difference in the rotatory power was any longer observed. But it appears from these experiments also that when the monacid sulphate is treated with an excess of sulphuric acid, it by no means passes at once into the state of diacid sulphate, but that this combination is formed only after the lapse of time.

When quinine is combined with hydrochloric acid, still different results occur. Thus :—

(*a*) $p = 9·979$ (crystallized salt in alcoholic solution), $l = 100$, $\alpha = -13·57°$.

(*b*) $p = 4·7043$ (crystallized salt dissolved in water, with addition of much hydrochloric acid), $l = 200$, $\alpha = -19·02°$.

These numbers give :—

For $C_{20}H_{24}N_2O_2$, $HCl+2H_2O$ ... ... $\alpha j = -135·98°$.
For quinine ... ... $\alpha j = -166·41°$.
For the salt in hydrochloric solution ... $\alpha j = -202·15°$.
For quinine in combination with HCl, in hydrochloric solution ... ... $\alpha j = -247·39°$.

It will thus be seen that in the determination of the rotation of the plane of polarization induced by quinine, much depends upon the nature and quantity of the solvent ; the temperature also influences the rotatory power of a quinine solution. If it be remembered besides, that quinine becomes strongly electric by friction, it will be evident that for such quinine, so long as it retains that condition, there would be found a molecular rotation different from normal quinine. It will be, therefore, understood why I have formerly* objected to the estimation of quinine by means of the polarimeter. Although I, nevertheless, at that time made the proposition to prepare the quinine tartrate from the mixture of cinchona alkaloids, and with this to test the rotatory power, I can only now, after performing the above recited experiments, express my sincere regrets at having made the suggestion.

I may mention here, also, that the γ-quinidine of Kerner,† appears to be nothing else than crystallized quinine. This alkaloid crystallizes in small efflorescent needles, and its sulphate resembles sulphate of quinine, which, like it, gives an oily and resinous precipitate with iodide of potassium. If water, at 32° C., be added to a warm alcoholic solution of quinine, until a milky turbidity is produced, the liquid, upon clearing, deposits above the resinous precipitate white prisms of quinine. At the same time the resinous cake gradually takes also a crystalline structure. These crystals, which are obtained with difficulty and only at a low temperature, are hydrate of quinine. Dried in the air,—

(1). 0·4640 gram of non-effloresced matter heated 120° C. gave 0·0690 gram H_2O.

(2). 0·374 gram of another specimen lost at 120° C. 0·0578 gram H_2O.

Calculated for $C_{20}H_{24}N_2O_2 + 3H_2O$.	Experiment I.	Experiment II.
$3H_2O$ 14·28	14·87	14·55

This hydrate of quinine appears under the form of white, shining, slender prisms, gradually becoming dull in dry air, which are often obtained of considerable length (7 centimetres). These crystals, at any rate, have not the pearly brilliancy which characterizes those of cinchonidine. I am, therefore of opinion that Duflos,‡ when he stated that he had obtained crystals with a pearly lustre from an alcoholic solution of quinine, had made his experiment upon quinine containing cinchonidine, and his crystallized quinine would therefore be only crystallized cinchonidine.

Finally, the substance called quinine by Reichardt,§ and many other chemists who have practised the analysis of cinchonas, must be mentioned. This substance was but an extract obtained either by means of ether or of chloroform, of which no ultimate analysis was made. It probably, therefore, in some cases—for instance, when obtained from certain huanuco barks—may not have contained any quinine at all, consequently, would not merit the name of quinine.

(*To be continued.*)

NOTES ON PANCREATIN.‖

BY RICHARD V. MATTISON.

The increasing popularity of pharmaceutical preparations of this valuable substance induces the writer to offer to the profession a few notes on the subject, hoping they may be of service in the elimination and proper exhibition of it in a medicinal form, which will be pleasant and agreeable both to the sight and palate.

Prefacing these remarks, a short notice of the pancreas and its action will be found intercsting. This is situated within the curve formed by the duodenum, and opens into

* *Berichte der deutschen chemischen Gesellschaft*, iv., 693.
† *Zeitschrift für Analytische Chemie*, vol. i., p. 150.
‡ *Handworterbuch der Chemie*, 2. Aufl. ii., 1016.
§ 'Reichardt, über die chemischen Bestandtheile der Chinarinden.' Brunswick, 1855.
‖ *American Journal of Pharmacy* [4] vol. iii., p. 531.

the intestine by a duct common to itself and the liver. In its anatomy it closely resembles the salivary glands, and the fluid elaborated by it, called *pancreatic fluid*, appears almost identical with ptyalin. Like that secretion, pancreatic fluid, when pure, is a colourless, transparent, and slightly viscid liquid, alkaline when fresh, quickly, however, on standing, becoming first neutral and then acid, differing, however, from saliva in containing no sulphocyanogen. It resembles albumen in being nearly wholly coagulated by heat, and also by the mineral acids, especially when concentrated; precipitated also by alcohol. When this precipitated coagulum is separated from the liquid, and water added to it, it is soluble, thus essentially differing from albumen.

Its specific gravity is from about 1·008 to 1·009, and contains from 13 to 19 per cent. of solid matter, of which, according to Schmidt, about 12½ per cent. is pancreatin.

The action of this peculiar principle upon starch is to change it to glucose, and upon fatty and oily substances to quickly emulsify them, thus rendering them easily absorbed and assimilated by the lacteals.

Bernard supposed the fat to be decomposed, and Fownes also states that the fat is resolved into fatty acid and glycerin. This is denied by most recent writers, and such is certainly not its principal action, no saponification apparently taking place, which fact may be easily proved by thoroughly mixing, with agitation, a solution of pancreatin with cod-liver oil. After emulsification, which almost immediately occurs, the oil may be separated by simply agitating the emulsion with ether or petroleum benzin.

This *emulsification* is the *essential* purpose of the pancreatic fluid, thus breaking up the fatty globules and allowing assimilation to proceed with rapidity, and in this respect is greatly superior to either saliva or albumen. Liquid fats are insoluble in the aqueous albumino-saline fluid, with which the vascular tissues are saturated; consequently no absorption can take place, and the oil passes from the patient in the same state in which it was administered. This occurs most frequently during the administration of cod-liver oil to phthisical patients, and the association of this oil with pancreatin offers a valuable and natural method of administration.

At the time when the subject was brought to the writer's notice, he was largely engaged in the manufacture of saccharated pepsin by the process of Mr. E. Scheffer (an excellent one, by the way), and the idea suggested itself that perhaps a solution of sodium chloride would precipitate pancreatin in the same manner as it does pepsin. After some preliminary experiments, the following was adopted as furnishing the best result :—

The pancreas is dissected and macerated in water acidulated with hydrochloric acid for about forty-eight hours, then separated, and the acidulated solution of pancreatin passed through a pulp filter until it is perfectly clear. To this clear solution is then added a saturated solution of chloride of sodium and allowed to stand until the pancreatin is separated. This is carefully skimmed off and placed upon a muslin filter and allowed to drain, after which it should be washed with a less concentrated solution of sodium chloride, and then put under the press. When all the salt solution has been removed, and the mass is nearly dry, it is rubbed with a quantity of sugar of milk, and dried thoroughly without heat, after which it is diluted until ten grains emulsify two drachms cod-liver oil. To this may be given the name of "saccharated pancreatin."

An elixir being suggested for the exhibition of this in an elegant form, the following formula was devised, and we think will be found very agreeable :—

Pancreas	No. vj.
Hydrochloric Acid	f℥iv.
Glycerin	q. s.
Water	Ciss.

Macerate the dissected pancreas for three days in the mixture of water and acid with Oiiss of glycerin added; then separate the liquid, strain and add f℥iiss oil of orange and a sufficient quantity of glycerin, to make the liquid measure Ciiss; this is then filtered until perfectly transparent. The result is a sweet acidulous elixir, one fluid drachm of which will easily emulsify half a fluid ounce of cod liver oil—a valuable addition to the number of preparations combining efficiency with pharmaceutical elegance.

METHENYL IODIDE.*

BY R. ROTHER.

Iodoform is best prepared by the process of Wittstein, which consists in gently heating a mixture composed of dipotassic carbonate, two parts; iodine, two parts; alcohol, 95 per cent., one part; and water, five parts, until the liquid becomes colourless. The bright yellow scaly precipitate is rinsed upon a filter, washed, and dried in the open air.

The yield is 17 per cent., or one-sixth of the iodine used.

It will be seen that this is not an economical process when reference is only had to the iodoform product, but Wittstein providently directs the purification and saving of nearly all the iodine which has passed into other combinations through the resulting reactions.

By evaporating the filtrate to dryness, mixing the residue with charcoal, calcining at a red heat, dissolving in alcohol, filtering, and again evaporating, nearly all the wayward iodine is secured as pure potassic iodide.

There are other methods somewhat different in principle, which give a greater yield of iodoform from the iodine employed, but Wittstein's process, for simplicity and general economy, excels them all.

Wittstein, in remarking upon the diverse reactions which the process determines, shows, firstly, that a large amount of iodine is lost to the iodoform yield by reacting directly with the carbonate, and thus producing potassium iodide and potassic iodate, as shown in the following reaction :—

$$3(K_2CO_3) + 6\,I = 5KI + KIO_3 + 3CO_2.$$

Secondly, that a portion of the iodine reacts directly with the alcohol, generating ethyl iodide, which escapes as vapour and hydric iodide, which, reacting upon the carbonate, forms potassic iodide and carbon dioxide evolved with effervescence. Ethyl iodide is quite appreciably given off, and entails a direct loss of iodine, which can not be recovered in an available form, unless some use can be made of it in this condition; however, ordinarily it would scarcely repay the effort of collecting.

Thirdly, appears the direct coalition between alcohol, potassic carbonate, and iodine, emerging again as methenyl iodide, potassic iodide, potassium formate, water and carbon dioxide, which he explains thus :—

$$C_2H_6O + 8I + 3(K_2CO_3) = CHI_3 + 5KI + KCHO_2 + 2OH_2 + 3CO_2.$$

Now since the product for which the process is worked is so small, therefore a large amount of expensive material has to be manipulated, and although both products are useful and staple, nevertheless the large manufacturers always charge a price for iodoform which approaches the total cost of the iodine consumed; hence the large producer pockets a gain he is not justly entitled to, and as the dispenser must adjust his price according to the manufacturer's demand, the consumer is consequently burdened ultimately with an exaggerated cost for a fictitious value, which, under the circumstances, seems like extortion in the last degree.

With a view to alleviate this irregularity and render the process less expensive and more productive, the writer resorted to a trial with various bases, believing that a less energetic metallic base would not seize the iodine so voraciously as to leave but a small remnant available for

* From the *Pharmacist*, vol. vi., p. 357.

the objective compound. For this purpose calcium carbonate, borax, and disodic carbonate were tried. However, none seemed to answer at all; disodic carbonate showed more disposition than the first two. However, the iodine during the digestion was held so loosely that a considerable portion sublimed into the neck of the bottle.

Upon this the writer's first impulse was to employ bromine to replace the iodine, in the stronger combinations with the potassic base, but in view of the fact that a great probability existed for the generation of an undesirable bromiodoform, the writer also abandoned this project.

Attention was next directed to the uselessly combined iodine, for a continuation of the process, and for this purpose the writer proposed to liberate this iodine and cause it to react a second and third time, or until consumed as iodoform if possible. Now, it is known that when a mixture of an iodide and iodate is treated with an acid so as to produce hydric iodide and hydric iodate, these new bodies will react upon each other, resulting in their total disruption into free iodine and water, thus :—

$$5HI + HIO_3 = 6I + 3OH_2.$$

Or, in case of potassic salts treated with chorhydric acid, thus :—

$$5KI + KIO_3 + 6HCl = 6I + 6KCl + 3OH_2.$$

Therefore, if after the separation of the generated iodoform, the colourless liquid is acidulated with chlorhydric acid, all the iodine combined in the first instance will again be freed; however, this treatment still leaves that which was absorbed in the second and third stages in an occluded state. To render this also available, the writer employed chlorine indirectly, or rather in a nascent state, by causing acid potassium chromate to act upon the potassic iodide in the presence of chlorhydric acid, which results in the liberation of the iodine and the formation of chromic chloride, thus :—

$$6KI + K_2CrO_4.CrO_3 + 14HCl = 6I + 8KCl + Cr_2Cl_6 + 7OH_2$$

Or

$$K_2CrO_4.CrO_3 + 14HCl = Cr_2Cl_6 + 2KCl + 6Cl + 7OH_2$$

And

$$6KI + 6Cl = 6KCl + 6I.$$

Therefore, the writer has modified the process in accordance with these results, and succeeded in converting the iodine wholly (excepting that carried off as ethyl iodide) into iodoform, by repeatedly freeing and allowing it to decompose additional alcohol.

The writer conducts the process as follows, and in order to secure a uniform product for each repetition, about one-sixth of the original amount of iodine is regularly added after each operation.

Four troy ounces of iodine; 4 troy ounces of dipotassic carbonate; 2 troy ounces of 95 per cent. alcohol, and 10 troy ounces of water are mixed in a comparatively large flask, and warmed in a water-bath until the solution is decolorized; the clear liquid is now decanted and the precipitate rinsed, with the addition of a little water, upon a capacious filter. The decanted liquid is now treated with chlorhydric acid, adding this gradually at first, and an excess of 2 or 3 ounces is then added, together with $\frac{1}{4}$ to $\frac{3}{8}$ ounce of acid potassium chromate, in powder; after a few moments, dipotassic carbonate is carefully added to neutralization, and then 4 troy ounces more is introduced, together with about $\frac{3}{4}$ of an ounce of iodine and 2 ounces of alcohol; this mixture is again digested in a water-bath, and when effervescence has ceased in the green solution, the supernatant liquid is poured off from the precipitate, and further treated as before. The precipitate is rinsed into the filter with the first product, and when the process is discontinued, the gathered crystals are well washed with water, and spread out in the open air to dry.

Thus the process may be continued indefinitely or until the saline accumulation becomes too great. When after several repetitions, the liquid gets too bulky, it may be condensed by evaporation.

The potassic carbonate does not seem to precipitate chromic hydrate from the solution, the formic acid renders this soluble in the alkaline liquid.

Wittstein has found that an excess of the carbonate is not injurious, but seems rather to be an advantage.

The writer finds also that an excess of chromate exerts no opposite tendency, and to judge from limited observations, it would seem that with this in the alkaline liquid in presence of sufficient alcohol, the iodine is not so largely absorbed by the alkaline base, as the yield of iodoform under these conditions is greater.

The only additional expense in this process is the chromate and chlorhydric acid, but the required quantity of the former is small, and the substance itself is cheap.

The ordinary commercial chlorhydric acid can be used, and therefore the additional outlay in this case is also trivial.

The most satisfactory results, however, are obtained by the use of wood spirit. In this case the iodoform yield at each operation exceeds one-third of the weight of iodine used. The reaction evidently differs from that with ethyl alcohol. An exceedingly irritating gas (to the eyes) is simultaneously evolved.

It will be apparent that this method, put into general use, ought to bring the price of iodoform within reasonable limits.

PHOSPHATE OF IRON AND ITS COMBINATIONS.*

BY CHARLES GEISSE POLK, M.D., OF PHILADELPHIA.

Iron has long deservedly held a very high place in the lists of tonics. At least one hundred different combinations have been proposed, and more than one-third of that number are now incorporated into the different pharmacopœias. These are divided into two chemical classes, the proto-salts and the sesqui-salts, designated ferrous and ferric salts, the former being universally esteemed as the more powerful remedial agents, the latter as the more easily managed pharmaceutical products. Of the former the proto-carbonate, the iron reduced by hydrogen, the proto-sulphate, the proto-citrate, and the proto-phosphate are especially esteemed. Of the latter the chloric tincture, the ammonio-citrate, the pyrophosphate, and alkaline tartrates receive high consideration. Notwithstanding the numerous objections very justly urged against the tincture of ferric chloride, it is, and probably ever will be, the most valued and most extensively used of the preparations of iron. The preparation I especially desire to consider in this paper, the phosphate of iron, although by no means a modern one, is scarcely ever used in its officinal form. Uncombined it has never gained much favour. The preparation is, however, a good one, and is capable of being combined so as to form some excellent chalybeate pills. The following formulas are very popular ones with me :—

℞. Ferri Phosphatis . . . . . ℥ i.
Quiniæ Sulph. . . . . ℥ ss.
Ext. Ignatiæ Amaræ . . . . gtt. vj.
M.

Divide in pills No. xxx. Take one three times a day.

℞. Ferri Phosphatis . . . . . ℈ ij.
Quiniæ Sulph. . . . . ℈ i.
Ex. Belladonnæ Alcoholic. . . . grs. v.
Ex. Aconiti Alcoholic. . . . . grs. iij.
Ex. Cannabis Indicæ . . . . . grs. x.
M.

Divide in pills No. xx. One pill three times a day.

℞. Ferri Phosphatis . . . . . ℈ ij.
Quiniæ Sulp. . . . . ℈ i.
Acid. Arseniosi . . . . . grs. i.
Morphiæ Sulph. . . . . gr. i.
M.

Divide in pills No. xx.

* From the *Druggists' Circular and Chemical Gazette*, January, 1874.

But, however valuable a pilular form of iron may be, it is not that which will hold the popularity of a solution, either in the form of a syrup, tincture, or elixir. Even the iron reduced by hydrogen, which is unquestionably the best restorer of iron to the blood, is comparatively little used. The proto-carbonate still holds the preference of the grey-headed members of the fraternity, while the soluble scaled salts with ammonium-citrate are preferred by the younger members of the profession; the choice is between the citrate and pyrophosphate, with perhaps a predominating preference for the latter. The bibasic phosphate constitutes the iron ingredient in nearly all the proprietary elixirs, sold under the names of Elixir Phosphate of Iron, Quinia, and Strychnia; Elixir of Calisaya ferrated, and Elixir of Gentian; the tribasic phosphate being ill adapted for the purpose, and a solution in an alcoholic menstruum being very unstable.

The theory, or rather theories, upon which the phosphates and hypophosphites have grown into the esteem of the medical world may thus be briefly stated:—Phosphorus, as is well known, is an important element in the brain and nervous system, the expression, "thoughts that burn," being a physiological fact as well as a poetic figure. Dr. Churchill, an American physician practising in the capital of France, conceived the idea that phthisis pulmonalis emanated from a deficiency of phosphorus in the system. This deficiency he proposed to remedy by introducing phosphorus into the system by means of hypophosphorous acid in the salts of lime and soda. The idea was fascinating, and infatuated a very large portion of the profession. They dreamed that the hitherto relentless upas of human existence was at length mastered, that no longer was its touch withering and its impress death, but that under the life-giving power of the hypophosphites the hectic flush would depart, the cough cease, the emaciated frame resume its former proportions, and as the cause upon which these accrued was removed, health and strength would be restored, and science would, indeed, be triumphant over the foe which heretofore had baffled human skill, and annually consigned to the grave the beautiful and lovely of earth. This beautiful dream, however, proved delusive; consumption still continued its ravages, and the hypophosphites were found to be less efficient than cod-liver oil, yet capable of greatly enhancing the curative power of the latter. But if the hypophosphites did not confirm those high hopes and lofty expectations, they proved to be a powerful remedial combination, capable of giving beneficial results in wasting diseases hitherto unattained by any known agent. They yet retain the esteem of very many intelligent physicians, although, I believe, the present estimate of them is below their intrinsic value. A preparation I have long esteemed, containing two grains of the hypophosphite of iron, one grain of the hypophosphite of quinia, and one forty-eighth of a grain of the hypophosphite of strychnia in each drachm, I make thus:—

℞.	Ferri Hypophosph.	grs. 192
	Quiniæ (alkaloid fresh)	grs. 96
	Strychniæ	grs. ij.
	Acid. hypophosph.	gr. i.
	Syrupi, q. s.	℥ xij.

Take the freshly precipitated hypophosphite of iron, the freshly precipitated quinia, and the strychnia, and add sufficient hypophosphorous acid to form a solution; mix it with sufficient syrup to measure twelve ounces; bottle and carefully cork. This preparation is a very valuable tonic, and seems to me to be more important than any other combination of the hypophosphites. Mixed with equal parts of the syrup of soda and lime hypophosphites, its value seems to be greatly enhanced. Sometimes, combined in equal proportions with the syrup of the hypophosphite of manganese, it proves a powerful restorer of lost strength and vigour.

This formula has proved sometimes very satisfactory:—

℞.	Ferri Hypophosph.	℈ ij.
	Manganesii Hypophosph.	℈ i.
	Quiniæ	℈ i.

Divide into twenty pills. Take one pill three times a day.

During the summer of 1857 I devoted especial attention to the study of tuberculosis, and having imbibed the doctrines of Dr. Paine, of the University of New York, directed my attention to the brain and nervous system, with especial regard to their influence over the respiratory system. Analyses of twenty autopsies of the victims of phthisis gave evidence of a marked diminution of the amount of phosphorus in the brain and nervous system, with apparent atrophy of the cerebellum, medulla oblongata, and pneumogastric nerves.

(*To be continued.*)

PROPOSED PHARMACEUTICAL BILL FOR IRELAND.

Deputation to the Chief Secretary.

On Thursday afternoon, January 15th, a deputation from the Apothcaries' Hall and the Chemists' and Druggists' Association of Ireland waited on the Right Hon. the Chief Secretary, at the Castle, for the purpose of impressing on his lordship the desirability of the Government passing a Pharmaceutical Bill for Ireland, similar in its provisions to that now in force for England. The deputation comprised—Dr. O'Neill, governor of the Apothecaries' Hall; Dr. Ryan, T.C., deputy governor; Dr. Leet, secretary; and Dr. Collins, Dr. Montgomery, and Dr. C. F. Moore, directors; Mr. E. M. Hodgson, President of the Chemists' and Druggists' Association; Mr. J. M. Goodman, treasurer; Mr. Wm. Hayes, secretary; and Mr. W. Ledger Erson, J.P.

Dr. Leet, on behalf of the Apothecaries' Hall, explained the object of the deputation, which was to endeavour to enlist the co-operation of the Government in having a legislative enactment passed regulating the profession of pharmacy in Ireland, similar to that adopted in England. It was of the most urgent necessity, for while it gave the apothecaries and druggists no pecuniary advantage, it would be a great benefit to the public at large. He mentioned the fact that what they now wanted was merely the second part of a bill introduced by Baron Dowse when Attorney-General, the first part of which (known as the Poisons Act) had already passed into law. He believed that, had time permitted, or were it not that Mr. Dowse had been meanwhile promoted to the bench, the measure would have been carried in entirety, as it seriously concerned the safety of the public. There were to his knowledge between 20 and 30 of the most important market towns in Ireland, with populations varying from 10,000 to 50,000, wherein there was no apothecary or competent person duly qualified to compound medicine, consequently causing great inconvenience to all classes. The General Medical Council, seeing the peculiar circumstances of the case, had adopted a resolution expressing their approval of such an act as they now sought, which was intended to enable the Apothecaries' Hall to grant certificates to persons who properly qualified themselves by a prescribed examination to compound medicines. The diploma of the Hall at present not only gave the recipient authority to compound medicine but also to practice as a physician—in fact, it was for all practical purposes equal to a degree for surgery. In Tyrone, Armagh, and other large populous districts in the North of Ireland, there were very few apothecaries. It was strange that though they annually sent out the usual number of apothecaries there was a great dearth throughout the country of persons qualified to compound medicines. But that was accounted for by the introduction of the Medical Charities Act, under which dispensary doctors were appointed, and that apothecaries having such high qualifications sought other spheres of practice. To meet that want they conceived the proposed bill was necessary, so as to give the public a guarantee that the persons who received a modified qualification

from the Apothecaries' Hall were competent to make up prescriptions—namely, by granting them a pharmacy licence, without having to undergo the present apprenticeship, which carried the double qualification. To be able to compound medicines required a certain scientific knowledge and education, a great deal of intelligence, and a considerable amount of training, and that would be looked after by the Apothecaries' Company before granting any certificate. Any opposition that had been previously offered to the bill as introduced by Mr. Dowse had been since withdrawn, and the Druggists' Association now gave the proposed measure, as altered in one clause so as to meet their views, their fullest concurrence.

Mr. Hodgson, as representing the Chemists and Druggists' Society, intimated to his lordship that that body deeply felt the necessity for the adoption of the proposed bill, which was simply a modification of the qualifications at present required by the Apothecaries' Company. Those who obtained certificates in pharmacy would not be entitled to practice medicine; and while thus the privileges of the medical profession would not be infringed upon, the public throughout the country would, through the druggists possessing such certificates, have the advantage of there being in the various towns persons fully competent to make up prescriptions. On the part of his association, he felt himself at liberty to state that the chemists and druggists of Ireland would offer no opposition whatever to the measure promoted by the Apothecaries' Hall.

In answer to the Marquis of Hartington,

Dr. Leet explained the powers conferred by the Act of Parliament in 1792 on the Apothecaries' Hall Company, with jurisdiction throughout Ireland, and stated that the additional power now sought was to grant pharmaceutical licences alone.

The Marquis of Hartington called the attention of Dr. Leet to his suggestion in a communication to that gentleman to the effect that the bill should be introduced by a private member. No better man could undertake such a measure than Sir Dominick Corrigan. Had he been consulted on the matter?

Dr. Leet replied that the draft vote had been submitted to Sir Dominick, who had expressed himself satisfied with it.

The Marquis of Hartington asked had any overtures been made to Sir Dominick with reference to the introduction of the bill?

Dr. Leet said the deputation concurred that the bill ought to be taken up by the Government.

The Marquis of Hartington said perhaps it ought, but the Chief Secretary had a great many matters at present to occupy him, and hitherto he had not given his attention to the medical question. He had listened with great attention to what had been stated. He admitted that there appeared to be a very strong case made in favour of legislation upon this subject. It would be necessary for him to make some further inquiries and to get some assistance, which he would ask from the medical department of the Privy Council in London.

Dr. Collins said that, from the support given to the measure by Mr. Warren when Attorney-General, he believed the Government were pledged to take up the question now.

The Marquis of Hartington did not think that the present Government were bound by Mr. Warren's action. If he saw his way to the passing of such a bill, and that there was no very serious opposition, he should be very glad to introduce such a measure; but he would immediately place himself in communication with the medical department of the Privy Council, and having got all the information he required from them, he would, if necessary, communicate with the Apothecaries' Society, through Dr. Leet, and the Druggists' Association, through Mr. Hodgson.

The deputation then retired.

THE CHEMISTS' BALL.

The Annual Chemists' Ball was held on Wednesday last at Willis's Rooms. There were about 320 persons present, and the gathering was a very successful one.

After supper the chairman of the evening (Professor Attfield) spoke as follows:—Probably few of those present are here for the first time, while many have met in these rooms at the Chemists' Annual Ball for eight consecutive years, for this is our eighth annual ball. The origin of the first of these agreeable parties was twofold—namely, a desire often expressed by students and other of the younger followers of pharmacy for an annual ball, and a suggestion made by our first secretary (Mr. Henry Smith) that such a gathering might be held for the benefit of the Benevolent Fund of the Pharmaceutical Society of Great Britain. This desire and this suggestion were warmly taken up, were at once encouraged by several of the elder followers of pharmacy, who are always ready to support whatever promotes good feeling and good fellowship amongst their brethren, and, most important of all, were raised from the region of desire and suggestion into that of reality and vitality by the personal approval of a large number of ladies. Since then nearly 300 ladies and gentlemen have annually assembled at the ball; primarily to enjoy a good dance in one another's society, and also on the understanding that any surplus receipts should be handed over to the Benevolent Fund already mentioned—a fund the aid of which every chemist and druggist in Great Britain has the right to invoke, though we pray that few may have the occasion. With regard to the first object, enjoyment, there can be no question that the chemists' ball has been a great success, while we have been able to contribute to the Benevolent Fund an average of twenty guineas yearly, or a total of about £150. This satisfactory result has been brought about by the co-operation of the many friends who simply come to the ball, by the efforts of the stewards, who alone distribute the tickets, by the members of the committee who make all arrangements for holding the ball, by the zeal and activity of one of the committee who does most of the hard work of the executive—the secretary, Mr. Watson—and above all, by the kind presence at one ball or another, in several instances at the whole eight, of so many ladies. The present gathering is as successful as those which have preceded it, indeed, as regards numbers, it is above the average; let us unite in wishing the ball, in wishing this additional rallying-point for the followers of our common calling, continued success, and after our usual and only toast give three hearty cheers for the ladies. "Success to the Chemists' Annual Ball" was them proposed and responded to by all present, and the cheers for "The Ladies" were given with a most hearty "three times three."

SOME PROPERTIES OF HYDRATE OF CHLORAL.*

BY M. FAITHORNE.

When heated above a spirit lamp hydrate of chloral does not inflame as the alcoholate does. The aqueous solution [of the alcoholate?] gives a precipitate with subnitrate of lead. When hydrate of chloral is agitated with the same liquid, a limpid solution is obtained.

Hydrate of chloral produces a notable lowering of temperature when mixed with sulphuric acid. It dissolves morphine, quinine, cinchonine, strychnine, veratrine, aconitine, and atropine. It both dissolves phenic acid and increases its solubility in water; the odour of the acid being much enfeebled at the same time. When mixed with glycerine, a crystalline substance is formed after some hours.

If warm nitric acid is added to hydrate of chloral mixed with potassium dichromate a blue coloration gradually makes its appearance; on the addition of ammonia this coloration passed to red. Caustic soda added to the same mixture, colours it bluish green; potash colours it blue.

The Pharmaceutical Journal.

SATURDAY, JANUARY 24, 1874.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square,*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ.'*

THE MEETING OF THE BRITISH PHARMACEUTICAL CONFERENCE FOR 1874.

AN idea in connection with the meeting of the Conference for the present year has been for some time past regarded with considerable favour, that the deviation from usual custom which will be made this year in holding the meeting in London, might be still further extended to altering the time of the meeting from the autumn to the spring, so as to make it coincide with the anniversary meetings of the Pharmaceutical Society. By such a course it was thought that several advantages would be gained both for the Conference meeting and for the meetings of the Society: the attractions of the Conversazione, it was thought, would induce many to come up in May to attend the Conference meeting who might not otherwise be disposed to do so, and on the other hand it was thought that, by bringing together, in time and place, the meetings of the two bodies, some regular attendants of the Conference meetings would also have a more convenient opportunity of taking part in the annual proceedings of the Pharmaceutical Society.

We must confess to having looked upon this arrangement as a very desirable one in many respects, although it is obvious that in the event of it being carried out, the consequent amount of business as well as pleasure which would have to be got through in the short space of one week, was somewhat formidable. We understand that this idea has been discussed at the late meeting of the Executive Committee held for the purpose of settling the time of the Conference meeting, and that its consideration has led to the recognition of several practical difficulties, which were deemed sufficient to make the alteration in the time of the meeting impossible.

Chief among these was the time requisite for organizing the Exhibition which is to be held in connection with the meeting for 1874. Next to this was the difficulty of getting papers prepared in time for a meeting in May. The deliberations of the Executive Committee consequently resulted in a unanimous resolution that the Conference meeting should be held in August, and on the Thursday and Friday immediately following the Council meeting of the Pharmaceutical Society, on the 5th of that month.

The proceedings reported upon the preceding page suggest the possibility that by the next time the British Association visits Ireland there will no longer be any obstacle to the simultaneous gathering of the Pharmaceutical Conference at the same place, in accordance with the practice which has been hitherto followed.

We also learn that Mr. L. SIEBOLD, of Manchester, has been selected from a number of candidates to fill the office of Editor of the Year Book, and we gladly take this opportunity of congratulating the members of the Conference, as well as British pharmacists generally, that the business of editing this useful volume has been placed in the hands of one whose acquirements so well qualify him for the duty.

THE ADULTERATION OF FACT.

IT is strange to find that those who have to deal especially with the subject of adulteration and its repression not unfrequently manifest a striking ignorance of matters with which they ought to be well acquainted in order to do their work effectively and equitably. A notable instance of this deficiency has recently been presented by our contemporary, the *Anti-Adulteration Review*, in an article on the "citrate of magnesia" case. The number of errors and misstatements contained in less than a column of that journal devoted to dealing with this case is so great that it is no wonder the writer comes to the conclusion that the conviction was just, and that "if misrepresentation be fraud, there can be no doubt as to the character of this particular case." By way of friendly warning as regards the future, we venture to correct some of these false premises. First, then, the fact that the application of the term "citrate of magnesia" to a certain article which is not citrate of magnesia is a misnomer is not in any way an indication that the conviction in the case referred to was just. The article commonly sold under the misnomer of "citrate of magnesia" is not only innocent and harmless, but it is entirely incorrect to state that it is "not the thing asked and paid for." Whether the preparations sold under this name really contain any magnesia or not is perhaps really a matter of very little importance so far as affects the question of adulteration or of fair and honest dealing, and to any one having the most general knowledge of the subject, it is simply absurd to suppose that the presence or absence of magnesia in this preparation can have anything to do with "cheapness" or the possibility of "underselling competing traders." We regret to see a journal whose object we sympathize with riding a hobby-horse in such reckless disregard of fact.

THE CANADIAN ESTIMATE OF THE CITRATE OF MAGNESIA QUESTION.

MR. PARTRIDGE'S decision respecting the sale of the so-called "citrate of magnesia," after disturbing the equanimity and exercising the ingenuity of English pharmacists, is now furnishing a topic of discussion to our American brethren. In the January number of the *Canadian Pharmaceutical*

Journal is given a short *résumé* of the case, and to this are appended the following editorial remarks :—

"As far as our own convictions are concerned, we cannot confess to any sincere regret at what has occured, although we sympathize with the pharmacist who has been made to suffer for the combined offences of a community. The matter might, certainly, have been better arranged, put in a less offensive form, or been made to rest upon the shoulders of a more deserving sinner, but, as the blow has been struck, and as it has been levelled at the flagrant representative of a system the existence of which all conscientious pharmacists must deplore, we see no great reason to complain.

"As citrate of magnesia, the commercial salt is a falsity and a humbug, and if the public have been ten or fifteen years in finding out this interesting fact, we can only blame them for their obtuseness. The trade in this salt has been built upon the reputation of another article. People had a high opinion of the virtues of magnesia, a compound bearing that name was prepared for them, they eagerly received it as citrate of magnesia, while, in reality, they have been taking a compound, which, in most instances, contains no magnesia, or at best, a trace of Epsom salts, and differs little from flavoured soda powders.

"We, as a community of pharmacists, have tolerated and perhaps upheld this state of things, while, at the same time, we have been advocating a high standard of trade morality, and discussing nice points of nomenclature—whether, for instance, *Magnesiæ citras* would not be more correctly rendered *Magnesii citras*. Truly we have been straining at a gnat and swallowing a camel, and it is no more than we deserve if the meal proves indigestible."

CYRENAICAN DRUGS.

Reporting upon the trade and commerce of Bengazi, in the Regency of Tripoli, Mr. Vice-Consul Henderson refers to some of the indigenous products of the Plain of Barka and the Peninsula of the Cyrenaica, which he describes as a magnificent and fertile country. The most precious product of this district Mr. Henderson considers to be the plant called by the natives "driâs," which, during a visit to the upper regions of the Cyrenaica in the autumn, he found growing in the greatest abundance. He thinks there can be little doubt that this plant is identical with the silphium, from which was extracted the laserpitium, esteemed by the Ancients as a remedy for nearly every disease, and at one time valued at its weight in gold. Mr. Henderson says that the "driâs' is a most deadly poison, at once fatal to camels and horses eating it; but that beyond doubt it possesses marvellous medicinal properties, he, himself, having seen most inveterate sores and wounds quite healed in a few days by its agency. During the spring of 1872 a French physician spent some considerable time in the Cyrenaica collecting the plant, and he shipped a large quantity to Paris, where it is reported to have been used with great success.

The plant known by the native name of "driâs," is the *Thapsia Silphium*, of Vivani, or *Laserpitium Derias*, of Pacho, which is sometimes considered to be only a form of the *Thapsia gigarnica*, L., of Southern Europe. In representing it to be identical with the ancient silphium, Mr. Henderson is in accord with most writers on the subject. Lindley, in his 'Flora Medica' (p. 53) says it is the only umbelliferous plant inhabiting these regions which will at all answer to the figures struck on Cyrenaican coins. But in a paper by Oersted, recently published in this Journal,* in which silphium is referred to a species of *Narthex*, at present unknown, one of the grounds for rejecting *Thapsia Silphium* is that the celebrated plant of antiquity was wholesome to cattle, whilst the "driâs" is poisonous, and has frequently proved fatal to camels. But it is curious to note that this author only speaks of camels being killed by it, a peculiarity that occurs also in other authors, whilst Mr. Henderson only speaks of it as being fatal to camels and horses. Strictly, neither of these can be called cattle. However this may be, there can be little doubt that the "driâs" is a plant possessing powerfully active properties, worthy of closer investigation than they have yet received.

Amongst the other indigenous products of the Barka and Cyrenaica country are the olive, date, caroub, juniper, cedar, arbutus, cypress, fig, myrtle, and numerous useful and beautiful evergreen shrubs, one of which, the "baturne," yields a medicinal berry. The climate is represented as one of the finest in the world—dry, healthy, and bracing—and for pulmonary complaints Mr. Henderson thinks it would be preferable to Madeira.

HOMŒOPATHIC POISON.

Another case of poisoning by so-called "homœopathic medicines" is reported in the *Medical Times and Gazette* (Jan. 3) by Dr. Henry Lewis, of Folkestone. He states that on the 15th of December he was called to see a lady whom he found in a state of stupor. When roused the pupils were seen to be widely dilated and she was incoherent in her speech. At the time she denied having taken anything to ease neuralgic pain from which she had been suffering, but the next morning she produced a bottle from which she confessed she had dosed herself, and which was labelled "tincture of aconite," with the name and address of a well-known "homœopathic chemist."

A QUERY AS TO SMELLING BOTTLES.

A correspondent writing under the name of "Pill Roller" informs us that some stationers in the North have been fined heavily for selling silver and gold pencil-cases without a licence. He suggests that it is worthy of consideration how far chemists and druggists are exempt from risk when selling smelling bottles with silver and gold tops.

At the close of the Vienna International Exhibition the collection of chemical and pharmaceutical articles exhibited by Messrs. John Bell and Co., and for which a prize was awarded by the jurors, was presented to the museum of the Austrian Pharmaceutical Society by Mr. T. H. Hills, who we learn has received from the Council of that Society a letter expressing their best thanks for the gift, and offering him, as a mark of their high respect, the diploma of Honorary Membership.

EXAMINATIONS IN EDINBURGH.

January 13th, 14th, and 15th, 1874.

Present—Messrs. Ainslie, Buchanan, Gilmour, Kemp, Kinninmont, and Young.

Professor Maclagan was present on the 13th and 15th, on behalf of the Privy Council.

MAJOR EXAMINATION.

One candidate was examined, and passed, and was declared qualified to be registered as a Pharmaceutical Chemist :—

*Thresh, John Clough .....Pontefract.

MINOR EXAMINATION.

Twenty-three candidates were examined. *Eleven* failed. The following *twelve* passed, and were declared qualified to be registered as Chemists and Druggists :—

Hicks, William King .....Harrow Road.
MacPherson, Colin Allen .....Edinburgh.
Jeans, Thomas Robert .....Mansfield.
Reid, James Arthur .....Bathgate.
Bray, William .....Dumfries.
Burley, William .....Edinburgh.
Fidler, John .....Liverpool.
Murdoch, John McGill.....Glasgow.
Blades, Josiah Brunt .....Leek.
Thom, Robert .....Glasgow.
Smith, Walter James .....Rochdale.
Holden, William Henry .....Staithes.

The above names are arranged in order of merit.

MODIFIED EXAMINATION.

Six candidates were examined. *Three* failed. The following *three* passed, and were declared qualified to be registered as Chemists and Druggists :—

Croydon, Edward Henry .....Hartshill.
Paterson, Archibald.....Glasgow.
Scott, John Gladstone .....Dumfries.

PRELIMINARY EXAMINATION.

The following is the result of the Preliminary Examination, held on the 5th inst :—

ENGLAND AND WALES.

Two hundred and thirty-two candidates presented themselves for examination, of whom *one hundred and seventeen* failed. The following *one hundred and fifteen* passed, and have been duly registered as Apprentices or Students :—

FIRST DIVISION.

Allen, Henry.....London.
Stevens, Alfred Jesse .....London.
Roper, Robert Frances.....Plymouth.
Hawkins, Frederick Robert.....Plymouth.
Equal. Greenwood, W.....Settle.
Equal. Jones, Jonah.....Aberdare.
Equal. Stroud, William .....Bristol.
Chaplin, John Henry .....Wakefield.
Townsend, Joseph Edward .....Peterborough.
Shenstone, James Chapman ...Colchester.
Equal Fawcett, Christopher Airey ...Ambleside.
Equal Kent, Benjamin John .....Boston.
Lance, Henry .....London.

SECOND DIVISION.

Equal. Equal. Broad, Henry James .....Stourbridge.
Equal. Equal. Hudson, James.....Harrogate.
Equal. Equal. Musgrave, Nesbitt .....Newark.
Equal. Bell, Robert .....Lancaster.
Equal. Dickinson, Charles William ...Stamford.
Biggs, Walter Lyle .....Hampstead.
Equal. Barker, Alfred William .....Saffron Waldon.
Equal. Bucher, William Henry .....Crediton.
Equal. Dolbear, John .....Torquay.
Equal. Hessell, James .....Rye.
Equal. Marshall, John David .....Boston.
Equal. Nicholls, Alfred.....Manchester.
Equal. Plant, Charles Plantagenet .....Leicester.
Equal. Welch, Henry .....Staunton-on-Wye.
Equal. Wolstenholme, Robert.....Bury.
Langdon, Frank Bowers .....Penny-come-quick.
Ford, Robert .....Plymouth.
Equal Davies, John.....Carmarthen.
Equal Lawson, Arthur .....Whitby.
Equal Ryle, Samuel.....Moses Gate, near Bolton.
Golding, John Frederick.....London.
Hunt, Tom George .....Snaith.
Equal. Bignold, Walter .....King's Lynn.
Equal. Fresson, Frederick Henry .....Stevenage.
Stonham, William Burne.....Maidstone.
Equal. Clarke, Willoughby .....London.
Equal. Jones, John Edward.....Swindon.
Equal. Phillips, Albert William .....London.
Equal. Taylor, Philip Neville .....Great Bridge.
Equal. Williams, Charles Edward .....London.
Equal. Willis, Joseph Darrington .....Northampton.
Morgan, Rees David.....Cwmbach.
Wholey, Thomas .....Gainsborough.
Ingall, Elfric Drew .....Greenhithe.
Equal. Borman, William Alan .....Lincoln.
Equal. Bousfield, William .....Hull.
Equal. Collins, Henry .....Ashton-under-Lyne.
Equal. Elliot, John Sebastian .....Woolwich.
Equal. Hartlande, Charles .....Oldbury.
Equal. Parkin, Joseph .....Selby.
Equal. Rowe, John Bullen .....Ilfracombe.
Equal. Stedman, Walter .....West Malling.
Equal. Williams, Hugh .....London.
Holdsworth, Arthur Thomas ...Birmingham.
Jones, John James .....Kidderminster.
Equal. Halstead, Harry .....Blackburn.
Equal. Jelley, George William .....Coventry.
Equal. Lloyd, Richard .....Carmarthen.
Wyatt, John .....Stourbridge.
Evans, John .....Carnarvon.
Equal. Brook, Charles Mytton .....Saltaire.
Equal. Gastrell, Horace Edwin .....Cheltenham.
Equal. Greatorex, Edward John .....Stapleton.
Equal. Hanson, Edward Albert .....Leeds.
Equal. Newsholme, Henry Wilkinson Hellifield.
Equal. Parker, Benjamin ..... Leeds.
Equal. Phillips, Alfred James .....Truro.
Equal. Roberts, John Richard.....Liverpool.
Equal. Roberts, William .....Beaumaris.
Equal. Toon, Frederick.....Eccleshall.
Long, John .....Southport.
Equal. Allwork, Frank..... .....Brighton.
Equal. Bethel, Arthur .....Manchester.
Equal. Bowker, Joseph.....Radcliffe.
Equal. Bridgewater, Francis Foster ...Deal.
Equal. Chadwick, Charles Edward.....King's Lynn.
Equal. Chamberlain, Charles John.....Portsea.
Equal. Cornwell, Thomas Chinsura ...Penzance.
Equal. Cowap, John William .....Stockport.
Equal. Darch, Alfred .....London.
Equal. Daubeny, George .....Sutton-in-Ashfield.
Equal. Dring, Herbert Johnson .....St. Neots.
Equal. Ewell, Richard Michael .....Sandwich.
Equal. Freeman, John Henry.....Ipswich.
Equal. Fry, Edward Alfred Augustus Taunton.
Equal. Harman, Arthur .....London.
Equal. Harsley, John William .....London.
Equal. Hermes, Eduard Siëgfried .....Chester.
Equal. Horne, John .....Wednesbury.
Equal. Hughes, Benjamin .....Denbigh.
Equal. Jervis, Arthur .....Sheffield.
Equal. Jevons, Wallis Byron .....Market Rasen.

* Passed with Honours.

Equal.

Kiloh, James .....London.
Laverty, Joshua .....Jersey.
Lister, Amos.....Bradford.
Mortashed, Henry Charles .....London.
Nicholson, William .....South Shields.
Parker, Selby.....Gainsborough.
Phillips, John A. .....Swansea.
Portway, Arthur Cyril.....London.
Priestland, Arthur .....Ross.
Quibell, Joseph Layne.....Gainsboro'.
Rhodes, John.....New Cross.
Rosson, John Henry.....Manchester.
Shorrock, John William .....Over Darwen.
Smith, Joseph Layburn .....Keighley.
Southey, Charles .....Belper.
Tanner, Richard Douglas .....Andover.
Wilks, Robert .....Skipton.
Williams, Thomas.....Bristol.
Wimshurst, Frederick .....Southboro'.
Wood, John ....Oldham.

SCOTLAND.

Twenty-seven candidates presented themselves for examination; of these *thirteen* failed. The following *fourteen* passed, and have been duly registered:—

FIRST DIVISION.

Dalziel, Alexander Logan. .....Kilmarnock.
Cummings, Charles .....Glasgow,
Paris, Walter.....Bathgate.
Porteous, William Nicol .....Edinburgh.
Colvin, John .....Kilmarnock.

SECOND DIVISION.

Whyte, Joseph A. F. .....Aberdeen.
Dickson, Samuel Clark .....Edinburgh.
Midgley, James Herbert.....Edinburgh.
Gammie, William.....Turriff.
Young, Andrew .....Glasgow.
Hicks, Henry Frame ... .Rothesay.
Singer, Robert .....Insch.
Andrew, John .....Catrine.
Shum, Arthur George .....Edinburgh.

The questions for examination were as follows :—

Time allowed : Three Hours.

LATIN.

N.B.—Candidates are not required to translate more than two paragraphs, and are recommended to select either Nos. 1 and 2 or Nos. 3 and 4.

Translate into English two of the following sentences :—

1. Planities erat magna, et in eâ tumulus terreus satis grandis. Hic locus œquo fere spatio ab castris utriusque aberat. Eò, ut erat dictum, ad colloquium venerunt. Legionem Cæsar, quam equis devexerat, passibus CC ab eo tumulo constituit.

2. Cæsar, quod neque colloquium, interpositâ causâ, tolli volebat; neque salutem suam Gallorum equitatui comittere audebat; commodissimum esse statuit, omnibus equis Gallis equitibus detractis, legionarios eo milites legionis decimæ, cui maxime confidebat, imponere; ut præsidium quam amicissimum, si quid opus facto esset, haberet.

3. Emplastrum et saponem simul liqua, et paulo antequam concrescant immisce salem in pulverem tenuem tritum. Extensum super alutam, parti affectæ quamprimum applicetur.

4. Misce, et lenum calorem adhibe, donec liquetur Hydrargyrum. Liquorem decoque; et quod restat tere in pulverem. Hunc in vas quam minime profundum conjice; tum ignem lenem adhibe, eumque paulatim auge, donec vapor ruber prodire cessaverit.

5. State the infinitive, perfect, and supine of the following verbs—lavo, augeo, jubeo, uro.

6. What cases do the following verbs take?—do, fio, interest, licet, rogo, utor, vescor.

7. Parse "Dico te posse vincere Romanos."

ARITHMETIC.

8. Reduce 2 weeks, 2 days, 19 hours, 12 minutes to the fraction of a month of 28 days.

9. Find the decimal of 15/10½ and state the value of ·625 of a cwt.

10. How many cubic feet are contained in a case measuring 10 ft. 6 in. long, 6 ft. 8 in. wide, and 4 ft. 10 in. deep?

11. How long would a fly be going round the earth at the rate of 10 yards a minute, supposing the circumference of the earth to be 24,857½ miles, and 365 days being equivalent to one year?

12. What is the value of 4 hogsheads of sugar, each weighing 6 cwt., 2 qrs., 14 lbs., at £2 8*s.* 6*d.* per cwt.

ENGLISH.

13. Parse the following :—

"The tender grace of a day that is dead
Will never come back to me."

14. Write from fifteen to twenty-five lines on *one* only of the following subjects :—

Fortitude.
Telegraphs.
Education.

The following is a list of the Towns at which the Examinations were held, with the numbers of Candidates annexed :

Proceedings of Scientific Societies.

NEWCASTLE-UPON-TYNE CHEMICAL SOCIETY.

At the third ordinary meeting of this Society in the theatre of the College of Physical Science, held December 18th, 1873, the following paper was read on—

Errors of Weighing, and their Influence on Results.

BY H. R. PROCTER.

In the following paper I cannot pretend to lay before the Chemical Society any new or original results, but have merely attempted to notice in a concise form the most important errors of weighing, and to give short details of the methods of correction, since, clearly as the principles involved are explained in most text-books, I have for my own part found their actual application rather puzzling.

I think it is only fair to myself to say that I had not seen the chapter on the subject in Professor Thorpe's text-book until my paper was in print, and it was too late to remodel it, or I should certainly have avoided going over so much of the same ground. As it is, I am encouraged to let it stand, since the methods I have given are not exactly the same as his; and since I find that, even in the last German edition of Fresenius, no notice is taken of the method of weighing by vibrations, and no detailed rules are given for the correction of weights.

In weighing, as in all other kinds of accurate measurements, the result is vitiated by errors of two kinds; first, those arising from inexact observation and incidental causes, and which are variable in each weighing. These we may call "*errors of observation.*" Secondly, we shall have errors arising from faults in the balance, unequal length of its arms, inaccuracy in the weights, and defects in the mode of weighing, which will occur constantly in all weighing, and which may be called "*instrumental errors.*" Errors of observation may be almost got rid of by taking the average of a large number of experiments; for though each observation will be more or less in error, it will happen that some of the values will be greater and some less than the truth, and the errors will counteract and destroy each other's influence on the mean result. This, it is obvious, will not be the case with the instrumental errors, for it will generally happen that these will occur constantly on the same side, and so cannot correct each other, but will remain uneliminated in the final average result. Before examining the special corrections which are necessary to remove these, we will consider a little more closely the variable or observation errors.

We have said that the most probable value is obtained by adding all the results of a series of experiments together, and dividing the sum by the number of observavations. This mean value will probably differ more or less from each of the individual results. From these differences we may calculate the accuracy of our experiments. If we square each of these differences, add them together, divide them by the number of observations less one, and take the square root of the quotient, we obtain the *mean error of a single observation*, and dividing this by the square root of the number of observations we obtain the *mean* or average *error of the final result*. The "*probable errors*" in each case are about $\frac{1}{5}$ less than the *mean errors*, and are obtained by multiplying the latter by $\frac{2}{3}$, or more accurately by 0·6745. The "probable error" is equally likely to be greater or less than the actual but unknown error. Without here considering the rather intricate reasoning which has led to these rules, we may employ them to estimate the scientific value of our determinations.

In the ordinary method of weighing, in which weights are put on until the pointer swings to equal distances on each side of the zero, there are several sources of inaccuracy of observation, even supposing the balance were perfect. In the first place, it is not possible exactly to hit the right weight in any finite number of trials, although we may come as near it as we please. Secondly, as the swing of the balance gradually diminishes, it is difficult to tell when the exact zero is obtained.

A much better method, more rapid, as well as more accurate, is as follows:—After adding weights in the ordinary way, till we are, say less than a milligramme below the weights required, we note the limits of an uneven number, say 5, consecutive swings of the balance. Finding the average limit of swing on each side, and again taking the average of these two we obtain the position in which the index would settle if the balance were at rest. This will be at some little distance to one side of the zero of the unloaded balance. Adding now 1 milligramme to the weights, another position of rest may be observed. Then, by rule of three, as the distance of the first point from the zero of the unloaded balance is to its distance from the point with 1 milligramme added, so is the fraction of the milligramme required to the whole milligramme put on. A numerical example will make this clearer. To avoid minus quantities we reckon the scale of the balance from the side on which the weight scale is hung, so that the centre of the scale will count 10 instead of 0, and additional weights will give greater readings. Fractional parts of divisions are estimated, which is very easy if the balance swings only once in 15 or 20 seconds. Suppose that with the weight w on the scale, our successive turning points are

				Means.	
Right	7·5	7·6	7·8	7·63	Position of rest.
Left	11·4	11·3		11·35	9·49.

and that we have similarly obtained 10·34 as the position of rest of the unloaded balance, and 11·29 with $w + 1$ mgr.; subtracting 9·49 from these we obtain the differences 0·85 and 1·80, and our required weight will be $w + \frac{8.5}{18.0}$ mgr., or $w + 0{\cdot}47$ mgr. Though this method looks rather complicated, it is really done very quickly, since there are no useless trials, as in the ordinary way; but the labour may be still further lessened by the construction of a table of deflections of the balance for 1 mgr., with different loads. Then for any observed deflection from zero the corresponding weight may be at once taken from the table. As specimen of such a table I give one constructed for my own balance at the end of the paper. Such table must be verified occasionally, as the sensitiveness of a balance is liable to slight variations. It is also necessary frequently to determine the zero point when heavy loads are used, whatever mode of weighing be adopted.

So far we have assumed that when the pointer was at the zero of the unloaded balance the two loads were truly of equal weight, but in order that this may be the case the two arms of the balance must be of exactly equal length, a condition which is never rigorously fulfilled. Indeed it is impossible that it should, since an error of only 1-10,000th of an inch in a balance with 14 inch beam would cause an error of nearly $1\frac{1}{2}$ mgr. with a load of 100 grms. For chemical purposes where only relative weights are required, this may be neglected, if the weights are always placed on the same scale. Where absolute weighing is necessary, as, for instance, in testing a set of weights, we must eliminate the error. I need scarcely advert to the methods of doing this by substitution and double weighing. In the first case the weights are tared, and the substance to be weighed is then placed on the same scale, and weights removed till a balance is again obtained. In the second, the substance is weighed first on one scale and then on the other, and the mean of the two results is taken, and the errors being equal and in opposite directions will balance and destroy each other. Another way is once for all to determine the ratio of the arms, and then the true weight is obtained from any observed weight by multiplying by this ratio; or still better, a table may be constructed giving the calculated corrections for different loads. As the ratio is very small it is best found by observing the deflection in the following manner:—The zero of the balance when oscillating

unloaded is observed; then two approximately equal large weights are put on—say 50 grms. on each scale, and the zero observed again. The weights are changed to the opposite scales to eliminate any small inaccuracy in their quality, and the process is repeated, finishing by observing the zero of the unloaded balance a second time. Then the means of the two loaded and two unloaded zeros are taken, and the difference between these, reduced to mgr., as described before (p. 189), is the correction to be added or subtracted for the load employed; and the ratio of the two loads so corrected is the same as that of the *opposite* balance arms. I need scarcely say that the addition must be made to the load *towards* which the pointer is deflected, or the *subtraction* from the *opposite* side. Having found the correction for any load, that for any other may be found by rule of three. Thus, if that for 100 grms. is 3 mgr., that for 50 will be 1·5 mgr. In my own balance, a very good one by August Sauter, of Ebingen, it amounts to about 2 mgr. per 100 grms., and consequently the ratio of the arms is as 1 to 1·00002. As the correction is small it is never necessary to apply it to the smaller weights, and indeed a table of values for every 5 or 10 grammes would generally be sufficient.

Another and still more important source of instrumental error is the inexactness of the weights; and no ordinary set, even of the best makers, is really accurate. It is, therefore, always necessary to examine them and make a table of corrections. The simplest way of doing this is to assume provisionally that the smallest weight, say the cgr., is accurate, and then to determine all the rest in terms of it, preferably by double weighing. Of course weights of the same name must be distinguished by marks of some kind—dots made with a centre-punch are as good as any. It will be easy to weigh one 1 cgr., against the other, and then with these to weigh the 2 cgr., and so on. Suppose the second cgr. is found (by deflection or the use of the rider) to weigh say 10·01 mgr., the two together must be called 20·01 mgr., and the error may go on accumulating till with the largest weights it amounts even to grammes; but this is of no consequence. If we have no normal weight with which to compare our set, it is generally best to assume the sum of the large weights as correct. Suppose, now, that they weigh 103·754 grm. in terms of the 1 cgr. weight instead of 100 grm., the true amount, we must divide all our observed weights by 1·03754 (or multiply by its reciprocal) in order to obtain a series of numbers which shall accurately represent the relative values of our weights, and which will add up to exactly 100 grm. That they do this is a proof of the correctness of the numerical work. If we always use the weights in the same order it will now be easy to make a table showing the whole correction to be added to any observed weight. As an example, I subjoin that for my own set. It will be seen that in some cases it amounts to almost half a milligramme, quite an important error in an organic analysis.

A source of error almost universally neglected is that caused by the weighing being conducted in air instead of in vacuo. To illustrate the principle by an extreme case, we know that while a cork weighed in water would weigh less than nothing, a lead bullet would lose comparatively very little. In a less degree the air has exactly the same effect as the water, and in weighing bodies of low sp. gr. with dense weights, such as brass or platinum, the loss may amount to something considerable. For instance, in weighing 100 c.c. of water with brass weights it would amount to 10·6 mgr. If absolute accuracy were required it would be necessary also to take account of the changes of density of the air as shown by temperature and barometric pressure, but for chemical purposes this could scarcely be important except in determination of vapour densities. I, therefore, content myself with giving at the end of the paper a table for correcting weighings with brass weights at ordinary temperatures, and refer for further information to special articles on such determinations. To show the importance of at least a rough correction even in ordinary chemical work, Professor Kohlrausch points out that in the common case of determination of Ag as AgCl in a weighed quantity of a dilute solution, the correction may influence the result as much as $\frac{1}{10}$ per cent.

In conclusion, I must say a few words on the influence of errors on results. It is but rarely that we can directly weigh the substance we are estimating, but in most cases we have to weigh some compound, and multiply the observed weight by a factor, to reduce it to that of the substance required. The errors will obviously be multiplied at the same time, and hence, other things being equal, the smaller the factor, or, in other words, the larger the atomic weight of the compound weighed, the less influence errors will have on the result. Thus, in an organic analysis, an error in weighing the substance at first goes directly into the result, while 1 mgr. error in the weight of the potash bulbs will only make $\frac{3}{11}$ mgr. and in the calcic chloride tube $\frac{1}{9}$ mgr. difference in the result. We should always, at least in scientific work, make a rough estimate, at any rate, of the probable influence of the various corrections, and only neglect them when we find their amount small compared to the probable error from other sources. This will frequently be the case, but not always, and the information as to the amount of accuracy we may expect from our results is often very important; as, for instance, in fitting an empirical formula to an analysis. Let us take the common case of sulphur determination as baric sulphate, say in a pyrites containing 50 per cent. Suppose I use 1 grm. of the substance, the probable error of weighing with my balance (as estimated from the differences in a series of ten weighings of the same mass) will be about 0·1 mgr. or only 0·01 per cent., the correction for inequality of balance arms, and the reduction to vacuo practically *nil*, as baric sulphate and pyrites are both weighed on the same scale and are nearly of the same density; while the error of weights may amount to nearly 0·05 per cent. Here we see that while all the other corrections may be disregarded, it would be quite inadmissible scientifically, whatever it might be commercially, to carry the percentage result to two places of decimals while neglecting the error of the weights. To sum up, the inequality of balance-arms may be neglected in all ordinary chemical work, the reduction to vacuo is only necessary when the substance has to be weighed in two forms of very different density, but the weights must always be corrected, and the zero point of the unloaded balance constantly observed, since its variation is one of the principal sources of observation error. It is well to estimate the probable amount of the latter by occasionally doing a series of weighings of the same mass and observing the unloaded zero-point each time; and, whenever we have a series of analyses of the same substance, we should calculate the probable error of the final results by the rules given above. If this were done it would, I venture to think, be found that only in very rare cases it is scientifically allowable to carry percentage results to two places of decimals, since even the errors of weighing alone, with excellent instruments and great care, will seriously falsify the last figure.

$$\frac{k}{1000} = 0{\cdot}0012\left(\frac{1}{\triangle} - \frac{1}{8{\cdot}4}\right)$$

If the weighed body has the density △, and its weight in air be m grammes, mk mgrm. must be added to reduce the weighing to vacuo.

On the motion of the President, the thanks of the meeting were given to Mr. Procter.

SOCIETY OF ARTS.

ON THE ENERGIES OF THE IMPONDERABLES, WITH ESPECIAL REFERENCE TO THE MEASUREMENT AND UTILIZATION OF THEM.

BY THE REV. ARTHUR RIGG, M.A.

Lecture VII.

*On the Energy of Heat, with especial reference to the Measurement and Utilization of it.**

(*Continued from page* 584.)

In a research of this kind, made with apparatus contrived as new thoughts and new experiments suggested, it was not to be expected that the tabulated results should speak with one consenting voice. They did, however, seem to proclaim this—that the mechanical equivalent of heat competent to give an increase of temperature of 1° Fahrenheit to 1 lb. of water was between 500 and 800 foot-pounds. Detecting and eliminating those elements which seemed to affect the accuracy of the result, he was enabled at last to come to this conclusion, that 772 lbs. was the exact number which was the mechanical measure, or, as it is commonly called, the mechanical equivalent of heat. That means this—he found how much a known quantity of water was raised in temperature by a recorded mechanical exertion, and he deduced the measure of that exertion needful to raise 1 lb. of water 1° on Fahrenheit's thermometer. Thus he found that that heat, applied to raise weights would lift 772 lbs. through one foot; that is, if you had 772 lbs. weights here, and lifted them a foot high, it would be the same thing exactly as applying the same force to 1 lb. of water, and raising the temperature 1° Fahrenheit.

There is a table written out mathematically, by means of which the 772 lbs. are deduced. Mr. Joule having made these experiments, others followed, and we have a table showing the means used, air, friction, steam, Daniell's battery, electro-magnetism, etc.; also the names of the experimentalists, and the mechanical equivalent of heat as determined by them. Although the results differ from Mr. Joule's 772 lbs., yet his figures are now generally adopted.

MECHANICAL EQUIVALENT OF HEAT BY DIFFERENT METHODS.

Means used.	Experimentalist.	Ft. lbs. per 1 deg. F.
Air	Regnault	776·47
Friction	Joule	774·73
Steam	Hirn	752·78
Electrical Induction.	Joule	823·86
Daniell's Battery	Weber	765·54
Electro-Magnetism	Favre	807·46
Current in Wire	Quintus-Icilius	729·08

The title of this lecture includes the words measurement and utilization. The utilization of heat is so important a commercial as well as scientific question, that there are one or two matters bearing upon it which may be worth present attention and much future thought from all. That we do not obtain in a steam-engine more than a quarter of the heat we expend in the furnace is now generally recognized. There is a table here, based upon Mr. Joule's calculations, which gives the number of horse-power—a technical term, meaning 33,000 units of work—which could be obtained by utilizing the heat required for passing nine pounds of ice through its physical and chemical changes. If we have 9 lbs. weight of ice, and attempt to melt and convert it into liquid, a certain amount of heat is absorbed, or rendered "latent," as it is called. At any rate, there is a quantity of heat that does not show itself upon the thermometer. Then, after it is converted to water, if we gradually raise the temperature to 212° there is another large quantity of heat rendered "latent" in the conversion of this water into vapour; and if we then convert that vapour which comes from the water into its elemental gases, viz., oxygen and hydrogen, another large quantity of heat is absorbed or rendered "latent." Now, take that process backwards; assume we can take this 9 lbs. of oxygen and hydrogen and reconvert them back again into ice, and that it was in our power to use the heat which had been given off, then we get the quantity shown in the table. If we burn a quantity of hydrogen in oxygen, it is converted into water; if one part of hydrogen and eight parts of oxygen are combined by an electric spark or other means, and converted into water at 212°, a number of units of heat equal to 1,451 horse power are obtained. If, then, we pass it still further into the form of water at 32° we should obtain 38 horse-power more; and if we then pass it from the form of water into the form of ice, we should obtain 30 horse-power. Therefore, if in obtaining 8 lbs. of ice from its primeval elements, viz., 1 lb. of hydrogen and 8 lbs. of oxygen, we could utilize as a mechanical agent all the heat set free, then from the data given we see that there would be obtained 1,519 horse-power of work. But we cannot obtain this. What becomes of the heat, where it goes, and why we cannot contrive to utilize it, are inquiries which yet perplex scientific students. Various surmises have been made, but none of them have been accepted, except as the vague guesses of an unsolved riddle, the best of which are taken, though there remains a lurking feeling that none of them are right.

The following is a copy of the table to which allusion has been made in the previous paragraph :—

MECHANICAL VALUE OF HEAT, DEVELOPED AS NINE LBS. OF WATER PASS FROM THE GASEOUS TO THE SOLID STATE.

		Units of Work.		Horse Power.
1 lb. of hydrogen and 8 lbs. of oxygen to water at 212°	develop	34,462 × 1390 (C.)	or	1451

* Cantor Lecture, delivered March 17, 1873; reprinted from the *Journal of the Society of Arts*.

Water from 212° to water at 32°	develop	180 × 9 × 772 (F.)	or 38
Water from 32° to ice	develop	143 × 9 × 772 (F.)	or 30

Total horse-power developed..... 1,519

There is another table bearing on this question, viz., the advantage of using steam at a higher pressure than what is called low-pressure steam. If we take water at 33°, that is just above the temperature of ice, and that be warmed until it attains the temperature 213°, it would occupy a bulk 1669 times as large as it was in the form of water. There is a relation between the pressures and temperatures which must be maintained, in order to preserve the whole of the water in the form of steam. These relations are expressed in the first two columns in the following table. The third column expresses the resulting volume of steam. The fourth column is the product of the pressure and the volume, and, therefore, represents the mechanical value of our unit of water. How much and at what rate this value or power increases with an increase of heat and a correspondent increase of pressure may be known by considering the figures in this fourth column. These figures represent the advantage of using steam at high pressures, and, therefore, high temperatures :—

STEAM FROM WATER.

Pressures.	Temperatures.	Volumes.	Pressure multiplied by volume.
lbs.	Deg. Fah.		
15	39	1	
15	213	1669	25,035
25	240	1042	26,050
35	260	765	26,775
45	275	608	27,360
55	288	506	27,830
65	299	434	28,210
75	308	381	28,575
85	317	340	28,900
95	325	307	29,165

The reason why we cannot work steam at some of these very high temperatures is this, that when we super-heat it, we thereby prevent any of it being converted into vapour, and if it is not so converted into vapour we have no means of lubricating the faces of our slide valves, and the consequence is, the metals being heated, they soften, then scratch and tear each other's faces, and the engine is soon destroyed. As soon as we can get slide valves made of some material which will bear this higher temperature without abrasion or scratching, then, probably, we shall be able to work super-heated steam economically.

The amount of steam converted into visible vapour, and cause of excessive loss of power in ordinary steam-engines may be made clear in this way. There is in the receiver of the air-pump a piece of sponge with a little water on it; if a portion of the air saturated with vapour be pumped out, a small portion of the water is converted into vapour, which you see deposited in a film on the glass. This is caused by the air being rarefied and becoming colder, therefore not competent to hold in solution as much vapour as it had previously done. Now, what takes place in this receiver is taking place in hundreds of steam-engine cylinders, and wasting pounds and pounds of fuel. As soon as the steam enters the cylinder it fills it, or rather it fills the part of the cylinder below the piston. Arrangements are usually made that a portion of the stroke may be accomplished by the expansive action of the steam. Now, as soon as the opportunity for expansion is presented, there is at once this deposit of moisture, and the deposit is indicative of a sacrifice of heat.

Now, this action of heat is not confined to liquids, it also extends to solids. Here is a piece of unannealed glass. Those present who have to deal with steam-engines know that it very often happens from some apparently unnaccountable cause that what are called the water-gauges of the boilers are broken. These breakages are in consequence of the glass tubes being unannealed; and if you are aware of the process by which tubes are made, you will see at once they cannot, without some special arrangements, be annealed. They are made by taking a solid ball of glass out of the pot; this is then blown into a globe; then a second man puts a pipe with a molten nodule of glass upon it on that part of the globe which is opposite to the pipe by which it was blown. The men run asunder, and so the globe is lengthened out into a tube and laid along the floor. This long pipe is then cut into gauge-tube lengths, and generally so sold. If one of these tubes be cleaned with an iron wire, having a piece of cotton wool wrapped round it, the wire being pushed up and down as is usually done, and the clean tube be restored to the boiler, it may, in two or three days or weeks, fall to pieces without any one being to blame, except those who put the wire through the tube. Here is a piece of glass very thick and strong, and in all respects very good glass, but unannealed. It is really a simple piece taken out of the melting-pot as a sample, to guide the manufacturer respecting the quality and colour of the articles that may be made from it. Now, in all probability, if this piece of quartz, less than the size of an ordinary pea, be allowed to drop gently into the sample flask, this strong flask (the glass is nearly one half an inch in thickness) may fall into pieces. There! You see the bottom has immediately dropped out, notwithstanding the thickness, and if it were left here all night it might crumble into half-a-dozen pieces before the morning. On one occasion I cleaned out a glass tube, about three feet long, connected with an air-pump, and in a thoughtless moment took a wire, attached some cotton wool to it, and drew it through the tube. In about half an hour there was a slight click—in a few minutes another click. On looking at the tube it was seen to be cracked. The slight but instructive noises continued, click after click, and crack after crack, and in the morning the tube was separated into many hundred pieces, though no one touched it. Workmen and servants are often blamed for the breakage of glass, which breakage arises from such a cause as this.

What are called Prince Rupert's drops are obtained by allowing molten glass to fall into water, and so falling the drops are suddenly cooled on the outside, and the consequence is that the molten glass in the interior is firmly bound beyond its power of resistance, even though it has a large amount of heat in it. If it had been free, the molecules of glass would have crystallized and arranged themselves according to the law which governs them; but being bound by the external film they cannot so arrange themselves. The heat contained in them cannot do the works of crystallization it was competent to do—it has become stored up or potential. Therefore, as soon as ever the equilibrium of the shell of the bulb is destroyed this heat gives out its work. In the interior of this bulb there is a large amount of potential energy; and if the equilibrium be destroyed by cracking off the end, in the same way as it was destroyed in the other case by dropping a little bit of quartz into the thick glass, we shall find it will manifest itself, and very possibly will break the glass bottle in which the Rupert's drop is placed.

(*To be continued.*)

Parliamentary and Law Proceedings.

POISONING BY STRYCHNINE.

An inquest was held at Stoke, last week, before Mr. Coroner Bone, respecting the death of Mr. Thomas

Whittle. Mr. Metham, surgeon, said he had known the deceased between two and three years. He had been constantly on his list mostly through occasional outbreaks in drinking. The frequent excesses of drink no doubt produced an injurious effect on the brain. The witness saw the deceased on the previous Saturday, when he appeared to be more than usually depressed. On Sunday witnessed visited deceased at his residence, when he complained that he was suffering violently from spasms. On the witness asking him for particulars, he requested his wife to leave the room. He then had a violent spasm and afterwards told witness that he had taken strychnine and prussic acid, which he said he had bought in Plymouth at several places. The witness remained with the deceased until he died. When the witness asked the deceased why he poisoned himself, he said, "I don't know why I did it; I was mad."

Mr. Joseph Allen, chemist, carrying on business in Bedford-street, stated that the deceased came to his premises on Saturday, stating that he had a favourite dog, which he valued very much, and as it was getting old he wished to poison it. He asked which was the best poison, whereupon the witness informed him that strychnine was the best. The witness served him with two grains (in weight) of strychnine, and the deceased signed the register book of sales of poison with his name and address.

Mr. Frederick Henry Foster, carrying on business at 2, Bank of England-place, said the deceased came to his shop about a month ago, and applied for some strychnine to kill a dog. Witness told him two grains would be sufficient to kill a dog, whereupon the deceased expressed a desire to have the dog killed as soon as possible. Witness then supplied deceased with five grains.

Mr. John Dampney, a chemist at Millbay, said the deceased came to his shop on Saturday, and was supplied with a quantity of prussic acid, for the purpose, as the deceased stated, of poisoning a dog.

After some evidence as to the circumstances of the deceased, the jury returned a verdict that the deceased died from the effect of administering to himself a quantity of styrychnine whilst in a state of temporary insanity.

Privilege of Peerage.

At the Westminster County Court, on Thursday, Jan. 15th, before Mr. F. B. Bailey, judge, an application was made, in the case of "Savory and Moore v. the Earl of Winchilsea and Nottingham."—Mr. Venn, solicitor, appeared for the plantiffs; the defendant was not represented.—In July last plaintiffs (who are the well-known druggists, of New Bond-street) obtained a judgment against defendant in this court for goods supplied, and as this judgment remained wholly unsatisfied, the present summons has been issued under the 5th section of the Debtors' Act, 1869, calling upon defendant to show cause why he should not be committed to prison for a term not exceeding six weeks for default in payment.—His Honour. intimated to Mr. Venn that it would be useless to call evidence or proceed with the hearing of the summons, as the defendant, being a peer, enjoyed immunity from arrest. —Mr. Venn said that owing to recent legislation this point was now open to discussion, but that if defendant relied upon his privilege, he was bound either to appear to the summons and claim his privilege, or to sue out his writ of privilege. By the 5th Section of the Debtors' Act, 1869, the court was empowered to commit to prison, for a term not exceeding six weeks, "any person," who made default in payment of any debt due from him in pursuance of any order or judgment. The words "any person" as quoted, were positive, comprehensive, and without any exception expressed, and therefore the "onus" rested upon defendant to prove conclusively that he did not come within the operation of the enactment. In support of this particular view, he cited the judgment of Lord Westbury in the case of the "Duke of Newcastle, appellant v. Morris, respondent, 40 Law Journal Reports," where the argument as to the liability of a peer to be adjudicated bankrupt rested upon the interpretation of the 69th Section of the Bankruptcy Act, 1861, which enacted that "all debtors, whether traders or not," should be subject to the provisions of that act, and where, upon giving judgment, Lord Westbury said that the onus rested upon the appellant to prove that he was not included within the comprehensive words "all debtors, whether traders or not," and in that case the decision was adverse to the privilege of the peer, and the adjudication in bankruptcy was confirmed.—His Honour remarked that, notwithstanding the liability of a peer to be adjudicated bankrupt he was still privileged from arrest or attachment for non-payment of money.—Mr. Venn admitted that at common law, and under certain decisions of an early date in the Term Reports, this privilege had been recognized, but contended that now the privilege must depend upon the interpretation of the two statutes at present in force —viz., "the Bankruptcy Act, 1869," and "the Debtors' Act, 1869," which for this purpose must be construed together. It was clear that under the 120th section of "the Bankruptcy Act, 1869," a peer could be adjudicated bankrupt, and dealt with generally under that Act as if he had no privilege whatever; and inasmuch as in the interpretation clause of the Debtors' Act, 1869, it was expressly set forth that the Debtors' Act should come into operation on the same date as the Bankruptcy Act, and that words and expressions defined or explained in the Bankruptcy Act should have exactly the same meaning in the Debtors' Act, he contended that a "person" coming within the provisions of the "Bankruptcy Act" must fall within the words "any person" in the Commitment Clause of the Debtors' Act.—His Honour here remarked that there was some doubt as to the due service of the summons, but, upon inquiry of the registrar, it appeared that defendant had called with the commitment summons at the court and said that he hoped they would imprison him, and his Honour suggested that, as defendant had plenty of leisure, he might not object to imprisonment.—Mr. Venn said he hoped that his honour would not disappoint the defendant on this head, as it was clear that he had received the summons and was determined not to pay his debts; but in any case defendant should be required to set up and prove his alleged privilege.—His Honour replied that, notwithstanding defendant's omission. the privilege still existed, and, in his judgment, it would be of no avail to have defendant committed, as he might subsequently claim his release and perhaps take legal proceedings for his arrest.—Mr. Venn remarked that plaintiffs would accept the risk if the Court would commit defendant, or even compel him to come there and rely on his privilege. He was quite able to pay plaintiffs' claim, but would not do so.—The application for committal was refused.—*Standard.*

Adulteration of Bread.

At the Tonbridge Petty Sessions, on Wednesday, a baker named Featherstone, who had traded in the town for 45 years, was charged with selling bread adulterated with alum. The inspector produced a certificate from Dr. Tidy, the county analyst, stating that in the sample 2lb. loaf left with him there were 14·8 grains of alum. Mr. Warner, who defended, wished to call the defendant to deny that any alum was used, but the magistrates (Mr. J. S. Talbot, M.P., and Mr. C. Powell) refused to hear him. The man who always makes the defendant's bread was then called. He deposed that no alum was ever used by defendant, who was a contractor under Government for supplying the staff of Royal Engineers in the town with bread. The same bread was served out to them as to the general public. The second officer in command said the defendant's bread was tested from time to time by the War Office chemist at Woolwich, but no trace of adulteration had ever been found. Mr. Warner asked that the case

should be adjourned to enable him to have an independent test. The Bench refused, saying they were willing that Dr. Tidy should re-analyse the half loaf produced in court. The defendant could not see that it was at all likely Dr. Tidy would, under the circumstances, alter his opinion. The Bench thereupon fined him 10s. and costs.

Review.

La Matière Médicale chez les Chinois. Par M. Le Docteur J. Léon Soubeiran et M. Dabry de Thiersant. Paris : G. Masson. 1874.

The opening up to commercial enterprise of China—a country of which so little has been known until within the present century—has naturally led, among other things, to inquiries concerning the materia medica and medical notions of that shrewd and ingenious people. During the past seventy years several works have been published upon those subjects, among which none have exceeded in value the laborious researches published by our own countrymen, Daniel Hanbury and Porter Smith.

The practical results of investigation of this kind, although sometimes not immediately apparent, are often of great importance. It is only necessary to review our own materia medica to see that many of our most valued drugs have resulted from the scientific researches of former investigators. The difficulties which beset the student of materia medica in China are greater than is perhaps generally known. The language itself must be no slight obstacle to the identification of the various substances met with. Several names are often applied to the same drug, according to the district from which it is derived, the quality of the article, and the different modes of its preparation. In other cases the same name is applied to different drugs similar in appearance, but derived from different sources. The tendency to sophisticate, which may be called the besetting sin of the Chinese, the jealousy of the natives, and unwillingness on their part to give the slightest information which they may imagine to be likely to diminish their profits, all operate to the same end. The flora of China also is not so well known as that of other countries, and there is therefore considerable difficulty in determining some of the drugs with certainty. Many of the roots also are only to be obtained in a sliced or comminuted state, and thus present still further obstacles to their identification. Considering these difficulties, then, the knowledge already attained in this subject is very considerable. The present attempt to increase our knowledge of Chinese materia medica has met with the appreciation which scientific investigations always deserve, and but rarely obtain—the results having been published at the expense of the French Government, by the recommendation of the Paris Academy of Medicine.

The work is prefaced by the report upon it read before the Academy of Medicine. This preface contains a good deal of interesting information, but a translation having already appeared in this Journal* there is no necessity for further notice of it here. The various articles of materia medica are classified under the heads of minerals, animals, and vegetables. The minerals are arranged under the elements of which they are compounds, with the exception of the silicates, which do not appear under silicon, but form a separate group—probably on account of their variable composition. A third group under the head of minerals, includes various fossils.

The animal substances are arranged in the following classes—Mammalia, Aves, Reptilia, Pisces, Mollusca, Insecta, and Arachnida. The vegetable substances are arranged according to their natural orders, commencing with Algæ and ending with Leguminosæ.

At the end of the volume there is a table of the contents representing the arrangement above-mentioned. Following this is a Chinese-French vocabulary, in which the Chinese names of the drugs are spelt as they would be pronounced in French, and explained by their French and Latin equivalents. No figures of any of the drugs are given, and the Chinese characters in no case appear, although to have had them would have added greatly to the value of the work. The Chinese characters would have been valuable, because the same syllable may be represented by several different characters, each with a different meaning. In describing each article of the materia medica its Latin name is first given (or when not determined, its supposed generic name), and then its Chinese name, spelt according to the French pronunciation, followed by the Chinese name as spelt by other writers, those most frequently quoted being Tatarinov, Hanbury, Porter Smith, and Debeaux ; only the French renderings of the Chinese names are given in the vocabulary. The above arrangement, though an excellent one in a scientific point of view, yet lacks the thoroughness of detail which is essential to every scientific work. Thus, we find toads, frogs, and salamanders under Reptilia ; iulus and scolopendra under Insecta ; crabs, woodlice, leeches, sea urchins, sea cucumbers, medusæ, corals, and sponges all included under Arachnida. We have experienced considerable difficulty in endeavouring to discover what arrangement of the natural orders of plants has been followed in the work, and have come to the conclusion that it must be a special one of the authors'. Although it appears in some respects to approach one or two of the methods followed on the Continent, yet in none of them do we find Orchidaceæ placed between Graminaceæ and Cyperaceæ ; Saxifragaceæ followed by Menispermaceæ ; or Violaceæ placed between Nelumbiaceæ and Pangiaceæ.

The neglect of these matters necessarily depreciates the value of the work, for as there is no alphabetical index to the work, the table of contents has to do duty for it, and an index is valueless if not easy of reference. Still, the attempt at a natural arrangement is a step in advance, and it presents the Chinese materia medica under a new aspect. The large number of substances at present undetermined, renders a classification of this kind by no means an easy task. This fact led us to suppose that the learned authors might have succeeded in determining many of those doubtfully named in the last work upon the subject ; this hope, however, has not been realized. Some of the errors in that work have found their way into the present one, probably owing to the authors not having seen Porter Smith's specimens. Thus *Lycoperdon squammatum* (*sic*) should have been *Lycopodium ;* the seed described by Porter Smith under the name of *Bungtalai*, and doubtfully referred by him to *Nephelium* or *Erioglossum*, is still referred to the same, although Hanbury has shown* that it is the seed of *Scaphium scaphigerum*. Our authors are, however, not alone in this oversight, as an article has very lately appeared in a French journal, giving as a fresh discovery that which was known in 1862. *Iris florentina* is said to be found in all the provinces south of Yang-tse-kiang, and to have yellowish-white flowers and reddish leaves. In this case there appears to be a double error, for the root is that of a dicotyledonous plant, which, judging from its appearance and strong odour resembling that of lovage or fenugreek, is probably a species of *Levisticum* and the description as given by the authors scarcely applies to *Iris florentina*, which De Candolle describes as having bluish-white flowers and glaucous leaves.

Lycoperdon giganteum is still retained under that name, although Cooke has shown that it is a *Polysaccum*.† The article described by Porter Smith as Bitter Bean, but which is Fenugreek seed, is omitted from the present work.

In some cases the same drugs appear twice over as being the products of different plants, apparently owing

* Vol. iii., p. 501.

* Pharmaceutical Journal, vol. iv., 2nd series, p. 110.
† Ph. Journ., vol. ii., 3rd series, p. 160.

to the authors not having seen specimens, or to a desire not to omit anything mentioned by other authors. Thus Tchuen-kiang is described as an *Angelica*, after Porter Smith, and in another place as an *Apium*, after Hanbury; Yu-shuh, which is evidently identical with the *Atractylodes alba* of Porter Smith, is described under that plant and again under Umbelliferæ, after Hanbury; *Lycium* in one place is described as derived from a Berberidaceous plant, and in another as a Solanaceous one; Kuen-pe appears first as a fungus, and afterwards as one of the Lycopodiaceæ, although Porter Smith's description evidently points to the latter, notwithstanding that it has been called a fungus by him. The identity of *Barkhausia repens* with *Picrorhiza Kurroa*, Royle, has not been noticed.

On the other hand, we notice that some of the mistakes in the last work upon the subject have been rectified. Thus *Oxalis acetosella*, which is not known to occur out of Europe, is replaced by *O. corniculata*, a thoroughly cosmopolitan species. *Eschscholtzia* is rightly altered to *Elsholitza* and *Smilax chinensis* now appears as *S. china*, and various generic names have been altered to meet the progress of science, the older names being given in parentheses. About 900 articles of materia medica are given in the work, of which nearly 200 appear not to have been noticed by English authors. These additions belong chiefly to the animal and vegetable kingdoms, and for the greater proportion of them simply the scientific names of the substances identified, with the Chinese names attached are given, without any description of their appearance or account of their properties. This is more especially the case with the vegetable products. As a scientific work the book must be considered a failure, the amount of information new to science contained in it being very small. As a compilation of the knowledge hitherto published the work is excellent, being more comprehensive and better arranged than any one of the kind yet published (excepting, perhaps, that of Hanbury, which is a model of arrangement and completeness, although it includes but a small proportion of the drugs of China), and it needs only a complete index to make it an useful book of reference to those interested in Chinese materia medica. A good deal of interesting information, brought up to the present date, is to be found here and there throughout the work, more especially with regard to those drugs which form articles of commerce. Among these we notice musk, edible swallows' nests, isinglass, insect wax, trepang, the vinegar medusa, rhubarb, camphor, opium, and tea.

BOOKS RECEIVED.

The Treasury of Botany, a Popular Dictionary of the Vegetable Kingdom, with which is incorporated a Glossary of Botanical Terms. Edited by John Lindley, M.D., F.R.S., F.L.S., and Thomas Moore, F.L.S. Illustrated by numerous Woodcuts. New and Revised Edition with Supplement Part I. a—k. Part II. l—z, London: Longmans, 1874. From the Publishers.

The Chemical History of a Candle. A Course of Lectures delivered before a Juvenile Audience at the Royal Institution. By Michael Faraday, D.C.L., F.R.S. Edited by William Crookes, F.C.S. London: Chatto and Windus. From the Publishers.

The Various Forces of Nature and their Relations to each other. A Course of Lectures delivered before a Juvenile Audience at the Royal Institution. By Michael Faraday, D.C.L., F.R.S. Edited by William Crookes, F.C.S. London: Chatto and Windus. From the Publishers.

A Course of Analytical Chemistry (Qualitative and Quantitative), to which is prefixed a Brief Treatise upon Modern Chemical Nomenclature and Notation. By William W. Pink and George E. Webster. (Weale's Educational Series). London: Lockwood and Co., 1874. From the Publishers.

Adulterations of Food, with Short Processes for their Detection. By Rowland J. Atcherley, Ph.D., F.C.S. London: W. Isbister and Co., 1874. From the Publishers.

Obituary.

Notice has been received of the death of the following:—
On the 28th December, 1873, Mr. George Baigent, Chemist and Druggist, of High Street, Winchester.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

Prices of Proprietary Articles.

Sir,—I presume a trade journal is the correct medium to ventilate trade grievances, and I shall appreciate a small space in your publication to express my disapproval of a practice on the increase lately, with a view to seeing if my opinion is entertained by others in the retail trade. I allude to the considerably increased price charged to us by some manufacturers of proprietary articles without proportionate increase of selling price. I am fully aware of the enhanced value of material and labour, but I cannot see the justness of making the retailer bear the whole burden, when the profit is, as it often is, not very large considering the stock kept, carriage, etc. I will not mention the articles to which I refer; it would not strengthen the case, but I cannot help thinking the maker should be careful how he reduces the retailer's profit if he considers or knows how much he depends upon him for keeping up the sale of his articles, however valuable they may be. The makers of many every-day articles are not known to us, and I take this opportunity of making known my grievance, hoping it may elicit a satisfactory explanation or an expression of others' views on the matter.

W. T. Gardiner.

Norwich, Dec. 20th, 1873.

[*** The matter our correspondent refers to no doubt presents the aspect of a grievance from the retailer's point of view; but there are other ways of looking at it which lead to the conclusion that little practical good can be done by discussing it. However, the tone of our correspondent's letter is so temperate that we readily afford the opportunity of expressing his views.—Ed. Pharm. Journ.]

Date's Ointment.

Sir,—In reply to Mr. Edwards, I beg to say that in sending the form for Date's Ointment, I had no intention of betraying anybody's secret; indeed, I did not think it was a secret at all. The form was given to me more than twenty-five years ago, by a person who had left Bristol at least twenty years before that, and I have no doubt it is pretty well known in that part of the country. Most of these secret forms do get known, but I greatly doubt whether the knowledge benefits any one except the proprietor. I have seen a good many of them in my time very jealously guarded, and kept under lock and key, so that the prying eyes of the apprentice or assistant should never see them, but all in vain; by one means or another they do get copied, and they are handed from one apprentice to another, with wonderfully little advantage to any of them, so far as I could ever see.

W. Wilkinson.

263, *Cheetham Hill, Manchester, Jan. 19th*, 1874.

Sir,—Possibly there was a time when Turner's Cerate, Turlington's Drops, and Trooper's Ointment were each a "proprietary article." Their day as proprietaries, however, has long since ended, as well as that of Date's Ointment, and now this, in common with the other above-mentioned, and divers others *once* proprietary, are prepared by every chemist, at least in Bristol.

Argus.

Bristol, Jan. 19th, 1874.

Hunter *v.* Freeland.

Sir,—Referring to the report of the above case which appeared in the Journal of the 10th inst., in which it is stated that although the damages awarded amounted to only £12, it is estimated that the costs, in consequence of the case being carried into the Supreme Court, would amount to between £300 and £400, I am now glad to inform you that a considerable deduction from that sum has been made. The auditor of the Court, in taxing pursuer's account, has struck off a sum of £50, and the Lord Ordinary who tried the case, when it was again brought before him, for the purpose of applying the verdict, after considering the whole circumstances of the case, has so far exercised his power of modifying expenses by striking off other £45.

The following letters from Dr. Littlejohn and Dr. Patrick Heron Watson, Edinburgh, which they kindly addressed to my agent a few days after the trial, will show the readers of the Journal the opinion which these eminent medical gentlemen formed of the case.

John Freeland.

Bathgate, January 18th, 1874.

[Copy].

Sir,—I am much gratified by your remembrance of me, but I must decline the fee you send me, as the sufferer is a druggist, and in my opinion has been unjustly treated.

(Signed) Henry D. Littlejohn, M.D.

Police Chambers, Edinburgh, Nov. 25th, 1873.

[Copy].

Dr. Watson presents his compliments to Mr. Officer, and begs to thank him for his kind note, and for its enclosed fee for professional services in the above case. Dr. Watson feels that the circumstances of the case are so much those of a member of his own profession that he does not feel himself at liberty to accept of any fee, and at the same time wishes to express his pleasure in having had an opportunity of rendering any services to one so nearly connected with his own profession, in circumstances when he seemed, through a misfortune, to have been laid open to a very vexatious prosecution.

16, *Charlotte Square, Edinburgh, Nov. 25th*, 1873.

Chemists' Assistants' Salaries.

Sir,—In last week's Journal (17th) a correspondent who signs himself "*The Whole Truth*" addresses you on the above subject.

I will not stop to quibble on grammatical errors, into which we are all liable to fall, but which do not affect the main points of the question.

I wish to express my opinion that I think your correspondent "*Whole Truth*" can have had no experience as an assistant, and not much as an employer, or he would not have taken it for granted that because he paid his assistant nearly £100 per annum, besides giving time, etc., others did likewise.

I will put it as a question to "*Whole Truth*" how many years had the said assistant been engaged in the business before entering his employ? what salary did he commence at, and how long before he rose to receive nearly £100 a year? what is his age (how many of the best and brightest years of his life has he spent in attaining this height of competence!), and is he manager of an establishment, or senior over any other assistants? (if so, how many of these latter receive less than £50 a year?)

"*Whole Truth*" is, I believe, quite right that assistants are allowed a fortnight's holiday every year by respectable houses. No doubt his allowing his assistant time and paying his salary during a lengthened illness was an act of unselfish kindness (which carried with it its own reward), but which, I am in a position to say, is far from being the practice of druggists generally.

In bringing to mind how many days and half-days he has given his assistant, does "*Whole Truth*" remember how often his assistant may have had to work long after *so-called* business hours (but this was a matter of course; the poor assistant being expected to be, like a "jack towel," always behind the door)?

Let us have the *whole truth* and hide nothing under the pretence of candour.

The position of chemists' assistants might perhaps have been better contrasted with that of mechanics, most of whom earn their £3 a week, some more, some less (having to provide themselves) and work far less hours. I will ask, can my fellow-assistants say, as a rule, that they get as much, or its equivalent? I lament to say that the rule is verified in places very few and far between (when found, make a note of), and to be looked on with awe and veneration.

To give my own experience: I have been eight years in the business, have had to undergo an expensive (to me) education to pass the examinations, and have succeeded; but still, cannot command nearly the sum "*Whole Truth*" names (he will find on inquiry that that (and generally less) is the sum given to assistants to live outdoors, and considered ample remuneration), and yet I am better off than nine-tenths of my fellow-assistants, and know many who are worse off than myself.

If "*Whole Truth*" gives an assistant entering his employ nearly £100 a year (how much less?) I am sure he will always have plenty of first-class men to choose from; I fancy I see many eager pairs of eyes glistening at the expectation of the coveted prize.

In conclusion, I think the proposition of "*Truth*" for forming a Chemists' Assistants' Association or Club well worthy the immediate consideration of my fellow-assistants; and if anyone will take it up, I shall be happy to subscribe towards it; and should be glad to hear from any gentlemen of a like opinion and position, and beg to remind them that "Those who would be free themselves must strike the blow."

Pharmacist.

London, January 20th, 1874.

We have also received a further communication on the above subject from "*Truth*," in which, after demurring to the importance of the point of grammar, urged by "*The Whole Truth*," he says:—"With regard to salaries we are not to be guided by what the minority of assistants are receiving, that is putting the cart before the horse, but by the majority. It is a well-known fact that chemists' assistants are the worst paid set of men under the sun, taking into consideration the heavy responsibilities, etc., that rest upon them; it is high time steps were taken for their improvement in this respect; and unless my fellow-assistants unite together they will always remain slaves to their employers."

"*Common Sense*" has also favoured us with a communication, in which he desires to inform "*The Whole Truth*" "That the picture he draws of the treatment his assistant receives at his hands is far from being a criterion of things in general, as at present existing between chemists and their assistants, but a solitary case in a thousand. And, moreover, were such really the case, as he assumes, the condition of chemists' assistants would not be equal in many respects to that of the working man." We do not print the whole of this letter, partly because the statements contained in it are mainly the same as those given above, and partly because we do not think that the tone of the language in which they are made would be conducive to the end the writer has in view.

G. P. W.—(1) Yes. (2) Yes. (3) Next October.

W. S. T.—(1) We cannot tell the names of plants from such imperfect specimens as those sent. (2) Messrs. Butler and McCulloch, Covent Garden.

H. A. is referred to the rule respecting anonymous communications.

C. B. A.—Briefly, because of the rule by which *c* becomes soft like *s*, before *e*. The question whether the Greek derivation of the word "pharmacentical" should entitle it to be made an exception to the English rule, you will find discussed and decided in the negative in the Pharm. Journ. 1st Series, vol. i., p. 178.

Dr. W. Handsel Griffiths writes to say that his attention has just been drawn, by an article in the *Canadian Pharmaceutical Journal*, to an error or misprint in his letter in this Journal of November 1st, relative to the removal of nicotine from tobacco-smoke, where he is made to say, "I substituted a solution of *tartaric* and citric acids for the water." It should have been *tannic* and citric acids. We may remark that the error did not occur through a misprint, but was due to Dr. Griffiths having written plainly "tartaric acid," and not tannic acid, in the MS. of the letter referred to.

Communications, Letters, etc., have been received from Mr. Hayes, Mr. Barnett, Harper, Phœbus, N. S. A., F. B.

ON QUINAMINE.

BY DR. J. E. DE VRIJ.

This new alkaloid of cinchona was discovered in the beginning of 1872 by Dr. O. Hesse, in the bark from *C. succirubra*, exported from British India. This discovery was mentioned in the *Chemical News* of April 29, 1872, p. 191, where the new alkaloid is described in the following terms :—"A well crystallized substance, not containing any water of crystallization, readily soluble in ether, in warm alcohol, and in petroleum ether (refined benzoline); and insoluble in water, in ammonia, and in caustic potassa; the alcoholic solution exhibits an alkaline reaction. With acids this alkaloid forms salts, which are readily soluble in water; the chlorhydrate is an amorphous substance, and the neutral sulphate is difficultly obtained crystalline. Quinamine does not exhibit fluorescence of its solutions, and with chlorine and ammonia does not yield the well-known reaction of quinine; in strong sulphuric acid quinamine dissolves without giving rise (unless heat be applied) to a coloration of that acid; when dissolved in nitric acid, the latter is first turned yellow by the quinamine, and next orange-red, after which the colouration disappears. Quinamine fuses at 172°; it is hardly bitter, tasted by itself, but its salts are somewhat so."

A year later Dr. Hesse published a remarkable paper on the cinchona-alkaloids,* in which he describes more fully his new alkaloid. He states that he found it in the red bark from Darjeeling, which contains generally only traces of it, so that it requires much exercise in this kind of investigation to prepare it. In rare cases he obtained about 0·1 per cent., and only once he obtained a sample of bark, of which one pound yielded 1·3 gramme, or about 0·3 per cent. pure quinamine.

In October, 1872, I was requested by his Grace the Secretary of State for India, to undertake the analysis of two samples of red cinchona quill bark, which had been received from the plantation in British Sikhim for that purpose. After having terminated my analysis of these samples, I stated in my report, dated 30th October, 1872, that these barks contained, besides the mentioned quantities of quinine, cinchonidine, cinchonine, and amorphous alkaloid, also the new alkaloid discovered by Dr. Hesse.

At that time I was only acquainted with that which had been published in the *Chemical News*, about this new alkaloid, so that I could ascertain its existence, but was not yet acquainted with the means to obtain it quite pure. When, therefore, Dr. Hesse published in April last his paper, in which he gives, not only an elaborate description of the properties, etc., of his new alkaloid, but also describes accurately how to prepare it, I applied his process on the small quantity of impure quinamine which I had preserved from the above analysis of the red bark from Sikhim, and succeeded in obtaining it pure. The experience which I had now obtained led me to investigate whether I could not find a more simple process, and as I was happy enough to find one, I suppose that its publication will enable every chemist who is in possession of red bark from British Sikhim to obtain this new alkaloid easily. I insist that the red bark must be for this purpose really originally from that locality, as I have failed to find even a trace of quinamine in the "uncrystallizable portion of the alkaloids from Indian red bark," of which Mr. D. Howard was kind enough to send me a good quantity at my request. As these uncrystallizable alkaloids did not yield a trace of quinamine, I am convinced that the red bark from which they are obtained must be from another locality. This is the more probable, as the Darjeeling red bark, although tolerably rich in mixed alkaloids, contains too little quinine to allow its use for the manufacture of quinine.*

My process for the preparation of quinamine is the following :—The mixed alkaloids obtained from the before-mentioned red bark are transformed into neutral sulphates, and the solution treated with Rochelle salt, whereby the tartrates of quinine and of cinchonidine are separated. After collecting these upon a filter, the filtered liquor is shaken with caustic soda and ether. By this process the amorphous alkaloid and the quinamine are dissolved by the ether with slight traces of cinchonine, whilst the bulk of this last alkaloid remains undissolved. After distilling the ethereal solution the residue is transformed into neutral acetate, and the solution of this mixed with a solution of sulphocyanate of potassium. By this reagent the sulphocyanate of the amorphous alkaloid is precipitated in the shape of a yellow, soft, resinous substance, whilst the sulphocyanate of quinamine remains dissolved. After subsiding and filtering, the solution is clear and quite colourless, and by addition of caustic soda the quinamine is precipitated. It is then collected upon a filter, washed, and dried. It can now easily be obtained crystallized by dissolving it in boiling spirit, from which it crystallizes in cooling. By this process I obtained from 135 grammes of the above mentioned red quill bark 0·51 grammes = 0·38 per cent. of pure quinamine.

The Hague, January 10th, 1874.

* *Annalen der Chemie und Pharmacie*, vol. 166, p. 267. This paper is now being republished in our columns.

* The mixed alkaloids hitherto obtained by me from red Darjeeling bark, were dextrogyre, whilst those obtained by me from red bark from Ootacamund were laevogyre.

PHOSPHATE OF IRON AND ITS COMBINATIONS.†

BY CHARLES GEISSE POLK, M.D., OF PHILADELPHIA.

(*Continued from page* 595.)

I also found that the excretion of the phosphates was very large during the progress of phthisis, and that whatever arrested the progress of the disease also diminished the quantity of these in the urine. I inferred from this that the pathological lesion consisted in some aberration, not of the phosphorus assimilating, but of the phosphatic eliminating function, and intimately connected with the functions of the pneumogastric nerve, spinal accessory, phrenic, and hypoglossal nerves. I became convinced that the seat of the disease was in the medulla oblongata; that through the pneumogastric nerve was transmitted, as by a telegraph wire, the morbid impression by which the digestive and assimilating function became impaired, and the tubercle originated in the lungs. It also appeared very probable that the great sympathetic was also deeply involved in this trouble, and contributed a liberal share of the fatal agency. While I regarded the diminution of phosphorus in the system in tubercular consumption as a concomitant and a coincident intimately interwoven with the origin of the disease, I have never viewed it as the disease *per se : autochthonic* in itself complete, and as to the cause sufficient, irrespective of co-operating and co-ordinating powers, impressions, or influences. I, nevertheless, deemed it proper to resort to the use of phosphoric acid with a twofold purpose, to secure the tonic influence

† From the *Druggists' Circular and Chemical Gazette*, January, 1874.

on the digestive powers, and the nerve stimulant effect it so promptly gives, hoping thus to reach important indications. Fifteen years' experience has justified my view. A very similar combination to one now highly esteemed was formed. Out of my speculating grew my syrup of the phosphate of iron, quinia, and strychnia, which, although not fulfilling my early sanguine expectations, is yet highly valued by myself and a dozen or more physicians. I prepared it thus :—

℞.	Sulphate of Iron	grs. 800
	Phosphate of Sodium	grs. 1280
	Sulphate of Quinia	grs. 384
	Dilute Sulphuric Acid	q. s.
	Aqua Ammonia	q. s.
	Strychnia	grs. 10½
	Syrupy Phosphoric Acid . . .	℥ iij.
	Syrup sufficient to make . . .	℥xxxij.

Dissolve the sulphate of iron in three ounces of boiling water, and the phosphate of sodium in six ounces of boiling water. Mix them and wash the precipitated phosphate of iron until the washings cease to be affected by a solution of the chloride of barium. Dissolve the quinia sulphate and the strychnia in two ounces of water by aid of dilute sulphuric acid, and precipitate the alkaloids by slowly adding ammonia water, and carefully wash them. Rub the phosphate of iron, quinia, and strychnia with four ounces of water, add the syrupy phosphoric acid and dissolve them. Then filter the solution into sufficient syrup to make thirty-two fluid-ounces. In the formula published in the *Druggists' Circular* it is directed that the syrupy phosphoric acid be mixed in ℥ xvi. of distilled water, the iron, quinia, and strychnia dissolved in the solution, and ℥ xviij. + ℥ ij. of sugar be added.

The formula here given produces rather a finer pharmaceutical product, and seems less impressible to atmospheric exposure. The formula given in the *Druggists' Circular*, however, will produce *quite satisfactory results* and answer every purpose. Easton's formula, published originally in Aitken's 'Practice of Medicine,' and by some erroneously called Aitken's formula, is prepared thus :—

℞.	Sulphate of Iron	℥ v.
	Phosphate of Soda	℥ i.
	Quinia Sulphate	grs. 192
	Dilute Sulphuric Acid . . .	sufficient.
	Aqua Ammonia	sufficient.
	Strychnia	grs. vi.
	White Sugar	℥ xiv.
	Dilute Phosphoric Acid . . .	℥ xiv.

Dissolve the sulphate of iron in one ounce of boiling water, and the phosphate of soda in two ounces of boiling water. Mix them and wash the precipitated phosphate of iron until the washings are nearly tasteless. Dissolve the sulphate of quinia in two ounces of water by the aid of dilute sulphuric acid, and precipitate the quinia by aqua ammonia, and carefully wash it. Dissolve the phosphate of iron and the quinia thus obtained, as also the strychnia, in the dilute phosphoric acid ; then add the sugar and dissolve the whole without heat.

This formula, the one having semi-officinal recognition, is somewhat defective, and precipitates the iron in a few weeks, so as to modify its therapeutical powers, and seriously impair its pharmaceutical beauty. The dilute phosphoric acid is not sufficient to dissolve the iron, quinia, strychnia, and sugar, and hold them in perfect solution ; the amount of sugar is not sufficient to preserve the preparation from deterioration by age and atmospheric influences, while the preparation by the above formula of mine seems to be free from these objections.

Being desirous of forming a concentrated syrup of much greater strength than the above, so as to be more convenient for use on the tented field, I devised the following formula in 1864 :—

℞.	Freshly Prec. Phos. of Iron . .	grs. 600
	Quinia, freshly precipitated . .	grs. 96
	Strychnia	grs. iij.
	Syrupy Phosphoric Acid . . .	f. ℥ iv.
	Water	℥ xiv.
	Syrup (very dense), q. s. ad . .	f. ℥ xij.

Mix the phosphate of iron, quinia, and strychnia in the syrupy phosphoric acid previously diluted with fourteen drachms of water, and dissolve them. Add sufficient syrup to measure twelve fluid ounces, and bottle with a tight-fitting stopper, so as to exclude the air entirely.

Each drachm will represent above five grains of the ferrous phosphate, one grain of the quinia, and one thirty-second of a grain of strychnia phosphate. There are about three grains of free phosphoric acid and about ten grains in basic combination of the same. Although a good preparation for an army surgeon, it is rather too powerful for private practice. Outside of my military practice I have never used it, although it was a great favourite of mine in the army hospitals.

In compliance with the wishes of several physicians, Mr. Theodore A. Polk, of Seaford, Delaware, prepares the syrup thus :—

℞.	Freshly prec. Phos. of Iron . .	grs. 192
	Phosphate of Quinia	grs. 64
	Strychnia	grs. 2
	Dilute Phosphoric Acid . . .	℥ x.
	Sugar	℥ viij.
	Essent. Tinct. Orange . . .	℥ iij.
	Oil of Cardamom	gtt. viij.

Dissolve the phosphates of iron, quinia, and strychnia in the dilute phosphoric acid. Rub the essential tincture of orange and oil of cardamom with the sugar. Mix altogether, and dissolve without heat.

LACTO-PHOSPHATE OF IRON AND LIME.

℞.	Freshly prec. Phos. of Iron . . .	℥ iij.
	Syrupy Phosphoric Acid	℥ vi.
	Concentrated Lactic Acid	℥ ij.
	Freshly prec. Phosphate of Lime .	℥ iij.
	Syrup of Orange Flowers, q. s. . .	♁ xij.

Add the phosphate of iron to the syrupy phosphoric acid, previously diluted with two ounces of the orange-flower syrup. Mix the phosphate of lime with the concentrated lactic acid, previously diluted with two ounces of orange-flower syrup, and dissolve. Lastly, mix the two solutions together and add sufficient syrup to measure twelve ounces.

I believe this formula, or a similar one, is destined, at no remote day, to attain the very zenith of professional confidence. I believe it possesses rare intrinsic merit, and embodies curative powers unequalled in certain forms of debility. In convalescence from acute diseases it promises much. Phosphate of lime is well known to be an important element in the human organism, a real essential in the phenomenon of life. Experiments made of depriving animals of it, by removing it from their food, have been attended with rapid prostration and exhaustion, while the restoration to the food restored them to their former condition. The waste of the phosphate of lime is very great during fevers and inflammations, and the depleted organism demands its restoration. True, nearly every article of food contains it in a greater or less degree, yet the stomach is weak, the digestive and assimilative powers impaired. The emaciated frame demands it in a more readily assimilable form, and this very condition is very excellently filled in the syrup of the lacto-phosphate of iron and lime. If given with an elixir of cinchona, the result would be greatly enhanced.

SYRUP OF THE PHOSPHATE OF IRON AND AMMONIA.

Heat phosphate of soda to redness. Take of the pyrophosphate of soda so obtained ℥ ij. Dissolve in one pint of water. Take of the sulphate of iron ℥iv. Dissolve in twelve ounces of water. Mix the solutions, collect, wash, and dry the precipitate at a gentle heat over a water-bath. Take of this precipitate ℥ i., liq. ammonia ℥ iss., water q. s. Dilute the ammonia water with an equal volume of distilled water, and rub it with the phosphate of iron in a mortar until the latter is dissolved. Then dilute to

seven ounces, and prescrve gentle heat until it is evaporated to six ounces, and add ten ounces of dense syrup. Each drachm contains four grains of the phosphate of iron with ammonium. The syrup is quite permanent and remarkably free from inky taste. It is no doubt a very good preparation. My partiality is, however, very strong for the following preparation :—

SYRUPUS FERRI ET AMMONII CUM QUINIÆ ET STRYCHNIÆ PHOSPHATI.

℞.	Ferri Sulphatis Granulati . . .	℥ vi.
	Sodii Phosphatis	℥ x.
	Acidi Phosphorici Anhyd. . . .	℥ xij.
	Acidi Nitrici, c. p.	℥ iij.
	Quiniæ Sulphatis	℥ i.
	Acidi Sulphurici Dil.	q. s.
	Aquæ Ammoniæ Concent. . .	q. s.
	Strychniæ Citratis	grs. xiijss.
	Sacchari Albi	℥ xxx.
	Aquæ Destillatæ, q. s.	℥ xlviij.

Prepare the anhydrous phosphoric acid by igniting phosphorus in dry oxygen. As soon as the combustion is completed dissolve twelve ounces of the white anhydrous phosphoric acid in sixteen ounces of distilled water ; add the nitric acid, place on a sandbath and apply heat until the fumes of nitric acid cease to be evolved. Dissolve the sulphate of iron in ℥ x of boiling water, and the phosphate of sodium in twenty ounces of boiling water. Mix the solutions and carefully wash the magma until the washings are tasteless. Dissolve the quinia and the strychnia in four ounces of water, and precipitate the alkaloids by slowly adding a weak solution of ammonia water, and carefully wash them. Add the phosphate of iron to six ounces of the solution of phosphoric acid, and apply gentle heat until dissolved. Dissolve the quinia and the strychnia in four ounces of the solution of phosphoric acid. Saturate the remaining solution of the phosphoric acid with the concentrated ammonia water. Lastly, add the solutions of the phosphate of iron, the alkaloids and the phosphate of ammonium together in a bottle of the capacity of three pints, introduce the sugar and sufficient water to complete the measure of forty-eight ounces.

The same result can be obtained by using twelve ounces of syrupy phosphoric acid. The iron, quinia, and strychnia being disolved in six ounces of the syrupy phosphoric acid and the remaining six ounces saturated with the concentrated ammonia water, mix them, and then add the sugar and water as above directed. The only objection that can be urged against this preparation is the very large amount of phosphoric acid, but when we consider that it is nearly all in basic combination, the objection is less than it first appears. I regard this ammoniated syrup of the phosphates as a very valuable addition to our list of remedial agents.

Each drachm contains five grains of the phosphate of iron, six grains of the phosphate of ammonium, one and one-fourth grain of the phosphate of quinia, and one-twenty-eighth of a grain of the phosphate of strychnia. If therapeutically inferior to the syrup of the phosphates of iron, quinia, and strychnia, as a tonic, the phosphate of ammonia adapts it to an especial range of diseases. The permanency of the syrup also entitles it to important consideration. This formula differs very much from one previously published, and seems to be a better one.

(*To be continued.*)

THE ALKALOIDS OF THE CINCHONA BARKS.*

BY O. HESSE.

(*Continued from p.* 592).

II. CONCHININE.†

The first information upon the cinchona alkaloid which I have named conchinine, we owe to Van Hejningen,* who, during the examination of a specimen of quinoidine, discovered this beautifully crystallizing base. Later, Pasteur† recognized its presence in commercial sulphate of cinchonidine, but as Henry and Delondre‡ had already given the name of quinidine to a base which they afterwards found to be identical with their quinine,§ Pasteur thought that those chemists were mistaken, and that in reality they had observed an isomer of quinine, identical with his alkaloid, and so he continued to give it the name chosen by those chemists. Not only Delondre,‖ after him, willingly adopted the erroneously named discovery, but many other chemists followed, so that this error extended, and was gradually introduced into all the chemical works speaking of this alkaloid.

Van Hejningen was of opinion that the β-quinine, as he called conchinine, was quinoidine in the purest form, and following him Strecker¶ also held it to be crystallized quinoidine. Later, Hlasiwetz** having found this alkaloid in commercial cinchonine, and not being able to decide whether he was dealing with a modification of quinine or crystallized quinoidine, rightly proposed for this body a new name, cinchotine. This alteration of name, as we know, found no acceptance ; but it was the occasion however of a treatise on the subject by Delffs.†† The memoir of Hlasiwetz also induced Hirschberg‡‡ to search for "cinchotine" in his "cinchonine," and indeed apparently with success, though the dull crystals that he obtained might well have been only cinchonine.

Finally this alkaloid was described by Kerner§§ under the name of β-quinidine, and Koch,‖‖ who named it β-quinine, first gave certain information that it existed in the bark of *Cinchona Pitayensis*. Although Stenhouse¶¶ retained for his alkaloid the name chosen by Pasteur, and J. E. Howard in his 'Nueva Quinologia' of Pavon, also adopted it, the latter chemist by wide and long experience has been gradually led to the conclusion that Pasteur's designation was very ill chosen, for he says, "All this (the research of Pasteur upon quinidine) is very excellent, with the exception of the terminology, for I can but say that I wish the name could have been retracted."

In the course of his memoir Howard said that a real relationship might happen to exist between conchinine and cinchonine, but not between quinine and cinchonine, since the cinchonine-yielding *C. mierantha* of Peru produced in the East Indies a large proportion of conchinine. From considerations based upon the possibility of such a relation, to which the chemical properties of both alkaloids especially testify, I had already*** named the alkaloid in question conchinine, and later††† made known the etymology of this word. The name conchinine for this base is

---

* Translated from the 'Vierteljahresschrift für praktische Pharmacie,' vol. xxii., p. 366.

† As will be seen, Dr. Hesse proposes to discard the name "quinidine," on the ground that it has been used for so many different substances that its retention would prolong the confusion. In its place he suggests the name conchinine for the alkaloid known as "Pasteur's quinidine." We think the advisability of this step is open to great doubt, and that it would have been preferable to have endeavoured to limit the well known term "quinidine" to one definite substance, and this the more especially as the new name "conchinine" is not so suggestive of similarity to quinine in its English as in its German form. We have also received a letter from Dr. De Vrij strongly deprecating the introduction of Dr. Hesse's new name.—ED. PHARM. JOURN.

preferable to "β-quinine" since then a confusion between that alkaloid and quinine in commerce would not so readily occur, and besides it is a definite term that does not throw upon the nature of the substance the doubts which inevitably result from the use of the word "quinidine."

At the commencement of 1860 De Vrij, while examining a *C. Calisaya* bark from Java, found a peculiar alkaloid very easily soluble in alcohol and in ether, crystallizing from the latter in pretty cauliflower-like tufts and lævogyrous. That this bark contained considerable quantities of conchinine had already been pointed out by Winckler* and Jobst† in their treatise on Java barks; but it was in 1869 that De Vrij‡ first convinced himself of the existence of this alkaloid in cinchona barks, consequently it was not possible that he previously separated it by his analysis from other substances and especially from quinine, so that it is quite probable that his new crystallizable cinchona alkaloid was a mixture of quinine and conchinine. All the experiments that I have since made with calisaya bark from Java tend to confirm me in this opinion.

As to the yield of conchinine, I must point out that this alkaloid is found in considerable quantity in the bark of *C. Pitayensis*, such as is brought from Popayan. This species of cinchona has for some years been cultivated in India also, but as other climatic conditions have there an influence upon the increase of cinchona than in its native country, Howard and others consider that this acclimatization might produce different results. Among the other cinchonas which contain notable quantities of conchinine may be mentioned also *C. amygdalifolia* and *C. ovata*, as well as many hitherto so-called East Indian Calisaya barks.

With regard to the Pitayo barks which are collected in the forests of Pitayo, in the province of Popayan, from *C. pitayensis*, and, according to Karsten, from *C. lancifolia* also, Henry showed in 1830 that they contained very much quinine and especially cinchonine; but in 1837, Peretti, then in Mailand, found in a Pitayo bark a so-called new base which he called "pitoyine." In 1839 Guibourt again examined this bark but could find only quinine and conchinine. Henry as well as Guibourt overlooked the conchinine and probably took it for quinine. Formerly I was of the opinion that Peretti had been the first to prepare conchinine in a pure state, but further researches on this subject showed that this was an error, and that Peretti had not examined a true Pitayo bark, but one from "China bicolorata," collected, according to Karsten,§ at Atacamez, west of Ibarra. In 1835 the republic of Columbia presented to Pope Gregory XVI. some of this bark, which consequently acquired a great reputation in Italy, and fetched a high price. This bark, after repeated experiments, I find does not contain any alkaloid; there is therefore no reason for retaining the name of "pitoyine," which Wiggers‖ has proposed to change to "bicolorin" or "tecamin."

I still prepare conchinine by the process formerly indicated by me. When this alkaloid is precipitated by iodide of potassium from a solution containing at the same time a pretty considerable quantity of cinchonine, the precipitate contains, as pointed out also by De Vrij, a little hydriodate of cinchonine, but the two hydriodates may be easily separated by boiling water or alcohol, in which the hydriodate of cinchonine is easily but the other salt difficultly soluble.

De Vrij¶ has published a very simple process for preparing conchinine, based upon the equivalent of quinoidine being about double that of tartaric acid. He dissolves together the corresponding two parts of quinoidine, and one part of tartaric acid, and thus obtains principally tartrate of quinoidine, while he thinks that the solution deposits the tartrate of conchinine, which is less soluble. But by his method mostly a mixture of cinchona alkaloids is obtained, from which, however, it is easy to extract the conchinine, by crystallizing the crude product from boiling water, and neutralizing the solution with ammonia. Upon the cooling of the solution, neutral tartrate of cinchonidine separates, mixed sometimes with a little tartrate of quinine, whilst the conchinine remains in the mother liquor, from which it can be precipitated, after heating, by iodide of potassium.

Conchinine turns to the right the plane of polarized light, as stated by Pasteur. According to him, $a\,r = +250{\cdot}75°$ at 13° C., which gives for the yellow ray, $a\,j = +327°$. My own experiments with this alkaloid have given a different result. I have dissolved the base in alcohol, after having estimated the water of crystallization by a special experiment.

(1) For $p = 3{\cdot}7787$ (anhydrous), and $l = 200$, $a = +21{\cdot}71°$.

(2) For $p = 3{\cdot}640$ (anhydrous), and $l = 200$, $a = +18{\cdot}94°$.

The rotatory power of conchine in alcoholic solution appeared to be, therefore—

	Experiment I.	Experiment II.	Mean.
$a\,j =$	$+260{\cdot}16°$	$+261{\cdot}14°$ . . .	$+260{\cdot}65°$.

With the neutral sulphate of conchinine I have obtained the following results :—

For $p = 2{\cdot}1400$ (anhydrous and in alcoholic solution), and $l = 200$, $a = +9{\cdot}71$, or—

For $2\,C_{20}H_{24}N_2O_2\,H_2SO_4 + 2\,H_2O$.	$a\,j = +216{\cdot}70°$.
For the anhydrous salt	$a\,j = +226{\cdot}87°$.
For conchinine	$a\,j = +261{\cdot}18°$.

This salt was afterwards dissolved in sulphuric acid, diluted to different degrees, and gave :—

(I.) For $p = 2{\cdot}4332$ (anhydrous), $SO_3 = 1$ molecule, and $l = 200$; $a = +13{\cdot}65°$.

(II.) For $p = 2{\cdot}4014$ (anhydrous), $SO_3 = 6$ molecules, and $l = 200$; $a = +13{\cdot}54°$.

Which would be for the anhydrous salt—

	Experiment I.	Experiment II.
$a\,j =$	$+280{\cdot}49°$	$+281{\cdot}91°$
For conchinine $a\,j =$	$+323{\cdot}06°$	$+324{\cdot}54°$

Finally, a test of the rotatory powers of the hydrochlorate of conchinine gave—

(I.) For $p = 2{\cdot}5362$ (anhydrous and in alcoholic solution), and $l = 200$; $a = +12{\cdot}31°$.

(II.) For $p = 1{\cdot}6910$ (anhydrous and dissolved in dilute HCl), and $l = 220$; $a = +10{\cdot}41°$.

(III.) For $p = 1{\cdot}6030$ (anhydrous and dissolved in concentrated fuming HCl), and $l = 200$; $a = +7{\cdot}42°$.

We have thus—

	Experiment I.	Experiment II.	Experiment III.
For anhydrous hydrochlorate of conchinine :— $a\,j =$	$+242{\cdot}68°$	$+279{\cdot}82°$	$+231{\cdot}44°$
For conchinine $a\,j =$	$+270{\cdot}03°$	$+312{\cdot}47°$	$+257{\cdot}52°$

From these results I draw the following conclusions :—When conchinine is combined with sulphuric acid, as a neutral salt, the rotatory power of conchinine is scarcely modified, but this is significantly augmented when this sulphate is converted into the sulphate with one molecule of acid; it then remains nearly constant, even in presence of a large proportion of sulphuric acid. In the state of hydrochlorate, however, conchinine possesses a rotatory power entirely different; as, for instance, when combined with that acid as a neutral hydrochlorate. With a

greater admixture of acid its rotatory power is augmented, as it is also by the addition of dilute acid, and the addition of concentrated acid so greatly increases it that the rotatory power surpasses that of free conchinine. It is probable, therefore, that Pasteur, in his estimation of [a], did not use pure alcohol to obtain a solution of the alkaloids for his researches, but a moderately dilute acid.

III. Quinidine.

Under this name I would designate provisionally an alkaloid which Kerner* formerly (before 1862) frequently met with in the sulphate of quinidine of commerce. This alkaloid, according to Kerner, appears under the form of large, short, usually truncate prisms, which effloresce but slowly. Its salts present a remarkable dissimilarity to the corresponding salts of quinine, both in their form and in their degree of solubility. The sulphate dissolves in from 180 to 300 parts of cold water. This difference of solubility appears to indicate that this alkaloid which Kerner named first "α-quinidine," and afterwards "quinidine"—is but a mixture. Should this conjecture not be confirmed, and should it be established that this body is a definite compound, I would propose to give it another name to avoid the confusion resulting from the employment of the word "quinidine."

Experiments made by me last year with the object of obtaining this alkaloid from commercial cinchona barks remained without result, but I intend to make further experiments in this direction, unless Kerner should make known his labours upon the subject.

(To be continued.)

A CHEMIST IN THE BUSH.

BY W. M. ROGERS.

The idea has lately occurred to me that a brief sketch detailing the every-day life of a chemist in the "wilds" of Tasmania, might not prove unpalatable to your readers or unsuited to your pages.

If you will take the trouble to refer to one of Stanford's maps of Tasmania, and run your eye along the northern shores of that island, abutting on to Bass's Straits, you are well nigh sure to encounter Port Frederick, the entrance to the River Mersey.

Taking this as a starting point and drawing your finger in a line almost due south until you arrive at a spot where the river suddenly contracts within a comparatively narrow margin, you will perceive marked, no doubt, a township under the name of Latrobe. Of quite a recent origin, in fact, barely twenty years old, this township, owing its existence almost entirely to agriculture, possesses within itself all the elements of prosperity, and in spite of changes of a feeble ministry, exhibits all the tokens of progression.

The inhabitants of the township proper do not exceed, probably, 400, but the surrounding district has a wide area, dotted over with numerous homesteads, whose occupiers have encountered and still encounter hardships which to an English farmer, if related in all their startling truth, would be regarded as inventions of the fictionist. The majority of the smaller proprietors hail from the Emerald Isle, with a sprinkling of a better class from the northern and midland counties of England, whilst a few of the more refined descendants of "good families" still reside in the immediate neighbourhood. Further westward, again, dwelling in habitations at intervals, on what is known as the north-west coast, may be found a few retired officers, who have served under the East India Company, and as members of the British Army, in virtue of which they receive annual pensions of from £200 to £600. There is no such thing as individual wealth amongst the members of this mixed community, and with the exception of the latter-named class, each one is struggling for existence on well-nigh equal terms. Salaries and wages, although higher than in England, are reduced to a similar footing by the increased prices for articles of necessity, one article of food, that is meat, only, can be excepted. With regard to the charges for physic more will be said anon. I can picture the astonishment, nay, even disgust, which a dapper young assistant from one of your West End establishments would of a surety display were he suddenly to be transported (not as a convict, of course), but for the purpose of taking charge of a *bonâ fide* business in the bush of Tasmania.

It requires a schooling, I assure you, O reader! whoever you may be, whether proprietor of one of those splendid West End establishments, or a young man contemplating emigration in search of improved fortunes, novelty, or merely change.

Yes, it requires a schooling, and more than this, a mind moulded perchance to adapt itself to circumstances, and capable of resisting the enervating influence of the many hours during which it is next to impossible to find active employment. Yes, the absence of this latter is the one thing which a young man fresh from the turmoil and excitement of a busy European city would mostly miss, and no doubt regret.

But, on the other hand, to the intellectual mind, and to one able to overcome the first feelings of depression consequent on the sudden change, there is a glorious sensation of liberty. And to one who goes forth with a determination to rightly make use of this glorious acquisition, there ensues a wide field for giving scope to the intellectual powers, which soon begin to soar above the mere humdrum of business, to be regarded only as means to an end, and not allowed to engross the whole of one's worldly existence. Yes, without in any way despising this means of gaining a livelihood, or neglecting the so-called drudgery of a pharmacist's occupation, the aspirant may gradually but effectively penetrate into those regions of philosophy, however humble may be his footsteps, which he had hitherto seen but dimly and from afar.

Yet must he anticipate difficulties, for the probability of meeting with one bent on a similar task, or having access to one who has already reached the goal are extremely faint and rare. But, though he may not all at once meet with human sympathy, what lacks he when surrounded by all glorious Nature, who patiently awaits but his signal to open to him her "holy of holies?"

After all the artificial excitement of a city life how dull and unattractive to the mere outward observer would doubtless appear our natural surroundings, tempered as yet with but little of architectural addition; but to you, gentle reader, perchance a humble worshipper of Nature, something of interest may be reflected from her magic mirror. Look to the southward and see tier after tier of ranges, rising gradually, until at length in the far distance may be distinguished one fellow towering above his neighbours—that is Mount Roland, visible far out to sea and attaining a height of over 4000 feet. To the north you perceive another range, at the foot of which lies the little township, surrounded, in fact, on every side by hills except an opening to the westward, the valley along whose base flows with swift current the noble river. Up this valley come the prevailing west and north-westerly winds, at times soft and gentle as a zephyr, at others with the force of a hurricane. Very healthy are these westerly breezes, coming fresh from the South Atlantic Ocean, and laden with the life-restoring ozone. Indeed, during my sojourn here upwards of four years no epidemics beyond attacks of influenza have occurred, and these, too, limited to a few mild cases. Now let us observe a peculiarity in the surface soil taken from various localities throughout this broad valley or depression, which is the prevalence of water-worn shingle and marine and fresh-water shells, an evident indication that the disturbances which caused the waters to retire have been of comparatively late occurrence. These marine deposits may be found too on the summit of the highest range hereabouts, with occasional

* Zeitschrift für Analytische Chemie, vol. i., p. 150; Archiv für Physiologie, vol. ii., p. 200.

patches extending to a considerable depth on the hill slopes, as though arrested half way down by some intervening cavity. Coal has been known to exist in the neighbourhood for some years, and in various places, half a mile or so from the river's course, may be discovered abandoned shafts, the old workings of some company now in a state of collapse. At the time I write, owing to increased demand for this fuel, the search is being renewed and speculation is becoming rife both in this and neighbouring colony of Victoria. One individual, comparatively a poor man, bids fair to accomplish what hitherto wealthy companies have failed to do, that is, discover a payable coal mine. He commenced boring some six months ago, and after various testings, hit upon a spot at the junction of two lines of range, running at oblique angles, where at the depth of some forty feet from the surface, he came upon a seam of the mineral from twenty to twenty-two inches in thickness. Some six feet above this was a layer of lignite a few inches thick, containing a large quantity of iron pyrites, with earthy and alkaline salts. For steam purposes this coal answers admirably, and several of the residents who have tried it on their open hearths speak highly of its heat producing qualities. The sulphur which it contains must however somewhat limit its use, but even in this respect it seems preferable to the coal hitherto found in this part of Tasmania. Of the more precious metals we cannot make much boast. Gold has been found in very minute particles in the creeks and tributaries within a few miles of us, but the result has not been of a nature to induce any organized search. About three years ago, however, myself with a few others cast in our lots, and having raised some £40 by subscription, sent forth an experienced miner into the "wilds" to prospect for gold. Whatever might have been the experience of this individual in the colony of Victoria he did not prove equal to the emergency of Tasmanian bush exploration, for the lad who accompanied him, a shrewd native youth, and accustomed to "rough it," told us that his mate quite broke down on the fourth day out, scared at the difficulties of making headway through the dense foliage and scrub which bordered the river and creeks. Fearful doubtless of becoming totally lost, he "made tracks" for the haunts of civilization with only a few specimens of iron and copper pyrites glistening in the crystal quartz, and to the uninitiated bearing strongly the appearance of the more precious metal.

About 100 miles to the westward, at Mount Bischoff, there has lately been discovered a tin-bearing locality. The lucky finder, after years of travel through the very heart of the bush, upheld by his unbounded faith in the mineral wealth of the country, is now in a position to take his ease, if he so chose, for the remainder of his life, his interest in the affair, at the lowest computation, being worth £20,000.

No gems of any great value have as yet, so far as I am aware, been found in this locality; but examine the bed of the river, and you will find many a bright-tinted stone, but none, unfortunately, worthy to rank with the jasper or emerald. Small specimens of the ruby may here and there be selected from the masses of water-worn quartz at the bottom of the creeks, which take their rise in the lofty ranges to the south-west. The diamond, so-called hereabouts, is nothing but a well-defined quartz-crystal.

I have seen from Flinder's Island some magnificent specimens; and it is not so long since that an amusing incident occurred. An unusually large crystal was enclosed in a chamois leather bag, and despatched to a well-known Melbourne firm, celebrated for its dealings in the more precious stones and minerals. On the strength merely of its weight and size—for only a privileged few were permitted to behold the stone devoid of its covering—a company was actually inaugurated to purchase this so-termed diamond. One would-be shareholder, however, more wise or suspicious than the rest, proposed that it should be passed under the observation of a noted mineralogist, and his opinion obtained thereon. Consequently, Mr. Clark, of Sydney, was sent for (the stone was too precious to intrust to the tender mercies of any single individual), and his arrival in Melbourne and examination of the false diamond, soon put a stop to the hubbub.

A friend of mine tells me that lately while superintending the cuttings for a tramway some eight miles from here, he came across some very pretty crystals embedded in a kind of amygdaloid rock, each almond-shaped cavity or spot containing them in numbers, specimens of which he has promised to bring me.

Now let us look on the surface, and see what claims our attention, for surely:—

"It is pleasant to note all things from the rush to the spreading cedar,
From the giant king of palms, to the lichen that staineth its stem."

Note first of all as most conspicuous the towering Eucalypti with their leaves—as it is now spring-time—of a more vivid green, and getting new coats to their backh or in other words renewing their supply of bark, of whics they have been stripped during the winter months. Very ghostly do these trees appear amidst a full forest with their trunks bare as they glisten white on moonlight nights. You will hear them designated popularly as white and red gum, peppermint, etc., etc. The blue gum (*Eucalyptus globulus*), of which you have heard through its late introduction as a febrifuge, does not thrive in this northern part of the island, but further south it is tolerably abundant. On the alkaloid extracted from the leaves principally, Mr. Bosisto, of Richmond, Victoria, has bestowed the name "Eucalyptene."* The volatile oils from *E. melaleuca* also furnish a very fair substitute for cajeput, which likewise belongs to the extensive family of Myrtaceæ. Just now you will perceive the air laden with the delightful wattle perfume; the *Acacia mimosa*, the blossoms of which you have doubtless seen in your greenhouses at home, but which thrive here most luxuriantly. On the river bank, and in moist places, you will find the "Dogwood Piscidia," the ash of which yields potash; as yet we have failed in procuring the alkali to any extent from other trees. A friend of mine having plenty of iodine, but no potash, lately went to some trouble to prepare the iodide, of which he found himself in immediate want, and it being a long distance to send to the northern metropolis (Launceston). I must not omit to say that it was from the dogwood he obtained his supply of potassa.

Manna from *Eucalyptus dumosa* is not found here in quantity, but further south is picked up in large fragments and eaten with gusto by the juveniles. I am not aware that it possesses laxative properties like its namesake from Egypt.

Although this is not the season for seeing a fern in all its quiet beauty, more especially those called the tree ferns, still there are numerous specimens of the smaller species worthy our examination. The Maidenhair (*Adiantum Ethiopium*) to wit, under the flowering box and wild raspberry (which latter is very common hereabouts) may be met with almost throughout the entire year. The Spleenworts (*Asplenium*) are a widely diffused genus, one especially (the *A. flabellifolium*) we find running. about everywhere. The *Polypodii* too are numerous The true *Aspidium* I have not yet met with.

And now to close this imperfect sketch with a bit of in-door gossip. Amongst a comparatively rude population (although some very intelligent men may be here and there met with) any elaborate display on our part is found to be both impracticable and superfluous. We go in for the purely practical, and our notoriety is to be founded on results only. We must needs combine the physician, the apothecary, the surgeon, and the chemist. Through this your humble servant was "once on a time" nearly

* Our correspondent does not seem to have heard of Mr. Broughton's unsuccessful search for this supposed alkaloid. —Ed. P. J.

getting into trouble with a black-visaged "Medico" who made a brief sojourn in the neighbourhood. That is to say he contested my right to give advice gratis, as the advertisements say, and to avoid difficulties I deemed it prudent to yield to the whim of the "legally qualified." Our patients or customers, by whichever title it may be thought proper to distinguish them, do not as a rule display any nicety as to the kind of bottle from which we may obtain their particular remedy or remedies, whether with gilt label and stopper, or simply a plain written strip and cork. What they require mostly is for you to minister to and alleviate the ailment from which they may be suffering. Do this and they will proclaim trumpet-tongued in your favour. During my bush experience I have ever observed a disposition on the part of the public to overlook little deficiencies in the way of appliances, and to be content with a plain exterior. They frequently express their gratification that a knight of the pestle and mortar has deigned to settle amongst them. Our charges, of a necessity, are much higher than those of your country, for instance, ℥i. to ℥iv. mixtures, 2*s.* 6*d.*; ℥vj and ℥viij, 3*s.* 6*d.* to 4*s.* 6*d.*; pills, per dozen, 1*s.* 6*d.* to 2*s.* 6*d.*; powders 1*s.* each, and so on in proportion. These charges, however, as a rule include advice, for, as before remarked, there is no resident medical gentleman, and consequently written prescriptions may be likened to angel's visits—few and far between.

INFLUENCE OF PRESSURE UPON FERMENTATION.*

BY HORACE T. BROWN, F.C.S.

In an investigation undertaken for the purpose of determining accurately the composition of the gas evolved during the vinous fermentation, the author noticed the fact that other gases, besides carbonic anhydride are evolved when glucose splits up under the action of the alcoholic ferment. He also found that the amount of atmospheric pressure materially affected the relative quantity and also the composition of the evolved gases unabsorbed by potash, and that these variations were accompanied by corresponding alterations in the liquid undergoing fermentation.

When the gas evolved after several hours' fermentation at 14°C. of malt worts previously freed from air was collected over strong solution of caustic potash the proportion of unabsorbed gas to the total amount liberated was about 1 : 3,000, and a rise in the temperature was generally accompanied by a slightly increased evolution of unabsorbed gas. The unabsorbed gas was found to be a mixture of nitrogen, hydrogen, a hydrocarbon, and in some cases nitric oxide; the following represents its percentage composition :—

Nitrogen	92·15
Hydrogen	4·85
C_nH_{2n+2}	1·67
Nitric Oxide	1·33
	100·00

The occasional evolution of nitric oxide was attributed to the "nitrous fermentation" of nitrates present in the water employed, since when the water was free from nitrates no nitric oxide was detected. The hydrocarbon did not occur in sufficient quantity to admit of an accurate determination of its nature, but as it was not absorbed by fuming sulphuric acid it was presumed to belong to the paraffin group. The hydrogen was not, as might have been supposed, indicative of the simultaneous occurrence of the butyric fermentation. Under a reduced atmospheric pressure the amount of gases unabsorbed by potash was found to increase, and this increase was mainly due to the more abundant evolution of hydrogen under these conditions; but no butyric acid was found. The increase of hydrogen was invariably accompanied by an increased quantity of acetic acid and aldehyd in the fermenting liquid, but no butyric acid was formed. The author thinks that hydrogen must be looked upon as a normal product of the alcoholic fermentation, and for various reasons he considers that water is decomposed during vinous fermentation, the dissociation of the water molecule being favoured by a reduction of external pressure. Nitrogen was evolved from solutions containing albuminoids but no nitrates; on the other hand none was observed during the fermentation of solutions containing abundance of ammonia salts, but no albuminoids. The author therefore infers that the nitrogen proceeds from the decomposition of albuminoids. The evolution of nitrogen, contrary to that of hydrogen, appears to decrease with decrease of pressure.

The results of numerous experiments pointed to the conclusion that diminished atmospheric pressure tends to retard in a remarkable manner the progress of the alcoholic fermentation; but the amount of this retardation did not appear to be directly proportional to the diminution of pressure, nor yet related to it in any simple way. The author, however, thinks it probable that by conducting a series of experiments upon exactly similar liquids, at the same temperature, some correlation would be found between the actual pressure and the alcohol formed. Still it is a fact that under diminished pressure there is always less sugar decomposed than during an equal interval of time at the ordinary pressure of the atmosphere.

The amount of carbonic anhydride produced from fermentations at ordinary pressures, as compared with the alcohol formed, was found to be subject to a variation of about 2 per cent. Moreover, the interesting fact was revealed that diminished pressure tends to increase the relative amount of carbonic anhydride, this increase varying, in the experiments made, from ·5 to 2·5 per cent. of the alcohol formed. If the equation of Guy-Lussac, $C_6H_{12}O_6 = 2\,C_2H_6O + 2\,CO_2$, were rigidly correct, every 100 parts of alcohol ought to correspond with 95·65 parts of carbonic anhydride. Pasteur found that during the fermentation of about 10 grams of sugar, alcohol and carbonic anhydride were produced in the ratio of 100 : 96·09. The difference between this last number and that indicated by the equation of Guy-Lussac he attributed to the simultaneous production of glycerine and succinic acid, according to the equation :—

$$49\,C_{12}H_{22}O_{11} + 109\,H_2O = 24\,C_4H_6O_4 + 144\,C_3H_8O_3 + 60\,CO_2$$

Succinic Acid. Glycerine.

If it be true that the excess of carbonic anhydride which is always found is entirely due to the production of glycerine and succinic acid, it appears evident that a reduction of atmospheric pressure favours this particular reaction.

In seeking for a sufficient cause to account for the comparatively slow progress of the alcoholic fermentation in a more or less perfect vacuum, it was thought not improbable that it might be found in the partial destruction of the torula cells constituting the parent yeast, through the carbonic anhydride held in solution by the protoplasmic contents of the cells being liberated, when pressure was reduced, with such violence as to rupture the cell-wall and arrest the vitality of the organism. But some portions of yeast having been placed under the receiver of an air-pump, and the air exhausted with considerable rapidity, no difference could be detected in the appearance of the cells when carefully examined under the microscope, neither was their fermentative action found to be materially modified. The only other reasonable explanation of the retarding influence of reduced pressure upon the alcoholic fermentation, the author considers to be that the organized ferment experiences greater difficulty in re-arranging the atoms of the sugar molecule, owing to the changed physical conditions of its environment; that, in fact, the sugar molecule is more stable under conditions of

*Abstract of two papers read before the Chemical Society (*Journ. Chem. Soc.*, vol. x. p. 570 and vol. xi. p. 973.)

low external pressure. It therefore became interesting to consider how this conjecture agreed with the conclusion of Sorby, that it is highly probable "that pressure weakens or strengthens chemical affinity, according as it acts against or in favour of the change of volume." In other words, that when the re-arrangement of atoms due to any reaction taking place slowly results in an increase of volume, pressure retards the chemical change, whilst the reverse holds good in those cases where there is an actual decrease in volume. Theoretically and experimentally it was found that a contraction in volume takes place during the alcoholic fermentation of a sugar solution, and the retardation of the fermentation under diminished pressure therefore affords evidence in favour of the correctness of Sorby's proposition.

With respect to the acetic acid formed, the proportion of which increased with diminution of pressure, the author for various reasons felt driven to the conclusion that acetic acid is sometimes produced directly from the sugar, and not by oxidation of the alcohol. Whether the splitting up of the sugar molecule under peculiar circumstances, according to the equation $C_6H_{12}O_6 = 3C_2H_4O_2$, is correlative with the functions of the ordinary yeast cells he is not prepared to say, but the fermentation appeared to be quite normal, and the microscope revealed no indications of the presence of the *Mycoderma aceti*. It is interesting however to note that the decomposition of the sugar molecule in this manner is just such a reaction as should, according to Sorby's law, be intensified by a decrease of pressure, because during the change there would be a large increase in the volume of the liquid.

GIGARTINA ACICULARIS AS AN ADULTERANT OF CARRAGEEN MOSS.*

BY J. DALMON.

The author has for some time frequently observed in French commerce the mixture of *Gigartina acicularis* with carrageen moss (*Fucus crispus*, L.; *Chondrus polymorphus*, Lam.), and he states that he has received specimens of moss containing as much as 40 per cent. of it. The mixture is readily discovered upon a moderately careful examination.

The *Gigartina acicularis*, Lam., belongs, like the *Fucus crispus*, to the order of Algæ, sub-order Choristosporeæ. It is distinguished from the latter by its cylindrical, cartilaginous, subdichotomous, flexuous fronds, with acuminate most frequently bifurcated branches, sending out lateral horizontal spiniform branchlets. The conceptacles are spherical, sessile, and thin. The mixture is also manifested by the light brown tint retained by the pedicels, which gives to the mass an appearance of a less uniform colour than that presented ordinarily by carrageen.

Placed in contact with cold water, the *Gigartina acicularis* absorbs it rapidly and in great quantity, and swells considerably. Treated with boiling water it dissolves, but in much less proportion than *Fucus crispus;* the jelly which it yields upon cooling is opaque, whitish, and without consistence. 100 parts of this alga leaves upon calcination 16 parts of a residue which retains the form of the plant. This ash dissolves partly in water. The solution is neutral; it is precipitated slightly by nitrate of silver, and abundantly by nitrate of baryta and oxalate of ammonia. The solution evaporated, and redissolved in alcohol and water gives, with phosphate of ammonia, a crystalline precipitate. The insoluble part of the residue consists of carbonate of lime and silica. Operating as above the following results were obtained:—

Chlorides of Sodium and Magnesium	0·60
Sulphate of Magnesia	1·20
Sulphate of Lime	6·60
Carbonate of Lime	5·40
Silica	2·20
	16·00

Calcination with potash and testing with an acid and starch showed no trace of the presence of iodine.

Practically the mixture of *Gigartina acicularis* with carrageen moss presents no advantage to the pharmacist, who would not obtain with this product a jelly presenting the consistence sought for in the preparation of jellies from carrageen. But the author considers that the remarkable quantity of lime salts which the *Gigartina* contains would render it a fairly active medicament in many cases, and especially in phlegmasies of the intestinal canal.

THE LESSER CENTAURY.

According to the *Journal Officiel d'Algérie*, an extraordinary quantity of the lesser centaury, *Erythrea Centaurium*, Pers., was sent from Algeria into France during the year that has just closed. Its Arab name is *Meurr el haneeh* ("the serpent's bitter"); Spanish, *El feld de tierra;* German, *Das gemeintausend Gatdenkraut.*

The plant is common in three provinces of Algeria. Europeans and natives collect it for their own use and for exportation; the tops being employed for making an infusion, 10 to 30 grams in 500 grams of water. It flowers from March to May, as also does its yellow flowered congener *Erythrea maritima*, Fries.; *E. ramosissima*, Pers.,* or *E. pulchella*, Fries., flowers from May to July, and *E. Spicata*, Pers., which grows in marshy lands, from June to August. In France the *E. Centaurium* enters into the composition of "banme vulneraire," "esprit carminatif de Sylvius," "thériaque," etc. It belongs to the Gentianaceæ and presents two varieties, which are considered by some botanists to be two species, the *E. major*, Link., and *E. latifolia*, Smith. It is called the lesser centaury because it is bitter, tonic and febrifuge, like the great centaury (*Centaurea Centaurium*, Linn.), which belongs to the Compositæ, and of which the root is used.

Two other gentians are found in Algeria, the *Chlora grandiflora*, Viv., considered by many botanists to be merely a variety of *C. perfoliata*, Linn., and the tiny *Exœum filiforme*, Wild, found in the marshes in the spring time. The *Chlora* is worthy of being cultivated in gardens because of its large yellow flowers, the same flower opens in the morning and closes in the evening, during at least a fortnight. Its Arab name is *tadger*.

ESTIMATION OF ACONITINE IN DIFFERENT ACONITES.†

BY O. ZINOFFSKY.

The estimation was effected by means of a solution of iodide of mercury in iodide of potassium:—

From 100 parts of	A. stoerkeanum.	A. napellus.	A. variegatum.
Fresh leaves, before the opening of the flowers	0·1699	0·1776	0·1670
Fresh stalks, before the opening of the flowers	0·1166	0·1236	0·1009
Fresh flowers, before expanding	0·3418	0·4350	0·4350
Fresh leaves, when the flowers are fully expanded	0·2710		
Fresh stalks, when the flowers are fully expanded	0·2770		
Fresh flowers, expanded	0·7294		

These numbers show that the flowers are always richer in alkaloids than the leaves and stalks.

* The "Muli Ali's Flower" mentioned by Dr. Leared in his list of Morocco Drugs (PHARM. JOURN. [3] iii. 622), as being used in dyspepsia belongs to the species.—ED. PH. J.

† *Journ. de Pharm. et de Chemie*, Jan. 1874, p. 82, from Wittstein's 'Vierteljahresschrift.'

The Pharmaceutical Journal.

SATURDAY, JANUARY 31, 1874.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square,*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

OUR EVENING MEETINGS.

QUITE in the infancy of the Pharmaceutical Society, almost before it had even gained sufficient coherence strictly to entitle it to such a name, it was contemplated, as one of the means by which sound pharmaceutical information could be diffused throughout the country, to hold periodical meetings, when papers recording the results of original research in the sciences related to pharmacy might be read and discussed. With the men who then were working so heartily for the good of pharmacists the conception of a plan was rapidly followed by an attempt to put it into execution. Thus it was that although through the "incomplete state of the infant Society, and in "the absence of the requisite accommodation, these "scientific meetings could not be established on a "scale which would be creditable to a public institu-"tion," a pharmaceutical meeting was held at 338, Oxford Street, on the 11th May, 1841, at which a paper was read, and to which medical men, as well as chemists and druggists, were invited. Other meetings were then announced, and a hope was expressed that in process of time meetings of this description would be officially instituted by the Pharmaceutical Society, and that papers would be furnished containing materials for a Journal of Pharmacy. The hope was fulfilled, and on the 12th of January of the following year the first pharmaceutical meeting was held in the new premises just then taken by the Society in Bloomsbury Square, when, after an address from the President, Mr. ALLEN, papers were read by Mr. SQUIRE, and Mr. (now Dr.) REDWOOD. How the Society has developed since that time is well-known; but the Pharmaceutical Meetings have not grown with its growth and strengthened with its strength. In early days, when papers bearing the names of such men as THOMSON, MORSON, DEANE, BELL, SQUIRE, REDWOOD, GARROD, GUIBOURT, PEREIRA, FOWNES, and many others, were forthcoming, it was thought necessary on one occasion to point out that these meetings were not the primary attraction which the Society offered to the pharmacist; but we fear that such a remark would be sadly out of place now.

It is in the remembrance of what has been, and the knowledge of the fact that up to the time of writing no paper has been received for the Pharmaceutical Meeting next Wednesday, that we find an excuse for calling attention to this subject; should the result be that steps are taken towards raising these meetings to the position that we conceive they ought to occupy, our object will have been accomplished.

What then are the causes that have led to such a result as that,—for the second time this session, and this time, after an interval of two months,—there is a difficulty in announcing the subjects for discussion before the time of meeting? Some of these appear to be unavoidable, but others we think might be controlled. There is the fact that a constant gleaning is going on for supplying the columns of this and similar journals; there are also now the competing claims of numerous provincial associations for papers that might otherwise have found their way to Bloomsbury Square; and further there is the holocaust of pharmaceutical research offered annually at the meeting of the Conference. All this must be admitted, but should not be deplored, since there must be ample material left to occupy the five evenings a year allotted to these meetings, and material, too, that probably would not be utilized in any other way.

With regard to the question as to the best means of increasing the interest of these meetings, since we write rather in ignorance of what has been done by those to whom this business is entrusted, anything we say must take the form of suggestions. And first, could not more assistance be obtained from the members of the medical profession, whose interest in the progress of scientific pharmacy nearly if not quite equals that of the pharmacist, and who must frequently have questions pertaining to the preparation of medicines pressed upon their notice, which they would like to refer to pharmacists to consider? If it were more generally understood that the Pharmaceutical Society would welcome such communications at these evening meetings, would papers like that of Dr. DYCE DUCKWORTH be such *rare aves in terra?*

Again, as respects internal assistance, passing by the question whether there might not be more frequent contributions from the representative men of the Society—the members of Council, professors, and examiners—might not the subject-matter for a very profitable evening be sometimes provided in the report of a committee appointed to consider a particular subject? The Paris Society frequently refers in this manner a subject brought forward by one of its members; the report on commercial "propylamine" was a valuable contribution towards clearing up the confusion which existed respecting that article, and another committee is now engaged in preparing a report on the various methods of estimating the alkaloidal value of cinchona barks.

Lastly, we would ask the question, how often the bye-law is complied with which states that "all communications intended to be made at such meetings shall be submitted to the President, or, in his absence, to the Vice-President, or to the Chairman of the meeting, for his sanction, and without

such sanction no subject shall be introduced ?" From an apparent neglect of this bye-law on various occasions, the earlier part of the time of the meeting has been occupied by the introduction of unexpected subjects, and the reading of announced papers has either been deferred or taken place at so late an hour as to preclude their proper consideration, to the disappointment of the authors and of those who came to take part in the discussion. Here, again, the example of our *confrères* across the Channel might be profitably copied. A few days since, a discussion having arisen in the Paris Society upon the education of apprentices, MM. Bussy and Bourgoin made a vigorous protest, and succeeded in maintaining the priority of scientific papers of which notice had been given.

We have thus thrown out a few hints upon the subject, but many others might suggest themselves if the matter were fully considered; our main object now is to attract the necessary attention to secure that, even if too late this session, another shall not commence without an effort to put our Evening Meetings upon a more satisfactory footing.

Since the foregoing was written we have received an intimation that at the Evening Meeting on Wednesday next a "Note on Iodide of Iron," by Mr. W. Murton Holmes, will be read. We hope that other papers will also be forthcoming, but this detracts in no degree from the opinion we have expressed above. The chair will be taken at half-past eight o'clock precisely.

PUBLIC ANALYSTS.

In commenting on a recent case (see p. 626) of prosecution under the Adulteration Act which resulted in a dismissal of the summons, and even induced the magistrate to abstain from inflicting penalties in some other similar cases, the *Medical Press and Circular* offers the following remarks:—

"Such instances are not, unfortunately, rare, and the question naturally arises why are persons appointed to such posts who are either incapable of detecting adulteration, or so careless in the discharge of their duty as to substitute mere guess-work for careful investigation. With the utmost charity let us allow possible excuses for mistakes from over anxiety to carry out the strict letter of the law, etc.; but when gentlemen become candidates and are appointed to positions of such public trust and confidence, armed with powers for the protection of the masses, second in importance, perhaps, to none in the State, and these in their individual capacities state upon oath that the milk examined in one case had been largely adulterated with water, which afterwards was proved to contain no added water, and another vouches that the loaf he examined contained 45 grains of alum, which in reality contained not a trace—when, we say, such things happen, we have no capacity for excuses, but feel that we must face the matter boldly for the sake of our profession, and in defence of an Act which is capable of so vast an amount of good, but which is in danger of being held up to public contempt by its faulty administration. We should consider ourselves as betraying our trust, and culpable of a gross dereliction of duty, did we, from interested motives, or from fear of giving offence, hesitate to draw attention to such an anomaly. It comes to this, the appointment of public analysts will have to be confided to the Government, or to some duly qualified corporate body competent to examine candidates so as to ensure the proper working of the Act, and the protection of the public against unfounded charges. Let us not be misunderstood in advocating a change in the system of appointments; we do not for an instant mean to infer that any looseness or irregularity in the present mode of election has resulted in the return of incompetent or negligent persons; on the contrary, we fully believe that local authorities have impartially and disinterestedly elected those whom in their opinion were best qualified to fill the office. Still, local boards are not expected to understand chemistry, and the result has also gone far to prove that medical men are not all chemists—not all qualified to occupy the posts obtained. Another question also presents itself as to how far the subjects embraced in the medical curriculum are calculated to fit members of the profession for the post of medical officer of health. Does State medicine receive that amount of attention its importance demands? This part of the subject, however, we must defer to a more suitable opportunity, our present purpose being simply to draw the attention of the proper authorities to anomalies which must be at once seen to. If we succeed in this both the profession and the public will be gainers."

The opinions here expressed are very much in accord with those we have at various times put forward in regard to the subject, and we are glad to find that a medical journal has not only recognized the fact that medical officers of health are not as a rule qualified to perform the duties of public analyst but has also had the courage to make this view of the matter public. We trust that something will ere long be done to save the working of the Adulteration Act from the disgrace into which it appears to be rapidly falling.

EVASION OF THE ADULTERATION ACT.

We learn from a local paper that Dr. Barclay, of Chelsea, in alluding to some of the difficulties that are met with in carrying out the Adulteration Act, mentions the case of a milkman, who, when asked for some milk by the inspector, deliberately emptied the contents of his can into the gutter.

SMUGGLED LEECHES.

Morocco furnishes a curious instance of smuggling in the article of leeches, which are shipped from Tangiers principally to Cadiz, and thence to South America and Havana. Although the trade returns would apparently indicate a considerable diminution in this industry—the numbers quoted as exported having fallen from 4,960,000 in 1867, to 335,000 in 1872—yet it is asserted that in reality as much business is done now in leeches as in former years, but there is much reason to suspect that great numbers are shipped in contraband.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

January 21st, 22nd, and 23rd, 1874.

Present (21st and 22nd)—Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Cracknell, Davenport, Gale, Hills, Linford, Martindale, Schweitzer, Southall, Taylor, and Umney.

23rd.—Messrs. Allchin, Benger, Carteighe, Corder, Davenport, Gale, Hills, Linford, Martindale, Schweitzer, Southall, Taylor, and Umney.

Dr. Greenhow was present on the 21st, on behalf of the Privy Council.

MAJOR EXAMINATION.

Six candidates presented themselves. *Two* failed. The following *four* passed, and were declared qualified to be registered as Pharmaceutical Chemists :—

*Druce, George Claridge.....Northampton.
Edwards, Charles .....London.
Fox, Charles Edward .....London.
Williams, William Francis .....London.

MINOR EXAMINATION.

Fifty-six candidates presented themselves. *Forty-one* failed. The following *fifteen* passed, and were declared qualified to be registered as Chemists and Druggists :—

*Wood, Alfred .....Sheffield.
Equal. Gresswell, Arthur.....Spalding.
Equal. Rippon, Edwin .....Stamford.
Cheetham, George Richard.....Bradford.
Equal. Polley, John .....Chester.
Equal. Warren, Francis William .....Weston-super-Mare.
Equal. Owen, Samuel .....Leominster.
Equal. Twemlow, Francis Ernest .....London.
Stephan, William Henry.....Chipping Norton.
Hoyles, George .....Lincoln.
Pritchard, Owen .....Bangor.
Barlow, Frederick.....Birmingham.
Roberts, Richard Pritchard.....Bangor.
Colley, Walter ....Birmingham.
Gooseman, John Brocklesby ...Grimsby.

The above names are arranged in order of merit.

PRELIMINARY EXAMINATION.

The undermentioned certificate was received in lieu of this examination :—

Certificate of the University of Cambridge.

Mawson, Thomas Oliver .....Sheffield.

* Passed with Honours.

Provincial Transactions.

LIVERPOOL CHEMISTS ASSOCIATION.

The seventh general meeting of the Liverpool Chemists' Association was held at the Royal Institution, on Thursday evening, January 15th. There was a very large attendance.

The Honorary Secretary announced the following donations :—The current numbers of the PHARMACEUTICAL JOURNAL ; 'Catalogue of the Library of the Pharmaceutical Society, 1873' ; the 'American Chemist' ; the 'Chemists' and Druggists' Diary, 1874,' per Mr. Mason ; a new powder-folder, from Messrs. Lynch and Co., London, per Mr. C. W. Bannister.

The President, Dr. Symes, said that he was glad to see so many present ; he thought it fully showed that they intended to make the second half of the session as profitable a one as the first had been.

Mr. Edward Davies, F.C.S., gave a lecture on "The New Gas," which was listened to with a great deal of interest.

Messrs. Poths and Semple, of London, exhibited some pharmaceutical utensils and certain chemists' sundries, among which were a fine analytical and dispensing balance ; hand-balances, with sliding-weights and dividing-beam, to weigh without weights ; various kinds of hydrometers and thermometers ; and a great variety of horn utensils and card-board boxes, etc.

A vote of thanks to Mr. Davies for his very able lecture, and to Messrs. Poths and Semple, for sending so many new and valuable articles for exhibition, brought the meeting to a close.

MIDLAND COUNTIES CHEMISTS' ASSOCIATION.

On Monday evening, January 19th, the third annual *soirée* of this Association was held at the Assembly Rooms of the Royal Hotel.

A large room adjoining the ball-room was devoted to an exhibition of scientific objects, and the thanks of the Association are due to the President and members of the Council who laboured so successfully in its preparation.

A fine collection of microscopes, with many new and choice objects, under the superintendence of Mr. Jones, was shown by some members of the Microscopical Society, aided by members of the Association.

Messrs. Southalls exhibited a rotatory pill machine, in action, and a large case of very fine chemicals and rare drugs ; while a fine electrical display was made by Messrs. Harris and Co.

Mr. C. Woodward, B.Sc , kindly lent a very ingenious apparatus for effecting the condensation of gaseous ammonia.

The London Stereoscopic Company showed their Jewel Kaleidoscopes ; and an Arithmometer or calculating-machine, of French construction, was kindly lent by Mr. Gilbee, of London ; while the large stereoscopes and graphoscopes lent by Miss Bailey served to entertain the fairer portion of the company.

The rooms were adorned with some very fine photographs lent by the President (Mr. Stirling Grieves), and by Mr. A. Day and Mr. Sunderland.

Early in the evening Mr. A. Cresswell, of the Midland Institute, delivered a semi-scientific lecture, abounding with humour, and exhibiting several chemical experiments from a new point of view.

The ball, which commenced shortly after eight, was kept up with much spirit until two.

The company numbered more than 200, and the Association is again to be congratulated on the success of the annual *soirée*, which we believe will be repeated on a still larger scale next year.

GLASGOW CHEMISTS' AND DRUGGISTS' ASSOCIATION.

The fifth General Meeting of the Glasgow Chemists' and Druggists' Association was held in Anderson's University, on Wednesday 21st January, at 9 p.m. Mr. John Currie, President, in the Chair ; there was a good attendance.

The secretary having read the minutes of previous meeting Mr. Kinninmont said that he had an objection to make against them in so far as they make him say that "every Chemist in the kingdom should do his utmost to get the Adulteration Act repealed ;" what he said, or what he intended to have said was that every one should do his utmost to have the act amended. He by no means objected to the act itself ; what he condemned was the manner in which it was being carried out.

Dr. Thorpe, professor of chemistry Andersonian University, Glasgow, then delivered an able and extemely interesting lecture on "The Life and Works of Thomas Graham." The lecturer gave a brief sketch of the life of Graham, and then explained some of his more interesting and valuable investigations.

The second part of the lecture was profusely illustrated by experiments. On the motion of the chairman a most hearty vote of thanks, was accorded the lecturer.

SHEFFIELD PHARMACEUTICAL STUDENTS' ASSOCIATION.

The first annual meeting of this association was held on Thursday Jan. 22nd, in the Music Hall, Tudor Place, when the president M. E. R. Learoyd addressed the meeting. He spoke of the want which had so long been felt in Sheffield of an association of this kind, of the examinations it was now compulsory for chemists' assistants to undergo, and hoped that members of the association would prove the truth of the old adage "Unitate Fortis" by helping each other to climb, round by round, the ladder of pharmaceutical learning and establish for themselves a status in society. He congratulated the association on the progress it had made during the past year and was very sanguine that the present year would be one of still greater success; two very learned gentlemen having promised to conduct a pharmacopœia class, which it was intended to organize, one of them taking the materia medica, and pharmacy, while the other superintends the practical chemistry.

After a few more remarks from the President and a vote of thanks to him had been passed, the annual report was read and adopted.

A vote of thanks was passed to the Sheffield Pharmaceutical and Chemical Association for their kindness in lending their room, museum, library, microscope, etc., etc.

A vote of thanks was also passed to Messrs. Ellinor and Harrison for their valuable assistance during the past year.

A member moved that the employers of the town should be solicited for shorter hours, as no time was allowed for study. The motion was reserved for future consideration.

The following officers were then elected for 1874:—President—Mr. E. R. Learoyd (re-elected). Committee—Messrs. Harrison, Atkinson, Husbands, and Wright. Librarian and Curator—Mr. G. M. Jones. Treasurer—Mr. W. G. Lancaster (re-elected). Honorary Secretary—Mr. G. B. Owen, junr. (re-elected).

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

Meeting of the Executive Committee.

January 22, 1874.

Present—Messrs. Groves (Chairman), Williams, Ekin, Carteighe, Benger, Umney, Martindale, Hills, Greenish, and Attfield.

The minutes of the previous meeting were read and confirmed.

Date of Meeting, 1874.—Mr. M. Carteighe, Local Secretary of the Conference for the current year, said that after communicating with several influential members residing in London, he had come to the conclusion that it would be desirable to hold the annual meeting of the Conference in May, in the same week as that in which the annual meetings of the Pharmaceutical Society of Great Britain were held. He therefore proposed a motion to that effect, which was seconded by Mr. Williams.

Mr. Martindale thought that the last week in September would be a more convenient time for London members of the Conference.

The Chairman considered that a May meeting would not give sufficient time for the preparation of papers.

Mr. Ekin thought that members not residing in London would prefer that the voice of the metropolitan members should prevail in deciding the question; at the same time he believed that country members would be more likely to attend a meeting at the end of July or the beginning of August.

Professor Attfield said that if the meeting were late in September there would not be time to get the 'Year Book' published in December; while if fixed for so early a date as May, they would scarcely have time to prepare for such an exhibition of pharmaceutical novelties and objects of interest as he hoped would be held this year. The last weeks of July were so occupied by examinations that he feared the rooms kindly offered to the Conference by the Pharmaceutical Society would not then be at disposal. There remained June, which was too near May, and the first week in August.

Mr. Hills had hoped that the meetings of the Pharmaceutical Society and Pharmaceutical Conference would have been held in one week in May. He could see objections to that as well as to other times, and could only again remind the Committee that the Council over which he presided was most anxious to afford every facility for promoting the success of the Conference meetings, whenever held.

Mr. Williams was quite sure that the Council of the Pharmaceutical Society would be especially glad to have such an exhibition as had been mentioned held in their rooms, under the auspices of the Conference. As to the time of meeting, the first week in July was a busy one for London commercial men. He thought that perhaps, circumstances would oblige the Committee to fall back upon the first week in August.

The resolution relating to May was then withdrawn.

Professor Attfield said that as there was but one opinion respecting the desirability of holding a pharmaceutical exhibition at the forthcoming meeting, an opinion so strongly in favour of the project as to materially influence decision as to the time of meeting, he thought that a resolution in favour of holding the exhibition would perhaps produce unanimity on the other question.

It was then proposed by Mr. Benger, seconded by Professor Attfield, "That it is desirable to hold an exhibition of objects of interest to pharmacists in connection with the next annual meeting of the Conference." Carried unanimously.

It was next proposed by Mr. Ekin, seconded by Professor Attfield, "That the Annual Meeting for 1874 be held on Thursday and Friday, August 5th and 6th." Carried unanimously.

Appointment of Editor of the Year Book.—Professor Attfield read applications from eight candidates, also letters from Messrs. Brady, Clayton, Parkinson, Reynolds, Schacht and Sutton, who were unable to be present at the committee, but had sent communications relating to the editorship and the merits of the candidates. After considerable discussion and careful deliberation, the election fell on Mr. Louis Siebold, Lecturer at the School of Pharmacy of the Manchester Chemists' Association.

Bell and Hills Research and Library Fund.—Mr. M. Carteighe proposed and Mr. Umney seconded, a motion authorizing the Treasurer to sell one bond of £50, and to expend the proceeds in aid of research or otherwise, according to the instructions of the Committee. Carried.

Professor Attfield proposed and Mr. Martindale seconded a motion "That £5 be placed at the disposal of Mr. Gerrard, to defray the cost of materials to be employed in a research on the official and other plasters." Carried.

Professor Attfield's Report of Work done since previous meeting.—Grant of Books to Bradford. As a result of instruction from Committee and correspondence with Mr. Rimmington, ten guineas' worth of books had been purchased, bound in calf, and stamped with the Bell and Hill device and duly forwarded to Bradford. In acknowledgment Mr. Rimmington wrote, "At a special meeting of the Chemists' Association of Bradford, it was unanimously resolved that the best thanks of the meeting be given to the Committee of the Pharmaceutical Conference for the very handsome present of books that has been forwarded to the Association."—*Research Fund.* £10 had been forwarded to Mr. Groves to defray expenses incurrred in further researches upon the Aconitines, and £10, voted to Dr. Wright at a previous meeting, would be sent at once to that gentleman now that the sale of a bond had been ordered.—*Assistant Secretary.* Mr. Robert Higgins Davies had been

appointed.—*The Year Book of Pharmacy.* The late date of the last annual meeting, and the sudden departure of the Editor for India, had caused, ten days' delay in the publication of the 'Year Book.' The volume had however been issued on the 6th of January and, before the 22nd, a copy sent to every member who had paid the annual subscription. The steps taken for the printing of the Editor's manuscript in his absence were also described.—*Circular respecting Unusual Doses.* Professor Attfield had communicated with the officers of the Conference and with Mr. Hampson on this subject, and the resolutions of the Conference, preceded by an introductory letter, had been printed in the form of a circular, nearly five hundred copies of which had been posted to the leading physicians of England, Scotland, and Ireland. Although no answer to the circular was requested, several letters commendatory of the course adopted by the Conference had been received. The medical and pharmaceutical press generally had also given favourable notices of the matter. Further, written copies of the circular-letter, signed by the President of the Conference, had been sent to the Presidents of the General Medical Council and Colleges of Physicians of London, Edinburgh, and Ireland, accompanied in each case by a short private note from the President of the Conference. From the English College the following reply has been received:—

"December, 11th, 1873.

"Sir,—I am directed by the president to acknowledge the receipt of your letter in reference to the recommendations passed at the Pharmaceutical Conference, and to inform you that the subject will be brought before the College at the earliest convenient opportunity.

"I have the honour to be, Sir,

"Your obedient Servant,

"HENRY N. PITMAN,

"*Registrar.*

"The President of the Pharmaceutical Conference."

—*Receipt of Subscriptions.* Up to the date of the last committee meeting (Sept. 17th), 700 subscriptions had come to hand as then reported; between that date and December 1st, 260 had reached the Professor. In reply to a request for the subscription, sent to nearly 1,000 members, 340 money orders had been received. Altogether, about 1,300 subscriptions had been paid, leaving more than 600 still due. In the course of a month or six weeks another application for the amount would be issued, accompanied by the statement that on receipt of the sum the volume would be forwarded by return of post.

Some discussion ensued on the question of filling up the vacancy on the Committee caused by the appointment of Mr. Siebold as Editor of the Year Book. It was recommended that no action on the subject should be taken until the next Annual Meeting.

The following gentlemen were unanimously elected members of the Conference:—Archer, Albert (Ridgeway), Ainslie, W. (Edinburgh), Biddiscombe, C. (London), Binnie, R. (Dumbarton), David, James (Bath), Davies, R. H. (London), Flower, J. J. (London), Galwey, R. J. (Dublin), Haslett, John (Belfast), Linay, Thos. (London), Jackson, Dr. H. W. (Sydney), Jones, John (Llanwrst), Skirrow, W. E. (Bingley), Thibon, Denis (Nice), Williams, W. J. (London), Wyley, J. (Coventry).

MEDICAL SOCIETY OF THE COLLEGE OF PHYSICIANS, DUBLIN.

At the meeting of the above Society on Wednesday, December 10, 1873, Sir Dominic Corrigan, Bart, M.P., M.D., in the chair, the following paper was read:—

THERAPEUTICAL REMEDIES RECENTLY INTRODUCED.*

BY WALTER GEORGE SMITH, M.D.

Of the new drugs which have been introduced into medical practice within the last few years, it is remarkable how large a share has been contributed by organic chemistry, and it is worthy of note that several of them, although well known to professional chemists, remained for years objects of purely technical interest before there was any thought of investigating their physiological or therapeutical qualities. Having this origin, and carrying with them into medicine their strictly chemical titles, it is not surprising that the nomenclature of some of them, although really simple, should appear perplexing to those who have not kept abreast with modern chemistry. Some of them, moreover, are rare and of difficult production, and hence are so costly that, for the present, however valuable they promise to be, they scarcely come within the pale of general practice.

In the hope, therefore, that the exhibition of the more important of the new remedies and physiologically active agents might prove of interest to the members of this Society, I have ventured to bring them down this evening; and, without any pretensions to reading a paper, I will pass them briefly in review, and will point out their salient properties in a necessarily cursory way.

On glancing over the list of names, I find that they can be arranged appropriately under three heads:—

I. *Alkaloids and active principles;* guarana, methyl-strychnia, emetia, apomorphia, ergotin.

II. *Hydrocarbides and their derivatives:* xylol, bromoform, iodoform.

III. *Alcoholic compounds:* nitrite of amyl, bromal, chloral, croton-chloral, propylamine (so-called).

I.—*Guarana.*—This drug is an example of an old remedy re-introduced, for it was first noticed as far back as 1817. In connection with its medicinal action, it is worth remembering that its active principle, the so-called *guarania*, is identical with the well-known caffeine or theine, a base which occurs also in Paraguay tea (Maté) and in the kola-nut of West Central Africa. Guarana is practically nothing but a convenient channel for the administration of impure caffeine. Curiously, the five genera in which caffeine is known to exist belong each to a different natural order.

Methyl Strychnia.—This remarkable body, $C_{21}H_{22}N_2O_2$ CH_3, HO is not only interesting in itself, and as a specimen of a now numerous class of organic substances, but is more especially noticeable as an illustration of a recent and novel method of inquiry, which can scarcely fail to bear important fruit. I refer to the study of the connection between chemical *constitution* and physiological action—a subject which has been so successfully prosecuted by various observers, notably by Crum Brown and Fraser, in Scotland; and by Pelissard, Jolyet, and Cahours, in France.

Brown and Fraser have shown that the *addition* of various organic radicals, *e.g.*, methyl and ethyl, to the molecule of some highly active bodies, such as the alkaloids, without destroying or altering the chemical integrity of the body, effects most extensive and unexpected changes in their physiological action. Iodide of methyl is inert in itself. For example, this very body, the hydrate of methyl-strychnium, produces a condition exactly the reverse of that produced by strychnia, and, in fact, instead of causing muscular spasms, due to increase of reflex excitability of the cord, it actually paralyses the peripheral terminations of the motor nerves, and it has accordingly been suggested as an antidote to strychnia poisoning. 0·1 gr. of hydrochlorate of strychnia caused death in a rabbit in half an hour, while 30 grs. of iodide of methyl-strychnium (containing 21·1 grs. of strychnia), previously administered to the same rabbit, produced no effect whatever. In other words, more than 200 times the amount of strychnia can be administered with impunity in the form of the ammonium base than as any of the ordinary salts of this alkaloid. The ammonium bases of brucia, thebaia, codeia, morphia, nicotia, and atropia, have also been examined with the like startling results.

In the case of atropia, the poisonous activity of the

* From the *Dublin Journal of Medical Science* for January, 1874.

base, instead of being so enormously diminished, is considerably increased, so that we cannot formulate any law as to quantitative alteration of toxic energy. Interesting as these researches are, too extreme importance should not be attached to them, and they throw little light upon the question of the respective actions of the different alkaloids.

Emetia.—This substance is noticed in conjunction with the next, apomorphia, because they are the only two bodies which can be fitly employed subcutaneously as emetics. As in the case of ergot, we should distinguish pure emetia, *i.e.*, the alkaloid, 15*s.* per ℥j., from the preparation sold in France under the name of "coloured emetin," which is nothing but a brown extract, and is 12*s.* per ounce. Pure emetia is at least three times as strong as the impure, and is recommended as a safe, rapid, easy, convenient, and agreeable form of emetic. The dose by the mouth is from $\frac{1}{18}$–$\frac{1}{6}$ gr., and subcutaneously, about $\frac{1}{30}$ gr. (1 in 30 water, with a little sulphuric acid). Its solubility in water is 1 in 1,000. Its salts are uncrystallizable, and are very soluble in water.

Apomorphia.—The alkaloids are steadily and deservedly gaining confidence every day, and atropia, morphia, strychnia, quinia, etc., are counted our most trusty remedies. But hitherto we have been restricted to bases derived directly from the plant, and apomorphia is the first example of an alkaloid introduced into medicine which has been derived by decomposition from a pre-existing and well-known alkaloid, *i.e.*, it is a product, and not an educt.

The ordinary emetics are usually bulky in dose, uncertain in action, and are apt to produce depressing nausea and prostration, and apomorphia opportunely presents itself as a convenient and unirritating emetic, the one of all others which acts most speedily, and with least trouble to the patient. It is prepared by heating morphia for two or three hours with excess of hydrochloric acid; or, similarly from codeia, which is methyl-morphia. The free base is unstable, and, originally white, turns green immediately on exposure to air. The hydrochlorate is more permanent, but even its watery solution begins to alter in a few minutes, and rapidly passes from an aquamarine tint to an emerald green colour, and ultimately becomes opaque. The physiological effects of the coloured solution are said to be similar to those of the recent solution, but it is less powerful, and is more irritating to the skin. $\frac{1}{30}$–$\frac{1}{20}$ gr. is a suitable dose for hypodermic injection. A solution of 1 gr. in 200 minims of water is a convenient formula. Occasionally giddiness, cerebral oppression, and præcordial anxiety have followed its use.

Apomorphia offers special advantages in dealing with refractory children, insane people, or with adults in some kinds of poisoning, when coma or delirium hinder oral administration. The only drawback is its costliness, and at present ℥i. costs £1, *i.e.*, 4d. a grain.

In illustration of its effects I will mention two cases in which I have employed it. Some time since I injected $\frac{1}{30}$ gr. of apomorphia from a green solution into the arm of a woman at the Adelaide Hospital. In 10 minutes the stomach turned without causing her pain or distress. On December 6th I injected $\frac{1}{20}$ gr. of apomorphia from a fresh solution into the arm of a patient suffering from spasm of the œsophagus, an affection to which he has been occasionally liable since an attack of cholera in 1867. He was of a peculiarly placid and unexcitable temperament. Five minutes after the injection the pulse had risen from 70 to 104, and he complained of a sensation of heat in the head and of nausea, which rapidly increased. In 10 minutes he was inclined to be sick, but could eject nothing, and there was a sudden call to stool. The bowels were moved a second time in 5 minutes more; motions thin, copious, and very offensive. After the expiration of 20 minutes the pulse had fallen to 56; he was sleepy, pale, and felt and looked much prostrated. Within 2 hours he had completely recovered. No effect was produced on the œsophageal spasm, which was absolute and complete for a period of 122 hours, when the "stomach opened" after a long continuance of retching, and he was able to swallow some food.

Apomorphia is a striking instance of the assistance which scientific chemistry may, and does, lend to therapeutics, and it establishes another link between chemistry and medicine. Moreover, it evinces the radical alteration produced in the physiological action of a substance by instituting an *apparently* slight change in its molecular constitution. In this particular case, the withdrawal of a molecule of water causes such a rearrangement of the atoms that we obtain new and unlooked for results, for apomorphia, $C_{17}H_{17}NO_2$=morphia, $C_{17}H_{19}NO_3$, minus water, H_2O.

Ergotin.—No better example than this can be brought forward of the confusion which results from the same name being applied to several distinct substances, or from a definite term being affixed to a body of unknown or uncertain composition. There are no less than 3 totally distinct substances included under the common designation *ergotin*, viz.: Wiggers' ergotin (1831), Bonjean's ergotin (1840), and Wenzell's ergotin (1864).

1. *Wiggers' ergotin* is prepared by acting upon the spirituous extract of ergot, previously freed from fat with water, whereby the reddish-brown powder is left behind. It has a bitter taste, and is insoluble in water and ether, and difficultly soluble in spirit. Like Bonjean's preparation, it is an impure substance. In doses of from 3-7 grs. it gives rise to a nauseous bitter taste, followed by a confused feeling in the head, running on to headache, dilatation of the pupils, fall in the pulse, and abdominal pain; 7 grs. caused further a sensation of dryness in the throat, lasting for several hours. It costs 5*s.* per drachm.

2. *Bonjean's ergotin.*—Prepared by exhausting the watery extract of ergot with spirit of wine, and evaporating the spirituous solution. It is a brownish-red extract, with a peculiar odour of roast meat, and a sharply bitter taste. It is completely soluble in water and spirit, and is evidently a complex product. Its action appears to be similar to that of Wiggers' ergotin. Cost, 1*s.* 6*d.* per ounce.

3. *Wenzell's ergotin.*—According to Wenzell, ergot contains two alkaloids, ecboline and ergotine, which can each be obtained as an amorphous, brown, feebly bitter powder, easily soluble in water and spirit, insoluble in ether and chloroform. The property of exciting contraction of the uterus is stated to reside in the ecboline, but this statement needs confirmation. These bases seem to rest upon a slender foundation, their relations to Wiggers' and Bonjean's ergotins is not determined, and, in short, as matters stand at present, it is impossible to give a satisfactory answer to the question—what is the active principle of ergot?

II.—Of the second group little need be said—further than to point to the specimens on the table.

Xylol.—Had a very short-lived run in the treatment of small-pox, in which it was administered in capsules, in doses of 10–15 m. It belongs to the small but important group of bodies known in chemistry as the aromatic hydrocarbides, from the agreeable odour of some of their compounds, *e.g.*, essence of bitter almonds. The first term of this homologous series is the familiar benzine or benzol, C_6H_6, and above this are five higher terms, the third of which is xylene or xylol, C_8H_{10}.

Its name is derived from ξύλον—wood, because it was first found among the oils which are separated from crude wood spirit by the action of water.

When we consider the importance of the group of hydrocarbides to organic chemistry, and call to mind that they are hundreds in number, exist in every variety of form, and with every variety of properties, thus constituting in themselves a compact and symmetrical range of series, mutually connected by simple laws, it seems strange how little medicine has borrowed from them, for, with the exception of the terebene series, including oil of turpen-

tine, and its numerous isomers, oil of juniper, oil of lemon, etc., it has not yielded much to the stores of therapeutics.

Chloroform, $CHCl_3$.—*Bromoform*, $CHBr_3$.—*Iodoform*, CHI_3.

These three bodies afford additional confirmation, were that needed, of the remarkable gradation of properties which exists between their halogen parents, Cl, Br, and I, and which extends throughout the majority of their combinations.

Thus Cl is a greenish-yellow gas.
Br is a red liquid.
I is a dark solid.

So we have—

$CHCl_3$—a colourless liquid.
$CHBr_3$—a reddish liquid.
CHI_3—a sulphur-yellow solid.

Bromoform is less volatile than chloroform, more easily decomposed by alkalies, and appears to enjoy much the same properties as iodoform, but it is irritant, and does not appear likely to fulfil any useful indications in practice.

They are all prepared in an analogous manner. *Iodoform* contains 90 per cent. of iodine, and yet its taste is mild and non-corrosive. It is not new, for it was discovered in 1823, and has been long in use on the Continent. There is much evidence in its favour, and from its non-irritating action, ready absorption, and peculiar anæsthetic effect locally, it seems surprising that it has not come into more general use. Dose, ½-1 gr.

III.—*Alcoholic compounds—Nitrite of Amyl.*—This liquid is the second example only of an organic nitrite being utilized in medicine, the other being nitrite of ethyl—the essential constituent of the old and well-known "sweet spirit of nitre." *Nitrate* of ethyl or *nitric* ether proper, is a heavier liquid than nitrite of ethyl, and does not appear well-adapted for practice on account of its irritating tendency.

This amylic nitrous ether was discovered by Balard in 1844, more fully investigated by Guthrie, in 1859, and again more thoroughly still by B. W. Richardson in 1863-64. We cannot doubt that we have here an agent of at least very remarkable and energetic powers, while it is noticeable that the morbid conditions in which the drug has been found serviceable were pointed out before it was used in practice. As a powerful and rapid modifier of the action of the heart, and as an extraordinarily active means of relaxing arterial tension, it stands alone; and with too scanty experience to pronounce positively on its precise powers for good or evil, we cannot mistake the prompt and effectual relief which it has in several cases given to the agony of angina pectoris and the paroxysms of spasmodic asthma. No doubt some serious consequences, such as troublesome headache and alarming prostration, have occurred after its use, but we should remember that much of the amyl nitrite, as sold, is very impure, and, in addition to not inconsiderable quantities of prussic acid, is liable to contain other organic compounds, *e.g.*, aldehyd and ethyl-amylic ether, which must interfere with its proper action. Unlike nitrite of ethyl, it does not appear to suffer decomposition by keeping.

Bromal, Chloral, Croton-Chloral.—Of these three bodies I may say, in brief, that ordinary or ethylic-chloral has secured for itself a firm position in medical practice; bromal offers little promise of utility; and croton-chloral is just entering upon its trial. They are all strictly analogous bodies, and are respectively the bromine or chlorine derivatives of aldehyds. Bromal is brominated ethylic (common) aldehyd; chloral is chlorinated aldehyd; and croton-chloral is a chlorinated derivative of crotonic aldehyd, *i.e.*, of the aldehyd, of crotonic acid, a constituent of croton-oil.

Bromal is prepared in a manner similar to that used for chloral, viz., by the action of bromine on alcohol. It is a colourless, oily liquid, sp. gr. 3·34, boiling above 212°, and, like chloral, forming with water a solid definite hydrate. It was discovered by Löwig in 1832. The hydrate $=C_2HBr_3O, 2H_2O$ (Watts). When administered to the lower animals (frogs, rabbits, and guinea-pigs) in doses of from 2–15 grs., the principal symptoms produced are irritation of the air passages, restlessness followed by imperfect sleep, and anæsthesia, and finally dyspnœa and death, either with or without convulsions. It has been given to man in a few cases of disease, viz., epilepsy, tabes dorsalis, and aortic valve disease, in doses of ½–1½ gr. and upwards. It is soluble in 6 parts of water. It is evidently possessed of considerable activity, for 1 gr. has, in the human subject, produced unpleasant results, and 4 grs. have caused great depression and severe pains in the stomach. It seems unlikely to prove useful either as a hypnotic or as an anæsthetic. It is too irritant, and does not appear to offer any advantages as a therapeutic means over other safer and speedier remedies. It is stated to be barely supportable in an emulsion containing 1 in 300.

Chloral.—Of this now so familiar drug I would only say that it, as well as bromal, supplies us with a fresh warning to take heed not to push chemical analogies too far when dealing with the phenomena of life, and we shall only be led astray by regarding the stomach as a warm test-tube, in which the chemist can work out his problems as unerringly as in the laboratory. Because chloral is decomposed by strong alkalies, or their carbonates, in accordance with a well-known reaction, into chloroform and formiate of the base, the specious theory was promulgated that the action of chloral was thus simply explained, and that it, in fact, was nothing else than the action of nascent chloroform gradually evolved within the system.

Although this theory has met with, and still finds, general favour, it has, in my opinion, no valid support, and cogent chemical and physiological arguments can be arrayed against it. I think it should be held that chloral exercises a specific action of its own upon the organism, which is not to be reasoned out from an exclusively chemical basis.

It is interesting to recall that the discovery of chloral preceded that of chloroform, for it was in 1832, while studying chloral, which he had just discovered, that Liebig for the first time met with chloroform.

Other varieties of chloral, *e.g.*, amylic and propionic, are known to chemists, and probably an indefinite number of chlorals could be obtained by suitable means. Liebreich, the introducer of ordinary chloral, has suggested a new chloral, which is possessed of some remarkable properties. To distinguish it from its predecessor, it is termed *croton*-chloral, *i.e.*, the chloral of the crotonic series. Dr. Hofmann found that some of the German chloral contained more or less of crotonic chloral, and its origin is accounted for in this way:—

The alcohol from which ordinary chloral is made in Berlin, by the action of dry chlorine on absolute alcohol, is purified by passing it over charcoal. Hence, by oxidation, some ethylic aldehyd is formed. This, when acted upon by the hydrochloric acid liberated in the reaction, suffers dehydration, and yields crotonic aldehyd $-2C_2H_4O - H_2O = C_4H_6O$; and this new aldehyd, acted upon by the chlorine gas, furnishes the new chloral, $C_4H_3Cl_3O$.

Most agents which act upon the nervous system affect it generally, or at least, engage in their sphere of action several important tracts. At the same time we possess some active drugs, which exhibit a remarkable determination to particular areas, *e.g.*, conium, curare, etc., and in this new compound, croton-chloral, we meet with a body which exerts a specialized and singular action upon a very limited nervous region.

When administered to animals it produces, first, anæsthesia of the head, then loss of reflex movements throughout the body, and finally death by paralysis of the medulla oblongata. In man, however, when given in small doses it produces anæsthesia of the fifth nerve, and of that alone, while the sensibility of the body generally, and the pulse and respiration remain unaffected. This singling out of an individual nerve will, if confirmed, stand alone, and is a curious and suggestive phenomenon.

Hydrate of croton-chloral closely resembles in appearance the ordinary chloral. It may be prepared by passing chlorine gas into allylene, or by acting upon dichlorallyl and formic acid with alkalies.

Propylamine (so-called).—This, the last subject upon which I will offer any remarks, has given rise to some discussion and to much confusion in the medical journals, but it may be disposed of in a few words. The principal points which I would urge are the importance of precise nomenclature, especially in organic chemistry, and the necessity of discriminating clearly between isomeric compounds, or, in other words, not to mistake identity of *composition* for similarity of *constitution*. So far back as 1817 it was announced that the fœtid odour of *Chenopodium vulvaria*, a British plant, commonly known as stinking goosefoot, was due to the presence of a volatile ammoniacal compound ready formed—the first example of a free alkali in the vegetable kingdom. More than thirty years subsequently (1851) it was shown that the same volatile base existed in many other plants, and in various animals (maybug), its most abundant source being herring brine, and it was at first identified with the chemical compound propylamine, *i.e.*, propyl-ammonia. For years this was generally accepted, and the drug was introduced into medicine under that name by Dr. Awenarius, of St. Petersburg, in the treatment of rheumatism more especially. Even in the last edition (1865) of Guibert's excellent History of "New Remedies," this substance is treated of under the erroneous title of propylamine. But it has been known for some years (1862) that true propylamine has a different origin, and exhibits widely different properties, and it has been proved that the so-called propylamine of commerce, obtained from cod-liver oil, herring brine, ergot, etc., is in reality trimethylamine, with which it is isomeric.

The ultimate composition of these bodies is C_3H_9N, but, of course, this formula in itself teaches us little, and we now know that there are at least three different bodies which own this empirical formula, and yet are totally distinct from each other. These bodies are—

$$\left.\begin{matrix} C_3H_7' \\ H \\ H \end{matrix}\right\} N\text{—A primary amine} = \text{true propylamine.}^*$$

$$\left.\begin{matrix} CH_3' \\ C_2H_5' \\ H \end{matrix}\right\} N\text{—A secondary amine} = \text{methyl-ethyl-amine, and,}$$

$$\left.\begin{matrix} CH_3' \\ CH_3' \\ CH_3' \end{matrix}\right\} N\text{—A tertiary amine} = \text{trimethylamine.}$$

We should remember, then, that as yet there is no such thing as real propylamine used in medicine, and what is styled so is undoubtedly trimethylamine.

The boiling-point alone will distinguish trimethylamine from propylamine, for the former boils at 40° F., and the latter at 121°. The dose of trimethylamine is 20 m. and upwards. It may be said what is the use of this dissection of formulæ, this contention about names—let chemists fight their own battles. To this I would answer, not only is the confusion of names mischievous, but the properties of these bodies are different one from another, and plainly all accurate knowledge is at an end unless names be used in their true signification. It is only because of their comparative novelty, and of the partial resemblance between propylamine and trimethylamine, that these two liquids have been confounded. Morphia and piperia are isomeric—their empirical formulæ are identical—yet no one dreams of confusing these two bases, for they are too widely apart in their origin and properties. In reference to the class of bodies to which trimethylamine belongs, viz., the amines (*i.e.*, organic ammonias), it may be observed that, as all the natural alkaloids are probably either secondary or tertiary amines, it is only rational that we should look for active agents among such as can be artificially prepared.

If we now take a glance over the history of *organic* chemistry, *i.e.*, the chemistry of the hydrocarbons and their derivatives, from its birth, half a century back, we shall see that the principal services rendered by chemistry to therapeutics distribute themselves through several epochs. First, chemical analysis came to our aid, and revealed the existence of distinct active principles in drugs, and explained their composition. To this study we owe the whole group of alkaloids, and the knowledge of such facts, for example, that the properties of cherry laurel water, or of emulsion of bitter almonds, are entirely due to the production of prussic acid. The poisonous qualities of bitter almonds had been indicated from antiquity, and those of cherry laurel from the beginning of the eighteenth century.

Then, advancing beyond the mere separation of immediate principles, chemists submitted animal and vegetable matters to the action of the most varied and powerful re-agents, and thus, through the study of chemical metamorphoses, whole groups of new compounds were opened up, and novel, simple, and less costly processes for the preparation of bodies previously known were disclosed. In proof of this may be cited the present commercial manufacture of benzoic acid from hippuric acid, and of glycerin by the aqueous saponification of fats.

In pursuing these intricate studies chemists were naturally led, not only to the consideration of known substances in varied aspects, but also to the discovery of entirely new compounds.

How pregnant with value this line of research has been to medicine will be manifest when I mention among its offspring creosote, carbolic acid, collodion, chloroform, chloral, apomorphia, &c.; while in the arts we have from coal, benzine, aniline, with its splendid colour-derivatives, and anthracene, from which the colouring principle of madder is artificially obtained. In more recent times still physiologists and therapeutists, not content with passively accepting information from scientific chemists, assume, in their turn, the position of teachers, and by the happy combination of their joint labours we may justly look forward to an array of discoveries, of which nitrite of amyl, chloral, and chloroform are the heralds.

In conclusion, I wish to say that my object in demonstrating these various drugs this evening was mainly on account of their possible novelty to some of the members, and to give them an opportunity of examining them at leisure. Some of the remedies were referred to chiefly from a chemical point of view, but I would not be understood as desirous of claiming too arrogant a position for chemistry in its relation to therapeutics, nor can therapeutics ever be built upon any one science, or be successfully studied without the co-operation of clinical observation.

But while I do not believe in the visions of those who see in the chemistry, and in the chemistry alone, of the future, a complete and harmonious system of therapeutics, the close and legitimate alliance which subsists between scientific chemistry and practical therapeutics cannot be too strongly upheld.

* There is also iso-propylamine known,

$$\left.\begin{matrix} CH(CH_3)_2 \\ H_2 \end{matrix}\right\} N.$$

SOCIETY OF ARTS.

On the Energies of the Imponderables, with especial reference to the Measurement and Utilization of them.

BY THE REV. ARTHUR RIGG, M.A.

Lecture VII.

*On the Energy of Heat, with especial reference to the Measurement and Utilization of it.**

(*Concluded from* p. 604.)

We will now pass on to a series of experiments, the object of which is to show the effect of heat in relation

* Cantor Lecture, delivered March 17, 1873; reprinted from the *Journal of the Society of Arts*.

to solids and liquids, and converting them into vapour. Mr. Wills, to whom we were indebted for assistance on the evening of the lecture on the energy of affinity, has kindly undertaken to exhibit some striking and instructive experiments. In this iron bottle there is condensed carbonic acid gas, which under ordinary circumstances is a gas, but when it is brought under a pressure of 700 lbs. to the square inch it becomes a liquid. To reconvert it from liquid into gas requires a large amount of heat. The conseqnence is, one part takes heat from the other, whilst a portion of it is sent forward in the form of vapour at the expense of the heat of the remainder. That remainder, therefore, becomes colder and colder, and appears in the form of ice and snow, as you see on turning the tap, and letting it escape into the room. The white substance which now is falling in the atmosphere of the room is carbonic acid snow. There is an apparatus for enabling the vapour to pass round and round in a copper vessel, and then escape at the handles; in so doing it absorbs a large quantity of heat, and therefore that which remains in the vessel freezes. We shall collect in this way a large amount of snow, which can afterwards be used for other purposes. Nearly a pound weight of this carbonic snow is now deposited in the copper vessel, and so cold is it, that on wrapping a piece of wet flannel round the vessel it freezes immediately. This snow can be held lightly in the hand without inconvenience, but if pressed a blister will at once be raised. Mr. Wills has taken a small portion upon his tongue, and breathing out the vapour as it melts, a candle is immediately extinguished. In the same way some of it may be put in a beaker, and the gas collected as the snow melts, when it will be found that a light cannot live in it. Again, here is a bottle of water, by putting some carbonic snow into it, and corking it up, we immediately get excellent soda-water. By pouring some ether upon it, the degree of cold is greatly increased by the rapid evaporation, so that the vessel becomes frozen to the stool upon which it stands, and a pound or two of mercury will soon be frozen into a solid body. Its temperature is about 130° below the freezing point. On placing the frozen mercury at the top of a tall jar of water, beautiful icicles are immediately formed in consequence of the intense cold.

Before closing, attention may be directed to the sources whence our supplies of heat are derived. The classification of these, and the character of the heat derived from them, may be studied in the tabular form.

There is one other matter to which the subject of last week's lecture bears a very extraordinary relation. Science investigations have established that a process of what is called dissipation of energy is going on. In the lecture on the energy of light, attention was directed to a remarkable testimony which, through modern science views, is thus given to Scripture. Let me add a few words on an equally remarkable one in reference to the energy of heat. In the case of light, reference was made to the beginning of the Bible; in this case of heat it is to the end of it. St. John (Rev. vii., 16), speaking of the new heavens, writes, "neither shall the sun light on them, nor any heat." How singularly in accord with this is the declaration (Rev. xxi., i), "There shall be no more sea, neither shall they thirst any more." Clearly, if the heat be not, there can be no water nor sea. Now, science testifies to the dissipation of heat, and thus unconsciously testifies to a gradual progress to that state which prophecy so plainly declares.

In closing this course of Cantor lectures on the energies of the imponderables, the thought re-presents itself, which was not an unfrequent visitor in the preparation of them, and which gained utterance in the first lecture in these words:—"It may be said, and with some show of reason, when the comprehensive title of these lectures is considered, a little well or completely done is better than much ill or very partially done. As a principle in education this is a truism. These Cantor lectures are not to be scholastic lessons; they may teach, but the primary object of them is rather to be suggestive of thought, to give food for reflection, material for development, to arouse inquiry, to provoke investigation, to leave, in fact, an unsatisfied impression that there is more than the lecturer has expressed, and that there is much for hearers and readers to consider. Such an unsatisfied feeling in relation to the energies named and the measurement and utilization of them it is the object of this course to create. If this result be attained, then, in those future years when by individual labour light shines where darkness now overspreads, there will be cause for thanks where perhaps, when these lectures end, an unsatisfied longing may alone be found."

Experience in the delivery confirmed the anticipation in my mind, and probably to your minds has suggested the question, why was so much undertaken with so little time in which to do it? Let the answer now given satisfy those who were not present on the first occasion, that however imprudent or unwise the judgment may have been, there, nevertheless, were method and object in it.

Probably the illustrative apparatus and diagrams which the room contained, but of which no use was made, may have assured some how much remains to give the zest of freshness to an extended research. Should any pursue this course they will find an interest at every turn which probably other pursuits cannot supply—an enjoyment with no after-reproaches, a provocation to cheerful thought and pleasant meditations, for:—

> "To him, who in the love of nature holds
> Communion with her visible forms,
> She speaks a various language."

They will further find an employment for leisure hours which soothes care by for a while removing it. They will find their eyes opened to sights of beauty and brightness to which the eyes of many are closed; they will be induced to permit their children, and their children's children, to acquire along with other knowledge that which surpasses, both in interest and in educative power, the writings of men in other days. Solomon and Pope, in this matter, have each given advice—one encouraging, the other discouraging, those studies these Cantor lectures suggest. Solomon wrote, more than two thousand years ago:—

"I was King, and gave my heart to seek and search out by wisdom concerning all things that are done under heaven."

He illustrates this and shows his knowledge of physical science by writing in the same chapter (Eccles. iv., 6-7) the following, which are clearly suggestive of what we call trade-winds, evaporation, condensation, etc., etc.:—

"The wind goeth toward the south, and turneth about unto the north; it whirleth about continually, and the wind returneth again according to his circuits. All the rivers run into the sea, yet the sea is not full; unto the place from whence the rivers come, thither they return again."

Pope wrote, more than one hundred years ago :—

"Know, then, thyself—presume not God to scan—
The proper study of mankind is man."

To follow Solomon is to find peace and pleasure ; to follow Pope is to find contentions and wars. Cunning craft and over-reaching are not in those pursuits with which we have been dealing, for you may rely upon it that—

"Nature never did betray the heart that loved her.
'Tis her privilege through all the years of this our life
To lead from joy to joy."

CHEMICAL SOCIETY.

Thursday, January 15th, 1874. Professor Odling, F.R.S. president in the chair. After the customary business of the society had been transacted, Mr. W. C. Roberts handed in a table supplementary to his paper read at the last meeting and containing complete analyses of all the standard trial plates still extant, dating from A.D. 1477, namely 17 gold plates and 14 silver ones. The first paper was "On the Action of Trichloracetyl Chloride on Amines:—I. Action on Aniline," by Dr. D. Tommasi and Mr. R. Meldola. This reaction gives rise to a substance called *phenyl-triacetamide* which crystallizes in lustrous plates. It is acted on by nitric acid, with production of *dinitrophenyl-triacetamide*, crystallizing in yellow needles. The next paper, by Dr. H. E. Armstrong, was entitled, "Note on the Action of Sodic Ethylate on Ethylic Oxalate and other Ethereal Salts," and the last, "On the Products of Decomposition of Castor Oil : I. Sebacic Acid," by Mr. E. Neison, giving an account of the preparation and properties of pure sebacic acid and of many of its salts.

The meeting finally adjourned until Thursday, 5th February, when there will be a paper "On the Action of Benzyl Chloride upon Camphor" by Dr. Donato Tommasi.

Parliamentary and Law Proceedings.

Death from Excessive Drinking and Overdoses of Chlorodyne.

On Wednesday, Jan. 21st, an inquest was held at Manchester by Mr. E. Herford, the city coroner, relative to the death of Thomas Hartley, aged 47 years.

Mary Hartley said the deceased was her husband. He had suffered from bronchitis and the liver complaint for six or seven years, but had not been under any doctor for 12 months. He had taken chlorodyne for his cough. Not feeling well on Monday he did not go to work, and he purchased a bottle of chlorodyne from Mr. Bowker's druggist shop, Deansgate. About seven o'clock on Tuesday morning he took a "mouthful" of the chlorodyne, and during the morning he said to witness, "I got threepennyworth of the stuff on Monday, and filled the bottle up with water." Deceased had taken a mouthful three or four times. At ten o'clock in the evening the deceased said he was very ill, and at his request witness went for his brother. On her return the man was found dead in bed. Deceased had been a heavy drinker. On Monday he had three half noggins and a two pennyworth of whiskey from 6 a.m. to 9.30. a.m. The rest of the medicine was taken during Tuesday night. He had taken two three pennyworths before. The last bottle was finished in three days.

Richard Methuen, druggist, Deansgate, said the medicine was served by his assistant. The quantity for threepence would be half an ounce, and half the quantity would poison a person. The deceased was understood to be a regular customer, and in that case the "regular dose," being mentioned was not necessary.

The jury returned a verdict of "Death from natural causes, accelerated by excessive drinking, and the overdoses of chlorodyne, and expressed the opinion that the label of the bottle ought to have contained proper directions as to doses."—*Manchester Courier.*

Alleged Adulteration of Food.

Mr. Martin, baker, of Mason-street, New-cross, appeared on Thursday, Jan. 22nd, at the Greenwich Police Court, to an adjourned summons for selling bread adulterated with alum. In this case there had been two analyses. The first, made by the local analyst, showed that there were 45 grains of alum to the 4lb. loaf. The second analysis was by Dr. Stevenson, of Guy's Hospital, who could not find any alum, though he made special search. Mr. Patteson dismissed the summons, and ordered the Greenwich district board of works to pay five guineas, the cost of the second analysis, reserving till a future day the question as to general costs. Mr. Pook, who had been engaged in the cases in which convictions had taken place, but the fines postponed, asked that the summonses might also be dismissed, on the ground that such convictions had taken place on the evidence of the local analyst, whose correctness of analysis had that day been disproved by the certificate of Dr. Stevenson. Mr. Patteson said that an error in one analysis was to be taken as an error in the others, and these summonses, as also two others not gone into, were dismissed, with the same conditions as to allowance of costs.—*Standard.*

Review.

A Course of Analytical Chemistry. By W. W. Pink and G. E. Webster. London: Lockwood and Co. 1874.

A short time ago the educational department of chemistry was in great need of a really good small elementary handbook of chemistry. Now, a few such have been written, and their well deserved success has stimulated so many men to write, that we are being overwhelmed with works of all sizes, each professing to supply an urgent want, and as a natural consequence many of them are crude, inaccurate, and, in a word, deplorable.

The one now before us constitutes a new volume of 'Weale's Educational Series,' but we fear we cannot say that we think it will add greatly to the reputation of the series, for it has never before been our misfortune to read a book containing so large a number of blunders both as to matter, arrangement, and language. This may appear to be very severe criticism, but a few extracts will amply justify it. Let us take in the first place some of the definitions we meet with. As a specimen of looseness of definition: "For fixed solids which do not vapourize, the atomic weights are referred to the element lithium, the atomic weight being determined by the amount of heat which any body contains when it is at the same temperature as lithium, both being the same weight, lithium being considered as seven." "All precipitates are solids in a state of powder." "Effervescence is the disengagement of gases from any liquid or solid." We might readily multiply such instances, but space will only permit the mention of one which completely baffles us. "Deflagration is the re-arrangement of the crystals of a substance, and is, in ordinary terms, the crackling of a body when exposed to heat" (p. 26). We thought at first that the authors meant *decrepitation*, but on p. 115 we are told that "upon heating chlorates a very violent deflagration ensues," and "if KCy be added, the deflagration is still more violent."

The atomic hypothesis is adopted with the most unhesitating readiness. It is true that we are told that "all bodies are *supposed* to be built up of an infinite number of small particles called *atoms*," and that "it is *assumed* that the different atoms possess power, lines of force, or *points of attraction* called *bonds* ;" but beyond the use of these words "supposed" and "assumed," the subject is treated as if the existence of atoms had been proved by the strictest logical process. It is to be imagined, however, that the authors did not fully appreciate the force of the term "infinite" in the above sentence. The mysteries of *gra-*

phic and *glyptic* formulæ are elaborately expounded, but here again the ideas of the authors seem to be very confused, for they speak of *four* systems; the *glyptic*, the *graphic*, the *empirical*, and the *constitutional*, whilst most people would consider the two former as merely modes of representing the latter. While on this point we may mention that it is stated that "this (graphic) form of formula has been adopted by Professor Frankland, and *generally throughout the kingdom*," which latter assertion we think will hardly be admitted by any one who has the slightest acquaintance with chemical literature. A subsequent assertion that empirical formulæ are "now not recognized by many colleges, or allowed in many examinations" will also, we feel assured, be repudiated by any one familiar with such matters.

A still more serious class of mistakes must now be hastily glanced at, namely, errors in statement of chemical facts. We are told that "platinum combines easily with silica and carbon"; that a platinum vessel must not be used in which to dissolve with hydrochloric acid "*any* substance containing manganese," because chlorine would be evolved which would attack the platinum, and a subsequent sentence implies that *all* green or black mineral substances contain manganic oxide. It is also said that "lead is present to a much greater extent in dilute sulphuric acid, as Pb is scarcely soluble in concentrated acid," the exact contrary being the case. Speaking of the purity of sodic hydrate, we are told that "sodic hydrate *should cause no effervescence*," but as no other substance is spoken of in connection with it, we can only suppose that it is not to effervesce spontaneously. Again, it is said that "*sodic carbonate* must completely volatilise"; "ferric chloride must be neutral to test paper"; "$COAmo_2$ is *sesqui*-carbonate of ammonia"; "chlorine is prepared by heating a mixture of sodic chloride, hydrochloric acid, and manganic oxide, but the last, MnO_2, *has no chemical reaction*," and the use of manganic oxide or ferric oxide, when preparing oxygen from potassic chlorate, is liable to contaminate the gas with traces of Fe or Mn. A dialyser is described as "a species of sieve, having sides and *top* of gutta-percha, and bottom of parchment. Sodic or potassic *oxide* (ONa_2, or OK_2), is constantly prescribed as a precipitant. We are told to keep hydrofluosilicic acid in india-rubber bottles, etc.

In the analytical tables we are directed to look for sodium in a solution to which sodic phosphate has been added, and for ammonium after the residue has, by express directions, been heated to drive off all ammonium salts. In testing for acids, $BaCl_2$ is said to evolve HF, or to cause effervescence by expulsion of CO_2, and these assertions are repeated on the next page.

These illustrations could be multiplied almost indefinitely, but we think that enough have been given to show that the authors have not succeeded in their endeavour "to prevent the confusion occasioned by many works on this subject," and we can only recommend them to take to themselves the advice they give on page 2 to "speedily endeavour to obtain a complete knowledge of the compositions of bodies," and (we would venture to add) of the English language.

It is the worst book we have seen; may it be the last of its kind!

BOOKS RECEIVED.

ELEMENTS OF CHEMISTRY: THEORETICAL AND PRACTICAL. By William Allen Miller, M.D., LL.D. Revised by HERBERT MCLEOD, F.C.S. Part II., Inorganic Chemistry. Fifth Edition, with Additions. London: Longmans. 1874. From the Publishers.

A PHARMACOPŒIA INCLUDING THE OUTLINES OF MATERIA MEDICA AND THERAPEUTICS FOR THE USE OF PRACTITIONERS AND STUDENTS OF VETERINARY MEDICINE. By RICHARD V. TUSON, F.C.S. Second Edition. London: J. and A. Churchill. 1874. From the Publishers.

Obituary.

Notice has been received of the death of the following:—

On the 17th January, 1874, Mr. Thomas William Cox Andrews, Pharmaceutical Chemist, of Norwich. Mr. Andrews had been a Member of the Pharmaceutical Society since 1853.

On the 10th January, 1874, Mr. William Barber, Chemist and Druggist, of Lavenham, Suffolk.

Notes and Queries.

[383]. CHILLI PASTE:—

SMEDLEY'S CHILLI PASTE.

℞.	Ol. Olivæ Pur.	2 lbs.
	Capsici Contus.	½ lbs.
	Cetacei	6 ozs.
	Ol. Lavand.	q. s.

Boil the chillies in the olive oil for seventy-two hours, then add the spermaceti previously melted, let stand until nearly cold, adding the oil of lavender to scent sufficiently. —S. J. COLEY.

[384]. COLOURS FOR CARBOYS:—

ROYAL BLUE.

℞.	Cupri Sulph.	℥ viij.
	Aquae ad	Coug. j.

Dissolve and add—

	Liq. Ammon. Fort.	q. s.
	Aquae ad	Cong. ij.

GREEN.

℞.	Cupri Sulph.	℥ ij.
	Liq. Ferri Perch. Fort. . . .	q. s.
	Aquae	Cong. ij.

Having used the above I can recommend them to J. R. H. Cold water that has been boiled in an open vessel is best.—W. THIRLBY, *Leicester*.

[385]. BROWN HAIR DYE.—I should be much obliged to any reader who would give me a good formula for a Dark Brown Hair Dye, several having been tried without effect.—G. N. FOWLER.

[386]. DR. JELLING'S OINTMENT.—J. N. F. asks for the true formula of Dr. Jelling's Ointment.

ELIXIR OF WILD-CHERRY BARK:—

(1.) Take	Wild-Cherry Bark, bruised .	4 ounces.
	Alcohol	5 fl. ounces.
	Simple Syrup	8 „
	Cold Water, sufficient.	

Macerate the bark for twelve hours in enough cold water to cover it; transfer to a percolator, add water gradually until the percolate measures 19 fluid ounces, and mix with the other ingredients. Colour according to taste, and filter.

(2.) Take	Fluid Extract of Wild-Cherry Bark . . .	4 fluid ounces.
	Water.	15½ „
	Simple Syrup. . . .	8 „
	Alcohol	4½ „

Mix and filter.

COPAL VARNISH WITH OIL:—

Take	Pale Hard Copal	2 pounds.
	Boiled Linseed Oil	1 pint.
	Spirits of Turpentine (about) . .	3 pints.

Fuse the copal, add the oil hot, with constant stirring;

then withdraw from the fire, and add gradually the turpentine, previously warmed.

COPAL VARNISH WITH ALCOHOL.

Take Gum Copal	1 ounce.
White Shellac	½ „
Alcohol	1 quart.

Powder the resins and put them in a jar with the alcohol; cork tight, and keep in a warm place, shaking occasionally, until all is completely dissolved.

REMEDIES FOR CHILBLAINS :—

(1).	Soap Liniment	2 ounces.
	Tincture of Cantharides	1 ounce.
	Oil of Cajeput	1½ drachm.

Mix together. Useful for unbroken chilblains. To be applied twice a day, with friction.

(2).	Nutgalls, finely powdered	1 drachm.
	Simple Cerate	7 drachms.
	Glycerine	2 „

Mix and rub into a uniform mass. A good dressing for broken chilblains.

CEMENT TO MEND INDIA-RUBBER SHOES :—

Take Virgin Caoutchouc	2 pounds.
Sulphide of Carbon	12 to 14 „

Cut the caoutchouc into thin slices, put it into a close vessel of tinned sheet iron, pour over it the sulphide of carbon, and, by means of a water bath, bring the temperature to about 86° F. The solution will take place promptly, but the liquid will thicken very soon, rendering the application difficult, if not impossible. In order to prevent this thickening the following solution must be added in a quantity sufficient to bring the mixture to the consistency of a thin paste :—

Take Virgin Caoutchouc	1 pound.
Powdered Resin	½ „
Spirits of Turpentine	3 to 4 „

Cut the rubber in pieces, heat in a suitable vessel over a moderate fire, until the gum becomes fluid ; then add the resin, and allow it to dissolve. When these materials are perfectly fluid, add the turpentine gradually, by small portions at a time.

The cement thus obtained is said to fully answer the purpose of gluing together rubber surfaces, as well as leather, or rubber and leather.—*Druggists' Circular.*

PRESERVATION OF OIL OF LEMON. — The addition of two ounces of water to each pound of fresh oil of lemon is said (*Pharmacist*, vi., 332) to make it possible to keep it unchanged and of fine odour for years. The water sinks to the bottom and carries down with it the mucilaginous matter which hastens the change to the terebinthate state.

CACAO CREAM.—The following formula for a "very elegant mixture for dressing the hair" is given by T. S. Glenn, of St. Louis (*American Journal of Pharmacy*, [4] iv. 9). In cold weather it is said to become quite hard, but a little heat soon renders it fluid.

℞	Ol. Theobromæ	℥xvi.
	„ Ricini	℥xcvi.
	„ Bergamii	℥vi.
	„ Limonis	℥iss.
	„ Citronellæ	℥iss.
	„ Lavandulæ	℥iv.
	Sp. Coloniensis, 95 per cent.	℥lxiv.

Melt the oil of theobroma, warm the castor oil and mix. Dissolve the essential oils in the cologne spirit. Fill the bottles two-thirds full with the first mixture, and then complete the other third with the perfumed spirit.

Correspondence.

THE REMUNERATION OF ASSISTANTS.

Sir,—The question of the remuneration of assistants is one of the utmost importance, and deserving of the greatest consideration ; and though it will be conceded by almost every one that the salaries of our young men are not so large as could be desired, it must be borne in mind that they have improved very materially of late years, and advanced in a greater proportion than the emoluments of their employers.

I am sure every one with true knowledge of the trade will corroborate me in this statement,—and though I should like to see an Association of Assistants formed, and wish it every success, I am sure that no advantage would be gained by assistants approaching their employers in an angry or hostile spirit, and that no combination or strike could possibly force up salaries to an unnatural height.

The truth simply is, that, under the present system of conducting business, both employers and employed are underpaid, and the remedy is by no means very apparent,—but with your permission I will touch upon this subject in another letter.

HYDE PARK.

S. W.—See Mr. Pocklington's paper on "Starches Microscopically and Polariscopically Considered," at p. 352 of the present volume of this Journal.

H. J.—(1) Some particulars respecting the use of hydrate of chloral in sea-sickness were given in the first volume of the present series of this Journal, pp. 465 and 500. (2) The formula of "Aitken's Syrup" will be found on p. 610 of the present number. (3) An index has been published at the completion of each volume.

"*Semper Viridis.*"—About 40 to 50 grams of melted yellow wax, added to the other ingredients previously mixed in a warm mortar and the whole allowed to become quite cold, will form a suitable mass. The oil of theobroma would probably answer, but more of it would be required.

J. D. M.—Phillips's Translation of the London Pharmacopœia of 1851 was published by Messrs. Highley and Son, 32, Fleet Street, and possibly might still be obtained from their successors, Messrs. G. Philip and Co.

W. E. S.—(1) Probably crystals of an oxygenated camphor or stearoptene, which occur together with a liquid hydrocarbon, cedrene, in the volatile oil obtained from cedar wood. (2) See vol. iii. of present series of this Journal, p. 604.

T. Perkin.—At present there is no restriction as to age ; but a new bye-law has recently received the sanction of the Privy Council (section 10, clause 16) which says that "after the 31st day of December, 1874, no person shall be admitted to the Major or Minor Examinations who shall not have attained the full age of twenty-one years."

"*Smoker.*"—We are unable to suggest any other plan.

W. J. S.—The question in its present form is too vague to allow of our giving an answer.

G. Neville.—We must refer you to our advertising columns, as the only part of this Journal in which currency could be given to your announcement, and we are rather doubtful as to the amount of credit it would reflect on them.

Mr. W. Wilkinson is thanked for his inclosure.

S. W. is referred to the rule respecting anonymous communications.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Bolton, Mr. J. Knowles, Mr. Harper, Mr. Bennett, Mr. G. Fowler, Mr. Greensell, Mr. Haslett, Mr. F. W. White, "West," J. E. M.

NOTE ON IODIDE OF IRON.*

BY W. MURTON HOLMES.

Having recently had occasion to make a mixture containing iodide of iron, and not being perfectly satisfied with its appearance, I was induced to make a few experiments, and I thought the results might be interesting to others. The prescription was as follows:—

℞.

Potass. Iodid.	℈j.
Ferri Iodid.	℈ss.
Syrup. Tolut.	℥ij.
Aq. Destill. ad	℥iv.

M. ft. mist.

In my first experiment the Pharmacopœia iodide of iron was used, being rubbed with a little reduced iron, and the solution filtered; the iodide of potassium was then added, and lastly the syrup. After it had been standing a few minutes, I noticed a flocculent precipitate, which soon collected and sank to the bottom.

A similar mixture was afterwards made by a friend; a clear solution being the result.

I was at a loss to understand the reason of this difference, and attributed it to various causes, the iodide of potassium among the number, which, however, answered the Pharmacopœia tests.

After two or three experiments it occurred to me that the syrup was, perhaps, the cause of the difference; I therefore made a solution of iodide of iron, to one-half of which I added the syrup (two drachms in four ounces), and afterwards the iodide of potassium. To the other half I added the iodide of potassium first, and then the syrup. In this case a precipitate of hydrated oxide of iron was formed almost immediately, whilst in the former the mixture remained perfectly clear, and no change took place for some hours.

This is curious, as showing the action of sugar in retarding the decomposition of the iodide.

I would suggest here, that when there is occasion to dispense iodide of iron in solution, that it is just as easy to weigh an equivalent quantity of iodine and mix it with a small quantity of reduced iron and a little water, whilst the result is more satisfactory, the Pharmacopœia preparation being so unstable and liable to deliquesce.

Since writing the foregoing, I have found that by adding to the iodide of potassium, dissolved in a little water, enough citric acid to neutralize the small quantity of free alkali it nearly always contains, a permanently clear mixture is obtained.

338, *Oxford Street, Jan. 28th*, 1874.

[*The discussion on this paper is printed at p.* 643.]

PHOSPHATE OF IRON AND ITS COMBINATIONS.†

BY CHARLES GEISSE POLK, M.D., OF PHILADELPHIA.

(*Concluded from page* 611.)

PHOSPHATE OF IRON WITH AMMONIO-CITRATE.

The phosphate of iron with ammonio-citrate is a very valuable preparation, and possesses several advantages over the bibasic phosphate with ammonio-citrate. The profession is indebted to Mr. Creuse, of the *Physician and Pharmaceutist*, for the proper method of preparing it in scales, and to Mr. R. Rother for the syrup form. For several years past I have been accustomed to prepare a syrup of this form of iron thus, using however the potassic citrate instead of the ammonic citrate:—

SYRUP PHOSPHATE OF IRON WITH POTASSIC CITRATE.

℞.	Liq. ferri tersulphatis	℥viij.
	Sodii phosph.	℥ix.
	Acidi citrici	℥xiv.
	Potassii bicarb.	q.s.
	Sacchar. alb.	℥xiv.
	Aquæ	q.s.

Dissolve the phosphate of sodium in one pint of boiling water, and slowly add to the solution the tersulphate of iron, stirring slowly until the phosphate of iron is completely precipitated. Then wash it in a funnel, on a muslin filter, until the washings are tasteless. Saturate the citric acid dissolved in one ounce of boiling water with the bicarbonate of potassium, add to the iron and apply gentle heat on a sand-bath until the iron phosphate is dissolved. If it is not dissolved readily a small amount of citric acid may be added, which very promptly secures a perfect solution. Evaporate to ten ounces, add the sugar, and continue a gentle heat until the sugar is dissolved. Each drachm represents fifteen grains of the citro-potassic ferro-phosphate.

This syrup can be very readily used as the ferric base of an elixir with quinia, cinchona or gentian. Or the sugar may be omitted and the process of scaled ferric salts followed, by which very perfect olive green scales may be obtained. It will be observed that the process is almost precisely like that followed for the pyrophosphate of iron, only the tribasic phosphate of soda is used instead of the bibasic phosphate.

SYRUP OF THE SUPERPHOSPHATE OF IRON.

Dissolve four ounces of glacial phosphoric acid in six ounces of water, raise the temperature to the boiling point, and add sufficient freshly precipitated phosphate of iron to saturate the solution, then introduce sufficient syrup to make thirty-two fluid ounces. If it be desired to unite quinia alone, or with strychnia, add the freshly precipitated alkaloids in the proportion of one grain of quinia and one-twenty-eighth of strychnia to each drachm, or two hundred and fifty-six grains of the former and eight grains of the latter to an ounce of water, and rub them up with nine drachms of syrupy phosphoric acid. Add sufficient syrup to the iron to form sixteen ounces, and sufficient syrup to the alkaloids to measure sixteen ounces, and add the two syrups together. This forms a powerful tonic, seldom disagrees with the stomach, is entirely void of the slightest inky taste, and proves a very effective preparation. Unfortunately, it is very unstable and deteriorates rapidly. This fault can be remedied by adding two ounces, instead of nine drachms of syrupy phosphoric acid, but then it will have the faults of the concentrated ferrous syrups without their tonic power, in relative doses.

In conclusion I may here remark that the syrup of the hypophosphite of iron, quinia and strychnia exceeds in its therapeutical value every other preparation here given. Pharmaceutically, however, it is not perfect, and I would be very thankful for an economical and practical mode of preparing it. To me this preparation is yet an unsettled problem. The expense of the syrup is also an obstacle to its general use.

The syrup of the phosphates of iron, quinia, and strychnia prepared by my formula is an article of great value, and will seldom disappoint those who trust it as a general tonic.

The phosphate of iron with ammonium-citrate is a mild chalybeate, very soluble, readily incorporated into compounds, either as elixirs, syrups, or pills, and thus fills a very important desideratum. It is therapeutically and pharmaceutically superior to the bibasic phosphate, which it is destined to supersede in many preparations where the latter is now employed. I do not believe bibasic phosphoric acid possesses any remedial powers. The phos-

* Read at the Evening Meeting of the Pharmaceutical Society of Great Britain, February 4, 1873.

† From the *Druggists' Circular and Chemical Gazette*, January, 1874.

phate of iron with ammonium phosphate is worthy of further investigation. The more I have used it the more I have been impressed with its great importance, the wider its range of application, and greater my confidence in its remedial power. In chronic engorgement of the uterus, attended with aching pain in the left iliac region, with tenderness on pressure, morbid sensibility along the course of the spine, deranged digestion, attended with constipation, head-ache, nervous derangement of the heart, attended with marked anæmia, I have found this combination to give better results than anything else in the manner of constitutional treatment. In fact, in nearly every case unattended with ulceration or organic disease this syrup, assisted by enemas of cold water (one pint being injected into the bowels upon arising from the bed every morning), and an occasional blister over the region of the uterus, gave very prompt relief, and produced a radical cure.

In certain forms of neuralgia it seems to exceed in its prompt and permanent relief every other known remedy. A few months ago I was consulted by a lady who had been for two years a victim of sciatica. Aconite, belladonna, bromide of potassium, iodide of potassium, colchicum, blisters, moxas, arsenic, morphia, quinia, and iron (the subcarbonate) had been freely used without any permanent benefit. I prescribed for her this preparation, to be taken in teaspoonful doses three times a day, increasing the amount of quinia however to two grains in each dose, twenty grains of hydrate of chloral, twenty grains of the bromide of potassium, and one drachm of the valerianate of ammonium, to be taken in a wineglassful of port-wine at bed-time, and a liniment composed of equal parts of saturated tincture of aconite (18 ozs. to the pint), chloroform, and sufficient camphor to saturate them. Within a week the suffering was much mitigated, and in six weeks after the cure seemed perfect.

In neuralgia of the face and head, the result has been extremely gratifying. Cases that had defied every other treatment often obtained relief from this syrup. About four months ago a gentleman about fifty years of age placed himself under my treatment. He was suffering intensely with neuralgia on the left side of the head, his eyesight very much impaired, and his intellectual faculties reduced almost to the condition of a puling babe. I placed him on this preparation. The improvement was remarkable. In one week the acute pain had subsided to a slight soreness; the eyesight was very much improved; the change in his physiognomy was very marked; the pale, haggard, woe-begone expression, so marked on his countenance at the beginning of my treatment, was replaced by a bright, cheerful face. He used twelve ounces of the preparation, and then, not being able to procure it, was persuaded to use Easton's syrup—that it was just as good. It seemed for a couple of weeks to do a slight benefit. The physician then placed him on bromide of potassium, and all the good he had received from the iron treatment was speedily undone.

In those cases of subacute rheumatism associated with anæmia, nervous debility, and slight cardiac trouble, in fact, the very numerous class of rheumatics found in low, damp, malarial situations, I esteem the syrup of the phosphates of iron and ammonia, with quinia and strychnia, very highly. I, however, use it in alternation with the following:—

℞.	Tinct. guaiac. amm.	℥ ij.
	Fluid. ext. colchici rad.	℥ ss.
	Potassii iodidi	℥ iss.
	Fluid. ext. cardamomi	℥ iij.
	Syrupus aurant. cort.	℥ iij.
	Aquæ ad	℥ viij.

Tablespoonful every four or six hours.

This treatment has been generally very satisfactory in my hands, and holds my confidence in a higher degree than any other.

Although one might, *a priori*, infer that the main good resulted in such cases from the last receipe, I do not think so. The phosphate of ammonia is one of the most valuable remedies in rheumatism. Quinia is well known as an anti-rheumatic, especially in the class of cases above referred to. In disease of the urinary and genito-urinary organs this combination does much good. While a medical officer in the Federal army, I had very rare chances of using this remedy, and watching the effect, as it only can be watched in an army hospital, during the late civil war; and, taking my own experience as a datum, I am very positive in my conclusion that it often did more good than I obtained from other remedies. In chronic diarrhœa, complicated as it very often was with Bright's kidney disease, this preparation often stayed the progress of this very obstinate malady, although I am sure not a single cure was permanent, except those sent to Northern hospitals, in which cases the removal from concurring and exciting causes did more advantage than could have possibly accrued from the entire paraphernalia of the materia medica.

In imperfectly cured pneumonia, where there has been extensive extravasation into the parenchyma of the lungs, the air-cells obstructed by the albuminous exudation, and a low state of inflammation still continuing, this preparation has given very good results, especially by adding about twenty grains of phosphate of ammonium to each dose. Such cases are generally diagnosed phthisis, dosed with cod-liver oil, and buried. A correct diagnosis and judicious treatment will cure nearly all of them. The diagnosis between phthisis and chronic pneumonia is too seldom, I fear, definitely determined. The rapid destruction of the lungs after acute pneumonia is too often erroneously attributed to tubercles, and the true pathological lesion overlooked. In such cases the syrup of the phosphate of iron and ammonia, with quinia and strychnia, is entitled to favourable consideration, and I have no doubt that very many would recover under judicious treatment who die from the sequelæ of pneumonia. In recommending the syrup of the phosphate of iron and ammonium, with quinia and strychnia, as a very valuable agent in the sequelæ of this disease, I need hardly remind the profession that the presence of inflammatory symptoms contra-indicate the preparation; the iron is very prejudical to the already irritable air-cells. Phosphate of ammonium and phosphate of sodium seem to have a marked influence. Ten grains each, given in an ounce of camphor-water, and repeated four or five times a day, very often modifies the condition materially, if it does not dissipate every inflammatory symptom. Inflammatory symptoms being removed, the iron combination can be used with marked benefit. Phosphorus certainly exerts a marked influence over pulmonary troubles. I have seen several cases of acute pneumonia treated by phosphorus in $\frac{1}{200}$ of a grain doses, and repeated every two or three hours. They did very well. The improvement was marked and rapid, and the cure effectual. I have however, never ventured to trust a patient of my own to such treatment.

The hypophosphites are unquestionably the best medium by which phosphorus can be introduced into the system, by which the curative impression can be transmitted. The hypophosphites of iron, ammonium, quinia, and strychnia seem to equal, if not surpass, the phosphates of the same salts in nerve trouble, surpass that combination in pulmonary diseases, but prove very much inferior in rheumatism, gout, uterine and kidney derangements. As a tonic, no combination yet devised, of iron and alkaloids, equals the syrup of the ferrous phosphate, with quinia and strychnia, made according to my formula.

GHAZEEPORE ROSE-WATER.

The following interesting information on the cultivation of roses and the preparation of rose-water at Ghazeepore has been taken from the Catalogue of the Indian Department at the Vienna Universal Exhibition, for which it was written by Mr. R. Saunders.

"The roses from which the celebrated Ghazeepore rose-

water is distilled came originally from Bussorah. These roses were first transplanted from Persia, and brought to the ancient, but now ruinous, Hindu city of Kanauj on the Ganges, and thence to Ghazeepore.

Somewhere about a century ago, Shaikh Abdullah (the father of the last Nawab Fuzl Alee Khan) made the first trial of a rose plantation in the vicinity of the city of Ghazeepore. Having experimented on a very limited scale in his own garden, he discovered that the soil of the environs of Ghazeepore was admirably adapted for rose-cultivation, and since that period it has by degrees been extended.

The celebrity of the Ghazeepore perfumes prepared from these roses very soon spread throughout India, and to other countries, while to this day they have been held in the highest possible esteem on account of the permanence of the odour, and the peculiar delicate fragrance of the scent for which they are specially appreciated in the mercantile world. Year after year traders come from immense distances to work temporary distilleries, for the season only, in order to replenish their stock of these delicious and precious rose-scents.

Culture of the Roses, and Plantation of Rose Gardens.—Unlike the propagation of the specimen roses of England, which depend chiefly on grafting, these rose trees are raised from cuttings which are planted out from nurseries after one year's growth at an expense of Rs. 25 per beegah. These slips are watered every five or six days till the setting in of the rains, and when once they have taken root they are finally transplanted to the field intended for the rose-garden. Here each rose tree is planted three feet apart from the other, and on an average 1000 shrubs are allowed to grow in each beegah of land.

Rose fields are kept scrupulously clean by constant weeding, and loosening of the soil around the roots. This operation takes place about three times a year. Leaf-mould, which is the best sort of manure for roses, is sprinkled all over the fields once a year, and twice a year the fields are irrigated by flooding them with well water. Priming takes place annually in the month of January. The flowering season is in February and March, when the blossoms are picked and collected each day before sunrise.

The average yield of flowers per beegah is from 30 to 60,000. These are sold to the distillers at a rate varying from 100 to 125 rupees per lakh (hundred thousand) of flowers. The total area under rose cultivation in Ghazeepore is estimated at about 200 acres, bearing an average rental of Rs. 4 per beegah.

Process of Manufacturing the Pure Attar of Roses.—A gallon, or half a gallon, of the best rose-water is kept in a large copper vessel in the cool night air, with a thin cotton covering over it. Before day-break the oily extract floating over the surface of the water is carefully collected with a pigeon's feather and placed in a phial.

The next day fresh flowers are added to the water, and it is again distilled, and the same process is continued for several days successively, till as much pure attar of roses is collected as is required. The whole quantity thus collected is kept in a phial and exposed to the sun for a few days, and as soon as the watery particles have evaporated pure oil, or attar of roses, is left in the phial, which sells by weight at Rs. 100 to Rs. 125 per tolah. This sort of attar being costly is generally made only to order, and the ordinary quantity produced each year rarely exceeds 5 or 6 tolahs. The rose-water left after eight or nine distillations again comes into use, and is sold in the market as the best of its kind. It is, in fact, a clear profit to the manufacturer, who is already amply repaid by the attar itself. The prime cost of a tolah of attar is fairly estimated at Rs. 72, viz. :—

Cost of labour	Rs.	12	0 0
Value of 50,000 rose flowers at Rs. 120 per lakh	Rs.	60	0 0
Total . .	Rs.	72	0 0

The margin left to the manufacturer after covering the cost of interest on outlay does not fall far short of 40 or 50 rupees per tolah, which it must be admitted is not at all a bad profit on the transaction.

Manufacture of the Alloyed or Ordinary Bazar-Sold Attar.—Sandal wood is well pounded and mixed with water, and then subjected to the usual process of distillation with roses. This gives a greater quantity of oily substance than could be expected from roses only. The same water is distilled over and over again with an additional quantity of fresh flowers as many times as suits the fancy of the manufacturer.

The value of this attar rises in proportion to the number of distillations, and the best of the kind sells at Rs. 10 per tolah down to the lowest rate of Rs. 2 for the inferior sorts. The process of collection of this attar is the same as that of the other, the only difference between the two being in the admixture or not of sandal wood oil.

It is difficult to estimate with any degree of accuracy the quantity of alloyed attar annually produced in Ghazeepore, for a large number of outsiders come every year, stop for the season only, and then carry off what they produce. Probably a maund would be near the mark, but the value cannot be accurately computed, owing to the great variety of rates for the different qualities manufactured.

Manufacture of Plain Rose-Water.—The process is simple, but the varieties are great according to the number of flowers allowed to each distillation. The ordinary rose-water is sold in huge spherical glass receptacles called "karábás," each containing 14 quart bottles. The average selling price of ordinary rose-water varies from Rs. 2 to 12 per karábá, and English quart bottles from 8 annas to 8 rupees each.

The usual cost of labour for each distillation yielding 24 bottles is one rupee. During the season numerous temporary rose-stills are worked by traders from different parts of India. Consequently it is very difficult to make even an approximate estimation of the actual quantity produced, but it is supposed to be somewhere between two and three hundred maunds.

GRANULES PERLÉS OR GOUTTES PERLÉES.*

BY M. SARMANT.

Ordinarily the granules are prepared by the process which consists in coating a certain quantity of nonpareil with a concentrated medicated solution. This mode of preparation offers no guarantee for the exact distribution of the active principle; hence the editors of the Codex rightly ordered that they should be prepared in the same manner as pills, by mixing the active substance with sugar of milk, gum and honey.

M. Sarmant thinks that this latter method, although preferable to the former, does not allow of a certainty that the granules so obtained all contain the same quantity of the active principle. He therefore proposes to prepare them in the following manner. Dissolve in water, by the aid of heat, the medicament it is desired to administer mixed with a certain quantity of gum and sugar, then introduce this mixture into a special apparatus, consisting of a cylinder formed of long articulated divisions, which are of an equal calibre from top to bottom, and subjected always to the same pressure, in such a manner that the drops which fall from these tubes all weigh 5 centigrams. Exposed to the air, these drops solidify and take a slightly flattened globular form, which they retain indefinitely.

The following is an illustration of the modification which, in various formulæ, allow of their adaptation to M. Sarmant's method of preparation :—

Fowlers's Solution (Codex).

Arsenious Acid	5	grams.
Carbonate of Potash	5	„
Distilled Water	500	„
Tincture of Melissa	15	„
	525	„

* *Journ. Pharm. et de Chimie* [4] xviii. 481.

Reduce by heat to 500 grams, and the solution will then contain one per cent. by weight of arsenious acid.

Sarmant's Formula.

Arsenious Acid	5	grams.
Carbonate of Potash	5	,,
Distilled Water	250	,,
Gum and Sugar	250	,,
Tincture of Melissa	15	,,
	525	,,

Reduce by heat to 500 grams, and the solution will then contain one per cent. by weight of arsenious acid.

By this method a large number of active principles employed in medicines may be accurately divided into doses.

FIRE.

To the readers of this journal the inquiry will be interesting how far chemists and druggists and the many trades connected therewith suffer from fire, and in order to gain information upon this point the annual report of Captain Shaw, the chief officer of the Metropolitan Fire Brigade, is of essential service. The report issued by this officer as to the occurrence of fire in London during the past year is more than usually interesting; and we may shortly examine it with the view of seeing how far our readers, or rather the trade in which they are engaged, has suffered of late in consequence of what the reporters term "alarming conflagrations." In Captain Shaw's report the trades are given alphabetically, and the first in the list are "apothecaries and dealers in drugs, but no chemical works carried on." During the past year no less than thirteen fires occurred at premises included in the above category, but fortunately none of these fires were seriously destructive. Notwithstanding that they were thus comparatively harmless in their effects, it is interesting to note the causes which led to their occurrence. Thus, three were caused by "light thrown down"; while one was attributable to each of the following causes:—escape of gas, seeking for an escape of gas with light, lime-slaking, phosphorus, defect in flue, spontaneous ignition, and lucifers. We next get to the chemists, who, we are pleased to find, have been very fortunate during the past year with regard to exemption from fire. Only three fires occurred at chemical works, and while one of these was the means of doing serious damage, two only resulted in slight damage. The origin of these fires is thus explained officially:—"overheat of drying-stove, 1; spark from fire, 1; and tar boiling over, 1." Passing through the list we come next to the wholesale druggists, who have been even more fortunate than the chemists in regard to the small number of fires which happened at their premises during the past year. The number is only two, and neither of these did much damage. The cause of one is said to be chemicals boiling over, and the other boiling acids. The drysalters in London last year only suffered from one fire, which was a very slight affair, and which was caused by the unfortunate breaking of a bottle of chemicals. During the past twelve months only four fires occurred at the premises of lucifer-match manufacturers, and only one of these caused serious destruction. The origin of two is explained by the over-heat of drying-stove, while one is attributed to spontaneous ignition, and one to "lucifers." Medical fixture dealers only suffered from one fire, which is ascribed to the somewhat curious cause of "light thrown from street"—a fact which indicates how easily fire is spread, and how careful we should be in regard to it. Generally speaking there is no doubt that, considering the list of London fires for the year just past, there is cause for satisfaction that the chemists and druggists, together with the other trades which are more or less connected with them, have been so singularly exempt from any serious conflagrations, and have suffered from such a remarkably small number of these occasionally disastrous and always unpleasant calamities. Comparing the chemists and druggists with other London trades in this respect, the comparison is most favourable to our readers, and doubtless the reason why they show so well in this list is to be found in the fact that they exercise a little care and precaution in the prevention of fires at their establishments. A little care, as a rule, is all that is required, but a little neglect is pretty certain to lead to some such result as that which necessitates the calling in of the services of the Brigade over which Captain Shaw so efficiently presides.

A most interesting subject of inquiry is the cause of fires, and some of the London fires are certainly to be attributed to very peculiar causes. Thus the origin of no less a number than 187 is thus concisely explained—"candle"! By this we are enabled to see how mischievously so useful an article as a candle may be used, and how occasionally it gives a little more illumination than is bargained for. Outsiders might be disposed to think that in a trade such as the manufacture of chemicals, where the materials are of so apparently dangerous a character, the liability of fire would be greatly increased; and yet these returns show quite the reverse. Thus, during the past year, the explosions of chemicals only caused one fire in London, while it must be remembered that nearly 200 were caused by "candle." Indeed, carefully examining the list of causes of fires, we are astonished to find how few are caused by chemicals or the business therein, and, on the contrary, how many are attributed to causes easily preventible, and which can only be traced to the grossest neglect. No less than 115 London fires were last year caused by what Captain Shaw describes as "light thrown down"—that is by people when they have done with a light pitching it anywhere, utterly regardless of the consequences, and caring not what evil results may ensue. The origin of twenty-nine fires is directly traceable to children playing with lucifers; escapes of gas caused 45; spirit lamp upset, 41; children playing with fire, 21; intoxication, 6; and smoking tobacco, 36. Without in any way endorsing the doctrines of the Anti-Tobacco Society, we would respectfully direct their attention to the last fact, as furnishing a new argument for their diatribes against the use of the "divine weed."

BISHOP TEMPLE ON EXAMINATIONS.

On Wednesday, the 28th January, the public distribution of prizes and certificates, awarded to pupils at the Christmas Examination of the College of Preceptors, took place in the theatre of the University of London, under the presidency of the Right Rev. the Lord Bishop of Exeter. In opening the proceedings his lordship delivered a valuable address upon the subject of examinations, which is here reproduced from the *Educational Times*.

"I have been asked to distribute the prizes to-day, and I hope I may be allowed to make a few remarks as an old schoolmaster, and to give a few words of advice to examiners, teachers, and scholars; to tell what is the use they can make of such examinations as this College is engaged in conducting, and the dangers that constantly attend them. The use to be made of them, although it is very clear to those who have studied the matter, is yet very often not so clear to the learners, who sometimes are not aware why it is that they should be subjected to these examinations, and what is to be gained from them. Generally speaking, it would be better if they would take the trouble to understand exactly what is the purpose of putting their knowledge to such tests, because by that means they would be most likely to make good use of the examinations. Their real purpose, then, is to secure both teachers and learners against the delusion, that is exceedingly natural and almost inevitable, of fancying that we know things that we do not know, and that we have taught things when we really have not done so. The worst of this delusion is, that the best teachers and the cleverest scholars are, perhaps more than any others, liable to be ensnared by it. When a very good teacher has put before

a scholar a perfectly lucid account of what he is teaching, he naturally believes that it has been carried away by the pupil; and again, in proportion to the clearness with which it has been understood by the learner, so does he believe that he has really mastered it; but it very often happens that, simply because the teacher has stated his knowledge so clearly, he has contributed to deceive the learner into the belief that he has learnt more than he really has; and very often clever boys, or quick-witted girls, who see what is said to them instantaneously, are most likely to go away with the belief that a thorough mastery has been obtained, whereas experience often shows that that would be a mistake. The old adage that "knowledge is power" is so true, that you may very fairly take power as a test of knowledge. Now when you come to apply the test, you constantly find this—the teacher has taught a particular subject, which he feels he has expressed quite clearly, and the learner has appreciated it and learnt it; and yet, when the learner is set down to utilize it, he finds he can make no use of it at all; that he cannot reproduce it or apply it. He finds, in fact, that his mind during the process has been entirely passive; and it is quite certain, unless there has been a spontaneous activity in the mind of the learner, and he has not really made what he has learnt part of the substance of his own mind, he has a great deal more to do before he can really be said to possess his knowledge. It is for the purpose of preventing this mistake that these examinations are held. We often find that when teachers fancy their pupils have obtained a thorough mastery of a subject, they are deceived, because they have not noticed that in almost imperceptible ways they have been doing for the pupil what he ought to be doing for himself. I have repeatedly gone into a school, and on examining it, say in arithmetic, have been told by the master, "It is very strange that the boys do not know it; I thought they knew it thoroughly." I have always asked them this, "When you have examined them, have you made them answer for themselves?" And the reply has been, "Yes; I have left them with themselves except just the very slightest possible help occasionally; just enough to prevent them from wandering about." That is the whole thing. That very little help is the thing which vitiated the examination altogether; and the test of real mastery is that the knowledge shall be produced without any help at all. When a man or woman in after-life come to use their knowledge, they will find that the knowledge is really of no use unless they are able to apply it absolutely without assistance, and without the slightest guidance to prevent them falling into the most grievous mistakes. For this reason these examinations should be used to guard us against this sort of mistake. I have said these words rather for the sake of the scholars than the teachers, because teachers are almost driven to find it out for themselves. I know, however, it is not by any means familiar to the learner, and I want, if I can, to get them to see the absolute necessity of using these examinations for the purpose to which I have been speaking, to test what they can do absolutely unaided. But now I wish to add what is, perhaps, still more important to all, as to the danger which always attends such examinations. There is a perpetual danger that they shall crush the study, as it were, into a mould; that the learner should learn, not with a view to knowledge, but with a view to being examined; that instead of the knowledge growing in the mind in the healthy and natural way, developing, as it were, from within, that the learner should be always looking forward to the black day when, perhaps, he may fail in his examination; that he shall always be asking himself, What sort of questions shall I be asked? and that he shall be endeavouring, if possible, to fit everything that he learns to what he anticipates will be in the paper that is put before him. In the same way there is a danger that the teacher, instead of studying the subject, shall study the examination papers; that these papers for one year shall be the guide for the teaching of the next, and that the teacher shall have constantly present to his mind the probability or improbability of particular questions being asked. In all these cases it is quite certain that examinations damage teaching. Learning, if it is to be worth anything, must have a spontaneous character, and must have a growth within the mind peculiar and proper to itself. It must be adapted to the mind of the learner. And, moreover, the teacher must adapt as he gives it to his own mode of teaching, and all this is liable to be set aside by the thought of the examination for which the teacher and learner are to prepare. Moreover, these examinations are intended to secure that there shall be such an absolute mastery of the knowledge as will be required in after life to be applied to practical purposes, and in all examinations there is an almost inevitable tendency not to make the examination at all like the sort of trial that will be found in life afterwards. Both in the examiner and in the examinee there is a natural tendency to have the answers neat, clear, and precise, and to frame the questions accordingly. But when the learner goes out into the world, he will never by any chance get precisely such questions as these to which to apply his knowledge. Thus, for instance, if he has studied physics or mechanics, and has answered a great many examination questions, all this will have been framed with a view to neat and precise answers; but when he comes into actual life he will find the presence of that awkward element, friction, which disturbs all calculations, and will never allow anything to come out neat and accurate at all. So, again, to take a different illustration. A learner has studied chemistry, and in doing so he has been dealing always in the laboratory with carefully prepared ingredients, as pure as they can be obtained; and this is the proper way, for you cannot study well unless you make your study as simple as you can. But when you go out into life, and have to apply that chemical knowledge, you never get the ingredients precisely such as you find them in the laboratory, but all sorts of foreign elements come in and disturb your calculations. So, again, to take an illustration from a different source. A learner has learned, with great pains, to write themes and essays, taking great care in the composition and arrangement of his sentences, and this is an admirable preparation for a great deal that he will afterwards have to do; but, nevertheless, in after-life he will inevitably find that he is often called upon to use this power under circumstances where he is no longer able to sit down and frame his sentences just as he would wish; perhaps he may be called upon to speak without any previous preparation; or to write without any time for thinking, or even, perhaps, without those means of information which he has been accustomed to use. Thus in many ways a man finds that there are difficulties in applying that knowledge which he carefully acquired in the process of education. For this reason it is that all through the process of acquiring knowledge it is essential that the mind should be fresh and vigorous, and maintain its own spontaneity; and in proportion as it loses that spontaneity, and gets to work by rule and according to routine, in that proportion will it be found that the knowledge acquired is not suited for the purposes of after-life. Hence, therefore, the danger that these examinations may have the effect of making knowledge more precise and more reducible, but less living; with less of the man's mind in it, and consequently with much less elasticity, and much less adaptability to the purposes for which it will afterwards be wanted. There is one rule which it has always appeared to me should be followed in these matters, viz., to make the examination follow the school rather than making the school follow the examination. We should, as far as possible, endeavour that the school should share in as free a course and as unfettered a choice as possible. Instead of putting before them a rigid course of examination, and saying, "Mould your teaching to that," we should rather say, "Let us know how you teach and we will endeavour to accommodate our examinations to that." And it is because I believe the College of Pre-

ceptors has endeavoured to follow this principle that its work has been so good. Nevertheless, what I have said may not be altogether out of place, because even if this principle be adopted, it is as well that it should be consciously expressed and held out as the end at which the College is aiming. It is as well, in a matter of this sort, that we should all know what we are doing, and see clearly the reasons for it. Although I may claim to have some knowledge of the matter, from long experience and the devotion of a life, I have no doubt there are many listening to me who are much better able than I am to say all this; but still I do not think it is at all unfitting that on such an occasion I should say it. I rejoice, therefore, to see the work that the College of Preceptors is doing. I rejoice to observe, from the report your Dean has sent to me, that the number of candidates has steadily increased from 1517 in 1870, to 2313 in 1873—an increase of over 50 per cent. And not only so, but the number of those who have passed the examinations has increased in a corresponding ratio, from 1070 in 1870 to 1584 in 1873—an increase also of more than 50 per cent. Meanwhile I have no doubt that both schools and examinations are improving step by step; that as time goes on the teachers are better able to put before their pupils knowledge in such a way that they can receive and reproduce it. At first it is often very difficult to do this. When these examinations were commenced it was exceedingly difficult to do anything of the kind; but in all schools, if they are doing their work well, there grows up a body of tradition of learning and of teaching; I do not mean rules whereby they bind themselves, but a kind of spirit whereby each successive generation of scholars and teachers is affected by what has been done by those who preceded them; and as time goes on the boys learn more and more from each other, and they see better what it is that their teachers are aiming at. And in schools of some standing it will always be found that the school itself, almost independent of the teacher, adds a great deal to what he teaches, simply by the way in which the school acts upon all who enter it. The consequence is that as time goes on these examinations are more and more put to their proper use, and more and more test the reality of the knowledge which is imparted. The pupils know how to, and do, use them better, to a great extent unconsciously, simply because they catch from one another the power of doing so; and the same with regard to the teachers. But at the same time it is necessary that I should warn you that as the advantage of these examinations increase, so also do their dangers. The danger of which I spoke just now is an existing and real one, and one which, as long as teaching goes on, we have perpetually to be watching against; for, depend upon it, nothing is so dangerous to real knowledge as to have it dried up, as it were, at the heart by the want of the true scientific aim and purpose both in teachers and learners. There is nothing which in the end will tell against the real efficiency of any teaching so much as to find that both teachers and learners are unconsciously—for I do not believe that any teachers would so far forget their duty as to do it consciously—drifting towards what has been so often and so properly condemned, the system of cramming for examinations. This danger is very real. The learner must still hold for his aim, not the passing of the examination, but the mastery of the knowledge; and if he observe that his teacher is teaching him something which, as far as he can see, will be of no use to him in the examination, he must still trust that the teacher is doing the wisest thing that can be done, giving him knowledge for its own sake; and he will inevitably find that in the end he will have gained far more than he may appear to have lost for the time. It is quite possible that in such a case the learner may not do quite so well at one particular examination, but he may be sure that if the teacher knows his business at all he is doing the right thing, and he ought to give his mind to it, and so follow the course marked out; learn to learn for learning's sake, and for the sake of really knowing that which he wishes to know; not merely for the sake of exhibiting his knowledge to his fellows, and perhaps winning a prize. It is excellent to do well in an examination, and it is excellent to win prizes; but it will not be an excellent thing, but a positive hurt, to any one who has made the passing of the examination, and the winning a prize, the real purpose with which he has studied. Therefore I beg you all, teachers and learners, to never let that temptation lay hold of your souls; for if you do, you will surely find that the true and real thing at which you all are aiming will escape you altogether."

THE PROPOSED PHARMACY BILL FOR IRELAND.

On the evening of Friday, 23rd January, 1874, a meeting of members of the Association of Licentiate Apothecaries of Ireland was held in Thompson's Dining Rooms, Donegall Place, Belfast.

On the motion of Mr. Pring, seconded by Mr. Grattan, Professor Hodges took the chair.

The Hon. Secretary (Mr. R. Bolton) stated that in reply to the circulars he had sent to Licentiates throughout Ireland, he had received replies from about one hundred and twenty gentlemen, up to the present, signifying their desire to become members of the Association.

A general discussion then followed, wherein it was agreed that it was a matter of surprise as well as regret that the body which was bound to protect their interests should now meditate the legalizing of a measure which would be most injurious to the Licentiates as well as to the public at large. It was also admitted that the diploma of the Apothecaries' Hall in Ireland should exist as a qualification in Pharmacy only, and not to enable to practise as a physician; and that the curriculum of study should be modified accordingly in the future.

The following resolutions were passed unanimously:—

Proposed by Dr. Stewart, seconded by Alderman Whitaker—

1. "That this meeting expresses the regret and indignation with which it has heard of the changes proposed to be effected by the Pharmacy Bill, about to be introduced by the Apothecaries' Hall of Ireland; and, in the interests of the public, earnestly deprecates and seriously resists any change by which the standard of pharmaceutical education would be lowered in this country."

Proposed by Mr. Grattan, seconded by Dr. Aickin—

2. "That a copy of these resolutions be sent to the Chief Secretary for Ireland, the different Medical Corporations, and all others interested in scientific and pharmaceutical education in Ireland."

Proposed by Dr. Wheeler, seconded by Dr. Gribbin—

3. "That a deputation, consisting of Mr. Pring, Dr. Ball and Alderman Whitaker, with power to add to their number, proceed to Dublin during the coming week to confer with the members of the Association there, and with them to carry out the objects for which the Association was formed, especially by opposition to the Pharmacy Bill."

On the motion of Mr. Pring, seconded by Dr. Aickin, Dr. Ball was requested to act as treasurer, and, he having consented, a subscription list was at once opened.

[Subscriptions, therefore, will be received by the treasurer at 21, Donegall Place, Belfast.]

Dr. Stewart having been moved to the second chair, the best thanks of the meeting were tendered to Professor Hodges for presiding. Proposed by Mr. Pring, seconded by Dr. Bolton.

Dr. Hodges then replied, expressing the pleasure it afforded him to act as chairman, and suggesting the desirability of promoting scientific and pharmaceutical knowledge by means of the Association.

The meeting then separated.

EXAMINATIONS AND THE REGISTRAR'S ANNUAL ANALYSIS.

EXAMINATIONS may be, and doubtless are, in the opinion of many who have to undergo them, of the tribe of "evils that the flesh is heir to," and are often as little appreciated as is the infliction of a cold douche upon one yet ignorant of the experience of the after-glow. But the increasingly important position they are taking in our national life is illustrated by the frequency with which they now become the subject matter of the utterances of our public men. Within a moderate space of time the words of, amongst others, the Archbishop of CANTERBURY, Bishop WILBERFORCE, Lord DERBY and Lord GRANVILLE, have furnished food for thought on this subject, and this week our pages record the ripe experience of Bishop TEMPLE. Nor have they been absent from election oratory, for on Tuesday the HOME SECRETARY, in his address to his constituents of the University of London, was able to face with comparative calmness the terrible catastrophe of a Liberal defeat, but he begged that those who heard him would never allow the boon of competitive examinations to be withdawn.

Another indication of the growth of public opinion upon this question is found in the fact that it is thought the time has come when a simplification of the variety of preliminary examinations now required by different public bodies can be profitably advocated, and the amalgamation of the local examinations of the Oxford and Cambridge Universities under a common board is suggested as the best method of effecting the object desired. Such are the recommendations adopted at a Conference of Head Masters of Schools held recently in London, and they are now in course of circulation, accompanied by explanatory remarks, and an appeal to private employers of labour and Joint Stock Companies that they would "confer a boon upon education" by requiring some educational guarantee from youths entering their service.

Fortunately the principle laid down in the latter part of this advice is now generally acted upon by pharmacists, and the practice already adopted by the Board of Examiners of the Pharmaceutical Society, of accepting in lieu of their own preliminary examination the certificates of any approved legally constituted examining body—provided Latin and arithmetic have been included in the subjects of examination—is in accord with the principles laid down in the former part. Such an examination is intended to mark the close of general, and the commencement of special, education. To meet the difficulty of different degrees of proficiency being required by different learned bodies or intending employers, three grades of examinations are proposed—a "Senior," "Junior," and "Preliminary," and it would of course be a mere matter of detail to decide which of these three would best satisfy the requirements of the Pharmaceutical Examining Board. The project is one that is, we think, much to be commended; the principle that a preliminary examination should be a test of general education is a sound one; and it is to be hoped that every year there will be a greater disposition on the part of parents to have this work performed whilst lads are yet at school, and by a scholastic body, instead of throwing it upon an examining board appointed rather with a view to its technical skill. Incidentally, it is instructive to note how wide-spread and varying in degree is the evil now generally known as "cram;" for one of the causes of the Conference above referred to has been the inconvenience occurring in schools through the variation of studies thought requisite in preparing scholars to pass different examinations.

Whilst discussing the subject of examinations, the opportunity may be taken of comparing, by the aid of the statistics given in the Bishop of EXETER'S speech, and the analysis of examinations presented to the Pharmaceutical Council this week by the Registrar, the results of the examinations by the Board of the College of Preceptors and by that of the Pharmaceutical Society. Some idea may thus be formed as to whether the number of failures is due to the Society's standard being unnecessarily high, or to the inferior education of the class of youths who are unsuccessful. It will be noted that as during last year 1584 out of 2313 candidates passed the College Board, the number of rejections could have been only about 31·5 per cent. But although certificates of having passed this examination are received in lieu of the Pharmaceutical Preliminary Examination—and therefore the latter cannot be considered a more difficult one—the number of rejections by the Society's Board in Scotland amounted to 41·35 per cent., and in England to as much as 48·14 per cent. of the whole.

The Major and Minor Examinations, according to the Registrar's analysis, approach rather more nearly what may be deemed a normal average, the rejections in the Minor being, in Scotland, 38·66; in England, 44·96 per cent.; and in the Major in England only 32·87 per cent., the total number in Scotland being, perhaps, too small to allow of the average being important. The results of last month's examination, however, when 41 out of 56, or 73 per cent., failed in the Minor, promise to spoil the average for the present year; and as the time approaches when the new regulations come into force, it is probable that a large number of candidates will enter the examination-room prematurely. We have no further

to seek than our own advertising columns to find one cause of failures, in the promises therein made to impart in a few weeks the information which is to do duty for the accretions of years. Whatever may be said of the number who pass under these conditions, it is evident that many more must and ought to fail. Mr. SCHACHT well remarked on Wednesday that Pharmacy is an art based upon science. Upon the breadth and solidity of the foundation laid depends much of the value of the superstructure, and this superstructure is best reared, not so much by the communication of the knowledge possessed by the teacher as by guidance into proper opportunities for the pupil's acquisition of it by personal experience. In the subjects of so practical an examination as the Minor is intended to be, "knowing, in relation to "the training of the mind, is the result of learning; "and learning is the process by which a child teaches "himself—by personal experience." The advantage of starting with some systematic knowledge, however small, of the sciences upon which Pharmacy is based —physics, chemistry and botany—cannot be overrated.

It would be presumption on our part to criticize the address of so famous a teacher as the late Master of Rugby; we have nothing but admiration for Bishop TEMPLE'S address. In it the danger of crushing study, as it were, into a mould, that the learner should learn, not with a view to knowledge, but with a view to being examined, and the danger that the teacher, instead of studying the subject should study the examination papers, have beacons of warning set upon them. Examinations, by the stimulus they impart, may be the channel of much good; but it is also undoubtedly true that the learner should "hold for his aim, not the passing of the examination, but the mastery of the knowledge." Where this object ceases to be striven for, "education" is no longer a fit term to apply to the work: it is degraded to a struggle on the part of the examinee anyhow to pass the examiner, and if under such conditions he fail—as fail he often does—he has no claim upon our sympathy.

A CORRESPONDENT of the *Pharmacist* calls attention to the abundance, in the United States' markets, of a substance known as "American Dandelion," but which is simply pure chicory root. Notwithstanding this, he says it is largely used by manufacturers in the preparation of liquid and solid extracts, which are afterwards labelled as preparations of *Taraxacum Dens Leonis*. This is an adulteration that, when met with in this country, is generally looked upon as accidental, occurring through the ignorance of collectors. But the reason now given for the substitution of one root for the other is that the chicory root yields fully twice as much solid extract as the true root, and consequently a denser fluid extract.

MR. F. M. RIMMINGTON, F.C.S., Pharmaceutical Chemist, has been appointed Public Analyst for the Borough of Bradford.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, February 4, 1874.

MR. THOMAS HYDE HILLS, PRESIDENT.

MR. ALEXANDER BOTTLE, VICE-PRESIDENT.

Present — Messrs. Baynes, Betty, Frazer, Greenish, Hampson, Mackay, Radley, Robbins, Sandford, Schacht, Shaw, Stoddart, Urwick, and Williams.

The minutes of the previous meeting were read and confirmed.

APPOINTMENT OF EXAMINERS.

The SECRETARY read a letter from the Privy Council approving the appointment of the Examiners recently chosen by the Council.

PRELIMINARY EXAMINATION REGULATIONS.

Mr. MACKAY drew attention to the last paragraph in the Instructions to Superintendents of Preliminary Examinations, directing that all the papers when sealed up shall be sent to the "Secretary." Unless some further intimation were sent to the Scotch Superintendents, the papers would be sent to the Secretary in London, instead of to the Secretary of the North British Branch in Edinburgh, as heretofore.

Mr. WILLIAMS thought it was the intention of the Council that all the papers should come to London. It seemed very absurd that examination papers should not come to be valued by those who had set the questions; and indeed the practice had been to send down to Edinburgh the answers to the questions and their values in marks, in order that the Board there might attach the same value to the answers as was done to those of English candidates. He hoped, therefore, that the matter being so entirely one of form, the Scotch Board would not think they were in any way treated with disrespect if the whole of the papers now came direct to London.

Mr. MACKAY said the Board in Edinburgh had their own powers and prerogatives, and he was sure they would not give them up. The value put upon the answers was always exactly the same as in England.

Mr. WILLIAMS hoped that if the Northern Board continued to conduct these examinations they would set the questions and value the answers themselves. He had not the slightest objection to this being done, if the examinations were held simultaneously with those in England.

Mr. HAMPSON quite agreed with the suggestion of Mr. Williams. He thought they ought not to interfere with the action of the Board of Examiners in Scotland, who were a distinct and responsible body.

Mr. SANDFORD also approved of this suggestion.

After some further conversation it was suggested that the question of examinations in Scotland would come up again later, when the matter could be disposed of.

RETIRING MEMBERS OF COUNCIL.

The lot being taken in the usual manner for the seven members of Council who should retire in May next, the following names were drawn :—

Bottle	Mackay	Sandford
Hampson	Robbins	Williams
Hills		

The following seven, who remained in by lot last year, now retire by rotation :—

Frazer	Shaw	Sutton
Owen	Stoddart	Urwick
Schacht		

The following seven will remain in office for the ensuing year :—

Atherton	Brown	Radley
Baynes	Greenish	Savage
Betty		

The following being duly registered as Pharmaceutical Chemists were respectively granted a diploma stamped with the seal of the Society :—

Druce, George Claridge
Edwards, Charles
Fox, Charles Edward
Thresh, John Clough
Williams, William Francis

Elections.

PHARMACEUTICAL CHEMISTS.

The following Pharmaceutical Chemists were elected Members of the Society :—

Druce, George Claridge .....Northampton.
Edwards, Charles .....London.
Farries, Thomas.....London.
Fox, Charles Edward .....London.
Thresh, John Clough .....Dukinfield.
Walton, Major Foulds ... .Sowerby Bridge.
Wood, Alexander .....New Brentford.
Woods, Joseph Henry .....Warrington.

CHEMISTS AND DRUGGISTS.

The following registered Chemists and Druggists were elected Members of the Society :—

Bellamy, Robert .....Hull.
Holmes, John Thomas .....Dublin.
MacRitchie, David .....Inverness.
Mercer, Allan ....Prestwich.
Mildren, William Williams .....Hayle.
Twaddle, Robert .....Glasgow.
Watson, Robert William.....Sheffield.

ASSOCIATES.

The following, having passed their respective examinations, and being in business on their own account, were elected "Associates in Business" of the Society.

Minor.

Bond, Charles Radcliffe .....Kingston, Surrey.
Bradshaw, John.....Adlington.
Brown, Richard Fearon .....Cockermouth.
Casely, Thomas..... .....London.
Chambers, Pearson .....Liverpool.
Cossey, James Davis..... .....Yarmouth.
Herbert, Samuel .....Keynsham.
Lucas, Joseph Michael Mark ...Gravesend.
Mellor, John Gilbert.....St. Neots.
Sangster, William.....Dufftown, N.B.
Scott, Thomas Alexander .....Chertsey.
Swinbank, John.....Bedale.

Modified.

Betts, William Maydwell .....Towcester.
Jones, Enoch Henry.....Bristol.
Lloyd, John .....Croydon.
Oakey, Joseph .....Rusholme.
Palmer, Henry Bridges .....Wingham.
Rowell, John Childs.....Reading.
Scott, John Gladstone.....Dumfries.
Scott, Joseph.....Preston.
Snook, Joseph John .....London.
Stones, William.....Manchester.
Trick, William Borrow .....Stoke Newington.

The following having passed their respective examinations were elected "Associates" of the Society :—

Minor.

Alderslade, William .....Southwark.
Barlow, Frederick.....Birmingham.
Chamberlain, Arthur Garratt...Leicester.
Cheetham, George Richard .....Bradford.
Colley, Walter .....Birmingham.
Corder, Sheppard Ransome .....Norwich.
Flint, Charles Bruce.....Glasgow.
Forewell, Henry .....Edinburgh.
Gresswell, Arthur.....Spalding.
Harrold, Charles Jesser .....Frome.
Hayton, John William.....Wigton.
Hearne, Frederick.....Strood.
Higginson, Alfred.....Manchester.
Hobbs, Thomas Henry Hurle...Wells.
Holden, William Henry .....Staithes.
Jarvis, Abraham .....Kingsbridge.
Jeans, Thomas Robert .....Mansfield.
Kemble, James .....St. Austell.
Purse, Alfred Dodds.....Sunderland.
Rhodes, Samuel.....Oldham.
Rippon, Edwin .....Stamford.
Spencer, James Hampson .....Manchester.
Strongitharm, William George..Birmingham.
Sturdy, Thomas Metcalfe.....Leeds.
Taylor, John .....Carlisle.
Thomas, Thomas Francis.....London.
Twemlow, Francis Ernest .....London.
Umpleby, Samuel Sayer .....Harrogate.
Vince, James.....Lancaster.
Willson, Alfred.....Landport.
Wood, Alfred.....Sheffield.

The following, having passed the Modified Examination, was elected an "Associate" of the Society :—

Modified.

Howson, Joseph Frankish .....Islington.

APPRENTICES OR STUDENTS.

The following, having passed the Preliminary Examination, were elected "Apprentices or Students" of the Society :—

Allen, Henry.....London.
Barker, Alfred William .....Saffron Walden.
Bennison, Richard.....Stokesley.
Bird, William.....York.
Blagg, Eli .....Hanley.
Borman, William Alan.....Lincoln.
Boucher, Edward Grove .....Birkenhead.
Boyfield, John Richard.....Boston.
Brend, Kenneth Benjamin .....Swansea.
Briggs, William Henry.....Wakefield.
Catcheside, Matthew Henry ...Hexham.
Chapman, Joseph George.....Binfield.
Clarke, Willoughby .....London.
Cornwell, Thomas Chinsura.....Penzance.
Davey, John Trimble .....Exeter.
Davidson, Alexander .....Insch.
Duckett, George .....Preston.
Elliot, Joseph .....York.
Ellis, James .....Southsea.
Elmslie, J. Alexander Robson...Aberdeen.
Esam, Richard .....Stamford.
Galloway, James Barker .....Liverpool.
Golding, John Frederick .....London.
Greatorex, Edward John.....Stapleton.
Greenwood, William.....Settle.
Gudgeon, Harry Atkins .....Northampton.
Heaver, Arthur William.....Norwich.
Holl, Edmund .....Scarborough.
Humphreys, Arthur .....Nottingham.
James, Isaac Rowland .....Aberystwith.
Jarvis, Clarence Frank .....Handsworth.
Jelley, George William .....Coventry.
Jevons, Wallis Byron .....Market Rasen.
Jones, Llewellyn .....Chester.
Kiloh, James .....London.
Langdon, Frank Bowers .....Plymouth.
Laurie, John .....Ipswich.
Laverty, Joshua .....Jersey.
Lister, Amos .....Bradford.
McDonald, Donald Frazer .....Edinburgh.
Mackay, J. Bunyan Lillie .....Inverness.
Mawson, Thomas Oliver .....Sheffield.
Midgley, James Herbert .....Edinburgh.
Owen, Rowland.....Holyhead.
Paull, John .....Brecknock Road.
Pentelow, Harry .....Oundle.
Plant, Charles Plantagenet.....Leicester.
Portway, Arthur Cyril.....London.
Pumphrey, John Henry .....Evesham.
Read, John Henry .....London.
Ridley, Edward Henry.....Manchester.
Richardson, William Henry ...Boston Spa.

Roberts, George Constable .....London.
Robertson, William .....Peebles.
Shum, Arthur George .....Edinburgh.
Simpson, Charles Alfred .....Fenton.
Sproson, Thomas Frederick.....Wolverhampton.
Taylor, James Henry .....Darrington.
Temple, Frederick Staveley.....Hull.
Toon, Frederick.....Eccleshall.
Wild, John.....Bury.
Williams, Charles Edward .. ...Bayswater.

A member who had neglected to pay his subscription within the proper time was restored to his former status upon payment of a fine equal to one year's subscription.

The Examinations.

Mr. Hampson said he had understood that when candidates came into the building they were asked if they had been students of the Society. He wished to know if this was the case.

The Secretary said the Board of Examiners were in perfect ignorance as to where candidates came from, or where they had received their education.

Mr. Hampson said he believed it was some one in the office, not the examiners who asked the question.

Mr. Urwick had also heard statements to the same effect, and he had been told that it was desirable for the Examiners to know where the candidate had received his education in order that they might frame their questions accordingly in order to prevent the success of cramming. He had not understood, however, that the question was put by the Examiners themselves, but by some one in the office. If a young man failed, who had not been educated at Bloomsbury Square, he might perhaps fancy he had not been treated so favourably as others who had enjoyed that advantage.

Mr. Williams thought it much better that such questions should not be asked, but at the same time some of the Examiners had told him they could often distinguish without much difficulty where young men had received their education ; and of course they could not prevent the Examiners forming their own opinion in this way.

Mr. Baynes said he knew the question had been put to candidates, had they been educated at Bloomsbury Square ; at the same time he was quite certain that it was done with no improper purpose, and that the Board of Examiners were quite above the least suspicion of partiality in any way.

The President said he might state from his experience at the examinations that no such questions were ever put to candidates by the Examiners.

After some further conversation.

The Secretary stated that for the last 16 or 17 years he had been in the habit of requiring candidates for the respective examinations to fill up a form, stating their name, age, residence, and whether they had attended the Society's Laboratory or lectures. This was done merely for the sake of obtaining useful statistical information for respective Laboratory or reference, but the Examiners had not the least opportunity of becoming acquainted with the particulars thus furnished.

Mr. Greenish suggested that the candidates should be called up into the room by number, and not by name.

The President said he would submit the suggestion to the Examiners.

Mr. Williams suggested that the Council should give some opinion as to whether the practice referred to by Mr. Hampson should be continued or not.

Mr. Hampson thought it unnecessary, as the same information could be collected in another way.

Mr. Betty thought the statistics thus obtained were valuable, and they could not be prepared otherwise without a considerable deal of trouble.

Mr. Schacht thought it very undesirable that any restriction whatever should be placed on the freedom of action of the Examiners in the performance of their duties ; and he, though not an Examiner, could conceive it quite probable that it might be a great assistance to know the name of a candidate and where he had obtained his education. He happened to know that some of the highest authorities, such as Dr. Michael Foster, made a distinct point to always find out the antecedents of the candidates.

The discussion then dropped without any resolution being passed.

The President said he had just received a telegram from Mr. Atherton, saying that he was detained at home by election business, and asking for the loan of some specimens from the Society's museum, for the chemists' conversazione at Nottingham, a fortnight hence.

It was unanimously resolved that the request be acceded to.

A letter to the Council from the Board of Examiners in Scotland was read by the Secretary, containing various suggestions as to some of the details of the Examinations.

Mr. Mackay suggested that the letter be referred to a Committee, which should be attended by a deputation from the Board of Examiners in Scotland, and by the London Board of Examiners. He also added that Dr. Maclagan, the Government Assessor in Scotland, had taken great interest in the Examinations, and would be very happy to attend the deliberations of the Committee. He would therefore move—

"That the letter of the Edinburgh Board of Examiners be remitted to a Committee of the Council to consider and report upon, and that a deputation from the London and Scotch Boards be invited to meet the Committee to discuss the whole matter previous to the said report being drawn up. The Council Committee to consist of the President, Vice-President, Messrs. Brown, Sandford, Schacht, and Williams."

Mr. Schacht seconded the motion. He thought it of the greatest importance that the Examinations in Edinburgh and in London should be as nearly as possible absolutely *identical*.

After some conversation the motion was adopted unanimously. It was also decided that the question of the Preliminary Examinations in Scotland, as previously referred to by Mr. Mackay, should be referred to the Special Committee by whom the new regulations for conducting the Preliminary Examinations were prepared.

The Registrar's report for the year 1873 (see page 637, opposite) was laid on the table, and ordered to be entered on the minutes.

REGISTRAR'S REPORT.

Preliminary Examination in April.

It was resolved—

"That the Preliminary Examination in April next be held on the second Monday in the month of April next instead of the first, the first Monday being Easter Monday, a Bank holiday."

Finance.

The report of this Committee was received and adopted. It recommended the payment of sundry amounts, amongst others the sum of £100 to the North British Branch, on account of current expenses.

Mr. Mackay said the Council of the North British Branch had for some time past felt that they were paying too high a rent for the accommodation they had, which was not sufficient for their purposes. They had now a prospect of something like eight cases of specimens coming from Singapore to the Society's Museum in Edinburgh, but there was really not room for their accommodation. They felt that they should get more room and pay less money; and as they had the power of breaking the lease in May next, he had taken the liberty of giving notice that they would take advantage of that power. They were, therefore, now on the look out for more suitable premises, as to which he would again communicate with the Council. He might add that since the rooms had been opened something like 1100 young men had taken advantage of the library, reading-room, and museum. He was happy to say that they had a very good museum, containing nearly everything in the Pharmacopœia, which was at all times open to students, whilst there was a separate cabinet, kept under lock and key, reserved for the use of the Examiners.

Mr. Hampson asked if the Society's Museum in Bloomsbury Square was open in the evenings, as well as the library.

Mr. Greenish said the museum was only open from nine to five o'clock.

Mr. Hampson thought it very desirable that the museum should be open in the evenings, and said he would take an early opportunity of moving a resolution on the subject.

Benevolent Fund.

The report of the Benevolent Fund Committee was read, recommending that the name of Mr. H. J. Bellingham, of Peckham, should be placed on the list of approved candidates for an annuity at the next election; also that the widow of a chemist and druggist, registered in October last, should receive from the Benevolent Fund the sum of £5 5*s*., the fee recently paid by her late husband. These recommendations were adopted.

Special Report on the Benevolent Fund.

A report was read from the Special Committee, appointed in November last, to consider what steps it is desirable to take to increase both the amount of subscriptions and the usefulness of the Benevolent Fund. It recommended that subscribers to the fund should have a larger proportionate influence in its distribution. It was proposed to effect this by giving to subscribers of half-a-guinea *two votes* at each election of annuitants, instead of one as heretofore; to subscribers of one guinea, four votes instead of one, and so on in proportion. It was also proposed that subscribers of five shillings should have one vote. It further recommended that the regulation that "No pension shall exceed the value of £45 yearly," should read, "Each pension shall be of the value of £30 yearly," the latter being the amount hitherto granted.

The report and recommendations were received and adopted, and a circular containing the proposed alterations in the regulations, and setting forth the claims of the fund, was ordered to be sent to each person whose name appears on the register.

Mr. Sandford said that the proposition made by Mr. Robbins was very meagrely set forth in the report of the Committee. Mr. Robbins had submitted to the Committee a proposition to increase the number of annuitants believing that the amount of annual subscriptions during the last three or four years would justify the Council in relying to some extent on the subscriptions for the future, instead of depending entirely upon the interest arising from the invested capital. The question was fully discussed, but the Committee did not submit any recommendation upon it, because they ascertained that there was no by-law or regulation binding the Council in any way, and that it was quite open to them at their meeting in June to decide upon recommending the election of as many annuitants in the ensuing October as they thought proper.

Mr. Robbins said he had intended on the previous evening to have proposed a recommendation that they should for the future cease to maintain the difference between the income derived from one source and that derived from another, viz., the funded property and the subscriptions; but, as Mr. Sandford had pointed out, there was nothing now to limit the action of the Council, and he was, therefore, quite satisfied to leave the matter as it was. He was very glad the Special Committee had been appointed, and that this subject had been ventilated so much, because he was quite sure that many members of the Council now saw the matter in a different light to what they did when it was first introduced, and he was also convinced that at the June meeting if there were five deserving candidates they would not agree to elect only one. He had gone into the figures at some length, and had shown pretty clearly that the Benevolent Fund was in a satisfactory state, so much so that for some years past the subscriptions had always been on the increase; at the same time they knew that the demands on the funds had increased also, but as it appeared they could depend to a certain extent on the annual subscriptions, and as it certainly appeared to be the case that the more they gave away the more subscriptions came in, he had no doubt the policy he advocated would be adopted. It was now found that the income from the invested capital was the smallest part of the annual income, and therefore it was desirable to elect a larger number of annuitants, especially as the amount received from subscriptions was greater than could be spent simply by giving small grants from time to time, as was the practice at present. For some years past they had had an annual income of £1200, and if they could calculate on that for the future, they would be able to elect 20 annuitants, and still leave £600 for casualties and investment. He was glad to find that several gentlemen who had looked into these figures had arrived at the same conclusion as himself, and he had no doubt that the subscriptions would come in even more freely and more largely when it was understood that the money would be distributed instead of being invested.

The Vice-President said he had hitherto been of opinion that they could not safely give annuities out of annual subscriptions. On looking into the matter, it appeared that the subscriptions were really as permanent a source of income as their invested capital and therefore he saw no reason why the change now proposed should not be adopted. He was also very sanguine that the alterations just made in giving a vote to each subscriber would introduce a large number of subscribers, and if he had the honour of sitting on the next Council he should be happy to support Mr. Robbins at the June meeting, in moving that a considerable addition be made to the number of annuitants in future.

It was then resolved unanimously that the Treasurer be requested to purchase £256 10s. 5d. consols, on account of the Benevolent Fund, making the total invested capital, £14,000.

Library, Museum, and Laboratory.

The report of this Committee was read, recommending the purchase of the following books:—

'Throat Hospital Pharmacopœia,' second edition; Bloxam's 'Laboratory Teaching,' second edition; Griffith's 'Chemistry of the Four Seasons,' second edition; Kay-Shuttleworth's 'Modern Chemistry,' second edition

Beasley's 'Book of Prescriptions,' fourth edition; Lescher's 'Elements of Pharmacy,' fourth edition; Carpenter's 'Microscope and its Revelations,' fifth edition; Rodwell's 'Notes on Natural Philosophy'; Muter's 'Key to Organic Materia Medica'; Wood's 'Year-book of Therapeutics, etc.,' 1872; Squire's 'Companion,' ninth edition (two copies).

Also that the following duplicates of books in the Library be purchased :—

Bentley's 'Botany'; Bloxam's 'Chemistry'; Cooley's 'Receipts'; Fownes's 'Chemistry'; Gmelin's 'Chemistry'; Garrod's 'Materia Medica'; Hofmann's 'Chemistry'; 'French Pharmacopœia'; 'German Pharmacopœia'; Proctor's 'Pharmacy'; Redwood's 'Supplement'; Royle's 'Materia Medica'; Ure's 'Dictionary'; Supplement to Watts' 'Dictionary.'

The Committee also gave a list of books to which they proposed an asterisk should be affixed in the catalogue, as indicating that they were not to be sent out from the library without special leave from the Committee.

The Committee reported that 500 copies of the new catalogue had been already circulated, and recommended that an additional 1000 be printed. They also recommended certain additions to the salaries of the officers on whom extra duties were thrown by the keeping open of the library in the evening.

The report and recommendations were received and adopted.

House.

The report of this Committee was read and adopted.

Parliamentary.

The report of this Committee was read and adopted. A letter from the solicitor was read, stating that he had not yet received the opinion of counsel on the points which had been referred to them.

Pharmaceutical Congress at St. Petersburg.

Mr. Greenish said the Secretary had just handed to him for translation a communication from the Secretary of the International Pharmaceutical Congress. In 1869 two gentlemen were deputed by the Society to attend the International Pharmaceutical Congress held in that year at Vienna, when it was determined that the next should take place at St. Petersburg in 1872. The letter now received stated that in consequence of the Franco-German war the meeting of the Congress had been deferred until August, 1874, and to assist in making arrangements for it, replies were requested to four questions on pharmaceutical subjects, one of which he did not quite understand without a more careful translation than he had yet been able to make. The replies were asked for before the 27th March next. He suggested that the subject be referred to a committee, when he would be prepared with a proper translation of the document. He was of opinion that it was most desirable that British pharmacy should be represented at the approaching Conference in St. Petersburg.

Mr. Williams thought this was hardly necessary, especially considering the length of the journey.

Mr. Greenish said the journey was not very difficult, and persons attending such conferences were able to travel on the Continent at half the usual railway fare.

Mr. Hampson quite agreed in the desirability of Great Britain being represented at the Congress. He had no doubt the gentlemen selected would be able to bring back some valuable information, and at any rate they would promote kind feeling and amicable relations, which were always desirable.

Mr. Urwick said he should rejoice to see any friendly ties established between British and continental pharmacists.

It was then resolved unanimously that the matter be referred to a committee, as suggested.

The Classified Register.

Mr. Shaw drew attention to the Register classified alphabetically according to places which was placed on the table last month by the Registrar, and said the question now arose what was to be done with it—whether it should be printed, or remain for reference. His own opinion was that it should be simply kept for reference, and that any local secretary who wished to have a copy of that part of the Register that referred to his own district should be supplied with a written copy from the office.

Mr. Hampson thought it was a question whether the Register should not be printed.

The Registrar said it would have to be altered all through before it could be printed, in consequence of the constant change of addresses going on.

Mr. Betty said this was a matter in which Mr. Atherton took a great deal of interest, and probably it would be better to let it stand over till next month, when most likely that gentleman would be present.

Mr. Radley said local secretaries had often felt the want of something of this kind, and he thought the information would be very useful to them; still, they were the only parties to whom it would be valuable, and therefore there seemed no necessity to go to the expense of printing it. It would be better to keep it in the office, and let each local secretary be furnished with such portion of the list as he required.

Mr. Mackay and Mr. Baynes also thought that a manuscript list would serve every necessary purpose.

The History of Pharmacy.

The Vice-President said, on referring to the minutes of the Council under date March 6th, 1872, he found a resolution to the effect that the historical sketch of the progress of pharmacy, by Mr. Jacob Bell, be reprinted, and that the then President, Professor Redwood, and Mr. Sandford be invited to undertake the continuation of the same to the present time. Unfortunately nothing had been done in this matter, but he thought the Council of 1872 were quite right in the view that, as thirty years had elapsed since the history of pharmacy had been published, it would be very desirable to have it completed and brought down to 1868, and it appeared to him that unless some steps were now taken to have this work completed it could never be done, because if they waited until the actors who had taken part in the proceedings of the Society during the last thirty years had passed away, the opportunity would be lost of getting information which never afterwards would be recovered. If they completed the history up to the time of the passing of the Act of 1868, they might then fairly look to the Year Book of the Pharmaceutical Conference to continue the work for the future. No one could be better fitted than the three gentlemen appointed in 1872 to complete this work, but he thought it would be expecting too much time and labour from any one of them to do it as a matter of independent work. It had therefore occurred to him and some others that if they wished to have it efficiently done they could not do better than apply to Dr. Redwood, the gentleman who was associated with Mr. Jacob Bell at the commencement of the Society, and with the Society ever since, and who, perhaps, had better means of getting assistance from outside than almost any other individual. He would, therefore, propose—

> "That Professor Redwood be invited to undertake the completion of the 'Historical Sketch of Pharmacy' up to the year ending 1869, and that a sum not exceeding one hundred guineas be paid to him for the work."

Mr. Baynes seconded the motion, which, after some conversation, was unanimously agreed to.

Additional Scholarships.

Mr. Schacht, in pursuance of a notice he had given, moved :—

> "That ten Scholarships be instituted, and be competed for at the same time and by the same process as the Jacob Bell Scholarships."

He said it must be taken for granted that it was a tolerably well-recognized duty of the Society to promote

the development of scientific pharmacy. This view had been specially adopted some time ago when an endeavour was made to arrange something like a system for more efficient education in the provinces. Certain suggestions had been made by which the funds of the Society could be utilized to that end, but from various causes they had practically fallen through, and very little as yet had been accomplished. The scheme which he had at one time ventured to suggest, from the discussion which it elicited, appeared rather to indicate that a feeling existed amongst those who took most interest in these matters that the operations of the Society should be directed rather to the encouragement of very high-class education in a few than to the cultivation and general development of it in many. That was a point which he should like to have fully discussed in order that something like a conclusion should be arrived at whether they should, as a Society, limit the assistance which they gave to the development of a high scientific standard amongst the few, or to enable the average mass to raise themselves to the standard required by law. The question appeared to him to run somewhat parallel to that which might be raised in connection with richer educational societies, of fellowships on the one hand and scholarships on the other; and, for himself, whilst one of the last to discourage fellowships, he still thought that in the present condition of scientific education amongst pharmacists such a system in their case would be like beginning at the wrong end. He had always had this idea present in his mind, that pharmacy was essentially an art, founded upon science undoubtedly, but still an art; and as it would seem to be a mistake for anybody anxious to acquire the perfect training of a seaman that he should devote all his energies to learning astronomy, while practical seamanship was the thing wanted—though of course that depended on the science of astronomy—so he thought, though it might be desirable that the two sciences of chemistry and botany should be cultivated, still pharmacy was a practical art rather than a science of pure chemistry or botany. This was the ground of his preference for the institution of scholarships which would enable young men, not so well placed as others for obtaining education, to enter the school, rather than having obtained men and passed them through the Examinations to give them bonuses to pursue their studies in the higher flights of science. This question perhaps would present itself somewhat differently if the students presenting themselves at the Examinations showed that they passed these tests very easily. But the facts were just the reverse—the statistics prepared by the Registrar showed that during the last year only 44 per cent. of the Minors were able to pass at all, and when it was remembered that only a moderate percentage of marks were required in order to enable a candidate to pass, this showed that only a very small percentage of those who come up were at all completely prepared for the ordeal. He had also taken some trouble to ascertain the proportion of those who passed in honours, and during the last year he found that they did not exceed 9 per cent. Now even this was not a very tremendous achievement, because a candidate who obtained only 65 per cent. of the possible marks would gain that distinction. It was therefore clear that the average candidates could not be looked upon as being placed upon a very high platform of cultivation. It was with the object of stimulating this class that he should propose the institution of some scholarships similar to those now existing, not simply because ten scholarships more would enable ten men to do something essentially good for themselves, but because these rewards would stimulate industry throughout the length and breadth of the land, and many might be encouraged to exert themselves more than at present, for every one person who would succeed there would be probably some 50 trying for it, which of course would result in very great gain to the individuals and consequently to the community. He had originally intended to propose that six additional scholarships should be instituted. It occurred to him that that number was scarcely sufficient, and he would therefore propose that ten should be the number. Of course the pecuniary point of view must not be lost sight of, but looking to the fact that they were now saving about £200 per annum on the educational portion of their establishment in that building, he thought they might even venture to establish ten scholarships, though he understood the expense would exceed £60 a year each; still he did not insist upon the particular number, and was willing to leave that blank, or to have the details modified or discussed in committee if desired.

Mr. STODDART seconded the motion. He said that although there might be only ten or twelve individuals directly benefited, still they would represent 1200 or 2000, all over the country, and he thought gentlemen in London had very little conception of how much many young men required coaxing in order to get them to apply themselves thoroughly to their studies. There were a certain number who would work well of their own accord, but the others required encouragement, such as these scholarships would afford. He had much pleasure, therefore, in supporting the proposition.

Mr. WILLIAMS said the expense of each scholarship was £62 12s. per annum. He viewed the proposal with a great deal of favour; but, at the same time, he thought it required consideration, particularly as to what would be the probable effect on the laboratory. The question occurred to him whether it would not prevent the entry of paying students by inducing men to compete for these scholarships who would otherwise attend as independent students. It would not be very desirable that they should give a better education to those who could not afford to pay anything than to those who could and did pay something for their own education. There was plenty of time yet to consider this matter, as it could not come into operation before next session; and he therefore suggested that it should be referred to a committee before a final decision was arrived at.

Mr. URWICK thought this suggestion a very good one, that it would tend to stimulate education throughout the country, and could not possibly injure the school; on the contrary, he thought it would benefit it.

Mr. MACKAY was very much pleased to find that the feeling of the Council seemed in favour of giving full consideration to this question. He understood that in establishing these scholarships a sum of money equal in each case to about £62 10*s.* would be required, rather more than half of which would go in fees to the professors, and the remainder be paid in cash to the student. But suppose that there were three successful candidates, one in the extreme part of England, another in the extreme part of Wales, and another in the extreme part of Scotland, it would be impossible for them to come to London and subsist on the £30 while they were taking the benefit of the lectures and classes. It therefore seemed quite possible that there might be many young men very deserving who would not be able to take advantage of the scholarship in that form. He thought, therefore, that the matter would require most deliberate and full consideration before it was finally decided upon.

Mr. SANDFORD suggested that the proposal should be referred to the Committee, saying he did so with the full desire to support the proposition.

Mr. URWICK suggested that the principle should be affirmed and the details left to the Committee.

Mr. MACKAY thought it better that it should go to the Committee first.

Mr. SCHACHT said he had omitted to draw a plain distinction, as he had intended, between this proposal and any which had formerly emanated from the Provincial Education Committee. He wished this to be regarded as a perfectly open question, neither metropolitan nor provincial.

The VICE-PRESIDENT said he quite went with Mr. Schacht, and to some extent farther, and he should like the Council to affirm the principle generally that it was

desirable that scholarships, similar in amount and character, be instituted, leaving it for the discussion of the Committee as to what should be the number of scholarships.

Mr. HAMPSON said there appeared a tolerably unanimous feeling in favour of the principle, and he thought they might decide upon that at once. He was sorry to say he was not very sanguine as to the great rush of successful students which would come upon their funds, and therefore he thought that even if ten scholarships were offered for competition they need be under no fear with regard to finding the necessary funds.

Mr. FRAZER said he felt some difficulty as to the words "similar in amount and character," as he was rather doubtful whether the examination was not at present rather too high, and whether it did not repel students.

It was then unanimously agreed to pass the resolution as follows, omitting the number of scholarships :—

"That scholarships be instituted and be competed for at the same time and by the same process as the Jacob Bell Scholarships."

It was then moved by Mr. SANDFORD, seconded by Mr. MACKAY, and resolved—

"That this Council refer the proposal to offer scholarships in addition to the Jacob Bell Memorial Scholarships to a committee, consisting of Messrs. Atherton, Betty, Hampson, Mackay, Sandford, Schacht, Shaw, Stoddart, and Williams."

Mr. SCHACHT said he should also be quite content to leave the second resolution, of which he had given notice, to the decision of the Committee, viz., "That in the conditions of eligibility for the Jacob Bell Scholarships the limit of age be altered from 21 years to 22."

THE CONVERSAZIONE.

It was resolved that the annual Conversazione be held on Wednesday, May 20th, and the Secretary was requested to write to the Lords of Committee of Council on Education, asking permission to use the South Kensington Museum on the evening of that day for such purpose.

PHARMACEUTICAL MEETING.

Wednesday, February 4, 1874.

MR. THOMAS HYDE HILLS, PRESIDENT, IN THE CHAIR.

The minutes of the previous meeting having been read, the following donations to the Library were announced, and the thanks of the Society were awarded to the donors :—

'Classified and Descriptive Catalogue of the Indian Department of the Vienna Universal Exhibition, 1873,' from the India Office, per Dr. Forbes Watson ; 'Year-Book of Pharmacy and Transactions of the British Pharmaceutical Conference, 1873,' from the Conference ; another copy, from Mr. Richard Bremridge ; 'Praxis Medica Boerhaaveana,' from Mr. L. J. Thompson.

NOTE ON IODIDE OF IRON.

The President then called upon Mr. W. Murton Holmes to read a "Note on Iodide of Iron." The paper is printed at p. 629, and gave rise to the following discussion :—

The PRESIDENT said this paper, though not very long, was important, for differences occasionally arose in making up prescriptions, and these little notes were very useful. He should be glad to see more such papers brought forward, because it was very important that mixtures and other preparations should be as nearly as possible uniform in their consistence and appearance.

Mr. WILLIAMS asked if he rightly understood Mr. Holmes that he found it advantageous to use an equivalent each of iron and iodine in making the solution.

Mr. HOLMES said he used an equivalent of iodine ; it did not much matter how much excess of iron you had.

The PRESIDENT remarked that even these little alterations ought not to be made unless with the knowledge of the medical man, but probably if these kind of papers were copied into medical journals physicians would see them, and very probably express their approval.

Mr. WILLIAMS said he had misunderstood Mr. Holmes' remark with regard to the equivalent of reduced iron. The reduced iron of the Pharmacopœia sometimes contained 50 per cent. of magnetic oxide, and therefore the equivalent of that would not answer the purpose intended. He did not quite see the advantage of using reduced iron over any other form of the metal.

Mr. HOLMES said it was more convenient.

Mr. RIMMINGTON asked if the precipitate would occur, supposing the iodide of iron and the iodide of potassium were perfectly neutral.

Professor ATTFIELD said in such a case he did not suppose it would. It seemed to him that the object of Mr. Holmes' paper was to suggest what could be done when the substance was not quite neutral. The paper was interesting in itself, and also suggested two important points—first, as to how far a dispenser was justified in departing from a prescription, and introducing something else to prevent some unpleasant appearance or effect. With regard to that point it should be understood, that in prescribing such a solution as iodide of potassium the prescriber probably believed he was prescribing iodide of potassium only, and not that salt containing free alkali. If the iodide of potassium contained alkaline matter, then it seemed to him that the chemist, in virtue of his knowledge of chemistry, was justified in producing a neutral article such as was intended, and in doing so to the best of his ability. The remarks of Mr. Holmes illustrated, secondly, a matter which was one of general principle, and as such was recognized in Chemistry, viz., that it was much easier to prevent the deposition of precipitates by the addition in the first place of the substances in which they were soluble than to redissolve the precipitate after it had been precipitated. This was a principle which often applied in Pharmacy. Hydrate of iron was only one of a multitude of inorganic substances which were soluble in solutions of such organic substances as sugar and in solutions of inorganic salts.

Mr. RIMMINGTON remarked that on the subject of the legitimacy of adding anything to a prescription, it appeared to him that chemists might be justified in correcting an error. By way of an illustration, this iodide of potassium and iodide of iron could not be perfectly correct, the precipitate being the result of an error ; therefore the correcting of the error fell within the domain of the chemist, and he would be justified in correcting it, as he would thus be carrying out rather than altering the intention of the physician. It was his intention, no doubt, that the thing should be all right, but as the ingredients might be slightly wrong the dispenser should correct them.

Professor REDWOOD remarked that with reference to this question they should consider not abstractedly what iodide of potassium was chemically, but what it was as ordered by medical men; and the Pharmacopœia recognized that iodide of potassium in practice might contain, what as a rule it did, with very rare exceptions contain, a little excess of alkali; therefore, the case should be treated as a practical one. If there were means of producing readily iodide of potassium perfectly free from the presence of alkali, without incurring too great a cost, the case would be different, and the formation of a precipitate would indicate a defect in one of the ingredients used. Mr. Williams would be able probably to enlighten them as to whether it were possible to rely on obtaining iodide of potassium perfectly neutral. Methods had been suggested from time to time for so making it, but it was not generally met with in commerce, nor would the process given in the Pharmacopœia insure its perfect purity. It therefore appeared to him that there could be no error in using it as recognized, and that they might naturally expect on the addition of iodide of iron that there should be a slight precipitate. The question as to whether that might be prevented by the addition

of some ingredient other than that prescribed was a more serious and important question. He did not think it would be safe to recognize the use of any substance of that description, although it might be very well to suggest such an addition to medical men, so that they might, if they thought fit, order the iodide of potassium to be first neutralized with a little acid.

Mr. WILLIAMS said it was perfectly true that the iodide of potassium of commerce was alkaline. It was possible to make it neutral, but the difficulty and expense of doing so practically prevented it. It seemed to him that a medical man who ordered iodide of potassium and iodide of iron supposed he was ordering a neutralized iodide of potassium, and not that he was ordering an incompatible. The question really was whether it was right to add some little ingredient by which that which was theoretically compatible, but practically was not, might be rendered compatible. He could not see any objection to the addition of a little mild acid, to bring the iodide of potassium into that neutral condition in which it would no longer precipitate the iodide of iron. He did not believe that any medical man in ordering that prescription intended that there should be a precipitate of iron or basic iodide of iron, and that really pharmacists might be excused, and even praised, for going out of their way a little and remedying such slight defects as must occur with ordinary commercial and medicinal iodide of potassium. This salt very frequently contained sulphate of potassium, or even chloride of potassium, which was still more injurious. Carbonate must also almost of necessity exist in it.

Professor REDWOOD said one thing must be borne in mind, namely, that there might be some very conscientious pharmacist who would not like to make any addition to the prescription, and accordingly there would be a slight precipitate; then the same prescription might be taken to another dispenser who by a little modification might prevent this, and thus the first man, simply on account of his conscientious action, would be blamed for having used something improper.

The PRESIDENT said that was why, in his opinion, chemists should go to the prescriber and get his approval of the modification.

Mr. RIMMINGTON asked whether anyone had tried the formula given in the PHARMACEUTICAL JOURNAL a month or two ago for tasteless syrup of iodide of iron; if not, he should recommend it to their notice: it was very nearly tasteless, and made an excellent and permanent syrup.

Mr. WILLIAMS said he had tried it, and liked it very much, but he understood it was patented, and this of course prevented its general use. It was very remarkable to find that iodide of iron and chloride of iron when combined with citrate of potassium formed a double salt that was almost tasteless; it was a beautiful compound, and ought really to become a recognized compound in Pharmacy. He believed it would be found as efficacious medicinally as any other, and it quite got rid of the nauseous qualities of the original compound. He did not think the qualities of citrate of potash and citrate of soda were yet appreciated, or the power of that wonderful acid, the citric, in disguising nauseous medicines. The new compound, citrate of bismuth, was, he believed, very valuable, and there were many other salts in which citric acid would play an important part. He understood, however, that with regard to the compound of citrate of potassium with iodide of iron and chloride of iron, the compound was patented, and therefore he could say no more about it.

The PRESIDENT suggested that if this compound were not patented, Professor Redwood might succeed in including it in the proposed additions to the Pharmacopœia.

Professor ATTFIELD, referring to the remark of Professor Redwood about a conscientious dispenser who would not depart from his prescription, drew attention to the Pharmacopœia, in which the conscientious reader would find after the words "Potassii Iodidi," KI. If this formula were regarded as the definition of iodide of potassium, the salt should contain nothing but potassium and iodine; but if it had "a feeble alkaline reaction," that property would show that it contained something beyond K and I, and the intelligent dispenser would consider what he should add to rectify alkalinity. He might hesitate between hydriodic acid, citric acid, or other acid; but if he had a conscientious desire to make the compound neutral, he would add an acid of some kind. The speaker thought that what should guide them in discussing this point was that most medical practitioners regarded iodide of potassium as a neutral salt, and he therefore considered that a chemist would be right in making its solution neutral whenever, from his knowledge of chemistry, he foresaw that alkalinity would be objectionable.

Professor REDWOOD thought that any one who attempted to interpret the Pharmacopœia in that way would very soon get into serious difficulties.

Mr. MARTINDALE asked if it would be competent to a dispenser to neutralize the spirit of nitrous ether when prescribed with iodide of potassium by correcting the acidity. It occurred to him that in case discoloration took place one would be fully justified in correcting the acidity of spirit of nitrous ether by a small quantity of liquor potassæ. Iodide of potassium varied a great deal in the quantity of free alkali it contained, but he thought it would be found practically, that if one drachm could be neutralized with one drop of dilute nitric acid, it was pure enough for practical dispensing, but when the alkali existed in a larger quantity than that it should be considered an impurity. He would suggest to Professor Redwood that the quantity of alkali allowable should be indicated in the Pharmacopœia, in order to prevent the use of that which sometimes came into the market, and which contained a considerable excess of free alkali.

Mr. BLAND said he had observed that commercial iodide of potassium was invariably alkaline; but neither Professor Redwood nor Mr. Williams had given the reason why that was the case. He did not think it depended so much on the difficulty of making a neutral salt as upon this fact, that when perfectly pure it could not be kept for any length of time. An immediate decomposition took place; iodine was set free, and some portion of iodate of potash was also formed. Another reason why pure iodide of potassium was not sent out was the difficulty of getting it in large and well-defined crystals. In the presence of an eminent manufacturer he spoke with diffidence; but he believed there was difficulty in getting large-sized crystals when the salt was perfectly neutral. Not only was this the case with iodide of potassium, but with many other salts which, when perfectly pure, did not readily form large, well-defined crystals. He believed the presence of a small amount of carbonate of potassium assisted in the formation of perfect cubes, and also tended to preserve it from that spontaneous decomposition which took place with the perfectly pure salt.

Mr. WILLIAMS said it was quite true that if the solution were perfectly pure you, as a rule, got bad and ill-formed crystals, which the public would not have. In fact, it seemed to be the rule that the more impure the solution the better the crystals. Probably the presence of impurities prevented the particles coming together so rapidly, and so made them arrange themselves more regularly when they did come together. It often happened that if some residual liquor were put aside as worthless, perhaps for some months, it would be found on examination to have deposited magnificent crystals. Pure bromide of potassium seemed always to crystallize badly.

Mr. RIMMINGTON, though not disputing the truth of what had been said, mentioned as a fact that some years ago Messrs. Southall of Birmingham used to make pure iodide of potassium almost transparent, and with beautiful crystals, the largest he had ever seen. It always seemed moist also. There might be great difficulty in the process, and he believed the manufacture had been almost given up; they certainly charged 3*s.* or 4*s.* a lb. extra for it.

Professor REDWOOD said they had formerly had some specimens of iodide of potassium in the state just described, very transparent and beautiful, but all he had ever seen of that description were alkaline; indeed, according to his experience, the more transparent the crystals the more strongly alkaline were they. Some years ago the Rev. Mr. Read took great pains to indicate a method of producing perfectly neutral iodide of potassium, but he always found that when in that state it rapidly acquired a slight yellow colour. The presence of a little free alkali appeared to prevent the decomposition. He could quite confirm what had been said as to the difficulty of forming large crystals from pure solutions. He had taken great pains for some years to get large crystals of pure carbonate of soda, but without success. Some years ago there was a specimen in the museum, which was unfortunately thrown away, ignorantly, and because it was rather unsightly, which had been very carefully prepared by Messrs. Howard, of Stratford, and was absolutely pure, to illustrate the fact that this salt could not be obtained in well-formed crystals from a pure solution. The presence of a little sulphate of soda appeared to greatly facilitate the crystallization of the carbonate, and probably other salts present in a solution of iodide of potassium produced a similar effect.

The PRESIDENT said it was very important that preparations of a definite character should always have the same appearance and strength, but he considered it also of importance that in such cases as the one they had been discussing the dispenser should see the physician and obtain his approval of the modification which was proposed to be made; and this would probably lead to the prescription being differently written in future. He was sorry to say that no other papers had been prepared for that evening, and ventured to hope that all members would take to heart the admonition which had recently appeared in the *Journal*, and use a little more diligence in this direction. To those persons, however, who did not come to the meetings, because they did not see papers advertised, he would say that during the last 33 years he had not missed more than six meetings, and had never failed to gain some useful information by coming.

THE ADDENDUM TO THE PHARMACOPŒIA.—LARCH BARK AND ARECA NUT.

Professor BENTLEY wished to ask a question of his colleague, Dr. Redwood, in his official capacity as Editor of the 'British Pharmacopœia,' as to the forthcoming 'Additions,' as he understood they were to be called, of that volume, and he hoped that Dr. Redwood would feel himself at liberty to answer it. He had heard on good authority that two new substances were to be added; and, if this were so, it seemed desirable that pharmacists should be made aware of it, in order that they might be prepared to introduce them when called for. Seeing the high position and reputation of the members of the Medical Council engaged in bringing out the 'Pharmacopœia,' he was quite prepared to believe that they had made repeated trials of these substances before recommending their introduction into the national 'Pharmacopœia.' They were *Larch bark* and *Areca nut*. The former had long been used as a tanning material, but he did not remember that it had been specially recommended for use in medicine until about ten years ago, when a paper by Dr. Greenhow appeared in the *British Medical Journal* on the value of tincture of larch bark in checking profuse perspiration and in certain bronchial affections; and he believed it had been used for some time in Ireland in similar cases. He should be glad to know if pharmacists had known it prescribed, and to what extent. On the table were samples both of the fresh bark and also of some which had been sent from Ireland, where it was often used, and was described as the inner bark. He should rather describe it, however, as the bark divested of its outer layer. With regard to the areca or betel-nut, it had been well known in this country for some time, particularly in the form of betel nut charcoal, and it was largely used in the preparation of the kind of catechu known as Ceylon catechu, which was formerly official in the 'Edinburgh Pharmacopœia.' He understood it was going to be introduced for its anthelmintic properties. Areca nut, had been used as a vermifuge from the earliest times, and was a popular remedy in India. It was rather remarkable, if it possessed well marked anthelmintic properties, that it had not received special notice to that effect in the Pharmacopœia of India, but in this volume it was slightingly spoken of. He understood, however, that some members of the Medical Committee had tried it, and found it to be one of the most useful remedies for tapeworm. He should be glad, therefore, to know if it were true that these two substances which he had named were coming into the 'Pharmacopœia.'

Professor REDWOOD said he saw no reason why he should not state that it had been suggested that these articles should be added to the Materia Medica. The supplement or addendum had been in type for some time, and it would be remembered he had brought the subject generally under the notice of the Society, in order to obtain their advice with reference to several articles which were proposed to be introduced. It had been in circulation amongst the members of the Medical Council for some time past, and they had been seeking information among their friends, pharmaceutical and otherwise, in different parts of the country. Certain modifications had been made, and certain substances which had been suggested were now put into form, and amongst others those which had been mentioned by Professor Bentley. It was to be hoped that the work would soon now be circulated. There had been much more delay than had been at first anticipated, but this had arisen from the fact that the members of the Medical Council wished to have the proposals in their hand, in order that they might judge for themselves, and obtain such information as they could before giving their sanction to them. He understood that the larch bark had been in somewhat extensive use in Ireland for some time, and had been found very efficacious in cases such as those mentioned when administered as a tincture, the formula being one part of bark to eight of rectified spirit, and the dose from 20 to 40 minims. The areca nut was administered in the form of a powder, as an anthelmintic, and there were some eminent members of the Medical Council who considered it the most valuable yet known at the present time for the expulsion of tape-worm. It was administered in somewhat large doses, viz., four to six drachms of powder mixed in milk.

Mr. MACKAY said that as far back as 30 years ago he was applied to by an eminent medical man in Edinburgh to prepare tincture of larch bark, which was used by him entirely as an astringent, and, according to him, with great success. It so happened that he had used the very proportions just mentioned by Dr. Redwood, viz., 2 ozs. of the bark to a pint of rectified spirit. At that time the bark was not to be got as an ordinary drug in the London market, and he had to cast about to see where he could get it. It so happened that he was acquainted with an extensive landed proprietor in Ayrshire, to whom he applied, and he accordingly gave instructions to his head forester to strip the bark at the proper time. The time came, and so did the bark; and had it been stripped properly it would have been enough probably to have supplied the whole of Great Britain for a very considerable time, but unfortunately there was a large proportion of woody fibre mixed with it, and a kind of excrescence on the outer bark, so that it was found nearly useless However, after stripping the woody fibre and the outside, he was about to make use of the middle bark, and since then, as the demand for the tincture still continued, he had been able to get excellent supplies in the neighbourhood of Edinburgh. As far as he knew, no other preparation but the tincture was made use of, but he found that other pharmacists besides himself were in the habit of preparing in Edinburgh, and therefore he was not at all surprised

to hear that it was likely to take its place in the next Pharmacopœia. As to the areca nut he could not say very much, and did not know that it had been used in medical practice in Edinburgh, though for many years it had been considered perhaps the best of all anthelmintics for greyhounds and other valuable dogs. Consequently he should not be surprised if it were found a valuable addition to the Pharmacopœia.

Professor ATTFIELD asked if there were likely to be any directions given as to the degree of fineness of the areca nut powder. It was well known that pharmacists in America were directed in the United States Pharmacopœia to sift their powders through special sieves, the size of which were mentioned. He asked this question because he believed that some persons considered that the activity of areca nut powder was partially mechanical, depending, in short, in some degree upon the size of the particles.

Professor REDWOOD was not aware of any intention to indicate the fineness of the areca nut powder, any more than that of rhubarb or jalap. It was well known that the preparation of medicinal powders was carried out much more systematically now than formerly, when most retail establishments prepared their own powders, and at a comparatively recent period he had known some London druggists make and sell powdered rhubarb in a state which any pharmacist now would consider quite unfit for use in medicine. Some pharmacists, particularly in Paris, laid great stress on the very minute division of substances administered as powders, and now-a-days, as a rule, they were reduced to the finest state of division. To this was owing the smooth, glossy appearance of powdered rhubarb. Although he was open to conviction upon this point, he did not think they could with advantage indicate the degree of fineness to which powders should be reduced, though such a thing might be useful where substances were directed to be reduced for the purpose of making tinctures, or anything of that kind.

Mr. URWICK said he had tried the areca nut powder on pointer dogs, and had found it of no effect when in very fine powder, but when administered in a coarse powder it proved effectual. It therefore appeared to depend for its effect partly on its mechanical action.

Mr. UMNEY said the powder of areca nut, as generally put up by grinders, would pass through a sieve having about 140 meshes per lineal inch, whereas powdered rhubarb would pass through a sieve of about 180 or 190 divisions, being the finest sieve made. Powders varied very much in their state of division ; thus, powdered caraway would scarcely pass through a sieve much finer than 60 meshes per inch, whereas jalap and rhubarb easily passed through one of double the fineness.

Mr. HASELDEN said he remembered an article which appeared in the Journal some years ago on larch bark, in which a form was given for preparing the tincture. It came, he believed, from Ireland, and for some time past he had been in the habit of making a tincture of larch bark for an Irish gentleman who came to England every year, and to whom it was prescribed, he believed, for dysentery. He had not experienced any difficulty in getting the bark. Areca nut he had known used for some time in several ways—in the first place as a tooth-powder, either pure or mixed with other powders ; and also in the shape of charcoal, though he could not undertake to say whether all the charcoal sold under that name was really made from the areca nut. He had also known it used for some years past as one of the best vermifuges for dogs, but had never known it prescribed for human patients ; probably the action would depend to some extent on the state of the powder. The adulteration of ipecacuanha powder had recently been noticed in the Journal, and he thought that the whole subject of powders and their adulterations might well be treated in a paper at another meeting, and hoped some one would take it up. He was not prepared to say that every druggist ought to grind his own powders, but he should certainly advise them to do so when practicable.

Mr. GREENISH said on reading the article to which reference had been made, on ipecacuanha powder, he had immediately sent for a sample, and had been examining it for the last two or three weeks ; he hoped to have a paper on the subject for the next meeting.

Mr. COLLINS thought it was open to considerable doubt whether the so-called extract of areca catechu was really produced from that plant at all. He did not mean that the plant did not produce any catechu ; but that which was known under that name to chemists always had rice husks about it, and did not seem to be produced from the areca. Dr. de Vrij had lately asked him this very question, and said he was not at all certain about it himself. He should therefore like to know whether any one had seen what might be termed a critical specimen, for these commercial samples certainly appeared very doubtful. He thought probably it was ordinary acacia catechu.

Professor BENTLEY, in answer to a question, said there would be no difficulty in getting larch bark ; but it was important that the British Pharmacopœia should clearly define what portion of the bark was to be used. With regard to the areca nut, he believed it was noticed in 'Braithwaite's Retrospect,' of 1864, and also in some papers in the *British Medical Journal* 10 or 11 years ago, where its anthelmintic properties were especially referred to. With reference to Mr. Collins' question, he had never examined the areca nut catechu minutely, but judging from casual observation he should say the probability was that it was the extract of areca nut. It had not the character of acacia catechu, for the fracture of this latter always presented a shining appearance, whilst the former had an opaque, rough appearance.

Mr. CANDY said larch bark appeared to be intended for employment on account of its astringent properties in checking perspiration or discharge, bronchial ailments, or dysentery. Presumably its stringency was due to the presence of tannin, and this therefore seemed to be a step in the opposite direction to what had been sometimes advanced, namely, the employment of active principles instead of crude substances. It seemed that the active principles were not always so useful as the crude substances, or there would be no necessity for introducing this article.

Provincial Transactions.

GLASGOW CHEMISTS' ASSOCIATION.

The Annual Festival of the Glasgow Chemists and Druggists, held under the auspices of the above association, was held in the Crown Hall, on Thursday evening, 29th January. Mr. John Currie, President, in the Chair.

The Chairman was supported on the platform by the following gentlemen :—Drs. A. M. Robertson, R. C. Moffat, and J. S. Nairne ; Messrs. Young, Gilmore, Mackay, Ainslie and Taite (Edin.), Kinninmont, Davison, (Ex Pres.) Clarke (Sec.), J. L. Hatrich, Fairlie, Galbraith, etc.

After tea the Chairman gave an address in which he alluded to the work that had been done during the session that was drawing to a close. He also referred to the "Assistants Branch" and stated that several excellent papers had been given by some of its members in competition for a prize offered by a gentleman connected with the drug trade.

A Concert followed, at the conclusion of which Mr. Alex. Kinninmont, in an admirable short speech, moved a vote of thanks to the strangers from Edinburgh.

Mr. Young (President of the North British Branch of the Pharmaceutical Society) responded. Dr. R. C. Moffat then proposed a vote of thanks to those who had taken part in the concert, which was carried.

A vote of thanks was then proposed to the Committee who had got up the evening's Entertainment by Mr. Gilmore, (Edin.) replied to by Mr. Clarke (Sec.), after which Mr. Taite (Edin.) moved a vote of thanks to the Chairman,

which was carried by acclamation. The Chairman suitably replied. At the conclusion of a short speech by Mr. Mackay the company parted, after singing "Auld Lang Syne."

An assembly afterwards took place.

LEICESTER CHEMISTS' ASSISTANTS' AND APPRENTICES' ASSOCIATION.

The half-yearly meeting of the members of the above Association, was held at the rooms, Halford Street, on Tuesday the 3rd inst. Mr. Wright, President in the chair. There was a large attendance. In opening the meeting, the President reviewed the work of the past session and congratulated the members upon the success that has attended the association, which has now reached its tenth session. The Hon. Sec. then read the following report. During the past half-year the attendance of the members at the meetings of the Socicty has been satisfactory. Fifty-five classes have been held, and three Lectures on scientific subjects have been delivered, by Messrs. W. J. Harrison, J. E. Weatherhead, and F. T. Mott, and the committee desired to express their thanks to those gentlemen for their kind services.

The arrangement of the specimens in the Materia Medica and Chemical Cabinet is now nearly complete, and the committee feel greatly indebted to the following firms for their liberal gifts towards furnishing it. Messrs. Barron, Squire and Co.; Cox, Gould and Co.; Maw, Son, and Thompson; Howard and Sons; and Wright, Sellers and Layman, (London); Messrs. Southall, Son and Dymond; (Birmingham); and Messrs. Richardson and Co. (Leicester).

Very extensive improvements have been effected in the Laboratory, a substantial working bench having been erected, and a most suitable set of bottles having been presented to the association by Messrs. Kilner Brothers of London. Ordinary experimental and analytical work can now be carried on. The Library has been increased during the past session by the purchase of Proctor's Practical Pharmacy, and by the presentation of a valuable series of the Pharmaceutical Journals, extending over a period of twenty-two years. Three members have passed the Minor and Modified examinations, during the last session. The total number of members has been thirty-four. Votes of thanks were then passed to the class teachers, Messrs. W. B. Clark, P.C.; T. Wright, P.C.; S. H. Cadoux, A.P.S.; C. B. Lomas, A.P.S., and P. Princep, A.P.S., to Mr. Cadoux who had undertaken the arrangement of the specimens in the materia medica and chemical cabinet, and to Messrs. Bishop and Shakespeare, who had superintended the fitting up of the laboratory.

A ballot was then taken for the new committee and officers which were elected as follows: T. Wright, P.C., President; S. H. Cadoux, A.P.S., Vice-President; Miller, A.P.S., Treasurer; E. J. Bishop, Hon. Secretary; E. H. Butler, A.P.S.; A. Shakespeare, and T. H. Lomas.

The meeting was then adjourned until Tuesday the 10th, inst., when the Treasurer's report will be laid before the meeting, and an inaugural address delivered hy the President.

Review.

VIENNA UNIVERSAL EXHIBITION 1873: A CLASSIFIED AND DESCRIPTIVE CATALOGUE OF THE INDIAN DEPARTMENT. By J. FORBES WATSON, M.A., M.D., etc., etc. London: W. H. Allen and Co.

Catalogues of the several departments of the Great International Exhibitions, it is well known, are of two classes; some of them are really worth a place in every reference library, while others are scarcely worth the paper upon which they are printed. Anyone acquainted with the London Exhibitions of 1851 and 1862, or of the Paris Exhibitions of 1855 and 1867, must be perfectly cognizant of this fact. Some of the catalogues and reports of these Exhibitions were very carefully prepared by competent writers, and so will stand as authoritative books on the several subjects. The catalogue, the title of which stands at the head of this notice, is one of the best we have ever seen. It treats in one volume of 246 pages of the resources and manufactures of our great Eastern Empire. The contents of the book are classified under the respective heads of mineral, vegetable, and animal substances, chemical and pharmaceutical preparations, food substances, textile materials, etc. In a long list of specimens illustrating the mineral wealth of the Empire, under the head of coal we read that "The coal trade in India is becoming of greater importance. The amount raised had increased between the years 1858 and 1868 from 220,082 tons to 484,642 tons, or considerably more than doubled. The mines are gradually being extended, and worked in a better manner than formerly, and the coal is sent to market in a better state." As an example of the care bestowed in the production of this catalogue, we may mention that to each kind of coal enumerated is appended a careful analysis, made in the laboratory of the Geological Survey.

Of salt, it seems that two varieties are produced and used in India, "One is produced by evaporation of the water of brine springs, salt lakes, and of the sea, and so artificially crystallized; the other, native rock salt, which is worked in several places, but most largely in the Salt Range, Punjab, and across the River Indus in the Kohat district. There is also a large amount of salt imported from Great Britain, and used chiefly in the neighbourhood of the port towns."

Food-grains, and pulse come in for a good share of attention. Wheat, of course, figures first, the extreme limit of which is stated to be at an altitude of between 13,000 and 15,000 feet. The natives themselves do not use the grain to any great extent, the bulk being disposed of by sale. The flour is mixed with that of some kind of pulse, and in this form is used for cakes or bread. The seeds of *Coix lachryma*, known as Job's tears, are used as food in China and Malacca, under the name of Eejin or Ee-yin. "It is," we are told, "the most remarkable among food grains for its chemical composition. Dr. Smith writes that 'it is larger and coarser than pearl barley, but it is equally good for making gruel. As it is sold for fivepence per Chinese pound, it makes an excellent diet-drink for hospital patients in China.' Dr. Hooker observes that 'a great deal of *Coix* is cultivated in the Khasia hills; the shell of the cultivated sort is soft and the kernel is sweet, whereas the wild *Coix* is so hard that it cannot be broken by the teeth; each plant branches two or three times from the base, and from seven to nine plants grow in each square yard of soil; the produce is small, not above 30 or 40 fold.' In Mason's Burmah it is stated that a species of *Coix*, with large esculent seeds, which are parched like Indian corn, are often for sale in the bazaars, and are cultivated very extensively by the Red Karens." Here is also an interesting note on the chickling vetch (*Lathyrus sativus*), which is used as food in many parts of India. "It will be remembered that Duvernoy ascribed such pernicious qualities to this pulse, as causing rigidity of the limbs, delirium, and other dreadful effects to such an extent that the Duke of Wurtemberg in 1671 prohibited its use by edict, which was confirmed by his successors. In the recent Pharmacopœia of India, attention was called to this plant in a special note, because 'the continued use of its seeds as an article of diet is apt, under certain circumstances to induce paralysis of the lower extremities. In one district in Bengal nearly 4 per cent. of the population were sufferers from it.'"

Under the somewhat lengthy head of "Pharmaceutical Preparations, Ethereal Oils, Perfumeries, Drugs, and other raw products for pharmacy and chemical industry," we have much valuable information on these points. The notes on the culture of the rose at Ghazeepore and of the

manufacture of attar and rose-water is so interesting that we reprint it entire in another column.

A lengthy list of indigenous drugs of India attracts our attention as we find in parallel columns the scientific name of the product, the provincial name, officinal part, physiological action, and finally the retail price of the article in the Calcutta bazaar.

We take for instance as example *Agathotes chirayta*, provincial name, Chireta; officinal part, whole plant; physiological action, bitter tonic. Price at place of production 8 annas per pound. Space will not allow us to notice these products at greater length, nor can we but direct attention to the sections including vegetable and animal oils and fats, dye stuffs and food substances. We have preferred to give a general view of the contents of the volume rather than to dwell entirely on that part with which we as pharmacists are most interested. The book throughout is well printed and we cannot say more in recommendation of it than to advise our readers to obtain a copy.

Obituary.

Notice has been received of the death of the following:—

On the 20th December, 1873, Mr. Edward Gould, Chemist and Druggist, of Moorgate Street, London.

On the 8th January, 1874, Mr. William Palmer Barrow, Chemist and Druggist, of Ipswich.

On the 26th January, 1874, Mr. Thomas Wilson Wigglesworth, Chemist and Druggist, of Sleaford. Mr. Wigglesworth had been a Member of the Pharmaceutical Society since 1869.

On the 28th January, 1874, Mrs. Mary Buckley, Chemist and Druggist, of Lees, near Manchester.

On the 29th January, 1874, at 2, Ockendon Road, Kingsland, Mr. James Mason, aged 34; for some years Manager in the Laboratory of Davy, Yates and Routledge, by whom he was much respected. Mr. Mason was formerly assistant to Dr. Redwood, of the Pharmaceutical Society.

Chemists' Assistants.

Sir,—Little as I wish to trespass on your valuable space, I still cannot allow "Hyde Park's" letter to pass without protesting against any such construction as he puts upon my letter, or those of the gentlemen who have preceded me. He is going far too much ahead of us or any of our declarations. I do not think any of us (assistants) ever advocated such views as "Hyde Park" imputes to us; we have been always the first to disclaim them.

"Hyde Park" evidently thinks we are going in for "trades-unionism," "coercion," "intimidation," etc.

The question raised is not entirely one of money, but also of time. How many hours do we spend behind the counter fishing for catchpennies, after respectable tradesmen and their assistants of other denominations have finished business, and thrown "dull care" to the winds.

As a rule, employers do not feel these extra hours; it is the poor assistant who has to answer the call of everyone that has a penny to spend.

As a class, we have been duly lectured and somewhat abused for not taking advantage of our opportunities (?) and spending our evenings (?) in study. But it must be remembered that ours is an occupation calling not only for bodily labour, but also for the continued exercise of the mental faculties. It is a labour of both body and mind, both of which at the end (?) of the day's business need rest rather than increased exertion; it therefore cannot be much wondered at that, at the first moment of freedom, the tendency is to get into the fresh air, and as far as possible from the smell of the physic.

I think it behoves us assistants to join together and ask our employers as a body, whether they will do anything towards shortening our hours of labour, and give us that opportunity for acquiring knowledge, the loss of which we deplore more than themselves. I am sorry to say that some of the best (historical) houses, who should be a bright example to their weaker brethren, are going backward and lengthening shop hours.

Should a Chemists' Assistants' Association be formed, and be successful in moderating these excessive hours, one of its first objects would be the establishment of a course of evening lectures, which would enable assistants to utilize their extra time and pass the necessary examinations; and which would, moreover, tend to repress those systems of "cramming" so much abroad, and to which this Journal so fully testifies.

"Hyde Park" says that assistants' salaries have materially improved, while the corresponding improvement has not taken place in employers' emoluments. I, however, venture to say (from my own and the experience of others, older and more fully acquainted with business than myself), that this is not a matter quite beyond dispute. However, admitting it for the nonce, I think it is in great measure due to the want of better relations, and the great estrangement which has all along existed between employers.

If "Hyde Park" can suggest any means for bettering the condition of assistants, he will earn the gratitude of the whole body, and they will be only too willing to aid him in carrying out any plans for the benefit of their employers.

PHARMACIST.

London, Feb. 4th, 1874.

The Society's Museum.

Sir,—As the Council have been kind enough to allow the library to be opened in the evening, might not the experiment also be tried with the museum. I have no doubt there are several men in the same position as myself—occupied all day—who would gladly avail themselves of the opportunity of using the museum after business hours. Leaving this in the hands of those who are better able to judge than myself, I am, etc.,

AN ARDENT STUDENT

T. T. C.—The preparation you inquire about is advertised as a proprietary article.

S. C.—The statement you refer to was quoted from the by-law which you will find on p. 943 of the present volume of this Journal.

H. McCallum.—Your communication respecting the addressing of your Journal has been handed to the Secretary.

E. B. Starkey.—Your wish shall be complied with.

N.—Such an addition would be a departure from the instructions of the Pharmacopœia.

"West."—We have never while making the preparation observed the formation of such a precipitate as you describe.

"Hydrocarbon."—(1) The liquids could be separated by fractional distillation, but the result would not be worth the trouble. (2) There would be no difference in the subscription; simply communicate your wish to the Secretary.

W. K. F.—The powder is rather darker than we should have expected it would be, but it is difficult to pronounce without careful examination. We should recommend you to submit it to a practical microscopist.

J. E. M.—The effervescence will be due to the carbonic acid evolved from the bicarbonate of potash, by the acidity of the subnitrate of bismuth. It is not possible to free the subnitrate from this acidity entirely without decomposing it, but in your case there seems to have been more present in it than there ought to have been. We advise you to test it.

COMMUNICATIONS, LETTERS, etc., have been received from T. W. White, J. E. Howard, Bolton, W. Smith, "Inquirer," A. L.

NOTE ON ARECA NUT.

BY CHARLES ANDREWS, M.P.S.

A question having arisen at the last Evening Meeting of the Pharmaceutical Society respecting the anthelmintic virtues of areca nut, and the degree of fineness to which it should be powdered, I am induced to state my experience as to the method of using the nut in India, acquired during a residence in the Bombay Presidency, where I have frequently known it to be used by the natives with very good effect as an anthelmintic.

The natives pick it off the tree, and *grate* it on an ordinary nutmeg grater. About a teaspoonful is administered, after the patient has fasted twelve to fourteen hours, either made up into a bolus with ghee (clarified butter) or floating on milk, the latter being the favourite method. It generally acts (without any other medicine being given) in about an hour after administration, and is efficacious for round as well as tape worms. It is used both for the human subject and dogs in the same manner and dose.

My opinion is that it is much more useful given *grated* than in a *fine* powder.

A celebrated "dog powder," which is largely sold, I believe to consist of nothing but this areca-nut powder.

CONTRIBUTIONS TO OUR KNOWLEDGE OF THE CINCHONA ALKALOIDS.*

BY O. HESSE.

Hager states in his commentary on the German Pharmacopœia that sulphate of quinine usually contains appreciable traces of sulphate of cinchonine, which the manufacturer does not attempt to remove. This statement is, however, contrary to my experience, according to which the sulphate of quinine produced under my superintendence in the manufactory of Messrs. Jobst, in Stuttgart, as well as that from some other German manufactories, which I tested in consequence of Hager's statement, is absolutely free from cinchonine sulphate.

Hager affirms that he detected the so-called cinchonine sulphate by means of pure chloroform. As I doubted the accuracy of this observation, on the forementioned grounds, I believed that I should be able to throw light on the matter by examining chloroform with reference to its power of dissolving the principal cinchona alkaloids. In this way I have ascertained that pure chloroform is an excellent separatant of the sulphates of these alkaloids, some being easily soluble in it, whereas others are difficultly soluble.

According to my experiments, the following are the quantities of chloroform (1·492) required to dissolve 1 part of anhydrous sulphates of

	Quinine.	Cinchonidine.	Conchinine.	Cinchonine.
At 61-62° C.	196	300	9	22·4 parts.
At 15° C.	about 1000	about 1000	19·5	60 „

On evaporation of the chloroform solution of these salts at a gentle heat, the quinine and cinchonidine sulphates remain behind in crystals, whilst the conchinine and cinchonine sulphates are obtained as a transparent amorphous mass.

If, therefore, quinine sulphate (one gramme) when agitated with pure chloroform (15 c. c.) gives a solution which on evaporation leaves a transparent amorphous residue, it follows that conchinine or cinchonine sulphate is present. If these salts are not present the residue of the evaporation is crystalline. When pure quinine sulphate is thus treated, 10 c.c. of the chloroform solution pass easily through a small plaited filter, and on evaporation (at 30-40°) the filtrate yields not more than 35 mgr. of crystalline residue. With cinchonidine sulphate, or a quinine sulphate containing a considerable quantity of this salt, it is impossible to obtain 10 c.c. of filtrate from the mixture, on account of the swelling up of the cinchonidine sulphate. The latter is converted into extremely fine needles, which soak up the chloroform solution like a sponge, and do not yield it again without pressure.

If the residue is crystalline, and does not amount to more than 35 mgr. from 10 c.c. of solution, the absence of conchinine and cinchonine sulphates may be determined by heating this residue with about 5 c.c. of water, adding 0·5 gramme of potassium-sodium tartrate, removing the precipitated quinine or cinchonidine tartrate by filtration after cooling, and mixing the filtrate with an equal volume of officinal solution of ammonia. If no conchinine or cinchonine salt is present the solution remains clear, but in the other case a precipitate is formed.

On treatment with pure chloroform, cinchonidine sulphate is quickly deposited in extremely delicate prisms, and on this account is bulky. Only traces of it are taken into solution, the greater part remaining in the undissolved residue. The salt is easily detected in this residue, after removal of the adhering chloroform solution, by pressing between folds of bibulous paper, by means of Kerner's test, *i.e.*, 5 c.c. of the watery solution mixed with 7 c.c. of officinal liquor ammoniæ will cause more or less turbidity, which eventually resolves itself into a crystalline yet flocculent precipitate.

In pure chloroform, then, we have an excellent means of rapidly deciding in a given case whether "quinidine sulphate" (as cinchonidine sulphate containing quinine is generally termed) contains conchinine or cinchonine sulphate, or is perhaps the conchinine salt only. The latter would be the case if, for example, 0·5 gramme of the salt dissolved with ease in 7 c.c. of pure chloroform. Since, then, the "quinidine salt," called conchinine sulphate by Hager, dissolves only slightly in pure chloroform, it certainly contained no conchinine sulphate.

According to Cullen and others, cinchonidine sulphate is an excellent febrifuge, but is excelled in this respect by quinine sulphate. On account of its low price it might be more extensively prescribed for the poor, and generally where, on other grounds, great expense is not advisable. On this account I regret the omission of it from the German Pharmacopœia.

Chloroform usually contains a small proportion of alcohol, which, as is well known, renders it more stable. A trifling difference in the amount of alcohol makes itself apparent in the proportion of quinine or cinchonidine sulphate dissolved, and on this account is allowed a residue of 55 mgr. for 10 c.c. of solution, which more than corresponds to the solubility of both salts. This number is not arbitrarily chosen, but has been ascertained by experiments with quinine sulphate which answered the tests of the Pharmacopœia.

A chloroform which contains more alcohol than is generally the case, dissolves a correspondingly larger proportion of quinine and cinchonidine sulphates. Six parts of a mixture of 2 vols. chloroform and 1 vol. absolute alcohol dissolves as much as one

* *Neues Jahrbuch für Pharm.*, Sept., 1873, p. 130.

part of quinine sulphate, $2C_{20}H_{24}N_2O_2,H_2SO_4+7\frac{1}{2}H_2O$ at 18°C. Cinchonidine sulphate also dissolves very readily in this mixture, which I use in examining quinine sulphate for the sulphates of sodium, magnesium, and calcium and other inorganic substances, salts of ammonium, mannite, cane sugar, milk sugar, and starch, since these do not dissolve in the mixture. Salicine itself is separated by it, if present in greater quantity than 1 per cent. One gramme of sulphate is introduced into a test-tube and 7 c.c. of the mixture are added. (Only 5 c.c. are requisite for solution, but 7 c.c. are ordered to compensate for unavoidable loss of solvent). The contents of the tube are shaken once round, the tube is corked and allowed to stand aside for about ten minutes; at the end of this time, if the salt is pure, it is entirely dissolved, leaving only a few fibres of paper introduced in the drying of the salt to trouble the clearness of the solution; these finally settle to the bottom, and are of course disregarded. But if the salt contain an admixture of any of the above-cited substances, these also subside to the bottom of the glass, and may then be known, in part, by their form. To determine them quantitatively it is only necessary to throw the mass upon a small filter, and afterwards to wash them with a little of the pure mixture.

This operation may be supplemented by the ignition test, which, since the carbon of quinine burns away with great difficulty, is an exceedingly protracted operation, and not unfrequently has led to misapprehension. A case recently came under my own notice, in which absolutely pure sulphate of quinine was said to contain sugar, or other difficultly combustible substance, because the operator could not succeed in burning away the carbonaceous residue of the quinine.

Of the remaining salts of these alkaloids, I will cite only the neutral hydrochlorates, which, without exception, dissolve very readily in pure chloroform, giving up to it their water of crystallization. On this latter account these salts should be previously dried at 100°C. At 15°C. anhydrous hydrochlorate of quinine dissolves in about an equal weight of chloroform.

The hydrochlorates of cinchonine and cinchonidine present this curious phenomenon—these salts dissolve indeed instantly in the chloroform, but the solution, after a short time, and at the original temperature, becomes thick and crystalline, owing to the formation of difficultly soluble compounds of the salts with the solvent. In such compounds, 1 part of cinchonidine hydrochlorate requires 13 parts of pure chloroform at 20°, and 1 part of cinchonine hydrochlorate requires 22·2 parts of pure chloroform at 15°C., for solution. On evaporation of the solution the cinchonine hydrochlorate remains behind as an amorphous resinous mass, which, without increase of weight, gradually changes into radiating crystals. It is the anhydrous substance $C_{20}H_{24}N_2O,HCl$. The different behaviour of quinine sulphate and cinchonine hydrochlorate with pure chloroform furnishes a ready and convenient method of detecting the latter salt when mixed with the former.

Finally, most cinchona barks, when treated with pure chloroform, yield a small quantity of alkaloids to it. The method devised by Bernatzik* for the discovery of a falsification of cinchona bark with quinoidine is therefore useful only under certain limitations.

* See before, p. 569.

FERRIC PHOSPHATE.*

BY R. ROTHER.

Ferric phosphate is usually considered to be a very definite chemical, susceptible of exact determination, and capable of entering into definite and soluble combinations with acids and various salts, particularly those of organic acids with a monad base. However, the resulting body as obtained by different methods of manipulation is not always identical, nor even chemically similar in the predominant points. Usually when a normal ferric sulphate in concentrated solution is poured into an excess of disodic orthophosphate, also in hot saturated solution, or if a basic ferric sulphate be similarly treated, the precipitated normal ferric orthophosphate will always be more or less contaminated with basic salts.

The solution of ferric orthophosphate in ammonium citrate is nevertheless a more stable and convenient preparation than the U.S. officinal ferric pyrophosphate. The latter salt is less soluble, and therefore more easily and elegantly scaled; but since the secompoundsare properly administered only in a liquid form, it is therefore an advantage to employ a salt of greater solubility, which especially is permanent in solution. The pyrophosphate when dry and exposed to light is rapidly discoloured and decomposed, and when in solution it is speedily converted into orthophosphate. The pyrophosphate is prepared by an exceedingly circumstantial process which ordinarily is impracticable, consequently the dispensing pharmacist will have to procure his supply from the wholesale manufacturer. But the ferric orthophosphate when dissolved in ammonium citrate, even if in the utmost concentrated state, will rapidly decompose, particularly in warm weather; however, in this respect the citro-ammoniacal pyrophosphate is precisely similarly disposed. The disruption is usually indicated by the formation of mould which invariably accompanies the destruction of the salt. Many soluble citrates are perfectly proof against spontaneous decay, yet when ammonia is present in the combination, the dissociation is not so easily counteracted, but if the compound in addition contains phosphoric acid, the climax of instability is insured. Ammonia is a fertile base for mouldy formations, but phosphoric acid will generate organic growths if only a trace of available material is present.

The citro-ammoniacal ferric orthophosphate, in concentrated solution, can be well protected by means of sugar; if this is added in sufficient quantity to form a dense syrup, the green colour of the solution is perfectly retained; but recently the writer has observed that a sample several years old, which during the hot weather had been stored away in a partially filled bottle in a dark place, had generated mould on the surface and become dark brown in colour. It was also noticed that a specimen three years old preserved with glycerin was perfect.

With the aid of sugar a solution can be prepared which is just half as strong in iron as the U.S. officinal solution of ferric citrate. However, when glycerin is employed the strength of the solution can be doubled; that is, made identical in iron strength with the solution of ferric citrate.

The writer has now adopted this latter strength, adding glycerin in the proportion of 4 fluid ounces in the pint of finished product.

When ferric sulphate in moderately dilute solution is treated with disodic phosphate, also in dilute solution, but only in equivalent proportion, then the liquid filtered off the precipitate will be acid, and it can be assumed that the acidity is derived from the presence of acid sodium sulphate (SO_4NaH).

But usually it is accepted that free sulphuric acid results, thus:—

$$(SO_4)_3Fe_2''' + 2(PO_4Na_2H.12OH_2) = 2(PO_4Fe'''4OH_2) + 2(SO_4Na_2) + SO_4H_2 + 16OH_2.$$

In medium concentration the free sulphuric acid will

* From the *Pharmacist*.

retain much of the ferric phosphate in solution, but if comparatively much water is present the affinity of the acid is weakened and most of the ferric salt will precipitate. Nevertheless, all methods for the complete precipitation of the ferric phosphate are based upon the use of sodium phosphate in excess on supposition that the decomposition leads to the formation of acid sodium sulphate and acid sodium phospate (PO_4NaH_2) in the solution. However, upon this premise it is fair to surmise that since acid sodium sulphate in the first instance dissolved the ferric phosphate largely, it would naturally exert the same action here; consequently the theory is erroneous, and we are justified in taking for granted that free phosphoric acid, in which the ferric salt is insoluble, is alone generated according to the equation :—

$$(SO_4)_3Fe_2''' + 3(PO_4Na_2H.12OH_2) = 2(PO_4Fe'''4OH_2) + 3(SO_4Na_2) + PO_4H_3 + 28OH_2.$$

The ferric phosphate when thrown down from dilute solutions is excessively bulky and gelatinous, and the latter condition renders the washing by filtration tedious and unsatisfactory, whilst the bulkiness and lightness seriously interferes with washing by decantation. Therefore, the writer has always endeavoured to precipitate it in the most compact and least gelatinous form. Concentrated hot solutions are very serviceable, in fact the only recourse to meet this end. The writer found an advantage was gained by pouring the strong solution of the ferric sulphate into the hot saturated solution of the sodium phosphate.

But lately the writer has reversed the method, and pours the sodium phosphate solution into the iron liquid. With this procedure, and the employment of hot concentrated solutions, the precipitate of ferric phosphate is again dissolved after each addition of the sodium salt, until over two-thirds of this has been added, when the precipitate will remain insoluble as formed, and rapidly augment upon each addition. The result of this manipulation was a more compact and granular precipitate, in which the presence of basic phosphate was totally prevented; in fact it was undoubtedly contaminated largely with the acid phosphate.

$$(Fe'''_2(PO_4H)_3).$$

The only objection to these precipitates was the slowness of their washing process, which was almost equal in tediousness to that of the gelatinous precipitates, owing to the fact that the water permeated them very gradually although more evenly than the former. Yet if after complete separation the precipitate was mixed with a great volume of water, the method of washing it through decantation applied admirably, because deposition occurred speedily and rather compactly.

The writer, therefore, has now abandoned either method entirely, and, with a view to save the large waste of phosphoric acid, resorted to an altogether new manipulation and modification of the general process, which, though not producing exactly normal phosphate, results in the complete precipitation of the iron and utmost utilization of the sodium phosphate ; so that practically no loss is experienced, since the precipitate contains all the iron and phosphoric acid, but not as one homogeneous compound, but rather as a mixture of acid and basic salt.

Two important advantages become prominently conspicuous, namely, the economy of the process, which saves one-third of the sodium phosphate ; and secondly, the production of a dense precipitate, which can be expeditiously washed by decantation, and finally pressed between muslin to separate most of the adhering water, without waste to the precipitate ; thirdly, the usual large excess of water adhering to the other precipitate is not present here, and therefore the necessary evaporation is avoided.

When sodium phosphate and ferric sulphate are employed in equivalent proportions, and a hot concentrated solution of the former gradually poured into a hot concentrated solution of the latter, the precipitate at first formed is again re-dissolved, until nearly all the sodium salt has been introduced ; but ultimately, after complete mixture, only a comparatively small portion of the iron will have been precipitated, probably as acid phosphate. If now, however, a moderately concentrated solution of disodic carbonate in equivalent proportion is gradually added to the hot mixture, the iron will be perfectly thrown out of solution as a heavy granular precipitate together with all of the phosphoric acid. Each addition of the carbonate is attended with copious effervescence, and the preliminary formation of a red precipitate, which the excess of hot acid rapidly converts into the light-coloured phosphate. An excess of carbonate added all at once, however, permanently discolours the precipitate, because basic phosphate, ferric hydrate, and sodium sulphate are produced, leaving the original sodium phosphate in a great measure untouched, but the manipulation, when carefully conducted, yields so little of the basic salt that only a faint yellowish colour distinguished this precipitate from the whiter and purer normal orthophosphate. The final phase of the reaction may be thus expressed :

$$(SO_4)_3Fe_2''' + 2(PO_4Na_2H.12OH_2) + CO_3Na_2\,10OH_2 = 2(Fe'''PO_4\,4OH_2) + 3(SO_4Na_2) + CO_2 + 27OH_2.$$

In practice it is necessary to add a slight excess of sodium phosphate and a small deficiency of carbonate to insure a mild acid reaction, which will prevent undesirable basic tendency in the ferric phosphate which finally remains.

This precipitate, after solution in the usual proportion of ammonium citrate, yields a greenish solution with a brownish cast ; the reddish tint results from the basic phosphate, but if an excess of ammonium citrate be used, the deep green colour is developed, since the ammonium citrate extinguishes the brown tint of the basic salts, converting them into the normal green, consequently more citrate is needed to produce the citro-ammoniacal compound with this phosphate than with the use of normal or acid ferric phosphate.

From these observations the writer has constructed the following elegant and expeditious process for the production of concentrated and absolutely permanent solution of the citro-ammouiacal ferric phosphate :—

Take of—

Ferrous sulphate in coarse powder	8 troy ounces.
Sulphuric acid . . .	1 troy ounce and 200 grains.
Potassium chlorate in crystals .	283 „
Disodic orthophosphate, cryst. .	11 troy ounces.
Disodic carbonate, cryst. . . .	4 „ „
Citric acid, cryst.	4 „ „
Ammonium carbonate	sufficient.
Glycerin	4 fluid ounces.
Water sufficient.	

Mix the sulphuric acid with 12 fluid ounces of water add the ferrous sulphate, and apply heat until complete solution results, then add the potassium chlorate, and stir until dissolved ; now dissolve the sodic phosphate in 20 fluid ounces of water with heat, and pour this, by gradual addition and with constant stirring, into the iron solution ; then dissolve the sodium carbonate in 4 fluid ounces of water, with heat, and pour this very gradually into the other mixture, stirring this well for a few moments after each addition until the bright red precipitate at first formed has again disappeared ; after the final addition, continue the heat a few minutes, and then dilute the mixture with water to the measure of 8 pints ; when the precipitate has perfectly subsided, draw the supernatant liquid off by means of a syphon, and pour on a fresh portion of water in similar volume to the first. After having thus washed the precipitate three or four times, remove all the water possible by means of the syphon, pour the precipitate upon a muslin strainer, and press it thoroughly.

Upon the citric acid pour 4 fluid ounces of water, and add ammonium carbonate in small fragments until the acid is perfectly neutralized.

Place the washed and pressed precipitate of ferric phosphate in a porcelain capsule, add to it the solution of

ammonium citrate, together with the glycerin, and apply a gentle heat until solution is complete; if necessary, mix this with water to the measure of a pint, and strain through muslin while warm.

If the solution of ammonium citrate contained acid salt, or if, during the solution of the phosphate, the heat upon the dense liquid had dissipated a part of the ammonia, then, after cooling, the solution may separate a crystalline deposit of acid ammonium citrate. Should this occur, the supernatant liquid is decanted, and a few drops of ammonia is added to the crystals at short intervals until perfect solution results in the formation of the exceedingly soluble and noncrystallizable normal ammonium citrate. An excess of free ammonia, however, colours the solution red; but if the excess that was added is not too great the reunion with the decanted portion will again restore the green colour throughout the whole solution. A most expeditious method for dissolving salts deposited in the bottom of bottles is to lean the receptacle at an angle of 45°, and change the position of it occasionally, so as to bring the liquid into the most advantageous contact with the mass for favouring its solution.

The ferric phosphate yielded by 8 troy ounces ferric sulphate approaches this in weight, but assuming that it is the phosphate, $Fe'''PO_4 . 4H_2O$, it should by theory only weigh 6 troy ounces and 3·34 drachms. However, the theoretical quantity of the phosphate, $Fe'''PO_4 . 5H_2O$, is 6 troy ounces and 7·48 drachms. Yet if we calculate upon the acid phosphate, $Fe'''_2\ 3(PO_4)H_3$, then only 5 troy ounces and 6·04 drachms should result.

From this comparison it is fair to conclude that the precipitate is the phosphate $Fe'''PO_4 . 5H_2O$, and hence one pint of the solution of ammonio-ferric citro-phosphate would represent about 7 troy ounces of the former compound, corresponding to about 12 troy ounces of the soluble double salt.

NOTES ON AROMATIC WATERS.*

BY JOSEPH P. REMINGTON.

This class of preparations has long found favour with physicians as a means of dissolving and administering such potent or disagreeable remedies as are readily soluble in water, and the increasing use of carbonate of magnesium in their manufacture (although probably not the best method) renders their preparation of easy accomplishment.

The first requisite is the selection of fresh essential oils. An aromatized water made from a stale and terebinthinous oil is the worst advertisement a pharmacist can have, whilst, if a fresh oil is at hand, even an aromatized orange water can be made which will serve many good purposes. The writer has used an orange water made in the usual manner with considerable satisfaction, and a very useful simple elixir resembling Curaçoa cordial may be made by taking of—

Aqua Aurantii (℥ij in a pint) . . .	f℥iss.
Simple Syrup	f℥iss.
Cologne Spirit	f℥j.
Spt. Vini Gallici (opt.)	f℥ss.

Mix.

Some formulas for simple elixirs direct the essential oils to be mixed with the spirit, and then a certain proportion of sugar and water added and filtered. The great objection to those made in this way is that when such are used in prescriptions with water in combination (and it is generally used in this way), a separation of the excess of oil takes place, which renders the preparation unsightly.

A delicately flavoured syrup of citric acid may be made which will be clear and bright, not disfigure the sides of the bottle, nor have the harshness that the officinal article possesses.

To make this, double the quantity of fresh oil of lemon prescribed by the U.S. officinal formula [4 minims] should be rubbed up with a small quantity of carbonate of magnesium, a little water added, thrown on a filter, then followed by more water, sufficient to form with the sugar and citric acid the syrup of officinal strength.

Compound aromatic waters are readily made, containing caraway, coriander, cinnamon, orange and orange-flower flavours, and form a means of preparing the host of elixirs that are now required:—

The mixed alkaloids to be dissolved in cologne spirit, syrup added, and the salt soluble in water, dissolved in the aromatic water.

* Read before the Philadelphia College of Pharmacy, Nov. 18, 1873 *(American Journal of Pharmacy)*.

CULTIVATION OF OPIUM IN INDIA.*

BY R. SAUNDERS, *Collector of Ghazeepore.*

The cultivation of poppy in India can be traced back as far as the sixteenth century. An allusion is made to the opium and saltpetre monopolies of the Emperor Akber in the reign of Queen Elizabeth, in the celebrated Ayeen Akber of Abul Fuzul, prepared during the latter part of the sixteenth century.

The poppy plant has been cultivated in Nepaul for many years, doubtless for as long or longer than in Bengal and the North-western provinces; and it may be that the opium from India was first introduced into China by the Nepaulese, and afterwards by the Dutch, who used to purchase the drug for export, long before the East India Company held possessions in this country.

The process of the manufacture in India at the present day is as follows:—

About the end of January the poppy plant commences to flower, and continues till March; the petals are watched, and are carefully collected in the following manner,—

The forefinger and thumb encircle the stem just beneath the pod, and, with the other fingers drawn inwards, a kind of tube is formed; this tube is then gently raised straight over the pod, and if the petals are matured they come off. They are never plucked off, as it would injure the pod. When a sufficient quantity has been collected in this manner, the cultivator proceeds to manufacture them into flat cakes, something like pancakes, or, as they are technically termed, flower-leaves, and the opium cakes are wrapped in these leaves.

The manufacture of the flower-leaf is simple and inexpensive. A circular-ridged earthen plate, about 12 inches in diameter, is placed over a slow fire, the required quantity of petals is then placed in it, and pressed with a damp cloth pad till they have adhered together; the flower-leaf is then removed and allowed to dry, when it is ready for use in the manufacture of opium.

In February the poppy plant is pretty well advanced, and the prospects of the season can then be fairly ascertained.

In some instances in January, but generally in February and March, the pods mature, and are lanced in the afternoon; the opium is allowed to exude and remain on the pod till the next morning, when it is scraped off gently with a small iron scraper, and the thumb or finger is then run over the incisions to close them. The number of incisions required to complete exudation of all the juice varies, and ranges from one to five and six, and occasionally to seven and eight in some isolated cases. The opium thus collected is placed in earthern or brass vessels slightly tilted to drain off the dew and any opium juice it may contain; and when the whole of the drug is collected and thus treated, it is carefully manipulated, put into a new earthen pot, and set aside in some ventilated and safe place. Should the opium be of low spissitude, it is exposed in some shady place (not in the sun), turned over occasionally and very carefully, so as not to injure the grain, and is so treated till it reaches the required consistency; and remains in the custody of the cultivators until it is weighed.

* From the Official Catalogue of the Indian Department at the Vienna Universal Exhibition.

After the opium has been extracted, the pods are allowed to dry and are then broken off and the seed collected. An ample quantity is kept by the cultivator for next season's sowings, and the remainder disposed of to traders.

The leaves of the plant are left on the podless stalks, and, when withered, are collected and delivered into the Government opium factory, and termed technically *trash*, for packing the opium balls in the chests, for which payment is made at the rate of 12 annas a maund.

The flower-leaves are weighed in March and April, and are sorted into classes. The first is of fine texture and colour, and from 8 to 10 inches in diameter; the second, slightly inferior in both texture and colour; and the third is of a roughish and thicker quality; as sorted they are weighed, and the weight of each quality is entered in the leaf weighment book, when the value of each quality is calculated at the rate of Rs. 10, Rs. 7, and Rs. 5 a maund.

The flower-leaves are despatched by country boats or carts to the factory at Ghazeepore, and on arrival are weighed, examined, and classified.

Before the opium weighments commence, the several books are prepared; new earthen jars and pots, with covers, are purchased and carefully weighed, coarse cloth, sealing wax, and twine for closing and sealing the jars, and baskets for holding the filled jars, are also purchased; every scale, beam, weight, pan, and reservoir is carefully examined and tested, and then the weighments take place.

After the opium has been brought in by the cultivators, it is tested, and samples of each consignment are taken for a careful chemical analysis, to the opium examiner's room, to detect adulteration. The opium is then stored in large wooden vats.

The pure opium, which is fit for the China provision, and the consumption of the local market, is stored in large wooden vats, each holding about 50 maunds (about 1½ ton weight); the opium derived both from the assameewar and chullan sources is not stored anyhow, but each parcel, according to its class, is emptied into a vat bearing the designation of that class; the light divisions are arranged in lines.

As much opium as can be removed from the vessels by light scraping is taken; that which adheres is afterwards removed by second scraping, and set aside for lewah; and that which persistently adheres is removed by water—this is called washings, and when evaporated is used in making lewah; the washings alone are valued at about Rs. 65,000 a season at the Ghazeepore Factory, and the opium thus recovered amounts to over one ton in weight.

When a vat is filled, the opium in it is stirred by long wooden poles daily until the drug is used for caking.

When there are about 2,000 maunds (about 75 tons) stored—we have accommodation for upwards of 6000 maunds—we can, if we possess the proper quantities of the various consistencies, commence caking. One may ask, but why have you not caked before you collected so much? The reply is, we are bound by order to cake at a consistence of 70°; that is, when the opium contains 70 per cent. of the pure dry drug and 30 per cent. water. We are allowed—as it is very difficult to hit off the consistence of 70° exactly when manipulating such a large quantity (nearly three tons) as we require daily for caking—to cake when the assay shows the opium to be above 69·50° and under 70·50°, so that we are allowed half a degree above and below the standard of 70°.

To prepare the opium for caking, a certain number of vats are marked of each class; a long iron instrument, something like a cheese-taster, is thrust from the top to the bottom of the vat (it forms half a hollow cylinder when open, and a complete cylinder when shut), and closed; the sample of opium is withdrawn, the contents of the sample drawn are thoroughly mixed up, and three specimens of 100 grains are assayed; the mean of the three results is taken as the correct consistence. By the same process the samples from all the vats, which have been marked, are taken and assayed; those which will give, when mixed together in certain proportions (by rule of alligation), opium at a consistence of 69·30 or 69·40° are exported to the alligation vats, and the contents of the selected vats are equally distributed over the seven alligation vats, so that the consistence of each may be uniform. The opium is then well mixed by rakes and by men walking about in it, and kneading it with their feet. At about 3 p.m. it is removed from these vats into the five caking vats; equal quantities being taken from each of seven alligation vats are distributed over the five caking vats. On the following morning the opium in each vat is again mixed by six men allotted to each, from 5 a.m. to 8 a.m. Four samples are drawn from each vat, and thoroughly incorporated together, and three specimens from this mass are taken for assay; this pertains to every caking vat. Should the whole of the assays of each caking vat come out above 69·50 and under 70·50, the agent of the Ghazeepore Factory gives the order to cake, or in his absence the principal assistant does so.

The cultivation of the poppy plant is rendered as far as possible both profitable and popular.

A large room, 944 feet long by 27 feet wide, accommodates the 250 cake-makers; each cake-maker has a number, and a place assigned for him to work at, the cake-maker's number being printed on the wall above his seat. Each man is provided with a wooden seat, and is furnished with a brass cake-mould, forming the half of a hollow sphere; he has also a tin vessel graduated so as to hold 4½ chittacks of lewah, the regulated quantity which is used in making the shell of each cake.

The opium produce per beegah ranges from one to fifteen seers, according to the quality of the soil, and the attention and care bestowed on the cultivation, and state of the weather. The profit varies, and ranges from Rs. 1 to Rs. 50 or upwards per beegah.

The following materials are used in making a cake, and as it is necessary that every cake should be of the same weight, viz., two seers, every precaution is taken to ensure the accurate determination by weight or measure (calculated for weight from actual experiments) of the articles which compose the cake. The proportion of each article is given in the table below:—

	Seers.	Chittacks.
Standard opium at 70	1	7·5
Lewah at 53	—	4·5
Flower-leaves	—	5·0
Water	—	·5
Trash	—	·25
Total weight of cake on the day of manufacture . .	2	1·75

The lewah now demands attention. Lewah is a paste made by breaking down opium in water which has been used for removing the traces of opium which adhere to the jars or vessels in which opium has been placed; this is called washings, or technically *dhoe*; the washings contain about 8 to 10 per cent. of opium; the opium is broken down in large vats containing about 800 cubic feet, and about 8 per cent. of pussewah is added to the lewah to render it smooth and glutinous.

When the lewah has a consistence of over 52·50 and under 53·50, it is called standard lewah; its consistence is determined every morning by assay, and, until it is of the proper degree caking cannot commence.

The lewah is delivered in bulk by weight, and the quantity to be used for each cake is measured by a brass cup, which delivers 4½ chittacks at 53°.

The poppy flower-leaves agglutinated by the lewah form the shell of the cake; five chittacks of dry leaves are required for each cake; but as the leaves vary in

weight according to the amount of moisture in the atmosphere, ten seers are steam-dried daily to ascertain how much moisture they contain; knowing this, an exact increase or decrease in the weight of leaves can be made, which is required to compensate for the moisture containcd. This control is necessary, since if five chittacks of leaves are used which contained much moisture, when the leaves parted with that moisture by evaporation in the dry months the cakes would be light.

The loss in weight which the leaves sustain by steam-dryings is determined on the day previous to their being required for use; the bulk required for the caking of the next day is weighed out and damped in the afternoon, so as to render the leaves supple and pliant; when dry they are crisp and break readily.

Having explained the preliminaries of caking, the method will now be described. Down the centre of the room the scales for weighing opium and the lewah vats are placed; there is a weighman for each scale and two assistants. The weighman weighs the opium on a very delicate scale, and one assistant searches the opium to ascertain finally that there are no extraneous matters in it; the second man arranges the movable tin pan, and places the opium on it.

When caking commences the caking-vat room doors are opened, and the opium is brought out in tinned sheet-iron vessels holding 20 lbs. each. One vessel is set before every scale, and a sufficient quantity for one cake having been searched is handed over to the weighman's second assistant, who adjusts the quantity in the pan. When the weighman declares it to be correct, the tin plate with the opium is taken away by a boy to his cake-maker, who has been supplied in the meantime with a tin cup filled with the requisite amount* of *lewah* for a single cake; he has also received the proper quantity† of leaves for one cake.

Having these by his side, the worker now rapidly forms in the brass mould the lower half of the shell of a cake, pasting by means of the lewah, leaf over leaf, until the thickness of about seven-sixteenths of an inch has been obtained. He allows in so doing the upper part of some of the leaves, which he tears in half and places vertically, to hang down outside the mould (with these he forms the upper half of the cake). The cake shell is principally made of half leaves vertically placed, other halves being inserted horizontally, so as to give equal strength in all directions. Having finished the lower half of the shell he takes the tin plate and accurately, to a grain, removes the opium into the half of the shell now ready for its reception; it is pressed upwards into the shape of a cone, some pieces of leaves are applied horizontally to it, then some lewah; now some of the parts of the leaves hanging down are pulled up and secured, more pieces are applied horizontally, and at last, having pulled up and properly arranged all the pieces of the leaves which were hanging around the cup, a whole leaf is applied to the top, and the cake is now finished.

It is a sphere of about the same size as a 24-lbs. spherical shot; it is removed from the mould and dusted with a little coarsely powdered poppy trash, so as to prevent its adhesion to the cup—made of burnt unglazed pottery—which is of the same shape as the mould in which the cake was made. It is now carefully placed in the cup while still soft, and it is carried out by the cake-maker's boy, who puts it in the sunshine on a little square of brick flooring, which has been allotted to the cake-maker whom he serves, and where a small board stands bearing his master's number.

Before removal, a paper ticket is pasted on the cake, bearing the cake-maker's number, and the date on which it was made; every cake has its ticket, so that we can at any time trace its history, and by this means we can hold every cake-maker responsible for the careful manufacture of his cakes; by means of these tickets, should anything be found wrong with any cake it can be brought home to the man who made it.

The caking begins generally at 10 a.m., and lasts till half-past one or two o'clock in the afternoon; usually 20,000 cakes are made daily.

The cakes are on the evening of the second day counted and sent to their destination in one of the cake godowns, where they and their cups are stored in racks.

The great object to be attained is to make the cake as carefully and compactly as possible by one operation, to have the shell even in thickness throughout, and to spread the lewah uniformly between the leaves. This can be attained by good cake-makers under strict supervision; cake-makers usually make sixty cakes a day; every good cake-maker gets twenty or more additional ones to make, for which they receive an extra allowance.

The flower-leaf forms an excellent covering; it is in every way suitable, but it has its drawbacks. It is affected by wet, and is liable to be attacked by mildew, borers, and white ants, while it will not resist hard pressure applied to any small area of its circumference; however, it certainly most effectually retains the moisture and aroma of the drug enveloped in it, and by its own fragrance adds to that which the opium *per se* contains.

The cake godowns are large and high brickwork buildings, with galvanized iron roofing, well ventilated by numerous windows and doorways. The windows have iron gratings fixed in the masonry outside, and skeleton doors are provided for the best godowns to admit of the entrance being closed while free circulation of air is not interfered with. All the doors and windows of the better-class godowns are further secured from thieves by galvanized wire netting, so that cakes cannot be cut up and passed out in large pieces.

Inside the godowns are wooden racks, extending nearly up to the roof; there are intervening rectangularly-placed passages traversing the frames to permit of ventilation. In these racks the cakes are stored in their cups.

Every third day the cakes, wherever placed, come down to the ground, are lightly hand-rubbed with a little trash, turned, replaced in their cups, and sent up again to be placed in the racks. The object of turning is to allow the shell of the cake to dry evenly.

The packing takes place only in dry weather, and after the morning dew has been dispersed.

Into a strong mango-wood chest, one yard long and two feet four inches wide, forty cakes are packed in two layers of twenty each; the balls are prevented from rolling about by each one being placed in a compartment; and in these chests, varying in number according to the year, the opium cakes find their way to Calcutta, whence they are shipped to China at the close of the annual Government sales, each chest realizing as much as £13, or, in other words, 1300 rupees, in an average good season.

* 5 chittacks. † 2 chittacks.

THE MOTIONS OF CAMPHOR AND OF CERTAIN LIQUIDS ON THE SURFACE OF WATER.

BY CHARLES TOMLINSON, F.R.S.

The author, who, as is well known, has studied the phenomena of the above subject for many years, in a paper recently published in the *Philosophical Magazine* refers to the additional light thrown upon it by the researches of Professor G. van der Mensbrugghe, of the University of Ghent, by means of the principle of surface tension of liquids, and then recapitulates as follows some of the principal observations made by former investigators.

Omitting mere guesses, such as that of San Martino, who, in 1793, attributed the motions of camphor to electrical action, we come to Sir H. Davy, who, in 1802, noticed that fragments of acetate of potash (then called acetite) move on the surface of water somewhat after the manner of camphor. The more irregular fragments rotate most quickly, whence it is concluded that the shifting of the centre of gravity had something to do with the phenomena, while the rectilinear movements were

attributed to currents descending from the salient points of each fragment, and so producing on it unequal pressures.

Carradori, in 1805, noticed that when a large drop of the milky juice of a euphorbiaceous plant is placed on the surface of water in a large vessel, a portion of the drop spreads, while another portion descends in threads, which accumulate at the bottom. If, then, the vessel be inclined so as to spill some of the water and so renew the surface, on returning the vessel to its first position the agitation will cause some of the milky filaments to rise to the surface, where they spread like the first portion.

These and a multitude of other phenomena, as noticed in my first 'Experimental Essay,' were attributed by Carradori to a "superficial attraction" (*attrazione di superficie*), which Dutrochet afterwards developed into the "epipolic force" (*force épipolique*).

In 1819 Barlocci covered fragments of camphor with gold leaf, and found that they did not move on the surface of water. The idea was that by preventing the formation of vapour, Venturi's theory, which attributed the motions to the escape of vapour, would be supported. It is further stated that perfect cubes of camphor do not move on the surface of water, on account of their perfect symmetry. This, however, is a mistake which several observers have fallen into; and we suspect that the cutting and shaping and handling of the camphor so as to confer upon it a geometrical form made it dirty, and that this was really the cause of its want of motion. I have frequently placed beautifully formed oblate spheroids of camphor on the surface of water, and these have continued to move about during some hours: but these figures were absolutely clean, for they were formed by dissolving camphor in strong sulphuric acid, and depositing a drop of the solution from the end of a clean glass rod upon the surface of clean water in a catharized glass 3½ inches in diameter. The acid dialyzes off and leaves the camphor in a compact, well-shaped button. Two or three drops may be deposited on the same surface; and the resulting buttons will sport about for a long time without interfering with each other's motions.

In 1824 a writer in Thomson's 'Annals' attributes the motions of camphor on water to the fact that the centre of gravity of each fragment and the centre of support are not in the same vertical. Another anonymous writer rejects this idea, on the ground that, if true, every irregular floating body ought to present the same phenomena as camphor.

I may here remark that during the many years in which the motions of camphor puzzled even the best observers, the idea was not seldom started that the shifting of the centre of gravity had something to do with the phenomenon. In 1863 Mr. Trachsel quotes an experiment by M. Gingembre (without reference), in which a cylinder of camphor, ballasted at one end with lead, was placed in water reaching halfway up the little pillar. After twelve hours' contact the camphor was cut half through at the level of the water, but not equally all round. This experiment (which really originated with Venturi) is quoted to show "the unequal power of solution in certain directions of the crystalline mass," and "this being one of the properties of camphor pointed out by Mr. Lightfoot, and from which he derives his well-written explanation of the cause of these motions when he says, 'the water upon which it floats, being capable of diffusing this vapour more readily in certain directions of the crystalline axis, thereby removes sufficient vapour-pressure at these points for the opposite side to drive about (by recoil) the nicely suspended particle.'"

In my reply to Mr. Trachsel, I state that nearly two years before I had pointed out the more rapid solution of camphor on a broken than on a natural surface, and also that the vapour theory was three-quarters of a century old. It was first started by Volta in 1787, adopted by Prevost in 1799 under the term *jet gazeux*, and is now being revived without any experimental basis being provided for it.

As to the disturbance of the centre of gravity being the cause of motion in a floating and partly soluble mass, we have only to secure a crystal of some soluble salt to a slice of cork by means of an india-rubber ring, so as to be a little lighter than water; and if this be set floating, the waste will be constantly disturbing the centre of gravity of the mass, so as to produce a rolling over and a slow progressive motion. But no explanation of this kind suffices to explain the gyrations of camphor, benzoic acid, citric acid, etc., which are so rapid under the most favourable conditions (namely, chemically clean glass and water, and a bright, warm, dry day) as to extinguish the form of the fragments and make them appear like a grey cloud on the water.

In 1825 the brothers Weber examined the subject of the camphor motions, and showed that a downy feather smeared with oil at the two ends will rotate on the surface of water. But other observers had already pointed out that an indifferent substance, such as sulphur, glass, earth, sugar, paper, etc. (as indicated by Carradori in 1808), smeared with a fixed oil, will rotate on the surface of water. But the first observation of this fact is older still. Franklin, in his celebrated letter to Brownrigg, on the action of oil in stilling the waves, dated November 7, 1773, states that while visiting Smeaton, near Leeds, he was about to show what he calls "the smoothing experiment" on a pond, when Mr. Jessop, one of Smeaton's pupils, spoke of an odd appearance on that same pond. "He was about to clean a little cup in which he kept oil, and he threw upon the water some flies that had been drowned in the oil. These flies presently began to move, and turned round on the water very rapidly, as if they were vigorously alive." The experiment was repeated before Dr. Franklin, who says, "To show that it was not any effect of life recovered by the flies, I imitated it by little bits of oiled chips and paper cut in the form of a comma of the size of a common fly, when the stream of repelling particles issuing from the point made the comma turn round the contrary way." The Doctor adds that "this is not a chamber experiment; for it cannot well be repeated in a bowl or dish of water on a table." The reason for this is want of chemical purity in the bowl or dish. The effect may be well shown in a clean glass five or six inches in diameter, by moulding small coracles of paper on the rounded end of a glass rod, pouring into one of these coracles a few drops of a volatile oil, and placing it on the surface of water. The paper-comma experiment is sometimes referred to as originating with the brothers Weber; but in truth their labours added nothing to the subject, nor does it appear that they intended to do more than glance at it. They do not settle anything, but, on the contrary, declare that the varied phenomena connected with the subject still remain unexplained. They are even inclined to fall back upon an electrical theory in order to explain the rapidity with which a drop of oil spreads on the surface of water.

In 1828 August described an experiment by Wirth, in which a metal ball is suspended at a short distance from the surface of water sprinkled over with powdered sealing-wax. On closing the hands over the metal ball the fragments of sealing-wax are set in motion, an effect attributed by Wirth to the magnetism of the human body, but by August to currents of air due to differences in temperature. He supports this view by showing that the effect can be produced by the action of a heated cylinder.

In 1836 Challis endeavoured to account for the spreading of a drop of oil on the surface of water by considering that the angle formed by the free surface of this drop and the common surface of the two liquids must be very small, and that consequently a thin film of oil must spread over the whole surface of the water, while a second drop would assume the lenticular form. I give Professor Challis's own words, since a similar theory was published by Du Bois-Reymond in 1858. He says:—"The angle of actual contact between two fluids is determined by the hydrostatical equilibrium resulting from the molecular attractions

of the two substances, the fluids being treated as incompressible. It thence appeared that this is an exceedingly small angle in cases in which the bodies in contact are not of very different specific gravities. Hence, in the instance before us, the angle of contact (that is, the angle which the surface of contact of the oil and water makes with the upper free surface of the oil) is very small. But since the drop is convex both at its upper and under surfaces, this is apparently an angle of considerable magnitude. In fact the theoretical angle of contact, or that which the upper surface of the oil makes with an imaginary surface drawn parallel to its under surface, and just beyond the sphere of the molecular action of the water, would be found by calculation to be of sensible magnitude. Consequently, that the angle of actual contact may be exceedingly small, the portion of the upper surface of the oil that lies within the sphere of the molecular action of the water must undergo a flexure near the visible periphery of the drop. Now in fulfilling this condition it seems probable that a very thin film of the oil spreads over the whole water surface (as there is no force to counteract), and gives rise at the same time to the visible spreading of the first drop. The film itself, being of less thickness than the radius of the sphere of the molecular action of the water, will not be perceptible to the senses. Such a circumstance having happened to the drop that first comes in contact with the water will prevent any that succeed from being similarly affected."

(*To be continued.*)

CINCHONA CULTIVATION IN JAVA.

The following letter from Herr Van Gorkom in Java, to Dr. Hasskarl, is published in the *Pharmaceutische Zeitung*, No. 85 :—

"*Bandong*, 15*th August*, 1873.

"I have already sent 188 chests of cinchona bark to Holland, and during this month 180 more will follow, so that the entire yield of 1873 (20,000 kilograms) will be in Amsterdam by November. Of the Ledger Calisaya bark, I export only 1200 kilograms ; this excellent bark contains always at least 5 per cent. of pure quinine, and will consequently be very much in request by the manufacturers. In the course of this year I shall collect a good quantity of seed, and then no other kind of Calisaya will be sown, so that after six or seven years all our barks will be superior barks for manufacturers. To this end they must content themselves with the kinds which are less rich, but which are of good value for pharmaceutical purposes.

"The plantations of 1865 to 1868 are at the present time somewhat thinned, whereby the remaining trees are placed in more favourable conditions, so that in a few years very thick bark will be obtained. Also the *C. officinalis* has proved to be a good manufacturer's bark, although the plantations are yet very young, and I intend to reserve extensive exportation until 1875, because then it can be regularly continued. As it is I should have been as well able to collect this year 100,000 as 20,000 kilograms ; but this yield demands much anxiety and oversight, and I am still too much wanting my skilled staff for the work of planting out, which by April, 1874—ten years after my undertaking the cultivation—will be completed to 2,000,000 plants ; after that the work will be more simple. The enterprise, therefore, only requires to be supported to become improved and reinvigorated.

"Moens continues his analyses ; all the barks which I export will be examined by him, and the trade may depend upon these analyses. I will take care that the results are published before the public sales.

"The cinchona powder, which I brought experimentally into the market, has not answered my expectations ; notwithstanding the low price it obtained, I am convinced that for pharmaceutical purposes, extracts, etc., it would be found equally suitable with the bark. I send at the present time a second sample of about 2000 kilograms, and hope that this will command a better price. It is an article requiring confidence, because the genuineness of such a powder cannot well be perceived exteriorly, and there is not the certainty that no adulteration has been permitted. Nevertheless, the dealers would well understand that I should not dabble in trade, and that the Government might even punish me by dismissal from office if I sought to lead them into error. The attention of private persons is turned more and more to cinchona culture. I receive fresh inquiries continually, and Herr Hofland, in Krawang, has already a splendid plantation of 100,000 trees, which he intends to raise to 1,000,000. I visited him last month, and was astonished at its fine condition. All this, however, does not prevent the lament raised a short time since by one of the Indian journals concerning the condition of our cultivation, which is already twenty years old, whilst the English have obtained such astonishing results in only ten years. But the editor of this Journal had not seen any of our cultivation, and he allowed himself to be guided by the light of English reports. Many of my friends wish that I should contradict this article ; but I rejoice that I can calmly leave such accusations unnoticed, and it is better that they should bluster to silence."

At the end of the above letter, in the *Zeitschrift des Allgemeinen österreichischen Apotheker-Vereines*—from which journal it is taken—is appended a report, prepared by Professors C. A. J. A. Oudemans and A. Stellingwerff, at the request of the Netherlands Trading Company, and published in the *Tydschr. der Nederl. maatsch. ter bevordering der nyverheide*, vol. xiv., p. 267. As this report deals very fully with the exterior appearance of the Java cinchona barks, it will probably not be unwelcome in this place.

"A. 107 chests of *C. Calisaya* bark distributed under five letters.

"(*a*). *Bark of Trees which were raised from Java seed* (23 chests containing 1825 kilograms).—The contents of the chests that were examined of this portion were not quite equal, but presented to some extent differences both in the form and appearance of the bark. These differences would be attributable to the varying age of the bark, since the old barks are more furrowed and wrinkled than the young. Compared with the American barks the superiority of these samples must be conceded, since, taken on the whole, the contents were very satisfactory, and the barks were not the inferior sort which was formerly brought from Java. This portion was sold at the average price of 121·8 cents (= 2*s*. 0¼*d*.*) per half kilogram.

"(*b*). *Bark from C. Calisaya trees, raised from Cuttings.* (23 chests, containing 1825 kilograms).—These were, so far as the exterior went, of excellent character, and were distinguished by their vigorous, healthy appearance. Some half quills taken at hazard from the bulk were ½ centimetre thick, and 2½ centimetres in diameter, proportions which are noteworthy. A whitish exterior surface with deep furrows having raised margins ; a beautiful uniform yellow-brown inner surface, and the bare places where the rubbing off of the bark scales had given rise to the so-called finger marks, stamped this bark at the first glance as a Calisaya. This portion was sold at the average price of 186·11 cents (= 3*s*. 0½*d*.) per kilogram.

"(*c*). *Bark in Irregular Pieces* (3 chests, containing 140 kilograms).—These pieces were irregular and short, but had a great similarity to both the before-mentioned lots. Having been taken from the under portion of the stouter branches, they were frequently ½ centimetre thick. Except in respect to form, the contents of these chests were judged equally favourable with the foregoing. They were sold at an average price of 116 cents (1*s* 11¼*d*.) per half-kilogram.

"(*d*). *Bark collected from Trees raised from Seeds from Madras* (5 chests, containing 346 kilograms).—According to the declaration of Van Gorkom, this kind yielded 5

* Calculated at the rate of 100 cents the florin = 1*s*, 8*d*. sterling.

per cent. of alkaloids, though least of quinine. As to the identity of this sort very great doubts are entertained. These chests contained quills of tolerable stoutness, some as thick as the middle finger, some even thicker; their exterior appearance was not so fine as that of the quills from (*b*), though in other respects satisfactory. With an equal diameter the bark itself was frequently thinner, splitting off in thin scales, so that not unfrequently the peculiar appearance arising from deep furrows with thickened edges would be absent. The doubt that exists as to the identity of this kind arises from the fact that the trees planted under the name of "*C. Calisaya* from Madras" do not agree in their botanical characteristics so entirely with those deemed to be typical in Java as that they can be considered certainly identical. This portion sold at the average price of 158·4 cents (= 2*s.* 7½*d.*) per kilogram.

"(*e*). *Bark from Trees raised from Seeds of C. Calisaya, obtained from America in* 1865 (4 chests, containing 261 kilograms).—According to the certificate of Van Gorkom these barks were characterized by their constantly high yield of alkaloids, of which generally more than three-fourths is pure quinine. These four chests were all examined by Messrs. Oudemans and Stellingwerff, and contained undoubtedly one of the most important cinchona products that have been yet supplied from Java. They contained quills of about 1½ to 2 centimetres in diameter, which resembled most those described above under (*b*), although not presenting so favourable an appearance. But on account of their large alkaloidal contents they deserve to be particularly recommended, and Messrs. Oudemans and Stellingwerff agree with Herr Van Gorkom that these trees provide a surer future for cinchona culture, and they approve in a high degree of his intention henceforward to plant only this one of the manifold varieties of *C. Calisaya*. The result of the sale has also vindicated this favourable opinion, since this portion was sold for the high average price of 4·56 florins (= 7*s.* 7¼*d.*) per half-kilogram.

"B. *Bark from C. Hasskarliana* (20 chests, containing about 1358 kilograms).—The quality of this bark was very good, and throughout was not of the inferior sort sent formerly. According to the statement of the quinine manufacturer Jobst, there was formerly obtained from this kind 3 to 5 per cent. of alkaloid, of which 1·7 per cent. was quinine. Likewise, the certificate now sent from Java fixes the amount of alkaloid at from 1 to 5 per cent., of which one-third to one-fourth is quinine. The *Hasskarliana* has consequently in respect to its chemical proportions remained stationary, or else on the whole improved. The average price for which it was sold was 141·2 cents (= 2*s.* 6¼*d.*) per half-kilogram.

"C. *Bark from C. succirubra; Red Bark* (5 chests, containing about 362 kilograms).—The alkaloidal contents were larger than in any of the other barks, and included comparatively little quinine, and much cinchonine and cinchonidine. Messrs. Oudemans and Stellingwerff on a former occasion recommended the company not to bring the *C. succirubra* bark from Java to public sale, since it possessed an unprepossessing exterior, and might produce an unfavourable impression at first sight. They further recommended that the Company should wait until a larger and probably better lot of this bark could be placed in the market. They are, therefore, the more pleased to be able to point out that a very marked progress has been made in the cultivation of this red bark. Upon an examination of that received it was thought not doubtful that a time will come when, at least as far as relates to external appearance, the Java red cinchona bark will stand on an equality with the American. But the commission does not place the fulfilment of this prediction in the immediate future, since the red bark from America comes into commerce in thick flat pieces, which are collected from old stems, whilst that from Java, on the contrary, would only be collected from young trees, and therefore appear in the form of quills. This parcel was sold at an average price of 114·8 cents (=1*s.* 11*d.*) per half-kilogram.

"D. *Bark from C. officinalis* (8 chests containing 407 kilograms).—This bark, judged according to its external appearance, the commission would rank with Loxa bark, although a cinchona bark, which, as is stated of this, contains 4 per cent. of alkaloids, half of which is quinine, must naturally be priced at a higher rate. It sold at 120 cents (=2*s.*) per half-kilogram.

"E. *Bark from C. coleoptera* (1 chest, containing 62 kilograms).—Amount of alkaloids 4 to 5 per cent., mostly cinchonine. This kind was now for the first time imported and offered for consideration. It includes quills which, in external appearance, stand between Loxa and Huanuco barks, and are generally overgrown with lichens. The impression of this new article was a favourable one. On account of its reported contents the commission was compelled to attribute to this bark a much higher commercial value than is awarded to Loxa and Huanuco barks. It was sold at 173 cents (=2*s.* 11*d.*) per half kilogram.

"F. *Bark of C. Pahudiana* (35 chests, containing about 2193 kilograms).—Amount of alkaloids 1·4 per cent., but little quinine. This *C. Pahudiana* bark also had a much better exterior than that formerly sent; it showed much more of the most esteemed characteristics of cinchona barks than formerly. In chemical value it stood about equally high with the American brown barks. It was sold for 128 cents (=2*s.* 1½*d.*) per kilogram.

"G. *Powder from Root Bark* (29 chests).—Amount of alkaloids, 2 to 3½ per cent.

"H. *Powder from Bark of C. Pahudiana* (2 chests).

"I. *Powder from C. Calisaya* (1 chest).

"Of the five chests opened for inspection, the contents of one appeared to be somewhat mouldy, probably because the powder was not sufficiently dry when packed; the contents of the remaining chests were perfectly dry, and possessed in a high degree the peculiar smell of cinchona bark. These three portions of cinchona bark powder fetched 15·6, 16, and 11 cents per kilogram."

"The entire produce of this second public sale of Java cinchona barks at Amsterdam amounted to quite 30,000 florins; at the first public sale there in March, 1872, 5937·25 kilograms were sold, which produced about 9000 florins. According to the opinion of Messrs. Oudemans and Stellingwerff the last importation shows a great improvement in this most important product of the East Indian colonies; a result the more surprising since the Java bark sold at the first public sales did not allow of very favourable expectations. It was then feared that the Java barks would not be able to compete with the barks from British India; this fear is no longer felt, since it is now justly considered that the result of the Java cinchona culture surpasses even that in India. Particularly noteworthy are the results from the plants which have been raised from the seed brought by Mr. Ledger from South America in 1865. It is remarkable that the portion of this seed purchased by the Dutch Government has succeeded much better than that which was sent to British India. This result is due principally to the zeal and good management of the Dutch cinchona planter, who, after this genuine sort had been once received, sought to increase it as much as possible by cuttings, since he mistrusted the uncertain results of sowing."

THE SIXTEENTH REPORT OF THE COMMISSIONERS OF INLAND REVENUE.

This report for the financial year ended 31st March, 1873, has only just come to hand, and as the reason for the delay in publication has not been given it is but fair to suppose there have been good grounds for it. We have only to turn to the first page in the report to find an evidence of the unparalleled prosperity of the country during the period to which the report relates; for we observe that the income from the excise alone increased from £23,386,000 in 1872 to £25,904,450 in 1873. And

although during that period the income tax was reduced from sixpence to fourpence in the pound, yet the income for the year from the inland revenue showed a net increase of £839,357. We are able to gather from the tabulated statements that the increase on spirit duty was £1,474,947; malt, £873,220; sugar, home made, £5862; and sugar used in brewing, £41,040. It is interesting to notice these increases, because they are gauges of the prosperity of the country. In times of depression of trade the artisan cannot afford to indulge to any extent in spirits, and sometimes it is even difficult for him to obtain his usual allowance of malt liquor, but from the fact that the consumption of spirits has increased $11\frac{2}{10}$ per cent., malt, $9\frac{2}{10}$, and sugar used in brewing 17,525,950 lbs., we are sure that the country was, during the financial year 1872, in a most prosperous condition. Taking the working classes in the aggregate, they obtain the necessaries of life as long as they can, and if out of the week's earnings there is a little to spare they then buy drink of some sort, so that, perhaps, of all the readings of our national prosperity there is none which gives such correct results as the malt and spirit duties.

Passing rapidly over the numerous items in this interesting report, we note that in the sister island the persons engaged in illicit distillation are rather higher in the social scale than formerly, for, instead of going to prison as heretofore, a larger number of them avail themselves of the privilege of paying the fine imposed by the magistrates.

The manufacture of sugar from beet does not appear to be greatly on the increase. In 1872 there was but one manufacturer, viz., Mr. Duncan, of Lavenham, and although he made a little more than in the previous year, the increase is trifling. There is one distiller also who manufactures spirits from beet, and he has considerably increased the quantity made in 1871, but we cannot say that these isolated cases look very hopeful towards the general establishment of these new branches of industry in England. It certainly seems surprising that both in France and Belgium the manufacture of sugar from beet should be carried on on a most extensive scale, and that the sugar so manufactured should have a ready sale to our English refiners, and yet no great efforts should be made here to compete with the foreigner in the production of an article in general demand in this country. The earthy taste of beetroot sugar, except of the finest kinds, will always unfit it for domestic use, but when we calculate the quantity used in the refineries in the United Kingdom it is a matter for surprise that one beet-root sugar manufacturer is the sole representative of this industry in Great Britain. The quantity of sugar made from starch for brewers is greatly on the increase, and we can only account for it by concluding that brewers do not very carefully estimate the extractive they obtain from this description of sugar. If they did we think they would think twice of the prudence of buying a sugar containing twenty per cent. of water at a high price, when ordinary raw sugar with four or five per cent. of moisture can be bought at a much lower rate. However, the chemical point of view is not always the one adopted by the public, and we can only dismiss the subject with the remark that if the brewers were a little more scientific this class of sugar would not be in great favour as a substitute for malt.

The obnoxious income-tax is referred to, and we are glad to see that the Commissioners have been restraining the zeal of some of their officers who have had to do with the assessment of this unpopular tax. The taxpayers of the metropolis have been made painfully aware of the power in the hands of the officials in making surcharges and increasing assessments. The extent to which this has been carried has lately been the theme at many recent political meetings, but we are glad to see the Inland Revenue Commissioners have taken their officials to task respecting their excessive and wrongly directed zeal.

From an increase in stamp duty received for patent medicines from £82,721 to £91,556, we may assume that pharmacists and others have had a fair share of prosperity, knowing as we do that after seasons of feasting medicine is required to get the system once again in tune.

In the appendix to the report we find as usual Mr. Phillips' report of the work done in the Inland Revenue Laboratory, and although it extends only over seven pages, it contains in a condensed form much interesting matter. Taking a general view of the report we are glad to see that there has been another increase in the permanent staff, and this appears to have been absolutely necessary in the interests of the department, from the large increase of work which had to be performed. We find that in 1872 no less than 14,031 samples were analyzed as against 12,128 in 1871, and that these samples were obtained, not only from the Inland Revenue, but also from the Board of Trade, Customs, and Admiralty. We also note that 4400 samples were examined by the chemical officers at the ten outports; so that the number of samples actually examined in London and the outports amounted to about 18,400.

We are shown that there was a steady increase in the consumption of tobacco, and that the quantity used amounted to 1 lb. $5\frac{3}{4}$ oz. per head of the population, or to put it more forcibly, 43,948,427 lbs. were cleared for home consumption. It would appear that adulteration was slightly on the decrease, as there were only found 212 samples adulterated in 1872, as against 404 in 1871. The samples of snuff examined passed through the ordeal in a satisfactory manner, for out of 26 only 1 was adulterated, the adulterant being rhubarb leaf.

Russian and Turkish cigarettes continue to be imported, but the English manufacturers appear to be successfully competing with the foreign manufacturers, as we find that the quantity of cigarettes exported increased from 8942 lbs. in 1870, to 21,784 lbs. in 1872.

At one time chicory was considered an adulteration of coffee, but now that the duties on each are equalized the substitution of one for the other is not a revenue fraud, although one of a gross kind on the consumer. The revenue has, however, been defrauded by the adulteration of chicory with dog biscuits and roasted rye, the percentage of adulteration varying from 2 to 10 per cent. Four samples were adulterated with oxide of iron. Grains of Paradise, liquorice, sugar, and caramel were used either as adulterants of beer, or of materials used in the brewing of beer.

Under the head of naphtha, we notice an interesting remark that one sample of alcohol to be used for methylation was found to contain wood naphtha, and that this detection led to the exposure of a great fraud on the revenue. We wonder whether these remarks apply to a methylated spirit maker who, about two years ago, undersold the other makers, and who has now left the country.

It is gratifying to observe that great care is still exercised in the examination of samples of lime and lemon-juice for the mercantile marine, and we hope to see the day when, by the adoption of proper diet and the use of good lemon-juice, scurvy will be banished from the Navy.

The report closes with reference to the work done under the Intoxicating Liquors Act, and we learn that it has been necessary to admit that when common salt is present in beer to the extent of not more than fifty grains in the gallon it cannot be considered an adulteration, on account of the variable quantities of common salt found in water used by brewers. We have for some time waited rather impatiently for this first report on the Intoxicating Liquors Act, because we have heard such dreadful reports on the adulteration of beer and spirits, that the public were led to expect the revenue authorities must make some startling discoveries. As, however, it is evident that the adulteration of beer and spirits is not general, we intend shortly to direct attention to some of the alarmist statements which have been recently and very improperly put in circulation respecting the adulteration of our national beverages.

The Pharmaceutical Journal.

SATURDAY, FEBRUARY 14, 1874.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square,*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE NEW REGULATIONS OF THE BENEVOLENT FUND.

The recent Report of the Special Committee, appointed last November to consider the management of the Benevolent Fund, ought to engage the special interest of every Chemist and Druggist on the Register. Much discussion has been caused, and many plausible explanations have been originated by the singular apathy with which the prosperity of this Fund has been regarded by many members of the trade, so far as it has been fair to judge by their abstention from contributing to it. The subject has more than once occupied the columns of this Journal, and it has been asserted that the want of sympathy has had its chief cause in the fact that the funds are not more liberally distributed, and that if it were found that instead of money being invested to meet future liabilities it was dispensed at once with greater reliance upon the future providing for itself, such a course would be speedily justified by a more extensive subscription list. The ground we have ventured to take in this matter has been that this would be no reason for withholding subscriptions, but rather for urging the views of the subscribers upon the Council of the Pharmaceutical Society, which has the administration of the Fund. We were confident that those gentlemen were ready and anxious to consider every suggestion for the improvement of this Fund.

Our confidence has been justified by the report adopted last week, which, although marked by considerable caution, virtually implies, we think, that the number of annuitants to be elected next October will probably depend upon the amount of money subscribed to the Fund between this time and next June. The proposition of Mr. ROBBINS, that the number of annuitants should be raised at once to twenty, was received with considerable favour; but, of course, the decision, according to the Bye-laws, will lie with the members of the next Council at their first meeting, and the present Council are unable to guarantee the action of their successors. Still, we believe that it may be inferred that gentlemen sitting on the present Council, who may also happen to be members of the next, will be prepared, should they think the amount received justifies them, to recommend an experiment in the direction of Mr. ROBBINS' scheme.

There are certain figures, however, that we may be sure will not be without their influence upon the decision. The amount required for twenty annuitants of £30 each will be £600; the interest received from the invested capital—now ordered to be increased to £14,000—will not be much more than two-thirds sufficient to meet this charge. The new Council therefore, should they authorize such an election, will not only be taking a large sum out of the current year's subscriptions, but also an equal sum from each future year during which the elected lives shall last. This will be a financial operation requiring a considerable margin of money, and such a margin should therefore be provided during the next three months by those who wish to see the operations of the Fund developed in this direction.

But although the Committee was not able to recommend present action upon this point it arrived at a most important conclusion upon another, namely, the proportionate influence in the distribution of the Fund to which subscriptions other than those to the Pharmaceutical Society shall entitle subscribers. In this respect the Council, acting on behalf of the Society and on the recommendation of the Committee, have decided in the most liberal manner. Hitherto the lowest subscription entitling to a vote has been half-a-guinea. But it has been thought that there might be a large class of persons who, not feeling able or willing to subscribe so much, would yet object to be shut out from all participation in the administration of the Fund. It has therefore been determined that in future a subscription of five shillings shall entitle to a single vote at each election of annuitants; that half-a-guinea shall entitle to two votes instead of one as heretofore; one guinea to four instead of two, and so on in proportion. It may appear to be a little inconsistent that the cost of a single vote should be a little less than half that of two; the object sought, however,—and we believe it will meet with general approval—is to widen the circle of subscribers as well as to increase the amount of subscriptions, and thus to make the contributors to the Fund as truly representative of the whole body of chemists and druggists as the recipients undoubtedly are. But the voting power of Members and Associates in virtue of their subscription to the Pharmaceutical Society remains unaltered, and it is hoped that the action of the Council in thus doubling the proportionate influence of subscribers to the Fund, will be accepted and acted on in the same liberal spirit.

The report has been made at a most opportune time; many of our readers will be remitting their annual payments to Bloomsbury Square, and we trust that if they have not already done so they will now make up their minds to accompany them with subscriptions to the Benevolent Fund. Moreover, the Secretary is about to send a circular containing an appeal on behalf of the Fund to every person on the Register of Chemists and Druggists. On former

occasions he has had to lament that *le jeu ne vaut pas la chandelle;* but surely a better response should be made to this fresh evidence of the desire to give catholicity to the Fund.

NEW WORK ON MATERIA MEDICA.

We learn from the *Journal of Botany* for February that Messrs. Macmillan are about to publish a work on Materia Medica by Dr. Flückiger and Mr. Daniel Hanbury, under the title of 'Pharmacographia Britannica,' a History of Drugs of Vegetable Origin used in Great Britain and British India.

PHARMACY AMONGST THE CANDLE MAKERS.

The fact that the vapours of balsams such as benzoin, storax, etc., often operate beneficially when inhaled by persons suffering from bronchial irritation and spasmodic asthma, has recently been applied in a novel manner by introducing these substances into candles, which, when burned, impregnate the atmosphere of a room sufficiently to produce the desired effect. It would be well if gas makers would turn their attention in the same direction, and supply gas which, if not medicinal, at least should not be poisonous.

In the Catalogue just issued from the India Office of the articles exhibited at the Vienna Exhibition some interesting information is quoted from the *Asiatic Journal* respecting the preparation of the celebrated "Wootz" steel in India. The ore from which it is made is one in which magnetic oxide of iron is combined with quartz in the proportions of about 48 per cent. of quartz and 52 per cent. of oxide of iron. The ore is found in considerable quantity in the form of low hills exposed above the surface of the surrounding country in many parts of the south of India. The processes of smelting and forging are conducted in a very primitive manner; but it is worthy of notice that the only fuel employed by the natives of India, throughout the various stages of iron and steel making, is wood charcoal.

The wood which is always selected to furnish carbon to the iron is that of the *Cassia auriculata*, and the leaf used to cover the iron and wood is that of the *Asclepias gigantea*, or where that is not to be had, of the *Convolvulus laurifolius*. The writer thinks it probable that the selection of particular kinds of vegetable matter to afford carbon to the iron may not be altogether a matter of fancy. The Indian steel maker of course knows nothing of the theory of his operations; he is satisfied with knowing that he can convert iron into steel by fusing it with what he calls "medicine;" and experience has taught him this medicine must be dried wood and green leaves. As different woods and leaves probably contain carburetted hydrogen in very different proportions, experience may also have taught the Hindoo that he can make iron pass into the state of steel more quickly and with a smaller bulk of particular kinds of vegetable matter than with others. The *Cassia auriculata* contains a large quantity of catechu, and the leaf of the *Asclepias* contains an acrid milky juice; but the leaf of the *Convolvulus* is in no respect remarkable.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN—NORTH BRITISH BRANCH.

The third meeting of the present session was held in the Society's Rooms, St. Giles Street, on Tuesday evening, January 27th, at half-past eight o'clock, Mr. J. R. Young, President, in the chair.

The following is an abstract of a lecture given:—

On the Use and Abuse of Food.

BY PROFESSOR ARCHER,

Of the Edinburgh Museum of Science and Art.

Professor Archer said the subject he had chosen that night for a single lecture was one which would certainly furnish ample materials for a very long course; and he hoped to live to see the day when in every university in Europe there would be a course of lectures delivered on this very important subject. Not only was that not the case at present, but in our English and Scotch universities there was no such chair as one for dietetics. That was the more surprising when they bore in mind that upon the simple question of whether we were to use food or abuse it depended our bodily happiness. By the abuse of food life was rendered miserable, and ample occupation for medical men trained in other branches of medicine was found. Now, it struck him, and it had always struck him, that this was beginning at the wrong end, and that they ought really to learn all about food, all about its application to the system, and by learning that be able to guard against a vast deal of the inconveniences they otherwise suffered.

He would inquire, in the first place, "What was food?" Food did not consist so much of all the materials which were put into the mouth, and passed from the mouth into the stomach, as all of that which if eaten could be rendered serviceable to the system after digestion. This food which was placed in the stomach was very much like the materials taken into the laboratory, for there it had to be worked up into a great variety of compounds, and distributed in a variety of ways into the system. Food was taken for two purposes—to restore the waste which was perpetually going on in the body, and to supply the fuel to what he might call the furnace of the laboratory, which did its work in furthering the process of assimilation of tissue-forming food. It was not generally borne in mind how constantly waste goes on in the body. No muscular action of any kind could take place in the body without some actual loss of weight. Food was required to restore this loss, and keep up a proper amount of matter in the body, and this food must be associated with some material which should keep up the vital heat in order that the body might assimilate the matter placed at its disposal.

There were various kinds of food. The first-class he should speak of was—absolutely necessary foods. In this class they had first, mineral foods. This mineral food consisted of water and salt, and what they might call the ashes of plants and animals—that was to say, the materials which were left after they were burned out either in the process of digestion or otherwise. After such burning there was a certain amount of mineral matter left behind in the bones and flesh of animals, and in the leaves and stalks of plants, which the human system required for supplying one of its wants. The second group consisted of carbonaceous, or heat giving matters. This second group included starch, sugar, fat, and acids. These consisted chiefly, in fact he might say altogether, of carbon, oxygen, and hydrogen. Their use was to serve as fuel by which the vital action of the body was kept up. The third group was the most important one, of nitrogenous or flesh forming substances—fibrine, albumen, and caseine—containing the absolute necessities of our existence.

The second class of foods consisted of what were called accessory foods, which were of use in alimentation but the exact function of which was not properly known. Such were the cellulose of plants, and the gelatine and gums of

plants and animals, which were certainly useful to the system, but the exact way in which they were assimilated and worked up was not clearly known.

The third class of foods, called auxiliary, was divided into two groups also. The first of these groups comprised the stimulants, such as alcohol and the volatile oils; the second contained the narcotics. In speaking of dietetics they placed things a little bit out of the way sometimes. For instance, they called tea, coffee, and cocoa narcotics, as well as tobacco and Indian hemp. These were none of them absolutely necessary, though some of them were really useful. In tea, coffee, and cocoa, besides the nutritious matter, there was another substance in each which was readily taken up by the system—theine. Unfortunately in the case of tea and coffee the theine was always associated with a very large quantity of astringent matter—tannic acid—and consequently these were often very injurious, and gave rise to dyspepsia in a very remarkable way. Of tobacco he was not going to say anything because he knew his opinion would be held to be perfectly useless by a large number. When in a healthy state the body was able to assimilate the various foods which it required, and a knowledge of these constituted the science of dietetics. His object in these remarks had been rather to point out to them how very much they were in want of information in this direction. There was not a single chair devoted to this science in any of our medical schools or universities, and, therefore, at present they had only to rely upon certain writers upon this subject who had stood forward for some time past as leaders. His object at present was rather to point out to them how very unreliable the very foremost of these writers was; because he considered it of the utmost necessity when they took up a subject for study that they should be exceedingly careful not to read books more likely to do harm than good. The only book which he knew professing to deal fully with the subject of dietetics was one which he now had before him, by a medical man who had the reputation of being the foremost in this subject for a long time—Dr. Edward Smith, of London, well known for his investigations into the action of theine. His present object was to point out some of the errors of this book; and if he showed them a few things which he had picked out of it in the most cursory way, and which were truly absurd, he was much afraid they would conclude that they should put down the bulk of the book as of the same kind. The author spoke of peas, beans, lentils, etc., as highly nutritious seeds, and went on to speak of them as of great value as food. As a matter of course, everything that was largely nutritious, if it were not associated with something else which counterbalanced that quality, ought to be classed with the very best kind of food. The author gave the scientific name of beans as *Phaseolus Hernandesi*, which was wide enough away from the proper name. He stated that they were "daily eaten in great quantities by the inhabitants of Mexico and Central America." He (Professor Archer) could not imagine why a man writing upon peas and beans should rush away to Mexico and Central America, as if these were plants known only in large botanical collections. Here we ate beans and peas just as they did in Mexico, and there was not one word said by the writer about the large production and consumption of them in Great Britain and Europe. The author spoke of the chick pea as largely grown in India and used there, and as being too delicate for this clime. The pods he described as hairy, and exuding an acid which was irritating to the hands, and injurious to the boots of those collecting the peas. Here he was evidently confounding two things, *Cicer arietinum* and *Mucuna urens*. In speaking of maize or Indian corn, Dr. Smith described it as "no doubt the product of sunny rather than of temperate climes." Now, everybody knew where maize came from, and that it was introduced in 1562 from America, and for a writer professing to give information about it to suggest that because it was raised in the tropical and sub-tropical climes of the world it must therefore be a native of sunny rather than of temperate climes was absurd. Dr. Smith gave millet as the heading for a series of things, and there were a large number of millets. The millet which he began with, was a small grain, as he said, scarcely larger than a pin-head. But then Dr. Smith had lost sight of the fact, if he ever knew it, that millet was a generic term applied to several different plants—in fact to plants of several different genera. They had this Chinese sort which Lord Elgin spoke of as plants growing five or six feet high; but then there were a large number of these plants having, not as Dr. Smith said, seeds of the size of a pin-head, but nearly as large as tares. The plant which Lord Elgin spoke of was really the sugar millet, *Sorghum sinensis*, a totally different plant which produced very little seed. Professor Archer then criticized some remarks of Dr. Smith on the subject of oatmeal porridge which he erroneously described as similar to the "hasty pudding" of the English, the fact being that the latter compound was made of fine wheaten flour instead of oatmeal. Then the author described maslin as "a mixed product grown in Yorkshire and other northern districts of England, and composed of two or three parts of wheat and one part of rye; but it is not very extensively used at the present time." He said nothing as to whether the plants were grown together or how they were mixed. Dr. Smith's remarks on the sweet potato (*Batatas edulis*), that it was rarely used in this country, although not unknown, but that it was in common use in Central America and other hot countries, "where the common potato does not grow or cannot be obtained," revealed great ignorance of the native country of the potato, which came from Peru, as did also the sweet potato. There was a most extraordinary mistake in a paragraph about the *Yucca*, which the author gave instead of *Jatropha*, the name adopted by botanists as the generic name of the plant which yielded tapioca and arrowroot; and he also stated that the same plant, the *Yucca*, yielded arrowroot. It seemed almost incredible, but there were hundreds of such mistakes. Then he went on to speak of the yam genus. In speaking of the plantain he said it was "cooked like other vegetables." Professor Archer said the only way in which he ever heard of plantains being cooked was their being fried. The author erroneously spoke of the horse-plantain as growing in India and on the Zanzibar coast. It grew in neither of these places, but in the extreme south of Africa and Ethiopia, and was the very plant which poor Bruce discovered and described as producing black seeds instead of the usual long fruit, which was set down as one of the aberrations of which he was said to be guilty, but which had since been all found to be truth. There was a rather rich little bit about the cabbage, which the author described as a most nutritious class of vegetables. In his remarks on the nettle the author spoke of the "medicinal virtues of its juices" as recommending it to use, while Professor Archer remarked, the real fact with regard to the nettle was that formerly, when green vegetables were fewer in number, the poorer classes cut off the young shoots just as they were appearing through the ground, and these were tied together and eaten like spinach. And they were very good too. But they did not drink the juice, which, like the juice of cabbage, was rather offensive in its own way. Then as to the fennel, Dr. Smith said, "Fennel (*Fœniculum vulgare*) was eaten in England many centuries ago, and is still used as an aromatic vegetable in the cooking of fish, but in various eastern countries the stem is eaten like rhubarb stalk, and offers an agreeable acidity." Most of them knew something of the fennel, but few of them he thought would find, as Dr. Smith stated, that it possessed any acidity, or an approach to it, in the stalks, which might tempt them to eat it as they would rhubarb. Dr. Smith spoke of the tomato being "boiled as a vegetable," but if they boiled tomatoes they would find very little left—they were very easily boiled away. The date Dr. Smith described as the "fruit of a palm,

growing extensively in the Sahara." He did not say in the oasis of the Sahara, but in the desert itself. That was a specimen of the way in which the book was written. Professor Archer also criticized Dr. Smith's remarks on the fig and the custard apple. He spoke of a hundred species of the former fruit while in fact we only used one species of edible fig. The guava was described as growing extensively throughout the east, and highly prized for the jelly obtained from it. Guava jelly, Professor Archer remarked, came from the West Indies, and the guava was certainly a West Indian plant, though it had been introduced into the east, simply because the fruit was a valuable one. But in Dr. Smith's book it was spoken of as belonging to the East only. The prickly pear was spoken of as growing in the island of Majorca, while the fact was that we never received any from Majorca, and the fruit grew more abundantly in other places in the Mediterranean, whilst its original country is South America. Yet in this book Majorca was given as the chief place to which we were to look for it. The banana and the plaintain were very closely allied, so much so that people who ate them could scarcely know one fruit from the other. But Dr. Smith said the banana was the delicious fruit of the palm (*Musa paradisiaca*). It was no more a palm than the palm was a cabbage. Then there were some remarks about strawberries which were rather more than any one could stomach. They were spoken of as abounding in the hotter countries, while the fact was that the further south you went the more difficult they were to grow. In the southern parts of North America, Dr. Smith said, they were "so abundant in the woods as to feed a large detachment of soldiers." "They were of delicious flavour, and growing upon bushes three or four feet high." Dr. Smith spoke of the pine-apple "*tree*" growing in every hedgerow in Zanzibar, the truth being that it was only a small plant. Of the quince, Dr. Smith remarked that it made "better marmalade than the orange." Now marmalade originally meant simply quince jelly, from the Portuguese name of quince—*marmar*. We had borrowed that name and applied it to the orange jam in use here, but for any one who knew anything of these things to say that the quince made better marmalade than the orange was a piece of very curious information. Professor Archer further criticized Dr. Smith's remarks on preserved ginger, and on almonds, pointing out that he spoke of the sweet and bitter varieties of the latter fruit as if they were two distinct species. After criticizing briefly some of Dr. Smith's remarks on the horse-chestnut and kola-nut, Professor Archer passed to the subject of condiments. He could not suppose that anyone would call either salt, vinegar, or pepper an element in cloves or in cinnamon, but Dr. Smith said that salt, vinegar and pepper were elements entering into the composition of all articles of the class of condiments. He might mean a little more than he said there. "Sago," Dr. Smith said was "the product of several palms, and principally of the *Cycas revoluta* and other trees in India, Ceylon, and many other Eastern countries." Sago, it was perfectly true, was the product of several palms, but the *Cycas revoluta*, put down as the principal one, did not happen to be a palm at all, and though something of the kind was said to be made from it by the natives, it certainly did not yield one single ounce of the sago of commerce. "Arrowroot," Dr. Smith said, was "a well-known food." Unfortunately, it did not seem to be very well known to Dr. E. Smith. He gave it as derived "chiefly from the palm tree (*Maranta arundinacea*), which had no right to be called a palm. After making some remarks on Dr. Smith's description of tapioca, cassava, and mandioca, Professor Archer referred to a statement by Dr. Smith to the effect that iron was one of the adulterants of sugar. Professor Archer said he certainly never detected iron in sugar, and he thought that if used in tea the iron, by darkening the tea, would be rather an advantage to some tea-makers. Manna was described by Dr. Smith as being the produce of Lebanon, Kurdistan, "and elsewhere, it is found on the leaves of various plants as the dwarf oak, tamarisk, and larch;" "it is also sometimes found on sand and stones, and is then whiter and purer than the tree-manna."

For this medical man, Professor Archer remarked, to say nothing of the manna ash of Europe, which yielded all the manna used in Europe, was very funny. For the tea plant Professor Archer pointed out that Dr. Smith gave four names—*Thea sinensis*, *Thea viridis*, *Thea bohea*, and *Thea assamensis*, without saying what was the proper name of tea. In conclusion, Professor Archer said he thought he had shown them enough to convince them that so far their chief guide in dietetics was not to be relied on, and therefore it was of the utmost importance that in reading they should study with great care to eliminate the few grains of truth in such a book as this from the very large quantity of very false chaff.

After some remarks on several of the points touched upon by Professor Archer, Mr. Tait begged to move a very special vote of thanks for the able and instructive lecture which had just been delivered. This was seconded by Mr. Ainslie and very cordially received.

Mr. Mackay thought that while the meeting conveyed thanks to Professor Archer they ought also to mention the high gratification felt by those present at the recognition bestowed upon Professor Archer by the Russian Government. Only yesterday a large and magnificent gold medal had been received by Professor Archer, accompanied by a diploma, explaining that the Emperor Alexander had bestowed the medal for the investigation of valuable matters instructive to the public, carried on for a long period as corresponding member of the Scientific Committee of the Ministry of the Domains of the Crown in Russia. The honour so conferred was one of which he felt assured both Professor Archer and his fellow citizens might well be proud.

The Secretary then stated that a slight misunderstanding had arisen in regard to the award of Mr. Hills' prize at the examinations in Scotland. When the money was handed over by the London President at the August meeting of Council the terms on which the books were to be awarded were distinctly stated. The successful candidate was to be the *highest in honours* connected with each Minor Examination held in Edinburgh. When it was announced here in December last that the first prize would be given in January, no allusion was made to the fact that no less number of marks than 650, being the pass number in honours, could be recognized as a success. The party gaining the highest number at their last examination did not reach 650, and was therefore not entitled to any prize under the conditions attached by the President to his kind and liberal donation. The party, however, appealed on the ground that this condition of gaining honours had not been made prominent enough, and the Board have therefore agreed to give the party a volume, but not as the "Hills' Prize," because it is desirable that the same rules should attach to the London and Edinburgh award. This arrangement is now very specially made known to prevent further confusion or future misunderstanding. No one, therefore, can obtain Mr. Hill's Prize of Books unless he has got at least the pass number in honours connected with his Minor Examination.

Specimens of quinoidine and sulphate of quinoidine, from Messrs. Howards and Sons, Stratford, London, were placed on the table as presentations to the museum of the Society.

Provincial Transactions.

NORTHAMPTON PHARMACEUTICAL ASSOCIATION.

On January 2nd, 1874, the members of the above Association gave a series of readings and recitations, and a very enjoyable evening was spent.

On January 22nd a meeting was held for general busi-

ness, at which some letters from Mr. J. F. Evans, a corresponding member, now at Sinimberghi's Pharmacy, Rome, were read, and thanks passed to the Pharmaceutical Society for 'Catalogue of Library,' and PHARMACEUTICAL JOURNAL, and to Mr. Evans for some Italian prescriptions.

A meeting was also held on February 3rd.

The Honorary Secretary, Mr. G. C. Druce, having read the minutes of former meetings,

The President, Mr. Masters, said that he had a most pleasurable duty to perform, viz., that of congratulating their worthy and indefatigable Secretary, Mr. G. C. Druce, upon the honourable and praiseworthy manner in which he had just passed his Major Examination, being the only one out of the four that passed who succeeded in getting that characteristic stellate mark attached to his name. He told the members that it always had been a rigid ordeal, and that it was still more so now, and that any person who succeeded in passing it, even if he had been studying at Bloomsbury Square, under the Professors there, was entitled to much credit; but when any one, as their Secretary had done, passed that examination without any help whatever, except that of his own exertions, and without giving up his business occupations, he characterized him as one in a thousand, and said that he could scarcely find words strong enough to express the credit which in his opinion was due to him, and concluded by saying that he thought all the members ought to feel proud that they belonged to an Association with which he was connected.

Mr. O. Wallis then read a paper on "The Chemistry of Sugar and Starch," in which he described the proximate vegetable constituents of plants, dwelling for some time on the saccharine and amylaceous principles, explaining the manufacture of cane sugar, and the methods of distinguishing it from grape sugar. He then described starch, the method of procuring it, its occurrence in plants, its chemical constitution, its reputed structure and appearance; and then showed how starch might be converted into glucose, how cane sugar was converted into grape sugar, and that into alcohol. The theory of malting was then described, and Mr. Wallis concluded an excellent paper by stating that very often substances met with in every-day life are found, upon examination, to be teeming with interest, and to well repay any trouble that may be taken in investigating them.

The discussion was taken up with interest.

The attendance, despite political attraction, was a good one. After a vote of thanks to Mr. Wallis for his paper, the meeting terminated.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, February 5th, 1874, Professor Odling, F.R.S., President, in the Chair. After the ordinary business of the Society was completed, a "Preliminary Notice on the Action of Benzyl Chloride on the Camphor of the Lauraceæ" (*Laurus Camphora*), by Dr. T. Tommasi, paper was read by the Secretary. Dr. C. R. A. Wright had a on the "Isomeric Terpenes and their derivatives: Part III —On the Essential Oils of Wormwood and Citronelle," being a detailed account of his experiments on these substances, a preliminary notice of which was communicated to the Society some time since. The other communications were a "Preliminary Notice on the Perbromates" by M. M. Pattison Muir, F.R.S.E.; and "on the Coals from Cape Breton, their Cokes and Ashes, with some comparative Analyses," by Henry How, D.C.L.;—the latter paper giving the amount of coke produced by slow and quick coking, from the main seam coal of Sydney mine, Nova Scotia, and the Lingan Coal; also analyses of the ashes left by these coals.

The meeting was finally adjourned until Thursday, February 19th, when there will be a lecture "On the Detection and Estimation of Adulteration in Food and Drinks" by Mr. J. Bell, F.C.S. Lectures are also announced for March 19th, "On Dissociation" by Mr. J. Dewar, F.R.S.E.; and for May 21st. on "The Sewage Question, from a Chemical point of view" by Dr. W. H. Corfield, F.C.S.

MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY.

At the Ordinary Meeting of the above Society, on the 16th December, 1870, a paper was read entitled—

METHOD OF CONSTRUCTION OF A NEW BAROMETER.

BY J. P. JOULE, D.C.L., L.L.D., F.R.S., ETC.

The condition of the instrument placed on March 18 in the Society's Hall proves that it is possible to use sulphuric acid on the top of the mercurial column without chemical action taking place. I have therefore proceeded to prepare other tubes with a view to test, by practical work, the merits of the new contrivance.

A tube of about 3-16th inch bore is selected. It is first cleaned by drawing a knotted string through it. It is then bent to the siphon shape, and near the longer end it is drawn to a capillary tube. It is then washed with nitric acid; afterwards with sulphuric acid. The sulphuric acid is then drained off. Mercury is next poured into the short limb. The end of the longer limb is then attached to my mercurial exhauster. On working this the mercury rises in the tube, and, being replenished by pouring it into the short limb, soon arrives at the height due to the atmospheric pressure. It carries with it the acid left adhering to the sides, so that, after a few hours, half, or, what is better, one-third, of an inch of acid stands above the mercury. Small bubbles of air are seen to arise, but, by leaving the tube in connection with the exhauster for a day or two, these finally cease. Mercury is then poured into the short limb until that in the longer rises nearly to the capillary part of the tube. This is then sealed and detached from the exhauster. Mercury is then removed from the shorter limb until it stands in the long one at a convenient height. Sulphuric acid is then introduced into the short limb until it forms a column equal to that in the longer limb. A small tube is finally attached to the short limb, and dipping a little way into a small bottle containing a small quantity of sulphuric acid, prevents the access of moist air into the short limb.

The tube thus completed possesses the following advantages:—1. There is the utmost facility in the movement of the column, so that the most minute changes of pressure are at once registered without any dragging. 2. The depression produced by capillary action is reduced to one-half, so that the syphon arrangement can be satisfactorily used as affording an accurate neutralization of capillary action.

PARIS SOCIÉTÉ ET ÉCOLE DE PHARMACIE.

At the inaugural meeting of the Paris School of Pharmacy and the Society of Pharmacy for the present session, Professor Riche delivered a lecture, in which he called attention to the manufacture of soda and chlorine, and the application of the phosphates in agriculture; three great subjects which he considered the pharmacist of the present day could not afford to ignore.

A GLANCE AT SOME CHEMICAL INDUSTRIES.*

BY M. RICHE.

Professeur agréyé at the Paris School of Pharmacy.

In the first rank of chemical substances must be placed carbonate of soda, of which nearly 600,000 tons are manufactured annually, nearly one-third being produced in Great Britain and about 130,000 tons or rather less than one-fourth in France. The process followed is that originally proposed by a Frenchman, Leblanc, in 1793, and it is based

*Abstract of a lecture delivered at the Inaugural Meeting at the Paris School of Pharmacy, *Journ. de Pharm. et de Chim.* [4] vol. xix. p. 58.

on the reaction between sulphate of soda, carbon and chalk. The sole important modification that has taken place in it is a mechanical one, in which the trying work for a man of manipulating continually an enormous weight of pasty mass at a white heat is accomplished by a rotating cylinder driven by steam power. But if it has not yet been found practical to replace this process economically by any other, it has long been sought to utilize the residues of the manufacturer, and the importance of the problem is illustrated in the fact that the whole of the sulphur of the sulphate of sodium employed is present in the residues, and that this sulphur represents the greater part of the immense quantity used in the manufacture of sulphuric acid.

These residues in which the sulphur exists in the state of sulphide of calcium are heaped up in the neigbourhood of the works and form enormous mounds from which runs a yellowish sulphurous liquid that infiltrates to the wells and watercourses, and especially during the summer emits noxious vapours, giving rise to complaints because of the resulting injury. So that by the process of Leblanc not only is there loss of the sulphuric acid used as an intermediary in the manufacture, but the manufacturer has to bear the incessant complaints of his neighbours. Hence one of the greatest desiderata of modern industry have been to recover the sulphur from the soda residues. Numerous plans have been proposed with this object, seeking to assist the oxidation of the sulphide of calcium by heat, air, water, and other agents, and afterwards to heat with an acid the mixture of polysulphite and hyposulphite produced ; an operation having as an effect the reduction of the sulphur, which can then again be used in the manufacture of sulphuric acid. Among these processes hardly any except one, that of M. Mond, has been applied and that only in a few manufactories, since it requires considerable skill, and only yields a maximum of 20 per cent. of the sulphur contained in the mare. At Dieuze, a method invented by Messrs. Hoffmann and Buquet, the chemists of the establishment, is adopted. It is based upon the ingenious idea of utilizing for one another the residue of the manufacture of soda and that of chloride of lime. After having oxidized the soda marcs by the action of air, water, and the sulphide of iron produced with the residues of chlorine, the sulphur is precipitated from it, either in a free state by the hydrochloric acid of these residues, or in the state of sulphide by the chloride of manganese ; then this sulphur and sulphide are converted in the retorts into sulphuric acid. Although this process offers inducements to those manufacturers who produce both soda and chlorine—and these are the most numerous—it does not appear to have been adopted outside of the establishment in which it was originated, and this is probably due in great part to the fact that it requires several different operations, considerable room, and expensive labour.

Meanwhile it must not be supposed that the manufacture of soda has spoken its last word, and two important events give ground for the hope that in a not very distant future either we shall cease to employ the sulphate of soda or else cease to make that sulphate with sulphuric acid.

In 1855, two Frenchmen, Messrs. Rolland and Schloesing patented a process for manufacturing soda based upon the treatment of chloride of sodium with bicarbonate of ammonia. From the double decomposition, there results a deposit of bicarbonate of soda, which by a slight heat is transformed into neutral carbonate and a solution of hydrochlorate of ammonia, which is used to regenerate the ammonia. This process did not give rise to a regular manufacture ; but it has been taken up by a manufacturer named Solway, first in 1863 and recently in 1872, and the considerable modifications which he has introduced, both in the regeneration of the ammonia and in the saturation of the ammoniacal chloride of sodium by carbonic acid, permit a hope of the generalization of this process, which theoretically is of great simplicity, and presents an advantage over Leblanc's in recovering the soda from the chloride of sodium directly and at the ordinary temperature, *i.e.*, without the expense of sulphuric acid and a large consumption of fuel. The other method is to draw off the sulphate of soda already prepared in the immense reservoir which covers the greater part of the globe, namely, the sea. After having shown that it is possible to extract from the mother liquors of the salt marshes sulphate of soda, chloride of potassium, and sulphate of potash, M. Balard, sought to manufature these salts and M. Merles de Salindres attempted to introduce this great discovery of the laboratory into the manufactory. After considerable time, money and skill had been spent in the attempt a considerable industry was established at Camargues, and it commenced to send into the market the salts of soda and potash, when the discovery at Stassfurt of immense saline beds, deposited in regular layers by the evaporation of the seas of former ages, led to a sudden fall of 50 per cent. in the price of chloride of potassium. Many would have lost courage, but that of the founders of this industry seemed to increase, and justifying the proverb "le gênic est une longue patience," they now send out their salts at a remunerative price, to compete with those from Stassfurt.

The following is a sketch of this process. The sea water left to evaporate spontaneously yields at first "sea salt." The resulting mother liquor conducted into reservoirs is allowed to evaporate until it has a density of 35° B. ; it then deposits the "*sel mixte*," consists of sulphate of soda and chloride of sodium. This second mother liquor submitted to a second evaportion to 37° B. gives a third product called "*sel d'été*," in which predominate the double chloride of potassium and magnesium and the sulphate of those two metals. The "*sel mixte*," redissolved and submitted to an intense refrigeration by means of immense Carres apparatus, yields a crystallization of sulphate of soda and a solution of chloride of magnesium. Finally the last liquors remaining after these various treatments strongly charged with magnesian salts are utilized. The chloride is converted into hydrochloric acid and magnesia ; the sulphate is used in England in the cultivation of clover, in the manufacture of alum and sulphate of baryta, and in calico printing.

The soda manufacture is intimately connected with that of chloride of lime, because the hydrochloric acid which is the complementary product of the sulphate of soda is used principally in the preparation of chlorine. This body, the active principle of chloride of lime and other bleaching agents, is still prepared by the process of Scheele in causing hydrochloric acid to react upon binoxide of manganese, and this industry furnishes a second example of a method which has lasted during three quarters of a century without modification, but which is much unsettled at the present time. Here again the subject is attacked on two distinct sides ; it is proposed to utilize the residues in regenerating the binoxide of manganese, not only on economical but sanitary grounds, and it is also sought to dispense with this intermediary.

The regeneration of the binoxide of manganese is a problem solved by a skilful English manufacturer, Mr. Weldon. The chlorine residues are treated with two equivalents of lime ; there results a mixed protoxide of manganese and calcium, which heated in a current of air yields binoxide of manganese mixed with lime, which is used to react again upon the hydrochloric acid for the production of chlorine. This process allows of the realization of a considerable economy and leaves inoffensive residues, and it has been established for several years in numerous manufactories. Nevertheless, it has the inconvenience of wasting lime and the acid necessary for its saturation. Mr. Weldon has therefore recently proposed another process in which there is the consumption of only hydrochloric acid and fuel. The binoxide of manganese is mixed with an equal quantity of magnesia, then treated with hydrochloric acid, which produces, besides chlorine, a double chloride of manganese and magnesium. This,

heated in a current of air, regenerates the binoxide of manganese and the magnesia,—which are again used in the manufacture—and produces a gaseous mixture of hydrochloric acid, chlorine and air in excess, from which the hydrochloric acid is separated by water. The chlorine is thus produced from two sources ; first, from the action of the binoxide of manganese upon the hydrochloric acid, then from the decomposition of the double chloride by heat. The chlorine from this latter source is suspended in nitrogen and an excess of air, and this dilution does not allow of the production of chloride of lime of a high standard. In this case Mr. Weldon collects the gas in a milk of lime, which he afterwards treats with hydrochloric acid to obtain from it the pure chlorine. This process was introduced a year since, near Liverpool, with success, and appears to have been adopted in some manufactories in Scotland.

The second system, mentioned above, the manufacture of chlorine without the intervention of binoxide of manganese, is the invention of another Englishman, Mr. Deacon. His method is extremely ingenious, and offers the immense advantage of permitting the substitution of the previously diluted hydrochloric acid by the hydrochloric gas as it issues from the sulphate furnaces, and thus effecting a great economy. The gas, mixed with air, after passing through brick passages kept at a temperature as near as possible to 400° C., circulates in chambers maintained at the same temperature, in which are piled up balls of clay impregnated with sulphate of copper : chlorine and water are formed, and the sulphate of copper is left unaltered. Notwithstanding the costly apparatus and the necessity for maintaining the temperature within narrow limits, also of the transport of a certain quantity of the sulphate from the first towards the latter chambers, and the difficulties met with both in carrying off the gaseous hydrochloric acid, and in making chloride of lime of high strength with chlorine diluted with air, this process has worked regularly for some years in several English manufactories. However it has not yet been demonstrated that it can be applied to the very diluted hydrochloric gas which escapes from the sulphate of soda furnaces towards the end of the calcination. But it is extremely important to realize this condition, because these last vapours are extremely difficult of condensation, and when they spread in the neighbourhood of the works furnish a mine of ruinous disputation to the manufacturer.

The third industry which I propose to discuss is of recent origin. Less important than the two others, it increases day by day, and is destined to become a source of wealth to France : I mean the industry of the agricultural phosphates.

The labours of Payen, Berthier, Rivot, Boussingault, Barral, etc., have established that phosphorus occurs in all plants, and that of the various organs of plants, the seeds of cereals—our principal aliment—yield the ash richest in phosphates. The salts, aided by water charged with carbonic acid and various saline solutions, penetrate into their tissues, and it is from the vegetable kingdom that men and animals draw the phosphates met with in their organisms, and which constitute the major part of their osseous frames. Consequently phosphorus is an element indispensable to organized beings, and it is the soil that supplies it to them. This truth had not escaped Davy, for he did not hesitate to attribute the present sterility of Asia Minor and Sicily—those ancient granaries of Rome—to the exhaustion of the phosphates from the soil by the exportation of corn during whole centuries. This absolutely terrestrial origin is peculiar to phosphorus ; for carbon, hydrogen, oxygen, and nitrogen—that is to say, the other constituent elements of living bodies—are supplied especially from the atmosphere. Consequently it is necessary to restore to the soil the phosphorus which the harvests remove from it, and this necessity is the more urgent, because the proportion of phosphates contained in the best soils is very small. For a long period it has been known that bones constitute a valuable improvement to land, and in 1813 Payen called the attention of agriculturists to the efficacy of the black from sugar refineries.

The English were the first to enter this path, and about 1820 they manufactured a manure from bones which appeared to be of such value that their ships went afar to purchase this substance, and it is said that certain battle-fields have not been exempted from their explorations. In 1818 Berthier discovered the first bed of natural phosphated lime in France, at Wisant (Pas-de-Calais) ; but it was Professor Buckland who, in 1822, first called attention to the mineral phosphates. He explored the soil of England in all directions, and announced that in the carboniferous limestone, the greensand, and the chalk, and in different tertiary beds, he had met with abundance of coprolites, which were the excrements of various animals, and especially of huge saurians, the bones of which were found in those regions. He pointed out that these nodular masses, formed principally of powdered bones, were very rich in phosphates of lime and were widely distributed. In 1843 Messrs. Daubeny and Widdington were sent from England to explore the Estramadura beds, but it was not until 1851 that serious researches were undertaken in France. Messrs. Meugg and De la Noue discovered numerous coprolitic nodules in the lower cretaceous stratum, and in 1855, M. Elie de Beaumont published in the *Moniteur* some valuable articles pointing out the utility of phosphates in agriculture and the geological strata in which they were found.

The first attempts in France to realize the industrial application of this substance were made in 1856, and since then the manufacture of the phosphates assimilable by vegetables has acquired a certain importance in the Ardennes, the Meuse, the Pas-de-Calais, and the Tarn-et-Garonne. Beds of fossil phosphates have also been noticed in several other departments, and quite recently in the department of Lot, and near to Bellegarde. Doubtless they would be discovered in other countries, if the search were conducted according to the precise indications contained in the words of M. Elie de Beaumont :—"In the strata of the lower cretaceous formation the nodules of phosphate of lime are the constant companions of the green beads of ferrous silicate commonly called by geologists glauconite."

The coprolites appear as nodules of variable shapes, some have the form of oblong pebbles, others occur in uniform masses, others again resemble potatoes or fir cones. Their size varies from 2 to 8 centimetres in diameter. Their colour is sometimes blackish brown, sometimes greenish grey. Fragments of bones, teeth, and shells are found in them. According to M. Bobierre, who has made numerous analyses of them, they contain from 32 to 70 per cent. of phosphate of lime, the average being about 50 per cent. The remainder is formed of phosphate of iron in small quantity, carbonate of lime, silica and clay. The animal matter has not entirely disappeared, for if they be heated with an alkaline solution, ammonia is given off accompanied by a perceptible odour of animal matter. Coprolites are porous, and permeable to liquids and gases. Reduced they rapidly undergo modifications in the air. M. Dehérain has observed that nodules containing 2·5 to 6 per cent. of water lose only 0·25 per cent. of earthy phosphates when submitted to the action of acetic acid, whilst after being exposed during three months to the air they contain 17·5 per cent. of water and yield to acetic acid 5 to 6 per cent. of phosphates. This powder, agitated in corbonic acid water, is perceptibly attacked after some days, and this action is increased by its exposure to air. The assimilation of the fossil phosphates is therefore not doubtful, especially after some months' contact with the air. They are especially efficacious in schistous and granitic soils, and their association with sulphate of ammonia or animal matters produces a manure of the highest order. The rapidity of this assimilation is such that in many cases coprolites are employed without any

other preparation than a careful pulverization effected in the following manner. The nodules are cleansed from adhering matters by a prolonged agitation in a current of water; they are then crushed in an apparatus constructed on the principle of a coffee-mill, and afterwards reduced to a fine powder under millstones.

This easy assimilation by vegetables, which connects the fossil phosphates with bones, animal black and precipitated phosphate, distinguishes them clearly and advantageously from the mineral phosphates properly so called, such as apatite and phosphorite, the assimilation of which is so slow that it is necessary to heat them with an energetic acid before employing them in agriculture. This operation, which is also applied to the fossil phosphates, constitutes in England a flourishing industry, and is conducted in the following manner :—the matter, reduced to a fine powder, is introduced, a small portion at a time, by means of a hopper into a cylinder of brass, or of pine-wood tarred and banded with iron, 2 metres long and 1 metre in diameter; strong sulphuric acid is then added and the mixture is stirred for several minutes by a cylinder of brass having arms; the resulting fluid is poured out and one third of its weight of powdered phosphate added. At the end of an hour the sulphate of lime sets, the product becomes solid and it may be pulverized between the fingers. If a perfect manure be required a small quantity of sulphate of ammonia or nitrogenous matter is added or sometimes sulphate of potash.

The phosphate of lime so prepared is called super-phosphate. It consists of a mixture of phosphoric acid, and various lime phosphates, among which predominates the soluble phosphate, $CaO2HO, PO_5$, which is usually designated under the name of acid phosphate. It is not the solution of this salt which acts upon the plants, for its extreme acidity would produce a fatal effect upon their delicate organs; but it reacts upon the bases contained in the soil to produce various phosphates, and principally upon the carbonate of lime in producing a bibasic phosphate, $2CaOHO, PHO_5$, a gelatinous substance, which, being readily soluble in water, and especially in water charged with carbonic acid, is very easily assimilated.

The industry of fossil and mineral phosphates, and of the compound manures prepared by their aid, is yet in its infancy in France, and to Frenchmen it is sad to see the English carry off from their soil the natural phosphates to return them afterwards at a considerably increased value in an assimilable state.

It is the duty of all educated men to contribute in their sphere of action to the encouragement of these industries; but in order to do this more surely it is necessary to know the principal obstacle to their development. This is the numerous frauds of which these products are the object; frauds the more tempting to the seller from the inability of the agriculturist to detect them, and the more serious to the buyer in that he does not discover the cheat until long after, through the decreased value of his harvest. Thus, under the names of super-phosphate of lime, fossil phosphates, phospho-guano, and guano with soluble phosphates and fixed nitrogen are sold mixtures in which the smallest quantity of the useful principle is suspended in the inert body. I have had, for example, occasion to analyse pretended guano which were but earth mixed with a little guano to give it the tint and odour of that manure.

If this be the principal cause which injures the sale of artificial manures, and consequently paralyzes the development of their manufacture, it is necessary, in order to cut at the root of the evil, that transactions in manures should be based upon a faithful analysis, which should guarantee their strength in nitrogen and soluble and insoluble phosphate, and this plan has been adopted by respectable manufacturers in the large manure markets for some years; but it is far from being generally followed in the smaller towns and rural districts. It is therefore necessary to create throughout France centres for analysis, in order to facilitate the transactions between buyers and sellers, and to guarantee the interests of both. No person is better fitted than the pharmacist to fulfil this important misson for the development of agriculture and consequently of the national wealth. It might be said that he alone, in the majority of districts is able to do it, because he alone possesses the knowledge necessary for analyses of phosphatic manures, which if not difficult are at least delicate. For this reason I have for several years passed introduced this kind of analysis in my course. These analyses in unpractised hands have given widely divergent results; on the other hand, various methods have been extolled, wrongly I believe, which appear by their simplicity, more apparent than real, to allow of agriculturists themselves testing manures. From this double cause it results that confidence in analysis is lost, and the remedy appears worse than the evil.

This is the duty that I would desire to see the young pharmacists prepare to undertake upon leaving this school, animated by the ardour of their age and the natural desire to acquire an honourable position by their labours. Many among them would find an interesting occupation, which in the course of time might constitute an important addition to the produce of their pharmacies; but especially they would thus become arbitrators between their fellow citizens, and would then experience an increase in the consideration which should always surround the pharmacist—a consideration to which he his quite entitled by his education and his studies.

Parliamentary and Law Proceedings.

Condemnation of Unsound Coffee.

Mr. Baylis, the solicitor to the Commissioners of Sewers, applied, on Tuesday, Feb. 10th, to Mr. Alderman Carter, at the Guildhall Police Court, in the City of London, to condemn a quantity of coffee which one of the sanitary inspectors of the City had seized as being unfit for human food.

Dr. C. M. Tidy, Professor of Chemistry at the London Hospital, said he had been to the office of Mr. Syers, 44, Lime Street, and examined 31 bags of something that was called "coffee," and three boxes of coffee and dust. One sample had been taken from 15 bags of coffee on one floor, one from 16 bags in the passage, and one from three boxes in the office. Mr. Syers did not object to their taking away the three boxes of coffee and dust, but he protested against their taking the bags, as they had been sold to go to the Continent. He had tested the samples and they were undoubtedly unfit for human food.

Mr. Alderman Carter asked whether Mr. Syers was prepared to admit that it ought to be destroyed?

Mr. Syers said he was not, for it was all sold to go abroad, and more was wanted. He had drunk it himself.

Mr. Alderman Carter said he should not like to join him in a cup of such a decoction. If Mr. Syers wished to have legal assistance he would adjourn the case, otherwise he would proceed to adjudicate upon it at once.

Mr. Syers said the coffee was not unfit for food and was sold to go to the Continent. He had seen worse coffee sold in Mincing Lane.

Mr. Alderman Carter said that for the credit of Mincing Lane he hoped Mr. Syers was mistaken. What was the value of it now in its present condition?

Mr. Syers said 25*s*. per cwt.

The Broker to Mr. Syers said the coffee was going to the Continent, and he did not not know what they were going to do with it there. He and Mr. Syers would guarantee that it should go abroad.

After some further discussion, Mr. Alderman Carter condemned the coffee, and ordered it to be destroyed.—*Standard*.

Review.

THE TREASURY OF BOTANY: a Popular Dictionary of the Vegetable Kingdom, with which is incorporated a Glossary of Botanical Terms. Edited by JOHN LINDLEY, M.D., F.R.S., F.L.S., and THOMAS MOORE, F.L.S. New and revised edition, with Supplement. London: Longmans. 1874.

The object of this useful work, as set forth in the preface to the first edition, is "the bringing together into the form of a dictionary a concise account of all plants concerning which a general reader would be likely to seek information." It must be admitted that this object has been thoroughly accomplished, considering the immense number of genera and species from which a selection had to be made, and the small space which could be allotted to each; the amount of information conveyed, and the terse and lucid manner in which the descriptions are given, render the work quite a treasure to those interested in any branch of botany. The student, instead of puzzling over the scientific diagnosis of a natural order or genus in some advanced botanical hand-book, will here find the same characters explained in a clear and homely manner; the amateur gardener desirous of knowing what the botanical name of some plant may be, which is known to him only by its familiar English name, on referring to the latter in this dictionary will find out what he wants to know; the student of economic botany in the same way may learn the botanical source and history of the various vegetable products met with in commerce; and the student of physical geography will here find much information usually sought for in special works on that subject.

In addition to these advantages there will be found, dispersed throughout the work, a glossary of botanical terms, a series of French names of species and genera, and a large number of local names for plants and vegetable productions in various parts of the world. For this reason the 'Treasury' will be found useful to the dispenser of French and other foreign prescriptions, and also to the student of the materia medica of other countries. The names of the contributors to the 'Treasury of Botany' are alone a sufficient guarantee of the correctness of the information contained in it. Among these we notice those of Balfour, Berkeley, Carruthers, Dickie, Masters, and others well-known as occupying a high position in regard to botanical science. In the present revised edition the editor acknowledges additional assistance from the following gentlemen, Messrs. Britten, Thiselton Dyer, Halliday, and J. R. Jackson.

Numerous corrections have been made in accordance with the progress of botanical knowledge, and the views held with regard to the limits of natural orders, etc., by writers of the present day. These changes will be easily seen on turning over the leaves of the work, for on account of the work being printed from stereotype, the type presents a slightly different appearance where alterations have been made. For the same reason it has been impossible to insert in the body of the work much additional information, which consequently forms a supplement of 97 pages at the end of the work. This, together with the corrections made in the body of the work, brings it up to the present day with regard to the information contained in it.

In a book of this kind, which covers such an immense extent of ground, it is hardly possible that a few omissions or oversights should not occur; thus we notice that Turkey rhubarb, Pareira brava, and Artemisia Cina have been overlooked, the first being still attributed to *Rheum palmatum*, the second to *Cisampelos pareira*, and the third is omitted altogether. Instances of this kind are, however, rare, and we may congratulate the editors upon the success which has attended their efforts to render the work a really useful book of reference. It should find a place in the library of every intelligent observer of Nature.

BOOKS RECEIVED.

INTRODUCTION TO THE STUDY OF ORGANIC CHEMISTRY. THE CHEMISTRY OF CARBON AND ITS COMPOUNDS. By HENRY E. ARMSTRONG, Ph.D., F.C.S. (Text-Books of Science.) London: Longmans. 1874. From the Publishers.

PHARMACEUTICAL LEXICON: A DICTIONARY OF PHARMACEUTICAL SCIENCE, containing a Concise Explanation of the Various Subjects and Terms of Pharmacy, with Appropriate Selections from the Collateral Sciences, etc. By H. V. SWERINGEN. Philadelphia: Lindsay and Blakiston. 1873. From the Publishers.

Obituary.

Notice has been received of the death of the following:—

On the 26th November, 1873, Mr. Henry Sprigg, Chemist and Druggist, of St. Neot's.

On the 16th January, 1874, Mrs. Elizabeth Adshead, Chemist and Druggist, of Dobcross, Saddleworth, Yorkshire.

Notes and Queries.

[386.] COCCULUS INDICUS.—Can any correspondent inform me what becomes of the "Cocculus Indicus" imported? I see that the stocks for the month ending January 31st, 1874, are 1066 bags, and the deliveries 47 bags. Is there any legitimate use for the same?—RICHARD STURTON.

FLUID EXTRACT OF SUMACH BERRIES.—Mr. J. P. Remington brought before the December meeting of the Philadelphia College of Pharmacy (*Amer. Journ. Pharm.* [4] iv. 7) the following formula for fluid extract of sumach berries (*Rhus glabrum*) which he stated was being largely prescribed in that city as an ingredient in mouth washes and gargles where the astringent and pleasantly acid properties of sumach berries were indicated:—

Sumach berries (in moderately fine powder)	16 troy ounces.
Glycerine	4 fluid ounces.
Alcohol,	
Water, of each a sufficient quantity.	

Mix half a pint of alcohol, three fluid-ounces glycerin, and five fluid ounces of water, and, having moistened the sumach with four fluid ounces of the mixture, pack in a suitable percolator, pour on the top the remaining portion of the sixteen fluid ounces of menstruum; close the percolator and allow the powder to macerate for four days; then open the percolator and continue the percolation until twenty-four fluid-ounces have been obtained. Of these, reserve the first fourteen fluid-ounces, and evaporate the remainder to two fluid ounces, mix with the reserved portion, and filter, if necessary.

A very good gargle and mouth wash may be made by taking—

Fluid ext. of Sumach berries	f℥iv.
Chlorate of potash	ʒij.
Glycerin, pure	ʒiv.
Water	℥vij.

Filter.

REMEDY FOR CATARRH.—The following mixture is said to have cured in about ten hours a very severe catarrh (*Neues Jahrb. für Pharm.*):—

Carbolic acid	10 drops.
Tincture of iodine	
Chloroform, of each	7·5 grams.

Some drops were placed in a test-tube, heated over a spirit lamp, and when evaporation commenced held under the nose. After two minutes the procedure was repeated, and it is stated that the troublesome symptoms soon disappeared.

The Proposed Extra Scholarships.

Sir,—With the view of making the conditions for competition as easy as possible, I beg to offer the following suggestions for consideration and discussion. That a modification should be introduced to the effect that winners of scholarships, besides receiving a cash payment, should (if they desire) be allowed to attend the laboratory at half the fixed scale of fees, such reduction not to extend beyond ten months from the time of entrance.

To allow the student to enter the laboratory at any period convenient to him, within a stated time after gaining the scholarship, and to attend for as short a time as he might require, would, I think, be generally acceptable to country students, and make the competition more general. On a future occasion I may perhaps trouble you with a proposition for evening lectures at Bloomsbury Square at the same fees as the morning courses; supposing that under the present regulations the professors would be allowed to engage assistants to lecture in the evening.

My idea is that if young men have equal facilities given them for obtaining sound instruction at convenient times, many would avail themselves of the opportunity rather than adopt the rapid method of preparation for examination now in vogue.

AMICUS.

Sir.—Every student ought to feel indebted to Mr. Schacht for his untiring zeal in the cause of education, and I was very pleased to see in last week's Journal that there is some probability of additional scholarships being instituted. But I feel, as Mr. Frazer remarked, "some difficulty in the words, similar in amount and character," for there is no doubt "the examination is at present too high," and I would respectfully suggest for the consideration of the committee, that the proposed scholarships should not be competed for according to the conditions for the Jacob Bell Scholarships. My chief reason for this is very well expressed by our editor in his article on "Examinations and the Registrar's Annual Analysis," where in reference to the Preliminary he says:—"Such an examination is intended to mark the close of *general*, and the commencement of *special*, education." If these scholarships are to benefit the class of young men that Mr. Schacht intends, it would be those who are serving an apprenticeship of four or five years, and are engaged behind the counter for at least twelve hours daily, and it cannot be expected that the little time they have at their own disposal should be spent in keeping up their knowledge of Virgil and German or French, but rather in acquiring a knowledge of Chemistry, Pharmacy, Botany, &c., subjects of far greater importance to them. I would suggest then that the examination should, as Bishop Temple says, "follow the school," and therefore should be on such subjects as a young man ought to require during his apprenticeship. Applying this suggestion to the present conditions for the Jacob Bell Scholarships, Virgil and French or German as well as English Composition and parsing should be expunged. Arithmetic might remain, and to Chemistry, Pharmacy, and Botany might be added Materia Medica and questions on the dispensing of Prescriptions. I think the limit of age should be twenty-two. If these regulations were adopted, it would in my humble opinion tend to promote Mr. Schacht's idea, viz., "scientific pharmacy."

A COUNTRY APPRENTICE.

Feb. 9th, 1874.

The Proposed Pharmacy Bill for Ireland.

Sir,—Permit me to say a few words in connection with the meeting of apothecaries lately held in Belfast to oppose the new Pharmacy Bill for Ireland.

I, as one of their assistants, am of opinion that these gentlemen have very little right indeed to oppose such a measure, knowing very well that the whole dispensing business in all the leading houses is conducted by assistants possessing the qualification of the Pharmaceutical Society of Great Britain; and if such persons are fully competent to manage the compounding departments of such fine establishments, surely they are equally able to take charge of houses for themselves.

In a well-known firm the partner who represents the Apothecaries' Society, neither manages his dispensing nor does he compound a prescription from one year's end till another. This remark is applicable in nearly all houses in Ireland. The dispensing is done by one or two pharmaceutical associates and a staff of junior assistants who are both hard worked and poorly paid for their laborious services.

It is well known by all the apothecaries that this Act would do great good to Ireland, but less to their pocket, and that seems to be the No. 1 in this opposition association.

They propose for the future that their curriculum of study be modified; that is, that the medical subjects which are not required to make a pharmacist be erased from their subjects of examination; but this is unnecessary, as the curriculum for a member of the Pharmaceutical Society is now fully equal to that of the Apothecaries' Hall of Ireland in its branches of pharmaceutical education.

A. P. S.

Belfast, 10*th February*, 1874.

[*** Our correspondent appears to be in error in regard to the facts of the case. There is no curriculum required in order to become a Member of the Pharmaceutical Society, and unfortunately at present no curriculum is enforced before passing the qualifying examination. So far as relates to the establishment of a compulsory course of study we entirely sympathize with the opinion which we believe is held by the apothecaries of Ireland, who are really the educated pharmacists of that country.—ED. PHARM. JOURN.]

"*Associate*" and *T. P. H.* are referred to the rule respecting anonymous communications.

J. B.—A minim is a definite weight—according to the B. P. one-sixtieth part of a fluid drachm; the weight of a drop depends upon the physical properties of a liquid, such as its density.

"*A Hater of Injustice.*"—The discussion having embraced letters on both sides of the question, it must be considered closed for the present so far as this Journal is concerned. Dr. Johnson's paper possessed an interest to pharmacists as tending to show that powerful compounds are sometimes supplied to patients as "homœopathic medicines" under conditions for which a pharmacist would be blamed were he to act similarly. The plea used in this your second letter—that the printed label directed that the dose of the medicine should depend upon the urgency of the symptoms, when probably the only judge of their urgency would be the patient himself, who might reasonably be excused for thinking he was dealing with an "infinitesimal" dose, would, we think, have as little weight with a coroner's jury as the *tu quoque* argument you also adopt. Your denial of the use by orthodox homœopathic practitioners of medicines or labels as described by our correspondents does not disprove that what has been called "pseudo-homœopathy" has not been practised by others, although it may do away with the necessity for a defence of a body of gentlemen who were not accused. Anyhow, even if such a defence be necessary, we disclaim any belief in the peculiar fitness of pharmacists for arbitrating upon the rival claims of the two systems of medicine.

W. S. (Chester) is referred to the rule respecting anonymous correspondents.

"*Wales.*"—No person is eligible for the Modified examination who did not register for the same on or before the 31st December, 1869.

"*A.*"—All advertisements for the PHARMACEUTICAL JOURNAL, and communications respecting them, should be sent to the publishers, Messrs. J. and A. Churchill, 11, New Burlington Street, in accordance with the notice that appears twice in every number. Your inquiry has been forwarded, but doubtless the delay caused by sending the advertisement so late to the wrong office was the cause of its non-appearance.

"*Pharmaceutical*" is referred to the rule respecting anonymous correspondents, and to the back numbers of the Journal.

T. B. Allkins.—The question is a legal one upon which we are unable to give advice.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. J. J. Smith, T. B. Groves, J. M. Fairlie, Gordon, "Better Pay," K. T.

NOTE ON IODIDE OF POTASSIUM.

BY T. B. GROVES, F.C.S.

Colourless crystals of Iodide of Potassium being almost invariably alkaline, the difficulty described by Mr. Holmes is not unfrequently experienced by others of the fraternity.

In my opinion, the most convenient way of dispensing this salt in combination with, say, Syrupus ferri iodidi is to dissolve it in a small quantity of water and then add a minute portion (a few drops will generally suffice) of the syrup, in order to cause a precipitate of the greenish carbonate. A drop or more (according to the alkalinity of the specimen) of dilute acid (I use hydrochloric), added cautiously, dissolves the carbonate, the disappearance of which indicates arrival at neutrality. The rest of the syrup can then be added, the mixture remaining bright. This is far more expeditious than using test paper, and equally satisfactory.

In 1856 I made a number of experiments with the view of producing for a photographer's use an iodide of potassium quite devoid of alkalinity. My first idea was to obtain the salt by boiling recently precipitated iodide of lead (obtained by treating a solution of acetate of lead with iodide of iron) with a solution of sulphate of potassium. The salt was so made, but the trouble of removing the metallic and other impurities introduced by the sugar of lead rendered the process an unsatisfactory one.

The simplest way is to treat commercial iodide of potassium with just sufficient water to dissolve it, then to neutralize its alkalinity with dilute sulphuric acid, and finally add a small quantity of spirit to hasten the separation of the sulphate so formed. The clear liquid, evaporated quickly to crystallizing point, and then set aside in a covered vessel to cool, deposits colourless crystals of the neutral iodide. These are of small size, and will, unless carefully secluded from the air, speedily turn yellow.

The mother liquor, exposed for spontaneous evaporation, also acquires a yellow colour, which deepens up to a certain point, but goes no further. On the contrary, it then begins to grow pale, until after a few days the yellow tint has entirely disappeared, leaving the liquid pronouncedly alkaline, as are the crystals that are obtainable from it, and which are, I need scarcely say, not prone to become coloured. It seems, then, that neutral iodide of potassium is unable to resist the combined attack of ozone and carbonic acid; but as soon as these agents have, by removing iodine, established a certain degree of alkalinity, their power over the compound ceases. The iodine then gradually leaves the liquid by evaporation, rendering it colourless and not amenable to further change, unless it be first made neutral by further addition of acid.

[*** In reference to this subject we have received a note from Mr. Alfred Southall, in consequence of his having noticed Dr. Redwood's statement at the Evening Meeting, "that according to his experience the more transparent the crystals of iodide the more strongly alkaline they were." Mr. Southall says this is quite different from his own experience; in manufacturing this chemical he always finds it necessary to have the solution as nearly neutral as possible, in order to obtain semi-transparent crystals, for if there was an excess of acid he would get the opaque crystals that many have a liking for.—Ed. Ph. J.]

MUSTARD AND ITS ADULTERATIONS.*

BY ARTHUR HILL HASSALL, M.D.

The mustard of commerce, when pure and genuine, consists usually of a mixture in different proportions of the farina, with more or less of the husk of the seeds of brown and white mustard, *Sinapis nigra* and *S. alba*, plants belonging to the natural order *Cruciferæ*, which contains a number of other plants that furnish pungent seeds. Sometimes it is made wholly from the brown seed, and at others the farina of the white mustard seed is the principal constituent.

Of these seeds no very complete quantitative analyses have as yet been made, although many highly important particulars have been ascertained respecting their composition. Thus, black or brown mustard, as it is now generally named, consists for the most part of *fixed oil*, *myronic acid*, $C_{10}H_{19}NS_2O_{10}$, combined with potash, forming *myronate of potash*, *vegetable albumen*, a *bitter principle*, a little *gum* and *sugar*, a *peculiar green substance*, *cellulose* and *mineral matter*. The myronic acid is converted into the volatile oil of mustard, *sulphocyanate of allyl*, C_4H_5NS, or $\left.\begin{matrix}CN\\C_3H_5\end{matrix}\right\}S$, through the agency of the *myrosin*, another constituent of brown mustard, when the two are brought into contact through the medium of water.

White mustard differs essentially in its composition from brown; it contains *fixed oil*, but in lieu of myronic acid, convertible as described into the volatile oil of mustard, a non-volatile, bitter, and acrid salt, termed *sulphocyanate of sinapine* ($C_{17}H_{24}NSO_5$, or $C_{16}H_{23}NO_5$,CNHS), *myrosin*, *gum*, *cellulose*, and *mineral matter*.

Now, it is on the volatile oil and the acrid and somewhat bitter salt that the pungency and acridity of mustard depend, and this is a strong reason why in the mustards of commerce the farina of the two species should be blended together. Of the two active principles the volatile oil is by far the more important, and hence the seed of the brown mustard possesses the greatest commercial value. Messrs. Henry and Garot affirm that brown mustard, as well as the white, contains the acrid principle; this statement the author has been able to abundantly verify, especially by the action of nitric acid, caustic potash, and ferric chloride on the alcoholic extract.

The acrid principle of white mustard appears to possess but little stability, and although it is stated by v. Babo to bear a temperature of 130° C., Dr. Hassall finds that it is readily affected by heat, and that it is not safe to evaporate the alcoholic solution containing it at a higher temperature than about 90° F. If subjected to a much higher temperature it quickly loses its acridity, and acquires a bitter caramel-like taste.

Of neither brown nor white mustard has any percentage analysis been given; and in the few cases in which the quantities of any of the constituents are stated they vary greatly, according to different observers. Thus, according to Pereira, the *fixed oil* forms about 28 per cent. of the seeds of black mustard, while Watts puts the yield at 18 per cent. only, but white mustard-seed, he says, furnishes 36 per cent. The *volatile oil* amounts to 0·20 per cent. according to Boutron and Robiquet; 0·55 per cent. according to Aschoff; and 0·50 per cent. according to Wittstock;

---

* Abstract of a paper in *Food, Water, and Air*, for February, 1874.

all which quantities are much below the mark. There is little or no difference in the amount of fixed oil furnished by the two descriptions of mustard,—that obtained by the author from the farina of brown mustard reaching 35·701 per cent., and that from the white mustard 35·768 per cent. Again, it is shown by the analyses given below that the volatile oil occurs in much larger quantities than those enumerated above, the amount which the author obtained from one sample being no less than 1·271 per cent.

The following are original percentage analyses of both brown and white mustard:—

Brown Mustard Farina.

Water	4·845
Fixed Oil	35·701
Myronic Acid	4·840
Myrosin and Albumen	29·536
Acrid Salt	3·588
Cellulose	16·765
Ash	4·725
	100·000
Volatile Oil	1·271
Nitrogen	5·068
Sulphur	1·413

The oil extracted by ether from the brown seed is of a bright and beautiful emerald green colour, owing to the presence of the peculiar green principle described as one of its constituents. So deep and remarkable is this colour of the oil that it would be very easy, by means of a graduated scale of tints, to determine with very tolerable certainty the percentage of brown mustard contained in any sample of mixed mustard. The small quantity of sugar found in mustard would, from the method of analysis pursued, be found with the bitter principle, and the gum with the cellulose.

White Mustard Farina.

Water	5·360
Fixed Oil	35·768
Acrid Salt	10·983
Myrosin and Albumen	27·484
Cellulose	16·295
Ash	4·110
	100·000
Nitrogen	5·285
Sulphur	1·224

These analyses, whether regarded from a scientific or practical point of view, are possessed of much interest. The fixed oil was obtained by exhaustion with ether, and it was found in all cases to be free from acridity or pungency. The volatile oil was determined by distillation into a strong solution of ammonia, after maceration of the mustard in water for some hours. The oil evolved was slowly acted upon by the ammonia, and after some hours was entirely dissolved, and from the solution by evaporation the volatile oil was recovered in the form of the crystalline sulphocyanate of allyl ammonium, $\left.\begin{matrix}CS\\C_3H_5\\H_3\end{matrix}\right\}N_2$; and lastly, from this the quantity of myronic acid present was calculated. The next steps in the analysis were to obtain the total amounts of nitrogen and sulphur in the mustard; the first was ascertained by combustion with soda lime in the usual manner; and the second by deflagration of the mustard and oxidation of its sulphur in a mixture of nitrate of potash and carbonate of soda. The acrid principle and the myrosin and albumen were then thus approximately ascertained:—As much sulphur and nitrogen were first deducted from the totals of these substances obtained as was necessary to the formation of the volatile oil actually found; next, the whole of the remaining sulphur, and as much of the nitrogen as was required, were then calculated into the acrid principle; lastly, the surplus nitrogen was calculated into myrosin, which has the same formula as vegetable albumen. But now having got approximately the amounts of acrid principle and myrosin, a further calculation had to be made. Myrosin contains about 1 per cent. of sulphur; this had to be deducted from the total acrid principle, thus liberating from that principle a small quantity of nitrogen, which in its turn was calculated into myrosin.

Both the brown and white mustard farina, after the removal of the fixed oil by ether, were successively treated with cold and boiling alcohol. In the case of the brown mustard the alcoholic extractive amounted to 13·36 per cent., and that of the white mustard to 12·11 per cent. The nitrogen and sulphur in both these extracts were determined, and, as might have been expected, since myronate of potash is to some extent soluble in rectified spirit, more sulphur was found in the case of the brown mustard than was required to combine with the quantity of nitrogen found, but it furnished by calculation 3·82 per cent. of acrid principle, while the white mustard yielded 5·41 per cent. of that principle only. It will be observed that in both cases the amount of total extractive obtained is much greater than can be accounted for by the amount of the acrid salt actually present, and the difference is probably in part due to a little sugar as well as other undetermined substances.

It will be noticed that no reduction of the sulphur existing in the form of sulphuric acid has been made in these calculations. The reason of this is that the quantity of sulphur met with in this form is so small as to be practically of no consequence. Thus, the sulphuric acid obtained from 100 parts of black mustard was only 0·0883 of a grain = 0·0353 of sulphur, while the same quantity of white mustard furnished 0·0560 grain of sulphuric acid = 0·0224 of sulphur.

In the original paper are given six analyses of farinas consisting of mixtures in different proportions of black and white mustard.

That all these samples were genuine was shown by the quantities of fixed oil, nitrogen, and sulphur obtained; and that they consisted of mixtures of the two mustards in different proportions—the higher qualities containing larger proportions of the brown mustard—was demonstrated by the different quantities of volatile oil obtained.

Analyses are also given of some mixed or adulterated mustards of different qualities. The analyses were conducted as in the case of the genuine mustards, the only difference being that an allowance was made for the nitrogen of the wheat flour.

From an examination of these analyses it is apparent that genuine brown mustard should contain about 36 per cent. of fixed oil, at least 1 per cent. of volatile oil of mustard, about 4 per cent. of acrid principle, and that it should furnish about 1·5 per cent. of sulphur, and 5 per cent. of nitrogen; that genuine white mustard should yield about the same amount of fixed oil, over 10 per cent. of acrid principle, and nearly the same amount of nitrogen and sulphur as

the black ; that the composition of genuine mustards, which are made up in various proportions of brown and white mustard seed, differs according to the quantities of each kind present, the relative proportions being determinable by analysis with considerable precision ; that in the mixed or adulterated mustards the proportions of fixed and volatile oil, of nitrogen and sulphur, are all much reduced, according to the extent of the admixtures, these consisting, in the mustards now reported upon, in all cases, of wheat flour and turmeric. Thus, the fixed oil was reduced in one of the samples from 36 per cent.—the normal amount—to about one-half, or 18 per cent. ; the volatile oil to 0·1 per cent. ; and the nitrogen to 3·32 per cent. ; while in another sample the sulphur was as low as 0·81 per cent. The amount of wheat flour and turmeric varied from 22·98 per cent. to 38·82 per cent., that is to say, from one fourth to one-third of the article.

It has already been pointed out that the turmeric is added to the mustard simply for the sake of its colour, and to cover and conceal the addition of the wheat flour. In favour of this addition Dr. Hassall believes that not a single reason can be adduced, except possibly that its use allows of the addition of a larger quantity of brown mustard seed than could otherwise be employed at a given price, and that thus the public gain an advantage, wheat flour being, of course, cheaper than white mustard, which, again, is less costly than brown mustard ; but this difference of the cost must really be very inconsiderable, and if obtained at the expense of the purity of the article, the practice should be abandoned. At all events, he thinks it is wrong and misleading to call these mixed articles by the name of mustard. By making mustard in all cases either entirely of the brown seed or of admixtures of the brown and white seed, a wide range in the qualities and prices of mustard can be obtained, and the mustard in which the white seed greatly predominates can be sold at a very low price. He trusts, therefore, that the time has now arrived for the abandonment of the use of wheat flour and turmeric in the manufacture of mustard, and that, if the sale of the mixtures still be allowed, the law will continue to render it compulsory that the mixed articles should be sold only as mixtures, and not under the name of mustard only. He even regards the manufacture of several varieties and qualities of the same article, as mustard, for example, a very great evil ; because the public suffers in pocket to a large extent thereby, the lowest qualities of these mixtures being constantly sold at the price of the higher, especially in poor neighbourhoods.

THE ALKALOIDS OF THE CINCHONA BARKS.*

BY O. HESSE.

(*Continued from p.* 613).

IV. Cinchonidine.

After becoming convinced that all the alkaloids that have been designated under the name of "cinchonidine" were identical with the cinchonidine of Pasteur, in the interests of the unity of chemical terminology, I had no hesitation in adopting Pasteur's name for this base, previously named by me "quinidine," although most of its properties incline more nearly to those of quinine than those of cinchonine. I consider also that upon another ground the name quinidine should not be used for it, namely, that under that designation other alkaloids are understood, and thereby great confusion would occur.

Amongst the salts of cinchonidine the neutral hydrochlorate requires notice, which crystallizes in monoclinic double pyramids, a form presented by no other combination of hydrochloric acid with a cinchona base. When an aqueous solution of this salt is concentrated at a gentle heat, as I on a former occasion stated, radiating crystals are obtained, which I then held to be the anhydrous salt. The hydrochlorate is very easily obtained in this latter form if the solution be a moderately supersaturated one. When these radiating silky-lustred crystals are allowed to remain a long time in the mother liquor, they are frequently observed to disappear, and are transformed into compact crystals with one molecule of water of crystallization. Estimation of the water in the radiating crystals gave the following results :—

1·7265 gram of air-dried matter lost at 100° C. 0·1585 gram H_2O.

0·8875 gram of air-dried matter lost at 100° C. 0·0825 gram H_2O ; it also gave 0·3415 gram AgCl.

These numbers lead to the formula $C_{20}H_{24}N_2O,HCl+2H_2O$, which :—

	Required.	Found.	
$2H_2O$	9·46	9·18	9·29
Cl	9·32	9·51	

When sulphate of cinchonidine is dissolved in boiling alcohol a salt containing $2H_2O$ crystallizes from the solution upon cooling in very slender white prisms. These gave :—

I. 0·605 gram of air-dried substance lost at 110° C. 0·030 gram H_2O.

II. 0·824 gram of air-dried substance lost at 110° C. 0·039 H_2O.

$2C_{20}H_{24}N_2O, H_2SO_4+2H_2O$

	Required.	Experiment. I.	II.
$2H_2O$	4·80	4·95	4·74.

This salt corresponds, therefore, with the sulphate of quinine crystallized from alcohol.

Like quinine, cinchonidine turns to the left the plane of polarized light. According to Pasteur $\alpha j = -141·61°$, according to Scheibler* $\alpha j = -113°$ (mean of eight observations). Having at my disposal an excellent polarimeter, I have checked these determinations, and in operating on a solution of the substance in absolute alcohol, obtained the following results :—

(I.) For $p = 3·1538$ and $l = 220$, $\alpha = -7·81°$.
(II.) For $p = 5·225$ and $l = 200$, $\alpha = -11·83°$.
(III.) For $p = 5·840$ and $l = 200$, $\alpha = -13·12°$.

From this is calculated—

	I.	II.	III.	Mean.
$\alpha j =$	−112·58°	−112·56°	−112·33°	−112·49°.

The supposed anhydrous neutral sulphate of cinchonidine gave in alcoholic solution—

(I.) For $p = 2·156$ and $l = 220$, $\alpha = -7·295°$.
(II.) For $p = 2·1175$ and $l = 220$, $\alpha = -7·18°$.

From which is calculated—

	I.	II.	Mean.
For $2C_{20}H_{24}N_2O, H_2SO_4$ $\alpha j =$	−153·79°	−154·12°	−153·95°
For Cinchonidine ... $\alpha j =$	—	—	−178·47°

Sulphate of cinchonidine in aqueous solution, with one molecule of SO_3 added, gave—

For $p = 2·388$ (anhydrous) and $l = 200$, $\alpha = -7·35°$.

And with six molecules of SO_3 added gave—

For $p = 2·3575$ (anhydrous) and $l = 200$, $\alpha = -7·08°$.

This gave, in the first case, $\alpha j = -153·8°$, or no material difference in the deviation ; for the second, $\alpha j = -150·15°$, or a slight decrease in the rotatory power of the alkaloid.

* Translated from the 'Vierteljahresschrift für praktische Pharmacie,' vol. xxii., p. 366.

* Berichte der deutschen chemischen Gesellschaft, vol. iv., p. 692.

Hydrochlorate of cinchonidine in alcoholic solution gave the following results :—

For $p = 5{\cdot}328$ (with H_2O as water of crystallization), and $l = 200$, $\alpha = -14{\cdot}67°$.

From which is deduced—

For the salt ... ... $\alpha j = -137{\cdot}66°$.

For the base as a neutral hydrochlorate $\alpha j = -162°$.

Dissolving afterwards this hydrochlorate in dilute hydrochloric acid, it gave—

For $p = 5{\cdot}328$ (with one molecule of H_2O) and $l = 200$, $\alpha = -15{\cdot}10°$, or $\alpha j = -141{\cdot}7°$.

In another experiment this substance was dissolved in hydrochloric acid diluted with an equal volume of water. This gave—

For $p = 4{\cdot}2376$ and $l = 200$, $\alpha = -12{\cdot}19°$, or $\alpha j = -143{\cdot}83°$, or for cinchonidine $\alpha j = -169{\cdot}29°$.

Here the value of $[\alpha]$ varies nearly indefinitely for the alkaloid dissolved in acid, according to the proportion of the acid and base ; but it is definite for the free base or one of its salts in aqueous or alcoholic solution.

I have thought it better to describe this examination of cinchonidine before occupying myself with the historical part of the question.

Cinchonidine was found in 1847 by Winckler* in "China Maracaibo," in the bark of *C. Tucujensis* (Karsten), as well as in an analogous bark of Huamilies cinchona, and was called quinidine. Afterwards, Von Leers† obtained it from Bogota or Caqueta bark, the bark of *C. lancifolia*, var. *vera*, called also, in New Grenada, "Tunita." This latter bark is still called in commerce "Carthagena bark," and at the present time shows variable quantities of this alkaloid. Climatic conditions and, perhaps, some other causes appears to exercise a great influence upon the structure of this bark, it becoming short fibred, and apparently rich in cinchonidine. Probably to this state is due a declaration of Koch,‡ that he once found in a Carthagena bark 1 per cent. of cinchonidine. But the difference which Koch sought to establish between this cinchonidine and his quinidine, an alkaloid contained, according to him, in a particular Carthagena bark, appears to me to be due simply to the fact that his quinidine was not completely free from quinine. This bark contains no peculiar alkaloid.

Although it was only in 1847 that Winckler first accurately described this alkaloid, it had been previously observed, in 1833, by Henry and Delondre, and named by them "quinidine." But this "quinidine" also contained a considerable quantity of quinine. Finally, in 1834, Henry declared that the "quinidine" he had studied with Delondre was identical with quinine, but that its greater purity was due to its capability of crystallization. An analysis made by Pelouze of this "quinidine" tended to confirm Henry in his opinion.

Henry and Delondre had not indicated in what species of *Cinchona* this alkaloid had been found. But when Pasteur had discovered the presence—rarely it is true—of an alkaloid, isomerous with quinine, in the sulphate of quinidine of commerce, and, without first proving it, had declared it to be identical with the quinidine described by Henry and Delondre,§ Delondre accepted the honour attributed to him, and described particularly the bark which contained this quinidine. This bark was also designated by Planchon, in 1864, under the name of "*quinquina à quinidine*," which, with other similar barks, appears to be employed in France in the preparation of quinidine.

In the meantime, Wittstein‖ received a cinchona bark which at first he called "China pseudoregia," but afterwards, following Wiggers, "China rubra granatensis." Wiggers compared this bark with the original barks which Delondre and Bouchardat had used for the illustrations in their work on Cinchona barks, and found it to be identical with the bark in which Henry and Delondre found their "quinidine." On the other hand, the chemical investigation which Wittstein carried out gave a different result, inasmuch as the alkaloid gave no green colouration with chlorine and subsequent addition of ammonia, and in composition it agreed with no other cinchona alkaloid. Wittstein, therefore, was of opinion that his alkaloid, which received the name of cinchonidine, was identical with Pasteur's cinchonidine, and that the nature of the quinidine of Henry and Delondre required yet to be cleared up.

Meanwhile, Dc Vrij examined a specimen of cinchonidine prepared by Wittstein, and found that it evidently consisted of a small quantity of sulphuric acid, but principally of cinchonine and Pasteur's cinchonidine. After a time however, Crawford* subjected this alkaloid to a further investigation, and showed that its hydrochlorate and sulphate were very easily soluble in ether. Consequently Wittstein's cinchonidine must be different from Von Leer's quinidine—corresponding to Pasteur's cinchonidine—since I have pointed out that both the neutral sulphate and hydrochlorate of that alkaloid are almost insoluble in ether.

In 1862, Kerner† described yet two other cinchonidines —an α-cinchonidine, and a β-cinchonidine. Of these the α-cinchonidine formed with hydrochloric acid a salt that crystallized constantly in rhomboidal octahedra.

When the cinchonidine was saturated with sulphuric acid and comparatively little water, after cooling and standing some time the solution usually became gelatinous. It turned the plane of polarized light to the right,‡ consequently differing from Pasteur's cinchonidine.

The β-cinchonidine, of which Kerner received a "sulphate" from France, formed with hydrochloric acid uniformly long hard rhombic prisms, but no rhomboidal octahedra. The pure β-cinchonine, crystallized in brilliant scales and needles. Later§ Kerner appears to have satisfied himself that his β-cinchonidine did not exist as a simple body ; at any rate, in his treatise on the cinchona alkaloids he has passed it over in silence as well as γ-quinidine.

That the hydrochlorate of cinchonidine sometimes crystallizes in prismatic crystals has been before stated, and it may be here generally remarked that there is no alkaloid yielded by cinchona the neutral hydrochlorate of which crystallizes in rhomboidal octahedra, and does not turn to the right the plane of polarized light. Obviously Kerner has been deceived in his observations upon the optical effects of his alkaloid, and that the α- and β-cinchonidine should be considered identical with Pasteur's cinchonidine, corresponding to Von Leer's quinidine.

THE MOTIONS OF CAMPHOR AND OF CERTAIN LIQUIDS ON THE SURFACE OF WATER.‖

BY CHARLES TOMLINSON, F.R.S.

(*Concluded from page* 656.)

It is remarkable that Professor Challis should have thought it theoretically probable that a thin [invisible] film of the oil spreads over the whole surface of the water and assists the visible [and slower] spreading of the first drop, because in some oils (such as oil of cinnamon) this thin film is visible. On depositing a drop of this oil on the surface of clean water in a clean glass $3\frac{1}{2}$ inches in diameter, an exceedingly thin but visible film is instantly drawn over the whole surface of the water, while the

denser film, which does not cover half the surface, spreads much more slowly. In the case of freshly distilled oil of coriander (the very remarkable cohesion-figures of which are given in one of my papers), the first thin film is accompanied by volleys of minute globules which extend to the edge of the water in radial lines. Other similar cases of essential oils might be cited; and even in the case of solid fats the evidence of a thin invisible film, covering the surface and arresting the camphor motions, seemed to be irresistible before the promulgation of the surface-tension theory. A stick of common mottled soap, or of tallow or lard, lowered into a large surface of water previously dusted over lightly with lycopodium powder, instantly clears away a large circular space (extending nearly to the edge of the glass). This effect is much more satisfactorily explained on the surface-tension theory than on the existence of a thin invisible film. But in the case of oils, whether volatile or fixed, it must be considered that a much greater tensile force is exerted in spreading some oils than others. When a film formed by a drop of a volatile oil nearly covers the surface of the water, there is still a sufficient residual amount of surface-tension to cause fragments of camphor to perform their evolutions; they skate through the film, cutting it up in all directions. But in the case of a film formed by so large a quantity as a drop of any fixed oil, the camphor fragments are motionless, whether on the film itself or on the adjacent water-surface. This was formerly supposed to prove the existence of a fatty film which, though invisible, destroyed contact between the water and the camphor; but now, in accordance with the new theory, the fatty-oil film so far reduces the tension as to leave no residual force sufficient to give motion to the fragments.

But if, as I have shown, a freshly distilled volatile oil does not prevent the motion of the camphor fragments, some deductions must be made from the statements of the earlier observers, which savour of the marvellous. Thus Volta, writing in 1787, says:—"If the water be defiled with any foreign substance, or its surface only slightly fouled with oily matter, if only the dust of the room or of one's clothes be upon it, the looked-for motions of camphor and of benzion will not take place, or will be so feeble as to be scarcely sensible. So also Prevost, writing in 1797, remarks that "if the surface of the water be touched with a pin previously dipped in oil, the motion of the camphor fragments instantly ceases, just as if they had been struck by lightning (*comme foudroyées*)." Venturi also, in 1797, says, "Touch the surface with oil, and an almost imperceptible film instantly advances over the whole surface, repels the fragments, and strikes them motionless as if by magic."

Now in all these cases I venture to say that the experiment was not performed under the most favourable conditions. It was known that the water must be free from grease; but I know of no reference on the part of these early inquirers to show that they took special means to make the vessel containing the water chemically clean, any more than the surface of the camphor or the knife with which it was cut or scraped. Hence, the initial tension of the water not being at a maximum, contact with a very slight portion of grease or oily matter would so far further lower it as to produce the sudden effects described. But if the experiment be repeated under the most favourable conditions, in which the surface-tension of the water is at its maximum, the water may be touched with a fixed oil, and the iridescent film resulting therefrom, though lowering the tension, will not do so to a sufficient amount to arrest the motions of the camphor fragments. For example, a shallow glass four inches in diameter was filled first with strong sulphuric acid and then rinsed out with tap-water and filled with the same. Fragments of camphor were extremely active on the surface, which was now touched with the point of a clean penknife that had been dipped into refined East India rape oil; a film of a splendid deep blue colour was produced, which instantly opened into a sort of lace pattern; but the fragments of camphor continued to rotate, not so vigorously as at first, but still with vigour. If the film of oil be first formed on the surface and the camphor fragments thrown upon it, they will also rotate. If instead of using the point of a knife to deposit the oil, a glass rod be employed and a drop be deposited, this, especially if the oil be heated, will flash out into a film, completely covering the surface of water in a vessel six inches in diameter. Under these conditions fragments of camphor do not rotate; but there is sufficient residual tensile force to give motion to creosote. A drop of this instantly repels the oil film, cuts it up in all directions, and moves over the surface with great vigour, the only sign of diminished tension being that the cohesion-figure does not open out into the usual brittle arc and so break up into a number of figures, but preserves one parent figure, from which volleys of small globules are discharged.

In the paper just referred to I give a number of cases in which a volatile oil film arrests the motions of creosote, and then evaporating, the water (according to the new theory) so far recovers its tension that the creosote suddenly starts into life and increases in vigour as evaporation proceeds.

Considering the mode in which surface-tension acts, it will naturally be supposed that the motions in question are not confined to camphor and a few other solids, nor to creosote and a few other liquids. In fact, fragments of any body that act by suddenly lowering the surface-tension at the spot on which they fall are liable to these camphor motions. Many salts act in this way, the last that I have observed being sulphate of aniline. The following solids also rotate:—Borneol, naphthol, thymol, nitro-toluol: this was inactive on water at 56° F., but very active on water at 90°, a crystalline needle sweeping over the surface at right angles to the length of the crystal. Binitrotoluol on water at 96°. Hydrochlorate of toluidin: a crystalline fragment darted to and fro in short jerks, as if surprised at the novelty of its situation, and then, accepting the conditions, moved rapidly over the surface in circular sweeps and quickly disappeared. Acetamid behaved in a similar manner. Lactid and oxamethan also rotate rapidly. Sulphaldehyd rotates rapidly in wide sweeps and soon becomes motionless. The same phenomena are exhibited by benzoic anhydride. Amidobenzoic acid also rotates rapidly, and quickly disappears; while the crystalline portion of nitrobenzoic ether sails round and round near the edge, and continues to do so for a long time.

Among liquids, a drop of toluidin on the surface of water, in a vessel 4 inches in diameter, affords an instructive illustration of surface-tension: the drop forms a figure for an instant something like that of creosote; it then bursts as with an explosion, dotting the whole surface with smaller figures, each of which also explodes; and the smaller particles resulting therefrom rapidly disappear amid lively agitations. A drop of phenyl-mustard oil quickly spreads into a large ragged film, which is torn into numerous fragments, covering the surface; and then each fragment gathers itself up into a well shaped lens. A second drop rests as a lens. A drop of monochloracetic ether spreads rapidly over the surface and rebounds to the centre, breaks up into numerous ovoid masses, with colour, which rapidly disappear with a remarkable opening out. When the whole has disappeared, the motes on the surface rush wildly to and fro. Formiate of ethyl produces a very pretty rose-engine figure with a central boss. Oxalate of ethyl forms a wide film with iridescent edges, and then, in waving figures, quickly disappears. Iodide of allyl gives a colourless film over the whole surface, then exhibits a magnificent display of iridescence, breaks up and instantly disappears. The following liquids also present interesting phenomena:—Nitrobenzol, nitrobenzoic ether, nitrotoluol, and cymol. It would be easy to extend the list both of solids and liquids that afford instructive illustrations of surface-tension, whether on the surface of water or on that of other liquids. A drop of

oil of lavender on the surface of liquid acetic acid forms a wonderfully active figure, which I have already noticed, together with the figures of various liquids on the surfaces of sulphuric acid, cocoa-nut oil, castor-oil, paraffin, spermaceti, white wax, olive-oil, lard, and sulphur, heated, where necessary, so as to render them sufficiently fluid.

In 1837 Dr. Pietro Savi had his attention directed to the following statements by De Candolle with reference to the contractile motions of plants :—"Si l'on place sur l'eau des folioles, ou des fragmens de folioles, du *Schinus Molle*, on voit l'huile volatile, contenue dans certaines cellules du tissu, s'echapper, non par un flux continu, mais par des saccades intermittentes, qu'on ne peut, ce me semble, rapporter à d'autres causes qu'à quelque contraction des cellules qui renferment ce suc." And again at page 287 of the same volume, with reference to the sudden and singular movements of the leafy fragments :—"Ces mouvemens sont dus à des jets intermittens d'huile essentielle, qui sortent des cellules, frappent l'eau, et determinent dans la foliole un mouvement de recul semblable à celui de l'éolipyle. On voit ici assez clairement un effet vital."

Dr. Savi shows, by a microscopical examination of the leaves in question, that no provision is made for the exertion of a contractile force, that fragments of the dried leaves move, that the motions are common to leaves of the *Terebinthaceæ*, *Euphorbiaceæ*, *Urticaceæ*, *Asclepiadaceæ*, and some others, and that the true explanation of these phenomena (which are physical, not physiological) is to be found in Carradori's attraction of surface, as explained in his memoirs.

In 1838 Morren showed that a leaf of the *Schinus Molle*, or American pear, placed on water had a jerking motion, while the surface became covered with a film of sweet-smelling oil. Another plant, the *Passiflora fœtida*, is furnished with hairs, one of which, plunged into water, discharges a small drop of oil, which, rising to the surface, expands and contracts several times, and then apparently bursts with violence, the smaller portions going through similar changes. These are well-known effects of surface-tension common to several oils and other liquids, as is also an experiment by Zantedeschi, in which a few drops of valerianic acid poured into water rise to the surface, go through a variety of contortions and evolutions, and excite the astonishment of the observer that dead matter should thus of itself become endowed with such active motion. A drop of isobutylic alcohol forms a similar figure, only more rapid in its action.

In 1838 I published a new method of producing Newton's rings. Referring to the facility with which oil spreads over the surface of water, it is stated that any oil, balsam, varnish, or essence not soluble in water will answer the purpose, or, if the oil or balsam, etc., be too viscid, it may be made sufficiently fluid by the action of heat. A single drop of oil, etc., may form a circular film from two to five inches in diameter with or without colour, depending on the thickness. Supposing the film to be without colour, the finger dipped in ether (or a piece of porous wood, or a camel's-hair pencil, or, as was afterwards adopted, a bit of sponge tied over the end of a glass rod) and held over the film, "we instantly see a repulsion or recession of particles ; a black spot is formed ; and round it the seven orders of rings appear in all their lustre and beauty. The rings remain just so long as the finger is wet with ether, which having evaporated, or the wet finger being removed, the rings contract in diameter and disappear altogether. These rings can be formed at any part of the surface of the film, and any number of times while the film endures."

Among the conditions enumerated are :—"The glass and the water must be perfectly clean and free from grease ; the surface of the water must be perfectly tranquil ; a clean glass rod must be dipped into the oil, and a single drop only be placed upon the surface of the water ; the ether must not touch the film, or it will destroy it, while if the ether be taken up by a body that has not a pointed or rounded termination the rings will not be formed, and there will only result a series of concentric figures, depending for form upon that of the end of the substance held over the film. Instead of ether we may employ solution of ammoniacal gas, pyroligneous ether, alcohol, or naptha. Strong ammonia sometimes breaks up the film and scatters it over the surface of the water."

A turpentine film, which is at first colourless, soon begins to display colour as the film becomes thinner by evaporation—a remark that does not apply to a film formed by a drop of the fixed oils of olive, rape, castor, nut, etc.

Films that exhibit some of the most splendid colours of thin plates may be formed from a drop of balsam of Peru or a turpentine varnish, such as copal varnish, carriage-varnish, gold-size, black japan, etc. If the ether be held over one of these coloured films, "we immediately get a series of rings as before, quite independent of the large rings which occupy the surface of the water. That part of the film subjected to the action of the ether no longer forms a portion of the original film, but is subject to the systematic arrangement which the ether produces. A film showing the colours of the 5th, 6th, and 7th orders only is, at that particular part which is subjected to the action of the ethereal vapour, made sufficiently thin to exhibit the rings of the 1st, 2nd, 3rd, and 4th orders, or of the 2nd and 3rd, or of the 3rd and 4th,—all depending on the quantity of ether taken up, the rate of evaporation, and the proximity of the ether to the film—in other words, on the comparative thinness of the film. Should the drop of oil, etc., form a lens instead of a film, the ether vapour will drive it with great energy over the surface of the water."

If the water be dusted over with a dry powder, the vapours of ether, etc., will powerfully repel the particles. "Turpentine and some of the volatile oils produce a similar effect upon powders ; and one volatile oil frequently repels a film formed by another."

The above details refer to the repulsion of films. "A strong and decided attraction may be exhibited by presenting to the film a drop of an acid of low boiling-point, such as nitric or pyroligneous acid. By such means an oil-film of the size of a crown piece may be reduced to the size of a sixpence ; and a film exhibiting colour will have all colour destroyed by the proximity of the acid, whose influence is to thicken the film. Sulphuret of carbon and an aqueous solution of chlorine produce a similar result." (pp. 545-549.)

In 1841 Sir David Brewster reproduced some of my results, probably without suspecting that he had been anticipated, although a full abstract of them was given in a then popular journal of wide circulation. Brewster formed a film of oil of laurel on water placed in a black vessel, or on the surface of diluted or real ink. He justly describes the rings produced as being splendid beyond description. He says :—"These thin plates of oil of laurel exhibit some curious phenomena which I believe have not been noticed. If we wet with water, alcohol, or the oil of laurel itself, the extremity of a short piece of wire, such as a large pin, and hold the pin in the hand so that its head may be above and almost touching the film, the film will recede in little waves of circular shape which form a new system of coloured rings ; and they become covered with the vapour from the fluid on the head of the pin in such small particles that they reflect no light, and the rings appear to be blackened. By withdrawing the pin the film is restored to its former state. The same effect is produced by heating the pin or the fluid upon it to promote evaporation." (p. 51, note.)

We now come to the time when Dutrochet published his elaborate essays on what he termed the epipolic force ; and as this forms a kind of middle term between the earlier and the more recent history of this wide subject, we may here conveniently pause for a time.

Highgate, N.

NOTES ON THE CHINESE OPIUM TRADE.

According to reports issued at various Chinese ports at the end of the year, the trade in opium does not show much fluctuation, and as regards imports remains about the same as in former years. The gross imports into Shanghai of Malwa opium amount annually to about 27,000,000 piculs, the description which is next in favour being Patna, and then Benares opium. The price of the native-grown article is much lower than for these sorts, and it is said that the increase in the cultivation of the poppy in China has had a most injurious effect on the consumption of the foreign drug, the import of which has remained perfectly stationary during the past five years, whilst the production of the native drug during the same period has more than quadrupled. Precise statistics of the growth of the poppy in China cannot be obtained, but according to the best authorities, there is no doubt that year by year it increases largely. It is reported by a gentleman who has lately made the overland journey from Peking to Chinkiang that the country between the Yellow River and the Yang-tzsé is covered with poppy-fields, where the drug is actively cultivated. The temptations, indeed, to its cultivation are very great, inasmuch as, according to the lowest estimate of the peasants themselves, it is twice as profitable as growing wheat; some even assert that it is six times as profitable, but that doubtless may be regarded as an exaggeration. So great has been the spread of poppy cultivation all over China that the subject has attracted—and not for the first time—the attention of the Imperial Government, and lately a decree appeared prohibiting its culture. It appears, however, that such decrees are not held in very great dread, and have not, in fact, the slightest effect, inasmuch as it would obviously not be to the interest of the officials to put down such a useful contribution to their exchequer, both public and private, and not insignificantly to the latter. Under these circumstances the opinion may confidently be expressed—and it is borne out by the principal opium merchants in Shanghai—that a gradual falling off in the demand for the foreign drug may be looked forward to; and, indeed, if the cultivation of the poppy continues to progress in China with the same rapidity in the future as in the past, the virtual extinction of the trade in Indian opium may be not unreasonably anticipated.

With regard to the opium trade in Tientsin, the diminution of the imports of Indian opium at that port is ascribed to the heavy inland tax upon the article, as well as to the competition of the native drug. The opium is now carried from the ports on the Yangtzse through districts where the tax is lighter, while the increased popularity of the native opium is shown by the recent re-exportation of all the Persian opium which had been previously imported with the idea that a trade might be done. Such, however, was not the case. It appears that in price the Persian drug competes with the native article much more successfully than Indian opium can do, but it is driven out of the market by the preference of consumers for the article of native production. We also learn from Foo-chow that the native product is increasing in popularity, while the demand for Persian opium decreases, and there is no business for what is imported. Some time since a stringent edict was issued at Pekin, prohibiting the cultivation of opium in all provinces, as being a contravention of the law; but, as we before remarked, while the wealth derived from its cultivation continues to be so much greater than can be derived from any other species of industry, there is little likelihood of the prohibition being carried into general effect. According to the statement of an opium cultivator, a mow of land planted with poppies yields five ounces of silver a-year, while ordinary crops of wheat would barely yield one ounce. There is little doubt that such a large source of profit must rather tend to increase than to decrease cultivation, especially if high prices be maintained. It is further important to note the statement that the native opium does not improve in quality, which would make it a still more formidable competitor of the foreign drug, but it appears that the Chinese product has this advantage—the habit of smoking it can be thrown off with comparative ease if the smoker desire it. Indeed, the Chinese consider that their own opium is less deleterious in its results than the foreign, hence we may see one cause of the increasing popularity of the former.

From reports from Neuchang, we learn that the authorities in the Province of Shinking have endeavoured to the best of their ability to carry out the edict for the suppression of the cultivation of the poppy, and have so far succeeded that the price of the native has risen to that of the foreign drug. No similar proceedings, however, are reported from any other districts. From most, in fact, an increase in the cultivation is reported. Thus Hankow feeds the large and fertile province of Szechuan, and when Baron Richtofen reported upon this province in 1872 he considered that the cultivation of the poppy there had reached its maximum, adding that, if the price of the article at Hankow were to increase, the cultivation of it would also progress. According to later authorities, this prediction as to increase in the cultivation has been realized, inasmuch as we learn from that district that opium is there produced to a very considerable extent, and that it is exceedingly improbable that its progress will be stayed by any efforts on the part of the officials.

ADDITIONAL NOTES ON PANCREATIN.*

BY RICHARD V. MATTISON.

Numerous inquiries regarding saccharated pancreatin, its doses, uses, etc., having been instituted since the publication of my last paper upon the subject, induces me to present a few further remarks upon this valuable and highly interesting substance. It is a fine white powder, almost tasteless, or with the slightly sweet taste of lactin. When mixed with water it is perfectly soluble, dissolving in between five and six parts of that liquid, and forming a perfect emulsion when mixed with liquid fats and a small quantity of water.

I would respectfully suggest the following formula for the proper exhibition of cod-liver oil in combination with pancreatin:—

℞.	Pancreatini Sacchar.	℥j.
	Aquæ	fℨiv.
	Sacchari Albi	℥vij.
	Olei Morrhuæ	Oiss.
	,, Gaultheriæ	gtt. xx.
	,, Amygd. Amar.	gtt. v.

M.

Rub the saccharated pancreatin with the sugar and water, in a mortar, until a thick syrup is formed; to this add the cod-liver oil, in which the essential oils have been dissolved. This forms a perfect emulsion, without difficulty. It separates, of course, upon standing, but can easily be shaken together again, forming an emulsion with slight agitation. This is certainly to be preferred to the thick mucilaginous emulsions made with gum arabic or tragacanth, which are usually so distasteful to patients, because of their being so thick.

By the above formula, a preparation can be furnished containing 75 per cent. of oil, in the condition in which the oil, as usually prescribed, enters the duodenum, thus rendering its absorption and assimilation by the lacteals comparatively easy, the molecular formation of the oil being completely broken up. To make the emulsion whiter a little lime water may be substituted, omitting an equivalent quantity of water, a partial saponification rendering the emulsion more permanent and more elegant in appearance.

The easy assimilation of this preparation having been

---

* Paper in continuation of former paper by the author (see the present volume of PHARMACEUTICAL JOURNAL, p. 592), read before the Philadelphia College of Pharmacy (*Amer. Journ. Pharm.* [4] iv., 53).

experimentally demonstrated by several of our eminent medical practitioners, it stands unrivalled in a therapeutical point of view as a standard pharmaceutical preparation of cod-liver oil.

The action of pancreatin upon albumen having frequently been stated, experiments were instituted in order to more closely examine this action. Accordingly, ten grains saccharated pancreatin were dissolved in one fluid ounce of water, with the addition of six drops of hydrochloric acid. To this thirty grains of coagulated albumen were added, and the whole kept at a temperature of 100° F., being occasionally agitated. At the end of six hours about twenty-five grains were dissolved, thus showing the correctness of the usually received statement, and at the same time showing its great inferiority to saccharated pepsin, which under similar circumstances would have dissolved from 120 to 180 grains.

The action of pancreatin upon starch was next observed, and a drachm of Bermuda arrowroot was mixed with a solution of ten grains of saccharated pancreatin in one fluid ounce of water, and kept at the temperature of 100° F. for several hours. At the expiration of this time the mixture was filtered, and the filtrate tested for glucose, abundant evidence of the presence of this substance being afforded by Trommer's and Fehling's tests. That this glucose was the product of the action of pancreatin upon starch was demonstrated by testing the arrowroot, which gave a negative result, and by a comparative test with the solution of glucose obtained by the above action of the pancreatin upon the arrowroot. Fifty minims of this solution, containing less than one grain of lactin, reduced the cupric solution much more readily than a similar solution containing ten grains of lactin, the purity of both specimens of milk sugar having been ascertained before using.

Although the strength of saccharated pancreatin is given as "ten grains emulsify two fluid drachms of cod-liver oil," yet when ten grains were dissolved in one fluid drachm of water, and one fluid ounce of oil added, perfect emulsification was effected in a very few minutes.

The experiment of digesting the pancreas in cod-liver oil was tried.

In a bottle labelled No. 1 a pancreas was digested in cod-liver oil, with frequent agitation. The oil was much changed, acquiring the appearance and smell of a badly oxidized oil. This change was very rapid from the moment of the introduction of the pancreas.

In a bottle labelled No. 2, a pancreas was digested in the cod-liver oil, under precisely similar circumstances, with the exception of the addition of half a fluid ounce of hydrochloric acid to the mixture. This sample presented the appearance of a fine oil, free from any indication of rancidity. When to this pancreatized oil a portion of water was added, a perfect emulsion was formed, to which more oil could be readily added without disturbing the emulsion. It was, however, deemed inferior to the emulsion of oil prepared according to the directions given, in which such good evidence is afforded of the superiority of saccharated pancreatin.

Philadelphia, January, 1874.

GINGER.*

Zingiber Officinale.

Ginger, as is known, is the dried rhizome or underground stem of a plant which is cultivated for that purpose in the tropical regions of both hemispheres. Its quality and commercial value differs considerably in different localities, and is influenced very much by the method of collection and preparation.

The following account of the cultivation of ginger has been received from the Hill States adjoining the Ambàlah district. Ginger is principally produced in Mahúr Mássá, Patrá, Dárrá, Kothi, Kotahi, Bágal, and Jayál. The best pieces of the last year's harvest are selected and placed in the corner of a house in the month Phágan ; the heap is then smeared over and covered with cowdung to keep the roots from drying up in Hár month, when the first rain falls. The land is ploughed up two or three times, and then divided off into beds, with a little raised edge round each bed, care being taken to make openings to let superfluous water run off, for if water stands on the crop, the roots will rot. Little pieces of the roots are then buried three inches deep in the soil at intervals of nine inches, and the field is next covered over with the leaves of trees, which keeps the soil moist, and over the leaves manure is spread to a depth of half an inch ; when it rains, the water, impregnated with manure, filters readily through the leaves to the roots. Artificial irrigation is not employed while the rain lasts, but from Assúh to Poh it is necessary. In the month Poh the plants are about two feet high ; for every one shoot there are eight tubers or parts of the root ; these are dug out and buried in another place for a month ; then they are taken out, exposed to the sun for a day, and are then fit for use.

In the months of Sawán, Bhadon, and Assúh, three times the field is weeded. A begah of land requires eight maunds of ginger to plant it, and yields 32 maunds for a first-rate crop.

Ginger fit for planting again, sells at eight to ten seers per rupee ; that for use only, at 24 to 32 seers per rupee.

In order to dry ginger into "sonth," the fresh roots are put into a basket, which is suspended by a rope, and then two men, one on each side, pull it to and fro between them by a bit of rope attached, and thus shake the roots in the basket ; this process is carried on for two hours every day for three days. After this, the roots are dried in the sun for eight days, and again shaken in the basket. The object of the shaking together is to take off the outer scales and skin of the roots. A two days' further drying completes the process, and "sonth" sells at three to four seers per rupee.

Turmeric is cultivated in the same manner ; when ready it is dug up, steeped in hot water a day and a night, and then dried.

* From the Official Catalogue of the Indian Department at the Vienna Universal Exhibition.

CASTOR-OIL SEED.*

Ricinus Communis.

The castor-oil plant is extensively cultivated all over India. It is sown in June by almost all the villages ; not extensively, but principally for their own use. Its cultivation can be extended all over Oude. The oil is extracted by bruising the seed and then boiling it in water ; the oil is afterwards skimmed off. This is the only seed out of which the oil is extracted by boiling, as in this case it is found cheaper than the method used for other seeds, which is by pressure.

The cost of the seed is one rupee per maund, and the price of the oil is from two to five seers per rupee, according to the abundance of the crop in the season. The proportion of the oil yielded is about half the weight of the seeds boiled ; it is only used for burning.

In Cuttack, the plant is grown all over the province, a good deal in patches of newly cleared land in the jungles of the Tributary States and Sumbulpore. The oil is extracted in two ways. It is used for burning and culinary purposes, and medicinally also. The local market is now 11½ peculs of the seeds per rupee. Both the native methods of extracting oil are wasteful and tedious, and therefore expensive. European oil-presses, and a knowledge of some methods of clarifying the expressed oil, seem only to be required to render the oil-seed crops of this extensive division of great value.

The large seeds, *Ricinus communis major*, are employed for lamp oil, and the small seeds of the variety *Ricinus communis minor* yield the medicinal castor oil.

THE ADULTERATION OF BEER AND SPIRITS.

ACCORDING to promise, we intend in this article to consider some of the extraordinary statements which have been recently made respecting the adulteration of beer and spirits, and what grounds there are for supposing that such adulteration is general.

At the outset it is necessary to define the term "adulteration" as applied to the sophistication of beer and spirits, and when this is understood there will be little difficulty in proving from facts which are beyond dispute that adulteration is not general, as alleged by those who make capital out of frightening the public, who try to make people believe that their ordinary food and drink are little better than poison. The General Licensing Act defines adulteration to consist of mixing with intoxicating liquor any ingredient deleterious to health, or any of the ingredients specified in the schedule of the Act. Now, it will be easily seen that beer when brewed in part or wholly from sugar, is not adulterated, and that a spirit vendor who mixes water with his spirits does not offend against the letter or spirit of the Act. We are aware that most people think beer is brewed wholly from malt and hops, and doubtless such persons will be horrified to know that in one year not less than twenty-one thousand tons of sugar are used by brewers in the United Kingdom. Yet this is the fact, and we are bold to say that the best judge cannot, from the taste alone, distinguish between a beer made from malt and one brewed from a mixture of malt and sugar. This is not surprising, when it is born in mind that brewing from malt consists in subjecting the malt to those conditions which are most favourable to the conversion of the maximum quantity of the starch it contains into grape sugar, by the action of the diastase which has been produced in the grain by the process of malting. When sugar is used it is generally cane sugar, but this is also converted into grape sugar in the mash-tun by the diastase in the malt. Whether grape sugar, therefore, is obtained from malt or from cane sugar is of little moment; and the brewer of the present day, who has to compete with his neighbours, finds that what he has to study is the cost of the grape sugar he requires, and consequently he increases or decreases the relative quantities of malt and sugar according to the fluctuation of prices in the market. A calculation has been made that in the United Kingdom nine hundred million gallons of beer are brewed annually; and yet we are told by the Commissioners of Inland Revenue, who take good care to protect Government interests, that their officials, who have to visit frequently all the breweries in the United Kingdom, only detected in the year 1872 six samples of beer, or of materials used in brewing beer, which were adulterated. Considering the enormous extent of our brewing industry, such a testimony as to the purity of the beer brewed is highly creditable to those engaged in the trade; and in the face of such facts we may rest contented, when taking our glass of Burton or of stout, that neither contains deleterious ingredients.

The first report of the Commissioners of Inland Revenue on the samples of spirits examined under the Intoxicating Liquors Act states "that none of the "samples sent up for analysis by the police or officers "of excise have been found to contain any of the "ingredients prohibited by the Act. Some of the "samples of whisky have been of a very inferior "quality. . . . It is probable that much of the "bad effect produced by drinking whisky, and which "is ascribed to adulteration, is due to the very dele-"terious fusel oil which is present in new whisky." A report like this is certainly not alarming, and especially when it is remembered that the 85 samples examined were obtained from Ireland and other places where complaints had been made of the bad quality of the spirits supplied, either in certain localities or by individuals. We may fairly assume therefore, that the whisky and other spirits examined were the worst of their kind, and if adulteration had been practised it would have been discovered. But the only deleterious ingredient detected was fusel oil, which is perhaps better known in the trade as "feints," or by chemists as amylic alcohol. This alcohol gives the character to Irish whisky, which has now become so popular. Its popularity has caused the whisky to increase in price on account of the increased demand, and this fact has induced many, who either cannot afford or are not inclined to keep their whisky two or three years to mature, to deceive the public by mixing new whisky with prune, muscatel, or low sherry wines, to impart to it a flavour and character which, without the aid of these artificial flavouring matters, can only be obtained by age. As the presence of these wines in Irish whisky is not deleterious to health, their addition is not prohibited by the Intoxicating Liquors Act. Scotch whisky, being made principally from malt, ripens much more rapidly than Irish, which is distilled chiefly from grain, and there is not that inducement in the former case to add flavouring materials as in the latter; much of the Scotch whisky of low quality, however, contains Hamburgh sherry in considerable quantity. This artificial mode of giving age to whisky will eventually be the means of decreasing the consumption; for the public, as a rule, cannot be deceived for any length of time by such devices.

The Report from which we have quoted contrasts very favourably with another to which we will briefly refer. It was printed in a Glasgow paper in 1872, giving the results of thirty so-called analyses of samples of whisky purchased from different tradesmen in Glasgow. Amongst the adulterants said to have been detected were wood-naphtha, shellac, turpentine, sulphate of copper, and sulphuric and hydrochloric acids. If thirty samples purchased promiscuously could produce such a fruitful crop of adulterants, we may fancy what dreadful stuff was sold as whisky in Glasgow, and we are almost surprised that many people who drank it were not poisoned. Luckily for the public, the results given were immediately questioned by several chemists of repute, and from the discussion that ensued in consequence sufficient evidence was given to throw an air of doubt on the accuracy of the analyses. Unfortunately it was not practicable to have the samples re-examined; if they had been, we feel sure very different results would have been obtained. The discussion had the immediate effect of allaying the excitement which had been caused by such startling reports; and since that time the subject of the adulteration of spirits has been carefully investigated by many chemists. We are glad to say we have since had no such results reported, and we may fairly conclude from our own experience, and that of our scientific friends, that the first Report of the Inland Revenue Commissioners gives a correct view of the condition of the spirit trade of the United Kingdom.

AMERICAN ELIXIRS.

The numerous formulæ for the class of preparations known as "elixirs" which have found their way to this country from the United States, have been highly suggestive of pharmaceutical bewilderment. The evil arising from their multiplication has for some time been the subject of complaint by our American brethren, who are sometimes not only compelled to keep for dispensing purposes elixirs bearing various names, but also a variety of preparations bearing the same name but concocted by different makers. A committee was appointed by the American Pharmaceutical Association to take into consideration the subject of elixirs and similar unofficinal preparations in all its bearings upon pharmacy, and if deemed proper, to report suitable formulæ for the guidance of the members. A report was consequently presented to the Association at its meeting last September at Richmond, Virginia, which was adopted, and ordered to be printed and circulated amongst the medical profession, with the suggestion that physicians, if prescribing elixirs at all, should prescribe only such formulæ as had been adopted by the Association. These formulæ were brought before the last meeting of the Philadelphia College of Pharmacy, a report of which will be found on p. 682.

Since, however, the abstract above referred to was prepared for publication, we have received (through the kindness of Professor Bedford, of New York, whom we take this opportunity of thanking), a copy of the entire report, as issued by Professor Maisch, the Permanent Secretary of the Association. In this the formulæ are accompanied by some prefatory remarks. The Committee state that the greatest commendation that can be bestowed on elixirs, as a class, is that they are too feeble to do much harm, even when containing strychnia. The Committee, however, have not been able to overtake some of the elixir manufacturers in the art of administering quinia, strychnia, and other bitter remedies in clear solution, without being accompanied by their characteristic bitter taste. This they confess might be due to a "want of a more profound understanding of the pharmaceutic art, in the domain of elegant pharmacy;" but they state that they have endeavoured to place the ingredients indicated by the formulæ in the vials, whilst those who have excelled them in the art of completely masking bitterness, may possibly have the active principles represented only by the labels.

We thoroughly sympathize with American pharmacists in their effort to make some head against this "pharmaceutical folly;" also we would heartily endorse the following *dictum* in this report, and commend it to the consideration of all prescribers and compounders of "philippic" preparations. "The "manufacture of preparations for, and the compound- "ing of, physicians' prescriptions should be an open "competition, entrusted only to thoroughly qualified "pharmacists. If this be granted, it is then unfair "for the physician to command the pharmacist of "one city to employ a pharmacist in a distant city "to prepare the remedies for his prescription, except "in remarkable cases."

The Council of the Society of Arts have arranged for an entirely new series of meetings for the discussion of the more recent applications of chemistry to Arts and Manufactures. They will be held on alternate Friday evenings, commencing on March 6th. The following are the subjects at present announced:—

March 6.—"On the Paraffin Industry." By Frederick Field, Esq., F.R.S.

March 20.—"On Anthracene and Alizarine." By Dr. Versmann.

April 10.—"On some Recent Processes for the Manufacture of Soda." By C. W. Vincent, Esq., F.C.S.

April 24.—"On Pyrites, as a source of Sulphur, Copper, and Iron." By Dr. C. R. A. Wright, F.C.S.

May 8.—"On Sugar Refining, with special reference to Finzel's Sugar Crystals." By Dr. Griffin.

May 22.—"On the Manufacture of Chlorine." By W. Weldon, Esq., F.C.S.

The second course of Cantor Lectures is now being delivered by Dr. Charles Graham, on the "Chemistry of Brewing," and this course will be followed by one on "Carbon and Certain Compounds of Carbon, treated in reference to Heating and Illuminating Purposes," by Professor Barff, M.A.

We learn from the *Brighton Herald* that the vacancy in the staff of Guy's Hospital caused by the sudden death of Dr. Dickson, the late Lecturer on Mental Diseases, has been filled up by the appointment of Dr. C. H. Savage, Junior Physician to Bethlehem Hospital. Dr. Savage is the youngest son of Mr. W. D. Savage, Pharmaceutical Chemist of Brighton, who has for many years been a member of the Council of the Pharmaceutical Society.

LEEDS CHEMISTS' ASSOCIATION.

The fourth monthly meeting of this association was held in the library of the Philosophical Hall, on January 20, 1874, when a paper was read by Mr. E. Brown on "Water." Mr. Brown not intending to restrict himself to a purely scientific or pharmaceutical view of his subject, invitations were given to others than those connected with the Association; but, owing to the political excitement induced by the general elections taking place, the attendance was small. Subjoined is a brief review of Mr. Brown's paper :--

Those substances that are our constant servants, on which we most depend, and that respond the most readily to the varied demands of an ever advancing state of civilization, are naturally those that most claim our studious notice, and that will best repay investigation. Of such bodies 'water' takes a prominent place, as it contributes to the health, progress, and comfort of men of all ranks, occupations, and circumstances. Pure water is nearly colourless and inodorous, possesses great solvent power, and enters largely into chemical combinations. About 100 years since, the compound nature of water, and the proportion of the gases composing it, were determined. Those gases, oxygen and hydrogen, possess apart properties the opposite, as regards fire, to what they do in combination; the one being very ready to flame, and the other the most active promoter of combustion. One pint of water yields on decomposition about 4½ hhds. of gas, *i.e.*, 1238 pints of hydrogen and 619 pints of oxygen, so that the sudden severance, or combination, of these gases would induce violent concussions or explosions; water thus supplying materials in nature for the most formidable disruptions. Water may be regarded as the oxide of the metal, hydrogen, the lightest of all bodies bearing a metallic title. Water forms hydrates, or combinations of undecomposed solidified water, with the oxides of certain metallic bases, and it takes the solid form also in crystallization with many salts. Its elements in like proportions, as in water, constitute the greater part of glucose, cellulose, and some other substances, containing only the components of water with carbon. The most observable property of water is its very general solvent power, indeed, no other substance equals it in this respect; here it takes the opposite course to what it does in hydration and crystallization, not adapting itself to the condition of other bodies, but reducing other substances to its fluid state; and on this property of water depends all the great variety of kinds of water that we meet with, the hard and soft, the crystal spring, and the many kinds of mineral waters; by this property is caused the saltness of the sea, a condition of much value, preserving as it does the purity of the ocean's waters, rendering the sea more buoyant, less easily frozen, making it a more suitable abode for fish, supplying submarine vegetations with materials for their growth, and submarine creatures with materials for their structures, while it carries salt to every coast, where otherwise salt would not readily be obtained. The sea water permits light to penetrate its depth to nearly 1000 feet, while at less than half that distance from the surface there is but twilight.

The true colour of the sea is ultramarine; this however is modified by the state of the atmosphere, by depth, sun-

shine, clouds, wind, and other influences. The sea varies, too, in different regions, and sometimes the lines of change of colour are very marked. The phosphorescence of the sea is a grand spectacle, and is usually accompanied by a disturbed electrical state of the atmosphere. The presence of water in the air, deepens the blue of the sky, renders the atmosphere a better conductor of sound, regulates the character of our sunrise and sunset; it forms the cloud and paints the rainbow; it promotes the mirage of the desert, the ignis fatuus on the marsh, the remarkable refractions and reflections of the polar regions, the aurora-borealis in the sky, and is to all plants and animals an essential to their development, and a condition of their existence.

Mr. Brown explained the formation and suspension of clouds, the causes of rain, the precipitation of hail, the forms of snow-crystals, etc.; and he made some remarks on the distribution of water over the land, and its services to commerce and in civilization,—also on its mechanical agency—by its free mobility, comparative density, and the operations it thus conducts; the formation of deltas, the causes and services of the wandering of rivers, the elevations and extent of certain lakes; its sanatory uses, its socializing influence in gathering cities, etc.; and concluded by some comments on its various appearance, its historic associations, and the moral suggestions—such as the power of unity, the susceptibility of influence, and the recompense to activity and generosity that water may prompt.

The lecture was illustrated by drawings and diagrams.

A vote of thanks was given to Mr. E. Brown, on the motion of Mr. Yewdall, seconded by Mr. J. Abbott.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL ASSOCIATION.

The annual general meeting of the above Society, for the election of officers, etc., was held in the rooms of the Society, at the Music Hall, Sheffield, on Thursday evening, January 29th. There was a moderate attendance.

The Council, in presenting their annual report, congratulated the members on the condition of the Association, several meetings having been held during the past year of a highly successful character, and though financially it had still to report a deficiency, yet this was not so great as might have been expected, and it was hoped that with careful management this might eventually be overcome. The Society having had several new members and associates added to it, derived therefrom renewed life. It was also gratefully noticed that a grant of chemical apparatus and books had been received from the Pharmaceutical Society for the use of the students, etc.

The report closed by an appeal to the members for their continued support and encouragement.

Upon the motion of Mr. W. Ward, F.C.S., the retiring President, Mr. G. A. Cubley was unanimously voted to the presidential chair for the coming year.

On taking possession of the chair, Mr. Cubley briefly addressed the meeting. In the course of his remarks he said that he hoped he might be enabled to follow in the footsteps of his predecessors, Messrs. Radley and Ward, and that if he could only maintain the status of the Society as they had done he should be amply satisfied. He referred to the necessity of continued united action on the part of all the members of the trade, and the importance of facilities being offered to the students while undergoing their professional education; and looked forward with hope to the time when they would have such an educational institute as should prevent any necessity for their youths having to visit London to receive a final polishing touch ere they went in for their examination. As the Pharmaceutical Society of Great Britain were now aiding them with grants, their own resources would be left more open to meet their annual claims. He further alluded to local trade matters, and concluded by proposing that the best thanks of the meeting be accorded to Mr. W. Ward, F.C.S., for the efficient manner in which he had occupied the position of President of the Association during the past year.

This being unanimously assented to, and Mr. Ward having duly replied, thanks were further tendered to the late Vice-Presidents, Council, Treasurer, Secretary, etc., severally, and having been acknowledged, the election of officers for the ensuing year was proceeded with, when the following gentlemen were found to have been appointed, viz.:—Vice-Presidents, Messrs. F. Hudson and W. H. Maleham; Council, Messrs. W. Ward, F.C.S., J. T. Dobb, Jervis, E. Wilson, Ellinor, J. H. D. Jenkinson, and R. T. Watson; Hon. Treasurer, Mr. W. V. Radley (re-elected); Hon. Secretary, Mr. E. R. Learoyd (re-elected).

The books and chemical apparatus presented to the Association by the Pharmaceutical Society were placed on the tables for the inspection of the meeting, and were much admired.

The following were unanimously elected:—As Members, Messrs. R. Thickett and Scott; as Associates, Messrs. Holmes, Atkinson, Reckless, and A. Hardwick.

This brought the meeting to a close.

Proceedings of Scientific Societies.

PHILADELPHIA COLLEGE OF PHARMACY.

The regular monthly meeting of the above College was held on Tuesday, January 20, 1874, under the presidency of Mr. Peter Williamson.

Mr. Richard Mattison read a paper on Saccharated Pancreatin and the Emulsion produced by the use of it and Cod Liver Oil, in continuation of his former note on the same subject (see before, p. 592). The paper is printed at p. 675 of the present number.

Mr. A. P. Brown, of Camden, stated that he had used saccharated pancreatin, and that physicians whom he had supplied with it had used it successfully. At the suggestion of one of his medical friends, he had treated the parotid gland by a process similar to that used for extracting pancreatin, and obtained a product which possessed in a degree the properties of pancreatin.

Pharmacognostical and Chemical Notes.

BY PROFESSOR MAISCH.

Professor Maisch presented specimens and read the following pharmacognostical notes on *Cortex Granati*, *Chiretta*, *Trompatilla* (a new remedy from Mexico, said to be successfully used in the treatment of hydrophobia), a new false Angustura, *Bouvardia triphylla*, and a report of an examination of a substance presented to him, which proved to be carbazotic acid.

It is desirable occasionally to call attention to drugs of handsome appearance and excellent qualities, if it be for no other purpose than to let the profession know how perfect by a drug may be preserved, even in commerce, so as to represent all its characteristics and show any admixture if such should be present. These considerations induce me to notice two drugs, Pomegranate Bark and Chiretta, which I recently obtained from Messrs. Cramer and Small, of this city.

Pomegranate Bark usually occurs in American commerce in small fragments of quills, which rarely attain the diameter of a finger. The bark in question is in single and double quills, varying in length from two and a half to seven inches, and from one-half to one inch in diameter. It has apparently been collected from the lower part of the trunk and the thicker roots, and agrees in all respects with the bark as usually seen in commerce, and which is evidently collected from the smaller branches of the tree and root. Those quills which are covered with a rather thick pale brownish-grey cork, more or less covered with irregular longitudinally cleft ridges, appear to me to belong to the root, while the trunk bark appears to have a thinner cork, with the fissured ridges in more regular longitudinal direction, and a colour more decidedly

grey, varied by patches of blackish brown. It will be remembered that Dr. C. Harz stated a few years ago that the commercial pomegranate bark is always the bark of the overground axis, but is sometimes mixed with the root bark in variable proportions. Both barks are said to be alike active as anthelmintics, but the medicinal reputation appears to be based mainly upon the effects of the bark of the trunk and branches.

Chiretta is, according to the U.S. pharmacopœia, the entire plant of *Agathotes Chirayta*, Don. As seen in commerce, it consists mainly of the roots and bare stems, with a few fragments of the leaves and flowers or capsules still attached, while the far greater portion of these organs have been broken off. The specimen shown, an original bundle, is 32 inches in length, five inches in width, and varying from one-half to one inch in thickness, thus presenting the form of an elongated parallelopiped in appearance ; its weight is about one pound. The stems fold back on themselves, so as to show principally the paniculate inflorescence, composed of numerous umbel-like cymes situated along the branches. The bundle is tied at both extremities and in the centre with a split cane, and the plant has the peculiar bitter taste to an intense degree.

A False Angustura Bark, which has been sold to a small extent in this city, was shown to me a short time ago. The small piece which I first saw was quite thin, covered with a greyish cork, exhibiting patches of an orange shade, while the inner surface was of a dark brown, so as to present at first sight an appearance reminding of the bark of *Strychnos Nux vomica*, which is usually designated as false angustura bark. The bark in question, however, is of such a fibrous texture that the idea of its probable identity with the strychnos bark is at once dispelled. The specimen shown is in slightly curved pieces, seven inches and less in length, and one-eighth of an inch and less in thickness ; intermixed with some half quills and a few quills. It consists altogether of the inner bark or bast layer, the outer bark having been thrown off by the cork. The suberous layer shows numerous small warts more or less confluent laterally, so as to form elevated patches, but mainly uniting in the direction of the axis to short, very irregular, longitudinal ridges. The cork is very soft, almost mealy, of a light brownish-grey colour externally, and of a decided pale orange-rust brown within. The surface layer being easily rubbed off, the orange-tinted patches are easily explained ; their colour, however, is never of the bright orange-red of the patches upon the strychnos bark. The inner bark consists of a dark brown parenchyma, in which coarse, light coloured bast fibres are imbedded in interrupted tangential rows. The inner surface of the bark is of a blackish-brown colour, very coarsely striated from the rather distant bast fibres, and often with patches of a soft wood closely adhering, which in some specimens has an almost copper-green tint. The bark breaks readily with a short but very distinct fibrous fracture, while the corky layer breaks much smoother, the bast fibres enclosed by it not protruding from the fracture to the same extent as those of the inner bark. The taste is purely bitter, and devoid of aromatic properties.

It will be observed that this false angustura bark differs very materially from both the true angustura and the strychnos bark. The former one of these two barks occurs in curved pieces, with a pale, almost ochre-coloured, cork, which is very friable and marked with suberous warts or by mainly longitudinal furrows. The inner surface is of a light brown-yellow, rather granular, not striate. The bark is very fragile and shows a smooth fracture, in which are numerous white shining striæ of crystals.

The latter (strychnos bark) is covered with a warty light greyish or yellowish friable cork, with frequently very large orange-red patches ; fracture nearly smooth, dark brown, divided by a lighter coloured line into two layers ; crystalline striæ absent ; inner surface even, grey-brown to blackish-brown, finely striate.

I have no means of ascertaining the origin of the false angustura bark, described above ; it most likely reached Philadelphia from New York.

Trompatilla, a Remedy for Hydrophobia.—Under this name was handed to me, by a friend, a sample of a drug which had been received by him from a friend residing in Mexico, where the article is said to be successfully used for the prevention and treatment of hydrophobia, for which complaint it is freely given in the form of decoction. It is stated to be obtained from *Bouvardia triphylla*, and consists of short segments of the stem and branches, varying from one-fourth to three-fourths of an inch in diameter, terete and slightly bent. The bark is thin, fragile, brown, and separates in a few pieces very readily from the wood, but adheres firmly to it in the largest number. The bark is covered with a comparatively thick layer of soft friable cork, which is rust-brown within, externally grey to blackish-brown, and marked with numerous shallow longitudinal fissures. The wood is rather hard, but splits easily and straight in the direction of the axis ; it shows concentric, somewhat irregular, zones, resembling annual rings, and is radially very finely striate from the numerous very fine medullary rays. The duramen has a purplish-gray tint, the alburnum is yellowish-white. There is no perceptible odour to either wood or bark ; the former is tasteless, the latter has a slight bitterish taste. The central pith is scarcely a line in diameter, and of a brownish to purplish-brown colour.

The genus *Bouvardia* belongs to the natural order of Rubiaceæ, tribe *Cinchonaceæ*, subtribe *Cinchoneæ*. De Candolle enumerates eleven species, all shrubby plants and natives of Mexico, having the leaves either verticillate or opposite. The scars on the specimens in question are three or four in a whorl, indicating that the plant belongs to the former section, and is most likely *B. triphylla*, Salisbury. The following description is translated from De Candolle (Prod. iv. 365.)

Bouvardia Jacquini, H. B. K., small branches triangular ; leaves somewhat rough, hairy beneath, smooth above, ternate, oblong ; corymbs subtrichotomous ; calyx lobes one-fifth the length of the roughish corolla tube ; corolla red, the tube $\frac{3}{4}$ inch long, varies with the leaves ; pubescent and glabrous.

The following synonyms are mentioned in the same place : *Ixora Americana*, Jacquin ; *Ixora ternifolia*, Car. ; *Houstonia coccinea*, Andrews ; *Bouvardia triphylla*, var. *a.*, Salisbury, and *Tlacoxochitl jasminiflora*, Hernandez.

Picric Acid Mistaken for Santonin. A vial found in a closet in a drug store, was labelled santonin ; the contents were crystalline, of a yellow colour, and of an intensely bitter taste, which prevented it from being used as santonin ; for the variety coloured yellow by light it might have been taken on superficial examination. It was handed to me for identification, and the investigation was performed at the College laboratory by Mr. W. L. Harrison of Petersburg, Va. The absence of santonin and of an alkaloid, especially berberina, was proved by appropriate tests, and the freedom from inorganic matter was established by incineration. The following summary gives an account of Mr. Harrison's examination.

The substance was in light yellow shining laminæ, taste very bitter and somewhat sour ; it reddens litmus and melts, when slowly heated, into a brownish-yellow liquid, which immediately becomes crystalline on cooling. When slightly heated it volatilizes unchanged ; at a higher temperature it takes fire, burning with a yellow, very smoky flame, and evolving irritating and very bitter fumes. It is soluble in cold water, forming a solution of brighter colour than the crystals themselves ; much more soluble in hot water, from which it crystallizes in thin long needles on cooling ; soluble in oil of vitriol, particularly when heated, and precipitated from the solution in the original state upon addition of water. With aqueous solutions of the alkalies it gives bitter, deep red solutions. Its aqueous solution, treated with excess of ferrous sulphate, then with excess of caustic alkali, gives a filtrate

of a deep blood-red colour, darker than the preceding, with alkalies alone. When sulphuretted hydrogen is passed to saturation into a saturated alcoholic solution, previously neutralized by ammonia, the liquid assumes an intense blood-red colour. These reactions and characteristics all correspond with those for picric acid.

PHOSPHORETTED RESIN.

Dr. W. H. Pile stated that he had made some phosphoretted resin according to the formula published by A. W. Gerrard, in PHARMACEUTICAL JOURNAL, December 6th, 1873, and re-published in *American Journal of Pharmacy*, January, 1874. He confirmed the statements made by the author, recommended the preparation, and laid particular stress on the directions to conform to the temperatures given in the process.

Mr. Edwin McC. Boring presented samples of Castile soap, and said that he had successfully cut very hard soap by previously heating the bars in an ordinary oven to between 150 and 200° F., care being taken not to leave them in long enough to make them too soft.

REPORT ON ELIXIRS.

Professor Maisch called the attention of the meeting to the circular issued by the American Pharmaceutical Association, containing the report of the Committee on Elixirs, John F. Hancock, Chairman; and he urged the adoption of the formulæ in order to secure uniformity. An extract of the report, giving the formulæ, will be found below :—

Compound Powder of Cochineal.

Take of Cochineal in Powder . . 120 grains.
Alum, in Powder . . . 120 „
Carbonate of Potassium . 120 „
Bitartrate of Potassium . 240 „
Mix. Keep in well-stoppered vial.

Compound Tincture of Cochineal.

Take of Compound Powder of Cochineal 120 grains.
Diluted Alcohol . . . . . 2 fl. ounces.

Slightly warm the diluted alcohol and mix with the powder; macerate in a stoppered vial for twelve hours, and filter for use. This is permanent, and imparts a beautiful red colour to elixirs and solutions which have no acid properties.

Spirit of Orange.

Take of Oil of Sweet Orange . 1 fluid ounce.
Stronger Alcohol . . 16 fluid ounces.

Mix. This is made in proportions to conform with the spirits of the U. S. P., and is a pleasant and convenient form of orange flavour.

Simple Elixir.

Take of Spirit of Orange . . . ½ fluid ounce.
Stronger Alcohol . . 4 fluid ounces.
Cinnamon Water . . 6 „
Syrup . . . . . 6 „
Mix.

This is a turbid mixture. For many purposes it is not necessary to filter before using, but generally it should be clear, particularly when used for physician's prescriptions, and in making some elixirs. Filtering-paper pulp, made by beating scraps of chemically pure filtering paper in a mortar, in the proportion of sixty grains of paper to half fluid ounce of water, added to sixteen fluid ounces of the elixir, agitated briskly for a few moments, and filtered, renders the elixir perfectly limpid. The paper is free from the chemical objections urged against carbonate of magnesium, chalk, etc., which are frequently used as clarifying agents.

The very pleasant taste and odour of this elixir, its freedom from colour and chemical impurities, commends it for general use as a medicating vehicle.

Red Elixir.

Take of Comp. Tinct. of Cochineal . : ½ fluid ounce.
Simple Elixir . . . . . 16 fluid ounces.
Mix.

This is sometimes preferred as a simple elixir because of its beautiful colour.

Elixir of Calisaya Bark.

Take of Tinct. Cinchona, U.S.P., 1870 . 22 fluidrachms.
Simple Elixir, sufficient to make 16 fluid ounces.

Mix and filter. This contains the *virtues* of two grains of Calisaya bark in one fluidrachm.

Elixir of Calisaya Bark with Iron.

Take of Elixir of Calisaya Bark . . . 15 fluid ounces.
Warm Distilled Water . . . 1 fluid ounce.
Citrate of Iron, *soluble* . . . 128 grains.

Dissolve the iron in the warm water and add the elixir. Filter, if necessary. Each fluidrachm of the unfiltered elixir contains one grain of the iron salt, and the virtues of nearly two grains of Calisaya bark.

Compound Elixir of Cinchona.

Take of Comp. Tinct. Cinchona, U.S.P., 1870 . . . . . 22 fluidrachms.
Simple Elixir, sufficient to make 16 fluid ounces.

Mix and filter. If not required for immediate use, this and also the Calisaya elixir should stand for about twelve hours before filtering.

Compound Elixir of Cinchona with Iron.

Take of Compound Elixir of Cinchona . 15 fluid ounces.
Warm Distilled Water . . . 1 fluid ounce.
Citrate of Iron, *soluble* . . . 120 grains.
Mix. Proceed as for Elixir of Calisaya with Iron.

Elixir of Citrate of Iron.

Take of—
Citrate of Iron, *soluble* . . . 256 grains.
Warm Distilled Water . . . 1 fluid ounce.
Simple Elixir . . . . . 15 fluid ounces.

Dissolve the iron in the warm water and mix with the simple elixir. Filter.

Elixir of Pyrophosphate of Iron.

Take of—
Pyrophosphate of Iron . . . 256 grains.
Warm Distilled Water . . . 1 fluid ounce.
Simple Elixir . . . . . 15 fluid ounces.

Make according to directions for Elixir of Citrate of Iron.

This is the same medicinal strength as Professor Diehl's formula.

Elixir of Citrate of Bismuth.

Take of—
Citrate of Bismuth and Ammonium 256 grains.
Warm Distilled Water . . . . 4 fluid ounces.
Water of Ammonia (drop by drop) sufficient.
Simple Elixir, sufficient to make 16 fl. oz. of finished elixir.

This is the same bismuth strength as Professor Diehl's formula, viz., two grains of citrate of bismuth and ammonium in each fluidrachm.

Elixir of Pepsin.

Take of—
Saccharated Pepsin, Scheffer's formula 256 grains.
Sherry Wine . . . . . 14 fluid ounces.
Simple Syrup . . . . . 2 „
Fluid Extract of Ginger . . . . . 25 drops.

Dissolve the pepsin in the wine; mix the fluid extract of ginger with the syrup, and mix altogether. Filter if necessary. Contains two grains of pepsin to the fluidrachm.

Elixir of Valerianate of Ammonium.

Take of—
Valerianate of Ammonium in Crystals 256 grains.
Compound Tinct. of Cochineal . . . ½ fluid ounce.
Simple Elixir . . . . . 15½ fluid ounces.

Dissolve the valerianate of ammonium in two ounces of the simple elixir, and carefully add water of ammonia until the solution is exactly neutral to test-paper. Mix with the balance of simple elixir, and then add the compound tincture of cochineal.

This is the formula of Professor C. Lewis Diehl, with the exception of the simple elixir. Notwithstanding this preparation contains a larger quantity than usual of the valerianate of ammonium (two grains of the salt in each fluidrachm), yet its unpleasant taste and odour is effectually masked by the fragrance of the simple elixir.

Elixir of Valerianate of Ammonium with Quinia.

Take of—

Sulphate of Quinia	128 grains.
Elixir of Valerianate of Ammonium	16 fluid ounces.

Mix. Filter if necessary. Sulphate of quinia is soluble in elixir of valerianate of ammonium to twice the quantity here ordered.

Compound Elixir of Sumbul.

Take of—

Tincture of Sumbul (Brit. Ph. 1867)	4 fluid ounces.
Syrup	4 „
Compound Tincture of Cochineal	½ „
Elixir of Valerianate of Ammonium	8 „

Mix.

The elixir is slightly turbid, owing to the resin of the sumbul, which, if filtered out, must lessen its medicinal powers. This is given as a type of *extemporaneous elixirs*, which should not be filtered, but dispensed with the direction, "*Shake the vial before pouring out each dose.*"

Elixir Pyrophosphate of Iron, Quinia, and Strychnia.

(C. Lewis Diehl's Formula.)

He says: "This requires particular manipulation, which precludes the use of simple elixirs.

"The following formula, the result of concert experiments of my friend, Mr. E. Scheffer, and myself, has been used by me since autumn, 1869, and I can recommend it as uniformly successful, when the manipulations are carefully conducted:—

Take of—

Sulphate of Quinia	60 grains.
Strychnia	1 grain.
Citric Acid	5 grains.
Stronger Alcohol	3 fluid ounces.
Spirit of Orange	80 minims.
Syrup	6 fluid ounces.
Pyrophosphate of Iron	½ troy ounce.
Distilled Water	7 fluid ounces.
Water of Ammonia	suf. quantity.

"Triturate the sulphate of quinia, strychnia, and citric acid together, until minutely divided, then add the alcohol and spirit of orange. Warm the syrup slightly (to about 150° F.) and add to the turbid mixture, when, upon stirring, the mixture becomes clear. To this add the pyrophosphate of iron, previously dissolved in the distilled water, and finally, carefully add water of ammonia, drop by drop, until the elixir is perfectly neutral to test-paper; filter. The finished preparation has a greenish yellow colour, a pleasant flavour of orange, and is permanent."

Bitter Wine of Iron.

(James T. Shinn's Formula, slightly modified.)

We have had several years' experience with the following formula, and it has given entire satisfaction to prescriber, dispenser, and consumer.

Take of—

Sulphate of Cinchonia	45 grains.
Sulphate of Quinia	15 grains.
Citric Acid	60 grains.
Citrate of Iron, *soluble*	240 grains.
Concent. Tinct. Fresh Sweet Orange Peel	3 fluid ounces.
Distilled Water	3 fluid ounces.
Sherry Wine	8 fluid ounces.
Syrup	2 fluid ounces.

Dissolve the sulphates and citric acid in two ounces of the water, and the iron in the remaining ounce of water; mix the two solutions, and add the other ingredients, previously well mixed together.

The only change from the original formula is in the kind and quantity of the orange flavour, for which we claim an improvement. (See *Proceedings of American Pharmaceutical Association*, 1864, p. 234.)

Elixir of Gentian with Iron.

Take of—

Extract of Gentian	128 grains.
Citrate of Iron, *soluble*	128 grains.
Distilled Water	1 fluid ounce.
Simple Elixir	15 fluid ounces.

Dissolve the extract and iron in the water, *warmed*, and add the simple elixir; filter.

Elixir of Bromide of Potassium.

Take of—

Bromide of Potassium	640 grains.
Red Elixir	16 fluid ounces.

Mix.

This contains five grains of the salt in each fluidrachm, and is given as a type. The red elixir does not seem to answer for the elixir bromide of calcium; caramel is a more suitable colouring substance for the calcium elixir. We prefer the simple elixir in this case, and to use no colouring substance.

Syrup of Liquorice Root.

Take of—

Select Liquorice Root, in moderately coarse powder	4 troy ounces.
Diluted Alcohol	suf. quantity.
Sugar	12 troy ounces.

Moisten and pack in a conical percolator; macerate for twelve hours; percolate to exhaustion. Place the tincture over a water-bath until reduced to ten fluid ounces, filter, and then add the sugar; lastly, sufficient distilled water to make sixteen fluid ounces of finished syrup.

The syrup of liquorice root, when carefully prepared, is more effectual and more convenient for masking the bitterness of quinia than is the very popular "compound elixir of taraxacum," and being free from the stimulating influence of alcohol, which is present in the elixir, is well adapted for children. The proper proportions will be one grain of quinia (any salt of it) to the fluidrachm, and if those for whom quinia is ordered will take the precaution to chew a small quantity of liquorice root previous to taking the quinia mixed with the syrup of liquorice, in the proportions here recommended, scarcely any bitterness will be observed. As a matter of course, acids mixed with quinia and liquorice syrup will immediately develope the bitter taste.

It has of late become fashionable to use glycerin as an antiseptic and solvent in elixirs, as well as other compounds of pharmacy, but our aversion to the general use of glycerin for internal administration, for various reasons, has prevented its introduction in our formulas.

The results of our investigations of liquid pepsin preparations will not warrant the introduction of more than the one formula, which is really a wine of pepsin, and has been found useful in many cases.

Mr. A. P. Brown stated that he had made some of these elixirs, and found them to answer their intended purposes well; the simple and red elixirs can be used as vehicles, and may be diluted with water without becoming turbid.

SOCIÉTÉ DE THÉRAPEUTIQUE, PARIS.

At the sitting of the above Society on Wednesday, January 28, under the presidency of Dr. Moutard-Martin, M. Martineau described a particular case in which he had administered for the second time, after an interval of a year, a draught containing 50 centigrams of hydrochlorate of trimethylamine to a patient suffering from articular rheumatism. On the second occasion it had the same effect as on the first, namely the almost sudden disappearance of the pain and swelling.

Metachloral and Caustic Pencils of Chloral Hydrate.—M. Limousin exhibited some specimens of metachloral and also of pencils of hydrate of chloral. The metachloral had been obtained by treating 1 part of hydrate of chloral with 3 parts of concentrated sulphuric acid, and washings the insoluble product obtained as long as the washing gave an acid reaction. The metachloral was afterwards dried with chloride of calcium, and reduced to a fine powder. The caustic pencils were obtained by mixing the hydrate of chloral with a small quantity of gum, and then coating them with a slight layer of paraffin, in order to preserve them from the action of damp air.

Metachloral, or insoluble chloral, has the same formula as anhydrous chloral (C_2HCl_3O), of which it is an isomeric modification. It is less caustic than hydrate of chloral, and it has the great advantage over chloral of not attracting moisture, and consequently allowing the treatment to be confined to a limited surface.

M. Dujardin-Beaumetz said that he had employed metachloral and recognized in it considerable advantages; he preferred it to iodoform, and he had obtained with it equally satisfactory, if not superior, results. Moreover, metachloral did not present the inconvenience which resulted from the penetrating and insupportable odour of iodoform. M. Beaumetz added, that in any case where the action of the powdered metachloral was found to be too irritating, its energy might be mitigated by mixing with it a certain quantity of lycopodium or other inert powder. He added that he had used the pencils of hydrate of chloral with advantage for the superficial cauterization of certain ulcerations. He also introduced them into the natural cavities, or into the fistulous passages of white tumours, to obtain the diminution and sometimes the cessation of local pain.

M. Martineau said that he had obtained very good results by the employment of hydrate of chloral in solution (1 part to 25 of water) for the dressing of cancerous surfaces, by means of charpie impregnated with the solution. He had obtained thus a modification of the surface, disappearance of the fetid odour, and diminution of the pain.

M. Constantin Paul said that he had obtained similar results in analogous cases—cancer of the womb and rectum—with suppositories containing one to two grams of hydrate of chloral, The calming effect appeared to be more prompt and more constant than that obtained with injections of carbonic acid.

M. Labée recalled the fact that Dr. Richardson had published some interesting observations respecting the external application of chloral, and that M. Francesco Accetella had, in 1871, recommended the employment of a solution of hydrate of chloral in external applications.

M. Isambert said that he did not share the enthusiasm of his colleagues for the properties of chloral. He had found its employment attended by inconveniences, and he regretted that the unlimited publicity that had been given to that medicament had prompted every doctor and patient to experiment with it. He had seen chloral, taken internally, often provoke a violent irritation of the stomach, and he found his patients not able to support it when administered as an injection.

M. Constantin Paul was surprised at the results obtained by M. Isambert. At the Bicètre he had had occasion to treat a large number of lunatics, during their period of mania, with injections of high doses of chloral. By this means he had avoided having recourse to the strait-waistcoat, and never had noticed a trace of intolerance.

M. Limousin said he had often seen the crystals of hydrate of chloral administered in doses of two to three grams in flour wafers, without the patients suffering an inconvenience.

M. Moutard-Martin said he had frequently administered chloral in the form of an injection, which was always well supported by his patients. He declined to admit—at least in a general sense—the irritating action of this medicine; he had himself taken for several days as many as eight of M. Limousin's *dragées* of chloral hydrate (equal to two grams) without experiencing any irritation. It was only after a prolonged use that he had begun to experience intolerance, and a sensation of heat, which he had found the use of the syrup or solution to determine much more rapidly.

It was generally considered that M. Isambert had employed the chloral with patients presenting a particular idiosyncracy.

Obituary.

Notice has been received of the death of the following:—

On the 24th January, 1874, Mr. William Munton Carr, Chemist and Druggist, of Eynsham, Oxon.

Notes and Queries.

[385.] DARK BROWN HAIR DYE.—*F. S. F.* sends the following recipe:—

℞

Argent. Nit.	℥iij. gr. xij.
Aquæ Destill.	℥viij.

Dissolve and add gradually Liq. Ammon. Fort. q.s. to precipitate the silver until re-dissolved.

Aquæ Lavand.	℥ss.

[386.] COCCULUS INDICUS is used very largely in all the breweries in England, to replace *Humulus Lupulus*, hence the intoxicating properties of pale ales.—E. SCHUMANN.

[*** We do not believe that the slightest grounds exist for the above statement; but if Mr. Schumann possesses any evidence of the general use of *Cocculus indicus* in the manner stated we shall be glad to receive it from him.—ED. PH. J.]

[387]. TINCTURE OF PHOSPHORUS.—Can any reader favour me with a formula for Warburton Thompson's Tincture of Phosphorus?—R. B. HARDING.

[*** The following formula given by Dr. Ashburton Thompson, in a paper "On the Use of Phosphorus in Neuralgia," published in the *Practitioner* last October, is probably what is sought by our correspondent:—

"Phosphorus	1 grain.
Absolute Alcohol	5 drachms.
Glycerine	1½ ounces.
Spirit of Wine	2 drachms.
Spirit of Peppermint	2 scruples.

"Let the phosphorus be dissolved in the alcohol with a little heat; at the same time warm the spirit and glycerine together. Mix the two solutions while hot, and add the spirit of peppermint on cooling. One drachm of this mixture contains one-twelfth of a grain of pure phosphorus. These ingredients form a mixture perfectly bright and clear, possessing almost no phosphoric odour or taste, and of a high degree of stability, even under exposure to light. The amount of spirit gives it a burning taste which may be sometimes objected to; but if the patient be warned of this, probably no further remark will be

made about it. So far from causing offensive eructations, it seems to have a tendency to arrest existing flatulency." —Ed. Ph. J.]

---

[388]. CAMPHOR INHALATION.—"*Inquirer*" would be glad to receive information respecting an easy and simple method of administering camphor by inhalation.

[*** The following is the formula for "Vapor Camphoræ" given in the 'Pharmacopœia of the Hospital for Diseases of the Throat':—

"Take of Spirit of Camphor . .	3 fl. drachms.
Rectified Spirit . . .	½ fluid ounce.
Water	to 3 fluid ounces.
Mix.	

A teaspoonful in a pint of water at 150° F. for each inhalation. To be inhaled slowly."—Ed. Ph. J.]

ANALYSIS OF THE ASH OF BOA-TAM-PAIJANG.—The seeds which some few years since were introduced under this name from Cochin China as a remedy for diarrhœa and dysentery, and were described in an article in this Journal (2nd series, vol. iv. p. 110) by Mr. D. Hanbury, who referred them to *Scaphium scaphigerum*, have recently been the subject of an ultimate analysis by M. F. Wurtz. 100 grams dried in a stove lost 11·5 per cent. of moisture; they then contained 84·9 per cent. of volatile and organic substances and 3·6 per cent. of fixed and mineral matters. The per-centage composition of the latter was as follows:—

Oxide of Manganese	17·096
Magnesia	14·083
Lime	12·750
Potash	7·222
Oxide of Iron	5·333
Phosphoric Acid	21·166
Carbonic Acid	14·250
Hydrochloric Acid	3·416
Sulphuric Acid	1·777
Loss	2·907
	100·000

The remarkable point in these results is the richness in manganese, a metal that is so rarely met with in plants.—*L'Union Pharmaceutique.*

SYRUP OF IODIDE OF IRON AND MANGANESE.—The following formula for the preparation of a syrup of iodide of iron and manganese is recommended by Mr. J. U. Lloyd (*Amer. Journ. Pharm.* [4] iv. 7) on the ground that it avoids the production of the large quantity of sulphate of potash, which results when the formula given in the U.S. Dispensatory and Parrish's Pharmacy is adopted:—

Sulphate of manganese . . .	240 grs.
Iodide of potassium	288 „
Iodine	744 „
Iron wire (small)	240 „
Sugar	17 oz. av.
Distilled water, q. s.	

Place the iodine, three ounces of distilled water, and the iron wire cut into small pieces, in a thin glass flask or a porcelain dish, shake or stir occasionally until the reaction ceases, and the solution has acquired a clear greenish colour without a tinge of yellow. Having introduced the sugar into a porcelain dish, filter the solution of iodide of iron upon it. Wash the filter by pouring into it two ounces of distilled water, allowing the same to filter into the sugar. Dissolve the sulphate of manganese and iodide of potassium separately in one-half an ounce of cold distilled water by trituration in a mortar; mix the two solutions together, and allow the sulphate of potash to precipitate, then carefully remove the mixture into a moistened filter-paper within a glass funnel, and allow the solution of iodide of manganese to filter upon the sugar. When well drained wash the precipitate within the funnel with one-half an ounce of cold distilled water, allowing it to filter into the sugar.

Finally, finish the operation by adding to the above enough distilled water to make the whole measure twenty fluid ounces: stir occasionally until dissolved, and filter.

Correspondence.

The Adulteration Act.

The numerous cases which have from time to time appeared in various publications throughout the country, in reference to the vexatious proceedings in connection with the operations of the Adulteration Act, induce me to ask a corner in the Pharmaceutical Journal for the present communication.

I do this the more readily as I perceive that arrowroot is, in some districts, the article pounced upon by the gentlemen who, in the capacity of inspectors, appear to act with what, doubtless, seems to them a very creditable zeal, but which, I humbly submit, is quite a misapprehension on their part as to the meaning and intentions of the operations of the said Act so recently enacted.

The following facts will speak for themselves, and may, I hope, assist in bringing about some modification of a measure doubtless beneficial if properly worked, but the very opposite, and therefore highly mischievous, if its general scope and real intentions have been misunderstood.

As an introduction to the following documents, I may shortly premise that two or three months ago I sent to a well-known firm in Greenock an original case of Port Natal arrowroot. This particular package was from a lot bought from one of the first houses in London. Not long since, the parties wrote me asking for a written guarantee as to the purity of the arrowroot I had sold them. Being an original package, I told them that, having examined the article before purchase, I believed it genuine, but declined any written guarantee, as I was not the maker.

Shortly after, I received the memorandum now sent, enclosing a certificate from the public analysts:—

"Sir,—You will see from the enclosed memorandum that we are prevented selling the last lot of arrowroot we had from you, on account of its being adulterated. We, therefore, return it to-day per rail. Please credit our account with 1 cwt.

"(Signed) Geo. and Jas. Morison.

"*Greenock, January 24th*, 1874."

"[*This certificate is given under the Act for the Prevention of the Adulteration of Food, etc.* (1872), *and refers only to the sample analysed.*]

"No. 206 F.

"Mr. D. Young, Inspector under the Food Act.

"Sir,—We have carefully microscopically examined the sample of arrowroot, No. 197, received from you on the 2nd inst., and find that it has been adulterated.

"The adulteration, which is not injurious to health, consists in the presence of from 10 to 20 per cent. of torrefied arrowroot, or other starch altered by heat.

"(Signed) Patterson and Ogilvie.

"*Greenock, January 10th*, 1874."

In accordance with the intimation conveyed in the note of Messrs. Morison, the case containing 1 cwt. of arrowroot came duly to hand, and I lost no time in taking out samples and sending them to four gentlemen for examination, whose

names and position in the scientific world as chemists and microscopists require no comment from me.

"Mr. Mackay,—I have carefully examined the sample of Natal arrowroot (with and without the polariscope) microscopically, and can certify that there is no trace of any other starch than that which is yielded by the *Maranta arundinacea*. The idea of torrefied arrowroot being used to adulterate it is simply nonsense.

"(Signed) THOS. C. ARCHER,

"Director of the Edinburgh Museum of Science and Art, and formerly Secretary of the Edinburgh Microscopic Society."

"*Edinburgh, Jan. 29th*, 1874."

"Sir,—I have chemically and microscopically examined the specimen of 'arrowroot' you placed in my hands, comparing it with the standard specimens in the Museum of the Pharmaceutical Society of Great Britain. It is genuine arrowroot of good quality.

"(Signed) JOHN ATTFIELD, F.C.S.,

"Professor of Practical Chemistry to the Pharmaceutical Society of Great Britain; Author of a 'Manual of Chemistry, General, Medical, and Pharmaceutical,' etc.

"17, *Bloomsbury Square, Feb. 4th*, 1874."

"My dear Sir,—I have submitted the sample of starch you left with me yesterday to a careful microscopic examination and am of opinion that it is genuine arrowroot, the starch of a *Maranta*. Some of the particles have a small crack, commonly observed in Natal arrowroot, but I can discover no evidence of its having been torrefied, nor can I discover any maize starch in it.

"(Signed) T. REDWOOD, Ph.D.

"Professor of Chemistry and Pharmacy to the "Pharmaceutical Society of Great Britain.
&c., &c., &c.

"17, *Bloomsbury Square.*
"*5th Feb.*, 1874."

"My dear Sir,—I have subjected to microscopic examination the sample of Natal arrowroot which you left with me. I made upwards of twenty demonstrations of it—collected from various parts of the sample, and thus several thousands of the undivided starch grains have been seen by me. Of these I have found only six which were ruptured and flaccid, and could in any way whatever have been subjected to undue heat, if indeed their broken state had to do with anything else than mechanical causes.

"To apply the term adulteration to this, supposing it had been tenfold greater in amount, appears to me an absurdity.

"(Signed) DOUGLAS MACLAGAN, M.D.,

"Professor of Medical Jurisprudence in the Edinburgh University, &c., &c., &c.

"28, *Heriot Row, Edinburgh.*
"14*th February* 1874."

So convinced was I that the Greenock analysts were in error, that I addressed them the following letter:—

"119, George Street, Edinburgh.
"*7th February*, 1874.

"Gentlemen,—Some time ago I supplied Messrs. G. and J. Morison, with an original case of Port Natal arrowroot.

"On the 24th ult. these parties wrote stating that the arrowroot so sent by me was returned by them in consequence of the same having been found adulterated; and in confirmation of this, they sent me a certificate signed by you, and in which you declare that sample of said arrowroot, having been carefully examined, was found to be adulterated to the extent of 10 per cent. or 20 per cent. with 'torrefied arrowroot, or other starch altered by heat.'

"You will observe that such an authoritative statement from you is somewhat serious to me, and as I have had the same arrowroot examined by several eminent chemists, who disagree with your statement, I will be glad to hear from you in reply whether you still adhere to your certificate given as on 10th January, 1874.

"I remain, your obed. servant,

"(Signed) JOHN MACKAY.

"Messrs. Patterson and Ogilvie, Greenock."

Three days afterwards I received the following reply:—

"Dear Sir,—In reply to your favour of the 7th inst., we beg to say that in consequence of your letter we have again looked at the sample of arrowroot to which you refer, and find that it contains torrefied starch as reported by us. The question of per cent. is not one to which we will adhere, because it is only given as an approximate estimate. The quantity varied in different examinations, for which reason we qualify the statement, 10 to 20 per cent, by using the word *about*. The presence of over heated granules in this sample may have been due to carelessness in manipulating the drying of the arrowroot; but whether that was the case, or whether torrefied starch was directly added, does not concern us in our capacity as food analysts; we simply reported upon the sample as we found it, and have left the explanation as to how it came to be in that condition to those best acquainted with the particular variety of arrowroot under consideration.

"With these explanations, therefore, we adhere to our certificate.

"(Signed) PATTERSON AND OGILVIE.

"*Greenock, 16th, Feb.*, 1874."

I refrain from making any further remarks, although I feel strongly that some alteration ought to be made with as little delay as possible in working out the real provisions of the Adulteration Act, and thus prevent much annoyance and considerable loss to those who are not only entirely free from blame in the ordinary course of business, but who have no desire whatever to trade in any adulterated article.

JOHN MACKAY.

"*Edinburgh, 16th Feb.*, 1874."

THE PROPOSED ADDITIONAL SCHOLARSHIPS.

Sir,—I have just been reading the letter by "A Country Apprentice" in your last, and, on considering the matter, I agree with him so fully that I send this in support of his ideas.

Let us take the case of a young man whose classical education was very imperfect, but who afterwards worked hard all day behind the counter at the practical, and in his spare time got up the theoretical; shall such an one be debarred from these scholarships because subjects are introduced which have no relation to pharmacy?

If any young man is so fortunate as to be well up in French, German, Italian, Greek, Natural Philosophy, etc., by all means let him try to retain his knowledge, for all these things will be a source of pleasure and profit in after life, and it is well said that "knowledge is power."

P. B.

THE PROPOSED PHARMACY BILL FOR IRELAND.

Sir,—Being desirous for the advancement of pharmaceutical education in Ireland I cannot allow the statements of your correspondent "A.P.S." in your last issue to pass unnoticed,—inasmuch as they are calculated to make a totally false impression with regard to the nature of the proposed Pharmacy Bill for this country,—as also the object in view in the formation of the association to which he refers.

I refrain from comment on that part of his statement having reference to the dispensing of medicines in large establishments by duly qualified assistants, and not by the proprietors themselves, and can excuse his ignorance on no other ground than that of his youth.

Some months ago I had occasion to write to you on the subject of "Pharmacy in Ireland," and then endeavoured to show your readers that we have two distinct classes claiming the title of Pharmacist,—first, we have the licen-

tiate of the Apothecaries' Hall, who is the *only* apothecary or chemist having a legal right to despense medicine from the prescription of a duly qualified physician or surgeon, and second, we have a class of men who keep open shop for the wholesale or retail of drugs and who dare not dispense a prescription under a heavy penalty, and consequently have had no training whatever for the most important part of a pharmacist's duty. Now, the proposed Pharmacy Bill emanates from the latter class, and is designed to secure for them what has been the legal right and privilege of the licentiate apothecary for almost a century, and what has cost him no small amount of his time and money;—and, further, the only ground, as far as I can learn, on which the druggist claims this privilege is that he has kept open shop for the sale of drugs for a period of years. No wonder that our apothecaries form themselves into a "defence association" to guard their own rights; and I trust that not only they, but also the medical staff of Ireland will be fully alive to the importance of guarding the Irish people against the wholesale admission of a body of untrained men to pactise the responsible duties of a pharmacist. That the present "Act" regulating the dispensing of medicines by the apothecaries in Ireland needs amendment, none seem more ready to admit than the apothecaries themselves, but the amendment cannot be such as that now under discussion.

That the formation of the association of which your correspondent complains can in any degree injure the position of the present apothecaries' assistant, I fail to see, and can come to no other conclusion than that "A.P.S." must be an assistant in the employment of some one of our "druggists," or else he has totally mistaken the mission of the "Apothecaries' Defence Association."

J. B.

Belfast, Feb. 16*th*, 1874.

Where is Miss Comp?

Sir,—Will you allow me to ask if any of your readers can favour me with an introduction to this young lady? There have been some rumours to the effect that she has been seen recently about the west end of the city of Glasgow, but I have been unable to find out her place of abode. She is very much wanted; several "valentines" resembling prescriptions, addressed to her and initialled "J.G.," have been seen of late, but for want of full particulars it is to be feared they have not reached their rightful owner. Perhaps she is a companion of Mr. Pil. Philip introduced some time ago by Mr. Greenish. I thought these mysterious individuals had disappeared for good and all, after the exposure they received. I trust all having the interest of pharmacy at heart will hound them down.

17, *St. George's Cross,* J. M. Fairlie.
Glasgow, 10*th Feb.* 1874.

Mustard.

Sir,—I have frequent enquiries, by letter and otherwise, as to pure mustard suitable for the pharmacy, and more especially as to how the relative proportions of the flour of the white seed to that of the black can be secured. Allow me once again to refer to this subject in your Journal by suggesting a very simple means of securing the object in view. The *pure* flours of the black and the white mustard seed can, without difficulty, be obtained separately of any good manufacturer, and by procuring a 2lbs. tin of white, and a 9lbs. keg of black, there remains only the trouble of mixing them together in order to secure the desired result, closely approximating to the theoretical proportions necessary to the greatest pungency, at the same time supplying the requirements of the Pharmacopœia without the misgivings of anyone's private monitor, or dread of the public analyst.

Thomas Greenish.

20, *New Street, Dorset Square, Feb.* 18*th*, 1874.

"On the Use and Abuse of Food."

Sir,—My attention has been called to the abstract of a lecture delivered by a "Professor" Archer on my recent work on Food, and which has appeared in your Journal. I have not the honour of his acquaintance, and, to my shame be it said, I did not know of the existence of so great an authority on Dietetics; but he has shown himself in the character of a "candid friend," and I offer my profoundest acknowledgments for the notice with which he has favoured me.

There are, however, some *slight* inaccuracies in his remarks, (if this distinguished "Professor" were not so trustworthy, I might have ventured to use the harsher word—mis-statements), and with your permission, I will with all humility submit a few feeble denials to his courteous consideration. I have *not* written that the *Cycas revoluta* is a palm, but have used the words "the *Cycas revoluta* and other trees." I *have* stated that the potato was obtained from Chili, but my other statement is also true, that it does not grow well and is not in general use in hot climates. There *are* 100 species of fig, and I did *not* say that they were all edible. The Sahara includes the oases in it, and I did *not* say that the Date-palm grows in the sandy desert. The Guava grows extensively in the East Indies, and I did *not* say that it belonged to the East only. The prickly pear does grow in Majorca, and I did *not* say that that was the chief place to which we were to look for it. Quince *does* make a better marmalade than orange, notwithstanding his jingle on the word marmar. I did *not* say that cabbage was a most nutritious class of vegetable, but that it represents the least nutritious class of food. The Yucca referred to is stated not to be a bad substitute for potato, and it *does* supply arrowroot. Iron has been found in low class sugars, and it is of no moment that he has not detected it. There are *several* generic names of the plants supplying arrowroot, and among others I *did* mention the Jatropha, and other Euphorbiaceous plants. I *did* refer to Manna, from the manna ash in the words "tree manna." Nettles are boiled in milk, and the juice *is* eaten as nettle porridge, whilst they are *not* eaten separately like spinach. I did *not* say that Maize was a *native* of sunny—but the *product* of sunny climes, and it does not grow to perfection with the amount of sun which we have here. The Phaseoli *are* beans eaten in Mexico, and I *did* refer to the use of beans and peas in this country. The tomato *is* boiled and stewed, and the plantain *is* fried or baked like other vegetables. The *stem* of fennel growing in the East *has* an agreeable acidity. I did *not* say that either salt, vinegar, or pepper was an element in cloves or in cinnamon. Hasty pudding *is* made in the Peak of Derbyshire with oatmeal as well as with wheaten flour.

I fear that your readers may now deem the whole subject very trivial, and I am sure that I ought to apologize to this "Professor" or Director of an Industrial Museum, for taking the liberty to point out these errors. The public do not expect great men to write legibly and they should not require them to read very correctly. Democratic changes are, however, imminent, and as no one can now stand on his dignity, perhaps this "Professor" might be induced to honour some free Elementary School in his neighbourhood with his presence.

Again offering my deepest respects to the renowned lecturer, I am, etc.,

Edward Smith, M.D., F.R.S.

140, *Harley Street, W.,*
Feb. 18*th*, 1874.

[*** As a matter of course we give insertion to Dr. Smith's reply to the trenchant criticism of his work by Professor Archer, though the fact that it came to us in the shape of a report of the proceedings of a provincial society left us no option as regards its publication. Having done this, however, we think the tone both of the criticism and reply justify us in saying that as regards any future communications on this topic we must exercise such discretion as will prevent this journal from being made an arena for personal recriminations.—Ed. Pharm. Journ.]

A Caution and Request.

Sir,—I shall be greatly obliged by your giving publicity to the following:—A scoundrel, having the air and bearing of a gentleman, is going about with a prescription of which the following is a copy:—

"Captain Ward, Royal Engineers. ℞ Tr. Ferri. Sesqui, ʒij.; Æth. Chlor. ʒiij.; Tr. Digital. ʒiij.; Aq. Pur. ʒij.

m. A tablespoonful three times a day, in a wineglassful of water. ℞ Syr. Chloral. Hyd., ℥j; Pot. Bromid., ℈iv.; Aq. Anethi, ℥iv. m. A fourth part each night. (Signed) H. B. Norman."

He enquires how long it will take to prepare, persists in waiting for it; perhaps says he is very anxious to get it quickly, his servant having omitted to pack with his traps the two bottles he obtained a few hours before at a neighbouring town.

The medicine prepared, he asks the cost, when he is afraid he has not so much change, and is sorry to ask the favour of change for a cheque. In this way he obtained on Saturday last, at Southsea, six guineas for one forged cheque, and at Southampton five guineas for another. Both cheques purport to be drawn by "C. H. Blennahassel, Colonel, Royal Enginecrs," on Cox and Co., Craig's Court, Charing Cross, in favour of "A. C. Ward, Esq., Captain, Royal Engineers," who he professes himself to be, and endorses the cheque in the shop.

His real name is E. H. Gahan. He is a most accomplished swindler, and has forged many cheques on Cox and Co., who ought to assist in bringing him to condign punishment. I saw four of his forged cheques, amounting to £60, at Portsmouth Police Station, yesterday.

In April, 1872, the Leicestershire Banking Company offered £100 for his apprehension, and he was only discharged from prison in December last, after eighteen months incarceration.

He is an Irishman, about 30 years of age. The following is a fair description of his appearance and dress on Saturday last:—Height, 5ft. 7in. or 8in., slim build, brown hair, light brown moustache, whiskers and beard close shaved off, the roots of shaven air being very visible. Oval, thinnish face. Wore a brown, stiff, felt hat (but that article of dress I think he often changes, leaving one behind at the hotels he visits), dark brown paletot overcoat, slaty-coloured trousers (probably if the weather is muddy will be turned up), lay-down collar, black, long necktie with red or crimson spots.

Professes to be in a nervous, shaken, state of health, result of five years service in India, from whence he says he has recently returned, and is anxious to learn one's opinion of the probability of his recovery. Is extremely chatty and over polite. Probably will talk about Cheltenham (where his mother really resides), and Canada, where—at Quebec—he was formerly a banker's clerk. Any of your readers who will cause his arrest and send me a telegram to that effect will confer an obligation on the trade and public generally, and especially on

ROBERT CHIPPERFIELD.

P.S.—Should, unfortunately, any of your readers have been victimized by him, I shall be glad if they will at once communicate with me.

Southampton, Feb. 16th, 1874.

A CASE OF REAL DISTRESS.

Sir,—I am far from being an advocate in any sense for irregular practice or irregular practitioners. But I cannot help seeing that the anomalous distribution of our medical charities, both parochial and others, and the wants of the poorer classes in our large centres of population form at once the cause and the excuse of much laxity in this direction. The widow, however, for whose sake I write this letter, was the wife of a man who, although never qualified by diploma, was not a quack. He had studied medicine and obstetrics under eminent professors—the late Dr. Waller amongst others—and he was very well qualified to practice except for the lack of diplomas. This fact, however, precludes his relatives from appealing specially to the medical profession. As, however, he was regularly apprenticed to a chemist and druggist, and exercised that business for many years, both at Malmesbury and in Shoreditch, I am emboldened to appeal to your readers for help for his widow, who is left almost penniless by the death of her husband in his 61st year, which happened in December last. The married daughters are quite unable to assist her, and for years past the poor man and his family had been struggling with poverty. Any sums, however small, will be thankfully received by the widow herself [Mrs. Newby, of 41, Hassett Road, near Homerton Station, E.], or placed to a fund being raised for her benefit by the Rev. Mr. Kelly, St. Monica's, Hoxton, E.

A HOSPITAL PHYSICIAN.

"*Botany.*"—Cooke's "Manual of Structural Botany," s published by Hardwicke, Piccadilly; price 1s.

K. T.—You will find some information respecting, and a formula for, the preparation you mention, in the last volume of this Journal (vol. iii. pp. 678 and 697).

E. W. Lloyd.—We have carefully examined the sample forwarded, and see no reason to suppose that it is other than it was represented to be.

A. L.—(1) Yes. (2) Yes. (3) No. (4) It is asserted by Pasteur that fermentation is caused by the development of organized germs in suitable media; and that each kind of fermentation has its specific germ, without the presence of which in favourable circumstances such fermentation cannot be produced. This theory has been applied by the great French chemist to the manufacture of beer and vinegar, but its correctness is strongly disputed. See papers in the present series of the Pharmaceutical Journal; in vol. 1 by Liebig and by Williamson; in vol. ii. by Pasteur, (p. 634) and by Petit, (p. 409).

"*Syrupus.*"—(1) The price of the "Treasury of Botany" is 12s., and of Armstrong's "Introduction to Inorganic Chemistry," 3s. 6d. (2) Apply to the Secretary for a copy of the Regulations of the Board of Examiners. (3) We must refer you to the author of the book in question for an answer.

"*P.*"—In a communication to the second series of the Pharmaceutical Journal (vol. v. p. 16), Mr. Charles Symes stated that lemon-juice heated to 150°C., and excluded from air at that temperature, will remain unaltered for several months, provided the operation be effected in the winter. Mr. Schweitzer some years since, found that the addition of ten per cent. of alcohol to fresh lemon-juice prevented decomposition.

J. E. H.—Your question will be best answered by quoting from the regulations of the Board of Examiners. On and after the 1st October, 1874, the candidate will be required to "recognize the ordinary chemicals used in medicine; to possess a practical knowledge of the processes by which they are produced, and the composition of such as are compound; and to explain the decompositions that occur in their production and admixture, by equations or diagrams."

W. O. A.—See the paper read by Mr. Haffenden, and the discussion thereon, at the British Pharmaceutical Conference at Brighton, PHARM. JOURN. [3] vol. iii., p. 212, also a paper on p. 575 of the present volume.

"*An Associate.*"—You will find numerous recipes for pomatums, etc., scattered through the pages of the present series of the Journal; from these we do not doubt your own judgment will enable you to select the article best suited to your purpose.

"*International Prizes.*"—"*Vinegar*" has favoured us with a cutting from a local newspaper in which a prize given by a contemporary in connection with its "Column for Students" is exaggerated into an international prize awarded by the "proprietor of a distinguished scientific paper in the metropolis for a chemical analysis of poisoned food." We are glad to notice that our "distinguished scientific" contemporary has expressed its disapprobation of such an objectionable proceeding.

A. B. H.—The question is one we do not feel qualified to answer. We should recommend you to refer the matter to the Registrar, or to consult your solicitor respecting it.

F. J. Barrett.—The specific gravity of Extractum Ergotæ Liquidum should be, as nearly as possible, 1·000.

"*Alpha.*"—Albata, or German silver, is an alloy composed of copper, nickel, and zinc.

W. J. S.—(1) We think the discolouration must have been due to the presence of a small quantity of an iron salt, arising from a slightly solvent action of the caramel. (2) Red orpiment is realgar, the disulphide of arsenic.

"*Quæstio.*"—(1) The wire might be used until it is all dissolved, but we doubt the economy of the process. (2) We cannot undertake to say.

A. A., A. P. S.—The borax has a solvent action upon the gallic acid similar to that which it has upon several other substances.

COMMUNICATIONS, LETTERS, etc., have been received from Quaestio, Querist, M. P. S.

NOTES ON THE ARECA PALM.

Areca Catechu, L.

BY JOHN R. JACKSON, A.L.S., CURATOR OF THE MUSEUMS, KEW.

Some interest having lately arisen amongst pharmacists with regard to the Areca palm (*Areca Catechu*, L.) owing to its proposed introduction into the British Pharmacopœia as an officinal plant, a few notes on the tree itself and its uses may not be out of place.

The Areca palm is a handsome tree, growing to a height of from 40 to 60 feet, with a slender, erect trunk, averaging from one to two feet in circumference. It has regular, pinnate leaves, and long, linear leaflets, of a rich, dark-green colour. The circumference of the trunk is annulated or distinctly marked with the scars of the clasping petioles of former leaves. The fruits are each about the size of a hen's egg, consisting of a fleshy looking drupe, which, however, on cutting is found to be very fibrous, containing a seed about the size of a nutmeg, and like that well-known spice, ruminated or marked with thick, reddish-brown irregular lines throughout its entire substance. These fruits are borne in large bunches, springing from the crown of leaves. The spathe itself is used in some parts for making drinking vessels, for nailing over the bottoms of boats, and various other purposes.

The tree is known best as the betel-nut palm, and is cultivated in nearly all the warmer parts of Asia for the sake of the seeds, which are not only chewed in large quantities by the natives in countries where they grow, but are shipped to countries where the palm is not cultivated. The average annual produce of one tree is said to be about three hundred nuts. The tree is largely cultivated all over India, as well as in China, but is more abundant, perhaps, in Malabar, North Bengal, the lower slopes of the monntains of Nepaul, and the south-west coast of Ceylon. In Travancore alone there are nearly ten millions of these trees, the annual value of the produce of which is estimated at £50,000 sterling. It is said that about 80,000 piculs of the nuts are annually produced on the coast of Sumatra. Many varieties of the betel-nut palm are known to the natives under different local names ; the nuts also vary much in size, but their quality depends upon their appearance when cut through, "intimating the quantity of astringent matter contained in them. If the white or medullary portion which intersects the red or astringent part be small, and has assumed a bluish tinge, and the astringent part is very red, the nut is considered of good quality ; but when the medullary portion is in large quantity the nut is considered more mature, and, not possessing as much astringency, is not esteemed so valuable."

The nuts are usually gathered between the months of August and November. The seeds are removed from the husk and boiled in water. In the first boiling the water becomes red and thick, and this is afterwards evaporated into catechu, but whether it is imported into this country as a commercial article is uncertain. The mode of collecting the catechu in Mysore is thus described :—"The nuts are taken as they come from the tree, and boiled for some hours in an iron vessel. They are then taken out, and the remaining water is inspissated by continual boiling. This process furnishes *kossa*, or most astringent *Terra japonica*, which is black, and mixed with paddy husks and other impurities. After the nuts are dried they are put into a fresh quantity of water and boiled again ; and this water being inspissated, like the former, yields the best or cleanest kind of catechu, called *coony*. It is yellowish-brown, has an earthy fracture, and is free from the admixture of foreign bodies."

For the purpose of chewing, the nut is cut into narrow strips and rolled up with lime in the leaves of the betel pepper. The mixture has a hot, acrid taste, and aromatic and astringent properties. The habitual use of the betel-nut is considered by the natives to be very wholesome, but the effects are said by some to be due as much to the ingredients used with it as to the areca nut itself. Its constant use causes the teeth to become black and the mouth and lips of a brick red colour. In some parts of China the nuts, bruised and powdered, are mixed with the green food given to horses, and they are thus considered a preventive against diarrhœa. In the north of China small pieces of the nut are boiled and the decoction is taken as a domestic remedy in various visceral affections.

Though the use of the betel as a masticatory turns the teeth black, it is said to preserve them from decay in a remarkable manner, and this may be the reason why some English chemists have introduced the pulverized charcoal into this country as a tooth powder.

In Borneo the flowers, which are fragrant, are mixed with medicines and used as charms for the cure of many diseases. In some parts of India the juice of the young tender leaves mixed with oil is applied as an embrocation in cases of lumbago, and a decoction of the root is a reputed cure for sore lips, so that whatever may prove to be the value of the areca nut as an anthelmintic in this country, it is certain that the tree is much esteemed for its numerous uses in the East.

BUCHU LEAVES.*

BY PROFESSOR F. A. FLÜCKIGER.

The leaves of species of *Barosma* growing at the Cape, known under the name of buchu leaves, are but little used, and have not yet been the objects of a chemical or a microscopical investigation, although worthy in a high degree of both. The smell of buchu leaves appears to the author not alone to depend upon the essential oil, for in this respect it is more suggestive of peppermint. By long exposure to the cold of winter he has obtained from the oil a well-crystallized camphor which melts at 85° C. and commences to sublime at 110° C. It dissolves in bisulphide of carbon, from which it may be obtained in fine needles that might well be taken for peppermint stearoptine. The elementary analysis gave, carbon 74·08, and hydrogen 9 to 10, but it was not sufficiently satisfactory to construct a formula from. The oil poured off from the camphor of *Barosma betulina* does not boil under 200° C., and after being rectified over soda, answers to the formula $C_{10}H_{16}O$. The crude oil turns the plane of polarization to the left.

The aqueous infusion of the leaves contains some mucilage, and a body which belongs probably to the

---

* Abstract of an article in the *Schweizerische Wochenschrift für Pharmacie*, Dec. 19, 1873.

quercitrin or rutin class; the extract is not altered by ferrous salts; it is coloured greenish brown by ferric chloride, and gives with acetate of copper a yellow precipitate which is soluble in potash. Further experiments are required to show what this body is.

In an anatomical point of view buchu leaves appear at first sight remarkable by the large spherical oil vessels, which however do not claim any especial interest. If a transverse section of a *Barosma betulina* leaf be made, three layers can be discerned in the inner tissue. The thickest, occupying the middle of the leaf, is coloured green by chlorophyll, which is much less the case with the considerably smaller layer occupying the space between the chlorophyll layer and the under side of the leaf. A third layer, in a section prepared in alcohol or oil, is scarcely perceptible. It appears as a small uncoloured zone directly under the epidermis of the upper side of the leaf, in which, differing from the under side, no oil vessels appear. There may be seen also the fibro-vascular tissue, the raphides, the cuticle and the epidermis constituting the skin tissue of the leaf.

If a section of *Barosma* leaf be placed in glycerine the epidermis of the upper side is raised by a mechanical action which resembles that which takes place when the epidermis of linseed, white mustard seed, quince seed, etc., is saturated with water. The delicate walls of the colourless cells in the last mentioned layer swell up, and protruding perpendicularly to the surface of the leaf, let a thick slime run out, in which the cell walls gradually disappear. At first there seems to be in this cellular slime an appearance of delicate stratification as in many other similar cases. The mucilage is not coloured by iodine, consequently it may be considered to approach nearer to cellulose. Under the influence of glycerine the mucilaginous layer of the leaves of *Barosma betulina* assumes the development described quite gradually; but it is produced much more quickly when the leaves are placed under water. In the latter case this layer occupies fully half the breadth of the section.

The leaves of the *Barosma crenulata* and *B. serratifolia* are, as is known, much thinner, being about half as thick as those of *B. betulina*. When these thinner leaves are placed in alcohol the mucilaginous layer remains scarcely perceptible, but in water it swells equally with that of the other kind. The breadth of this layer is then proportionately much more considerable in the thinner species, taking up two-thirds the breadth of the section of a leaf.

Whilst we are accustomed to find the epidermis to be the seat of the mucilaginous formation in the seeds, and to meet with special mucilage cells in the cortex, in the buchu leaf this function belongs to a row of cells (collenchyma) in the interior, without the epidermis having any share in it, if we, at least, leave out of consideration the fact that here and there isolated prolongations of cells extend from the epidermis into the mucilaginous layer.

The author does not know whether other leaves present similar conditions; in *Althæa* leaves, after quite a cursory examination, this appeared to him to be no more the case than in those of *Sesamum indicum*, which are tolerably mucilaginous. *Empleurum serrulatum*, on the other hand, resembles *Barosma*.

RHEUM OFFICINALE.

BY PROFESSOR BAILLON.

The following information respecting the new species of *Rheum*, which is now considered to be the true origin of the officinal rhubarb, has been supplied by Professor Baillon to M. Regnaud for insertion in a new edition of Soubeiran's 'Traite de Pharmacie.'*

"Besides the *Rheum Rhaponticum*, which yields the Rhapontic rhubarb, Linnæus recognized four species of the genus *Rheum*, to which have successively been referred the origin of the true rhubarbs of China and Russia. These were the *Rheum Rhabarbarum* (afterwards named *R. undulatum* by Linnæus himself), *R. compactum*, *R. palmatum* and *R. Ribes*. The latter, to which has been attributed the origin of Persian rhubarb, or rather of the products which are received through Persia, has never been more than a culinary herb. As to the three other species, they have all contributed (from the root) certain European and native rhubarbs.

"A species more recently discovered in India, *R. Emodi* or *R. australe*), has, like the preceding, been considered to yield the Chinese and Russian rhubarbs; but it would appear that it only produces a kind peculiar to India.

"As to the true plant, a native of Thibet, which furnishes to commerce both the Russian and Chinese rhubarbs, it has only been known since 1867, in which year M. Dabry de Thiersant, consul-general of France at Shanghai, procured from Thibet some stalks of the species which yields this valuable drug, and which, cultivated in the garden of the Faculty of Medicine at Paris and in the Vallée de Montmorency by M. Girandeau, have received from M. H. Baillon the name of *Rheum officinale*. It is a very large species, exceeding a man in height, and remarkable for the considerable development of its inflorescence. The flowers are whitish, having a very deeply concave receptacle, with a marked perigynic insertion of the stamens, which in other respects resemble those of all the genus *Rheum*. The gynæcium is inserted profoundly in the most depressed portion of the receptacular cavity, and the edges of this cavity are furnished with well-developed unequal glands of a beautiful green colour at their summit. The leaves of this species answer perfectly to the indications formerly given by Bokharian and Chinese merchants to Pallas and others concerning the true officinal rhubarb plant, namely, that the leaves have a limb of a delicate green colour, in shape like an open fan, and also as analogous as possible to that of the leaves of the *Ricinus communis*. It is by this that the species is especially distinguished from *R. palmatum*, to which more than any other the origin of this medicament has been referred in recent times, upon the authority of Guibourt. But the leaves of the latter are whitish, unequally trilobed, and more or less pointed at the top. The *R. officinale*, however, belongs to the same botanical section as *R. palmatum*, as well as *R. hybridum* and *R. dentatum*, which are different plants, but have the same nervation. Here the nerves diverge at starting from the base of the limb, they are then palmate, and the two lateral nerves are destitute on the outside, for a certain distance from their base, of all parenchyma. Above this point the base of the parenchyma forms a kind of auricle, which renders the limb markedly cordate at the base. The dimensions of the limb extend to nearly a metre

* 'L'Union Pharmaceutique,' vol. xv., p. 21.

in each direction ; it is however a little broader than it is long, and the petiole is about the same length. In the plants that have been raised, some leaves have been noticed which were more than a metre and a half long. Their edges are unequally divided into triangular lobes a little unequal among themselves, and the nerves, ramified and prominent beneath, are in this species, together with all the surface of the parenchyma, entirely covered with a fine white down. When the plant has become fully developed it has scarcely any roots, for these are gradually destroyed, and the plant draws its nourishment from the soil only by small adventitious roots which could not be employed in medicine. But, contrary to the other species enumerated, and of which the root can be prepared and employed, this developes above ground a stem and cylindro-conical branches, 20 or 30 centimetres high, and of the thickness of an arm or a leg. These are the only portions which, cleansed from the so-called bark, divided transversely and longitudinally, and properly dried and prepared, can be used in medicine. They bear leaves, and after the fall of these, there remains on the surface only the brown dried base of the petioles, together with the remains of the ochrea ; these vestiges together constitute the pretended bark.

"In the axil of each of these aërial leaves there is necessarily a bud. These acquire frequently a considerable development, and are elongated into leafy branches ; such is the cause of the ramification of the aërial portions of this plant. Each of these buds, detached at a suitable season, will in its turn easily take root from its base, and may thus be used to multiply the plant. Since each of these buds sends off a collection of cellular, fibrous and vascular elements, which it directs obliquely across the true fleshy, spongy bark, towards the ligneous axis of the stem, this, as well as the large branches, is permeated by oblique systems having the same structure as the branches. The presence in the true Thibet rhubarb of the stellate spots which are seen in sections, answers, therefore, precisely to the morphological nature of the portion employed as a medicament."

THE ALKALOIDS OF THE CINCHONA BARKS.*

BY O. HESSE.

(*Continued from p.* 672).

There remains now only the cinchonidine of Wittstein to be considered. As Crawford stated that its sulphate was readily soluble in ether, it was hoped that it might have been easily separated from the other sulphates, which are difficultly soluble in ether. But all experiments in that direction remained fruitless, so that I resolved to apply to Professor Wittstein himself, who at my request willingly gave me the small quantity of alkaloid which remained from his experiment. But he was no longer able to provide me with a specimen of the bark. It seemed to me, however, certainly important to obtain the bark also, because it was the one which Howard had asserted contained a special modification of Pasteur's cinchonidine, which he named "paltochine" from *Cinchona Palton*. It was, therefore, with great pleasure that I found my efforts in this direction did not remain without result, for Professor Wiggers sent to me (1) a portion of the bark upon which Wittstein had operated, and (2) specimens of the same bark, which Professor Wittstein had obtained for Professor Wiggers from the house of Ammon and Geith, at Nuremburg. Lastly, I was indebted to Professor Flückiger for a specimen of this bark, which he had himself obtained direct from the above-named firm. The whole of the specimens were completely in accord with each other.

Howard attributed this bark at first to the *Cinchona Palton*, Pav., though he afterwards referred it to another species, which he named *C. rosulenta*, which Weddell reckons as a sub-species of *C. succirubra*. From this species is also derived the Ocaña bark that in recent years has been frequently met with in commerce.

In the above-mentioned bark Wittstein found 3·2 per cent. of alkaloids, which consisted principally of cinchonidine, and were entirely free from quinine and cinchonine. In a letter written from C. Zimmer to Geith, the former stated that this bark contained a new alkaloid, but not any quinine.

According to my analysis of this bark by a method which I know to give exact results, it contains as follows :—

I. *Wittstein's Bark.*—17·1 grams were used, and were found to contain : 0·049 gram of amorphous base, which was not coloured green by chlorine and subsequent treatment with ammonia, and probably was cinchonicine ; also 0·084 gram of cinchonine, and 0·292 gram. of neutral tartrate, dried at 100°, containing 0·232 of alkaloid.

II. *Ammon* and *Geith's Bark*, not quite like the preceding, 20 grams were used : they contained 0·051 gram of amorphous base, probably cinchonicine, 0·438 gram of hydrated tartrate and 0·112 gram of cinchonine.

The percentage yield of these specimens of bark in alkaloid was therefore as follows :—

	Experiment. I.	Experiment. II.
Cinchonine	0.49	0.56
Cinchonidine	1·35	1·72
Amorphous Base (*Cinchonicine*)	0·25	0·25
	2·09	2·53

That these two analyses should not exactly agree is what might be expected ; but it would appear that this bark contains a considerable proportion of cinchonine, which Wittstein allowed to mix with his cinchonidine. The alkaloid obtained as tartrate was exactly identical with the alkaloid obtained from Wittstein's preparation in the following manner. The compound was dissolved in dilute sulphuric acid, the solution, slightly warm, neutralized with ammonia, and then tartrate of potash and soda was added, whereby a copious crystalline precipitate was formed, and only cinchonine was to be found in the mother liquor. The precipitate, well washed with cold water, was decomposed with ammonia, and the alkaloid was then allowed to crystallize from boiling alcohol. It was thus obtained in shining scales and needles, which contained no water of crystallization ; it was lævogyrous, and fused at 202° C. (corrected observation 207° C.).

An analysis was made of this substance, dried at 100° C., which gave :—

I. 0·245 gram. gave 0·173 H_2O. The estimation of the carbon is wanting, as the india-rubber tube between the potash apparatus and the potash tube became defective during the experiment.

II. 0·1446 gram gave 0·412 gram CO_2 and 0·105 gram H_2O :—

	Calculated for $C_{20}H_{24}N_2O$.	Wittstein's formula required.	Found. Wittstein.		Hesse.	
C	77·92	77·14	77·36	77·27	.....	77·69
H	7·79	7·14	7·18	7·29	7·84	8·06

Of the salts of this cinchonidine it was sought to prepare the neutral hydrochlorate, which, according to Crawford, could not be produced. For this purpose an alcoholic solution of the base was exactly neutralized with hydrochloric acid, and the solution cautiously evaporated ; whereupon the salt quickly crystallized out in white needles, but these, after the lapse of a few days, were

* Translated from the 'Vierteljahresschrift für praktische Pharmacie,' vol. xxii., p. 366.

varied by octahedral crystals. The hydrochlorate so obtained was only sparingly soluble in ether.

The chloroplatinum salt, obtained in the usual manner, resembled exactly the ordinary platinochloride of cinchonidine. Dried at 120° C. it gave :—

I. 0·3487 gram 0·0960 Pt.
II. 0·2976 gram 0·0826 Pt.

Calculated as :—

$C_{20}H_{24}N_2O$, $2HCl + PtCl_4$. Pt = 27·40.
$C_{18}H_{20}N_2O$, $2HCl + PtCl_4$. Pt = 28·49.
Experiment I. gave . . . Pt = 27·50.
Experiment II. gave . . . Pt = 27·75.

The neutral tartrate, obtained by decomposing the hydrochlorate with tartrate of potassium and sodium, presented the characters of the ordinary cinchonidine salt.

0·559 gram dried at 120° C. yielded 0·025 gram H_2O= 4·47 per cent. (calculated 4·48 per cent.).

The neutral sulphate also resembles the ordinary cinchonidine sulphate, and, like that, when crystallized from water and not effloresced, contains six molecules of H_2O. Crawfurd spoke of this salt as easily soluble in ether, but my experiments have indicated that it possesses no other characters of solubility than those of the ordinary cinchonidine sulphate.

Lastly, the acetate has to be compared with the ordinary acetate of cinchonidine, and here again no difference can be observed between the two salts.

From these experiments it therefore follows that Wittstein's cinchonidine was a mixture of cinchonine and Pasteur's cinchonidine. The proportion of cinchonine to cinchonidine was probably as 1 : 2 ; whilst in the bark it is nearly 1 : 3.

Next we must examine how it stands with respect to paltochine, which, according to Howard, is contained in Wittstein's cinchona bark, as well as in *C. peruviana*, and which is also produced during the manufacture of cinchonidine. It was conceivable that between cinchonidine and cinchonine a compound should be formed analogous to racemic acid, which under certain conditions would be decomposed, but in others would exhibit peculiar properties.

To obtain some certain information on this point, at first equal quantities, but afterwards the before mentioned proportions of the two alkaloids, cinchonine and cinchonidine, were taken, glycerine was poured over them, and they were then exposed to a temperature of 170° C. Gradually the alkaloids dissolved in the glycerine, without anything worthy of note being observed. After the lapse of an hour the heat was removed, and the cooled mass exhausted with ether ; upon evaporation crystals were deposited, among which the forms of cinchonine and cinchonidine could be clearly distinguished ; consequently no combination had taken place. Similarly, no combination could be detected when equal quantities of both alkaloids were dissolved together in boiling alcohol and neutralized with sulphuric acid. It was noticed, however, that in this latter case the sulphate of cinchonidine dissolved more easily in the solution containing sulphate of cinchonine than in pure water. But when this solution was concentrated it did not deposit a double salt, and both sulphates crystallized at a suitable concentration in the forms peculiar to them. In all cases therefore where the sulphate of cinchonine and the sulphate of cinchonidine occur together in solution, the supposititious alkaloid—*i.e.* a mixture of cinchonine and cinchonidine—will be originated.

According to my experiments the "carthagine," said by Gruner to be discovered in the "China flava dura" or "Carthagena China dura," is also a mixture of alkaloids. I am indebted to Professor Wiggers for the authentic material used in these experiments also. The pseudoquinine of Mengadurque also appears to have been analogous to paltochine.

It now remains to ascertain how the foregoing results, obtained with Wittstein's cinchona bark, can be brought into agreement with those obtained by Henry and Delondre in their investigation of their quinidine.

Delondre and Bouchardat describe the cinchona bark in question under the name "red bark of Mutis," and stated that they had obtained from it 1·2 to 1·4 per cent. of sulphate of quinine. This result agrees satisfactorily with mine, if we substitute "sulphate of cinchonidine" for "sulphate of quinine." Since those chemists did not know of Winckler's discovery of cinchonidine, they consequently represented all the barks which contained cinchonidine as containing quinine instead. For they state explicitly that the red bark was the bark in which Henry and Delondre were so fortunate as to find quinidine. But they meant by this quinidine the quinidine of Pasteur, *i.e.*, conchinine, of which this bark happens not to contain a trace. That those chemists were not operating upon conchinine, but upon quinine mixed with cinchonidine, would also appear from the following.

The quinidine of those chemists forms with acetic acid a well crystallized salt. This property belongs to quinine as well as to cinchonidine, but not to conchinine,* the acetate of which is amorphous, and is deposited as a syrupy mass upon the evaporation of its solution. Further, the quinidine of those chemists gives with hydrochloric acid a salt which sometimes appears in crystals, resembling those of crude boracic acid, and sometimes in needles. These properties recall those of the hydrochlorate of cinchonidine. Also, the sulphate solution gives with iodide of potassium a semi-crystalline precipitate, which after solution in hot water yields upon the cooling of the solution white prisms of hydriodate, which evidently consist only of hydriodate of cinchonidine, since they cannot be those of hydriodate of conchinine, the difference in solubility of the latter in hot and cold water being insignificant.

From alcohol Henry and Delondre obtained crystals with 5·8 per cent. of water of crystallization. Conchinine always crystallizes from alcohol with $2\frac{1}{2}H_2O$, but readily loses $\frac{1}{2}H_2O$ in dry air, the pellucid transparent crystals becoming at the same time milk-white and opaque. But then they always contain 10 per cent. = $2H_2O$, which they give off when heated to 120° C., without being in the least fused. But Henry and Delondre's quinidine fuses together with heat ; it behaves just like a mixture of one part of quinine and two parts of cinchonidine crystallized from alcohol, when quickly heated. Finally it should also be mentioned, that according to Bouchardat and Boudet† the quinidine of Henry and Delondre is lævogyrous, whilst conchinine, as we have seen, rotates a beam of polarized light considerably to the right.

We have also in the quinidine of Henry and Delondre essentially the same alkaloid as that of which Winckler first gave a satisfactory explanation, and of which he believed himself to be the discoverer. Although this alkaloid by usage should retain the name of quinidine, yet I would now protest against it, because it is a name that has been used and would be used sometimes for one and sometimes for another alkaloid.

(*To be continued.*)

THE VARIOUS PREPARATIONS OF KOUMISS AND THEIR USE IN MEDICINE.‡

BY V. A. JAGIELSKI, M.D. BERLIN,

Late Physician in the Prussian Army, etc.

Though authorities may differ on other points of the subject, they all unite in the opinion that chronic diseases, and especially those of a consumptive or emaciating nature, are developed by anti-hygienic influences. Logically, then,

* The acetate of conchinine of Van Hejningen deposited crystals after a long time, which were a mixture of cinchonidine salts.

† *Neues Jahrb. Pharm.*, vol. xxiii., p. 288.

‡ From the *British Medical Journal*, Feb. 21st, 1874.

to combat these diseases, and to cure them, particularly in their early stages, they must be treated with means which will correct or arrest the morbific impulse. Primarily, the atmospheric conditions which surround the patient ought to be suitably chosen; and secondly, but no less urgently, the diet must be so regulated, if possible, as to act the part of both "physic and food." In this relation, the practice of medicine is becoming more and more distinguished, in both its "science and humanity", by the importance which it now gives to dietetic remedies in therapeutics. We have in them facilities for the physiological and chemical treatment of certain obstinate diseases that resist purely remedial agents, and they are real handmaids of the greatest service to the practitioner. Chief of these remedies, and indeed, epitomizing them, is the milk of animals, because in its composition it comprises all the nutritive requirements of the body. Yet, perfect as milk is in all the elements of a facile alimentation, disease has oftentimes so enfeebled the digestive powers, that even it cannot be assimilated in sufficient quantity to maintain healthy life. Fortunately, however, there is a chemical sensitiveness in milk, which predisposes it to such physical and internal changes as will enable it to accomplish the prompt and perfect nutrition of the organism by overcoming the pathological obstacles. We have an example of this in the koumiss of the Tartars, which is fermenting mare's milk. Its magic effects are manifested in the robust constitution and the complexions of the nomadic people of the Russian Asiatic steppes, who during the warmer season live exclusively upon it, to recruit the health and strength which they have lost through the privations and exposures of the previous winter.

That milk will undergo vinous fermentation, and yield a certain quantity of alcohol, is not generally known. Every educated person, however, has heard that the Tartars drink the milk of their mares in a state of fermentation, called koumiss. Samara and Orenburg were the first places which were chosen for a resort of cure in chronic chest diseases. To Dr. Stahlberg belongs the great merit of inducing the Russian Government to assist him in opening the first koumiss institution in Moscow, and afterwards in Tsarskoe Silo, near Petersburg, the milk of mares being used which were expressly imported from the Tartar steppes; and it is from Vienna that we have heard recently of the great success of koumiss, introduced again by Dr. Stahlberg.

The milk of all animals is convertible into koumiss by one and the same method; but, as the several milks differ among themselves in the quantitative relation of their components, so also will there be corresponding variations in the koumiss which is produced from them. Qualitatively, however, the koumiss from different kinds of milk may be considered uniform, as has been shown in my special work on koumiss published in 1870, and in my paper in the *Milk Journal*, April 1871. More immediately in connexion with this paper, however, I present the analytical results of Wanklyn, obtained from cow's milk *medium koumiss*. A quart bottle of this medium or B koumiss* (manufactured in London by E. Chapman and Co.), which holds about 12,000 grains of koumiss, contains as follows:—(It was examined when twelve days old; specific gravity, at 62° F. 10.28.)

Water	10,662	grains.
Alcohol	192	,,
Casein and Albumen	128	,,
Lactose	582	,,
Lactic Acid	130	,,
Fat	36	,,
Ash	90	,,
Carbonic Acid	180	,,
	12,000	

* This analysis is not contained in J. A. Wanklyn's book on *Milk Analysis* published by Trübner and Co., 1874, which gives only "Full" Koumiss tables.

The 90 grains of ash contain, approximately, 60 grains of phosphate of lime and 30 grains of mixed chlorides of sodium and potassium.

The three gradations of koumiss, designated as Nos. 1, 2, and 3, represent the irrepressible changes which it undergoes in time, while fermentation continues in the bottles. In the process of conversion of the milk into koumiss, the following changes take place. By the interaction which is promoted, casein is set free in a highly attenuated molecular condition. The lactose is partially converted into alcohol, carbonic, and lactic acids; and incidentally a bouquet of fragrant volatile products is generated (according to Morfit), which may perhaps be regarded as adjuvant in the remedial effect of the koumiss. The fermentation, once started, will continue, no matter how cold the temperature, or how closely the koumiss may be corked in bottles. Thus, the products arise in time from the minimum in No. 1 to the maximum in No. 3. In passing through these gradations, the koumiss retains all its general properties, but changes some of its specific adaptations, as will be explained directly. In all cases, the koumiss is a milk-like fluid. In its fresh No. 1 state, it is a still liquor, and has an agreeable, sweetly-acidulous taste, recalling sweet almonds. As it approaches the No. 2 gradation, it becomes more acidulous, assumes a sparkling character, and requires to be drawn from the bottle through a special tap. In No. 3, the sweet taste is replaced wholly by the acidulous, which also has sometimes a slight shade of bitterness; and the koumiss not only sparkles, but rushes through the tap in a rich creamy foam. These changes progress so rapidly in warm weather, that the bottles should be kept in a cold cellar, and treated with the same care as champagne wine. The distinctive character of koumiss is that of being the most assimilable of nutriments. Every quart bottle contains, approximately, 970 grains of solid respiratory and plastic food, according to Wanklyn, and each of its elements is in a state to promote digestion of the others by the feeblest stomach.

The original koumiss of the Tartars is made from mare's milk; but, in my judgment, cow's milk is an equally good raw material, if not better; and there is no doubt that this koumiss gives highly successful results in proper cases, as shown here, in Odessa, Warsaw, Cracow, etc. It is not thin, like mare's milk; and besides, it gives a koumiss free from every disagreeable odour and taste. Moreover, cow's milk, by its composition, affords facility for varying the composition and consistence of the koumiss-product according to the indications of particular cases. This is an important consideration, as through its means the chemist is enabled by his proper skill to make full koumiss, pure whey koumiss, medium koumiss, and extra kinds of special composition for special diseases, like diabetic koumiss, etc.

The physical and chemical characteristics of koumiss render it an aid upon which we can rely with great confidence for the treatment of extreme debility and all the phases of impending marasmus. A long and favourable experience justifies me in giving an empathic assurance on this point. Koumiss not only contains a large proportion of lactic acid, which is a prime constituent of the gastric juice, but holds the casein in that state of vitality which gives it the property of metamorphosing itself and the other constituents of the milk into healthy lymph and blood.

The physiological features of the several constituents of koumiss may shortly be specified as follows.

The *lactic acid* activates the digestive powers, diminishes the temperature and the frequency of the pulse, and regulates the mucous secretion. It has an additional specific action in certain diseases, as, for instance, in diabetes.

The *casein*, *albumen*, and *fat*, restore the plastic and heat-giving materials of the body, and act as a chemical inspiration, so to speak, to promote assimilation of its associate constituents.

The *lactose* increases the weight of the body and gives heat.

The *alcohol* produces sleep, diminishes heat, and forms fat.

The *carbonic acid* allays nausea, calms gastric irritation, augments diuresis, increases the energy of the heart's impulse, and diminishes the frequency of the heart's contractions.

As to the more minute acids and fragrant compounds, I prefer not to speak until my experience and observations in regard to them have become more mature.

It will thus be seen that the process of double fermentation in the artificial preparation of cow's koumiss has done nearly all the preliminary work which would fall otherwise on the digestive organs. There is no other derivative of milk or any other substance which can be substituted for it with corresponding advantages, for it may constitute a sole diet, as my own experience has proved, in many cases of chronic dyspepsia, both simple and complicated. Dr. Braczinski of Berlin speaks in his monograph of koumiss from cow's milk as one of the most valuable aids in the medical practice of Warsaw; and Dr. Neugebauer of Warsaw makes a special mention of a case, in his private practice, of a young nobleman, presenting all the symptoms of tabes dorsalis, which was entirely cured in six weeks by treatment with cow's milk koumiss. This confirms my own experience with a mild case of a similar kind. Dr. Küttner, in Dresden, has also reported to me many gratifying results which he has obtained with koumiss in dyspepsia and debility. Dr. With of Brunerhaven writes in strong favour of fresh koumiss for all catarrhal diseases of the stomach, bowels, lungs, and in anæmia. In Dr. Kwasnicki's Polish translation of my treatise on koumiss (1870), there is a note which records Dr. Nowakowski's and Dr. Przystanski's confirmation of my own experience in the use of cow's koumiss. An appendix to the same translation gives the clinical experience of Professor Chalubinski at the University of Medicine in Warsaw, which prompts him to recommend earnestly the use of cow's koumiss in catarrhal disease of the mucous membranes of the gastro-intestinal and respiratory tractus, and in debility from whatever cause. Dr. Edward Charlton, the late Surgeon-Major Ross, and Dr. R. Dawson, have also written to me in praise of koumiss as a valuable dietetic remedy; and Dr. Campbell Morfit, of the U.S.A., found, in his own case, that the British koumiss acts with the most decided benefit in catarrhal diseases and obstinate constipation, and increases weight rapidly. Mr. Ceely of Aylesbury, and many other brethren in this country, share the same opinion as those whose families I had the pleasure of advising. Neftel, Stahlberg, Schnepp, Marra, Weinberg, etc., have contributed largely to the medical literature of this subject, which has in the last few years increased considerably, as I presently count over thirty authors, who all agree on the main points of therapeutical success of koumiss, from whatever milk it may have been prepared. I will not prolong this paper by enumcrating the cases reported in those works, as I shall arrange them in a proper order in the second edition of my treatise on koumiss; but so much I must say, that all these authors confirm the brilliant therapeutical results described so well by the father of koumiss literature, Dr. John Grieve of Edinburgh, late physician to the Russian army, when his paper, written with emphasis and with an undeniable noble feeling throughout, was read by Dr. Black, July 12th, 1784, in Edinburgh, regretting that koumiss should still remain unknown in the most enlightened parts of Europe, although a horde of Tartars, etc., had been using it for some ages past. I only do my duty in paying the greatest possible respect to the memory of Dr. Grieve, because even to-day his correct conceptions, his skilled judgment, his well defined indications, have not found a better and nobler expression on this subject after the lapse of almost a century, and I willingly indorse Virchow's words,—"I have two faults over which I rejoice conscientiously: the one, that I consider the old physicians as 'brave' observers; and, perhaps the still greater one, of believing in their therapeutics."

Passing on to the indications of koumiss, I purposely omit to speak more specially of its physiological effects, which can only be understood by the full knowledge of its separate ingredients, and the operation of each; involving investigations that belong rather to a separate work, including the cumulative effects or sum total of the effects of koumiss.

Full Koumiss (A) is made from cow's milk, preserving the whole of the cheesy matter and as much of the butter or cream as is compatible with digestion and manufacture. It is adapted for cases of great emaciation with weakness of the digestive organs, when little liquid and no solid food can be taken; also for all complaints which are not of a febrile character, the bodily temperature especially not exceeding 100 deg. Fahr.; and for patients who have previously improved under the use of *Medium Koumiss* (B). This is the artificial representant, as nearly as possible, of the mare's milk koumiss, not obtainable in this country; and can be made by mixing ass's milk with cow's milk in the proper proportions, or by adjusting the natural components of cow's milk alone, so as to diminish the casein and butter and augment the lactose and salts, thus making the koumiss more facile of digestion. It is suited to delicate or sensitive stomachs, which revolt against the buttermilk taste of the full or A koumiss, in which the cheesy matter proves too rich; and is also a more sensitive koumiss, of more agreeable taste, so as even to satisfy a very capricious palate. Should there be in some exceptional cases a dislike even to the B koumiss, then I would prescribe, especially for children or ladies, whey or C *Koumiss* No. 2 or 3, mixed with one-third part of fresh milk, warmed, if wanted, at the time of drinking, to be taken at first in small doses frequently during the day (one pint bottle *per diem*), increasing every two days *usque ad libitum* (three or four pints and more per day). Some persons, again, will prefer a little sugar dissolved in a tablespoonful of warm water put first into the tumbler, then the fresh milk, and on this let the koumiss out with all its force to mix thoroughly. A small quantity of champagne wine with it will augment the alcohol in a very pleasant way, if necessary.

The specific gravity of B koumiss varies between 1035 and 1070 in its fresh state, though, by the process of fermentation, it may sink below 1028 in consequence of the lactose breaking up into lactic and carbonic acids and alcohol. It may be used for diseases of the stomach and lungs instead of solid food, especially when the patient frequently asks for an acidulous drink, which in this case will not raise the temperature or irritate the stomach by a too sudden ingestion of solid matter. In this koumiss is also found that, in the second stage of fermentation, the cheesy matter appears in separate layers, which, however, by shaking, can be easily reduced to a homogeneous milky fluid by combining with the serous layers, and the molecular condition is then so uniform that no flakes are noticeable, as in the genuine mare's milk koumiss. I may notice here that cheesy matter in the solid form, separated from the milk by means of rennet, curds, etc., is quite indigestible, even in small quantities, and can only be adopted for food when fermented in the shape of Stilton or Cheshire cheeses, etc., which are prepared, with or without the addition of cream, all over the globe; whereas, in a well fermented koumiss, the cheesy matter appears as a homogeneous, soft mass, which constantly develops bubbles as long as it is moist, and the flakes dissolve on the tongue like snow, with an acidulous and a pleasant sensation. No wonder, then, that it does not give the stomach the slighest trouble in digestion or absorption; and I can safely say that I have never found any other form of cheesy matter, by any course of preparation, that possessed similar properties, although I have made innumerable attempts to produce a soft cheese which would prove digestible in larger quantities, so as to replace

loss of flesh in certain wasting diseases. In my experiments, I found that the dry residue of koumiss, after filtration or evaporation, affords a granular mass of acidulous taste, containing undecomposed lactose, albumen, and salts, which, when made into lozenges with the necessary additions, are so easy of digestion, that a few of my friends consumed nearly a pound of them after dinner—*pour la bonne bouche et digestion!* I would not seem, however, to recommend A koumiss after a hearty meal, though I shall never forget Plymouth, where, after reading my paper on koumiss, a very eminent gentleman contended in sober earnest that, having taken some of Chapman's Full Koumiss in the museum, for the supposed purpose of removing indigestion after a full breakfast that had disagreed with him, instead of feeling better he became worse, as if a "plenus venter digerat libenter" when it becomes still more extended.

I have been often called upon to answer most amusing questions with regard to koumiss, though I must confess I correct with the greatest pleasure the errors committed by others on the subject of milk-fermentation. Many look upon koumiss as a drug-medicine, and think that with one or two bottles, taking a tablespoonful every two hours, a decided effect ought to follow; just as some persons fancied that guano, when first introduced, would make plants grow *ad oculos demonstrandum* (before their own eyes!). I regret that the age of wonders has passed, although there is still a credulous portion of humanity to conjure up wonders in their own imagination. Koumiss is, however, undoubtedly entitled to be regarded as a medicine that "heals to nourish, and, in nourishing, gives strength and weight in the shortest possible time;" which is a truth daily confirmed in proper cases. In any case, this remedy is, at all events, harmless, occasioning no anxiety to the physician, and much more likely to produce the good effects he desires, especially in cases where drug-treatment is apt to fail. I ought to state that I never had the opportunity of procuring a sufficiently large quantity of mare's milk for koumiss, so as to make fair trial of it in practice; and my conclusions as to the comparative merits of mare's and cow's milk koumiss are strictly of a deductive nature, based on the analysis.

FORMULÆ FOR PEPSIN PREPARATIONS.*

BY HENRY BIROTH.

All formulæ for elixirs and other preparations containing pepsin, heretofore published in the various pharmaceutical journals, differ so greatly in regard to doses, as well as the mode of preparing, that the demand for *uniformity* and *simplicity* in these preparations has become quite necessary. Now, for the last two years I have been manufacturing pepsin, and consequently have paid much attention to the different preparations in which pepsin is used. The results are the following formulæ, which I submit to the pharmaceutical profession. They are based upon the dose of the remedies used therein, and their simplicity is evident. Elixirs, etc., can be prepared according to these formulæ instantly, when prescribed or kept on hand, in the smallest quantities; they are elegant, palatable, and may be modified by the physician *ad. lib.*

The dose for children is from a half to one *tea*spoonful; for adults, from a half to one *table*spoonful.

Each teaspoonful contains, in grains—

Pepsin.	Iron.	Bismuth.	Quinine.	Strychnia.
2	1	$\frac{1}{2}$	$\frac{1}{4}$	$\frac{1}{128}$

Each tablespoonful contains, in grains—

Pepsin.	Iron	Bismuth.	Quininc.	Strychnia
8	4	2	1	$\frac{1}{32}$

Syrup of Pepsin.

Powdered Pepsin	256 grains.
Muriatic Acid	1 drachm.
Syrup Orange Flower Water	16 ounces.

Mix.

Wine of Pepsin.

Powdered Pepsin	256 grains.
Muriatic Acid	1 drachm.
Sherry Wine	16 ounces.

Mix.

Elixir of Pepsin.

Powdered Pepsin	256 grains.
Muriatic Acid	1 drachm.
Orange Flower Water	8 ounces.
Bitter Almond Water	2 ounces.
Simple Syrup	2 ounces.
Glycerin	2 ounces.
Deodorized Alcohol	2 ounces.

Mix.

Elixir of Pepsin and Iron.

Elixir of Pepsin	16 ounces.
Citrate of Iron, soluble	128 grains.

Mix.

Liquid Pepsin.

Powdered Pepsin	256 grains.
Muriatic Acid	1 drachm.
Glycerin	6 ounces.
Water	10 ounces.

Mix.

Aromatic Liquid Pepsin.

Powdered Pepsin	256 grains.
Muriatic Acid	1 drachm.
Glycerin	6 ounces.
Orange Flower Water	8 ounces.
Bitter Almond Water	2 ounces.

Mix.

Elixir of Pepsin and Bismuth.

Elixir of Pepsin	16 ounces.
Ammonio-Citrate of Bismuth	64 grains.

Mix.

Elixir of Pepsin and Quinine.

Elixir of Pepsin	16 ounces.
Sulphate of Quinine	32 grains.

Mix.

Elixir of Pepsin, Iron, and Bismuth.

Elixir of Pepsin	16 ounces.
Citrate of Iron, soluble	128 grains.
Ammonio-Citrate of Bismuth	64 grains.

Mix.

Elixir of Pepsin, Iron, and Quinine.

Elixir of Pepsin	16 ounces.
Citrate of Iron, soluble	128 grains.
Sulphate of Quinine	32 grains.

Mix.

Elixir of Pepsin, Iron, Quinine, and Bismuth.

Elixir of Pepsin	16 ounces.
Citrate of Iron, soluble	128 grains.
Ammonio-Citrate Bismuth	64 grains.
Sulphate of Quinine	32 grains.

Mix.

Elixir of Pepsin, Iron, Quinine, Bismuth, and Strychnia.

Elixir of Pepsin, Iron, Quinine, and Bismuth	16 ounces.
Sulphate of Strychnia	1 grain.

Mix.

Remarks.—To obtain a good preparation, pepsin has to be treated with water and acid, allowing it to swell and dissolve; then filter, and add the other ingredients, alcohol last. The salts of iron and bismuth should be perfectly soluble, otherwise a few grains of carbonate of ammonia are to be added when rubbed together.

* From the *Pharmacist* for February.

PREPARATIONS OF INDIAN HEMP.*

The dried leaves of bhang are sometimes smoked alone or mixed with tobacco; but the more common form of taking bhang is to make it up with flour into a cake, or a majún or sweetmeat, which has a green colour. There is also a common method for habitual drinkers of "banghí," viz., of infusing the leaves in cold water in a pestle and mortar, and pouring off the clear liquor through a cloth strainer.

The eating of these sweetmeats by persons unaccustomed to them produces the most violent mania and excitement, and the eyes become red and inflamed.

I recollect, says Baden Powell, at Lahore, a case of attempted suicide by a youth, where it appeared he had purchased sweetmeats which contained bhang, of which he was not aware; he had not even taken bhang before. After a time he became almost frantic, rushing wildly about hither and thither, and at last threw himself into a well, whence he was fortunately rescued; after this, he fell into a kind of heavy sleep or stupor and then recovered. Persons who are accustomed to the excitement of bhang are not usually so violently excited.

The common majún to be met with in the bazaars is often merely sugar, perhaps with ghí, and the bhang without the other ingredients.

The principal forms in which hemp is met with in the markets of the East† are: 1, *haschich;* 2, *bhang;* 3, *gunjah;* 4, *churrus;* 5, a variety of electuaries, pastes, etc., in all of which butter or some other oleaginous matter is the basis of formation.

I. The first, or *haschich*, is the Arabian name given to the dried tops of the plant grown in Upper Egypt, the meaning of the word being "herb," or "*herbe par excellence;*" the tops are gathered some time before the seeds are come to maturity.

II. *Bhang* is an Indian preparation, consisting of the larger leaves and capsules, which, according to Dr. O'Shaughnessy, is the cheapest form used in India, and therefore in common use among the lower orders for smoking, etc.; from it is prepared an intoxicating drink, and it forms a part of the confection called majoon.

III. *Gunjah* is the chief Indian form of the dried plant, and consists of the dried tops of *Cannabis* after flowering and from which the resin of the leaves has not been removed; it is chiefly sold in the Calcutta bazaars for smoking, in bundles two feet long and three inches in diameter; the colour is dusky green, the odour agreeably narcotic, the whole resinous and adhesive to the touch. The specimens I have examined consist of a central stem with branches, round which are aggregated elongated oval masses about 1½ inches long, and closely pressed together by adhesive resinous matter; when steeped in water these masses can be teased out, and are found to consist of the tops of the plant—that is, the flowers, fruit, and smaller leaflets.

IV. *Churrus* is the resinous secretion alone, and is, therefore, the most powerful shape in which hemp may be used; but it is at the same time expensive, and is not met with in Europe, except as a museum specimen. The specimens in Dr. Christison's museum are variously-sized nodulate, round masses, from the size of a pea to that of a walnut, and of greenish black colour. It is collected during the hot season by scraping the leaves and tops. Dr. O'Shaughnessy states that in Central India and Nepal men in leathern dresses brush forcibly through the plants, and the resin which adheres to them is then scraped off. And Dr. McKinnon states, that in Nepal the resin is gathered on the backs of native coolies. Dr. Royle says, "The glandular secretion is collected from the plants on the hills by the natives pressing the upper part of the young plants between the palms of their hands, and scraping off the secretion which adheres."

V. In the preparation of the electuaries, etc., butter is used as the means of separating the active principle, consequently these compounds are very apt to become rancid.

They are thus described by M. Charnac in the "Annuaire de Thérap." for 1846:—1. Preparations mixed with honey or melted sugar. 2. A more active form called *haschich kava-mesk* (musked drug), containing musk, essence of roses and almonds, of pasty consistence, and of the colour of impure honey; the quantity used being about the size of a walnut. 3. Two kinds are found at Smyrna, called Israël, the one a fine powder, the other a roll of firm mastic consistence. 4. A black round kind has great aphrodisiac repute among the Fellahs, but in this case it is found that cantharides is added to increase the effect.

At Cairo the compound from which the various conserves are prepared is thus made. Equal parts of well-sifted haschich, butter, and water are put in a vessel on the fire; after some boiling, the water is dissipated, the residue is twisted in a cloth to isolate the fatty matter, and to this the different spices are added.

Haschich is to the Arabians what opium is to the Turks and Chinese. *Hachach*, signifying in Arabian drunkard, is the epithet applied to those who eat haschich.

The Arabians smoke the powdered plant, free of seeds, which contain fatty, disagreeable-tasted matter, along with tobacco.

VI. Landerer describes a tincture of hemp used at Cairo, called chatsraky, made by infusing in spirit for three weeks, with a gentle heat, the varnish-covered bark sliced from the stems when the plants are in flower.

As the activity of the preparations of hemp depends on the presence of a resinous varnish on the leaves, and consequently, as the most active of these is found to contain the largest quantity of resin, it becomes a matter of great importance to decide upon the proper period for collecting the plant.

M. Gastinell, an apothecary at Cairo in 1849, states that he found the active powers of hemp to depend on a resinous matter which forms on the leaves as the seeds ripen. Again, M. de Charnac observes, that in Egypt the tops of the plants are used at the end of flowering, but before complete maturity of the seeds. And Mr. Jameson, Director of the Botanic Gardens at Saharumpore, makes a like statement in a letter dated 17th August, 1849. As this letter contains an interesting account of hemp in that part of India, it has appeared to me to be well worthy a place in this essay. He says:—

"In Kimaon and Gurhwal *cannabis* is grown in large quantities, partly in order to obtain its resinous secretion, and partly for its bark, from which a strong coarse cloth called *bungila* is manufactured; it forms the dress of the poorer inhabitants, particularly through Gurhwal. It is sown in July and October. From the female plants only the churrus is procured. Towards the beginning or middle of October the seeds begin to form, and when in this unripe state the upper part of the plant is pressed between the palms of the hands, it deposits upon them a yellowish-green secretion, which is scraped off with a blunt knife; this is the well-known churrus. From the male plant bhang and cath are prepared. Bhang is prepared by drying the leaves and other parts of the plants, both male and female, and is thus used:—A small quantity is put into a mortar with a little water and pounded, the refuse water being thrown away; an additional quantity of water is then added, from half a pint to a pint, depending on the strength required, and well mixed; it is then strained through a fine cloth, the residue thrown away, and the liquid is ready for drinking, a wine glassfull or more being taken at a time. Gangah is the thin preparation, and is the produce of the upper portion of the stem, that is about 1½ foot; it is only used in the hookah, to smoke; this also applies to the churrus. The gangah is carefully dried and mixed with an equal

* From the Official Catalogue of the Indian Department at the Vienna Universal Exhibition.

† Derived from a memoir by Alexander Christison, J.B.S.E., "On *Cannabis Indica*, Indian Hemp."

quantity of tobacco, and well rubbed together in the palm of the hand; it is then ready for the hookah. We have thus three preparations:—1, churrus; 2, bhang, or subzi; 3, gangah, or ghangah. The first is only prepared on the hills, and the two latter are common to both hill and plain, but bhang is principally prepared in the latter. At Bhaeit, about 16 miles from Saharumpore, it is prepared in large quantity, and is subject to a heavy duty; yearly from 40,000 to 50,000 maunds are produced (a maund is equal to 80 lbs.) The reason why the churrus is not prepared in the plain is because the plant does not secrete the resinoid principle, showing that its secretion is connected with climate. But still, the plants are identical in external characters, and you will, I think, find that the European and Indian plants are also identical. In order to ascertain the fact, I send you a small packet of hemp seeds procured at one of the Gurhwal villages, where it is grown in vast quantity. In your letter you say that the active principle forms on the stems and leaves; this is not the case, as it is only procured when the seeds are in an unripe state; attempt to procure it before this period, and none will be forthcoming. It will appear strange how ignorant natives can distinguish female from male plants. Were you to see the plant growing, your surprise would soon be removed; the female plant when ready for making churrus has at its upper part a 'bunchy' appearance, whereas the male plants have become by this time mere stems and leaves, the flowers also having fallen off.

"In October, in crossing the Himalayas from Almorah to Missouri, I have passed through dozens of villages 6000 to 8000 feet above the level of the sea, and seen hundreds of men, women, and children, all employed in making churrus. The plant grows to a height of from 10 to 14 feet."

VARIOUS METHODS FOR THE PREPARATION OF BINIODIDE OF MERCURY.*

BY E. B. SHUTTLEWORTH.

In devising or selecting a formula for the preparation of any compound, there are three considerations which are essential to a correct and satisfactory conclusion. These are, that the contemplated product be obtained (*a*) of the best quality; (*b*) at the lowest cost; (*c*) with the least trouble. As a general rule, the relative importance of these conditions is indicated by the order in which they are given; quality is, or should be, the great essential, while cost and convenience are of secondary consequence. Too often, however, this order is reversed, and all considerations are made subordinate to that of cost; but, in no case can this be justifiable; it is only when the matter of quality is satisfactorily settled that we are at liberty to decide in favour of that process which promises to be the most economical. The question of economy is, however, to the pharmacist a most important one, and, in cases of scarcity of material or high prices, merits his best attention.

A case in point is that of the red iodide of mercury—a compound which is almost invariably prepared by the pharmacist. The recent inflation in the price of iodide of potassium, and the high figure which it at present maintains, demand the utmost economy in its use. In view of this it may be opportune to review the various processes which have been devised for the preparation of the biniodide of mercury, so that we may be able to obtain the best results with the least possible expenditure of materials.

The first process which might be noticed is that in which the biniodide is formed by a direct union of the elements composing it. Mercury and iodide are triturated, or agitated together, a little alcohol being added to control the reaction. In inexperienced hands this process yields an imperfect product, is exceedingly wasteful and troublesome, and may be so dismissed.

A better process is that of the British Pharmacopœia:—4 parts of perchloride of mercury, dissolved in 60 parts of boiling water, are mixed with 5 parts of iodide of potassium, in 20 parts of boiling water. The iodide is, theoretically and practically, one-tenth of one part in excess of that actually required for the decomposition. Its object is to prevent contamination of the product with the mercuric salt. This excess appears useless, first, because, with any ordinary care, the operator can ascertain the moment the decomposition is complete; and, again, if any slight excess of mercuric salt happened to be present, it would certainly be removed in the subsequent copious washings to which the biniodide is subjected. This excess is not only wasteful as far as the iodide of potassium is concerned, but of the biniodide also, as the latter salt is soluble in the former. The use of boiling water is unnecessary, as the quantity ordered would, if cold, dissolve the salts readily. The precipitate from a hot solution is more granular than that from one which is cold, and for the preparation of ointments it will be conceded that the finer and softer salt is to be preferred.

In the process of the U. S. Pharmacopœia the excess of iodide is the same as that of the B. P., but cold water is applied for solution.

The most satisfactory and economical results I have obtained from the decomposition of the salts alluded to, have been by employing 4 parts of the mercuric salt, in powder, dissolved in 64 parts of cold water, adding a sufficient quantity of solution of iodide of potassium (4·9 parts in 10 parts of water). The yield will be 6·7 parts of a salt sufficiently dry to be pulverulent. This is very little short of the theoretical yield; 271 parts $HgCl_2$ require for decomposition 332 parts KI, and should produce 454 parts (6·701) HgI_2.

Another method which may be easily and economically pursued is that in which iodide of iron is used instead of iodide of potassium. The relative prices of iodine and iodide of potassium are generally as 21 to 19, and 254 parts iodine are equal to 332 of iodide of potassium. If, therefore, we mix 3·75 parts of iodine with 4 parts of cold water and sufficient iron wire to saturate, allowing the mixture to stand for several hours, heating towards the close of the reaction, we shall obtain a solution of iodide of iron equivalent in iodine strength to the quantity of iodide of potassium required to decompose 4 parts of perchloride of mercury. The yield will be about 6·7 parts, and the quality of the product is equal to that produced in any other way, but the precautions of using the iron solution as soon as possible, and of washing the precipitate as soon as deposited, must be observed; otherwise the product might be contaminated with a basic ferric chloride, which in time is thrown down. It will be seen that this method is as economical as could well be devised; the operator getting the profits of the manufacturer of iodide of potassium, minus the labour of the former in making the iodide of iron.

The last process which we shall notice is that devised by Mr. Williams, described in the *Chicago Pharmacist*. In this, the use of a large quantity of water for the solution of the mercuric salt is obviated by employing a concentrated solution of chloride of ammonium, in which the mercuric salt dissolves readily. Four parts of perchloride of mercury are dissolved in four parts of water to which 2 parts of chloride of ammonium have been added, 5 parts of iodide of potassium are dissolved in 5 parts of water, and the solutions are mixed. It will be seen that, in this way, 9 parts of water suffice for solution, while otherwise, at least 70 would be required. This is a great convenience, especially when large quantities are operated upon; but, according to trials which I have made, the method is not economical, on account of the biniodide being soluble in the solution of chloride of ammonium. By draining the newly formed salt as soon as deposited

* From the *Canadian Pharmaceutical Journal*.

the loss may be rendered smaller than if water were at once added to the mixture; but the product will not exceed 6·150 parts against 6·701, the theoretical yield, or 6·700, the yield by the method with simple water. In large operations, some of this dissolved biniodide may be recovered by evaporating to dryness the drainings and first washings, washing away the deposited chloride of ammonium, and thus leaving the more insoluble biniodide. The operation must be performed quickly, or the biniodide will also dissolve. Williams's method cannot be recommended except where expedition and convenience are considerations paramount to that of cost. The product is of a darker colour and more granular than by other methods, and somewhat resembles that prepared by the old Edinburgh process, in which the compound formed by a direct union of mercury and iodine is dissolved and crystallized from a solution of chloride of sodium.

A word in regard to Williams's method for purifying the green iodide of mercury.* I have lately tried this plan and found it to work very satisfactorily, being equally efficient, quite as convenient, more expeditious, and much more economical than the process with alcohol. The washing may be best performed by repeated agitation and decantation, using fresh solution of chloride of sodium.

DROPS.†

BY HORATIO N. FRAZER.

The importance of accuracy in the compounding and dispensing of medicine can only be measured by its service in the prevention and cure of disease, and since the time when its preparation and use were first regarded and studied as an art, much thought and labour have been expended on devices for making standards by which intelligent aids to the medical profession would be able to dispense and give the medicine with a uniformity tended to convince all parties concerned that the original idea and directions of the physician had been correctly understood and carried out.

The results of these efforts in a practical form have been made apparent by the almost universal use of the pharmacopœias in the different countries where they are published, by the profession for which they are made; the benefit derived from their use making it thought necessary in some countries to enforce it by law, the absence or non-enforcement of which law creates so much confusion at times in the United States.

Notwithstanding these standards have been made and endorsed by the highest authority, approximate measures are very often used by physicians in their prescriptions, sometimes with a want of knowledge which in an apothecary would be called culpable, but more often with a thoughtlessness which oftentimes entails serious consequences. And the use of the word drops is not the least of these.

A drop, as defined by Webster, is "the quantity of fluid which falls in one small spherical mass," or the smallest bulk of liquid which can be conveniently measured. More definitely, it means that portion of a liquid which separates from the bulk of the liquid when its weight overcomes the attraction of its particles to it, and will vary with the fluidity of the liquid, its weight, the amount of solid matter held in solution by it, the temperature at which it is dropped, and the size and shape of the vessel used.

The idea generally meant to be conveyed by the term drop is the bulk of a minim. But from the annexed table it will be seen that it varies from about one-third to nearly twice its measure, and is consequently unreliable for preparing medicine. An instance occurred a short time ago, which came to the knowledge of the writer, where the difference between the size of the drop from the nose of a dispensing bottle and the end of the stopper, made such a difference in the appearance of a prescription that the druggist lost the trade, not only of the patient but of several more on that account.

This is an evil which a druggist cannot avert, for even under the same circumstances, the bulk of no two drops from the same bottle are exactly equal, and the remedy for the evil rests, not with the pharmacist, but with the physician, whose duty it is, and whose interest it willsoon be, to protect him from it.

Below is added a table of the number of drops to a fluid drachm of United States officinal medicines that are usually given in the form of drops, together with some of the unofficinal which are more generally used; it was noticed that the drops from a two or four ounce prescription bottle, were in every case smaller than those from a quart or pint tincture, ranging from ten to twenty more to the fluid drachm:—

† From the *Pharmacist* for February.

The Pharmaceutical Journal.

SATURDAY, FEBRUARY 28, 1874.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square,*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

PUBLIC ANALYSTS.

WHEN we undertook some weeks ago in dealing with this subject to express the opinion that Dr. STEVENSON'S article in the *Practitioner* of last January was in many respects injudicious, and, considering recent occurrences, exceedingly ill-timed, we did so with no desire to be hypercritical, and least of all was it our disposition to bear hardly upon those chemists who occupy the position of official analysts. However, it was impossible to overlook the fact that the work done by these public officers, ostensibly in the interests of the community, has been so repeatedly of a merely "harassing" nature in regard to traders that there is a risk of the application of the Adulteration Act becoming, under existing conditions, a public scandal.

We should very much regret to see such a result brought about in any way, or to find that at the very onset of an attempt to make the skill of chemists generally available for the public good, discredit should be thrown upon such services. But it seems that our friendly admonitions upon this subject have been strangely misconstrued by the Editor of the *Practitioner*, who has been wrathfully excited by our remarks, and has, with Hibernian energy of language, devoted five pages of his journal to denouncing their error and perversity. He commences by the announcement that in doing so he is merely acting under urgent compulsion, though we fail to recognize any foundation for this statement, and think, on the contrary, that he might have improved the character of his journal by publishing something more useful and interesting to his readers than the flimsy rhodomontade he has produced under the heading "Spiritus Etheris (*sic*) Nitrosi."

By an ingenious assumption, the article which is made the subject of this diatribe is termed a "drug," and it is assumed that the writer of the article in the PHARMACEUTICAL JOURNAL was at the time labouring under intoxication "with the success of the accused druggists whom he so warmly supported." This condition is supposed to have prevailed to such an extent that the writer, in "the excitement of his immoderate joy" makes apparent his real hopes and intentions of "driving a coach-and-four" through the Adulteration Acts. Within the short space of the half-page occupied with these introductory flourishes of the editorial shillelah, most of the leading facts of the case referred to are misstated or distorted; but it would probably be superfluous to correct these errors, as our readers are well acquainted with the real circumstances, and we do not hesitate to rely upon their recognizing the fact that the tone of our article was rather that of lamentation than rejoicing.

The Editor of the *Practitioner* wisely abstains from dealing with "the arguments" by which, he asserts, we sought "to throw discredit on the attempts of analysts to pin tradesmen down to a definite standard of purity in the articles they sell," and we greatly commend his discretion in doing so. But he cannot contain himself in regard to the manner in which we speak of Dr. DUPRÉ. Here the pent-up vials of his wrath burst their bonds and flow over, and his readers are informed that this is "not to be tolerated." This gushing declaration, unfortunately involves an impeachment of Dr. DUPRÉ, not only as regards the propriety of his conduct as a public analyst, but also as regards his veracity. We are aware Dr. DUPRÉ has been suspected, and in some instances accused, of having himself instigated the prosecutions in regard to *Spiritus ætheris nitrosi*. It has also been considered that if such were the case he very gravely exceeded his legitimate functions, and we are disposed to concur with this opinion, inasmuch as we hold that the public analyst should retain a fully independent position, by restricting himself to the establishment of facts alone, without laying himself open to the imputation of "hobby riding." In our comments upon the Westminster case we incidentally expressed this opinion, though we felt bound to accept Dr. DUPRÉ'S repeated distinct declarations that he had nothing to do with those proceedings being taken. The Editor of the *Practitioner*, however, represents Dr. DUPRÉ as having instigated the prosecution, and then quarrels with us for condemning the false position in which he placed himself. Confusion worse than this it is impossible to imagine, and Dr. DUPRÉ may well say, "Save me from my friends."

In the same incoherent vein it is asserted that the view of the facts of the prosecution on which we are told this Journal "presumes to lecture Dr. DUPRÉ" is demonstrably incorrect, and after some study of the subject the *Practitioner* proceeds to denounce certain fallacies assumed to have been adopted by Mr. ARNOLD and ourselves. First, that the article was not a "medicinal but only a popular preparation." This fallacy, however, is neither ours nor Mr. ARNOLD'S, but only a creation of the *Practitioner's* fancy.

Then it is asserted that it is not true Dr. DUPRÉ'S inspectors asked for and purchased "sweet spirits of nitre." Whether it be so or not, we cannot say, but if any one cares to refer to the evidence of Mr. ROGERS, the inspector, they will see that, while the summons was for selling spirits of nitrous ether, he distinctly states he asked for "four ounces of sweet spirits of nitre." Our view of this is that the whole proceeding was a muddle.

The next fallacy of which we are accused is the

proposition that nitrous ether is cheaper than alcohol. Here again the fancy of our contemporary has been at work. We certainly have not furnished any ground for this charge. Again, we are accused of adopting as a third fallacy, the opinion that the preparation of the Pharmacopœia cannot be made of uniform strength, or kept unaltered. To those who are readers of this Journal, it is needless to offer any refutation of such a statement; but we may just mention in proof of its want of foundation, that the very same journal in which appears the article that has so profoundly moved the Editor of the *Practitioner*, there is a report of a discussion on this subject, in the course of which it was clearly shown, as on many previous occasions, that spiritus ætheris nitrosi can be made of uniform strength according to the process of the British Pharmacopœia.

It was therefore unnecessary to bring forward any analytical evidence of Dr. DUPRÉ'S to demonstrate this fact, or to disprove an imaginary statement to the contrary. But the table of analytical results which our contemporary publishes introduces a new feature of bewilderment. We reproduce the details of these analyses, in order that we may not be supposed to misrepresent them.

	No. 1.	No. 2.	No. 3.
Specific gravity . . .	·824	·836	·839
Corresponding alcoholic strength	89·5 p.c.	84·8 p.c.	83·6 p.c.
Real nitrous ether . .	1·35	2	1·98
Free volatile acid, as acetic acid	1·19	none	·9
Free fixed acid . . .	trace	none	none.

The analysis No. 2 refers to a sample prepared by Dr. DUPRÉ according to the pharmacopœial process in February, 1872. The analysis No. 3 represents the condition of this sample in November, 1873. The analysis No. 1 represents a sample purchased by Dr. DUPRÉ of a "very famous wholesale establishment," and labelled "Spiritus Ætheris Nitrosi, Brit. Pharm." This latter sample, it is stated, was seriously deficient in nitrous ether, and otherwise obviously impure and carelessly made.

Without dwelling on the fact that in these analyses there is no very great difference in the amounts given of "real nitrous ether," we may at least point out that the preparation described as having been made by Dr. DUPRÉ is, according to the data given, very unlike what it should be according to the Pharmacopœia. This is the more remarkable, since Dr. DUPRÉ adopts a method of analysis which is represented as indicating the true amount of nitrous ether. This method was described by him at the trial, though with somewhat unaccountable reluctance. The only interpretation we can put upon the fact that the analysis above quoted gives 2 per cent. instead of 10 per cent. as the amount of real nitrous ether in the Pharmacopœia preparation is that the Editor of the *Practitioner* has got into a fog and misrepresented Dr. DUPRÉ.

We are glad, however, to find it possible to agree with our contemporary in something, and we cordially concur with him in the opinion that the Westminster Board of Works was feebly represented on the occasion in question. We would also suggest that they were equally ill-advised, and that in future attempts to do public service in repressing adulteration, one essential requisite for attaining success will be the possession of some real acquaintance with the circumstances of any case they take in hand. To avoid miserable failure, waste of time, and persecution of unoffending tradesmen, such knowledge is essential, and without it it is only by chance that those engaged in conducting a prosecution can escape being made to appear ridiculous.

The Editor of the *Practitioner* further takes us to task for venturing to throw doubt on Dr. STEVENSON'S allegation that "shameful" irregularity exists in the strength of citrate of iron and quinine as sold in the shops; but again this instance of our "presumption" is imaginary. We refer him to what we really did say on this subject, and we also advise him to obtain information as to the conditions which mainly determine the manufacture of inferior qualities of this and other pharmaceutical preparations. If he succeeds in obtaining this, and will publish it in his journal, he may, perhaps, contribute towards the abolition of the practice somewhat more effectually than by indulging in sensational declamation.

THE PARIS SCHOOL OF PHARMACY.

During a recent discussion on the French budget M. P. BERT asked for a first annual grant of 400,000 francs to be expended in reconstructing the "École Supérieure de Pharmacie" at Paris. The reasons which he urged in favour of the grant were that the present establishment was without sufficient collections, without laboratory, and without *matériel*. He said that there were five hundred pupils paying 100 francs per year for the laboratories, although the school was only organized for 200; consequently there were many for whom room could not be made in the laboratories, and these pupils were prevented from passing their examinations. Moreover, the foundations had become unsafe, and there was a danger that at any moment the whole building might fall into ruins. The motion was eventually withdrawn on the understanding that the Government intended to ask next year for a considerable sum of money to be applied to the national scientific establishments. It transpired in the course of the discussion that the city of Paris is the proprietor of the School of Medicine in Paris, whilst the state is the proprietor of the School of Pharmacy.

COCCULUS INDICUS.

WE notice that the *Lancet*, in referring to a recent question in our Notes and Queries' column, as to whether there is any legitimate use for the *Cocculus Indicus* imported into this country, replies—"We say certainly not; and have no hesitation in affirming

that a very large proportion of it is put into malt liquor, to give it strength and headiness." As considerable diversity of opinion exists upon this subject we think our contemporary would be doing a public service in publishing the evidence it doubtless possesses upon which such a statement is made. We would also take the liberty of suggesting that it would be as well to give at the same time the correct authority for the insertion of the word "largely" in the statement that "grains of paradise, liquorice and sugar are largely used as adulterants" of beer, which is at present referred to the report of the Superintendent of the Inland Revenue Laboratory. We have understood that report to say that adulteration was detected in only six samples of beer, or of materials used in brewing beer, during 1872, from all the breweries in the United Kingdom. It should also be remembered that sugar can be used in any quantity in brewing beer, provided the quantity used is entered on what is termed "The Brewers' Entry Paper." It is then charged with duty equivalent to the malt duty. It is only when not so entered that its use is considered by the revenue authorities as an adulteration, or rather as a fraud on the revenue.

ECHOES OF THE PAST.

Although we have no wish to disinter a disagreeable subject that has now slept in peace for some time, a paragraph quoted in the *Bulletin* of the Bordeaux Society of Pharmacy from the *Tribune Médicale*, under the title "The duties of a pharmacist interpreted by an English jury," is at once so racy and true that we reproduce it without further comment :—

"Dr. L. was called to attend an "*alcoolique*," attacked by *delirium tremens*.

"He prescribed half an ounce of tincture of digitalis in an equal quantity of distilled water.

"Mr. Fisher, the pharmacist, refused to execute the prescription.

"Whilst the physician protested and the pharmacist resisted, the patient died.

"An inquest was held; opinions were divided. The affair was laid before the jury, who declared—

"(1) That death was the result of natural causes, accelerated by the abuse of drink.

"(2) That the pharmacist, Mr. Fisher, was wrong in not executing the prescription of Dr. L.

"Meanwhile the therapeutists continue to argue.

"We have asked ourselves how the English jury would have decided the contention in the case where, Mr. Fisher having executed the prescription, it had been proved that the patient had died poisoned.

"It is probable that the verdict would have been drawn up in the following terms :—

"(1) Mr. X. is dead naturally.

"(2) Drink has assisted him to die.

"(3) Tincture of digitalis has done the rest.

"(4) Mr. X. is therefore dead according to rules.

"(5) Nevertheless, Mr. Fisher was wrong in executing the prescription of Dr. L.

"Rabelais said, 'The practice of medicine is a farce played with three characters, the physician, the patient, and the disease.' Is there not here an opportunity of adding, 'And played sometimes with a fourth, the jury, which is certainly not the least amusing of the four?'"

INTRODUCTION OF TEA.

We have been favoured with a communication from Mr. Daniel Hanbury, in which he states that having recently had occasion to search some old newspapers in the British Museum, he observed the following advertisement in the *Mercurius Politicus*, No. 435, September 23rd to 30th, 1658. Though it is probably well known to antiquaries, it may be interesting to some of our readers :—

"That Excellent, and by all Physitians approved, *China* "Drink, called by the *Chineans*, *Tcha*, by other Nations "*Tay alias Tee*, is sold at the *Sultaness-head*, a *Cophee-* "*house* in *Sweetings* Rents by the Royal Exchange, "*London*."

POISONING BY MISTLETOE BERRIES.

In the *British Medical Journal* for February 21, Dr. J. Dixon, of Whitehaven, publishes a case of a boy who exhibited severe symptoms of poisoning after eating mistletoe berries. The patient was fourteen years of age, and was found lying in the street in a state of insensibility, within forty minutes of the time of eating the berries. The first impression was that he was in a state of alcoholic intoxication, but no trace of alcohol was found in the breath or subsequent vomit. An emetic of sulphate of zinc was administered, which brought off eight partly masticated berries. There were indications of considerable cerebral hyperæmia, which was appropriately treated, and the boy was well the next morning. He stated that soon after eating the berries he began to feel giddy, and from that time had no recollection of what transpired.

According to the *Bulletin Thérapeutique*, an attempt made by a Paris merchant to utilise the sewage of that city in the cultivation of lâbiate plants in the plain of Gennevilliers has been so successful that at the present time three hectares of land are devoted to the raising of peppermint alone. The plant is said to grow with such vigour that three collections are made in each year, whilst the essential oil obtained from it by distillation is asserted to be superior in delicacy of aroma and flavour to that imported from England. So satisfied are the directors of the Pharmacie Centrale with the results, that they express their readiness, should any pharmacien be sufficiently enterprising to extend the experiment to the neighbourhood of the manufactory at St. Denis, to undertake to use all the products.

An Evening Meeting of the Pharmaceutical Society will be held on Wednesday next, when the following papers will be read :—"Note on the Decomposition of a Lozenge," by Mr. T. Greenish; and the "Chemistry of Ngai Camphor," by Mr. Sydney Plowman, Senior Bell Scholar in the Society's Laboratories.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON,

February 18th, 19th, and 20th, 1874.

Present—Messrs. Allchin, Barnes, Benger, Bottle, Carteighe, Corder, Cracknell, Davenport, Gale, Linford, Martindale, Schweitzer, Taylor, and Umney.

Dr. Greenhow was present on the 18th, on behalf of the Privy Council.

MAJOR EXAMINATION.

Four candidates presented themselves and passed, and were declared qualified to be registered as Pharmaceutical Chemists :—

Pank, Philip Durrell .....North Walsham.
Cooke, William Kendle .....Brighton.
Savage, John Welch.....Wells.
Roach, Herbert William ... .London.

MINOR EXAMINATION.

Seventy-nine candidates were examined. *Forty-five* failed. The following *thirty-four* passed, and were declared duly qualified to be registered as Chemists and Druggists :—

*Knights, James West.....St. Ives.
*White, William Thomas .....London.
Bettle, Joseph Alfred .....Bedford.
Equal. Harding, Edward .....Greenheys.
Equal. Smith, Thomas James .....Spalding.
Knight, Alfred George.....Swansea.
Equal. Brooks, Charles Theodosius.....London.
Equal. Jesser, Alfred Henry .....Southampton.
Equal. Peat, Joseph .....Workington.
Scobie, James .....Perth.
Kirby, Thomas William .....Liverpool.
Equal. Equal. Baker, John Hopper.....Bristol.
Equal. Equal. Green, Alfred .....Wakefield.
Equal. Cox, Joseph Bethell .....Lynn.
Equal. Gardiner, William Eustace .....London.
Whitney, William John .....London.
Wardley, Samuel Frederick.....Lowestoft.
Equal. Cross, John .....Northampton.
Equal. Davies, Thomas.....Liverpool.
Wrack, Frederick George.....Lincoln.
Cardwell, Ernest .....Lytham.
Equal. Equal. Holgate, Sam Verity .....York.
Equal. Equal. Martin, John Wesley .....Stratford.
Equal. Agger, Joseph Edward .....King's Lynn.
Equal. Budworth, William Seth.....Bolton.
Equal. Jones, Evan Jones .....Lampeter.
Parminter, Urban.....Exeter.
Thomas, Archibald .....Northampton.
Turner, George Thomas ....London.
Equal. Dampney, Richard Shephard ...Chard.
Equal. Heath, Frederick Devon .....High Wycombe.
Robinson, Thomas Ward.....Hull.
Equal. Evans, Evan Thomas .....Carmarthen.
Equal. Gibson, James .....North Shields.

The above names are arranged in order of merit.

PRELIMINARY EXAMINATION.

Certificates were received in lieu of the Society's Examination, as follows :—

Certificates of the University of Cambridge.

Hardwick, Arthur.....Sheffield.
Piper, Walter George .....Norwich.
Poulton, Arthur.....Newton Abbot.
Robinson, Alfred Edward.....Birmingham.

Certificates of the Royal College of Surgeons.

Gallienne, William J. Norman...Torquay.
Munro, Hugh .....Hampton Wick.

Certificate of the Society of Apothecaries.

Thorpe, Henry Stanley .....Hertford.

Certificate of the College of Preceptors.

Burford, George Henry .....Ipswich.

* Passed with Honours.

ERRATA.

On p. 619, col. 1, Mr. Cracknell's name should have appeared in the list of Examiners present on the 23rd of January.

On p. 637, col. 2, line 9 from top, the name of John Taylor should have been inserted in the list of "Associates in business" as of Torquay, instead of in that of "Associates" as of Carlisle.

Provincial Transactions.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

SESSION 1873-4.

The fifth general meeting was held in Anderson's University, on Wednesday, 18th February, at 9 p.m.; Mr. John Currie, president, in the chair.

The minutes of the previous meeting having been confirmed, the Secretary (Mr. J. A. Clarke) made a short statement in connection with the late festival, in which he said that owing to the illness of the Treasurer an exact financial account could not be given.

An apology for absence from Mr. Kinninmont was then read, after which Mr. John Hunter proposed a motion to the effect—"That the members of this Association should subscribe 1*s*. each towards raising a fund for the purchase of a microscope for the use of the members of the Association, and that the Pharmaceutical Society should be applied to for a grant of £5 towards the same object."

Several members spoke in connection with the motion, all disapproving of asking from the Pharmaceutical Society so small a sum as £5, and it was suggested that the money should be obtained rather by each member subscribing a little more than was stated in the motion.

The Chairman thought that a subscription ought to be started for a library, as well as for a microscope, and he asked Mr. Hunter if he would embody that in his motion.

Mr. Hunter then withdrew his motion, substituting the following :—"That a committee be formed for the purpose of canvassing the various districts of the city, for subscriptions for the purchase of a microscope, and also for the foundation of a library."

This motion was seconded, and agreed to.

A paper being passed round, subscriptions to the amount of £5 were promised, although the number of members present was small.

Members of committee were then appointed. The Chairman gave notice that at the next meeting of the Assistants' Branch a paper would be read by Mr. Bray.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, 19th February, 1874. Professor Odling, F.R.S., President, in the chair. The ordinary business of the society being completed, the President called on Mr. James Bell, of the Laboratory, Somerset House, to deliver his lecture "On the Detection and Estimation of Adulteration in Articles of Food and Drink."

The Lecturer, after some preliminary remarks on the fiscal regulations with regard to adulteration, began with a description of the microscopic appearance of the various kinds of starch, as many of them, from their cheapness, are largely employed for the purposes of adulteration. He then considered the characters of pure coffee, and of the various substances used to adulterate it, pointing out the most convenient methods for their detection. Tea,

pepper, and mustard were afterwards treated of in the same way. Owing to want of time, Mr. Bell was unable to complete his lecture, so that the adulteration of cocoa, tobacco, and beer was not touched upon. This admirable and instructive lecture was copiously illustrated by the most beautifully executed drawings of the structure of the various substances, as exhibited under the microscope. After the lecture many of the Fellows availed themselves of the opportunity afforded them of looking over the extensive collection of microscopic preparations connected with the subject. We hope to be able to publish a fuller abstract of this lecture next week.

The meeting was finally adjourned until Thursday, March 5, when the following papers will be read—"On the Condition of the Spontaneous Inflammability of Charcoal," by Mr. A. F. Hargreaves. "Researches on the Action of the Copper Zinc Couple on Organic Bodies: Part IV., On Ethyl Bromide; Part V., On the Bromides of the Olefines," by Dr. J. H. Gladstone and Mr. A. Tribe. "Action of Benzyl Chloride on Camphor: Part II.," by Dr. D. Tommasi. "Action of Trichloracetyl Chloride on Urea," by Dr. D. Tommasi and Mr. R. Meldola. "On Sulphocyanide of Ammonium and Sulphocyanogen," by Dr. T. L. Phipson. "On the Action of Hydrogen on Finely Divided Metals," by Mr. A. Tribe.

Parliamentary and Law Proceedings.

Prosecution under the Pharmacy Act.

On Tuesday, February 17, at the Gainsborough Police Court, Mr. Marwood Sanderson, chemist and druggist, of Lofthouse, was summoned by Superintendent Prest for having sold a preparation of strychnine to one Louise Dixon, on the 29th December, without having duly recorded the same.

Mr. Buchanan, coroner, said that on the 31st December last he held an inquest at Lofthouse on the body of one Louise Dixon. Evidence was given to show that death had been caused by poisoning from strychnine. A paper was found in deceased's room, bearing a label, "Sanderson's vermin destroyer," or something of that sort. This afforded a clue as to the source whence the poison had been procured, and he himself called at defendant's shop, where the assistant said that Louise Dixon went to the shop, asking if they kept any vermin killer. He told her that they did, at the same time telling her that it was a dangerous poison. She said that it was required for some rats which came from an adjoining stable, and he then sold her the preparation. The assistant said it was customary to keep a record of the sales of poison, but the deceased woman went out of the shop before he had an opportunity of getting the poisons book duly filled up.

Defendant's assistant deposed to the accuracy of the coroner's statement, and Mr. Betell, analytical chemist of Middlesbrough, said that he found the powder contained about 15 per cent of strychnine.

In answer to the case, defendant said he was sorry he had not been at home himself, because when he had any doubt about the intentions of people who wanted poisons, he always mixed up some spurious or harmless compound, and labelled it as the genuine article.

The Bench imposed a penalty of £5 and costs.—*Middlesborough Daily Gazette.*

The Charge of Poisoning by Morphia at Carlisle.

At the Carlisle Assizes, on Friday, February 20, before Mr. Justice Denman, Dr. Alexander Charles McLeod was charged with the manslaughter of his wife, Annie McLeod, on the 15th of October last.

Mr. Thurlow and Mr. Fenwick appeared for the prosecution; Mr. Charles Russell, Q.C. and Mr. J. H. Fawcett defended the prisoner.

Mr. Thurlow briefly stated the case to the jury. He said the prisoner at the bar was charged with the manslaughter of his wife under very peculiar and most distressing circumstances. It appeared that he had formerly been a surgeon in the Madras Army, and had been in India for 20 or 30 years. Having left India, he and his wife had come to reside in Carlisle a year or two ago, where they appeared to be strangers. He was a surgeon of long standing and experience, and one would imagine he ought to have understood all ordinary matters with respect to the administration of medicine. The charge against the prisoner was that he so negligently—indeed, with criminal negligence—administered to his wife a poison called morphia, on the 15th October, that she died from the effects of it. Some short time previous to the 15th October, it appeared the deceased woman and the prisoner had the misfortune to have one of their children ill of typhoid fever, and owing to having nursed the child in its illness, Mrs. McLeod was in a weak and bad state of health, and for some days previous to the above date, she appears to have obtained no sleep whatever. In the middle of that day Mrs. McLeod appears to have been very ill indeed, and the prisoner determined on getting something to make her sleep. He therefore went to the shop of a chemist named Todd, and bought 20 grains of morphia. The general opinion, he believed, amongst medical men was that one-half, one-quarter, or one-sixth of a grain of this medicine was quite sufficient to give to a patient at first; it depended to a large extent whether a person had been addicted to taking it, for if so, then it could be given in much larger quantities; but he was unable to lay before them whether the deceased woman was in the habit of taking this morphia; that might be thrown out by the two learned gentlemen who defended the prisoner. The prisoner went to the chemist and bought this morphia, for which he paid 8*d.*, taking a bottle with an old label upon it endorsed, "muriate of morphia," and that bottle would be produced, so that the jury would see that it could hold 20 grains of morphia quite easily when shaken down. This was about four o'clock in the afternoon, and he appears to have gone home, but instead of giving the deceased one-sixth or one-eighth of a grain he had given her a grain, and to have repeated increasing doses every half-hour, up till near seven o'clock, when it was supposed he must have given his wife about 16 grains of the morphia; and it appeared he had even administered it to her without weighing it, the consequences being that she shortly afterwards became so ill that she eventually died. The learned counsel proceeded to blame the prisoner for not having called in medical assistance to his wife earlier, and said that, being in the midst of so many distinguished medical men, he was very much in fault. After referring to the treatment administered by Drs. Walker and McLaren when called in to see the deceased, Mr. Thurlow concluded by reminding the jury that if they were of opinion that the prisoner had administered this morphia to the deceased heedlessly, negligently, and criminally, thereby causing death, then it would be for them to find a verdict of manslaughter; if, on the other hand, they thought it had been accidentally administered, then it would be their duty to acquit him.

Evidence having been given by the servants in support of the opening statement,

William Rushton deposed that he was assistant with Mr. Joe Todd, druggist. Dr. McLeod came to the shop on the 14th or 15th of October last. He asked for 20 grains of muriate of morphia. Witness supplied him and weighed it carefully. (Identified the bottle.) Wished to replace the old label on the bottle with a new one, but defendant objected, as the bottle belonged to a medicine chest, Witness charged him 8*d.* for it. Had no doubt it was 20 grains.

By the Judge: Would not have sold that quantity to any one not a medical man.

Cross-examined: Dr. McLeod had previously got morphia in the form of a paste. At the Coroner's inquest,

when the bottle was produced with the residue, witness said he thought there would be ten or twelve grains left. The bottle was then more than half full. Dr. McLaren interrupted by saying it was not so much. Had no entry of the sale in his book.

Dr. Robert Walker deposed that about seven o'clock in the evening of the 15th of October, Dr. McLeod called at his house, and said his wife was very ill and he was afraid she had taken too much morphia, and he asked him to go and see her. On the way, he told him his wife had been attending upon a sick child, that she had had very little sleep for about a week, that he had given her some morphia to make her sleep, but he did not know how much. He said he had given her one grain at first, and after that a dose every half-hour in unknown quantities; he guessed the doses. The first dose, he said, he gave her about half-past four. He said she did not go to sleep till after the last dose. He seemed in a very excited state. Mrs. McLeod was lying on the hearthrug in the drawing room, with a blanket round her. She was insensible—in a state of coma. Her breathing was difficult; her pupils were contracted; she was livid on the face. Witness tried to rouse her by shaking her, but failing to do so, went for a stomach-pump, and injected hot water. The fluid which came out was of the colour of port wine. Dr. McLeod said he had given the morphia in port wine. Was away scarcely five minutes in going for the stomach-pump. On his returning, found her in the lobby rolled in a blanket. He again tried to rouse her, and did all he could by applying mustard plasters to her legs and ammonia to her nostrils, but failed.

By His Lordship: Dr. McLeod helped him.

Cross-examined: About 8 o'clock he sent for Dr. McLaren, who gave her an injection of atropine, which is an antidote to morphia. He was with her till about 10 o'clock, when she died. In his opinion the deceased died from the effects of morphia. He made a *post mortem* examination along with Dr. McLaren.

By his Lordship: The *post mortem* alone would not have been conclusive. It indicated she had died by some opiate. There was no apoplexy. The *post mortem* appearances were consistent with death from morphia; otherwise no other cause apparent. All the organs were healthy. Morphia was a very ticklish drug, and had to be administered very carefully.

The Judge: Is it not a fact that sometimes a person in a state of disease will stand more deadly poison than a person in health?

Dr. Walker: That is so.

Mr. Thurlow: What dose will produce death.

Dr. Walker: One grain has produced death.

The Judge: Do you know that of your own knowledge, or from reading?

Dr. Walker: From reading.

The Judge: Yes, but have you not read of a much larger quantity not proving fatal?

Dr. Walker: I have heard of 20 grains not proving fatal.

Dr. Walker, in answer to questions from the Bench, said he thought it was a case for the administration of morphia; he thought one grain was too much to begin with, and that to repeat the dose every half hour was too frequent. This was a matter of judgment, and in his judgment it would be wrong to do so.

Cross-examined: Dr. McLeod did all he could to assist in attending upon his wife, and was perfectly candid in speaking of what he had done. In conversation, he did not seem conscious that he had made an error. Witness knew he had been in the profession 33 years, principally with the army in the East, where morphia is very considerably used. There is a complaint which has all the symptoms of of delirium tremens but is not produced by drunkenness; the principle characteristic being insomnia. He had heard of cases where persons, without being guilty of intemperance, had, in fact, delirium tremens. In such cases the first thing is to produce sleep, and if the ordinary means failed, medicine should be used—morphia, chloral, bromide of potassium, digitalis, and other preparations. Morphia is supposed to affect the patient rather rapidly, but the rapidity would depend in some degree upon whether the patient had had solid food or not. There is an opinion that the effect of doses of morphia is not cumulative—that, operating quickly, its effects pass off rapidly. Witness did not quite subscribe to that opinion, but it is an opinion of some. He had heard of as many as forty grains being taken in a day with impunity. He had heard of a patient taking as many as 22 grains of acetate of morphia, which has the same relative strength.

Mr. Russell: Have you not heard of 180 grains being given in a day?

The Judge: That is an extreme case, and will not help you at all.

By the Judge: I have heard that morphia administered in a hot country like India passes off more rapidly than in a cold climate like ours.

Dr. McLaren deposed that he was sent for by Dr. Walker at 20 minutes to 9. He confirmed Dr. Walker's evidence, and the results of the *post mortem*. He was of opinion that death was caused by some preparation of opium. Soon after he went in, prisoner gave him a bottle with a little morphia in it—less than three grains. The bottle was about a fourth full. At the coroner's request, he tested the capacity of the bottle; 20 grains, loosely put in, filled it, but by shaking it could be reduced to half that bulk. When Dr. McLeod showed him the bottle he told him he had given his wife the whole of ten grains except what was left there; that he had first given her a weighed grain about four o'clock, and that afterwards he had given her larger doses which he had guessed from the first dose, and he said he should have gone on giving it until it produced an effect. Witness asked him if Mrs. McLeod was in the habit of taking morphia, and he said "No." In witness's judgment Dr. McLeod's treatment was not proper. The doses were excessive. Morphia generally takes effect in twenty minutes to half an hour. Within certain limits morphia is cumulative. It passes much more rapidly out of the system than a mineral poison. A second dose given after the first has taken effect increases the effect of the first dose. The effect has been delayed in some instances as long as six hours; and in giving a second dose in such cases it should be a smaller dose, except in a case of great urgency.

This was the case for the prosecution, and Mr. Thurlow summed-up his evidence, which, he argued, substantiated his contention that the prisoner had shown gross and criminal negligence and carelessness in the case. The only controverted point was the quantity of morphia in the bottle, but he contended there was sufficient proof that it contained 20 grains, and as only three grains were left, Dr. McLeod must have given her 17 grains.

His Lordship intimated that there were two cases in 'Russell on Crimes' in which the law laid down applied to the present case. The law in those cases was expounded by Chief Baron Pollock and Chief Justice Cockburn; the gist of which was compressed into this question by the Judge: Taking all the circumstances into account, was the prisoner guilty of such gross negligence as to make him criminally answerable?

Mr. Russell next proceeded to address the jury for the defence. After referring to the painful circumstances of the case he spoke of the prisoner's long service and medical experience in India, where, he urged, the use of morphia was more widely known. He quoted from an analogous case in which Lord Ellenborough had said that it would be a case of manslaughter where death resulted from the grossest ignorance or the most criminal conduct. He also quoted a case where a druggist, having two bottles before him, put the ingredients into the wrong bottles, which resulted in the death of one of the parties who partook of the contents of the bottle; with reference to this case Chief Justice Earle had said that they ought not

to call upon the prisoner for his defence, and that they could not convict unless there was such a negligence as the law meant by the word felonious. The learned counsel contended that had the deceased been any other lady than his wife to whom he had administered the morphia, there might have been an action in the civil court. Then with regard to the amount of morphia contained in the bottle, he contended that it had never been clearly proved that there were more than ten grains in the bottle. He next proceeded to speak of the effect which morphia had upon the human system compared with other poisons; and concluded his address to the jury by impressing upon their minds that it was to afford ease to his wife and restore her to health which prompted him to administer to her the morphia.

Dr. Robertson, physician for more than 25 years at Nottingham, said some eight years ago he gave his practice into charge of Dr. McLeod, and in his opinion he was a most careful practitioner.

This was all the evidence for the defence, and

The Judge then proceeded to sum up. He said that the law was that whether a man be a medical man or not, if he dealt with dangerous medicines he was bound to bring to the use of them proper skill, and he was bound also to use proper care and attention, so that no person should be injured by his want of skill or attention in dealing with dangerous ingredients. He further considered it made no difference whether he was dealing with a patient, or acting as a volunteer medical man dealing with a friend, or even with his wife. But he would admit that there might be cases where the circumstance that a man was dealing with those most dear to him would be an element in considering whether he exercised his best judgment and did his very best in the conduct of the case. As to the present case he would assume that there was ample evidence that the death of Mrs. McLeod was caused by an administration of morphia; but still, if any of them had grave doubts upon that point they must give the prisoner the benefit of such a doubt. Assuming that morphia had brought about death, the Judge proceeded to speak of the properties of the drug, which he pointed out was extremely variable in its effects, and while it produced one effect upon one person it produced a very different effect upon another person. What constituted criminal negligence? If a man brought adequate skill to the administration of a drug, if he brought due care and honest attention to the case, then he was not criminally responsible for any error of judgment; but if, on the other hand, a man did not bring proper skill and knowledge to the use of a poison, if there was clear—he would not say gross, for that expression might mislead them, and lead them to suppose that everything short of gross negligence was not criminal negligence—negligence, then he would be criminally responsible, and it would be for the jury to find the prisoner guilty.

After a short consultation the jury returned a verdict of Not Guilty.

Prosecutions under the Adulteration Act.

Alleged Adulteration of Bread.

At the Edgware Police Court on Wednesday, February 18th, William Smith, baker, of Harrow, was summoned for selling bread adulterated with alum.

The bread had been analysed by Dr. Redwood, the county analyst, who had certified that it contained alum.

At the application of Mr. Fryer, who appeared for the defendant, an adjournment from the first hearing of the case had been granted for the purpose of obtaining a further analysis.

Dr. Redwood now deposed that he had found alum present equal to 40 grains in the 4lb. loaf.

In cross-examination by Mr. Fryer, he said the bread was burnt in a platinum dish, and dissolved in porcelain dish. He could not say that the analysis was conducted by his own hands throughout. The boiling on porcelain would, in some instances, evolve silica, which might give alum in the result, but such was not the case in this instance.

Mr. Fryer then called

Professor Wanklyn, who said that he had analysed a sample of bread by order of the Court, and found that there was no alum present.

Mr. Serjeant Cox, said that the evidence was so conflicting that the summons must be dismissed, each party to pay their own costs.

The above report appeared in the columns of the *Daily Telegraph*, where it has been succeeded by the following correspondence:—

"TO THE EDITOR OF 'THE DAILY TELEGRAPH.'

"Sir,—With reference to the case tried yesterday at Edgware, and reported in your paper of to-day, in which a baker was charged with having adulterated his bread with alum, on a certificate signed by me as public analyst for the county, I trust you will allow me to state that although the chemical evidence received by the magistrates was evenly balanced for and against the fact of alum being present in the bread, such would not have been the case if other evidence which was tendered had been received. At the previous hearing of the case, it was arranged that portions of the bread to which my certificate referred should be analysed by Mr. Wanklyn on behalf of the baker, and by some other analyst on behalf of the prosecution. The chairman of the Quarter Sessions proposed Dr. Hardwicke as the third analyst, and his analysis went to prove that the bread contained more than forty grains of alum to the 4lb loaf; but, as Dr. Hardwicke was not present, the presiding magistrate refused to receive the certificate or even to allow it to be read or referred to. I had also made two analyses of the same bread subsequent to the one on which my certificate was founded, and these were made entirely with my own hands, and one of them by a process in which the imaginary objection urged by Mr. Wanklyn to my first analysis could not apply; but I was not allowed by the Bench to state these results, which fully confirmed the accuracy of my first analysis.

"The result of this and some other cases in which proceedings have been taken under the Adulteration Act shows the necessity of having legal assistance to conduct the prosecutions, instead of leaving them, as the county cases are now left, to be conducted by the Inspectors. This is especially the case where the defendants are professionally represented. I consider that the failure of the case heard yesterday at Edgware was entirely due to the want of legal assistance in preparing and presenting the evidence for the prosecution.—I am, &c.,

"T. Redwood,

"Professor of Chemistry to the Pharmaceutical Society of Great Britain, and Analyst under the Adulteration of Food, Drink, and Drugs Act.

"17, Bloomsbury Square, Feb. 19."

"TO THE EDITOR OF 'THE DAILY TELEGRAPH.'

"Sir,—Dr. Redwood's letter, which you publish to-day, is calculated to convey a somewhat erroneous impression respecting what he is pleased to term 'the failure of the case heard yesterday at Edgware.'

"Whilst quite agreeing with Dr. Redwood that the two unfortunate bakers were defended by Mr. Fryer (who conducted their case) with conspicuous ability, I am disposed to attach some importance to their being entirely innocent of the crime which had been laid to their charge.

"I say most distinctly that they are innocent, inasmuch as there is no real evidence against them; and, on the other hand, there is most positive proof in their favour. The evidence against them was a report of Dr. Redwood's

setting forth that the bread they were selling contained some forty grains of alum in four pounds of bread. This report was based upon an analysis of Dr. Redwood's, wherein 1000 grains of the bread, after being burnt and treated with certain chemicals, yielded some 0·2 grains of a certain white precipitate.

"By an error of Dr. Redwood's this 0·2 grains of white precipitate was reckoned as alumina, and calculated as indicating 40 grains of alum in the 4lb loaf, whereas, even if it proceeded from alum in the bread, it must have been phosphate of alumina, and would indicate only about 22 instead of 40 grains of alum in the 4lb. loaf, as had been certified.

"The analysis was quite untrustworthy, as, I think, any chemist who should chance to see these details will admit. Dr. Redwood described himself as having burnt up 1000 grains of bread and mixed the resulting ash with nitric acid, and actually evaporated the mixture to dryness in a porcelain vessel. Such a proceeding is calculated to charge the mixture with silica and alumina. Having done this, Dr. Redwood renders the mixture powerfully alkaline, and then boils it in the porcelain dish; and, in short, the Doctor appears to have taken pains to ensure the presence of silica and alumina in the liquid to which he ultimately applied the test for alumina.

"It is not surprising to me that under these circumstances Dr. Redwood obtained 0·2 grains of alumina; but I do not regard this 0·2 grains of alumina (or phosphate of alumina) as any evidence against the bakers.

"Inasmuch as I have myself burnt up 1,500 grains of the same bread, and having carefully abstained from the addition of silica and alumina, have not been able to detect any alum, I consider that I am justified in maintaining that the two bakers have not alumed the bread.

"Such being the facts of the case, I do not suppose that any number of Crown advocates could have extricated Dr. Redwood from the difficulties which he attributes to Mr. Fryer's advocacy.—I am, Sir, yours, etc.,

"J. Alfred Wanklyn.

"117, Charlotte Street, Fitzroy Square, Feb. 20."

"TO THE EDITOR OF 'THE DAILY TELEGRAPH.'

"Sir,—A controversy on scientific technicalities would be out of place in the columns of a newspaper, and therefore I do not propose to follow the example of Mr. Wanklyn in your impression of to-day, but I must beg to be allowed to deny the statement and inferences contained in his letter to the effect that I had described a certain precipitate as alumina which was really phosphate of alumina, and that I had used apparatus in conducting the analysis from which that alumina might have been derived.

"The precipitate to which I referred was not phosphate of alumina, but alumina, and the quantity which, speaking from memory—for I was not allowed to refer to my notes—I represented as rather less than two-tenths of a grain, was 0·18 grain, which corresponds to 44 grains of alum in a 4lb. loaf. Dr. Hardwicke's analysis of the same bread indicated 46 grains in that quantity, and two subsequent analyses made by myself closely coincided with my previous result.

"The question of the possibility of the alumina found having been derived from the porcelain dish used in the process is a practical one which chemists only can decide; and I am quite willing to rest my reputation upon the assertion that Mr. Wanklyn's objection is a perfectly imaginary one, which I defy him to substantiate.—I am, Sir, yours, etc.,

"T. Redwood.

"17, Bloomsbury Square, Feb. 21."

Adulteration of Tea.

At the Sheffield Town Hall, on the 17th February, before Ald. Fairburn and H. Harrison, Esq., Messrs. Edward Davy and Thomas Potter Davy, of South street, Sheffield Moor, tea dealers, were summoned for unlawfully selling "as unadulterated a certain article of food, to wit, a quarter of a pound of tea, which was then in fact adulterated." The information was laid by Mr. Croft, the chief sanitary inspector; and Mr. Binney appeared for the defence.

Mr. Croft, in opening the case, stated that he appeared on behalf of the Health Committee. The case was one of very great importance, and it was the first that had occurred in Sheffield. The Health Committee was not desirous of pushing the matter to the extent of seeking a very heavy penalty. It was the wish of the committee to protect the public without placing any undue restrictions on trade, and the present case had been brought to test the question. The proceedings had been taken solely with the object of protecting the public, and not with the view of harassing the commerce and trade of the town.

Henry Bramwell, one of the inspectors appointed by the corporation to assist in carrying out the Adulteration of Food Act in Sheffield, said that on the 19th December he purchased at the shop of the defendants on Sheffield Moor a quarter of a pound of tea for sixpence. He told the assistant who served him that he had purchased the tea to have it analysed, sealed the packet in his presence, and took it to Mr. Allen, the borough analyst. Mr. Staniforth, inspector, gave corroborative evidence.

Mr. Allen, the borough analyst, was then called. He said on the 19th Dec. the last two witnesses brought him six samples of tea. He analysed the one in question and he found the tea was free from sandy or magnetic matter, and no foreign leaves were detected. There had been considerable adulteration by the addition of exhausted tea leaves, thus adding to the weight and bulk of tea, and considerably reducing its strength. Such adulteration was not injurious to health. The adulteration was to the extent of 25 or 30 per cent. Exhausted tea-leaves were largely used in the adulteration of tea.—In answer to Mr. Binney, Mr. Allen said the method now adopted by chemists for analysing tea was much more uniform than it was nine months ago. Opinion as to the best mode of analysing tea had very much changed during that period, and the methods were much more perfect. He based his conclusion on the results obtained by three distinct methods. The percentage of tannin was less than he had found in any one of a large number of genuine teas, and the woody fibre was higher. The proportion of the ash soluble in water also clearly proved the tea to have been previously infused in water. As compared with the average composition of genuine black tea, the three methods he had employed corresponded in pointing to an adulteration by exhausted tea-leaves to the extent of about 30 per cent., or about 20 per cent. as compared with the poorest genuine tea examined.

Mr. Binney said whether the defendants had offended against the law or not, it was plain that the present state of the law placed persons in similar positions to the defendants under very great hardship. They had not only to bear with the merchants in China—and it was well-known how teas were prepared there—but with persons in London, who were credited with adulterating tea. The defendants purchased tea which was made up in China and sent to England, and they had not the slightest means of ascertaining whether the article sold to them was what it was represented to be. By ocular inspection adulteration in such a case could not be detected, and therefore the defendants had only the same means of ascertaining whether the tea was pure or not as the authorities had adopted in this case. If his clients had infringed the law they had done so most unwittingly, for it was utterly impossible for them to ascertain the genuineness of the teas they sold. Speaking of the state of the law, he referred to the action the Sheffield Grocers' Association had taken in the matter, and read the letter which they had received from the Home Office. He contended that the amount of difference in this case was not sufficiently gross to warrant the bench in convicting. He thought it would be sailing

very much too near the wind to convict respectable tradesmen of such an offence, when there was nothing injurious and no foreign matter in the tea. The tea simply contained exhausted leaves; and he could not see the difference between selling tea of a low quality and toning down good tea with exhausted leaves. He did not dispute that tea of a low quality had been sold; but then only 2s. per pound was paid for it. He hoped the bench would not convict his clients of the offence, as they had not knowingly or intentionally offended.

The Bench retired to consider their decision, and on returning into court Mr. Fairburn said it was very evident that the Act of Parliament contemplated the protection of the public against the adulteration of food. The magistrates were there to carry out the Act of Parliament, and under the circumstances they felt bound to convict the defendants. The fine would only be a nominal one, as it was the first case of the kind that had come before them. They could easily see the very great difficulty under which tea dealers were placed, but it was no excuse that they were ignorant of the adulteration. The onus was thrown upon them of selling a genuine article. No doubt this Act of Parliament was operating to a great extent rather hardly upon tea dealers, still it only showed the necessity of respectable tea dealers trading with men who would not sell them an adulterated article when representing it to be pure. The defendants would have to pay a fine of 20*s.* and costs. In imposing that fine, the magistrates considered they were only protecting the public. They considered the tea had been adulterated and they were satisfied that they had only carried out the Act.

Adulteration of Mustard.

At Longton, on Wednesday, Feb. 18, Mr. John Grainger, grocer, Normacot, was summoned for selling adulterated mustard. The report of the analyst was produced stating that the mustard was largely adulterated with flour and turmeric, and that it was not actually injurious to health when used as a condiment, but was valueless for medical purposes. Mr. Welch, for the defence, said it was hard that tradesmen should be proceeded against in reference to food which they did not adulterate. The magistrates said it was not their duty to criticize the law, but to administer it as they found it. Mr. Welch said the law would be altered before long. Defendant was fined 1*s.*, the costs being £1 17*s.* 6*d.* Two similar charges were heard against other defendants and the same fine and costs inflicted.

Obituary.

GEORGE MEGGESON.

On the 21st February, 1874, Mr. George Meggeson, Pharmaceutical Chemist.

The late Mr. George Meggeson was of Yorkshire birth and parentage, and served his apprenticeship in one of the York wholesale drug houses towards the close of the last century. He then came to London, and conducted the business of Widow Stavely and Co., wholesale druggists, with great satisfaction to the estimable lady at the head of the firm, and the greatest friendship continued to exist between them during her lifetime. On that business being relinquished, he commenced business in conjunction with some partners, under the firm of Cook, Farley, and Meggeson, upwards of sixty years ago, in the same premises as at present continued by his successors in Cannon Street. Mr. Meggeson took the travelling department, principally in the northern counties and Scotland, where his energy and perseverance, uniformly honourable mode of dealing, and high sense of integrity, endeared him to everyone with whom he came in contact. Like many mercantile men, at some periods of a long career in life, he met with crosses and losses in the path in which he moved, and not the least were those of some of his early partnerships. His indomitable energy and honesty of purpose enabled him, however, to surmount all difficulties, and on taking the management of the business into his own hands his enterprise was ever alive to the advancement of his varied pursuits, and not the least important of those was the manufacture of the medicated lozenges so well known to the trade in connection with his name.

After retiring from business, several years ago, he devoted his time to many useful purposes, and amongst others was elected a member of the Council of the Pharmaceutical Society, upon which he continued to serve until 1864. He was particularly useful in regard to the financial affairs of the Society.

In politics he was a liberal-minded Conservative. As a companion his affability and friendship were greatly esteemed; his kindness of heart and hospitality was unbounded. He married late in life, and leaves a widow to mourn the loss of one so highly and justly appreciated. Throughout a long life he enjoyed excellent and robust health, so much so that within a few months of his death he was able to visit Hastings; but only to return home to Gunnersbury, where he slowly, peacefully and calmly sunk to rest at the age of about ninety. Without physical pain or mental disturbance, George Meggeson passed away after a long, busy, and useful life, leaving behind an affectionate remembrance which it will take long to efface from the minds of those who knew him intimately, valued his friendship, and esteemed his character.

WILLIAM PROCTER, JUN.

Intelligence has just been received of the death of this distinguished American pharmacist, who was for many years the Editor of the *American Journal of Pharmacy*, and one of the Professors of the Philadelphia College of Pharmacy. From a letter received from Professor Bedford, of New York, by Mr. Henry Deane, which has been kindly placed at our disposal, we learn that he died shortly after midnight on the night of Monday, February 9. He had lectured with unusual acceptance the previous evening, and on returning home had expressed to his wife his pleasure with the attention of the students, and his own satisfaction with the lecture. After a very pleasant chat they retired about twelve o'clock. Soon Mrs. Procter noticed a change in his respiration and spoke to him; then tried to rouse him. As he did not answer, she called her son, and immediately returned to the bedside, but in the meantime Mr. Procter had expired. He had long been troubled with an affection of the heart, and a *post mortem* examination disclosed considerable ossification of the aorta. He was buried by the side of his first wife, in the cemetery at Mount Holly, in sight of his country home.

Mr. Procter was in 1853 elected an Honorary Member of the Pharmaceutical Society of Great Britain. He was also an Honorary Member of the Pharmaceutical Conference.

Notice has also been received of the death of the following:—

On the 13th February, 1874, Mr. John Anstey Chave, Pharmaceutical Chemist, of Uxbridge. Mr. Chave had been a Member of the Pharmaceutical Society since 1842.

On the 16th February, 1874, Mr. Charles Bunn, Pharmaceutical Chemist, of St. Botolph Street, Colchester. Mr. Bunn had been a Member of the Pharmaceutical Society since 1853.

On the 21st February, 1874, Mr. John Rigby Lewis, Chemist and Druggist, of Runcorn.

On the 13th February, 1874, in his 71st year, Mr. James Routledge, for many years a member of the firm of Davy, Yates and Routledge, Park Street, Southwark.

Correspondence.

Follow the School.

Sir,—As a constant reader of your Journal, and as one who has always taken a deep interest in pharmaceutical progress, permit me to express my gratification that attention is again being drawn to pharmaceutical education. For a long time past I have seen, with regret, advertisements in various journals which indicate that the wide-spread evil of "cram" seems to flourish to an unprecedented extent in English pharmacy. It was, therefore, with much satisfaction that I noticed in your recent leading article, in which you refer to Dr. Temple's remarks on examinations, also in your correspondence columns, distinct advocacy of the principles of examination following the school (by school I suppose is meant the shop and the college), in opposition to the baneful practice which apparently obtains of the school following the examination. In parenthesis, let me say that I have much too high an opinion of the Council and professors of the Pharmaceutical Society to suppose for one moment that either would descend to encourage "cram," which means superficial and useless information; if they did, the benches of their school would be crowded, and not, as I lament to see, thinly attended.

In veterinary education the system of examinations following the schools is carried out with great success. As some of your readers may like to know how this object is accomplished, I will give them a brief description of our mode of working.

The Board of Examiners at the Royal College of Veterinary Surgeons consists of one or more eminent anatomists, physiologists, chemists, and botanists, together with several leading practical veterinary surgeons. The professors at the teaching schools are also *ex officio* members of the court; they are present at the examinations, but do not question the candidates for diploma.

Such is the wholesome dread of "cramming," and the importance attached to methodical study by those intrusted at the present day with veterinary education, that no person can present himself for examination for diploma whose regular attendance on the prescribed lectures, demonstrations, and practical instructions has not been certified in writing, first by each professor to the principal of his school, and subsequently by the principal to the Council of the Royal College. I may add that the Royal College only recognizes those schools that are incorporated with it by charter, or by the Queen's sign manual. My readers will now see that in the veterinary world the principle of the examinations following the teaching, and not the reverse, is carried out, and that it thereby recognizes the fact that those whose lives have been spent in teaching are better judges of what are the requirements of genuine education than those who have not had the same kind of experience.

In the interests of sound education, in the interests of pharmacists, and in the interests of the public at large, it is imperative that those who have the power to confer licences to practice pharmacy should not grant a privilege of such literally vital importance to anyone "crammed" with just sufficient knowledge (? knowledge) to pass the required examination.

In order that the evil of "cramming" may be crushed, and genuine pharmaceutical knowledge fostered, it seems to me that the Examining Board at Bloomsbury Square should, if possible, be constituted like that of the veterinary profession—namely, of men practically engaged in pharmacy and of scientific teachers of eminence; also that they should both unite in endeavouring to establish that course of education and that kind of examination which would pass none but those who had been thoroughly educated in the principles and practice of their art.

In conclusion, allow me to express the hope that the time is not far distant when the Pharmaceutical Society will justify the power vested in it by the Government, as well as the confidence placed in it by the public, by insisting on every candidate for its diploma giving evidence, not only of his having been in a shop for three years, but also of his having diligently pursued systematic courses of practical and theoretical instruction at a School of Pharmacy recognized by the Society's Council.

Richard V. Tuson, F.C.S.,
Professor of Chemistry, Materia Medica, and Toxicology, in the Royal Veterinary College.

Where is Miss Comp?

Sir,—Permit me to introduce to Mr. J. M. Fairlie's notice the recipe for the "Mist. Composit." of J. G., an M.D. and Fellow of the Faculty of Physicians and Surgeons, Glasgow, which I presume is the "Miss Comp" he is in search of, as it is often ordered as "Mist Comp," and as J.G. writes somewhat indistinctly, the "t" has perhaps been mistaken for a second "s". But the following will show there is not much of mist(ery) about it.—

℞ Hydrochlor. Ammon. . . . . ℥ss
Acidi Hydrochlor. dil. . . . . ℥ii
Syrupi Eastoni. . . . . ℥ii
(*vel* Syr. Ferri. c. Quinæ et Strych. Phosph.)
Decoct. Tritici Repen. ad . . . . ℥viij ℿ
Ft. Mist.

This recipe under the above mystical cognomen is intended to be dispensed at the establishment of one who prides himself in being a member of the Pharmaceutical Society. It shows there is some "tacit understanding" between the two individuals interested, and that they know and can appreciate the value of the old Scotch saying "If you claw me I'll claw you."

The prescriptions are (for this is not the only one) sent *under cover* addressed to the chemist; and at other times, a card with the chemist's name and address in full is handed the patient, with the injunction that they are only to be dispensed at that establishment. Unfortunately for their plans, however, some patients look with considerable suspicion on this dictation by the physician what chemist to go to, and assert their independence by showing that they have a mind of their own, generally by going to the chemist they are in the habit of patronizing. Thus, of course, these plans come to be known, and as all right-thinking people will agree, deserve to be exposed.

It is a pity for their own sakes that gentlemen of such position and respectability should lend themselves to artifices of this nature. In this age of enlightenment some patients are as able to read prescriptions as chemists themselves, and if there is anything that will tend to lower the two professions in the eyes of the public to the level of quackery it is such miserable tactics. I could say more on the subject, but conclude in the meantime by expressing the hope that the pharmaceutical and medical press will give the system no peace until it is entirely abolished.

A. P. S.

Glasgow, 24th Feb., 1874.

R. Chipperfield.—We do not think there is anything objectionable in the notice you refer to.

"*Inquirer*"—So much would depend upon the conditions of sale, that the question is one for a solicitor to answer. We may remark however that it is a mistake to suppose that a "patent medicine stamp" confers or protects proprietary rights in any preparation.

"*Student.*"—(1) Membership of the Pharmaceutical Society is not necessary in order to be placed on the Register of Chemists and Druggists; there is therefore no compulsory annual subscription. (2) It is only requisite for you to keep the Registrar informed concerning any change of address.

"*Maranta.*"—A candidate who fails in an examination is not eligible to present himself at a fresh examination until after an interval of three months.

"*Querist.*"—Dissolve the sulphate of iron in a little of the water, add the tincture of tolu to the compound tincture of camphor and pour these into the remainder of the water, agitate, and add the acid and the iron solutions last. A little resin will separate; this might be prevented by the addition of two drachms of mucilage added to the water before the addition of the tinctures, but such would be exceeding the strict letter of the prescription. The only other alternative would be straining out the separated resin, which would be more reprehensible.

Communications, Letters, etc., have been received from Mr. E. Lloyd, Mr. T. Luke, Mr. G. W. Fowler, Inquirer, A. P. S.

NOTE ON A DECOMPOSED LOZENGE.*

BY THOMAS GREENISH, F.C.S.

During my stay at Bradford, Mr. Rimmington put into my hands two ginger lozenges, one in an early, the other in a more advanced stage of decomposition; these lozenges formed part of a parcel sent to him from a London house several years ago. Very soon after they came into his possession, some of them showed symptoms of change which rendered the lozenges unfit for sale, and they were returned to the maker. The two now in my possession, are all that remain, and they were retained in order to watch the progress of decay. The change commenced in different parts of the lozenge at or about the same time, and it seemed as though at these particular spots some ingredient had absorbed moisture, which, gradually extending, had ultimately broken down the lozenge into a soft mass having the consistence of granular honey, but rather more tenacious.

Mr. Rimmington had observed and watched the growth of a fungus on one of these lozenges: it is visible to the naked eye as a small greyish white spot. To determine the probable cause of the decomposition and the nature of this fungus were the objects I had in view in the microscopic examination to which I subjected them. The small spot consisted of the mycelium or root processes of one or more fungi. I took a small portion on the point of a knife and transferred it to the slide; under a power of about 120 diameters, I observed a fungus of which I made a drawing at the time. There was also another, but as the latter is one of almost universal occurrence in all decaying vegetable matter, I shall not further allude to it; but to the former one I shall have occasion to refer again. I then took a little of the more fluid portion of the lozenge, diluting it with water, and under a power of 600 linear I found the oospore, which in the cryptogamia is equivalent to the seed in the higher order of plants.

Pursuing the investigation further, I placed on another slide a little more of the soft gummy matter, and with a power of 250 linear, I found that it was a mass of apparently little else than starch grains, and the granules were those of the potato; but the hilum was scarcely perceptible, and the lamination invisible.

In an examination of starch grains, the size and form of the granule, the shape of the hilum, also its position on the larger or smaller end, the distinctness of the lamination concentric round the hilum or in segments, together with the general outline, serve to distinguish one starch granule from another. In the examination of dextrin, which is starch in an altered condition, it will be found that the hilum is indistinct, and the lamination almost obliterated. The cause of the lamination in starch granules is said by Nageli to be due to the originally homogeneous deposit in the cell in process of growth becoming differentiated, separating into layers containing different amounts of water.

The starch present may have formed part of the composition of the lozenge as starch, or it may have entered as dextrin. I have found that when granules of starch have been exposed to moist heat, some of the granules are broken, the *débris* of the broken granules being present, others are distorted. If exposed to a comparatively dry heat, the starch granules have some parts of their structure exaggerated, as, for instance, an enlargement of the hilum, and other characteristic markings. From the absence of lamination and the imperfect condition of the hilum, I have concluded that these lozenges are largely composed of starch in the condition of dextrin, and that the hygrometric character of the dextrin was the predisposing cause of their destruction. The dextrin and glucose of Germany are the produce of the potato starch, while that of English manufacture consists mainly of sago.

At this point the next question arises—Whence comes this fungus? It is a micro-fungus of the same genus as that to which the potato disease is said to be due. I would say it is found associated with the potato disease. I cannot satisfactorily account for its presence, but will advance a theory which may or may not be accepted. I have already shown that the lozenge is mainly composed of dextrin, and that the starch granules of which the dextrin is composed are those of the potato; it is also well known that after a potato has shown symptoms of disease and is rendered unfit for food, the starch granules remain intact, and are utilized. It points, therefore, to the possibility, perhaps probability, that the dextrin found in these lozenges was the produce of diseased potatoes, that some of the spores of the fungus clung to the starch, passed with it through all the vicissitudes to which it was exposed in its conversion into dextrin, entered with that substance into the lozenge, and finding in the decomposing lozenge a nidus suitable for its development, threw out its mycelium and fructified, giving rise to the fungus, the subject of the present inquiry.

If the habit of intelligent observation, such as was shown by Mr. Rimmington, were more generally cultivated, our evening meetings would never be in want of interesting and instructive subjects.

[*The discussion on this paper is printed at p.* 721.]

* Read at the Evening Meeting of the Pharmaceutical Society of Great Britain, March 4, 1874.

ON A PECULIAR CAMPHOR FROM CHINA.*

BY DANIEL HANBURY, F.R.S.

Although the Chinese make large use of ordinary camphor, that is to say, of the camphor produced in Japan and Formosa by *Cinnamomum Camphora*, F. Nees et Eberm., it is well known that they attach a much higher value to the camphor obtained in Sumatra and Borneo from the stem of *Dryobalanops aromatica*, Gärtn.

But there is a third kind of camphor standing intermediate in value between these two, and much less known, to which I desire to draw attention.

Rondot, in his work on Chinese commerce,† published in 1848, after speaking of the camphor of China, and before describing Malayan or Dryobalanops camphor, has a remark in reference to the drug under notice, to the following effect:—

> There exists also another sort of camphor, extremely white, which is extracted from the leaves of a plant known in China under the name of *Ngai*, a variety of *Artemisia*. It occurs in crystals, which are very pure, clear, brittle, with a shining fracture; it is much esteemed in China.

Our author quotes the prices of these sorts of camphor for the *pecul* of 133⅓ lb., thus:—

* Read at the Evening Meeting of the Pharmaceutical Society of Great Britain, March 4, 1874.

† *Etude Pratique du Commerce d'Exportation de la Chine*, Paris, 1848. 34-38.

Formosa camphor	25	dollars.
Japan camphor	30	„
Ngai camphor	250	„
Malay camphor, first quality	2000	„
„ „ second quality . . .	1000	„

Other references to Ngai camphor are very slight, and imply that the writers had no practical acquaintance with the substance. Such, in fact, was my own case: I only knew of Ngai camphor by name, and I therefore drew attention to it in the *Admiralty Manual of Scientific Inquiry* (1871), by asking the following question—"*What is the camphor said to be obtained from a species of Artemisia* (*Wormwood*) *called* Ngai?" This brought a reply from Mr. Frederic H. Ewer, of the Imperial Maritime Customs, Canton, who kindly sent to me specimens of Ngai camphor, together with a small branch of the plant from which it is made.

The specimens represent two forms of the camphor, the one a perfectly colourless crystalline substance, in flattish pieces, as much as an inch in length; the other, which Mr. Ewer regards as the crude state of the drug, is a crystalline powder of a dirty white, mixed with some fragments of vegetable tissue. The purer sample has an odour scarcely distinguishable from that of ordinary camphor; but the odour of the other is perceptibly contaminated with a smell like that of wormwood. Ngai camphor, like that of Dryobalanops, sinks in water. The investigation of its other properties and its chemical relations having been undertaken by my friend Professor Attfield, will form the subject of a separate communication from his pupil, Mr. Sydney Plowman.

The plant sent by Mr. Ewer is no species of *Artemisia*, though a member of the same order. It proves to be *Blumea balsamifera*, DC., a tall, coarse-looking, herbaceous plant of Eastern Asia, an abundant weed in Assam and Burma, and common throughout the Indian Islands. It is well-known to emit when bruised a strong odour of camphor, and in Burma, a crude camphor is even extracted from it. Many years ago, a European named O'Riley purified some of this camphor, and attempted to bring it into notice as an article of commerce. According to Mason,* he made more than 100 lb. of it, which he sent to Calcutta, where it was reported to be as good as ordinary camphor.

It is probable that the *Blumea* is not the sole source of Ngai camphor, for according to Mr. Ewer the character 艾 (*Ngai*) is applied to designate several plants, including both *Labiatæ* and *Compositæ*. The camphor is used not only in medicine, but also in the manufacture of the scented kinds of Chinese ink. Mr. Ewer states that about 15,000 dollars' (£3000) worth is annually exported from Canton to Shanghai and Ningpo, whence it finds its way to the ink factories of Wei-chau and other places.

THE CHEMISTRY OF NGAI CAMPHOR.†

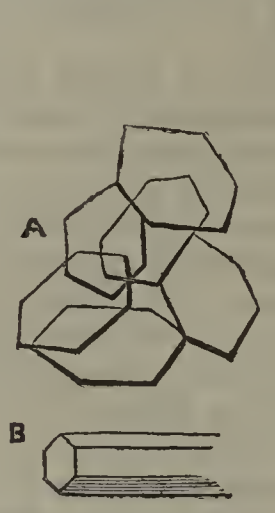
BY SYDNEY PLOWMAN,

(*Senior Bell Scholar in the Laboratories of the Pharmaceutical Society of Great Britain.*)

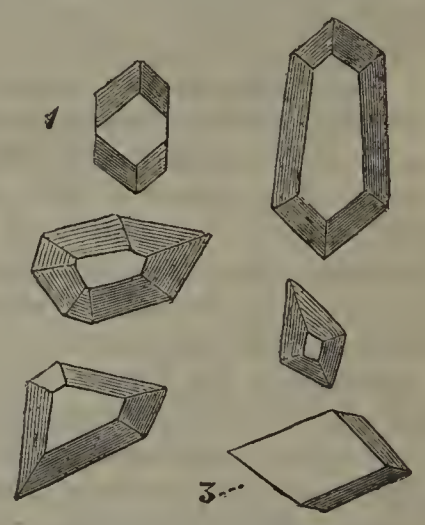
In this paper I desire to record the results of a partial chemical and physical investigation of a new camphor. Rather less than half an ounce of this substance was given by Mr. Daniel Hanbury, F.R.S., to Professor Attfield, and the Professor kindly placed it in my hands with the suggestion that I should endeavour to ascertain whether it was identical with, isomeric with, or distinct from, either Borneo camphor or the common laurel camphor, its appearance, odour, etc., indicating its alliance to one or other of these camphors. The amount of Ngai camphor at disposal being very small, its physical characters were first investigated, and afterwards such chemical operations conducted as involved the least expenditure of material.

Ngai camphor occurs in non-transparent grains, possessing considerably greater hardness and brittleness than laurel camphor. On the upper portion of the bottle in which it had been kept for several months numbers of small, separate, well-defined crystals were formed by its spontaneous sublimation. Laurel camphor placed under exactly the same conditions in another bottle sublimed much more freely, so that masses of crystals rather than single crystals were deposited in the upper portion of the bottle in which it had been kept. A specimen of Borneo camphor, although it has remained in the museum of the Society for several years, has not sublimed in the slightest degree, for the bottle still remains entirely free from adhering crystals.

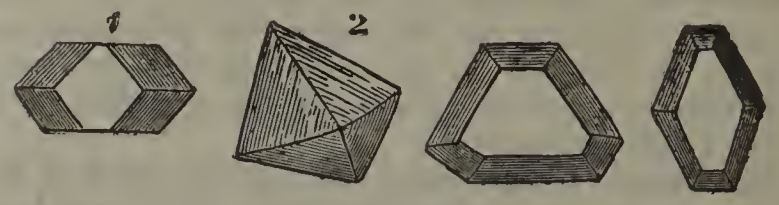
In order to compare their crystalline forms a grain of each was placed in separate tubes, covered with microscopic glass, and exposed for a month to a temperature at no time exceeding 24° C. The sublimate of laurel camphor, when viewed microscopically, was found to consist of masses of six-sided tabular crystals with a few six-sided prisms scattered amongst them. Their volatility was so marked that even while under the microscope they lost the sharpness of their angles and soon degenerated into ill-defined masses.



CRYSTALS OF LAUREL CAMPHOR.



CRYSTALS OF NGAI CAMPHOR.



CRYSTALS OF BORNEO CAMPHOR.

The Borneo and Ngai camphors, on the other hand, sublimed in singularly beautiful, well-defined, and for the most part solitary crystals, which preserved their angular sharpness extremely well. They resembled each other in a remarkable degree, and it would be impossible to give any characters by which they could be distinguished, some of the crystals of the two

* *Burmah, its People and Natural Productions*, 2nd ed., 1860. 483.

† Read at the Evening Meeting of the Pharmaceutical Society of Great Britain, March 4, 1874.

being absolutely identical in outline (1). They were principally of a pyramidal form, with a varying number of sides, generally truncated, but sometimes perfect, then appearing as the halves of octahedra (2), while a few seemed to belong to the doubly oblique prismatic system (3).

As a great difference in the volatility of each had been observed, the tension of the vapour of each was next sought to be obtained. In order to determine this, a small fragment of each was introduced into one of three barometer tubes placed side by side in a mercurial trough, and allowed to remain twenty-four hours. After making due allowances for the variation of the atmospheric pressure, the mean depression of the mercurial column in two experiments was in the case of laurel camphor 4·5 millimetres, of Ngai 2·8 millimetres, and of Borneo 2 millimetres. The thermometer in each experiment stood at 12° C.

Fragments of each after immersion in water floated, but on placing them under the exhausted receiver of the air-pump, so that interstitial and adhering air might be removed, the Ngai and Borneo camphors readily sank, while the laurel camphor persistently floated. The specific gravities of the Ngai and Borneo camphors were therefore taken by placing a weighed quantity in a specific gravity flask with camphor water (the density of which does not differ appreciably from that of distilled water), exposing *in vacuo* for some hours, and proceeding in the usual manner. The specific gravity of laurel camphor was determined by obtaining a fully saturated solution of camphor in a mixture of spirit and water, in which a fragment floated indifferently in any part after exposure *in vacuo*. The specific gravity of the liquid was determined in the usual way, and of course represented that of laurel camphor. By these modes of procedure the specific gravity of laurel camphor was found to be ·995, that of Ngai camphor, 1·02 and of Borneo, 1·011.

The melting point of each was found by introducing a small quantity into a thin narrow tube, sealing one extremity and immersing in melted paraffin, and gradually heating till the little column of camphor became transparent, and noting the temperature of the surrounding paraffin ; by so doing the melting point (or rather, the mean of the melting and solidifying points) of laurel camphor was found to be 177° C., of Ngai camphor 204° C., and of Borneo camphor 206° C.

Laurel camphor, exposed to a stream of washed but not dried gaseous hydrochloric acid, at the ordinary pressure and temperature, absorbed it rapidly, and in a few minutes became a colourless, perfectly transparent liquid. Ngai camphor under the same conditions absorbed the gas extremely slowly, and though kept in a constant current for several hours, did not absorb sufficient to become fluid, but still remained in fragments, though surrounded by a small quantity of a colourless liquid. It seemed after the lapse of some time to cease to absorb more gas, for no further apparent effect was observed after a certain point was reached. Borneo camphor when treated in a like manner behaved in every respect similarly to Ngai camphor.

Gaseous hydrochloric acid, dried by passing it through strong sulphuric acid, when passed over laurel camphor, quickly converted it, as before, into a colourless liquid. The Ngai camphor was affected by the dried gas as by the moist, but somewhat more slowly, while the Borneo was not visibly acted upon at all, even after exposure to the stream of dried gas for many hours ; but on removing it, it was found that the grains adhered together, showing that some slight absorption had taken place.

Berthelot and Pélouze each state that Borneo camphor, when left in contact with moderately concentrated nitric acid, is converted into a floating oil, which, when added to water, deposits a body identical with laurel camphor. Ngai camphor, when left in contact with nitric acid of a specific gravity of 1·42 for an hour was found to be changed into a yellowish floating oil with the evolution of dense, ruddy fumes. This oil when separated and added to water, with constant stirring, gave a deposit possessing exactly the odour of laurel camphor, and this deposit, when collected, washed, and dried by exposure in a bell jar over sulphuric acid was quickly converted into a liquid by passing a stream of dried hydrochloric acid gas over it. It was impossible to perform any more experiments in this direction upon it, since the whole of the Ngai camphor at disposal was so extremely small that scarcely sufficient for this experiment could be used without giving up some equally important operation. It would, however, have been very interesting to have obtained sufficient of this deposit to have made an ultimate analysis of it, so as to have determined whether it had the same composition as laurel camphor.

Laurel camphor, when treated in a similar manner with nitric acid, yielded an oil floating on the acid, without, or with very slight, evolution of nitrous fumes. This oil, when separated and added to water, yielded a deposit having a terebinthinate as well as a camphoraceous odour.

On making an ultimate analysis of each camphor, the following results were obtained :—

		Experimental.	Theoretical.
Laurel camphor . .	C	78·2	78·94
	H	10·44	10·52
	O	11·36	10·54
		100·00	100·00

		Experimental.	Theoretical
Borneo camphor . .	C	77·66	77·92
	H	11·68	11·69
	O	10·66	10·39
		100·00	100·00

		Experimental
Ngai camphor . . .	C	77·56
	H	11·6
	O	10·84
		100·00

It should be stated that the Ngai camphor used in the combustion was in the state in which I received it. The crystals appeared to be pure, but the amount was insufficient to admit of the performance of any operations having purification as their object. The Laurel camphor and Borneo camphor were also simply museum specimens.

The substance used for the combustions was chromate of lead. This was first fused, to burn off any dust possibly existing in it, and next powdered and heated throughout the whole length of a long tube while air was passed over it. By these means any moisture possibly absorbed during the powdering was removed. The ends of the tube were then closed while it was still being heated, and the contents, as soon as cool, were transferred, with the camphor, directly into

the combustion tube, mixed with a wire, the absorption tubes attached, and the operation set going at once. It was considered that by these means the presence of any moisture was completely avoided. The oxygen was estimated as usual by difference.

The vapour density of Ngai camphor was determined by Hofmann's process. This consists of a graduated barometer tube, containing mercury, into which is introduced a small quantity of the substance under examination. This tube stands in a little cup, also containing mercury, and is itself enclosed in a larger tube, having an outlet at top and bottom. A delicate thermometer is suspended between the tubes. The vapour of oil of turpentine, or of some body having a high boiling point, is then passed through the space between the tubes. The substance readily volatilizes at a temperature much below its boiling point in air, since it is under greatly diminished pressure, and since a weighed quantity has been introduced the volume of the vapour can be read off, and after due corrections for temperature and pressure the vapour density can be calculated in the usual manner.

Ngai camphor, under these conditions, readily volatilized at a temperature of 158° C., and under a pressure of ·094 metre, though its boiling point, under ·760 metre pressure, is probably about 210° C. The vapour of Ngai camphor read off when both the temperature and height of the mercurial column were constant, gave a density of 78·98. This does not quite agree with the formula that might be deduced from the ultimate analysis ($C_{10}H_{18}O$), for that would give a density of 77, but considering the difficulties of the process it was considered fairly consistent with it.

The conclusion arrived at from the above experiments is that Ngai camphor is isomeric with Borneo camphor; that is to say, it possesses the same elements in the same centesimal proportions, the same number of atoms in the molecule, and as far as can be determined the same chemical constitution, but differs in physical properties, viz., its much higher volatility, its perceptibly different odour, and somewhat greater hardness and brittleness. It has been omitted to mention that Ngai camphor has an odour closely approximating that of laurel camphor, but much less powerful, while Borneo camphor, in addition to its weak camphoraceous odour, has a disagreeable peppery one also.

Ngai camphor may, therefore, like Borneo, be looked upon as a monatomic alcohol of the series $C_nH_{2n-3}HO$, viz., $C_{10}H_{17}HO$, the aldehyd of which is laurel camphor, $C_{10}H_{16}O$.

I cannot conclude these remarks without tendering my most sincere thanks to Professor Attfield for the great encouragement and many suggestions I have received at his hands during the investigation.

[*The discussion on this paper is printed at p.* 722.]

NOTE ON A PROPOSED METHOD OF STORING AND DISPENSING SMALL QUANTITIES OF HYDROCYANIC ACID.*

BY F. BADEN BENGER.

The uncertain strength of hydrocyanic acid as met with in pharmacy has formed the subject of frequent lamentation from pharmacists and medical men for many years past.

Mr. Towerzey, in a paper read at a recent meeting of the Bristol Pharmaceutical Association, was, I think, the last to point out this variation of strength, arising, as he said, mainly from the highly volatile nature of the HCN, and its consequent loss every time the bottle was opened. Mr. Towerzey ended, as others have done, by suggesting a metallic cyanide as a substitute. Hydrocyanic acid is, however, a remedy not likely to disappear from physicians' prescriptions very suddenly, and I therefore venture to bring before the Society a little contrivance for storing and dispensing small quantities of it, which I believe will be found useful. It consists, in fact, of a bottle from which the contents may be removed without taking out the stopper. A small glass tube, shaped like the barrel of an ordinary half-ounce syringe, is drawn out to a rather long, fine point at one end, and sealed in the flame of a spirit lamp or Bunsen's burner; it is then filled with the acid and a piece of vulcanized sheet india-rubber tied *tightly* over the mouth. When required for use, the point is scratched with a file and broken off; by pressing the finger on the india-rubber diaphragm any required quantity of acid can be taken out, only the same bulk of air entering the tube when the pressure is removed. It is then placed, with its point below the surface of mercury, in a little upright glass vessel.

By this method the only loss of HCN is the small quantity which diffuses in the air contained in the tube as it is gradually emptied, and is not sufficient to be of practical importance. It is of course necessary to bind the india-rubber tightly over the mouth of the tube, which should be of yellow glass, or varnished by a dip in solution of shellac coloured with coralline.

Vulcanized india-rubber must be used, as the HCN diffuses rapidly through pure india-rubber.

Not the slightest deterioration was found to have occurred in acid so kept for fourteen days. These tubes can be filled and sent out by wholesale houses instead of bottles, and can be as easily re-filled.

* Read at the Evening Meeting of the Pharmaceutical Society of Great Britain, March 4, 1874.

COD LIVER OIL AND THE METHODS OF MASKING ITS TASTE.*

BY M. GUICHARD.

The introduction of a new medicinal product—cod liver oil bread—gives a certain interest to the consideration of the various methods that have been recommended for the administration of cod liver oil. In the first place, let us consider in a few words how the oil is prepared. The methods of preparation, varying in each country, may all be reduced to the choice of livers of good quality, cleansing them, and removing the oil that will run from them without the application of heat; a small quantity of colourless oil is thus obtained. The livers are then heated, either by means of the sun or in a water bath, or in a double-bottomed vessel heated by steam, the temperature being maintained between 60° and 70° C.; they then yield a quantity of nearly colourless or slightly coloured oil, which is allowed to cool, and filtered. These are the two medicinal oils. The livers, next heated over a bare fire, furnish at first a light oil that is used for burning, and, being further heated, a brown oil that is used industrially. For these latter oils they also mix with the picked livers others taken from unhealthy fish. Instead of being white and roundish, these are angular, rather long, and sometimes spotted with green and red. In Newfoundland, when the oil has been removed which runs off at the temperature of boiling water, the residue is simply submitted to pressure, and a brown oil is thus obtained. The residues from these various operations are

* *Répertoire de Pharmacie*, N.S., vol. ii., p. 1.

employed as manure. It is therefore the colourless or slightly coloured oil that should be used in medicine.

Cod liver oil is taken with facility by young children, who become quickly accustomed to its taste. This is not the case, however, with older children and adults, for whom it is therefore sought to mask the flavour. It has been recommended to take the oil before a meal, pinching the nose, then swallowing the oil, and afterwards a few spoonfuls of soup before releasing the nose. Others have said that the oil should be taken in the middle of a meal, previously placing upon the tongue a pinch of salt, and afterwards chewing a crust of bread and washing the mouth with a draught of wine or coffee. Again, it has been recommended to take a glass of ferrated water, rum and water, or a peppermint lozenge after swallowing the oil. For the eructations precipitated oxide of iron is given. To take the oil enclosed in capsules would evidently be the best means of attaining the object, but it is necessary to take too large a number.

In other cases the oil has been associated with substances of various natures intending to disguise the taste without diminishing its therapeutic properties ; but it is necessary sometimes that the action of the adjuvant should not be lost sight of. Cod liver oil has been associated with various syrups,—syrup of iodide of iron, anti-scorbutic syrup, syrups of orange peel, cinchona, tolu, etc. Ferrated cod liver oil, oil with 0·05 per cent. of essence of bitter almonds added, or shaken with double its volume of cherry laurel water ; oil with 1 per cent. of essence of eucalyptus added, or 20 drops of either to each spoonful, have all been proposed. Chloral has been added in the proportion of 10 per cent. of the oil. It has also been attempted to make a paste with the oil and powdered gluten to be taken in unleavened bread. The cod liver oil bread just introduced has the same object, but I do not think that this product will have a greater success than the other, to which it is much inferior. I think that the heat would act upon the oil, and that the altered products which resulted would predispose the oil to rancidity. It is therefore a product that should be eaten fresh, and consequently could only be prepared in large towns. To the foregoing I will add two methods hitherto unpublished. The first was mentioned to me by the late M. Deschamps, of Avallon, and consists in preparing a salad with cod liver oil. M. Deschamps spoke very highly of this plan, which is certainly not more extraordinary than that of the bread, and at least does not induce any alteration in the oil. The other plan is to crumble small pieces of sardine into a spoonful of oil. Children take very well to this association, and I have seen it succeed with many persons to whom I have recommended it as a last hope. They commence by eating the sardine alone, then with the oil of the sardine, and afterwards for this is substituted the cod liver oil. Another method recently indicated consists in heating 400 grams of the oil, 20 grams of roasted coffee and 10 grams of animal black in a closed flask for a quarter of an hour in a water-bath at 50°C. The mixture is left in contact during two or three days and shaken occasionally, then filtered : it appears only to have the taste of coffee.

Other processes consist in the introduction of the oil into a pharmaceutical preparation, which modifies more or less its appearance. Such are the various forms of jellies, and cod liver oil cream, which is an emulsion of equal parts of oil and mucilage of gum tragacanth, aromatized with a little alcohol and essence of bitter almonds. The syrups of cod liver oil are of the same nature. The following is the formula of a ferruginous syrup recommended in Germany :—

Powdered Gum Arabic	68 grams.
Distilled Water	60
Syrup of Lacto-phosphate of Iron	180
Pale Cod Liver Oil	250
Essence of Bitter Almonds . .	6 drops.

At other times, these syrups contain the oil more modified. Such is the following formula, where the oil is partly saponified :—

Pale Cod Liver Oil	100
Powdered Gum Arabic	50
Cherry Laurel Water	20
Orange Flower Water	20
Simple Syrup	200
Calcined Magnesia.	4

M. Deschamps, of Avallon, has recommended a soap of castor oil to be taken in 20 centigram pills, but it is necessary to take from 40 to 60 per day. Other processes suppress the cod liver oil and replace it by such substitutes as the iodized and phosphoretted oils and the extract of the water of cod livers. All these preparations might be useful in certain circumstances, but evidently cannot replace cod liver oil. As to the extract of the water of cod livers, it appears to me to want at least one important element—the oil. Finally, the last method of administering it is as an injection.

NEW PROCESS FOR THE MANUFACTURE OF UNALTERABLE BEER.*

BY M. PASTEUR.

It is well known that beer is eminently unstable ; during the heat of summer it does not resist for more than a month or six weeks the causes of its deterioration. The wort which is used in its preparation is still more difficult to preserve. At a slightly elevated temperature the beer wort may become, in the course of a few hours, especially in stormy weather, the seat of various alterations. These alterations exercise a great influence upon the processes of manufacture, and it may be safely stated that all the practices of the art of brewing are dominated by the necessity of fighting against their disastrous effects. One of the most expensive of the practices adopted to secure to a certain extent the preservation of wort and beer consists in the employment of ice and more generally of low temperatures.

What, then, are these changes which so influence this important industry? If they were known, might we not hope to combat them by more simple and economical means than those at present adopted? In a paper, of which the following is an abstract, recently read before the French Academy, M. Pasteur described a further utilization in the art of brewing of the results of his investigations respecting the phenomena of fermentation. The following are the more essential conclusions arrived at by M. Pasteur :—

1. All the changes in beer, whether manufactured or in the course of manufacture, and in the wort used in its production, are correlative with the development and multiplication of microscopic organisms, which he calls, for this reason, "*ferments de maladie.*"

2. The germs of these ferments are introduced from the air, the original ingredients, and the utensils used.

3. Whenever a beer does not contain any of these living germs, which are the immediate cause of its spoiling, that beer is unalterable, whatever may be the temperature of its manufacture or storage.

4. He states that he has demonstrated that in the employment of the actual processes of the brewery all the worts, yeast and beers contain the germ of the *maladies* peculiar to those substances.

If such beer as is met with in commerce, manufactured by the processes adopted in the breweries of France, Germany or England, be exposed in bottles to a temperature of from 15 to 20° C., after an interval of a few weeks it invariably alters and becomes unfit for consumption. In some exceptional cases, preservation would not be possible except by the addition of a larger quantity of hops than usual. At the same time, and parallel with the progress of the alteration itself, there occurs a multiplication of various microscopic organisms. If beer wort be

* *Comptes Rendus*, lxxvii., 1140.

placed in a vessel open to the air, but sheltered from any dust in the atmosphere by the opening being at the end of a sinuous tube, in the manner adopted in M. Pasteur's well-known experiments, it will remain in a perfect state of preservation for months or even years. But if a drop of commercial beer be introduced—since the most limpid beer always contains a few globules of yeast in suspension—the alcoholic fermentation is set up on the following day and the must is converted into beer. If beer so prepared be kept at the temperature of summer heat it undergoes alteration, and M. Pasteur finds that with the globules of yeast are always associated to a greater or less extent the *ferments de maladie* before referred to. He therefore infers that germs of these ferments exist in all commercial beers. But if beer specially prepared so as to be free from all germs of *ferments de maladie* be added to the wort, then the resulting fermentation produces perfectly sound beer, free from all living organisms other than the globules o falcoholic yeast.

M. Pasteur's investigations have led him to the conclusion that both wine and beer are liquids not alterable in themselves ; the causes of their alteration must be sought outside of their nature and composition. They undergo chemical modification, such as becoming flat, when exposed to contact with oxygen, or "age," in consequence of reactions between the constituent elements, principally under the influence of slow and sparing oxidization. But these changes of the liquid do not correspond to the "état maladif," properly so-called ; often they contribute to its amelioration. For beer to become "sour," "putrid," "lactic," it is necessary that foreign organisms should become developed in its interior. This is true of all temperatures, and beer free from these organisms might make a tour of the world without undergoing any other fermentation than the alcoholic. The same may be said of beer wort, which, if previously boiled, so as to destroy the vitality of the germs it might contain, will remain unaltered if it be protected from the dust that floats in the air.

The same order of facts are presented by beer yeast, but here we have to do with more complex phenomena. Beer and beer wort are dead substances, indestructible until submitted to exterior causes of deterioration ; but the yeast, on the contrary, is a living organism. That beer yeast is eminently changeable is well known. During the summer, and even at the lowest temperature, it alters its consistence in a few days, acquires a putrid odour, and loses its activity as a ferment. These alterations are accompanied by the development of microscopic organisms, bacteria, vibrions, lactic ferment, and various moulds. The question arises whether these have their origin in a modification of the yeast cells or in the dust of objects with which the yeast has been in contact.

In reply, M. Pasteur states that he has succeeded in preparing a pure yeast free from all foreign germs. In this state it appears as inert as a mineral substance, and neither mould, vibrions, bacteria, or acetic or lactic ferments ; not even the *Mycoderma vini*—so near to yeast in its structure and mode of development—appears in it. Further, it preserves its fermentative character, although, when compelled to live for some time upon its own substance, its protoplasm is profoundly modified, as happens always with cells when the usual phenomena of assimilation are suspended.

M. Pasteur does not give precise details as to how he prepares this pure yeast, but he says the method is based on the following physiological facts. Whilst beer yeast lives and multiplies in contact with the air more rapidly and easily than in contact with carbonic acid, the *ferments de maladie*, on the contrary, are impeded in their life and propagation by the presence of oxygen. He considers that in this characteristic they resemble the vibrio which he believes to be the butyric ferment, and which oxygen deprives of movement and of action as a ferment. The result of this peculiarity has been that the attempt to manufacture beer in closed vessels free from contact with air, according to the process introduced by M. Pasteur some time since, has failed hitherto, from the conditions favouring the production of these noxious ferments. Profiting from this difference in the action of pure air upon yeast and the *ferments de maladie*, he obtains a small quantity of pure yeast, which added to beer wort previously boiled and carefully sheltered from contact with the dust of the atmosphere, readily multiplies and yields a plentiful supply.

These are the principal points of M. Pasteur's communication so far as they would interest the readers of this journal, and it is not necessary to give technical details. It will be sufficient to say that after the wort has been raised to ebullition in its preparation it is kept sheltered, only pure yeast is added, and fermentation allowed to take place. After this the beer may be treated in the usual manner, as, with the exception of the *Mycoderma vini* and the *Mycoderma aceti*, the foreign ferments do not find a suitable medium for their development in finished beer, and these two may be excluded by simple precautions. M. Pasteur states that beer so prepared and kept in ordinary recently tarred vats, or in bottles, is preserved indefinitely, even at a temperature of 20° to 25° C. Far from becoming spoilt with the lapse of time, it appears to improve by a kind of "ageing" analogous to that which takes place with wines.

NOTE ON NUTMEG STEAROPTENE*

BY PROFESSOR FLÜCKIGER.

According to previous writers, the stearoptene which is obtained in extremely small proportions from the essential oil of nutmeg,—either from *Myristica fragrans*, Houtt., or *M. fatua*, Houtt. (*M. tomentosa*, Thimb.)—is soluble in water. The author has obtained it beautifully crystallized from spirit in extremely light scales, the form of which is not determined. Notwithstanding often repeated recrystallizations it retained the smell of nutmegs. It melted at 54° C., and, as might have been expected, was by no means soluble in water, but only in the ordinary solvents of substances of this class. By glacial acetic acid it is at first coloured red. This short notice, it will be seen, is full of contradictions of what has been previously published respecting myristicin. Even its composition differs from that found by Mulder. The mean of four analyses made by Dr. Buri, in the author's laboratory, gave C=75·4, H=12·28. The author proposes to attempt to construct a formula from these results, and also to study the deri vatives of this stearoptene.

SAFFLOWER.†

Carthamus Tinctorius.

These seeds yield by expression an oil which, when properly prepared and refined, is transparent and of a light yellow colour. It is used in India for culinary and other purposes. This oil deserves more attention than it has hitherto received in this country, and if once fairly introduced, there is no doubt whatever of its becoming a staple import. It is used in some of the Government workshops as a "drying oil." It is believed to constitute the bulk of the celebrated "Macassar oil." The seed is exported under the name of Curdee or safflower seed. In Oude it is sown in October, either alone or along the edge of wheat crops ; both light and heavy soils are adapted to it. It is cultivated in every village, but not extensively. There would be no difficulty in further cultivating it to any extent. The cost of the seed, which is called "Barré," is 18⅔ seers per rupee, and the cost of the oil is from three to four seers per rupee.

* From the *Schweizerische Wochenschrift für Pharmacie*, Dec. 19, 1873.

The Pharmaceutical Journal.

SATURDAY, MARCH 7, 1874.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

ADULTERATIONS IN FOOD AND DRINK.

EVERY day brings fresh testimony to the fact that there has existed, and still exists, a lamentable amount of popular ignorance upon the subject of the detection of adulterations in food. We therefore think that Mr. JAMES BELL did good service in the lecture which he delivered recently before the Chemical Society on "The Detection of Adulterations in Articles of Food and Drink."

The lecturer first pointed out that the practice of adulterating articles of food and drink was not of recent date, for that Acts of Parliament for the suppression of such practices were passed a century ago. Until the passing of the recent Adulteration Act, the suppression of adulteration had been confined to the Revenue authorities, and although such action had been intended primarily for revenue purposes, yet the public were much benefited, for no commodities are vended so pure as those which are subject to revenue supervision. As starches of various kinds have been extensively used for adulterating mustard, spices, cocoa, etc., a very elaborate description of many of them was given, and how by their form, size, and markings they may be distinguished. The various physical and chemical properties of coffee and its principal adulterants were next commented upon, and it was stated that, combined with the use of the microscope, the specific gravity of an infusion is one of the best means of determining the percentage of adulteration, especially when chicory or other sweet roots have been used. Tables showing the comparative colouring power of coffee, and its various adulterants, and also the specific gravity of infusions of the same, were exhibited, but the former is only regarded as a preliminary test. The microscopic tissues of coffee, which are characteristic, are the spindle-shaped "flights," and the thick-walled irregular cells, and these are distinguished very easily from the thin-walled cells, spiral tissue, and dotted tubes common to the various roots. Chicory and dandelion are distinguished from other roots by the presence of laticiferous tissue, but it is only an experienced microscopist who can distinguish the one from the other. The seeds used for adulteration, such as beans, peas, etc., may be microscopically identified by the tissues of the outer integument and by the starch cells, and also by the starch granules, which are often found whole, even after roasting. Other substances recently found were rye, acorns, locust beans, dog biscuits, and mustard husks.

The next subject taken was tea, and the lecturer minutely described the microscopical structure of the serrations, hairs, and the cells composing the epidermis of the tea-leaf, and showed how they differed from similar structures of the elder, sloe, willow, etc.: but it appears that adulteration of this kind is seldom now attempted. Such adulteration as is now practised is mostly done abroad, and principally consists of facing the tea with a greenish powder. Two specimens of facing powder used in Shanghai were exhibited, one of which consisted entirely of Prussian blue, and the other corresponded in composition to soapstone with an admixture of oxide of iron. It has been said that turmeric is sometimes used in the facing of tea, but the lecturer had never met with a case of the kind. To examine the facing powder, a portion of tea should be agitated with water in a test-tube, filtered through muslin, and the sediment which subsides examined microscopically and chemically. Prussian blue is readily recognized by its bright blue angular fragments, which are turned brown by potash. One sample of tea was shown adulterated with 20 per cent. of ground quartz, and 8 or 9 per cent. of magnetic oxide of iron, and another with magnetic oxide of iron only, and in both cases the adulterant was so artfully rolled up within the leaves that there was nothing suspicious in the appearance of the tea, but it felt exceptionally heavy. A specimen of tea imported as "Maloo mixture" was also exhibited, which was found to consist of exhausted tea leaves which had been redried. The method relied on for proving the presence of exhausted tea leaves consists in estimating the amount of ligneous matter, tannin, and gum in the sample; and, if such leaves be present, the first of these will be found in excess, and the two latter deficient, unless catechu, or some such body, and gum, have been added in making up the tea. In twelve samples of tea, as ordinarily imported, the amount of ligneous matter ranged from 47·66 to 60·12 per cent.; the gum from 4·06 to 7·15 per cent.; and the tannin from 9·50 to 18·19 per cent., excluding a sample of Assam fannings, which only gave 3·70 per cent.

The last subject taken was pepper, and samples of ordinary white and bleached peppercorns were exhibited, both of which, but especially the latter, were largely coated with chalk. The ordinary adulterants of pepper were stated to be linseed meal, mustard husks, rice, the bran and flour of various cereals, etc., the microscopical characters of which, as well as of genuine pepper, were minutely described. Some of the adulterants may be readily detected; for instance, if rice has been used, the particles, from their camphor-like appearance, may be picked out by the use of a pocket lens; fragments of mustard husks may be recognized by the naked eye from their cup-like shape; and if ground chillies are present, the pepper should be diffused in water and filtered

through a hair or muslin sieve, when the deep red particles of the chillies may be picked out and recognized by the taste.

INDUSTRIAL CHEMISTRY.

THE Council of the Society of Arts have recently made arrangements for the delivery of a series of lectures on subjects coming under the above heading, and in doing so they have manifested a very praiseworthy recognition of one of the most pressing necessities of the present time, viz., a more general attention to the scientific aspects of our manufacturing industries. The first lecture of the series was delivered on Friday evening, by Mr. FREDERICK FIELD, F.R.S., the subject being, "Paraffin and its Manufacture." The attendance was very large, and the account given of the discovery and preparation of this interesting material was highly interesting. Several entirely new methods of purifying paraffin were illustrated by very striking experiments. The lecture table was covered with various forms of candles, etc., made of artificial paraffin, as well as the natural material known as ozokerite, and great interest was shown on the part of the audience. The chair was taken by Professor ODLING, who prefaced the lecture with some introductory remarks on the importance of industrial chemistry, in which he happily and forcibly illustrated how much that subject is or ought to be a matter of every-day interest to every one. We heartily wish success to the enterprizing attempt made by the Society of Arts to popularize and promote the consideration of matters which are so essentially connected with our national welfare.

THE SCHOOL OF PHARMACY.

IT will be seen by reference to the advertisement of the School of Pharmacy in the present Journal, that the courses of lectures on Chemistry and Pharmacy, and Botany and Materia Medica have just recommenced. To students who have but a limited time at their disposal, the present period is a very favourable time for studying at the School of Pharmacy; for between the 1st of March and the 31st of July, they have the opportunity afforded them of not only attending in the laboratory, and at the usual courses of Chemistry and Pharmacy, and Botany and Materia Medica, but *also* the summer course of Systematic and Practical Botany, at the Royal Botanic Society's Gardens, in Regent's Park.

POISONING BY HYDRATE OF CHLORAL.

THE *Lancet* states that a case was mentioned at a late medical meeting at Wiesbaden of a man, aged 36, who swallowed six drachms of hydrate of chloral with the intent to commit suicide. When received at the hospital half-an-hour afterwards, he was in a profound sleep, with congested face, heavy breathing, and pulse 100. After a short time the face became livid, and the respiration intermittent; this again was followed by general pallor, absence of pulse, and contraction of pupils. Electricity was used at intervals to induce regular breathing, and subcutaneous injections of nitrate of strychnia to stimulate the heart's action; and finally the patient awoke "quite refreshed," thirty-two hours after the ingestion of the chloral.

IT is announced that on Saturday, March 14, a lecture will be delivered in the Museum, in the Royal Botanic Society's Gardens, Regent's Park, by Professor BENTLEY, "On the Properties and Uses of *Eucalyptus globulus* and other species of Eucalyptus." The lecture is to commence at 4 o'clock.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL,

Wednesday, March 4th, 1874.

MR. THOMAS HYDE HILLS, PRESIDENT.

MR. ALEXANDER BOTTLE, VICE-PRESIDENT.

Present: Messrs. Atherton, Greenish, Hampson, Radley, Robbins, Sandford, Savage, Schacht, Shaw, Stoddart, Sutton, Urwick, and Williams.

The minutes of the previous meeting were read and confirmed.

CONVERSAZIONE.

The Secretary read a letter from the authorities at South Kensington Museum granting the use of the building for the Conversazione in May next. A committee was appointed to carry out the arrangements.

THE HISTORICAL SKETCH OF PHARMACY.

A letter was read from Professor Redwood, undertaking to edit and complete the 'Historical Sketch of Pharmacy,' in accordance with the request of the Council at their last meeting.

DEATH OF MR. MORSON.

The PRESIDENT said: Gentlemen,—It is with feelings of much regret that I have to inform you, the Pharmaceutical Society, and all connected with it, have just sustained a great loss in the death of our valued friend, Mr. Morson, which occurred yesterday. Mr. Morson had been out of health for some months, but when I saw him about three weeks ago, I little thought he was so near his end. Mr. Morson was one of the founders of the Society, and was Mr. Jacob Bell's right hand from the commencement of the Society until Mr. Bell's death in June, 1859, when Mr. Morson was vice president, and was elected president in July of the same year. Mr. Morson was on the Council from 1841 to 1850, and again from 1854 to 1870. Mr. Morson always took the greatest interest in the Society, and for years had been constant in his attendance—calling at Bloomsbury Square almost daily to see what was going on. He was one of the first examiners, and remained on the board for twenty-eight years. Mr. Morson was a most intelligent man, possessing a great amount of information on a variety of subjects. He was also an excellent scientific chemist, was Fellow of the Linnæan Society, and member of the Royal Institution, and was well acquainted with many of the leading scientific men on the Continent. Mr. Morson was a most interesting and genial companion, and a man I was always proud of as belonging to the same calling as my own; and with your permission I will move that a letter of sympathy and condolence be sent to the family.

The VICE-PRESIDENT said: I rise with feelings of the deepest sympathy to support the proposition of our President. I feel, gentlemen, that pharmacy in general, and our Society in particular, have lost a most sincere and earnest friend. I recollect Mr. Morson as being attached to this Society from its earliest days. I had the honour of sitting at this Board under his presidency, and often admired his tact and his sound judgment on matters of business. I think the fact of Mr. Morson having been the third vice-president and the fourth president of the Society speaks much for the position he held in days when it was in its infancy; and though we know that his death has happened in the natural order of things, we cannot help feeling deep regret at his passing away from us. I hope we shall all endeavour to follow his bright example. I have much satisfaction in seconding the proposal of our President, that a letter of condolence and sympathy be sent to his family.

Mr. SANDFORD and Mr. WILLIAMS also spoke in very feeling terms of the late Mr. Morson, with whom they had both been on terms of great intimacy, the latter having been, in early life, for ten years assistant to Mr. Morson.

The motion having been carried, the President and Vice-President and Messrs. Sandford and Williams were appointed to draw up the letter.

The President also alluded to the recent loss of another old member and friend of the Society, Mr. Geo. Meggeson.

DONATION TO THE MUSEUM.

A letter was read from Mr. Peter Squire, accompanying a specimen of Coca (*Erythroxylon Coca*), which he had been requested by Dr. Sieveking to present to the Society. The letter was ordered to be entered on the minutes, and thanks awarded to Dr. Sieveking.

The following letter was read from Dr. Flückiger, of Strassburg, and ordered to be printed :—

"Strassburg, 20th Feb., 1874.

"Dear Sir,—I beg to return my best thanks to you and the Pharmaceutical Society of Great Britain for PHARMACEUTICAL JOURNAL, 1870, 1871, 1872, 1873, kindly sent, and since continued, to the library of the Pharmaceutical Institution of our University.

"I hope that members of your Society, or students, desirous of becoming a little acquainted with the scientific part of pharmaceutical education in this country, will be so kind as to call on me and to afford me the opportunity of proving my grateful feelings respecting English pharmacy, to which I am so much indebted.

"Believe me to remain, dear Sir,

"Yours very respectfully,

"Professor FLÜCKIGER,

"Director of the Pharmaceutical Institution.

"Thomas Hyde Hills, Esq.,

"President of the Pharmaceutical

"Society of Great Britain."

Mr. GREENISH said he was sure any English pharmacist visiting Strassburg would meet with a very kind reception from Professor Flückiger. Only the previous week he had received from the Professor a copy of his very interesting paper on Buchu leaves, a translation of which had appeared in the PHARMACEUTICAL JOURNAL. The original paper, however, was illustrated by two beautiful drawings, which assisted greatly in the comprehension of the details. He hoped that at one of the Society's evening meetings the Professor of Botany might be induced to point out, by means of a black board, the principal results of Professor Flückiger's investigation.

Mr. SUTTON also spoke from personal experience of the kindness with which Professor Flückiger received English visitors connected with pharmacy.

HONORARY MEMBERS.

Mr. SANDFORD drew attention to the fact that any gentleman who desired to propose the election of honorary members must put the names on the list during the following month. He gave notice of his intention to propose Professor Bentley.

Mr. SCHACHT said if no objection were made, which he did not apprehend, he should propose the name of Dr. Porter Smith, who had been a donor to the museum, and always showed himself ready to impart any information he possessed.

The following being duly registered as Pharmaceutical Chemists, were respectively granted a diploma stamped with the seal of the Society :—

Cooke, William Kendle.
Pank, Philip Durrell.
Roach, Herbert William.
Savage, John Welch.

ELECTIONS.

MEMBERS.

Pharmaceutical Chemists.

The following Pharmaceutical Chemists were elected Members of the Society :—

Cooke, William Kendle .....Holt.
Galloway, George Ross.....Inverness.
Roach, Herbert William .....London.
Savage, John Welch..... .....Wells, Somerset.

Chemists and Druggists.

The following registered Chemists and Druggists were elected Members of the Society :—

Balkwill, William Hancock.....Kingsbridge.
Carr, John.....Hamilton, Canada.
Jones, Henry.....Wimborne Minster.
Miller, Thomas Stark ....Broughty Ferry.
Sirett, Henry.....Brackley.
Williams, Thomas Howell .....London.

ASSOCIATES.

The following, having passed their respective examinations, and being in business on their own account, were elected "Associates in Business" of the Society.

Minor.

Dunston, Alfred .....Timberland, nr. Sleaford.
Lloyd, Edward ... .Abergele.
Peach, Richard Walter .....Donington.
Sale, Thomas John .....Lowestoft.
Sykes, Edwin John .....Buxton.

Modified.

Barlow, George Edward .....Pocklington.
Macdonald, John .....Old Swan, Liverpool.
Thirlby, William .....Leicester.

The following having passed their respective examinations, were elected "Associates" of the Society :—

Minor.

Agger, Joseph Edward.....King's Lynr.
Bladon, William George .....Cheltenham.
Bolt, Richard Taunton.....Tavistock.
Broomfield, Robert William ...Harrogate.
Budworth, William Seth .....Bolton.
Capes, John Henry Cooper .....York.
Cole, Edward Henry.....Leeds.
Donald, David .....Perth.
Evans, Evan Thomas .....Carmarther.
Feaver, John.....Truro.
Fisher, Sidney .....Wolverhampton.
Gibson, James ....North Shields
Green, Alfred .....Wakefield.
Herbert, John .....Kingston-on-Thames.
Holgate, Sam Verity .....York.
Jesser, Alfred Henry ....Southampton.
Kemp, George ....Birmingham.
Martin, John Wesley ... .Stratford.
Parminter, Urban.....Exeter.
Polley, John .....Chester.
Shaw, Stephen .....London.
Stamford, Frederick.....St. Austell.
Symonds, Henry ....Norwich.
Thompson, Frank Farrow .....Cambridge.
Wardley, Samuel Frederick.....Lowestoft.
Warren, Francis William.....Weston-super-Mare.

Modified.

Bradsley, Joshua .....Glasgow.
Penrose, Thomas Samuel.....Launceston.
Wavell, William John .....Brighton.

The following having passed the Preliminary Examination, were elected "Apprentices or Students" of the Society :—

Allwork, Frank .....Brighton.
Bathe, Frederick James .....Chippenham.
Bevan, William.....Ipswich.
Brasnett, Robert John.....King's Lynn.
Cant, Hemington .....Stratford.
Dixon, Richard Dobson .....Sharow.
Embley, John .....Brierfield.
Ford, Robert .....Plymouth.
Gallienne, W. J. Norman .....Torquay.
Greenwell, Alexander John.....Newark.

Hardwick, Arthur.....Sheffield.
Harman, Arthur .....St. John's Wood.
Harpham, John.....Newark.
Harsley, John William.....Sheffield.
Hartlande, Charles .....Oldbury.
Hart, James .....Sunbury.
Hay, Richard Mayman.....York.
Horton, Thomas .....Peterborough.
Hunt, Tom George .....Snaith.
Jones, Thomas Glynne.....Llanidloes.
Jones, John Thomas.....Pembroke.
Lec, Alexander Milne .....Strichen.
Matthews, Arthur.....Bristol.
Mead, Charles John .....Wimborne.
Munrow, Hugh.....Hampton Wick.
North, Josiah .....Reading.
Nowell, Barns .....London.
Pollard, George Frederick .....Burnley.
Porteous, William Nicol .....Edinburgh.
Poulton, Arthur .....Newton Abbot.
Reade, Leonard James.....Wolverhampton.
Stahr, Victor Emanuel .....London.
Townsend, Joseph Edward .....Peterborough.
Thorpe, Henry Stanley .....Hertford.
Whyte, Alexander .....London.
Wood, Edward James .....Reading.
Wright, Robert.....South Shields.

The name of William Robert Jones, of 6, Belvedere, Runcorn, Cheshire, was restored to the register.

The following were appointed Local Secretaries for their respective towns :—

Hogarth, William.....Preston.
Robinson, Alfred Francis .....Darlington.
Sant, George .....Woodstock.
Grindley, William.....Chester.

Finance.

The report of this Committee was read and adopted, and sundry accounts were ordered to be paid.

Benevolent Fund.

The report of this Committee was read ; it contained a circular which had been drawn up by the special Committee to be sent to the trade, and recommended the following grants to be made :—

To an aged chemist and druggist residing at Kelvedon, in Essex, £10.

To the widow of a chemist and druggist residing at Leeds, £20.

An application from another widow, residing at Bristol, which had not arrived in time to go before the Committee, was mentioned by Mr. Stoddart, and after a short discussion, a grant of £10 was made in this case also.

The name of Edwin Markland, of Kelvedon, Essex, was ordered to be placed on the list of approved candidates for annuities.

Library, Museum, and Laboratory.

The report of this Committee was read. It recommended the purchase of the following books :—'Miller's Elements of Chemistry,' 'Lindley and Moore's Treasury of Botany,' 'Armstrong's Organic Chemistry,' 'Schorlemmer's Chemistry of the Carbon Compounds,' 'Wight's Icones Plantarum Indiæ Orientalis.'

It appeared that the average daily attendance in the library was 14, and in the evening 2·45. The report and recommendations were adopted.

House.

The report and recommendations of this Committee, which simply dealt with certain small repairs, etc., to the premises, were received and adopted.

The Jacob Bell Memorial Scholarships.

A letter was read, asking if a young man might be allowed to compete for the Bell Scholarship, notwithstanding that he could not comply with the regulations as recently amended. One of the grounds of his application was that, owing to deafness, he intended to leave the practical business of pharmacy, and study scientific chemistry as a profession. The Secretary was directed to reply that the Council could not admit the applicant to compete except in accordance with the regulations.

Pharmaceutical Congress at St. Petersburgh.

A report was read from the Committee appointed at the Council at their last meeting to consider the following letter :—

"*The Organization Committee of the Fourth International Pharmaceutical Congress in St. Petersburgh*, 1874.

"[No. 3.]

"15th January, 1874.

"To the Pharmaceutical Society of Great Britain.

"At the sitting of the International Pharmaceutica Congress at Vienna, on 10th September, 1869, the next session was fixed for the year 1872, and St. Petersburgh chosen as the place of assembly. From motives of expediency, and in accordance with the wish of several foreign societies, the Congress was, however, postponed till 1874.

"After overcoming all opposition, and with the highest sanction to holding the same, the Organization Committee, in the name of the Pharmaceutical Society of St. Petersburgh, gives notice to your esteemed Society that the fourth International Congress of Pharmaceutical Societies and Unions will take place in St. Petersburgh in August, 1874.

"The following questions have been submitted for discussion :—

"1. How far the personal responsibility of the pharmaceutist extends in executing the duties of his calling.

"2. What would be the best mode of organizing the Apothecaries' Committee of Revision.

"3. Is it necessary that the pharmaceutical professorship should be held by a pharmaceutist ?

"4. Has not the time arrived for instituting an international pharmacopœia ?

"In case your esteemed Society would wish to submit any further question, you are requested to send the same to the Committee before the 15-27th March next, in order that the ministerial sanction to these questions may be obtained, and the programme of the Congress published in time.

"(Signed)

"The President of the Organization Committee,

"H. Schroeder.

"Secretary, E. Rennard.

The Committee reported that they were not able to suggest any questions for discussion at the Congress in addition to those already named ; but they were of opinion that it was desirable to send a representative or representatives to the Congress at St. Petersburgh, in August, 1874.

Mr. Schacht inquired on what grounds the Committee recommended the sending of a deputation to the Congress.

Mr. Williams said he had voted against the proposition in committee, but the grounds upon which it was carried were, that it would be only right, graceful, and proper that a deputation should go to St. Petersburgh, to show the interest taken in England in foreign pharmacy, and, if possible, to give the Pharmaceutical Society and its members the benefit of a report as to the character of Russian pharmacy. The question of the formation of an international pharmacopœia was one which no doubt might usefully be discussed, though his own opinion was against such a proposal at present, except probably in a very modified form, and having reference only to a limited number of very powerful drugs or preparations.

Mr. HAMPSON, as one of the Committee who had voted in favour of a representative going to the Congress, said he understood the opinion of the Council at the previous meeting was almost unanimous in favour of such a step. He would therefore only very briefly state the grounds on which he supported it. In the first place, he thought it desirable to send a representative for the sake of showing a national friendly spirit, but beyond that it was also desirable that the Society should be represented, and that our representative should, when necessary, give an opinion on the points brought under discussion. He understood the German pharmacists, when occasion served, always showed a very friendly feeling towards this Society; and when previous conferences had met without English representatives being present, their absence was openly referred to with regret. It was difficult to estimate the exact value of the step, but on the face of it it seemed very desirable.

Mr. SCHACHT said there was no doubt a great deal in the observations just made, which every one must cordially agree with; but with regard to the question of an international Pharmacopœia, he thought it was entirely a matter for the future, and questioned whether there were ten pharmacists in the whole of England who had formed any opinion upon the subject. On that ground, therefore, it was quite unnecessary to send a deputation. Taking the general desirability of such a thing as being admitted, it was a question whether they could afford the expense; and as at a committee meeting on the previous evening a proposal for taking certain steps in the direction of education had been postponed until the balance-sheet was prepared, in order that it might be clearly seen what the financial position of the Society was, he should certainly feel disposed to oppose the grant for any purpose likely to lead to such problematical good as the suggestion now brought forward. He meant no disrespect whatever to the Committee who had made the recommendation, in asking to let the matter stand over, as other matters had to do, for a short time.

Mr. GREENISH could not think the discussion at the Congress would be limited to the four questions of which they had heard. At the first three Congresses it was very much regretted that their Society was not represented. If Spain, Italy, France, and Austria could each send representatives to such a conference, surely Great Britain should not be unrepresented there. Considering the advance of pharmaceutical education in this country during recent years, he thought the time had arrived when the British pharmacist should take his position abreast of his colleagues on the Continent.

Mr. SANDFORD said they had sent a deputation to Vienna on a former occasion, but he never heard that anything particular came of it.

Mr. GREENISH said that the Journal of that date contained the remarks made by their representatives at that Congress.

After some further discussion, the recommendations of the Committee were received, but not adopted, with the view to the matter being further considered before a decision was arrived at.

PARLIAMENTARY.

The report of this Committee was read, recommending that proceedings be taken in the case of a person who had infringed the Pharmacy Act. The Solicitor was now in attendance, and read the case and opinion which had been submitted to the late Attorney-General and counsel, with reference to several points arising out of the Adulteration of Food and Drugs Act. It was a somewhat lengthy document, and after its perusal an animated discussion arose as to the desirability of publishing it in the Journal. It seemed, however, to be the general opinion that it would be more likely to mislead members of the trade than to give them really useful information; and it was ultimately resolved—

"That the case and opinion be open, in the discretion of the Secretary and the Solicitor, for the use of chemists and druggists when threatened with or actually defendants to proceedings under the Adulteration Act."

Mr. HAMPSON thought a more practical course of action would be for the Parliamentary Committee to meet and consider whether something could not be done in influencing the present Government to alter the Adulteration Act. There was no doubt that amendments would be brought forward in the new Parliament, which met to-morrow; and they ought not to allow any opportunity to pass without doing what they could to procure such alterations as seemed desirable.

Mr. SANDFORD thought Mr. HAMPSON'S suggestion a very good one, and would be very happy to second a resolution to that effect. It was then resolved unanimously—

"That the Parliamentary Committee be requested to consider the objectionable points of the Adulteration Act as affecting chemists and druggists, and that they at the earliest convenient time take steps to represent to the Government the objectionable points of the Act of Parliament, and urge upon the Government the necessity of their amendment."

The report of the Committee was then received and adopted.

POISONING BY VERMIN-KILLER.

Mr. SUTTON took the opportunity while the Solicitor was present, to ask him a question with regard to a poisoning case which had recently taken place before the magistrates on the borders of Suffolk, where a woman had attempted to poison a child with a vermin-killer obtained from a veterinary surgeon, which contained strychnia. Fortunately vomiting set in, and the child was not killed; but it appeared that the person who sold the poison made no entry of the sale, and did not appear to be aware of the obligation to do so. When the trial came on, he would most certainly be asked how it was possible for persons to get poison in that way, and he wished to know what steps should be taken to investigate the case, so as to punish the seller.

The SOLICITOR said the Society could proceed against the seller for infringing the Registration clause, but the police could proceed for selling the poison without conforming to the proper regulations. The Society always felt some reluctance to proceed in these cases, especially where a veterinary surgeon was concerned.

Mr. SUTTON said the magistrate had asked him about it, and he had given it as his opinion that the police should be directed to take action in the matter.

The SOLICITOR said that was the proper course to be adopted.

The VICE-PRESIDENT said it was important that it should be noticed in such a case as this that the Act did not allow veterinary surgeons to sell poisons.

ADDITIONAL SCHOLARSHIPS.

The report of the Special Committee appointed to consider the proposal for instituting additional scholarships was read. It stated that, after much discussion, it was deemed necessary to have definite information as to the probable income and expenditure of the Society in future years, before coming to any resolution upon this point, and instructions, therefore, had been given for the necessary statement of account to be prepared. The Committee, however, recommended that the limit of age for the Jacob Bell Scholarship should be altered from 21 to 22.

Mr. SCHACHT said it was much against the wishes of some of the members of the Committee that the question had been postponed, but it was done in deference to the very strong expression of two of the officials with regard to the probable income of the Society in future. He was very glad to find, therefore, from the balance-sheet, which was just about completed, that during the past year there had been a purchase of Government securities to the amount of £2500.

The report of the Committee was then received and adopted.

PRELIMINARY EXAMINATIONS.

The Committee appointed to consider the new regulations for conducting the Preliminary Examinations reported that they had had considerable correspondence in reference thereto, and the replies from all the centres appointed had been satisfactory, with the exception of Newcastle-on-Tyne, in which town no person had been found to undertake the duty of superintendent. The Committee recommended the addition of Aberystwith to the list of centres already approved by the Council.

They also recommended, that the consideration of the method of conducting the Preliminary Examination in Scotland be deferred until after the deputation from the Board of Examiners in Scotland visited London in the course of the present month.

The SECRETARY said that of the superintendents recommended for appointment, fifty-five were members of the Society and pharmaceutical chemists, and four members chemists and druggists. The deputies named were—Thirty-five members, pharmaceutical chemists; eight members, chemists and druggists; one associate in business; two pharmaceutical chemists not members; nine chemists and druggists not connected with the Society; and two persons not on the register of chemists and druggists.

The report and recommendations of the Committee were received and adopted, and the following appointments were made:—

SUPERINTENDENTS OF EXAMINATIONS.

England and Wales.

Barnstaple	Goss, Samuel.
Berwick-on-Tweed	Carr, William Graham.
Birmingham	Southall, William.
Boston	Marshall, Robert.
Brighton	Gwatkin, James T.
Bristol	Stoddart, W. W.
Cambridge	Deck, Arthur.
Canterbury	Bing, Edwin.
Cardiff	Cross, William.
Cardigan	Jones, J. E.
Carlisle	Thompson, Andrew.
Carmarthen	Davies, R. M.
Carnarvon	Lloyd, William.
Cheltenham	Smith, Nathaniel.
Chester	Grindley, William.
Colchester	Manthorp, Samuel.
Darlington	Robinson, Alfred F.
Doncaster	Dunhill, W. W.
Dorchester	Evans, A. J.
Exeter	Walton, Ralph.
Guernsey	Arnold, Adolphus.
Hereford	Jennings, Reginald.
Hull	Bell, C. B.
Jersey	Ereaut, J., jun.
Leamington	Jones, S. U.
Leeds	Reynolds, Richard.
Leicester	Cooper, Thomas.
Lincoln	Maltby, Joseph.
Liverpool	Abraham, John.
Lynn	Atmore, George.
Macclesfield	Bates, W. J.
Manchester	Wilkinson, William.
Northampton	Bingley, John
Norwich	Sutton, Francis.
Nottingham	Atherton, J. H.
Oxford	Prior, G. T.
Peterborough	Heanley, Marshall.
Plymouth	Balkwill, A. P.
Portsmouth	Rastrick, J. L.
Preston	Hogarth, William.
Reading	Hayward, W. G.
Salisbury	Atkins, S. R.
Scarborough	Whitfield, John.
Sheffield	Wilson, Edward.
Shrewsbury	Cross, W. G.
Southampton	Dawson, O. R.
Stafford	Averill, John.
Swansea	Brend, Thomas.
Taunton	Prince, Henry.
Truro	Serpell, Samuel.
Worcester	Witherington, Thomas.
York	Davison, Ralph.

Scotland.

Aberdeen	Davidson, Charles.
Dumfries	Allan, William.
Dundee	Hardie, James.
Edinburgh	Mackay, John.
Glasgow	Kinninmont, Alexander.
Inverness	Galloway, G. R.
Perth	Reid, Neil.

DEPUTY-SUPERINTENDENTS OF EXAMINATIONS.

England and Wales.

Barnstaple	Symons, William.
Berwick-on-Tweed	Carr, Robert.
Birmingham	Churchill, W. J.
Boston	Pilley, Henry Thomas.
Brighton	Savage, W. W.
Bristol	Schacht, G. F.
Cambridge	Church, H. J.
Canterbury	Amos, D.
Cardiff	Kernick, S. P.
Cardigan	Williams, John.
Carlisle	Hallaway, John.
Carmarthen	Davies, R. M., jun.
Carnarvon	Jones, John.
Cheltenham	Barron, William.
Chester	Hodges, William.
Colchester	Shenstone, J. B. B.
Doncaster	Shaw, Henry W.
Dorchester	Durden, Henry.
Exeter	Delves, George.
Guernsey	Collenette, A.
Hull	Baynes, James.
Jersey	Ereaut, John.
Leamington	Davis, Henry.
Leeds	Smeeton, William.
Leicester	Cooper, Henry.
Lincoln	Battle, John Scoley.
Liverpool	Shaw, John.
Lynn	Willis, Cottingham.
Macclesfield	Wood, Richard.
Manchester	Wilkinson, George.
Northampton	Mayger, W. D.
Norwich	Corder, Octavius.
Nottingham	Fitzhugh, Richard.
Oxford	Thurland, Henry.
Peterborough	Buckle, Frank George.
Plymouth	Balkwill, George.
Portsmouth	Rastrick, Robert J.
Preston	Barnes, James.
Reading	Timothy, T. N.
Salisbury	Orchard, E. J.
Scarborough	Fryer, Charles.
Sheffield	Ward, William.
Shrewsbury	Cross, W. G., jun.
Southampton	Spearing, James.
Stafford	Averill, Henry A
Swansea	Layng, Thos. B.
Taunton	Fouracre, Robert.
Truro	Richards, J. E.
Worcester	Virgo, Charles.
York	Cooper, Thomas.

Scotland.

Aberdeen	Kay, J. P.
Dumfries	Carruthers, R. B.
Dundee	Laird, William.
Edinburgh	Ainslie, William.

Glasgow ..... ,, Davison, Thomas.
Inverness..... Galloway, George.
Perth ..... Strang, Peter.

THE MUSEUM.

In pursuance of notice, Mr. HAMPSON moved:—

"That the Museum be opened from 9 a.m. until 5 p.m., and from 7 p.m. to 10 p.m., daily, except on Saturday, when it shall be open from 9 a.m. to 2 p.m., and that the Library and Museum Committee be requested to arrange for the carrying out of this resolution."

He said he brought this motion forward, feeling it was rather anomalous to have the library open in the evening, and the museum closed, and he was emboldened in the present course by the fact, that when the proposition for opening the library in the evening was considered, it met with the unanimous sanction of the Council. He was told, however, that the attendance at the library was not very good; but he thought it not unlikely, if the museum were opened also, it would lead to a much better attendance. Assistants were generally allowed certain evenings in each week, and this was very often the only time they could occupy themselves in reading special books or viewing museums of such a character.

Mr. GREENISH seconded the motion.

Mr. BOTTLE was sorry to differ from two gentlemen whose opinions he so much respected; but he thought this was not a movement in the proper direction at the present time, because he did not think it likely that the museum would be very much used, and there would be a considerable difficulty and expense in carrying out the arrangement.

Mr. ATHERTON did not think there would be any insuperable difficulty in arranging for some one to take charge of the museum in the evenings for the time required, and suggested that the matter should have a year's trial.

Mr. SHAW said it appeared this matter had not yet been brought before the Library, Museum, and Laboratory Committee. That would seem to be the proper course, because the Committee could discuss the matter fully, and consider what arrangements were necessary.

After some further discussion, the following amendment was proposed and carried :—

"That the matter be referred to the Library, Museum, and Laboratory Committee to consider and report to the Council."

REPORT OF EXAMINATIONS.

February, 1874.

ENGLAND AND WALES.

Examinations.	Candidates. Examined.	Passed.	Failed.
Major	4	4	0
Minor	79	34	45
	83	38	45

Certificates received in lieu of the Preliminary :—

University of Cambridge	4
Royal College of Surgeons	2
Society of Apothecaries	1
College of Preceptors	1
	8

The SECRETARY read a memorandum from the Board of Examiners, expressing their satisfaction at the efficient manner in which the Curator (Mr. Holmes) had replenished the specimens of Materia Medica and Botany used for the examinations.

NORTH BRITISH BRANCH.

The SECRETARY read a letter from the Secretary of the North British Branch, stating that the Council of their Branch had resolved to take larger and more convenient rooms at 119, George Street, Edinburgh, at an annual rental of £75, to which they would move at Whitsuntide term. The premises had been taken on lease for five years, with the option of leaving in three years.

PHARMACEUTICAL MEETING.

Wednesday, March 4th, 1874.

MR. THOMAS HYDE HILLS, PRESIDENT, IN THE CHAIR.

The minutes of the previous meeting having been read and confirmed, the following donations were announced, and the thanks of the Society awarded to the donors :—

A specimen of hydrochlorate of amylamine, from Mr. Robbins; some Bergamot oranges, from Mr. Clayton; some fine specimens of myrrh; an original bundle of Cannabis Indica; some nux vomica bark, from Mr. A. H. Squire; germinating cocoa-nut, from Mr. Hetherington.

The President drew attention to a specimen of Coca (*Erythroxylon Coca*), presented by Dr. Sieveking through Mr. Squire, and also to some photographs of Indian scenery, sent over by Mr. C. H. Wood, Quinologist to the Indian Government. They were exhibited by Mr. Baldock, F.C.S. Also to a book of botanical specimens, from Messrs. Butler and McCulloch, Covent Garden.

COCA.

Professor BENTLEY said it was well known that Coca, the botanical source of which was *Erythroxylon Coca*, had recently been recommended in this country by Dr. Sieveking as a new medicinal agent. Attention was first called to it by Spence, well known for his travels in South America, who described the leaves as being chewed by the natives, who attributed to them the most extraordinary properties. It was asserted that, by their use, a person was enabled to go a considerable time without food, and an enormous quantity was used in South America, as much, according to Johnston, as 30,000,000 lbs. annually. Other writers did not speak so highly of it as Mr. Spence; but there was no doubt it did possess some very powerful properties, not serving as a food, but still allaying the feeling of hunger. It was also used by mountaineers, who said it enabled them to reach high elevations without difficulty of respiration. Like most substances used in this way, it had injurious narcotic effects upon the constitution; and a new base had been discovered in it, to which the name *Cocaine* had been given. *Coca* had been used for some time on the Continent as a remedial agent, and to some degree in England; and several years ago he had called attention to it as being worthy of an extended trial.

NOTE ON A DECOMPOSED LOZENGE.

Mr. GREENISH then read a note on a decomposed lozenge. The paper is printed at p. 709, and gave rise to the following discussion :—

The VICE-PRESIDENT could not quite adopt Mr. Greenish's theory, because though he had noticed the decomposition described in ginger lozenges, he had never met with it in other lozenges. This seemed to show that it arose from some other cause than the decomposition of dextrin derived from starch. He had also found that this decomposition, which began with a few little specks and rapidly extended, was much more frequent when the lozenges were exposed to the air than when carefully stored in stoppered bottles. Indeed, by using care in this respect, there was little danger to be apprehended. It would be interesting to know whether similar decomposition had been noticed in other lozenges than ginger.

Mr. HAMPSON was disposed to coincide with Mr. Bottle's opinion, having also noticed the susceptibility of ginger lozenges to fungoid growths. This seemed to show that the decomposition arose from the ginger, and not from the starch dextrin used generally in the preparation of lozenges.

Mr. COOPER said he had noticed the same occurrence in

pepsine lozenges, for which he was totally unable to account.

A Peculiar Camphor from China.

Mr. Daniel Hanbury, F.R.S., then read a paper on "A Peculiar Camphor from China." This was followed by a paper on "The Chemistry of Ngai Camphor," by Mr. Sydney Plowman. The papers are printed at pp. 709 and 710, and gave rise to the following discussion :—

The President, in inviting discussion on Mr. Plowman's paper, said it was very pleasing to see students in the laboratory coming forward with papers of this practical kind, and he hoped they would have many such in future.

Mr. Moss said Mr. Plowman had gone very thoroughly into his subject, and had shown that in many respects Ngai camphor was identical with Borneo camphor, whilst in some others it differed from the latter ; but there was one important character which he had not investigated, viz., the action of an alcoholic solution on the plane of a ray of polarized light. Common laurel camphor rotated the ray to the right, and so did Borneo camphor; this new variety might or might not do the same. If he understood rightly, Mr. Hanbury referred Ngai camphor to a composite plant, and it was known that from the volatile oil of feverfew flowers, there was deposited a camphor, which, though it had precisely the same composition as laurel camphor, rotated the ray to the left. It might therefore be that the Ngai camphor, though it had the same composition as the Borneo, might rotate the ray to the left, so that in this one natural order (*Compositæ*) there would be two camphors, one bearing the same relation to Borneo camphor as the other did to laurel camphor. Mr. Plowman had determined the specific gravity in a very ingenious manner ; but perhaps he might have managed it with less trouble by fusing a little in a spherical mould, introducing a horsehair into it whilst melted, and subsequently weighing the cooled and solidified globule in the ordinary way.

Mr. Plowman said it had occurred to him to perform the experiment with polarized light, but it would have been almost impossible to do so without sacrificing the whole of the camphor at his disposal. With regard to the specific gravity, the objection to Mr. Moss's project would be, that the specific gravity of Ngai camphor was so very near to that of water itself, that a fair quantity must have been used. Moreover, in weighing it in water, it would have been difficult to secure free play of the balance, so that he doubted whether his own method were not more trustworthy.

Professor Attfield thought the remarks of Mr. Moss were very useful, and would no doubt lead Mr. Plowman to continue his researches when he obtained more material. The biological and chemical relations, which Mr. Moss had alluded to, were very interesting ; indeed, his own impression of the usefulness of the paper was pretty much that suggested by what had fallen from Mr. Moss, namely, that it would throw light on the isomeric relations of the different camphors. It certainly seemed probable, from the results which Mr. Plowman had obtained, that this Ngai camphor was the twin-brother of Borneo camphor, just as feverfew camphor was the twin-brother of ordinary laurel camphor. Researches of this kind had more than pharmaceutical or therapeutical interest, for they were researches into a domain of chemistry which had not been much explored until recent years—a domain in which they found substances extremely closely allied, but not identical. A former Bell scholar of the Society, Mr. Pedler, had thrown light on compounds similarly related, in a research which might briefly be described. Some years ago, M. Pasteur found that ordinary fusel oil, amylic oil, was really composed of two distinct amylic alcohols, resembling each other in chemical properties, but differing in their action on a ray of polarized light, the one turning the ray to the left, the other having no action on the ray. Mr. Pedler, reflecting on this fact, was able to harmonize the apparently contradictory observations and statements of eminent chemists. Frankland and Duppa had noticed that valerianic acid, the oxidation product of amylic alcohol, had a strong action on polarized light, whilst a previous observer, Wurtz, had found that valerianic acid had no action on polarized light. It occurred to Mr. Pedler that probably one observer had prepared his valerianic from the active amylic alcohol, and the other from the inactive. Forthwith, Mr. Pedler set to work to produce the two amylic alcohols in the pure state, separated them from each other, and prepared from each some valerianic acid. The two specimens of acid, identical in all common properties, he then examined, and, sure enough, found that valerianic acid obtained from rotatory amylic alcohol was itself rotatory, whilst that from the non-rotatory alcohol was non-rotatory. So in the case of the camphors. There was ordinary laurel camphor which rotated the ray considerably to the right, whilst its twin-brother, the feverfew laurel camphor, turned the ray in the opposite direction. Further, when the two were oxidized by nitric acid, you got two camphoric acids, each of which twisted a ray of plane polarized light, the dextro-rotatory camphor giving dextro-rotatory camphoric acid, whilst the other gave levo-rotatory camphoric acid, a mixture of the two acids being, as might be expected, inactive. By acting on Borneo camphor with nitric acid, as Mr. Plowman had said, you got an oil, which, in contact with water, gave you ordinary camphor; and, by similarly acting on Ngai camphor, an oil resulted, which, in contact with water, gave what apparently was ordinary camphor. Now he (Professor Attfield) would venture to predict that the camphor obtained by oxidation and hydration from Borneo camphor would differ in its action on polarized light from that which was obtained by the action of nitric acid and water upon Ngai camphor. He would not be surprised if the one product thus obtained proved to be common laurel camphor, and the other fever few laurel camphor. At all events, he thought Mr. Plowman would find the Ngai camphor and its products to be isomers of Borneo camphor and its products, and hoped that gentleman would continue his researches, and carry them out to the utmost limit.

The Dispensing and Storing of Hydrocyanic Acid.

A note by Mr. F. Baden Benger was then read, "On a Proposed Method of Storing and Dispensing Small Quantities of Hydrocyanic Acid." The paper is printed at p. 712, and gave rise to the following discussion :—

The President said this was an interesting paper, because these little points of practice were always valuable. He should like to know if any gentleman had seen such an arrangement before.

Mr. Umney said it was quite new to him ; he did not think it would meet with much favour with wholesale houses, on account of the difficulty in packing it safely.

Professor Attfield said another objection occurred to him, viz., that the mercury in which the point of the tube was placed might get upset; and if it were not replaced, the risk of alteration of the acid might be greater than before. This, however, might be avoided if, instead of placing the vessel in a cup of mercury, an india-rubber cap were placed over a thicker quilled extremity. The tube might also be graduated with five-minim or ten-minim marks.

The President then read the letter from Professor Fluckiger which appears in the proceedings of the Council.

Researches.

The President, in terminating the proceedings, said he hoped they should have more papers from students in the laboratory of a similar character to that just read by Mr. Plowman.

Professor Attfield said he hoped so too, but that unfortunately very little inducement was held out to students to do more than acquire sufficient practical chemical knowledge for the purposes of every-day pharmacy. It was extremely seldom that a pupil stayed long enough in the Society's laboratories to conduct the simplest gravimetric

analyses. Even the Bell scholars, who commenced with some knowledge of chemistry, and who worked for a whole session, could not be expected to reach the confines of chemical knowledge in ten months, much less attempt any exploration of regions previously unknown. Of Senior Bell scholars something might be expected; but, unfortunately for research, at the close of Mr. Plowman's tenure, the Senior Scholarship would cease to exist.

NORTH BRITISH BRANCH, EDINBURGH.

A meeting was held in the Society's Rooms, St. Giles Street, on Wednesday evening, 25th Febuary, at half-past 8 o'clock. There was a good attendance. Mr. J. R. Young, President, in the Chair. Dr. M'Kendrick, Assistant-Professor of Physiology in the University, gave an address on the Chemistry of certain Physiological Processes which take place in digestion, nutrition, and excretion. After showing that both physical and mental work resulted in the waste of the tissues, Dr. M'Kendrick said that in order to make up for that waste it was absolutely necessary that new material should be introduced into the body. That was the physiological explanation of the necessity of food. He then enumerated the various quantities of the different kinds of food required to maintain a man whose work entailed an average waste of material, and explained that milk, by which the young of all mammals were at first nourished, was a typical food, because it contained a due proportion of all the constituents essential to proper food. Having then examined the chemical action of the saliva, the gastric juice, the bile, and the pancreatic and intestinal juices in disintegrating and preparing for absorption the material of the food, and having given a brief outline of the chemistry of the blood and a description of the channels for removing the products of the several processes, he concluded by remarking that he had said sufficient to show that a great many of the functions of the body were, after all, purely chemical and physical processes, and that just as physiologists had been able to apply exact methods, physical and chemical, to the observation of the subject, had they been advancing in their knowledge of physiology. It was at one time supposed that all these were vital actions dependent upon vital force. No doubt they were concerned with vitality; but digestion, respiration, and even nutrition, to a certain extent, might be regarded as chemico-physical processes.

A hearty vote of thanks was passed to Dr. M'Kendrick for his interesting and instructive lecture.

The Secretary drew the attention of the meeting to the alterations connected with the examinations, some of which were to come into operation on 1st October, 1874, and on 1st January, 1875, also on 1st January, 1877. He further mentioned that having recently been supplied from London with full printed particulars as to the nature of those changes, he would be glad to supply copies to all those who wished for them.

The Year Book of Pharmacy, and three monthly numbers of the Pharmacist from Chicago were laid on the table as presentations to the Library of the Society in Edinburgh.

Provincial Transactions.

BRISTOL PHARMACEUTICAL ASSOCIATION.

At the January Friday evening meeting, Dr. Porter Smith gave a discourse on "Chinese Medicine and Pharmacy." The subject was illustrated by a large number of specimens of Chinese materia medica collected by Dr. Smith during a lengthened residence in Central China. This collection now forms part of the museum in Bloomsbury Square, and was kindly lent for the occasion by the Council of the Pharmaceutical Society. We hope soon to have the opportunity of presenting Dr. Smith's highly interesting paper in the pages of this Journal.

At the evening meeting, held on Friday, February 15th (Mr. Schacht, the President, in the chair), a lecture on Ozone was given by Dr. Watts, F.C.S., of Oxford.

Abstract of Lecture on Ozone.

BY DR. WATTS, F.C.S.

About the year 1785, Van Marum, having the opportunity of working with the great electrical machine belonging to the Teyler Museum (Geneva), occupied himself in performing again the experiments of Priestley and Cavendish, and studied the action of the electric spark upon various gases. His work, which was extensive, and published in several volumes, was unfortunately wholly empirical; neither were his observations accompanied by any deductions, theoretical or otherwise, likely to further the advancement of chemical or physical science. However, he noticed as a fact that the passage of the electric spark through atmospheric air or oxygen developed in the gas a peculiar odour, and that the gas thus electrized was capable of attacking mercury. To use his own words: "Oxygen standing over water experiences *no* effect on electrization, but the gas acquires a very strong odour, which appears to me to be very distinctly the odour of the electric fluid." It is, therefore, to the sagacity of Schönbein, who fifty years later, 1840, re-discovered this odorous gas of Van Marum, that we are really indebted for the first recognition of ozone as a distinct variety of matter. He observed that the oxygen gas resulting from the decomposition of water by the action of a powerful electric current possessed an odour similar to that which had previously been noticed by Van Marum, and he succeeded in establishing the facts that a body not necessarily identical, but possessing similar properties, was formed under the three following conditions:—1. When electric sparks are passed through air. 2. By electrolysis. 3. When certain bodies, especially phosphorus, are slowly oxidized in air or oxygen. He therefore discovered the most important means for the production of ozone, and, as an after-work, established its principal properties and reactions. The properties of ozone are now very generally known. It liberates iodine from potassium iodide; discharges vegetable colours; oxidizes metals; converts many metallic protosalts into persalts; and exerts generally an energetic oxidizing power.

At this period it was not known that the reactions of ozone resulted simply in the oxidation of the substance submitted to its influence; but in 1845 Marignac and De la Rive showed that the final result of its action upon potassium iodide was potassium iodate; that manganese oxide was produced from the corresponding chloride, etc.; and from such evidence they drew the very legitimate conclusion that ozone was, as regards its constituent matter, probably identical with ordinary oxygen. Their opinion was very materially strengthened by the succeeding investigation of Fremy and Becquerel (Annales de Chimie [3], xxxv. 62), who, while verifying the whole of Marignac's work, succeeded in converting pure oxygen entirely into ozone. This they effected by passing the electric spark through the gas, the latter being in contact with solution of potassium iodide; in this manner the ozone was constantly decomposed with liberation of iodine, while the oxygen gas gradually disappeared.

Schönbein was now obliged to reject his original opinion that ozone was a new elementary body, but at the same time he refused to adopt the conclusion of Marignac and of Fremy and Becquerel, that it was oxygen which had assumed, under the electric influence, a particular condition of chemical activity. He preferred, on the contrary, to erect an interpretation of his own, which was at that time not only wholly unwarranted by analysis, but in direct contravention of some of his own experiments, viz., that ozone was a peroxide of hydrogen. This assumption was for a long time supported by the experiments of Williamson in England, who found *water* in the products of the decomposition of ozone by heat;

and also by those of Baumert in Germany, who endeavoured to show that the weight of oxygen absorbed by a solution of potassium iodide did not correspond with the theoretical weight calculated from the proportion of iodine liberated.

The absolute freedom of ozone from any proportion of hydrogen was, however, definitely established in 1856 by Professor Andrews, of Belfast, with whose work a new era opens in the history of ozone. Having pointed out the causes of error in Williamson's and Baumert's experiments, he first showed that the weight of oxygen absorbed and amount of iodine liberated did exactly correspond; and afterwards, in 1860, in conjunction with Professor Tait, published a series of precise quantitative experiments, which were more successful in unravelling the question of the constitution of ozone than those of any chemist who had preceded them.

1. Their first point was that oxygen under the electric influence contracted in volume, and that the gas when thus contracted gave the reactions peculiar to ozone. That the contracted gas, when submitted to a heat of about 300°, re-expanded to its original volume, while at the same time the ozone reactions disappeared. 2. That the amount of iodine liberated from a solution of potassium iodide, by bringing the ozonized gas in contact with it, exactly corresponded to, or was the exact chemical equivalent of, a weight of oxygen, equal in volume to the amount of contraction after electrization; and hence that the contraction of any given volume of gas could be ascertained, without actual measurement, by estimating the quantity of iodine which it was capable of liberating. 3. That the absorption of oxygen from the ozonized gas was unattended by any further contraction in volume. Andrews and Tait succeeded in deducing no satisfactory chemical expression for the composition of ozone, but shortly afterwards Dr. Odling put forward the suggestion that, inasmuch as the formation of ozone was attended with contraction of the original oxygen, and inasmuch as there were satisfactory reasons for supposing the molecule of ordinary oxygen to be already composed of two atoms, the *simplest* constitution which it was possible to assign to the molecule of ozone was that it was formed by the addition of a third atom to the previously existing oxygen molecule, and to represent it by the expression O_3=2 vols. It will be seen that upon this supposition all the phenomena observed by Andrews and Tait are satisfactorily explained.

In 1872 Sir Benjamin Brodie published in the *Philosophical Transactions* the result of nearly fourteen years' work on "the action of electricity upon various gases," a large portion of which time was devoted to the study of the quantitative reactions of ozone. Operating with the then newly-devised induction tube of Siemens, he succeeded in ozonizing oxygen to a much greater extent than had hitherto been possible; and employing a novel arrangement of gas pipette, he was enabled to measure and transfer, without loss, different volumes of this eminently alterable gas. Soret had shown in 1865 that when oil of turpentine or cinnamon was brought into contact with ozonized, and consequently contracted, oxygen, that further contraction took place, and that apparently the whole molecule of ozone was absorbed; but he failed to show that the final diminution was *exactly* twice the initial contraction, which would have been the case if Odling's suggestion were correct. Brodie's experiments afford precise information upon this, as well as upon most other points in connection with ozone. Using sodium hyposulphite, he found that the ratio of the entire diminution in *volume* suffered by the original oxygen to the diminution in *volume* of the electrized oxygen, was, as a mean of twenty-seven experiments, 3·02 to 2·02, and the same numbers were obtained when turpentine was employed. By employing stannous chloride, he ascertained that the *weight* of oxygen absorbed from the ozonized gas was exactly three times the *weight* of the oxygen absorbed from the same gas by potassium iodide. By these experiments the molecular formula of ozone, O_3, was finally and definitely substantiated.

The various points were illustrated during the lecture by experiment.

MANCHESTER CHEMISTS' AND DRUGGISTS' ASSOCIATION.

The third ordinary monthly meeting was held at the rooms of the Association on Wednesday evening, January 14th. There was a good attendance. It had been announced that no special paper would be read, but the proceedings would be of a conversational character.

The Chairman (Mr. W. S. Brown) gave a short address, in which he referred to the recent prosecutions under the "Adulteration of Food and Drugs Act," to the prospective alteration in the requirements of the Board of Examiners of the Pharmaceutical Society, and other subjects of interest to the meeting.

A general conversation then took place on the topics introduced by the chairman.

Mr. Louis Siebold exhibited a small balance of American manufacture, which he considered extremely suitable for pharmacists' use. It was sold at a very moderate price, and was nevertheless capable of being used in delicate analyses.

Mr. W. Wilkinson made some remarks on the phosphoretted tolu resin prepared as suggested by Mr. Abraham, jun. He had found that a small quantity of water was absorbed by the resin in the process. This fact had not been noticed in the published report of Mr. Abraham's communication.

Mr. Pidd had made some experiments in the hope of discovering an accurate method of determining the strength of dilute spirit by observing its action when combined with iodine on starch, but had failed to obtain very uniform results.

The fourth ordinary meeting was held in the Memorial Hall, Albert Square, on Wednesday evening, Feb. 25th. Mr. W. S. Brown, President, in the chair.

Tea was provided, and there was a large attendance of members and associates.

Mr. John Plant, F.G.S., delivered a lecture on "Coal: its Origin and Chemistry." The lecturer illustrated his subject by a remarkably fine collection of specimens, drawings, photographs, maps, etc., and his accurate knowledge of the subject, combined with a very happy delivery, rendered the lecture a great treat to his hearers.

A cordial vote of thanks having been awarded to Mr. Plant for his gratuitous services, the meeting terminated.

LIVERPOOL CHEMISTS' ASSOCIATION.

The ninth general meeting was held at the Royal Institution, February 12th, the President, Dr. Symes, in the chair.

The minutes of the previous meeting were read and confirmed.

Donations to the Library:—'Year-Book of Pharmacy,' and 'Proceedings of the British Pharmaceutical Conference at Bradford, 1873,' from the Executive Committee; current numbers of the Pharmaceutical Journal, etc., to the museum; a specimen of neutral iodide of potassium; six specimens illustrating the various stages in the manufacture of pure glycerine; also a specimen of crystallized glycerine, from Mr. Mason.

Mr. Alfred H. Mason, F.C.S., Vice-President, read papers on "Crystallized Glycerine," and "Croton Chloral."

Mr. Mason said:—At a time when the organ of the pharmaceutical profession deplores the lack of a single paper for the evening meeting of what we are pleased to call our parent society, it is somewhat a good sign to see two or three papers announced for our general meetings. In the subjects I am about to bring before your notice I do not aspire to any originality. It is scarcely to be expected in these days of high pressure in our daily duties

that we can do much in this way, but I think that if we take any given subject, glean all the information we can, and bring it forward in a concentrated form, even if it only calls up old remembrances to most of us, it must have a freshness for some; or if we watch the progress of any new therapeutical agent (some of us may have better opportunities for doing this than others), it may lead to healthy discussion, from which we may gain much information, and so conduce to the prosperity of our Association.

Crystallized Glycerine.

In a paper which I had the honour to read before you last session on Glycerine* I stated, taking high authority, that glycerine was uncrystallizable. This statement I must correct, and in substantiation call your attention to the specimen of crystallized glycerine which is presented to your museum. My attention was first drawn to this in a report† upon the articles exhibited in the Vienna Exhibition, which stated that "Sarg exhibited several glass vessels filled with some beautiful crystals of glycerine." The statement added—"Like phenoline, benzoline, and many other organic combinations, glycerine only crystallizes in a state of perfect purity, and the minutest foreign matter deprives it of this property; once in a solid state it will only melt in a high summer temperature. Under certain conditions the crystals attain a size which allows their angles to be measured." I have obtained a specimen of this glycerine,‡ which was supplied in a narrow-mouthed bottle, labelled, "*Krystallisirites Glycerin. Patent F. A. Sarg's, Sohn & Co.*" The result of my examination convinced me that absolute purity was not necessary to bring the specimen to the crystalline form in which it now exists. Being very hygroscopic, atmospheric influence of mean temperature is quite sufficient to liquefy it, and, once liquid, exposure to intense cold will not cause it to congeal. The peculiar mousey odour is present. Contact with calcic oxalate produces slight turbidity, and heated with sulphuric acid and absolute alcohol there is discoloration. The method of production, being patented, is a secret; it commands a fancy price. Its usefulness is questionable; as a chemical curiosity it is interesting.

In the discussion which followed, Mr. Martin Murphy, F.C.S., said the specimen was very interesting. He was of opinion that, as in carbolic acid, the presence of water was sufficient to prevent crystallization.

Mr. Edward Davies, F.C.S., said he had a specimen of carbolic acid, with one atom of hydration, which was in a perfect state of crystallization, and had been so for some months.

Mr. T. F. Abraham had observed a remarkable phenomenon, that if crystallized carbolic acid had become liquid from atmospheric influence, if the stopper of the bottle were just twisted tight, crystallization would again set in.

The President, Dr. Cooke, and others took part in the discussion.

Croton Chloral.

In this paper, Mr. Mason gave the chemical history, formation, and physical characteristics of croton chloral hydrate—its therapeutic value, dose, and pharmaceutical application.

An interesting discussion followed.

On the motion of Mr. Abraham, seconded by Mr. Murphy, an unanimous vote of thanks was conveyed to Mr. Mason for his communication, and carried with acclamation.

YORK CHEMISTS' ASSOCIATION.

The ninth annual meeting of this Society was held on Friday evening, the 20th of February, at the King's Arms Hotel, the President, Mr. George Dennis, in the chair.

The following report was read by the Secretary (Mr. T. W. Wilson):—

"During the past year your committee have held meetings and considered various questions affecting the welfare of the trade generally, and this Society in particular; and they have great pleasure in recording their satisfaction at the unanimity which has prevailed amongst the members.

"The Adulteration Act, introduced into the House by the Member for Birmingham, is now exciting great anxiety, and numerous prosecutions have been instituted throughout the country. Your committee have given this their serious attention, and it became a question with them whether some steps should not be taken to assist in protecting the interests of the whole body of chemists and druggists, and more especially the members of this Society. Seeing how multifarious are the articles dealt in by our trade generally, we are rendered particularly liable to prosecution at any time. Your committee have, however, thought it expedient to leave this question for the consideration of the annual meeting.

"The annual dinner, held on the 16th of April last, was in every way satisfactory, the heartiest good feeling and cordiality being manifested by all present. Your committee would recommend that a similar reunion be held at as early a date as convenient.

"The annual statement of accounts for the past year showed a balance in hand of the Treasurer (Mr. Thomas Cooper) of £4 19*s.* 3*d.* This is somewhat less than that of the previous year, which may be accounted for by the falling off of two or three members, and the death of another,—but the committee venture to express their satisfaction that this will bear favourable comparison with previous years."

The balance-sheet having been audited, a vote of thanks was accorded to the officials of the Society, who were unanimously re-elected. The annual dinner was appointed to take place on Tuesday, the 17th of March.

A long discussion ensued on the provisions of the Adulteration Act, and it was resolved—"That this Society present a memorial to the city Council, asking them to defer the appointment of a public analyst for this city until some alteration has been made in the Adulteration Act, and that communications be addressed to the city members asking for their co-operation in getting the Act revised, or a fresh bill introduced during the ensuing session."

Proceedings of Scientific Societies.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

The Adulteration of Butter.

On Saturday evening, January 17, at a meeting of the Society of Medical Officers of Health, held at the Scottish Corporation Hall, under the presidency of Dr. Hardwicke, a paper was read by Dr. C. Meymott Tidy upon "Butter and its Adulteration."

Dr. Tidy said that butter was generally prepared from cream collected from time to time and allowed to get slightly sour. It was then churned, or, in other words, rapidly stirred. The best temperature for churning was from 50 to 55 degrees Fahrenheit, and hence most churns had an outside vessel either to warm or to cool the apparatus as it appeared necessary. Churning should not be too slow, or the flavour of the butter would be entirely destroyed, nor too fast, or the butter would be soft and frothy. Butter was also made from fresh cream and from entire milk. This should stand until it was sour, and then be churned at a higher temperature than cream—namely, 60 degrees. More butter was obtained from entire milk than from cream, but there was more work in the churning and it took longer. Milk on an average yielded from 4·5 to 5·5 per cent. of butter, and it might be roughly stated that a cow yielded about one pound of

* Pharm. Journal, April 12th, 1873.
† *Chemist and Druggist*, July 15th, 1873.
‡ Kindly supplied by Messrs. Schmedes and Co., London.

butter daily. It was next taken out of the churn and washed with water, so as to get out the adherent whey. That operation was important, as the butter would otherwise decompose more rapidly. It was then salted, about 4 per cent. of salt being a fair quantity to be added. The amount of stearin, olien, and palmatin in the composition of butter was practically *nil*. The first adulteration of butter was water. Let them dry 100 grains of pure butter in a weighed capsule for several hours at 220 degrees Fahrenheit, and from 5 to 8 per cent. of water would be produced. Water was incorporated with the butter chiefly when it was in a semi-solid state, and also by beating out and sprinkling. He had been able thus to incorporate 28 per cent. of water with butter. Out of 130 samples of butter purchased at different shops in Kent seven contained from 7 to 9 per cent. of water, 21 from 9 to 10 per cent., 34 from 10 to 13 per cent., 42 from 14 to 17 per cent., 17 from 18 to 24 per cent., and 9 over 25 per cent. Thus, water might become a very serious adulteration of butter. It was his practice, when analysing butter in his capacity as public analyst, to state in his certificate the amount of water if over 10 per cent., and to leave the magistrate to draw his own conclusion. The next adulteration was salt. To trace this they should incinerate the remainder of the 100 grains used for drying. In 12 specimens of undoubtedly pure butter, the average amount of salt traceable was 5·2 per cent., and out of 27 samples of butter indiscriminately purchased he found that two contained less than 3 per cent. of salt, two between 3 and 4 per cent., three between 4 and 5 per cent., four between 5 and 6 per cent., ten between 6 and 7 per cent., two between 7 and 8 per cent., one between 8 and 9 per cent., two 10 per cent., and one 17 per cent. Over 7 per cent. of salt he considered excessive. Adulteration was also produced by the incorporation with butter of dripping, lard, suet, and other fats. These could not be mixed with butter when they were in a melted state, but only when they were cold, and hence the mixture was never perfect. The fats, unlike real butter, contained stearin, palmatin, etc., in considerable amount. To trace the presence of these fats let them note the melting and solidifying points. Butter melted upon an average at 75 degrees, and solidified at 63, dripping melted at 79·5, and solidified at 72·5, and suet melted at 82, and solidified at 75. Another test was the taste. The taste of real butter could be detected even when it had been most extensively mixed. Pure butter melted quickly on the tongue, and there was no sense of granulation, but when adulterated with other fats it melted far more slowly, and a peculiar granulated feeling in the mouth was produced as the last few grains disappeared. The odours of butter and of dripping were easily distinguishable, but the smell of lard when mixed with butter was not soon detected. Good butter was generally of a rich yellow colour, entirely uniform, but when adulterated the colour was very much paler, and it was marbled, owing to the imperfect admixture of other fats. He regarded streaky butter generally with suspicion. In good butter a uniform surface was produced by passing a clean knife rapidly over it, but impure butter had a granular appearance. Dr. Tidy concluded by describing other but more technical ways of detecting bad butter, such as the action of ether and the use of the microscope with polarized light.

At the instance of Dr. Hardwicke, the Society passed a cordial vote of thanks to Dr. Tidy for his interesting remarks on so important a subject.

A short discussion ensued, in which Dr. Stevenson, Dr. Bernays, and Dr. Tripe joined, and the general conclusions of the lecturer were confirmed. Dr. Bernays observed that from 5 to 6 per cent. of water undoubtedly improved butter, and the addition of more than 7 per cent. of salt would render it uneatable. When in a butter sold for 1*s.* per pound he found no less than 22½ per cent. of salt and water he could not think it cheap at the price.

The above report, which appeared in the *Times*, having been republished in *The Grocer*, has called forth a vigorous protest from a correspondent of the latter journal in respect to one statement that Dr. Tidy is reported to have made—namely, "That butter is generally prepared from cream collected from time to time and allowed to get slightly sour." Again, "That butter may be prepared from milk, which should stand until it is sour before being churned."

In the course of his remarks the writer says :—"Dr. Tidy, by his name and authority, licenses a practice which is, in fact, the principal cause of the quantity of vile stuff that is produced, and that people are condemned to see placed upon their tables in the form of butter. . . . . The difference between good butter and bad is generally the difference of preparing it from sweet cream or sour, and this means again the difference of a little increase of labour in making it frequently enough to ensure the cream being sweet. The best butter is that which is made every day from cream of only twenty-four hours' standing. . . . . I have, for the sake of experiment, made butter in every way that I have any knowledge of its being able to be made—with sweet cream, with sour, with cream skimmed from the milk, with milk and cream together after standing twelve hours or more, with milk almost warm from the cow, with raw cream, and with clotted cream. The result of my experiments is most undoubtedly to show that with all or any of these methods excellent butter can be obtained, except from the sour cream. It also has proved that not only is the butter very inferior that is made from sour cream, but that there is no advantage whatever to be gained by allowing it to become sour, except the slight save in the labour of making it more frequently. It yields exactly the same quantity of butter when sweet as when sour. Cream when sour becomes thick, and in churning the butter comes perhaps a little quicker than with sweet raw cream. But if a rapid and easy mode of churning be desired, it can be far better arrived at by following the Devonshire custom of scalding the milk, when the cream, which rises completely to the surface, becomes very thick on cooling, and can be made into butter in a few minutes in a basin, and by being stirred with a spoon I have seen butter come in two minutes and a half. Cream taken off a given quantity of milk scalded in this fashion yields exactly the same amount of butter as an equal quantity of the milk unscalded produces when churned unskimmed, showing that the whole of the butter is extracted from the milk by either method. Butter churned from sweet milk is excellent in flavour, and is perhaps superior to any other in texture, the large proportion of liquid in which the butter comes appearing to have the effect of working the particles together with more uniform smoothness. The process, however, entails such an increase of time and labour above that required for churning cream, and with a result in no way compensating for this expenditure, that few people, I should think, would use this method of making butter except those who adhere to it from old custom. . . . . The one great principle in the manufacture of good butter is the making it from cream the sweetest of the sweet. The mode of churning is entirely secondary."

Obituary.

THOMAS NEWBORN ROBERT MORSON.

Mr. Morson died at his residence, 38, Queen Square, Bloomsbury, on the 3rd instant, in the seventy-fifth year of his age. The announcement of the death of one so extensively known and respected, will, we are sure, be received with deep regret wherever the intelligence is conveyed, not only in this country, but abroad. Of English pharmacists there is perhaps none whose reputa-

tion has been so wide-spread as that of Mr. Morson, and there have been few, if any, who have acquired and maintained so high a character in the scientific department of pharmacy, especially as a manufacturer of what are called high-class chemicals.

He was born at Stratford-le-Bow, in the eastern suburb of London, and received his early education at Stoke Newington. Having lost his parents while he was yet young, and being left without family guardian or connections, he was thrown to a great extent upon his own resources; but he possessed within himself an endowment more valuable than worldly inheritance. With a mind remarkable for activity and power of perception he overcame the difficulties of his early life, became the founder of a business of world-wide reputation, and formed acquaintance, which ripened into intimate friendship, with some of the greatest chemists and philosophers of the age in which he lived. When only fourteen years of age he was apprenticed to an apothecary in Fleet Market (now Farringdon Street), but he had no liking for medical practice, and therefore adhered to the pharmaceutical rather than the medical and surgical part of the business he was placed in. His predilection lay in the direction of chemistry, and this was probably favoured by the circumstance of his being thrown into association with men of kindred tastes, who formed a little society for the investigation of scientific subjects, and whose meetings were held in the neighbourhood of Fleet Street. It was here he first made the acquaintance of Faraday, and acquired so strong a bent in favour of scientific chemistry, that he determined to make its application as far as possible the aim of his future pursuits. After the expiration of his apprenticeship he went to Paris, and entered the establishment of M. Planche, a pharmacien, with whom he lived for some years. He thus acquired a thorough knowledge of the French language as well as French pharmacy, and made the acquaintance of men whose friendship he cultivated in later years. He was still a young man when he returned to London and established himself in business as a chemist and druggist in the house in which he had been apprenticed, in Farringdon Street, the late proprietor, Mr. Morley, having retired from the retail department, which was previously associated with his practice.

The chemist and druggist of those days was generally a chemist only by name, but not so Mr. Morson. In a little room at the back of his shop was produced the first sulphate of quinine made in England, and the same may be said of morphia. Nor were these operations merely experimental. From entries in his ledger it appears that he supplied sulphate of quinine to a wholesale druggist at eight shillings a drachm, and morphia at eighteen shillings a drachm. His chemical knowledge and manipulative skill were now bringing him into notice, and he was frequently applied to for rare chemicals; but the premises in Farringdon Street did not admit of the cultivation of this branch of the business, which was, nevertheless, the most congenial to his taste. We have heard him say that he would probably have hesitated for many years before engaging more extensive premises (for he was naturally cautious and very averse to speculation), had he not been encouraged and supported in that step by the lady to whom he had just then united himself in marriage, and who with much spirit and judgment added ample pecuniary means. He moved from Farringdon Street to Southampton Row, and soon afterwards purchased premises in Hornsey Road, where he built a laboratory for the manufacture of creasote, morphia, and other chemical products. We need not further trace his career as a chemical manufacturer, for in this capacity he is everywhere known, at least by name.

But Mr. Morson's fame has not been merely that of a manufacturer. He was a man of enlarged mind and cultivated intellect. Thrown upon the world in early life, with absolutely no relations, he was, nevertheless, surrounded by men of talent and high position, with whom he associated on terms of mutual friendship. He was a member and regular attendant of the meetings of the Royal Institution, and a prominent member of the Society of Arts. His house was a place of resort for men of genius, where Graham and Fownes as chemists, Robert Brown, Bennett, Bowerbank, and Gray as naturalists; Muller, Johnson, and Cruickshank as artists; Richard Horseman Solly and Captain Bagnold as patrons of science and art, with many others of kindred tastes, found hospitable reception and congenial associations. A Sunday evening in Southampton Row or Hornsey Rise often afforded an opportunity for the social intercourse of men such as those we have named, who found ample scope for the discussion of their favourite topics in Mr. Morson's company.

We have hitherto referred to a time when pharmacy in this country had not yet quickened from the embryo state of its existence prior to the establishment of the Pharmaceutical Society. When vitality began to be manifested among the previously inert members of the disunited body with which Mr. Morson was associated rather by name than in character, it could not be supposed that he would be an inactive observer of what was passing around him. Accordingly, we find him in the foremost rank of those who originated the Pharmaceutical Society, and there was no one more frequently consulted, or whose opinion carried greater weight among his fellow-workers in the cause of pharmaceutical regeneration. He was constantly appealed to by his friend Jacob Bell on any difficult questions, and articles prepared for publication in the PHARMACEUTICAL JOURNAL were often submitted to him, and, to use an expression of Mr. Bell's, were frequently seasoned with the "Attic salt" from Southampton Row.

Mr. Morson, at this period, had an European reputation as a scientific manufacturing chemist, and his character in this respect, together with his acquaintance with many of the scientific celebrities of the Continent, as well as his familiarity with the French language, enabled him to render great service to the young Society, in the development of which he took a lively interest.

Distinguished foreigners, attracted by the proceedings of English pharmacists, were generally entertained by Mr. Morson. French was almost as freely spoken as English, not only by Mr. Morson himself, but by the members of his family, who had received much of their education in France; and here, therefore, might be found, when they were staying in London, those scientific foreigners who took an interest in pharmacy. Guibourt, Cap, Liebig, Mitscherlich, Rose, and many others of similar stamp, have been guests at various times at Southampton Row, Queen Square, or Hornsey, and have been indebted to Mr. Morson for an intimate acquaintance with the Pharmaceutical Society, its provisions and proceedings. Mr. Morson was for many years on the Council of the Pharmaceutical Society; he was for a still longer period a member of the Board of Examiners, and he used to be a very constant attendant at the evening meetings of the Society. In 1844 he was elected Vice-President of the Society, and for four successive years he continued to fill this office, after which he was made President for a year, and again for about two years in 1859-60.

Mr. Morson retired from the Council of the Pharmaceutical Society in 1870, but his interest in the objects and operations of the Society remained undiminished, and up to the time at which his last severe illness commenced, he was almost a daily visitor at 17, Bloomsbury Square. His health, however, had sensibly failed for many months before his death, and he often expressed himself as sensible that his end was approaching. In the early part of January he had an attack of paralysis, from which he never recovered. Although he did not live to extreme old age, yet, we may say of him, that the work he was enabled to accomplish has entitled him to be classed among the most distinguished of the pharmacists of this country.

Evening Lectures.

Sir,—As the new regulations for the Minor Examination will come into operation in October next, when candidates will be required to possess a more extended knowledge of the principles of chemistry, I beg to propose, for the advantage of those students who cannot attend the morning lectures, that evening lectures on Chemistry be given at the same fees, provided that 50 students enter their names before September; and that it be announced weekly in the Journal. If the Chemistry course should prove a success, I hope the Council will also announce lectures on Botany and Materia Medica.

So long as the Society continues an educating body, I think more real good can be done at Bloomsbury Square, with its well organized and efficient staff than could be accomplished by any scheme of provincial education, and also at far less cost to the Society. In passing, I would remark that we are all very much indebted to Mr. Schacht for bringing forward the subject of extra Scholarships, and I quite coincide with him in wishing to see the rank and file of pharmacy brought up to a good standard throughout the country.

If the Society grant these Scholarships, they will prove a great stimulus to country students, who in studying for them will be preparing themselves to receive more advanced technical instruction at Bloomsbury Square afterwards.

Amicus.

What is Sweet Spirit of Nitre?

Sir,—One of your correspondents, some time after the late sweet spirit of nitre prosecution, reported in your issue of Dec. 6th, very pertinently asked what was sweet spirit of nitre. As far as your columns are concerned, I can see no reply has been vouchsafed to him as yet. I therefore venture to ask you to refer him to the Spiritus Nitri Dulcis, P.L. 1745, which I presume was the standard in those days for that at present, at least, vexatious article. In your issue of November 8th, you were kind enough to publish a letter from me, in which I suggested that the opinion of the trade and the analysts might be given as to what is the standard for an article, whether the B.P. or the so-called *popular* article, always assuming that the latter was according to some Pharmacopœia, and I indicated as a test case sweet spirit of nitre. Now there are many others which I might have selected, but as this is the very one which was so soon after the bone of contention, I hope you will pardon and insert the following remarks.

When Dr. Dupré gave evidence that the article supplied and analysed, no matter whether as spirit of nitrous or nitric ether, or sweet spirit of nitre, was sp. gr. ·867—and that was inferentially substantiated by the evidence for the defence as the right thing—it must be clear to everybody that somebody had added 10 per cent. of water, if we are to take even the weakest spirit strength (or highest sp. gr.), ·850, of any of the pharmacopœias of this country as a standard; but if, as the counsel for the defence is reported to have said, the Pharmacopœia might be thrown to the winds, why I suppose we may have any percentage of water added to the official article. However, that will not do for cow's milk. By the way, there are no characters or tests at page 169 B.P. for that. As regards the trade, some wholesale druggists and manufacturing chemists also openly advise their customers by their price lists that they supply P.B., sp. gr. ·850 and ·900. One says B.P., P.L., and *seconds;* and another, a medallist at several exhibitions, quotes sp. gr. ·834, ·845, and ·850. Well, disclaiming all intention of riding a harassing hobby, I would invite opinion where amongst all these is the public scandal. If you will permit me, in elucidation of the very evident want in the Adulteration Act—I mean some method of fixing a standard for all manufactured articles which have not derived or coined names—I will add an experience, which shows how some chemists and druggists look upon the matter. A customer of the firm I have the honour to represent told me when I waited on him just after the report, that one of his neighbours came to him in great trepidation about the possible results of further analyses, and wanted to know how to meet them. Our friend laughed outright at the other's terror, and replied, The more purchases for analyses from him the better he should like it, as he did not know of anything but the Pharmacopœia as a guide. I may add, he always insists on being so supplied; and so now, I think, should every one who has the handling of medicines or drugs, or whatever names you choose to call them by.

A Drug Traveller.

What becomes of the Cocculus Indicus?

Sir,—Three weeks ago I asked the question, "Is there any legitimate use for the 1066 bags of Cocculus Indicus now held in stock" in London? I have not as yet had a satisfactory answer to the question, considering the importance it may assume. The Pharmaceutical Journal should be the medium for solving and answering such a question. We have here a narcotic drug coming into our country in vast quantities, as I suppose each bag averages 112lbs. It has always been considered a drug, and yet never entered into any pharmacopœia preparation.

Fifty years ago druggists, when the laws were not so strict as they are now, used to sell this berry for one purpose and only one—that was, for catching fish, making them drunk, and causing them to go floating down the stream, just as drunken men now go floating along, and commonly make a short float of it. Now I would ask another question, "Is it unreasonable to suspect that when many a bench of magistrates sit in solemn conclave over a drunken man, and commit him to gaol for a month, they ought to sit in solemn conclave over Cocculus Indicus? This would be cutting at the root and beginning at the beginning.

Is there no test for Cocculus Indicus in decoction or extract, and where are our analysts who are constantly summoning people for putting 15 per cent. of water into milk?

Richard Sturton.

Cambridge, March 4th, 1874.

*** We hope some correspondent will throw light upon this subject, to which attention has several times been called in this journal, and not long since in the House of Commons by Lord Enstace Cecil.—Ed. Pharm. Journ.

S. Steele.—It is not compulsory to pass the Major examination.

W. G. Bladon.—The remarks at the Council scarcely bear the interpretation you put on them. It would be unwise to initiate a discussion on School in that restricted sense of the word in which you write. In recent numbers of the Pharmaceutical Journal, School has been treated as including pupilage in the shop as well as some thoughtful study under competent teachers; and the proposition was that the function of the examiners should be restricted to the testing of such training; in short, that examination should not lead but follow education.

A. Cross.—We are not aware that the point has been decided. It is a question that should be referred to a solicitor.

"*Inquirer.*"—Rub the extract to a thin paste with a few drops of water; add the liniment, and shake well together. Label, "To be shaken."

G. W. Fowler.—We believe that in some parts of the country Syrupus Papaveris is sold under that name.

J. W. Martin.—Your letter has been handed to a member, who has promised to bring its contents directly under the notice of the Board.

"*Narcissus.*"—Bentham's 'Handbook of the British Flora' or Hooker's 'Student's Flora of the British Islands.'

"*Zero.*"—The works mentioned are suitable for the purpose, but, as a rule, it is advisable to have the most recent editions.

W. S.—The mixture cannot be made without the ammonia causing a separation of the quinine as a resinous mass, which is soluble in ether. See the "Characters and Tests" for Ferri et Quinæ Citras in the British Pharmacopœia.

"*Excelsior.*"—Pereira's 'Elements of Materia Medica,' edited by Bentley and Redwood; Garrod's 'Essentials of Materia Medica,' Royle's 'Manual of Materia Medica,' or Scoresby-Jackson's 'Note Book of Materia Medica.'

Communications, Letters, etc., have been received from Messrs. Armstrong, Arnall, Towerzey, Symes, A. Deck, Wilson, H. A. Howe, J. McMillan, Justitia, Statim, T. P. H., A. B.

FERROUS PHOSPHATE.

BY GEORGE CLARIDGE DRUCE.

This preparation, like so many of the iron compounds, is very unstable, exposure to the air, and more particularly to high temperatures when drying, causing rapid oxidation, and converting it into a more insoluble and consequently less useful form.

Ten samples were tested by means of a standard solution of red chromate of potassium, with the following results :—

	Pharmacopœia per centage of purity.
No. 1	72·
„ 2	98·
„ 3	53·2
„ 4	54·4
„ 5	2·
„ 6	104·
„ 7	5.
„ 8	100·1
„ 9	72·8
„ 10	73·6

Nos. 1, 3, 4, 9, and 10 were ordinary shop samples ; 1, 4, and 9 were imperfectly washed, showing decided presence of sulphates ; No. 3 will be afterwards referred to ; No. 5 was a very old trade specimen, yellowish white in colour and almost completely oxidized ; No. 7 was made according to official process, but dried at a *high* temperature ; No. 8 was a fine specimen, and though at least two years old, was of full strength and free from sulphates ; No. 2 was prepared in small quantity, and washed till perfectly free from sulphates ; No. 6 was also specially prepared, and when dried mixed with an equal weight of sugar ; after two months' time it was again tested, and showed no appreciable variation in strength.

No traces of arsenic were found in any of the samples, with the exception of No. 3, which gave unmistakable evidence of its presence, and on a special analysis showed that arseniate of iron had been given instead of the phosphate.

I believe the phosphate of iron might be kept longer unchanged were the freshly washed precipitate mixed with sugar, so that the powder dried at 140 might represent 50 per cent. of ferrous phosphate : its name might then be changed to *Ferri Phosphas Saccharata*.

CHLORAL HYDRATE AND CAMPHOR.

BY J. F. BROWN.

When camphor in fine powder is rubbed in a mortar with an equal weight of pure crystallized hydrate of chloral, the mass becomes damp, and slowly dissolves to form a syrupy liquid, strongly resembling glycerine in appearance.

A rise in temperature of about 3° Fahr. accompanies this change, showing that a chemical reaction of some kind must evolve heat more than sufficient to counterbalance the loss of sensible heat which always attends the passage of a substance from the solid to the liquid state.

No acid or irritating fumes, however, were perceptible during the solution, and the resulting liquid was neutral to test paper.

It was unaffected by solution of silver nitrate, left a greasy stain when dropped upon paper—permanent for some hours—and retained the taste and smell of its components.

A slip of paper dipped into it did not ignite very quickly when brought near a light, but burnt with a bright white flame, having emerald green edges.

It was readily soluble in alcohol and ether, but distilled water converted it into a soft translucent solid, from which, after some time, hydrate of chloral appeared to be dissolved out, leaving the camphor in crystalline grains.

These facts appear to point to an abstraction of water by the camphor, and solution of the latter in the liberated chloral ; but such an avidity for water is not shown by camphor under ordinary circumstances, and the cause of this curious liquefaction is not easily discernible.

[*** Some time since the *Medical Record* quoted from an American source a statement that if camphor be powdered by rubbing it in a mortar with a few drops of spirit, and an equal weight of chloral hydrate added, a liquid is produced which is a valuable local anæsthetic. Mr. Lennox Browne, writing to the *British Medical Journal* (March 7th, p. 304), confirms this statement, and says that it is of the greatest value as a local application in neuralgia. Mr. Browne having employed it during several months, has found great and sometimes instantaneous relief to follow its application in every case. It is only necessary to paint the mixture lightly over the painful part and allow it to dry. The application never blisters, though it may occasion a tingling sensation of the skin. The compound has also been found of great service in the relief of toothache.—Ed. Ph. Journ.]

THE ALKALOIDS OF THE CINCHONA BARKS.*

BY O. HESSE.

(*Continued from p.* 692).

V.—Cinchonine.

Cinchonine was first observed by Dr. Duncan, of Edinburgh ; it was afterwards, in 1811, more closely investigated by the Portuguese physician, Gomez, and declared to be the active principle of cinchona bark, until Houtton-Labillardière remarked that the cinchonine prepared according to the method of Gomez possessed an alkaline property ; and this observation being communicated to Pelletier and Caventou, who were occupied in the investigation of cinchona barks, they characterized this substance, in 1820, as a true vegetable alkaloid.

The slight solubility of this alkaloid in alcohol allowed of its preparation in a state of purity from its first discovery ; nevertheless, as it belonged to the difficultly combustible class of substances, several formulæ were constructed upon the basis of imperfect analytical results. Thus Pelletier and Dumas proposed $C_{39}H_{39}N_4O_3$, and Laurent $C_{19}H_{11}N_2O$, until Regnault acknowledged the formula of Liebig, when doubled, to be the most correct.

Notwithstanding that the behaviour of this base with alcohol rendered the preparation of pure cinchonine easy, yet its properties and salts were too little studied ; and thus it became possible for cinchonine from Huanuco bark,† under the name of "huanokine," and that from quinoidine,‡ under the name of β cinchonine, to be again introduced into chemical literature as newly discovered. The crystallizable cinchonine of Howard§ must also be referred here, the sulphate of which was apparently prevented from crystallizing through a slight excess of sulphuric acid.

After having ascertained by repeated investigations that

* Translated from the 'Vierteljahresschrift für praktische Pharmacie,' vol. xxii., p. 366.

† Annalen der Chemie und der Pharmacie, vol. c. p. 341.

‡ Archiv für Pharmacie, ciii. 273.

§ Neues Repertorium für Pharmacie, vol. xvi. p. 426.

only one cinchonine was produced, namely, that discovered by Pelletier and Caventou, it became necessary to repeat my comparative experiments, since E. Willm and E. Caventou,* had asserted that all cinchonine was accompanied by a slight mixture of a second very similar alkaloid, hydrocinchonine, which could not be separated except by decomposing the cinchonine by means of permanganate of potash. In order to decide this point I prepared hydrocinchonine according to the directions of Willm and Caventou, and made the following observations.

The hydrocinchonine crystallizes in shining colourless prisms, soluble in alcohol in nearly the same proportion as cinchonine. It dissolves at 20° C. in 534 parts of ether, and at 16° C. in 1360 parts of water. In boiling water it is notably soluble, the solution depositing, upon cooling, the greater part of the dissolved substance in small prisms. The alcoholic solution has an alkaline reaction, and can be neutralized by acids, yielding neutral salts which crystallize well. Of these the hydrochlorate crystallizes in colourless prisms, readily soluble in water and alcohol, difficultly in a solution of common salt. The hydriodate crystallizes also in white prisms, which dissolve with difficulty in a solution of iodide of potassium, easily in water, and very freely in alcohol. The neutral sulphate resembles the ordinary sulphate of cinchonine, both in form and solubility, as the neutral and acid tartrates resemble the corresponding cinchonine salts. If excess of bicarbonate of soda be added to an aqueous solution of the tartrate the alkaloid gradually separates as a mass of crystalline warts, and carbonic acid is disengaged. Tartaric acid does not, therefore, prevent the precipitation of the hydrocinchonine. If a solution of it in dilute sulphuric acid be mixed with a solution of permanganate of potash, the latter is decolourized at the ordinary temperature, after a considerable time.

With the help of the latter reaction, it was not difficult to obtain the substance in question from cinchonine which had been prepared from barks of *C. succirubra*, *C. Pitayensis*, *C. Calisaya*, *C. ovata*, and *C. lancifolia*, var. *discolor*. Large, well formed, apparently homogeneous crystals of sulphate of cinchonine, as well as small crystals, the first and the last crystallization, and the mother liquor, all yielded hydrocinchonine. In general, 19 parts of crystallized permanganate of potash dissolved in cold water were used in completely decomposing the cinchonine of 17 parts of sulphate of cinchonine dissolved in very dilute sulphuric acid. In operating at the ordinary temperature, and adding the manganic solution drop by drop to the acid solution whilst stirring, no disengagement of gas could be noted. In all cases a relatively small quantity of hydrocinchonine was obtained. This constancy in the yield led me to suppose that hydrocinchonine might be only a decomposition product of cinchonine, formed according to the following equation :—

$$C_{20}H_{24}N_2O + Mn_2H_2O_8 = C_{20}H_{26}N_2O + 2MnO_2 + 4\,O.$$

The cinchonine would in this case acquire hydrogen as quinine does under analogous circumstances, only here the oxygen remaining from the decomposition would react upon a fresh quantity of cinchonine.

We have seen that hydrocinchonine is considerably more soluble in water than cinchonine. If, therefore, an aqueous solution of sulphate of cinchonine be partially precipitated by ammonia, and the precipitate be left for some time in contact with the supernatant solution, eventually, if hydrocinchonine be actually present in the cinchonine, a solution would be produced containing comparatively much hydrocinchonine, which, after a small addition of permanganate of potash would be obtained pure. Experiment showed to me, however, that in fact the cinchonine could be decomposed with a small quantity of manganate, but that the formation of hydrocinchonine in any quantity worth mentioning did not occur. Further, cinchonine, which under other conditions would easily have yielded some hydrocinchonine, was boiled with water, and this solution acidulated with SO_3, and treated with solution of manganate, but again no appreciable quantity of hydrocinchonine was obtained.

From my experiments I inferred that cinchonine contained no hydrocinchonine, but that the latter was formed in small quantity during the oxidation of cinchonine, and further experiment showed me that a certain portion of this was again decomposed. Hydrocinchonine, therefore, must be classed with the decomposition products, and is not within the limits of the present memoir.

With respect to the properties of cinchonine, it should be mentioned that if the pure alkaloid be boiled with an aqueous solution of sulphate, oxalate or hydrochlorate of ammonia, the alkaloid is gradually dissolved, whilst ammonia is evolved. From this solution the cinchonine salts of the respective acids crystallize upon cooling and after the necessary concentration. In this manner the neutral oxalate of cinchonine can easily be prepared.

Experiments relative to the rotatory power of cinchonine had already been made by Bouchardat, which gave for it in alcoholic solution $\alpha\, r = +237{\cdot}5°$; in a weak solution of the hydrochlorate $\alpha\, r = +190{\cdot}4°$. De Vrij gave for Pelletier's cinchonine in solution as hydriodate $\alpha\, j = +242{\cdot}58°$, and for Erdmann's huanokine $\alpha\, j = +242{\cdot}55°$. In my experiment the cinchonine was dissolved in 95 per cent. alcohol, and with this solution the following data were obtained :—

I. For $p = 1294$, and $l = 220$, $\alpha\, j = +\ 6{\cdot}45°$.
II. For $p = 10{,}409$, and $l = 220$, $\alpha\, j = +5{\cdot}18°$.

According to these experiments—

	I.	II.	Mean.
$\alpha\, j =$	$+226{\cdot}50°$	$+226{\cdot}46$	226·48

Neutral sulphate of cinchonine, $2\,C_{20}H_{24}N_2O,\ H_2SO_4 + 2\,H_2O$, in alcoholic solution, gave—

For $p = 5{\cdot}00$, and $l = 200$, $\alpha = +20{\cdot}05°$; or
$\alpha\, j = +200{\cdot}5°$; or
Cinchonine $\alpha\, j = +244{\cdot}12°$.

The same salt gave—

I. With 1 molecule of SO_3 added in aqueous solution, when $p = 4{\cdot}7687$, and $l = 200$, $\alpha = +20{\cdot}46°$

II. With 6 molecules of SO_3 added, also in aqueous solution, when $p = 4{\cdot}7088$, and l 200, $\alpha = +\ 19{\cdot}80°$.

After twenty-four hours this solution still gave a deviation of $+19{\cdot}81°$, consequently no variation from the former worth mentioning.

From these experiments may be calculated—

		I.	II.
For the salt . .	$\alpha\, j =$	$+214{\cdot}40°$	$+210{\cdot}24°$
For the alkaloid	$\alpha\, j =$	$+261{\cdot}49°$	$+255{\cdot}86°$

On the other hand, the hydrochlorate, $C_{20}H_{24}N_2O\,HCl + 2\,H_2O$, gave—

I. In alcoholic solution, when $p = 3{\cdot}3558$, and $l = 220$, $\alpha = +12{\cdot}16°$.

II. In aqueous solution, strongly acidulated with hydrochloric acid, when $p = 3{\cdot}3373$, and $l = 200$, $\alpha = +12{\cdot}62°$.

We have, therefore—

		I.	II.
For the crystallized hydrochlorate	$\alpha\, j =$	$+164{\cdot}58°$	$+189{\cdot}07°$
For the alkaloid	$\alpha\, j =$	$+203{\cdot}58°$	$+233{\cdot}52°$

The specific rotatory power of cinchonine is therefore increased if the alkaloid be in combination with sulphuric acid, so that with 1 molecule of base and $\frac{1}{2}$ molecule of acid it equals + 244·12°, but with equal molecules of base and acid + 261·49°. This augmentation amounts in the first case to 17·74°, and in the second to 17·37 ; consequently a mean of 17·56° for each molecule of sulphuric acid entering into combination. But as soon as the highest point of saturation is reached, a further addition of acid causes a diminution of the rotatory power. Hydrochloric acid, on the contrary, in the proportion of equal molecules, decreases the rotatory power ; but this is

* Annalen der Chemie und der Pharmacie,

increased when the acid is present in excess. It will, therefore, be seen that an estimation of cinchonine by means of the polariscope, like that of the before-mentioned alkaloids, is highly complicated, and cannot easily be made with any pretension to exactness.

(*To be continued.*)

THE EUCALYPTUS PLANTATIONS OF ALGERIA.

A correspondent of the *Pall Mall Gazette* writes as follows :—The Eucalyptus, a tree of the myrtle family, was introduced from Australia into Algeria about eleven years ago, and flourished surprisingly. It was not, however, until within the last seven years that any extensive plantations were made. A few days since we made an excursion to visit those on the estates of M. Trottier, M. Ramel, and M. Cordier. The seeds from which these trees have grown were mostly sent by Mr. Edward Wilson, whose persistent generosity in aid of all efforts for acclimatization cannot be too gratefully acknowledged.

On M. Trottier's estate at Hussein Dey we walked under tall trees, the *Eucalyptus globulus* (blue gum trees), on an average fifty feet high, which seven years ago were planted with seeds not so big as a mustard seed; this particular plantation was on bad soil, and had not had very experienced care, yet the growth of the trees was marvellous. In this ever-green wood all around us were tall reddish smooth stems, with the bark hanging down in a ragged, untidy manner, for the tree sheds its bark in winter, and grey willow-like leaves were waving on flexible boughs. For about twenty-five feet the stems of the trees in the inner part of the plantation rose up with no branches at all, but on the skirts of the wood the trees sent out branches in the light and air nearly to the ground. It produced a curious impression to walk in the dim twilight of this Australian-African forest, and to think that this was also a wood of the miocene period. Beautiful is not the word I should apply to its appearance, but in exchange for bare sun-baked earth or deadly swamps I must say these Eucalyptus forests are most grateful and the smell delightfully resinous, warm, and gummy. The multitude of birds in the branches and their busy twitterings added much to the pleasant impression. I measured these trees as I walked along, and found them from forty to forty-five inches in circumference, those on the borders of the wood always of course a few inches larger. M. Trottier thinks the red gum, *Eucalyptus resinifcrus*, which is not yet planted in any great numbers, will be the most hardy tree, and consequently best suited to the neighbourhood of Algiers; one red gum which I measured was thirty-one inches in circumference and its age just six years, having been sown in February, 1868. This tree was in the perfection of health, and the same may be said of all the Eucalyptus trees in the plain.

All the large plantations in Algeria are the *Eucalyptus globulus*, but as time goes on, varieties are being tried. On M. Cordier's magnificently wooded farm in the dismal region of the Maison Carrée, we saw a hundred different kinds of Eucalyptus. We were accompanied by some gentlemen who were the principal authorities on trees in this colony, and they seemed to expect much from the *E. Colosea*, which is a hardier tree in the sun than the *globulus*, and is already growing in the desert at Lagouat. M. Cordier showed us one *E. globulus* which was eleven years old, and measured eighty-one inches in circumference, and he told me of some at Bonfarik in the plain which were some inches larger and not so old. There seemed to be a general impression that the Eucalyptus was a fever-destroying tree, and of the greatest importance to the colony from that point of view; but as general culture goes on, as well as plantations, the sanitary improvement in the plain ought not all to be set down as certainly due to the *Eucalyptus globulus*. The aromatic odours of these gum-tree plantations in the dismal part of the plain at the mouth of the fever-breeding River Harach instead of the malaria vapours is certainly an incalculable benefit; but I will not assert positively that the fever is destroyed. If the growing forests are judiciously managed, they must be a source, in fourteen or fifteen years, of great profit, as wood is very dear here, and the Eucalyptus is a fine hard wood, and makes excellent sleepers for railways, and is useful in all places where a sound wood that will stand damp is required. We walked in the four-year-old plantations at the Maison Carrée, where are 20,000 gum trees on ninety acres of unhealthy soil; these trees are now from fourteen to twenty feet high, and look as if they would grow to large forest trees after their fashion in about six years more.

Many village communities in the plain have planted scores of gum trees in this neighbourhood, and feel the benefit, but at present there is certainly an exaggerated manner of speaking of the Eucalyptus. It is praised as a scent, as cigars, as a medicine, as a tonic, as a throat lozenge, and above all as a bath. Branches and leaves are put into hot water, and I am assured by those who have tried it, that such baths remove rheumatic pains, neuralgia, and the debility left by the malaria incidental to the country. The flower of the Eucalyptus tribe is very like the myrtle flower; it is very full of honey, and attracts a multitude of flies and bees, and the birds naturally follow, for they find not only food, but thick, warm, leafy cover in winter, and shelter from the burning sun in summer. Some species of Eucalyptus have large and very beautiful flowers. We noticed with delight the gorgeous red staminous flower of the *E. tetraptera* bursting the pyramidal top of its square-sided flower-box.

Finally, our opinion is that the Eucalyptus tree may prove the most powerful element of civilization as yet put in force in the coast of North Africa; that in a very few years it will be self-sowing, and thus take its place as a naturalized subject, there is very little reason to doubt. At Cannes, on Lord Brougham's grounds, the young trees come up from the seed of the old ones under their branches, and in a few years we may confidently expect the same process to take place in Algeria. This year the seed ripens plentifully on the seven-year-old trees. Thus, in a few years we may see the one thing most longed for on the Barbary coast—that is, shade from the fierce sun. We may also have a most profitable crop, and the healthy influence of these resinous-scented gum trees as a counteraction against malaria. The Eucalyptus tribe seems to meet not only the requirements of health, comfort, and pleasure, but of commerce and general prosperity.

POPPY SEED.*

Papaver Somniferum.

The seeds yield by expression about 50 per cent. of a bland and very valuable oil, of a pale golden colour, fluid to within 10° of the freezing point of water. It dries easily, is inodorous, of agreeable flavour, and partially soluble in alcohol. By simple exposure to the rays of the sun in shallow vessels the oil is rendered perfectly colourless. It is expressed by means of a heavy circular stone, placed on its edge, made to revolve by a long lever, and the apparatus is worked by draught bullocks.

The seed has no narcotic qualities, but has a sweet taste, and is used, parched, by the lower class of natives as a food; it is also much used by the sweetmeat-makers as an addition in their wares. This and the seed of the Teel (*Sesamum orientale*) are the only seeds, with the exception of the cocoa-nut, which are used for that purpose.

THE COPPICING OF CINCHONAS.

We learn, says the *Agricultural Gazette* of India, quoted in the *Gardencrs' Chronicle*, from a recent report of the superintendent of the Bengal Cinchona Plantations, that most satisfactory results have been obtained in the

* From the Official Catalogue of the Indian Department at the Vienna Universal Exhibition.

Sikkim plantations, by treating the *Cinchona succirubra* as a coppice tree. This result does not in the least surprise us; we have long been under the belief that most varieties of Cinchona, and certainly the succirubra, would, when cut over and coppiced, yield far better results than if barked under the so-called mossing system, advocated by the Superintendent of the Neilgherry Plantations. It is, we think, much to be regretted that coppicing has not had a full trial on the Neilgherries; but we are glad to learn that the Madras Government have at length determined to give coppicing a fair trial. It is well that this experiment should commence in time. In a few more years the roots of Cinchona trees may have passed down into the inhospitable subsoil, and the growth of the trees may be stopped, when coppicing may be the only choice. The high cultivation applied to the surface soils of the plantations at Sikkim and on the Neilgherries will have done much to keep the roots of the trees in the cultivated upper soil; but, whether this is so or not, coppicing experiments on a sufficiently large scale should no longer be delayed in our Government Cinchona plantations. We agree thoroughly with Dr. Henderson, in thinking that the methods of culture in these experimental plantations cannot be too varied, provided always that the experiments are carefully conducted, and the results thoroughly observed and recorded by competent persons.

PRELIMINARY ACCOUNT OF AN INVESTIGATION ON THE TRANSMISSION OF SOUND BY THE ATMOSPHERE.*

BY JOHN TYNDALL, D.C.L., LL.D., F.R.S.

This notice embraces the scientific results of an inquiry on Fog-signals, undertaken at the instance of the Elder Brethren of the Trinity House, and communicated with their friendly concurrence to the Royal Society.

The investigation was begun on the 19th of May, 1873, and continued till the 4th of July. It was resumed on the 8th of October, and continued to the end of November. It also includes observations made during the dense fog which enveloped London on December 9 and the succeeding days.

Gongs and bells were excluded from this investigation, in consequence of their proved inferiority to other instruments of signalling. The experiments were made with trumpets blown by powerfully compressed air, with steam-whistles, guns, and a steam syren, associated with a trumpet 16 feet long.

Daboll's horn, or trumpet, had been highly spoken of by writers on fog-signals. A third-order apparatus of the kind had been reported as sending its sound to a distance of from 7 to 9 miles against the wind, and to a distance of 12 to 14 miles with the wind. Holmes had improved upon Daboll; and with two instruments of Holmes, not of the third but of the first order, our experiments were made. On the 19th of May at 3 miles distance they became useless as a fog-signal; at a distance of 4 miles, with paddles stopped and all on board quiet, they were wholly unheard. At a distance of 2 miles from the Foreland the whistles tested on May 19 became useless. The 12 o'clock gun, fired with a 1lb. charge at Drop Fort in Dover, was well heard on May 19, when the horns and whistles were inaudible. On the 20th of May the permeability of the atmosphere had somewhat increased, but the steam-whistle failed to pierce it to a depth of 3 miles. At 4 miles the horns, though aided by quietness on board, were barely heard. By careful nursing, if I may use the expression, the horn-sounds were carried to a distance of 6 miles. The superiority of the 18-pounder gun, already employed by the Trinity House as a fog-signal, over horns and whistles, was on this day so decided as almost to warrant its recommendation to the exclusion of all the other signals.

Nothing occurred on the 2nd of June to exalt our hopes of the trumpets and whistles. The horns were scarcely heard at a distance of 3 miles; sometimes indeed they failed to be heard at 2 miles. By keeping everything quiet on board, they were afterwards heard to a distance of 6 miles—a result, however, mainly due to the improved condition of the atmosphere. Considering the demands as to sound-range made by writers on this subject, the demonstrated incompetence of horns and whistles of great reputed power to meet these demands was not encouraging. On the 3rd of June the atmosphere had changed surprisingly. It was loaded overhead with dark and threatening clouds; the sounds, nevertheless, were well heard beyond 9 miles. On June 10th the acoustic transparency of the air was also very fair, the distance penetrated being upwards of $8\frac{3}{4}$ miles. The subsidence of the sound near the boundary of the acoustic shadow on the Dover side of the Foreland, and before entering the shadow, was to-day sudden and extraordinary, affecting equally both horns and guns. We were warned on June 3rd that the supremacy of the gun on one occasion by no means implied its supremacy on all occasions, the self-same guns which on May 20th had so far transcended the horns being on this day their equals and nothing more. The 11th of June was employed in mastering still further the facts relating to the subsidence of the sound east and west of the Foreland; the cause of this subsidence being in part due to the weakening of the sonorous waves by their divergence into the sound shadow, and in part to interference.

The atmosphere on the 25th of June was again very defective acoustically. The sounds reached a maximum distance of $6\frac{1}{2}$ miles; but at 4 miles, on returning from the maximum distance, they were very faint. The day had, as it were, darkened acoustically. On this day the guns lost still further their pre-eminence, and at $5\frac{1}{2}$ miles were inferior to the horn. No sounds whatever reached Dover Pier on the 11th; and it was only towards the close of the day that they succeeded in reaching it on the 25th. Thus by slow degrees the caprices of the atmosphere made themselves known to us, showing us subsequently that within the limits of a single day, even within a single minute, the air, as a vehicle of sound, underwent most serious variations. The 26th of June was a far better day than its predecessor, the acoustic range being over $9\frac{1}{4}$ miles. The direction of the wind was less favourable to the sound on this day than on the preceding one, plainly proving that something else than the wind must play an important part in shortening the sound-range.

On the 1st of July we experimented upon a rotating-horn, and heard its direct or axial blast, which proved to be the strongest, at a distance of $10\frac{1}{2}$ miles. The sounds were also heard at the Varne light-ship, which is $12\frac{3}{4}$ miles from the Foreland. The atmosphere had become decidedly clearer acoustically, but not so optically; for on this day thick haze obscured the white cliffs of the Foreland. In fact, on days of far greater optical purity, the sound had failed to reach one-third of the distance attained to-day. In the light of such a fact any attempt to make optical transparency a measure of acoustic transparency must be seen to be delusive. On the 1st of July a 12-inch American whistle, of which we had heard a highly favourable account, was tried in place of the 12-inch English whistle; but, like its predecessor, the performance of the new instrument fell behind that of the horns. An interval of twelve hours sufficed to convert the acoustically clear atmosphere of July 1st into an opaque one; for on the 2nd of July even the horn-sounds, with paddles stopped and all noiseless on board, could not penetrate further than 4 miles.

Thus each succeeding day provided us with a virtually new atmosphere, clearly showing that conclusions founded upon one day's observations might utterly break down in the presence of the phenomena of another day. This was most impressively demonstrated on the day now to be referred to. The acoustic imperviousness of the 3rd of July was found to be still greater than that of the 2nd,

* Communicated to the Royal Society, January 15th, 1874. (Proceedings, vol. xxii. p. 58).

while the optical purity of the day was sensibly perfect. The cliffs of the Foreland could be seen to-day at ten times the distance at which they ceased to be visible on the 1st, while the sounds were cut off at one-sixth of the distance. At 2 p.m. neither guns nor trumpets were able to pierce the transparent air to a depth of 3, hardly to a depth of 2 miles. This extraordinary opacity was proved conclusively to arise from the irregular admixture with the air of the aqueous vapour raised by a powerful sun. This vapour, though perfectly invisible, produced *an acoustic cloud* impervious to the sound, and from which the sound-waves were thrown back as the waves of light are from an ordinary cloud. The waves thus refused transmission produced by their reflection echoes of extraordinary strength and duration. This, I may remark, is the first time that audible echoes have been proved to be reflected from an optically transparent atmosphere. By the lowering of the sun the production of the vapour was checked, and the transmissive power of the atmosphere restored to such an extent that, at a distance of 2 miles from the Foreland, at 7 p.m., the intensity of the sound was at least thirty-six times its intensity at 2 p.m.

On October 8 the observations were resumed, a steam syren and a Canadian whistle of great power being added to the list of instruments. A boiler had its steam raised to a pressure of 70 lbs. to the square inch; on opening a valve this steam would issue forcibly in a continuous stream, and the sole function of the syren was to convert this stream into a series of separate strong puffs. This was done by causing a disk with twelve radial slits to rotate behind a fixed disk with the same number of slits. When the slits coincided a puff escaped; when they did not coincide the outflow of steam was interrupted. Each puff of steam at this high pressure generated a sonorous wave of great intensity; the successive waves linking themselves together to a musical sound so intense as to be best described as a continuous explosion.

During the earlier part of October 8 the optical transparency of the air was very great; its acoustic transparency, on the other hand, was very defective. Clouds blackened and broke into a rain and hail shower of tropical violence. The sounds, instead of being deadened were improved by this furious squall; and, after it had lightened, thus lessening the local noises, the sounds were heard at a distance of $7\frac{1}{2}$ miles distinctly louder than they had been heard through the preceding rainless atmosphere at a distance of 5 miles. At 5 miles distance, therefore, the intensity of the sound had been at least doubled by the rain—a result entirely opposed to all previous assertions, but an obvious consequence of the removal by condensation and precipitation of that vapour the mixture of which with the air had been proved so prejudicial to the sound. On this day a dependence was established between the pitch of a note and its penetrative power—the syren generating 480 waves being slightly inferior to the horns, while generating 400 waves a second it was distinctly superior. The maximum range on October 8 was 9 miles. On October 9 the transmissive power had diminished, the maximum range being $7\frac{1}{2}$ miles. On both these days the syren proved to be superior to the horns, and on some occasions superior to the gun.

On the 10th and 11th, a gale having caused our steamer to seek safety in the Downs, we made land observations. The duration of the aërial echoes was for the syren and the gun, 9 seconds; for the horns, 6 seconds. The duration varies from day to day. We sought to estimate the influence of the violent wind, and found that the sound of the gun failed to reach us in two cases at a distance of 550 yards to windward, the sound of the syren at the same time rising to a piercing intensity. To leeward the gun was heard at five times, and certainly might have been heard at fifteen times the distance attained to windward. The momentary character of the gun-sound renders it liable to be quenched by a single puff of wind; but sounds of low pitch generally, whether momentary or not, suffer more from an opposing wind than high ones. We had on the 13th another example of the powerlessness of heavy rain to deaden sound.

On the 14th the maximum range was 10 miles, but the atmosphere did not maintain this power of transmission. It was a day of extreme optical clearness; but its acoustic clearness diminished as the day advanced. In fact, the sun was in action. We proved to-day that by lowering the pitch of the Canadian whistle, its sound, which had previously been inaudible, became suddenly audible. The day at first was favourable to the transmission of the longer sound-waves. After a lapse of three hours the case was reversed, the high-pitched syren being then heard when both gun and horns were inaudible. But even this state of things did not continue, so rapid and surprising are the caprices of the atmosphere. At a distance of 5 miles, at 3.30 p.m., the change in transmissive power reduced the intensity of the sound to at least one half of what it possessed at 11.30 a.m., the wind throughout maintaining the same strength and direction. Through all this complexity the knowledge obtained on July 3 sheds the light of a principle which reduces to order the apparent confusion.

October 15 was spent at Dungeness in examining the performance of Daboll's horn. It is a fine instrument, and its application was ably worked out by its inventor; still it would require very favourable atmospheric conditions to enable it to warn a steamer before she had come dangerously close to the shore. The direction in which the aërial echoes return was finely illustrated to-day, that direction being always the one in which the axis of the horn is pointed.

The 16th was a day of exceeding optical transparency, but of great acoustic opacity. The maximum range was only 5 miles. On this day the howitzer and all the whistles were clearly overmastered by the syren. It was, moreover, heard at $3\frac{1}{2}$ miles with the paddles going, while the gun was unheard at $2\frac{1}{2}$ miles. With no visible object that could possibly yield an echo in sight, the pure aërial echoes, coming from the more distant southern air, were distinct and long-continued at a distance of 2 miles from the shore. Near the base of the Foreland cliff we determined their duration and found it to be eleven seconds, while that of the best whistle echoes was six seconds. On this day three whistles, sounded simultaneously, were pitted against the syren, and found clearly inferior to it.

On the 17th four horns were compared with the syren, and found inferior to it. This was our day of greatest acoustic transparency, the sound reaching a maximum of 15 miles for the syren, and of more than 16 for the gun. The echoes on this day were continued longer than on any other occasion. They continued for fifteen seconds, their duration indicating the atmospheric *depth* from which they came.

On October 18th, though the experiments were not directed to determine the transmissive power of the air, we were not without proof that it continued to be high. From 10 to 10.30 a.m., while waiting for the blasts of the syren at a distance of 3 miles from the Foreland, the continued reports of what we supposed to be the musketry of skirmishing parties on land were distinctly heard by us all. We afterwards learned that the sounds arose from the rifle-practice on Kingsdown beach, $5\frac{1}{2}$ miles away. On July 3rd, which, optically considered, was a far more perfect day, the 18-pounder, howitzer, and mortar failed to make themselves heard at half this distance. The 18th was mainly occupied in determining the influence of pitch and pressure on the syren sound. Taking the fluctuations of the atmosphere into account, I am of opinion that the syren, performing from 2000 to 2400 revolutions a second, or, in other words, generating from 400 to 480 waves per second, best meets the atmospheric conditions. We varied the pressure from 40 to 80 lbs. on the square inch; and though the intensity did not appear to rise in proportion to the pressure, the higher pressure yielded the hardest and most penetrating sound.

The 20th was a rainy day with strong wind. Up to a

distance of 5½ miles the syren continued to be heard through the sea- and paddle-noises. In rough weather, indeed, when local noises interfere, the syren sound far transcends all other sounds. On various occasions to-day it proved its mastery over both gun and horns. On the 21st the wind was strong and the sea high. The horn-sounds, with paddles going, were lost at 4 miles, while the syren continued serviceable up to 6½ miles. The gun to-day was completely overmastered. Its puffs were seen at the Foreland; but its sound was unheard when the syren was distinctly heard. Heavy rain failed to damp the power of the syren. The whistles were also tried to-day, but were found far inferior to the syren. On the 22nd it blew a gale, and the Galatea quitted us. We made observations on land on the influence of the wind and of local noises. The shelter of the coastguard station at Cornhill enabled us to hear gun-sounds which were quite inaudible to an observer out of shelter; in the shelter also both horn and syren rose distinctly in power; but they were also heard outside when the gun was quite unheard. As usual, the sound to leeward was far more powerful than those at equal distances to windward. The echoes from the cloudless air were to-day very fine. On the 23rd, in the absence of the steamer, the observations on the influence of the wind were continued. The quenching of the gun-sounds, in particular, to windward was well illustrated. All the sounds, however, gun included, were carried much further to leeward than to windward. The effect of a violent thunderstorm and downpour of rain in exalting the sound was noticed by observers both to windward and to leeward of the Foreland. In the rear of the syren its range to-day was about a mile. At right angles to the axis, and to windward, it was about the same. To leeward it reached a distance of 7⅓ miles.

(*To be continued.*)

PROFESSOR HUXLEY ON SCIENCE TEACHING AND EXAMINATIONS.

On the occasion of his installation as Lord Rector of the University, on the 27th of February, Professor Huxley chose for the subject of his inaugural address, "Universities; Actual and Ideal." The address, which is published *in extenso* in the current number of the *Contemporary Review*, contained many references having special interest to pharmacists, such as limitation of the subjects of the medical curriculum, the true objects of university endowments, the endowment of research, teaching in the lecture room, and examinations.

Referring to the activity of thought in the present day, the Professor said:—

"Men are beginning, once more, to awake to the fact that matters of belief and of speculation are of absolutely infinite practical importance; and are drawing off from that sunny country 'where it is always afternoon'—the sleepy hollow of broad indifferentism—to range themselves under their natural banners. Change is in the air. It is whirling feather-heads into all sorts of eccentric orbits, and filling the steadiest with a sense of insecurity. It insists on reopening all questions and asking all institutions, however venerable, by what right they exist, and whether they are, or are not, in harmony with the real or supposed wants of mankind. And it is remarkable that these searching inquiries are not so much forced on institutions from without, as developed from within. Consummate scholars question the value of learning; priests contemn dogma; and women turn their backs upon man's ideal of perfect womanhood, and seek satisfaction in apocalyptic visions of some, as yet unrealized, epicene reality."

After a tribute to the disposition shown in recent changes by the universities to meet the needs of the present day, a rapid sketch was given of the origin of such institutions, commencing with the dictum of Charlemagne, that "right action is better than knowledge; but in order to do what is right, it is necessary to know what is right":—

"In a couple of centuries, the schools he sowed broadcast produced their crop of men thirsting for knowledge and craving for culture. Such men gravitating towards Paris, as a light amidst the darkness of evil days, from Germany, from Spain, from Britain, and from Scandinavia, came together by natural affinity. By degrees, they banded themselves into a society, which, as its end was the knowledge of all things knowable, called itself a '*Studium Generale*;' and when it had grown into a recognized corporation, acquired the name of '*Universitas Studii Generalis*;' which, mark you, means not a 'Useful Knowledge Society,' but a 'Knowledge-of-things-in-general Society.'"

The development of the University was traced, and this led up to the subject of endowments, upon which Professor Huxley said:—

"In Aberdeen, these endowments are numerous, but so small that, taken altogether, they are not equal to the revenue of a single third-rate English college. They are scholarships, not fellowships; aids to do work—not rewards for such work as it lies within the reach of an ordinary, or even an extraordinary, young man to do. You do not think that passing a respectable examination is a fair equivalent for an income, such as many a grey-headed veteran, or clergyman, would envy, and which is larger than the endowment of many Regius chairs. You do not care to make your University a school of manners for the rich; of sports for the athletic; or a hot-bed of high-fed, hypercritical refinement, more destructive to vigour and originality than are starvation and oppression. No; your little bursaries of ten and twenty (I believe even fifty) pounds a year enable any boy who has shown ability—in the course of his education in those remarkable primary schools which have made Scotland the power she is—to obtain the highest culture the country can give him; and when he is armed and equipped, his Spartan Alma Mater tells him that, so far, he has had his wages for his work, and that he may go and earn the rest.

"When I think of the host of pleasant, monied, well-bred young gentlemen, who do a little learning and much boating by Cam and Isis, the vision is a pleasant one; and, as a patriot, I rejoice that the youth of the upper and richer classes of the nation receive a wholesome and a manly training, however small may be the modicum of knowledge they gather, in the intervals of this, their serious business. I admit, to the full, the social and political value of that training. But when I proceed to consider that these young men may be said to represent the great bulk of what the Colleges have to show for their enormous wealth, plus, at least, a hundred and fifty pounds a year apiece which each undergraduate costs his parents or guardians, I feel inclined to ask whether the rate-in-aid of the education of the wealthy and professional classes, thus levied on the resources of the community, is not, after all, a little heavy? And, still further, I am tempted to inquire what has become of the indigent scholars, the sons of the masses of the people whose daily labour just suffices to meet their daily wants, for whose benefit these rich foundations were largely, if not mainly, instituted? It seems as if Pharaoh's dream had been rigorously carried out, and that even the fat scholar has eaten the lean one."

After some remarks respecting the "value of Science as knowledge and discipline," he expressed his gratification that the Scotch universities had added natural history and chemistry to the subjects of examination. He then said:—

"I do not know what the requirements of your examiners may be, but I sincerely trust they are not satisfied with a mere book knowledge of these matters. For my own part, I would not raise a finger, if I could thereby introduce mere book work in science into every Arts curriculum in the country. Let those who want to study books devote themselves to Literature, in which we have

the perfection of books, both as to substance and as to form. If I may paraphrase Hobbes' well-known aphorism, I would say that 'books are the money of Literature, but only the counters of Science,' Science (in the sense in which I now use the term) being the knowledge of fact, of which every verbal description is but an incomplete and symbolic expression. And be assured that no teaching of science is worth anything, as a mental discipline, which is not based upon direct perception of the facts, and practical exercise of the observing and logical faculties upon them. Even in such a simple matter as the mere comprehension of form, ask the most practised and widely informed anatomist what is the difference between his knowledge of a structure which he has read about, and his knowledge of the same structure when he has seen it for himself; and he will tell you that the two things are not comparable—the difference is infinite. Thus I am very strongly inclined to agree with some learned schoolmasters who say that, in their experience, the teaching of Science is all waste time. As they teach it, I have no doubt it is. But to teach it otherwise, requires an amount of personal labour and a development of means and appliances, which must strike horror and dismay into a man accustomed to mere book work, and who has been in the habit of teaching a class of fifty without much strain upon his energies. And this is one of the real difficulties in the way of the introduction of physical science into the ordinary University course, to which I have alluded. It is a difficulty which will not be overcome, until years of patient study have organized scientific teaching as well as, or I hope better than, classical teaching has been organized hitherto. . . . .

"When the material well-being of the country depended upon rude pasture and agriculture, and still ruder mining; in the days when all the innumerable applications of the principles of physical science to practical purposes were non-existent even as dreams; days which men living may have heard their fathers speak of; what little physical science could be seen to bear directly upon human life, lay within the province of Medicine. Medicine was the foster-mother of Chemistry, because it has to do with the preparation of drugs and the detection of poisons; of botany, because it enabled the physician to recognize medicinal herbs; of comparative anatomy and physiology, because the man who studied human anatomy and physiology for purely medical purposes was led to extend his studies to the rest of the animal world. Within my recollection, the only way in which a student could obtain anything like a training in physical science, was by attending the lectures of the professors of physical and natural science attached to the medical schools."

Professor Huxley then alluded to the responsibilities of the medical practitioner, and appealed to the medical students present not to spare even so much as an hour for studies which did not tend directly to fit them for their duties. He continued :—

"If I had the power to remodel medical education, the first two years of the medical curriculum should be devoted to nothing but thorough study of anatomy and physiology, with physiological chemistry and physics; the student should then pass a real, practical examination in these subjects; and, having gone through that ordeal satisfactorily, he should be troubled no more with them. . . .

"We are told that the medical man ought to be a person of good education and general information, if his profession is to hold its own among other professions; that he ought to know botany, or else, if he goes abroad, he won't be able to tell poisonous fruits from edible ones; that he ought to know drugs, as a druggist knows them, or he won't be able to tell sham bark and senna from the real articles; that he ought to know zoology, because—well, I really have never been able to learn exactly why he is to be expected to know zoology. There is, indeed, a popular superstition, that doctors know all about things that are queer or nasty to the general mind, and may, therefore, be reasonably expected to know the 'barbarous binomials' applicable to snakes, snails, and slugs; an amount of information with which the general mind is usually completely satisfied. And there is a scientific superstition that physiology is largely aided by comparative anatomy—a superstition which, like most, once had a grain of truth at bottom; but the grain has become homœopathic, since physiology took its modern experimental development, and became what it is now—the application of the principles of physics and chemistry to the elucidation of the phenomena of life.

"I hold as strongly as any one can do, that the medical practitioner ought to be a person of education and good general culture; but I also hold by the old theory of a faculty, that a man should have his general culture before he devotes himself to the special studies of that faculty and I venture to maintain, that, if the general culture obtained in the faculty of arts were what it ought to be, the student would have quite as much knowledge of the fundamental principles of physics, of chemistry, and of biology, as he needs, before he commenced his special medical studies. . . . .

"Methuselah might, with much propriety, have taken half a century to get his doctor's degree; and might, very fairly, have been required to pass a practical examination upon the contents of the British Museum, before commencing practice as a promising young fellow of two hundred, or thereabouts. But you have four years to do your work in, and are turned loose, to save or slay, at two or three and twenty.

"Now, I put it to you, whether you think that, when you come down to the realities of life—when you stand by the sick-bed, racking your brains for the principles which shall furnish you with the means of interpreting symptoms, and forming a rational theory of the condition of your patient, it will be satisfactory for you to find that those principles are not there—but that, to use the examination slang which is unfortunately too familiar to me, you can quite easily 'give an account of the leading peculiarities of the *Marsupialia*,' or 'enumerate the chief characters of the *Compositæ*,' or 'state the class and order of the animal from which Castoreum is obtained.'

Next in order the endowment of research was dealt with as follows :—

"If a student of my own subject shows power and originality, I dare not advise him to adopt a scientific career; for, supposing he is able to maintain himself until he has attained distinction, I cannot give him the assurance that any amount of proficiency in the Biological Sciences will be convertible into, even the most modest, bread and cheese. And I believe that the case is as bad, or perhaps worse, with other branches of science. In this respect Britain, whose immense wealth and prosperity hang upon the thread of applied science, is far behind France, and infinitely behind Germany. . . . .

"Great schemes for the endowment of research have been proposed. It has been suggested, that laboratories for all branches of physical science, provided with every apparatus needed by the investigator, shall be established by the State; and shall be accessible, under due conditions and regulations, to all properly qualified persons. I see no objection to the principle of such a proposal. If it be legitimate to spend great sums of money on public libraries and public collections of painting and sculpture, in aid of the man of letters, or the artist, or for the mere sake of affording pleasure to the general public, I apprehend that it cannot be illegitimate to do as much for the promotion of scientific investigation. To take the lowest ground, as a mere investment of money, the latter is likely to be much more immediately profitable. To my mind, the difficulty in the way of such schemes is not theoretical, but practical. Given the laboratories, how are the investigators to be maintained? What career is open to those who have been thus encouraged to leave bread-winning pursuits? If they are to be provided for by endowment, we come back to the college fellowship system, the results of which, for literature, have not been

so brilliant that one would wish to see it extended to science; unless some much better securities than at present exist, can be taken that it will foster real work.

"In the meanwhile, there is one step in the direction of the endowment of research which is free from such objections. It is possible to place the scientific inquirer in a position in which he shall have ample leisure and opportunity for original work, and yet shall give a fair and tangible equivalent for those privileges. The establishment of a faculty of science in every university, implies that of a corresponding number of professorial chairs, the incumbents of which need not be so burdened with teaching as to deprive them of ample leisure for original work."

Finally, the system of teaching and examination came under review:—

"But supposing the professorial forces of our university to be duly organized, there remains an important question, relating to the teaching power, to be considered. Is the professorial system—the system, I mean, of teaching in the lecture-room alone, and leaving the student to find his own way when he is outside the lecture-room—adequate to the wants of learners? In answering this question, I confine myself to my own province, and I venture to reply for physical science, assuredly and undoubtedly, No. As I have already intimated, practical work in the laboratory is absolutely indispensable, and that practical work must be guided and superintended by a sufficient staff of demonstrators, who are for science what tutors are for other branches of study. And there must be a good supply of such demonstrators. I doubt if the practical work of more than twenty students can be properly superintended by one demonstrator. If we take the working day at six hours, that is twenty minutes apiece—not a very large allowance of time for helping a dull man, for correcting an inaccurate one, or even for making an intelligent student clearly apprehend what he is about. And, no doubt, the supplying of a proper amount of this tutorial, practical teaching is a difficulty in the way of giving proper instruction in physical science in such universities as that of Aberdeen, which are devoid of endowments; and, unlike the English universities, have no moral claim on the funds of richly endowed bodies to supply their wants.

"Examination—thorough, searching examination—is an indispensable accompaniment of teaching; but I am almost inclined to commit myself to the very heterodox proposition that it is a necessary evil. I am a very old examiner, having, for some twenty years past, been occupied with examinations on a considerable scale, of all sorts and conditions of men, and women, too,—from the boys and girls of elementary schools to the candidates for honours and fellowships in the universities. I will not say that, in this case as in so many others, the adage, that familiarity breeds contempt, holds good; but my admiration for the existing system of examination and its products, does not wax warmer as I see more of it. Examination, like fire, is a good servant, but a bad master; and there seems to me to be some danger of its becoming our master. I by no means stand alone in this opinion. Experienced friends of mine do not hesitate to say that students whose career they watch, appear to them to become deteriorated by the constant effort to pass this or that examination, just as we hear of men's brains becoming affected by the daily necessity of catching a train. They work to pass, not to know; and outraged science takes her revenge. They do pass, and they don't know. I have passed sundry examinations in my time, not without credit, and I confess I am ashamed to think how very little real knowledge underlay the torrent of stuff which I was able to pour out on paper. In fact, that which examination, as ordinarily conducted, tests, is simply a man's power of work under stimulus, and his capacity for rapidly and clearly producing that which, for the time, he has got into his mind. Now, these faculties are by no means to be despised. They are of great value in practical life, and are the making of many an advocate, and of many a so-called statesman. But in the pursuit of truth, scientific or other, they count for very little, unless they are supplemented by that long-continued, patient 'intending of the mind,' as Newton phrased it, which makes very little show in examinations. I imagine that an examiner who knows his students personally, must not unfrequently have found himself in the position of finding A's paper better than B's, though his own judgment tells him, quite clearly, that B is the man who has the larger share of genuine capacity.

"Again, there is a fallacy about examiners. It is commonly supposed that anyone who knows a subject is competent to teach it; and no one seems to doubt that anyone who knows a subject is competent to examine in it. I believe both these opinions to be serious mistakes; the latter, perhaps, the more serious of the two. In the first place, I do not believe that any one who is not, or has not been, a teacher is really qualified to examine advanced students. And in the second place, examination is an art, and a difficult one, which has to be learned like all other arts.

"Beginners always set too difficult questions—partly because they are afraid of being suspected of ignorance if they set easy ones, and partly from not understanding their business. Suppose that you want to test the relative physical strength of a score of young men. You do not put a hundredweight down before them, and tell each to swing it round. If you do, half of them won't be able to lift it at all, and only one or two will be able to perform the task. You must give them half a hundredweight, and see how they manœuvre that, if you want to form any estimate of the muscular strength of each. So, a practised examiner will seek for information respecting the mental vigour and training of candidates from the way in which they deal with questions easy enough to let reason, memory, and method have free play.

"No doubt, a great deal is to be done by the careful selection of examiners, and by the copious introduction of practical work, to remove the evils inseparable from examination; but, under the best of circumstances, I believe that examination will remain but an imperfect test of knowledge, and a still more imperfect test of capacity, while it tells next to nothing about a man's power as an investigator."

PRESENTATION TO MR. ARCHIBALD PATERSON, CHEMIST, GLASGOW.

A number of the friends of Mr. A. Paterson entertained him to supper in the Waverley Hotel, on Friday evening, the 6th inst., on the occasion of his leaving the firm of W. and R. Hatrick and Co., wholesale druggists, to commence business on his own account in Govan. Dr. A. M. Robertson occupied the chair, and Mr. Jas. L. Hatrick acted as Croupier. After supper, and the usual loyal and patriotic toasts had been proposed and responded to, the Chairman, in proposing the toast of the evening, "The Health of Mr. Paterson," delivered an appropriate speech, and concluded by handing to Mr. Paterson an address and a purse of sovereigns, in the name of a large number of subscribers. The toast was drunk with enthusiasm, Mr. Paterson replying in feeling terms.

The other toasts were—"The Drug Trade," proposed by the Croupier, and acknowledged by Mr. James M. Fairlie; "The Glasgow Chemists and Druggists' Association," proposed by Dr. Moffat, and acknowledged by Mr. Jos. A. Clarke (Secretary); "The Medical Profession," by Mr. J. L. Hatrick, acknowledged by Dr. Thomas Dryden Moffat; "The Ladies," by Mr. J. R. Sutherland, acknowledged by Mr. Dunn; "The Chairman," by Mr. Paterson, and "The Croupier," by Mr. J. McMillan.

The evening was spent in a most agreeable manner.

The Pharmaceutical Journal.

SATURDAY, MARCH 14, 1874.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE AMENDMENT OF THE ADULTERATION ACT.

THERE is now a wide-spread feeling existing that the Adulteration Act will require considerable and careful revision if it is to escape the fate of becoming a dead letter through the impossibility of outliving the numerous absurdities which crop up in connection with it from day to day. Therefore, although the inconveniences suffered in connection with it by pharmacists have hitherto been rather those of apprehension than otherwise, it will doubtless have been noted with satisfaction that at the last Council Meeting of the Pharmaceutical Society the Parliamentary Committee was requested to consider the objectionable points of the Act as affecting chemists and druggists, with the view of bringing them before the Government and urging the necessity of their amendment. The time is none the less opportune in that the Marquis of SALISBURY, who showed his interest in the subject by taking charge of the present Act whilst it was passing through the House of Lords, is a member of the Government to whom the objections will be submitted.

Such a step must not be construed as showing any sympathy with those who are rightly convicted of adulterating their goods. As Dr. VOELCKER remarks, in the valuable paper which we print in another part of the present number, the honest dealer has nothing to fear from having what he supplies examined. The danger is, that frequently the case has to be decided by an authority as ignorant of the subject "as a new born babe," assisted by an analyst positive in proportion to his ignorance and inefficiency. Among other defects of the Act, many of its provisions are obscure. Mr. Justice BLACKBURN has said of one section that "it was so drawn that it was difficult to say what it meant." Others involve hardships that have repeatedly drawn from magistrates the semi-apology that they are compelled to administer the law as they find it. It is not, therefore, surprising that the answers to the questions recently submitted by the Council to the late ATTORNEY-GENERAL and his colleagues, were of such a nature that their publication was thought to be more likely to mislead members of the trade than to give them really useful information.

Notwithstanding this, a medical contemporary says that the account of the proceedings does not read as if the ATTORNEY-GENERAL'S opinion was highly favourable to the practice of selling adulterated drugs, and that the cautious reticence of the Council may perhaps serve as a cogent hint to chemists not to make unpleasant inquiries as to the meaning of the law, but to make their arrangements to comply with its strict letter. This is called a sensible suggestion, and a hope is expressed that it will be acted upon.

We need not say that the insinuation with regard to chemists and druggists is uncalled for by any proceedings that have hitherto taken place under the Adulteration Act. Indeed, were we inclined for a *tu quoque*, we might remind our contemporary that of the four prosecutions, which are all that have hitherto been carried to a hearing in relation to medicinal substances, that which—because of its failure—has called forth the greatest amount of indignation on the part of certain medical journals was against a medical practitioner.

But the chemists and druggists are not alone in seeking for a revision of the Act. In all parts of the country the subject is exciting considerable discussion. We learn from the *South London Press* that at a numerously attended meeting of the tradesmen of Camberwell, held last week, a resolution was carried to the effect that an Association should be formed for the purpose of assisting in carrying out the provisions of the Adulteration of Food, Drink, and Drugs Act, so that while it should effectually protect the purchaser, it might not weigh unjustly on the trader. The resolution also pledged the new Association to watch the interests of all trades in furnishing such legal assistance and competent analysts as may be necessary, and to assist the public in obtaining unadulterated articles.

The meeting recognized that the object sought by the Act was a good one, but felt that the manner in which it had hitherto been carried out was faulty. As ratepayers they objected to the heavy expenses thrown upon the rates through the blundering of persons engaged in enforcing the Act. It was considered also that there was a great difference between the retail dealer who sold the goods as he received them from the wholesale dealer, and who might have been selling an adulterated article for years without knowing it, and the one who adulterated himself, yet both were punished alike. To protect the former, and to assist in causing the punishment to fall upon the real offender, is to be the *raison d'être* of the new Association.

COCA LEAVES.

As a contribution to the information sought by Dr. Sieveking, as to whether the extraordinary virtues attributed to the leaves of *Erythroxylon Coca* might not prove available for therapeutic purposes, Mr. Alexander Bell, of Nelson in Marsden, writes (*British Medical Journal*, March 7th), that large quantities of the leaves and various preparations from them, have for some years past been imported into this country

where they have been successfully used in dyspepsia, flatulency, colic, convulsions, and in the debility following severe acute affections, anæmia, scurvy, etc. Three or four drachms of the leaves, either chewed or in infusion, or ten to fifteen grains of the hydro-alcoholic extract, are a medium dose. In large doses, it is said to cause delirium, and finally cerebral congestion. In small doses, it acts as a stimulant, facilitates digestion, and relieves the sensation of fatigue. In moderate doses, it excites the nervous system in such a manner as to render the performance of muscular exertion much easier, and producing a sensation of calmness. The above appears to be the substance of the statements made in a pamphlet published by Dr. Mantegazza, in 1859, a translation of which appeared at that time in this Journal, and was also referred to in an article that appeared in 1870. *

WASTE PIPES OF CISTERNS.

The Water Companies Act of 1872 empowers the Companies, when the arrangements for a constant supply are completed, to demand that all waste pipes from water receptacles shall discharge the overflow above ground in such a manner as to call attention to any defective points in the apparatus for regulating the supply, and thus prevent the waste of water. In a recent report to the Vestry of Marylebone parish, Dr. Whitmore points out that this regulation will also accomplish a higher and far more important object, and that by disconnecting the waste pipes with the drains, it will prevent the waste of human life. The *Medical Times and Gazette*, commenting on this report, instances a house in Harley Street, the sanitary arrangements of which were inspected in consequence of the death in it of a professional gentleman from enteric fever. The arrangements were found to be generally excellent, with the serious defect, that the waste pipes from the water-cisterns passed directly into the drains; and thus, in the event of the traps not being effective, allowed the sewer gases a ready means of access to the water.

Mr. Morson was buried on Saturday last at Highgate Cemetery. A considerable number of pharmacists attended to pay their last tribute of respect to the deceased. Besides Professor Redwood and Mr. Henry Deane, there were present, Mr. T. H. Hills (President of the Pharmaceutical Society), Mr. A. Bottle (Vice President), Mr. Williams (Treasurer), Professors Attfield and Bentley, Messrs. Sandford, Greenish, Hampson, Bremridge, Bird, Taylor, Preston, and others.

The Honorary Membership of the Ontario College of Pharmacy has been conferred on Dr. W. Handsel Griffiths, author of "Notes on the Pharmacopœial Preparations," "Posological Tables," and other works.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, March 5th, 1874. Professor G. C. Foster, in the chair. After the minutes of the previous meeting had been read and confirmed, and the ordinary business of the Society transacted, a paper "On the Spontaneous Combustion of Charcoal" was read by the author, Mr. A. F. Hargreaves, in which he pointed out the best wood for charcoal for the manufacture of gunpowder, and also the best method of charring it. It appears that if it is ground too soon after being burnt the charcoal is liable to take fire spontaneously.

The other communications were, "Researches on the Action of the Copper-Zinc Couple on Organic Bodies: Part V., On the Bromides of the Olefines; Part VI., On Ethyl Bromide," by Dr. J. H. Gladstone and Mr. A. Tribe. "Researches on the Preparations of Organo-Metallic Bodies of the C_nH_{2n} Series of Hydrocarbons," by Dr. D. Tommasi. "Note on the Action of Trichloracetyl Chloride on Urea," by Messrs. R. Meldola and D. Tommasi; and "The Agglomeration of finely divided Metals by Hydrogen," by Mr. A. Tribe.

The meeting was finally adjourned until Thursday, 19th March, when there will be a lecture "On Dissociation," by Professor J. Dewar.

THE FARMERS' CLUB.

DR. VOELCKER ON MILK, ITS SUPPLY AND ADULTERATION.

At the monthly meeting of the above Club on Monday, March 2nd, an important and interesting discussion took place on the subject of milk, with especial reference to its adulteration. The subject was introduced by Dr. Voelcker in a paper, of which the following are the principal points:—

Milk may be regarded as a kind of model food. It supplies all the various elements of nutrition which are required to build up the bony frame and muscular tissue of the young, and, at the same time, supplies materials for the support of respiration and keeping up the animal heat of the body. Undiluted with water, milk is both a readily digestible and valuable, if not indispensable, article of food for children. Breeders of high-priced shorthorns know full well how essential it is to the early development of a sound and strong frame, round which the flesh and fat may be afterwards deposited in symmetrical forms, not to stint the calf in milk; and it is to be feared that the children of the artisan and the poor in towns and of the agricultural labourer in the country frequently are not nearly so well supplied with milk, both as regards quantity and quality, as the progeny of a well-cared for herd

of shorthorns, or Ayrshire or Devon cows. If it be remembered that the bodily health of the adult is affected in no small degree by the amount and quality of the food with which the infant from the time of its birth and throughout the period of childhood is fed, and also that much physical suffering might be prevented if children were not stinted in a milk diet, it is doubly desirable that the scanty allowance of milk in which the children of the poor are generally indulged should be unadulterated and of the best quality that can be procured. We hail, therefore, with pleasure the enforcement of the Food Adulteration Act, for there can be no question that before the Act came into practical operation, the milk sold alike to rich and poor in London and other large towns was watered much more generally, and to a greater extent, than it is at present in places where public analysts keep a watch over the milkman. Every honest dealer in milk entertains the same feeling with regard to the intentions of this Act, and the measure of success with which it has been carried into practice; for it cannot be to the interest of the upright dealer to have to meet the competition of the unprincipled retailer who waters his milk in the barefaced manner so prevalent in London and other towns a few years ago. The honest dealer has nothing to fear from having the milk which he supplies examined; and a wholesome check upon milk adulteration is put by the infliction of a penalty, still more by the publicity which is given to cases in which persons have been convicted of having sold adulterated milk. Nevertheless, the Food Adulteration Act requires to be carefully scrutinized, and to be revised in not a few of its details, if it is not to defeat, in a great measure, the very object for which it was passed. In carrying out legislative measures of the nature of the Food Adulteration Act great care should be taken to make provisions which shall render it impossible to inflict undeserved injury upon the honest trader. Unfortunately purveyors of milk, in not a few instances, are placed at the mercy of men whose want of practical knowledge of the various circumstances which affect the quality of milk is well matched by their inexperience and want of skill in conducting chemical operations. Numerous recent trials afford convincing proofs of the fact that the presiding magistrate at times knows as little about milk as a new-born babe, and that the greater the ignorance of the analyst the more positive he is generally in making wanton statements. No wonder, then, that the honest dealer is alarmed by the reckless operations of medical inspectors and the reports of food analysts, in consequence of which occasionally the innocent has to share the fate of the guilty. It is somewhat surprising that nothing has been done as yet, either by the dairy farmers in the country or by the proprietors of town dairies, or by the milk trade generally, to expose the arbitrary decisions which have been given in milk prosecutions during the last twelve months on the strength of analytical reports, which bear internal evidence of gross ignorance of a practical acquaintance with milk and its chemical constitution. I shall have to enter more fully upon the subject of milk adulteration, and find opportunity to show that several of the assertions which have been made by milk analysts are based on gross ignorance, and that in the interest of the fair and upright dealers, no less than in the interest of the consumer, it is desirable at once to relieve analysts who display such a degree of practical unacquaintance from their functions of food analysts. With regard to the supply of milk, we have to consider—(1), the country supply; (2), the town produce; (3), the supply of preserved or condensed milk. The question frequently asked is, Should milk be supplied exclusively from the country, or may it not be supplied equally well from town-fed cows? Another question is, Is country milk better than town produce, or *vice versâ?* And a third question is, What is the best food for milk-cows?

1. *Country Milk.*—Cows kept on nutritious grass and hay, and abundantly and exclusively supplied therewith, as a rule produce richer milk and of a finer flavour than town-fed cows. An example of such extremely rich country milk brought under my notice, produced from cows kept on very good pasture land, contained in 100 parts:—

Water	83·90
Fatty matters (pure butter)	7·62
Caseine (curd)	3·31
Milk-sugar	4·46
Mineral matter (ash)	·71
	100·00
Percentage of solid matters	16·10

Such rich country milk, however, seldom finds its way into the hands of milk dealers, nor does milk from cows fed exclusively upon grass often contain as much as 7½ per cent. of pure butter. On the contrary, if pastures are overstocked, and the herbage is naturally poor, and the food supply in consequence is insufficient to keep cows in a thriving condition, the deficiency of food tells immediately both upon the quantity and the quality of the milk. A striking instance in point came under my notice when I resided at the Royal Agricultural College, Cirencester. The cows (16 or 18) were out in September on grass, but the pasture was poor and overstocked, and hardly enough grass was grown to meet the demand for restoring the daily waste to which the animal body is subject, and the supply of food consequently was ill adapted to meet an extra demand of materials for the formation of milk. Under these circumstances I found both the morning and evening's milk very poor, as the following analyses made with average samples from the milk of all the cows will show:—

	Morning.	Evening.
Water	89·95	90·70
Fat (pure butter)	1·99	1·79
Caseine (curd)	2·94	2·81
Milk-sugar	4·48	4·04
Mineral matter (ash)	·64	·66
	100·00	100·00
Solid constituents	10 05	9·30

Here we have two practical illustrations showing how largely the quality of the milk is affected by the amount and richness of the natural pasture upon which the cows are kept. In the case of the cows kept in the rich pastures the milk contained, in round numbers, 7½ per cent. of butter; whilst the badly-fed cows, also out on grass, gave milk so poor as to yield in one instance barely 2 per cent., and in the other about 1¾ per cent. of butter. My analyses were not made with the milk-produce from a single cow, but with a fair average sample of the whole produce from some 16 or 18 cows which were milked in my presence. It thus appears that country milk may be either very rich or be very poor. Speaking generally, country milk from cows out on rather poor and overstocked pastures is poor, and compares very unfavourably with the milk from town-fed cows. According to careful records, 245,458 gallons of milk were produced in seven years by a herd, averaging 65 cows (shorthorns), or 535 gallons were produced by each cow per annum, the food being grass and hay, with roots and straw in winter. Putting 530 gallons of milk against 28 tons of this green food, we have 1lb. of milk to every 11 or 12lbs. of grass, or as nearly as possible 100 gallons of milk to every ton of hay. If the object of the dairy farmer is to produce milk for the town, it will not pay him to keep grazing dairy-stock on growing grass, and he will find it to his advantage to feed the cows in houses upon cut grass, supplemented by oil-cake meal, brewers' grains, and similar purchased food. As a matter of economy, milk can be produced as economically in or close to large towns as in the country, for any extra expense to which a town dairy-farmer may be

put is made good by the expense of carriage to the nearest railway station, and the railway charges. The advocates for the town producc of milk maintain that in warm weather a good deal of milk is spoiled during its transmission by railway. However, by observing the following simple rules country milk may be sent by rail on long journeys without spoiling even in very hot weather. 1. The milk should be drawn from the cow in the most cleanly manner, and strained through wire-cloth strainers. 2. The milk should be thoroughly cooled immediately after it is drawn from the cow. This may be done by a milk-cooling apparatus, specially constructed for rapidly cooling milk, or simply by placing the can in which it is contained in a vat of cold water, deep enough to come up to the height of the milk in the can containing it, and by using at least three times as much cold water as the milk to be cooled; the milk should be occasionally stirred until the animal heat is expelled. The milk should be cooled down as rapidly as possible to a temperature of about 55 degrees. 3. The evening's and morning's milk should be cooled down separately, and be sent in separate cans, and not mixed together if it can be avoided. 4. No milk should be kept over to deliver at a subsequcnt time. 5. The pails and strainers employed on the farm should be thoroughly cleaned, scalded in boiling water, and dried morning and night. 6. Immediately before the milk is placed in the cans they should be thoroughly rinsed with clean cold water, and great care be taken to keep the cans and milk free from dirt or impurities of any kind. When the cans are not in use they should be turned down on a rack, with the tops off. 7. Before the cans are returned to the country they should be thoroughly rinsed out with clean water and scalded with boiling water. 8. In very warm weather it is well to put the milk cooled in cans covered over with a coarse flannel casing, which may be kept wet for a considerable time.

2. *Town Produce.* As regards the quality of milk from town-fed cows, I would observe that I have had a very large experience in the examination, both of country and town-milk, and am bound to say that, as a rule, London milk, when undiluted, is considerably richer in cream than country milk. I ascribe this to the fact that cow-keepers in large towns mostly are men of business, who find it profitable not to stint their cows in food, and to supply them with a better and richer description of food than that which the ordinary run of dairy farmers provide for theirs.

3. *Preserved and Desiccated Milk.* When milk is evaporated at a low temperature, and a little sugar is added when the process of evaporation is nearly completed, the residue which is left on final evaporation on being reduced to powder constitutes a white powder with a yellow tinge, which dissolves for the greater part in boiling water. The solution resembles in appearance and taste milk, and answers pretty well as a substitute for milk for ship's use, or when fresh milk cannot be obtained. Desiccated milk, if well prepared and perfectly dried, may be kept in closed bottles for many months without undergoing any change, but it does not dissolve perfectly in water, and is deficient in the agreeable taste which characterizes good fresh milk. Usually a portion of the cream is removed before the evaporation of the milk; for if the whole milk is condensed by slow evaporation, the desiccated milk is very apt to assume, after a short time, a bad taste resembling rancid butter. The following are analyses which I made some time ago of two samples of desiccated milk:—

	No. 1.	No. 2.
Moisture	4·06	1·78
Fat (pure butter)	8·73	16·32
Caseine	20·25	20·37
(containing nitrogen)	(3·24)	(3·26)
Phosphate of lime and magnesia	2·34	2·33
Alkaline salts	2·48	2 91
(containing phosphoric acid)	(0·26)	(0·31)
Sugar	62·14	56·29
	100·00	100·00

The second sample, it will be seen, contains nearly twice as much fat (pure butter) as the first, which was evidently produced from skim-milk. The sample No. 1 had a nice taste, and, notwithstanding the deficiency of butter, was a superior preparation in comparison with the second sample, which had a disagreeable taste of rancid butter. A much better description of concentrated milk has been prepared for a good many years past in America, under Borden's patent, and a few years since an American Company—the Anglo-Swiss Condensed Milk Company—has established a factory at Cham, near Zug, in Switzerland, for the production of pure Swiss preserved milk. This company, with a capital of £12,000, employs about sixty operatives in the factory. The number of cows hired for the year is 1440, and the average amount of condensed milk prepared daily during each of the 365 days of the year is 110 cases, of four dozen each of 1lb. cans; these equal 1,927,200 cans as the product of the year. The price of the crude milk is about 2*d.* per quart; and the daily cost of the tins or cans made at this establishment amounts to £16 10*s.* About one-half of the product is sent direct to London, where one-half is consumed, while the remainder goes for ships' stores, is exported to the colonies, and sent to the provincial towns of England. One-half of the produce not sent to London is distributed over Germany, and there is some demand from France and Russia. The milk is evaporated down *in vacuo* at a uniform temperature of 160 deg. Fahr., with the addition of the best refined white sugar, until it reaches the consistency of thick syrup or honey. It takes about seven hours to condense the milk, 75 per cent. of its original bulk in water being driven off. The condensed milk thus prepared has been preserved in good condition for years. Mixed with three to four pints of water it readily dissolves, yielding a somewhat sweet but agreeably tasting fluid, having a flavour of boiled milk. It consists of nothing but cows' milk and the best white sugar, and is well adapted for use during long voyages and in all other situations where good cows' milk is not readily procurable. A sample of preserved milk prepared by the Anglo-Swiss Company on analysis yielded the following results in my laboratory:—

Water	24·89
Fat (pure butter)	8·36
Caseine (curd)	10·15
(containing nitrogen)	(1·624)
Milk and cane-sugar	54·18
Mineral matter (ash)	2·42
	100·00

About one-half of the solid substances of the condensed milk consists of sugar added in the process of condensation. The remainder consists of butter, caseine, milk, sugar, and ash constituents. It is but right to state that the analyses of other samples of preserved milk prepared by the Anglo-Swiss Company show about ten per cent. of butter and somewhat less water than I found in the sample analysed by me. Those who take a special interest in the manufacture of condensed milk will find a full account in a highly interesting paper, illustrated by many woodcuts giving a full description of the necessary apparatus and the processes of manipulation, by Mr. X. A. Willard, of Kerkimer, New York, published in vol. xv., new series, part 1, 1872, of the Journal of the Royal Agricultural Society of England. The success of the Anglo-Swiss Company naturally created competition. Condensed milk factories were established at Gruyères and half-a-dozen other places in Switzerland, in Bavaria, in Holstein, in Ireland, and in England; but failing to produce first quality preserved milk, and wanting in prestige and other causes, they have ceased to manufacture, with the exception of Mr. Newman's Irish condensed milk factory at Mallow, near Cork, and the English Condensed Milk Company, whose works are at Aylesbury, Buckinghamshire.

Food appropriate for producing much and good Milk.—

The influence of food on the quality of milk is very striking. A half-starved cow yields but little milk and poor milk. On the other hand, the liberal supply of peas or bean-meal, or oil-cake, and other food rich in nitrogenous and phosphatic elements of nutrition, tells directly, both on the quality and quantity of the milk. The finest flavoured milk and butter are produced by cows fed in summer entirely on grass and rich permanent pastures, and in winter on nothing else but hay, made of fine sweet grass. Turnips yield a watery milk, and are objectionable, on account of the turnipy flavour which they give to the milk. Mangolds are less objectionable, but should not be given to milk-cows without an allowance of 3 to 4lbs. of meal per head. Of all kinds of meal, none is equal in milk-producing properties to bean or pea-meal—a fact which finds a ready explanation in the circumstance that bean or pea-meal contains on an average from 25 to 28 per cent. of nitrogenous constituents, or the same class of compounds to which the curd of milk belongs, and that it is likewise rich in phosphates or bone-earths, in which milk abounds. Egyptian lentils answer equally well with bean-meal, for they resemble intimately in composition beans or peas. Linseed-cake produces much and rich milk, but unless it is pure and fresh cake of the finest description, it seriously injures the quality of the milk. Fine decorticated cotton-cake is both rich in fat and in nitrogenous constituents, and like all food rich in nitrogen it also contains a large proportion of phosphates, and is thus admirably well adapted for milk-cows. Rape-cake is likewise an excellent food for milk-cows, provided it is free from an undue admixture of wild-mustard seed, which frequently occurs in rape-cake made from Indian seed to an extent which renders it perilous to stock. The best rape-cake is green German rape or Rubsen cake, one of the cheapest and best concentrated kinds of food that can be given to milk-cows. Bran or pollard, as is well known, produces good and rich milk. Nothing can be better as an auxiliary winter food for milk-cows than 4lb. of bran made into a thin mash, to which about 3 to 4lb. of bean-meal is added. Along with this about 25lb. of mangolds, and a due proportion of hay or hay and straw chaff will supply a food-mixture which produces much and first-quality milk. Brewers' grains are the staple food in town-dairies, and they are much more nutritious than their appearance seems to warrant. Even in the wet condition in which they are obtained from the breweries, and holding from 75 to 77 per cent. of water, they contain a fair proportion of ready-made fat and flesh forming matters. Desiccated grains contain from 7 to 8 per cent. of oil, and about 18 per cent. of nitrogenous compounds. Dried brewers' grains make good milk, and are fully as valuable as a food for milk-cows as barley-meal. Another useful and, comparatively speaking, cheap food for milk-cows is palm-nut meal, but its quality and value differ greatly. The best palm-nut meal contains 19 to 20 per cent. of oil and fat, and is made from the partially-expressed kernels of the palm-nut; its value as a food for fattening stock or for milk-cows depends principally upon the proportion of fatty matter which is left in the meal. The fatty matter in palm kernels is a white, agreeably tasting fat, of almost the same consistency as butter.

A good deal has been said and written for and against feeding milk-cows upon sewage grass. One the one hand, sewage-grass has been praised as the most nutritious kind of grass for milk-cows; and, on the other, the adversaries to all schemes of applying sewage to land have endeavoured to prejudice the public mind by denouncing the produce from grass land irrigated by sewage as innutritious and a highly dangerous food for milk-cows. Like all very succulent produce, the grass from sewaged land is more watery, and, in consequence, not so nutritious as the produce from rich permanent pastures. It is, nevertheless, a most acceptable food to the dairy-farmer, who usually gives along with it to his cows some bean or other descriptions of meal or auxiliary concentrated food, and, under proper management, there is not the slightest ground for suspecting that sewage-grass when given to milk-cows will render the milk they yield unwholesome or dangerous to the youngest child. If sewage could not be usefully applied to Italian rye-grass to be turned into milk and butcher's meat, all sewage-irrigated schemes would long ago have fallen to the ground. Convinced as I am that the produce from a properly managed sewage-farm supplies an increased amount of good and wholesome food, the greater part of which is especially useful to cow-keepers, I can only express the hope that all town authorities, who at present allow large quantities of plant-food to run to waste, polluting our rivers and watercourses, will ere long set apart a portion of land, if such can be found appropriate for sewage irrigation, on which Italian rye-grass, cabbages, and mangolds can be raised in large quantities by means of sewage, for the special advantage of cow-keepers, and the benefit of the community at large.

Milk Adulteration.—Milk is a whitish liquid of an agreeable, sweetish taste, and faint but pleasant odour, depending in some measure upon the nature of the food upon which the cows are fed. It is essentially an emulsion of fatty particles in a solution of caseine and sugar of milk. The fatty matter is not contained in milk in a free state, but enclosed in little cells of caseine, which occurs also in milk in a state of solution, and is precipitated spontaneously as curd when milk gets sour. Viewed under the microscope, milk appears as a transparent fluid, full of small, round, or oval, and more or less angular bodies—the so-called milk globules. When milk is left undisturbed for some time, these milk globules rise to the surface, forming the cream of milk. Skim-milk has a bluer colour, and is more transparent than new milk, containing its full share of milk globules or cream or butter globules. The amount and quality of the food given to cows exercises a most remarkable influence on the quality and composition of milk. Besides this, the season of the year, distance from the time of calving, the breed and size of the cows, and several other circumstances which will suggest themselves to practical men, have a greater or less influence on the yield of milk and its quality. When residing at Cirencester College, with a view of ascertaining what may be the variations in the course of a year in the quality of milk on one and the same farm, I took samples of the milkings of all our milch cows, and analysed the morning's and evening's milk of the first or second day of each month. The milch cows were out at grass from May till the end of October, and as the herbage then became so scarce as not to afford sufficient nourishment, they were fed in the evening at the stall on roots and hay, &c. It will be seen by the appended analyses that both the morning's and evening's milk in September were extremely poor. The poverty of this milk was therefore evidently due to an insufficient supply of food. The milk produced on two other farms in the neighbourhood during the same month, on being analysed, was found to contain 12½ per cent. of solid matter, including 3½ per cent. of fat (pure butter), and the same percentage of curd; showing that on both farms where the cows were supplied with a sufficient amount of nutritious food, the milk was of good quality, whereas on the College farm the scanty supply of poor grass had the effect of producing poor milk, containing 90 per cent. of water, and only 2 per cent. of fat. The influence of food on the quality of milk was also clearly visible in the cows of the College farm. On account of the insufficiency of the grass, the cows were driven into the stall and there supplied with roots, hay, and meal. The milk became better at once, for the morning's yield then contained 12½ per cent. of solid matter, and in this nearly 4 per cent. of butter. The concentrated food which the cows received in the evening was evidently made into good rich milk during the night. At this time the cows were put on grass early in the morning and allowed to pick up what they could. This was not much, as their anxiety in the evening to be let into their stalls clearly showed. The influence of a stinted supply of grass

was noticed at once in the poverty of the evening's milk. The percentage of solid matter fell to $9\frac{2}{3}$ instead of $12\frac{1}{2}$ per cent., and the butter to 3 instead of 4 per cent. I would direct especial attention to the fact that these analyses were not made with milk of a single cow, but that of the whole herd, and as the milch cows were kept entirely for the use of the College, there can be no question as to the genuineness of the supply.

COMPOSITION OF MORNING AND EVENING'S MILK PRODUCED ON THE ROYAL AGRICULTURAL COLLEGE FARM, CIRENCESTER.

		Percentage of					
		Water.	Butter (pure fat).	Caseine and Albumen.	Milk-sugar.	Mineral Matters. (ash.)	Nitrogen.

	Evening	86·00	4·12	3·62	5·46	·80	·58

I have alluded specially to these variations in the quality of milk as influenced by food, because some statements have lately appeared in a little work on milk analysis written for the special benefit and instruction of food-analysts, "a new class of men," which has lately been "constituted to watch over the food of the country." I leave it to you to form your own opinions from the following extracts taken from this treatise. According to the author, country milk of average quality contains in 100 parts by weight:

Water	87·55
Fat	3·08
Caseine	4·04
Milk-sugar	4.62
Ash	·71
	100·00

Town-fed milk, according to his analysis, contains in 100 parts by weight:

Water	85·94
Fat	4·00
Caseine	5·02
Milk-sugar	4·31
Ash	·73
	100·00

It will be seen that the latter milk shows a difference of one-third more of fat and one-quarter more than the amount of caseine contained in the former, and a corresponding smaller amount of water. These differences are sufficiently striking to show, at all events, that milk has not a uniform composition. Nevertheless, our author says, "Milk exhibits great constancy of composition; the effect of variations in the diet of the cow showing itself in the amount of the secretion, rather than in its quality;" and again, "As will be readily comprehended, this constancy of composition is a cardinal fact in milk analysis. If milk were variable in strength, as urine is, chemical analysis would fail to detect the watering of milk. That milk is a secretion of constant, or only slightly varying, composition, lies at the very root of the subject of this treatise." In the face of the evident contradictions between the facts given and the opinions expressed by this same author, I think I need not detain you by criticizing other portions of the treatise, but leave you to draw your own conclusions as to the value of the frequent use he makes of what he calls "normal milk." One might as well talk of a "normal potato," or a "normal cabbage," or a "normal pig." On passing along on the top of an omnibus a short time ago, I was somewhat amused at seeing an advertisement of a wine merchant of his "standard sherry," and I am surprised that standard or "normal" milk is not advertised, as it might be with quite as much reason as "standard sherry." A great deal has been said and written about milk adulteration. Sheep's brains, starch, chalk, and pipe-clay are said—on what authority nobody has ever decided—to have been found in milk; but the basis for these statements exists only in the imagination of credulous or half-informed scientific men, who, in want of more profitable occupation, take to book-writing. It would be difficult to understand where all the sheep's brains should come from; nor is it probable that chalk or other insoluble substances not easily kept in suspension, should be employed in adulterating milk. I have never found myself, nor have I ever met any chemist who has found, any of the clumsy adulterations often referred to in popular treatises on food. Milk adulteration resolves itself into one of two things—either the addition of water, or the abstraction of cream; and the question which naturally arises is, Can we detect to a nicety how much water has been added or how much cream has been abstracted from a given sample? I have, perhaps, had as much experience in the examination of milk as anybody in England, and I fearlessly say that, owing to the natural variations in milk, it is utterly impossible in all cases to ascertain whether a small quantity of cream has been removed from milk, or an inconsiderable proportion of water has been added to it; and I further maintain that it is a reckless proceeding on the part of any analyst to assert that milk has been adulterated with exactly 8 per cent. of water, or with 13·75 per cent. of skimmed milk, as in one case, or with 16·25 per cent. as in another. Such assertions can only be made by young and inexperienced men, for whose special instruction such milk treatises as I have above referred to are compiled. No wonder that men who entertain such inconsistent views of "normal milk" should be led to give reports in which they positively assert that they have found 16·25 per cent. of skimmed milk, because the amount of fat did not come up to their standard by a few decimals. I may state, in passing, that in a recent case the milkman, who was accused of selling milk adulterated with 16·25 per cent. of skimmed milk, was fined in the "mitigated penalty of £5," with the alternative of ten days in gaol. In the course of the trial testimony was given by a worthy town councillor, who had carried on business as a temperance hotel-keeper, that the accused had been known to him for the last twenty years, and had during the whole of that time supplied him with milk. He further expressed his opinion that no better milk was to be obtained than that of the accused, against whom he had never known any complaint. A well-known chemist, moreover, was called for the defence, and, on the strength of the analysis, he pronounced the milk to be of the quality of good ordinary country milk, quoting, in support of his opinion, no less an authority than the late Professor Johnstone, but apparently to no purpose, because the amount of fat contained in the milk differed in a trifling extent from what the food analyst conceived to be the amount contained in "normal milk." A medical man, called in support of the prosecution, gravely stated that milk containing 16·25 per cent. of skimmed milk would be prejudicial to the health of the very young, although its effects would be hardly appreciable on an adult. Instances of this kind would be

very ludicrous but for the serious consequences involved, and the injustice which, no doubt, is frequently dealt to honest dealers. Let it, however, be clearly understood that I have no intention of throwing cold water upon the system of chemically examining milk. All I desire to show by these observations is, that milk analyses should be conducted by men upon whose practical experience and acquaintance with the subject reliance can be placed. Chemical analysis can do much in the way of revealing adulteration of food, and there is no difficulty in discovering whether milk has been skimmed or watered to any great extent. As the result of my own experience, I may state that milk may be considered rich when it contains from 12 to 12½ per cent. of solid matters, 3 or 3½ of which are pure butter. If it contains more than 12½ per cent. of solid matter and has 4 per cent. or more of fat, it is of extra rich quality. Such milk usually throws up from 11 to 12 per cent. of cream (by bulk) after standing for 12 hours at 62 degrees Fahr., and it has a specific gravity varying from 1·028 to 1·030. Good milk of fair average quality, as has been stated already, contains from 10½ to 11 per cent. of dry matter, including about 2½ per cent. of pure fat. It yields 9 to 10 per cent. of cream, and has a specific gravity of about 1·030. Poor milk contains 90 per cent. or more water, and has a lower specific gravity than 1·027. Such milk does not yield more than 6 to 8 per cent. of cream. Skimmed milk throws up still less cream, has a bluer colour, and is more transparent, and when undiluted with water has a slightly higher specific gravity than new milk. Good skimmed milk has a specific gravity of about 1·033, and poor skimmed milk 1·028 to 1·030. Milk purposely watered yields only 5 to 6 per cent. of cream, and invariably has a lower specific gravity than 1·025. If milk is both skimmed and watered, it yields less than 4 per cent. of cream, and possesses as low a specific gravity as 1·025 to 1·026. A great many experiments have led me to the conclusion that within certain limits the specific gravity is the most trustworthy indicator of quality. Some of the objections to the use of hydrometers or instruments for taking with accuracy the specific gravity of milk, are based on the mistaken opinion that cream is lighter than water. This, however, I have ascertained is not the case. Cream, I find, is lighter than milk, but denser than water, in the proportions of 1012, or even 1019 to 1000. The addition of cream, therefore, cannot depress the specific gravity of milk in the same degree as the addition of water. A low specific gravity thus always indicates a large proportion of water ; at all events, I find that milk rich in butter is of a specific gravity a good deal higher than milk adulterated with even a little water. Some years ago I made some accurate gravity determinations of pure milk before and after skimming, and of samples mixed purposely with 10 to 50 per cent. of water.

	Sp. gr. at 62° Fahr. Before Skimming.		Sp. gr. at 62° Fahr. After Skimming.
Pure milk	1·0314	.....	1·0337
With 10 per cent. water	1·0295	.....	1·0308
With 20 per cent. water	1·0257	.....	1·0265
With 30 per cent. water	1·0233	.....	1·0248
With 40 per cent. water	1·0190	.....	1·0208
With 50 per cent. water	1·0163	.....	1·0175

It appears from these results that good pure milk has a specific gravity of 1·030; skimmed milk being a little higher; and, further, that milk, having a specific gravity as low as 1·025, is either mixed with water or is naturally very poor. If the gravity should sink to 1·023 or less, it is unmistakably mixed with a considerable quantity of water. A useful instrument for approximately determining the percentage of cream is a graduated glass tube, at the top of which the cream may be allowed to collect, and its quantity may be read off. There can be no doubt about the fact that, before the late Adulteration Act, the milk of London was shockingly adulterated, and it was high time that a check should be placed upon the malpractices of milk-dealers. I am, however, anxious that the Act should not become ridiculous in the eyes of a discriminating public, for several recent milk-prosecutions have shown that the wisdom of the wise (food analysts) in more than one or two instances is truly foolishness, even in the sight of any ordinary dairyman. I should advise rigorous prosecution in every case of flagrant or unmistakable adulteration ; but whilst those entrusted with the enforcement of the Act draw the line so finely as they too frequently do at present, between pure milk and that which has been tampered with, serious mistakes must and will necessarily arise, to the discredit of all concerned in the matter, and sometimes, perhaps, to the irrecoverable loss of the reputation of an innocent man.

Parliamentary and Law Proceedings.

Poisoning by a Lotion.

Mr. F. Price, coroner, has held an inquest, at Salford, touching the death of Mary Cooper, 52 years of age. Deceased, who was the wife of an operative dyer, had been ailing for about 12 months, and had been attended by Dr. Cran. She had had several bottles of medicine, and on Friday morning previous to her death her son fetched her a bottle from Dr. Cran's surgery. After tasting the contents, deceased's husband said, "It's very hot ;" to which she replied, "Never mind, if it will do me good." The doctor did not say that he would send her a lotion to rub her legs with, and thinking the medicine was to be taken internally, the husband gave her a tablespoonful. This was about half-past 11 o'clock on Friday forenoon, and in about 10 minutes afterwards deceased complained of feeling very queer. Cooper then examined the bottle, and took it back to the surgery. Dr. Cran was out, but having told Mrs. Cran of what had happened, the doctor visited deceased as soon as he returned home, between 12 and 1 o'clock the same day. Deceased, who was at times insensible, died at 2 o'clock on Monday morning.

Dr. James Cran, Regent Road, said he had attended deceased since Christmas. She was suffering from general debility and rheumatic pains in her legs. He saw her on Thursday, and said he would send her a lotion to rub her legs with. He generally told his patients when he intended to send poison as a lotion, but did not recollect whether he took that precaution in this instance. He prepared a lotion for deceased containing liniment of belladonna and aconite in equal proportions. They were both strong poisons, and the bottle was labelled "poison." On learning that deceased had taken some of the lotion he visited her, and endeavoured to administer an emetic, but found she could not swallow it. He then sent for Dr. C. Clarke, and the emetic was administered by means of a stomach-pump. It had the effect of making deceased vomit, but she still suffered from the effects of the poison, two teaspoonfuls of which were more than sufficient to cause death.

The jury returned a verdict to the effect that deceased died from taking a poisonous lotion inadvertently administered by her husband.—*South London Press.*

Poisoning by Arsenic.

A remarkable case of poisoning is reported to have occurred at Thursley. A family named Coombes were seized with alarming symptoms of virulent poisoning, which were followed by the deaths of the father, mother, and three children. An inquest on these bodies was held on Monday afternoon, at the Half Moon Inn, Thursley, before Mr. George H. Hull, the coroner for West Surrey. Three other members of the family at the time of the visit of the jury were lying in a hopeless state, all suffering from poisoning symptoms. Since that date, however, the medical man in attendance has written to the *Times* stating

that he has hopes of their recovery. The coroner having taken evidence to identify the bodies, Sergeant Bundy, of the Surrey County Constabulary, stated that he had discovered that the father of the family had brought from the farm, on which he worked as a shepherd, a bucket holding about two gallons and a half, which had contained for a long period a composition for dressing sheep. This bucket he had washed out, and it had been used as a receptacle for containing the water drawn from the well for the use of the family. The bucket had been taken to Dr. Stevenson, the county analyst, who had found that it was impregnated with arsenic to such a degree as to make it dangerous for use as a receptacle for water. The coroner adjourned the inquest for a week.

Prosecutions under the Adulteration Act.

ADULTERATED BUTTER.

At the Axbridge Petty Sessions, held last week, Emma Ham was summoned for wilfully admixing with butter an injurious ingredient, viz., a large proportion of common fat and colouring matter.

Mr. Bailey appeared for the defendant, and pleaded not guilty.

A girl stated that on the 29th ult. she went to the defendant's premises for half a pound of butter. Whilst there she saw the defendant mixing up butter in a pan. In the pan was water and some white matter, but she did not know what. Mrs. Ham made her up the butter from the pan whilst waiting.

Cross-examined by Mr. Bailey: She saw some butter on the flats; it was made up into half pounds. There was white stuff in the pan; it might have been butter.

Mr. Bailey, prior to calling any witness, said, according to the Act, it must be proved that the defendant mixed and sold butter similar to that now produced, which had been analysed.

The case was briefly discussed by the magistrates, and ultimately the charge was withdrawn.

There was a second summons issued against defendant, charging her with selling adulterated butter. The deposition taken above was used as evidence in this case.

Superintendent Gillbanks informed their worships that he received the butter produced from Elizabeth Hembry, grandmother to the girl, on the 9th inst. He had sent it to Mr. Stoddart, county analyst, and received an answer to the effect that the butter sent him for analysis was the worst that had come under his notice, one-fourth of it being common fat and colouring which the analyst considered to be injurious.

Mr. Bailey contended that prior to conviction, it must be proved that the butter was adulterated to the knowledge of defendant.

The Bench overruled the point, adding, that if they took such meaning of the Act, there could be no stop put to adulteration.

For the defence, a sister of the defendant, who was in the house at the time of the butter being supplied to the girl Hembry, said she saw nothing mixed with the butter.

Mr. Bailey said the husband was a large butter dealer, and that if the butter sold was adulterated, it was so done prior to being brought to his house.

The Chairman thought it an extremely bad case. Defendant was liable to a heavy penalty, but the Bench would mitigate the fine to £5, and all costs.

ALLEGED ADULTERATION OF MILK.

At Wolverhampton, on the 27th February, Mr. John Rudler, appeared before Mr. J. Spooner, the Stipendiary Magistrate, charged with selling adulterated milk. Mr. Cartwright appeared for the prosecution, Mr. Dallow defended. Captain Segrave proved that he delivered a sample of milk obtained from the defendant to Mr. W. L. Scott for analysis. Mr. Scott, who said he was analyst for the northern division of Staffordshire, for the county of Derby, and for the borough of Hanley, deposed to receiving from Captain Segrave the bottle of milk produced. Witness analysed a portion of it, and gave his report to Mr. Dallow. Mr. Dallow produced the report. Mr. Spooner cautioned the witness that in any future case of this kind his report must be delivered to the court, and to no other living being. His worship read the clause of the Act bearing upon this point. Mr. Scott, continuing his evidence, said he examined the milk very particularly; and in the first instance he found it extremely sour. That would affect the analysis. In his opinion there was no adulteration whatever. Mr. Spooner: Did you test the milk as an independent analyst, or as acting on the part of the defendant? Witness: I treated the matter upon a perfectly independent basis, though acting upon the instructions, so to speak, of Mr. Dallow. My report was only given to Mr. Dallow a few minutes before we came into Court. Mr. Spooner: There seems to be no case where scientific men are employed, in which you can't get evidence on both sides. I suppose it is owing to the uncertainties of science. Mr. Scott then gave some details of the results of four examinations, the conclusion he came to being, that the milk in question was undoubtedly of excellent quality, and contained rather more than one per cent. of solids above the average of Staffordshire milk. Witness's standard for South Staffordshire milk was 9·50 of deoleolized solids, and for North Staffordshire 9·45. Mr. Jones was also examined. He said that, according to Mr. Scott, who adopted a higher standard than he did, the milk in question would be more adulterated than had been represented. Mr. Scott's figures showed 6·27 as the amount of extra water in the milk; whereas witness (Mr. Jones) put the quantity at 1½ per cent. only, because he adopted a lower standard.—Mr. Spooner: Who shall decide when doctors disagree?—Mr. Jones: This is only a matter of simple calculation. The character of the milk was not much changed since it was first examined.—Mr. Dallow thought Mr. Jones and Mr. Scott had better go through their figures together.—After some discussion between Mr. Jones and Mr. Scott with respect to their respective analyses, Mr. Jones, in reply to Mr. Dallow, said the milk was of average quality. One and a half per cent. of adulteration would be something less than a tablespoonful of water in a quart.—Mr. Spooner: But we don't want even the tablespoonful; if we desire to have water in our milk at all, we would rather water it ourselves. He was of opinion that the two scientific witnesses were in opinion as wide as the poles were asunder.—Mr. Dallow said the remark had been made in the course of the case that it was "very unfortunate" that he (Mr. Dallow) had communicated with Mr. Scott in this matter. All that he had done was to request Mr. Scott to call upon Captain Segrave for the sample of milk in his possession, for the purpose of making his analysis.—Mr. Spooner: And you, at the same time, intimated to him that you, or your client, would see him paid.—Mr. Dallow: Certainly, I did.—Mr. Spooner: You having done that, Mr. Scott does not come before this Court as the witness contemplated by the Act of Parliament. What I wanted was a witness totally unconnected with either one side or the other, but you having communicated with Mr. Scott, and given him to understand that he would be paid by you, makes him your witness.—After some further remarks, Mr. Dallow said that as there was a doubt in the case—the scientific witnesses being directly opposed to each other as to the results of their respective analyses—his client ought to have the benefit of the doubt by the case being dismissed.—Mr. Spooner said the question for his decision was really one that he was not competent to decide, viz., as to whether Mr. Jones was right, or whether he was wrong, and Mr. Scott was right? That was a question which he certainly would not take upon himself to decide. If, as the Act contemplated, the defendant being dissatisfied with the analysis made by Mr. Jones, a competent analyst had been appointed by the Court to make an independent analysis without any leaning to either one side or the other, then he (Mr.

Spooner) should have felt justified in accepting his evidence, and deciding thereon. But he could not regard Mr. Scott in any other light than a witness for the defence. If, however, both sides expressed a wish that he should do so, he would still appoint an independent analyst to make an analysis on the part of the Court.—Mr. Dallow agreed to this, and the names of several well-known analytical chemists were mentioned, but as the legal gentlemen engaged could not agree as to the appointment of any one of them, Mr. Spooner said he must decide the case himself. If the defendant chose to pay the costs he would not fine him; if, however, he declined to accept this offer, he should impose the nominal penalty of 1*s.* and costs.—Mr. Dallow, on behalf of the defendant, said the costs would be paid.—The costs were then paid, and the parties left the Court.—*Wolverhampton Chronicle.*

Review.

INTRODUCTION TO THE STUDY OF ORGANIC CHEMISTRY. The Chemistry of Carbon and its Compounds. By HENRY E. ARMSTRONG, Ph.D., F.C.S., Professor of Chemistry in the London Institution. London: Longmans. 1874. Pp. 349, small 8vo.

This is the new volume in Messrs. Longmans' series of cheap text-books for artizans and students in public and other schools. It appears in the same form, and nearly the same size, as the small text-book of Inorganic Chemistry written by the late Professor Miller, and of which a highly favourable opinion was expressed some time ago in these columns.

But Dr. Armstrong's is a work of totally different character, and although we have nothing to say of it except in the way of praise, it cannot be regarded as a sequel to little 'Miller.' No student, however perfectly he might have mastered the contents of the volume on Inorganic Chemistry, would be in a position to read the present work so as to understand it. This, however, must not be understood to convey a reproach to either of the books in question, but simply to indicate that another is yet wanting to bridge over the interval which at present unquestionably separates them.

The volumes in this series are in fact very unequal in scientific rank, some carrying the reader into tolerably elevated regions, whilst the pretensions of others are of a far humbler, though perhaps not less useful character.

Dr. Armstrong's treatment of his subject is somewhat original, certainly very different from that of other authors of existing text-books. Ignoring altogether those practical matters, interesting chiefly to the manufacturer, to the physiologist, and to the pharmaceutist, which have hitherto so largely occupied the pages of text-books of similar design, he devotes himself exclusively to the systematic study of series rather than of individual compounds.

The arrangement of the matter is almost precisely the same as that of the second volume of Naquet's well-known and admirable 'Principes de Chimie,' but the new work presents advantages over 'Naquet' in conciseness, in the adoption of a modernized and systematic nomenclature, and in the very free use of *general* formulæ.

"The first part deals with the methods employed in ascertaining the composition of carbon compounds; the representation of carbon compounds by empirical formulæ, and by formulæ which not only express their composition, but also to a certain extent picture their nature, is then briefly discussed. After a short description of the action of various re-agents on carbon compounds, the compounds of carbon with oxygen, with sulphur, and with nitrogen, are briefly considered. The great family of hydrocarbons are next described; and the remaining families of carbon compounds are then considered in the order of their relation to the hydrocarbons which are regarded as forming the parent series." (Preface.)

The families thus referred to are all comprised under seven heads, namely, alcohols, ethers, aldehyds, acids, ketones, amines, and organo-metallic compounds. The description of every family or sub-family of compounds commences with a short definition; an account is then given of general methods by which the compounds of the series have been obtained, and afterwards their behaviour under the influence of various general re-agents is described. Several tables are also given which exhibit all the known members of several homologous series and their isomerides, with their boiling points and other physical characters.

A glance through a book of this kind carries the mind back to the work of twenty years ago, and compels a tribute to the memory of Laurent and Gerhardt, to whom we are so largely indebted for our modern chemical system. Homology and the idea of types, somewhat modified and developed, it is true, are still the fundamental principles of our classification. Gerhardt considered that chemical formulæ were only capable of expressing relations and analogies, the best being those which render evident the greatest number of such analogies. What chemist of the present time can honestly declare that his formulæ do more than this?

We are very glad to observe that Dr. Armstrong, trained as he has been in the very newest of new schools, has not been led into extravagancies as to the significance of the formulæ which, in common with other chemists, he employs. On the contrary, referring (p. 27) to constitutional, or so-called structural formulæ, he says: "We possess no real knowledge as to the internal constitution of chemical compounds, or of the mode of arrangement of the atoms of which bodies are presumed to be made up, and although rational formulæ *may* represent the proximate constitution of chemical compounds, yet, in the present state of our knowledge, it is advisable to regard them simply as condensed symbolic expressions of the chemical nature and mode of formation of the compounds represented; they enable us, so to speak, to decipher at a glance the chemical history of compounds."

There is just one question which we think is deserving further consideration by the author, not because we have any objection to the hypothesis he puts forward, but because of the intrinsic importance of the subject itself. The fact is familiar to all students of chemistry that countless instances are known of two or more bodies exhibiting the same composition, but totally different properties. Such bodies are said to be isomeric, polymeric, or metameric with one another according to the nature and extent of the differences between them. The explanation of isomerism has occupied the minds of chemists, perhaps more than any other subject, during the last few years, and the hypothesis very generally received goes under the name of the "position theory." Briefly stated, this theory pretends to explain the differences observed in isomeric compounds by assuming that the atoms constituting the molecules of those compounds are arranged in different relative positions. Taking the example quoted by the author, nitroethane, $(C_2H_5)-NO_2$, may be supposed to have the nitrogen combined with the carbon, whilst in ethyl nitrite, $(C_2H_5)-O-NO$, the nitrogen is coupled to the carbon by an intervening atom of oxygen.

The author rejects this view, which, it may be here observed, has probably never been accepted *literally* by any but a few bigoted adherents of the old form of the atomic theory, and he proposes another which really appears to differ from it only verbally. He says (p. 31), "The phenomenon of isomerism and of metamerism is unquestionably intimately connected with the amount of heat evolved in the reactions, giving rise to the formation of isomerides. . . . The production of isomerides by different series of reactions is, then, probably to be accounted for by the circumstance that different amounts of heat are evolved in the several series of reactions, so that finally bodies possessing different energies are formed. This supposition, that isomeric (and metameric) compounds are bodies which, having the same composition, yet possess

different energies, would also serve to explain their different behaviour under the influence of reagents."

Now, although the author is quite justified in calling attention to the necessity for a closer study of the thermal phenomena which accompany chemical changes, we do not think that he has here got hold of an essentially new idea. We know that if we lift a body from a lower to a higher level, as from the floor to the ceiling, a certain expenditure of energy is involved. That energy, if we choose so to arrange it, may have its source in the heat of chemical action ; still it is not lost in lifting the body, but is simply stored up, and is capable of being reproduced without diminution, and in its original form of heat, whenever the body descends to its former level. Now, we may believe that a precisely similar process goes on in the change of a chemical compound into an isomeride. A certain amount of energy, originally in the form of heat, becomes potential by reason of the change of position which has been effected in some atomic group contained within the molecule. According to the old hypothesis, then, no less than according to the new, a certain amount of energy becomes, so to speak, latent ; the older view gives some sort of explanation of this, the new one nothing of the kind, and this seems to be the only essential difference between them.

Whether, as suggested by Dr. Armstrong, this transformation of actual into potential energy is really attended by exalted *chemical* activity is in some cases at least questionable. Hofmann's recent interesting transformation of methyl-aniline into an isomeric compound—toluidine—by protracted heating to a high temperature, furnishes a case in point which would be well worth discussion. The subject is, however, at present in great obscurity.

In conclusion, we willingly bear testimony to the accuracy and clearness of style which characterize every page of the book before us, and we believe that a careful study of its contents will enable a student more readily to acquire a comprehensive and philosophic view of the whole subject than perhaps any manual we have had brought under our notice.

Obituary.

NEIL ARNOTT, M.D., F.R.S.

On Monday, March 2nd, Dr. Neil Arnott died in the eighty-sixth year of his age. This distinguished physician was born in 1788 at Arbroath, in Scotland, and received part of his early education at the Aberdeen Grammar School, where he was a schoolfellow of Lord Byron. He gained in competition a bursary in Marischal College, and there studied natural philosophy under Professor Copeland. In 1806 he entered as a pupil of Sir Everard Home at St. George's Hospital, London; and after a visit to the East, in the East India Company's service, in 1811, he commenced as a medical practitioner in London. In 1827 he published his well-known work, "Elements of Physics, or Natural Philosophy," which has passed through several editions, and received the author's revision in 1864. Upon the foundation of the University of London, Dr. Arnott was nominated a member of the Senate, and in 1837 he was appointed one of the Physicians Extraordinary to the Queen. In 1838 he was elected a Fellow of the Royal Society. The same year he published his treatise on "Warming and Ventilating." Practically carrying out his theory, he afterwards constructed the stove which bears his name. This gained for him the Rumford medal of the Royal Society and, in conjunction with other inventions, the gold medal of the Paris (1855) Exhibition, as well as the Cross of the Legion of Honour. He was also the inventor of the well-known ventilating chimney valve and the water-bed ; but in no case did he seek to protect his inventions by a patent, being anxious that the public should benefit from a full and free use of them.

Besides his active labours towards the improvement of sanitary knowledge, Dr. Arnott was a munificent donor for educational purposes. To the four Scottish universities he gave one thousand pounds each for the endowment of Scholarships in Natural Philosophy, and to the Aberdeen Mechanics' Institute five hundred pounds. In 1859 he gave to the University of London two thousand pounds for a scholarship. For many years Dr. Arnott had given up medical practice in order to devote himself to scientific studies.

FORBES WINSLOW, M.D.

Another well-known member of the medical profession, Dr. Forbes Benignus Winslow, died at Brighton on the 3rd inst., of bronchitis and pneumonia, after a few days' illness. Dr. Winslow was the ninth and youngest son of Captain Winslow, of the 47th Regiment, and was born in 1810. He received his preliminary education at first in Scotland, and afterwards in Manchester and London. His professional studies were commenced in New York, but, returning to England, he pursued them at University College, and afterwards at the Middlesex Hospital, under Sir Charles Bell. He passed the College of Surgeons in 1835, graduated as M.D. at Aberdeen in 1849, and in the following year was elected a Fellow of the Royal College of Physicians, Edinburgh. Dr. Winslow was the author of numerous treatises, chiefly upon subjects relating to mental diseases. In the earlier period of his practice he held an appointment on the *Times* staff. He was also for sixteen years the editor of the 'Quarterly Journal of Psychological Medicine,' which he originated.

Dr. Winslow's name is familiar to the public from having been selected by the Crown on various occasions to give evidence in criminal cases relative to the state of mind of the accused.

Notice has been received of the death of the following :—

On the 1st February, 1874, Mr. Henry Augustus Tanner, Chemist and Druggist, of Kingswood Hill, near Bristol.

On the 3rd March, 1874, Mr. Simon Matthews, Chemist and Druggist, of Lechlade.

On the 3rd March, 1874, Mr. Joseph Wrangham, Chemist and Druggist, of Wheelgate, Malton.

On the 5th March, 1874, Mr. John Tweddell, Chemist and Druggist, of 112, Camden Road, London.

On the 6th March, 1874, Mr. James A. Kellett, Chemist and Druggist, of Wigan.

Notes and Queries.

[385]. DARK BROWN HAIR DYE.—The following appeared in the Journal some time since, and is a good dye :—

No. 1.

℞	Acid. Pyrogallic.	gr. iv.
	Aq. Destill.	℥ij.

M.

No. 2.

℞	Arg. Nit. Cryst.	℥j.
	Gum. Acaciæ	℥j.
	Aq. Destill.	℥ij.

M. s. a.

NEMO.

[389]. HAIR RESTORER.—Can anyone give a recipe for a Hair Colour Restorer (not a dye) that is really successful, and does not contain lead, or any other injurious ingredient ?—P. T.

[390]. COMPOUND SYRUP OF CAMPHOR.—Can any correspondent favour me with a form for making "Compound Syrup of Camphor ?"—M. P. S.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

What is Sweet Spirit of Nitre?

Sir,—The answer to the question put by your correspondent, "A Drug Traveller," in the Journal of Saturday last, may have more than a passing interest to many members of the Society. "What is Sweet Spirit of Nitre?" and for the information of all whom it may interest I give the following from an ancient Dispensatory.

"Spiritus Nitri Dulcis."

"Take of Rectified Spirit of Wine one quart; *Glaubor's* Spirit of Nitre, half a pound. Mix them by pouring the Spirit of Wine on the other, and distil the Mixture with a gentle heat, as long as what comes off will not raise any Fermentation with a Lixivial Salt."

"In the *Pharmacopœia Reformata* we are told that the Direction of continuing the Distillation only till what comes over ferments with a Fixed Alcaline Salt, is sufficiently troublesome and unartful. If the Spirit of Wine be highly phlegmed, and six Parts instead of four be added, and the Spirit of Nitre be pure and strong, almost the whole Mixture will rise in the heat of a Water-Bath, be greatly odorous, and sufficiently dulcified, so as not to give any, or but very little, Marks of Acidity upon the Affusion of an Alcali. The Spirit of Nitre should be distilled from equal parts of strong Oil of Vitriol and well-dried Nitre, with a gentle Fire, and the Spirit of Wine should be drawn over from a thoroughly dried Fixed Alcaline Salt."

This being a specimen of pharmaceutical literature of a century and a half ago, I have given an exact copy, including capitals, etc. I will not obtrude myself on the attention of pharmacists by entering into a critical analysis of this formula, and an estimation of what would be the product. But the second paragraph, or appendix to the formula, states, "almost the whole of the mixture will rise in the heat of a water-bath, be greatly odorous, and sufficiently dulcified, so as not to give any, or but very little, Marks of Acidity upon the Affusion of an Alcali." But by a simple mental estimate of the quality of the product, there can be little doubt but the specific gravity would be that of the B. P., and the amount of hyponitrous ether quite as great or greater, seeing that half a pound of the strongest nitric acid is used for two pints of alcohol pure.

The author goes on to say that "it promotes Sweat, provokes Urine, allays Thirst, corrects fœtid breath, and has particular Virtues in Scurvy. It is conveniently taken upon an empty stomach, to twenty or thirty Drops or more in Wine, Mead, or Beer."

May I ask how much of the modern article might be taken to produce any of the benefits here enumerated? Let the wise ponder these things.

F. M. Rimmington.

Bradford, March 9th, 1874.

Re Cocculus Indicus.

Sir,—More than thirty years ago, soon after my apprenticeship to pharmacy commenced, I was often employed bruising Cocculus and doing it up in 1 lb. packets for a brewer in the city I lived in. He used to call for it himself late in the evening. After some time—I think about 1838—he ceased buying it, saying the excise had found a test for it which gave a green colour when it had been used! (What was that?) However, malt became cheaper, and it was not of so much importance. Since then I had never been asked for Cocculus, except in small quantities for fish poisoning; until being in business for myself in 1868 I had it regularly ordered with certain quantities of borax and sal ammoniac by a gas-fitter, who tells me it gives a peculiar and desirable tint to certain bronzes. Query—What can be its action on lacquers, and do any of the thousand bags find their way to Birmingham for that purpose?

I have often thought picrotoxine might prove a remedy of some power in neuralgic affections. Does it enter into any of the patents for their cure?

J. S. L.

March 7th, 1874

Sir,—Many "a young man from the country" could tell the dispensing chemists in large towns that powdered Cocculus Indicus is used extensively in rural districts as a dressing for lice in cattle, and that grains of paradise, the other mythical adulterant of beer, is in common use for horse powders among agriculturists.

M.P.S. (by examination).

Castle Donington, March 9th, 1874.

The Proposed Scholarships.

Sir,—I read with much interest in the Journal of Saturday the sensible remarks of "Amicus" with regard to the proposed scholarships. They would certainly be a great stimulus to country students, as the Bell Scholarships are now; but I certainly think that the hint thrown out by Professor Attfield in his concluding remarks at the meeting on Wednesday comes nearer the point. There should be at the Square a few scientific young men who would not be in haste to leave their studies in order to pursue the ordinary business of pharmacy. There are a few among our ranks—perhaps the number is very small, but still there are a few—who, if there were sufficient encouragement given them, would be scientific enough to relinquish the practical profession of pharmacy and pursue their chemical studies at the Square for several years, until they could fairly lay claim to some real knowledge of the science. It would be a pity to alter the age for the Bell Scholarships to twenty-two, as they should be intended for students who have just completed apprenticeship; but the additional scholarships might be open to students under twenty-two or twenty-three, and by this means I think a few scientific men might be retained at the laboratory. It was quite right to remove the Senior Bell and establish another Junior, as one was not sufficient; but now that extra scholarships are talked of, they should be as much as possible in place of the Senior Bell. In these of course there would be no need of classical subjects; in fact, almost the whole of the questions might advantageously be on chemistry. With apologies for this hastily written and "meandering" letter, I beg to remain, etc.,

Syrupus.

March 9th, 1874.

"*Quærens.*"—(1) A double decomposition takes place and the mass is reduced temporarily to a pasty consistence by the water of crystallization. (2) Because a small quantity of tannate of quinine is formed. (3) You must exercise your own judgment in accordance with circumstances.

"*Litmus.*"—(1) The ethereal extract is well suited for external application as a vesicatory or rubefacient (Pereira). (2) The presence of the seeds would interfere with the flavour. (3) The B.P. preparation is not pure sulphate of beberine, but probably a mixture of more than one principle. (4) Soften by heating it in a water-bath.

"*Peter Simple.*"—There is no exemption in favour of the persons mentioned.

"*Junket.*"—The exact nature of the action of rennet is not known.

"*Statim.*"—We believe that such a collection may be obtained from Messrs. Butler and McCulloch, King Street, Covent Garden.

"*Member.*"—Some formulæ are given in vol. iii. p. 443.

Crystallization of Carbolic Acid.—Mr. T. F. Abraham writes that the report of what he said at the Liverpool Chemists' Association about carbolic acid (Pharm. Journ., p. 725) is not quite correct. What he said was, that he had noticed in cold weather, when handling a mixture of pure carbolic acid with 5 per cent. of water, that the screwing round of the stopper would sometimes start the process of crystallization, which would then in a few seconds run from the stopper through the whole bottle, forming a solid mass.

"*Hampton.*"—You will find the information you ask for in Dr. Voelcker's paper on p. 742.

H. A. Howe.—Probably the best way would be to dissolve out the lime salts with hydrochloric acid, and precipitate the phosphate from the solution by means of chalk.

Communications, Letters, etc., have been received from Mr. J. H. Butler, Mr. J. M. Fairlie, Mr. Young, J. McNeile, "Hampton," M.P.S.

RICINUS COMMUNIS.—ANALYSIS OF THE LEAVES OF THE PLANT.*

BY E. S. WAYNE.

Having observed a crystalline deposit in the fluid extract of the leaves of the *Ricinus communis*, which preparation I have made for several years past from the leaves of the plants grown in this vicinity, and which has been used by several of our physicians as a galactopoietic agent with satisfactory effect, and having a desire to know what this substance was, I was induced to make the following analysis of it, and to extend my researches further.

The crystalline deposit above mentione dhad the appearance of a mass of colourless prismatic crystals, imbedded, more or less, in a mass of chlorophyll, which had also separated from the fluid extract. A portion of the deposit was removed for examination, and was treated with alcohol ; the crystals were left undissolved. Water was then tried as a solvent, in which they dissolved, and the solution upon concentrating deposited long prismatic crystals, which were found, upon examination, to be nitrate of potassium.

This fall, in making another quantity of the fluid extract, which required filtration to separate a quantity of chlorophyll deposited, I noticed that the greenish mass on the filter was glistening with crystals, and, upon treating some with water, obtained from it a large quantity of nitrate of potassium.

The presence of it in this mass was evidence that that the salt existed as such in the leaves of the plant, which was also shown to be the case during the combustion of leaves and stems, they burning with scintillation and decrepitation almost like nitre paper.

Becoming interested in the subject, I was tempted to extend my researches, and accordingly submitted the leaves to a careful analysis for the presence of a proximate principle, and the analysis of the ash of the plant. Analysis of the leaves failed to show the presence of any substance having the properties of an alkaloid, but proved that they did contain a proximate principle, crystallizing in square prisms and tables.

This substance was obtained by the following process :—The powdered leaves were exhausted by percolation with dilute alcohol, and the percolate evaporated in a water-bath to expel the alcohol and separate chlorophyll and resin ; these were separated by filtering. The filtrate was of a dark brown colour. To it was added moist hydrated oxide of lead, and the mixture repeatedly shaken during the day ; by this treatment the tannic acid present and a large portion of the colouring matter were removed. The solution filtered from the oxide of lead was of a pale amber colour ; this was then evaporated to a syrupy consistence. About one ounce of extract was left, which was exhausted with eight ounces of alcohol, and the alcoholic solution set aside for spontaneous evaporation. As the alcohol evaporated, a crystalline substance commenced to form, and from the extract above mentioned, from one pound avoirdupois of the leaves, about 60 grains of the substance was obtained of a pale yellow colour, which was dissolved in alcohol, and the solution treated with purified animal charcoal. The solution left to spontaneous evaporation deposited the substance in colourless crystals, prismatic and tabular in form.

The portion of the extract insoluble in alcohol was tested for glucose, but none found present.

The crystalline substance was then submitted to the following tests :—

Concentrated sulphuric acid: No change cold or by heating ; by heat it dissolves to a colourless solution, which, upon being diluted with water, deposited it again as a white pulverent mass.

Nitric acid : No change.

Hydrochloric acid : No change.

Sulphuric acid and bichromate of potassium : After standing some time, a green colour.

The hydrochloric acid solution, upon the addition of solution of chloride of mercury, formed a white precipitate.

Heated with potash, ammonia was given off.

Heated upon platina foil it fuses, and, upon further heating, it ignites and burns with a sooty flame.

Heated in a glass tube, it fuses, volatilizes, and condenses in a crystalline form in the cool portion of the tube.

The fused mass, upon cooling, forms a mass having a radiated crystalline appearance. It is soluble in alcohol and water.

Taste bitter, resembling that of wild cherry bark when chewed.

From the above behaviour with re-agents and its crystalline form, it is evident that the substance obtained from the leaves is identical with that obtained by Prof. Tuson from castor seeds, and named by him Ricinin.*

From experiments made with the substance from the leaves, it is evident that it has no claims to be called an alkaloid, as it has no action on litmus paper, and solution of iodohydrargyrate of potassium gives no precipitate with it. Yet it contains nitrogen, as proven by the production of ammonia when heated with potash.

All of the tests made with the substance from the leaves compare with those of Ricinin from seeds.

The analysis of the plant is an interesting one, showing that a peculiar proximate principle exists in all parts of it, the same as found in the seeds. Also that the leaves contain a large percentage of nitrate of potassium, and in this respect equal to that of tobacco.

An analysis of the ash of the leaves shows that they are very rich both in alkalies and phosphoric acid.

500 grains of the leaves were incinerated, which required some manipulation, as the ash was found to be readily fusible, and perfect combustion consequently impossible ; but by charring the mass only, and then dissolving out the soluble portion with water, combustion was accomplished. 120 grains of ash = 24 per cent., was obtained, the analysis of which gave the following results :—

Lime	33·40
Magnesia	6·20
Potash	27·15
Soda	2·12
Peroxide of Iron	·70
Phosphoric Acid	6·68
Sulphuric Acid	2·90
Chlorine	1·63
Carbonic Acid	16·20
Silica and Sand	2·41
Loss	·61
	100·00

From the above, when the size of the plant, its luxuriant growth, etc., are taken into consideration,

* From the *American Journal of Pharmacy* for March.

the culture of it must be a very exhausting one upon the soil, the fertility of which must be rapidly decreased by the drain of potash and phosphoric acid. Whether it is the custom to restore to it the stalks and leaves after the crop of seed has been gathered, I do not know ; but they should be, and thus by their decay restore these again to it: or they should be burnt and the ash scattered broadcast upon the land from which the plants have been taken.

ANALYTICAL NOTES ON OXIDE OF TIN.

BY G. WELLBORN.

This substance is commonly known as "putty powder," and is stated by Professor Redwood, in his Supplement to the Pharmacopœia, to be the peroxide. It is obtained by exposing melted tin in a reverberatory furnace, and calcining the dross (stannous oxide), which is raked from the surface of the metal, and subsequently calcining the dark grey stannous oxide, when it becomes converted into stannic oxide, which is a pale buff-coloured powder.

Having recently to analyse a powder containing three unknown metallic compounds, I was somewhat surprised to find a fourth metal appear in the course of the analysis. It is not necessary to describe in detail the operations performed for the detection of all the metals present in the powder. It was, however, ascertained to contain calomel, oxide of lead, oxide of tin, and acid tartrate of potash, and, knowing from the conditions under which the analysis was undertaken that one of the metals must occur as an impurity, or adulterant, it seemed probable that the oxide of lead was the compound which should not have been present, and that it was introduced with the oxide of tin.

Lead was readily found on treating the powder with cold dilute hydrochloric acid, filtering from the insoluble portion, and then passing sulphuretted hydrogen through the filtrate. There was an abundant black precipitate, which, after being washed, dissolved completely on being heated with dilute nitric acid. The solution was evaporated to dryness and re-dissolved in water. On adding chromate of potash and iodide of potassium to separate portions of this solution, precipitates were obtained characteristic of the presence of lead.

In order to ascertain whether the oxide of tin was mixed with oxide of lead, I procured a sample from the same source, and treated twenty grains of it with boiling dilute nitric acid until nothing further was dissolved. The acid solutions were then filtered and the residue, insoluble in nitric acid, washed: the washings were added to the filtrate, and the whole evaporated to dryness. A white crystalline powder was left, which decrepitated when heated, and evolved ruddy fumes: the residue was pale yellow: on heating it in the inner blowpipe flame with carbonate of soda on a charcoal support, small beads of soft, malleable metal were obtained.

Another portion of the above crystalline powder was dissolved in water, and a little of the solution treated with chromate of potash, gave a pale yellow precipitate. Iodide of potassium added to a fresh portion also gave a yellow precipitate solution in boiling water, and deposited again on cooling in shining yellow scales.

Dilute sulphuric acid gave a fine, heavy, white crystalline precipitate. These reactions showed unmistakably the presence of lead.

The residue, insoluble in nitric acid, after being washed and dried at a low temperature, was nearly white, and weighed 7 gr.: after ignition it weighed 5 gr., and became a pale buff colour.

Conceiving that oxide of lead might be a common adulterant of oxide of tin, I obtained samples from two other sources, and submitted 20 gr. of each to similar treatment. The quantity of oxide of tin was the same in the three samples, viz., 5 gr., the remaining 15 gr. being made up with oxide of lead.

The nitrate of lead obtained from 20 gr. of impure oxide of tin weighed 21 gr., which is equivalent to 14·148 gr. of oxide of lead. The molecular weight of the nitrate being 331, and that of the oxide 223. The weight of oxide which may be obtained from 21 gr. of nitrate is found by the following equation:—

$$\text{As } 331 : 21 : 223 : x = 14{\cdot}148.$$

The residue, insoluble in nitric acid, was proved to be oxide of lead by fusing it in a covered porcelain crucible with cyanide of potassium ; washing away the soluble portion and heating the finely divided metal thus obtained with concentrated hydrochloric acid, it dissolved with effervescence. On adding this solution to a solution of mercuric chloride it caused a white precipitate. On the addition of more of the hydrochloric acid solution the precipitate became black, owing to the reduction of the mercuric chloride.

Twenty grains of the impure oxide of tin was moistened with concentrated nitric acid ; in a few seconds it swelled considerably, cracked, and fell into a light, amorphous powder, with evolution of great heat. It appeared to undergo hydration in a similar manner to lime when it is moistened with water.

I had not, previously to undertaking the above analysis, the least suspicion that oxide of tin was an article liable to sophistication: but oxide of lead at 6*d.* per lb. and oxide of tin at 3*s.* 6*d.* explains in a forcible manner why we should find the two keeping company in "putty powder."

THE ALKALOIDS OF THE CINCHONA BARKS.*

BY O. HESSE.

(*Continued from p.* 731.)

VI.—Aricine.

Aricine was discovered in 1829 by Pelletier and Caventou, and almost at the same time by Leverköhn, in a bark described as a false calisaya bark. According to Delondre and Bouchardat, the tree which yields this bark grows in the forests of Santa Anna, and according to Weddell it is the *Cinchona pubescens,* Vahl. The former authors stated further that the bark of this tree was only of small value, as it contained barely 0·06 per cent. of alkaloid, which after sufficient purification perfectly agreed with quinine. In another bark, nearly related to it, the "china cusco fusca," which was collected in the forests of Cusco, scarcely 0·03 per cent. of an alkaloid was found, the sulphate of which also resembled the sulphate of quinine. Aricine was not referred to this bark.

On the contrary, Wiggers† stated that Delondre and Bouchardat did not operate upon the same bark as that examined by Pelletier and Coriol ; he also declared, on the ground of physiological examination of authentic barks, that the yellow Cusco bark and the brown Cusco bark were not essentially different from one another. Wiggers therefore named the true aricine-yielding Cusco bark "Cusco vera." On account of its complete uselessness,

* Translated from the 'Vierteljahresschrift für praktische Pharmacie,' vol. xxii. p. 366.

† 'Pharmakognosie,' p. 413.

this bark, which according to Winckler contained 1·4 per cent. of aricine, has completely disappeared from commerce. At a later date Manzini examined the pale "tenchina," said to be yielded by the *C. ovata*. But as in most of these cases one and the same description of bark is said to be derived from several species of *Cinchona*, so this happens on a large scale in the present case, since the following species have been named as yielding this "tenchina" bark,—*C. ovata*, Pav., in Peru; *C. lutea*, Pav., and *C. decurrentifolia*, Pav. (*C. purpureseens*, Wedd.), in Ecuador; and the doubtful *C. viridiflora*, which latter, according to Weddell, should be classed with *C. Pelletierana*, whilst Howard derives the yellow Cusco bark from *C. Pelletierana*. Not thereby lessening the confusion, Weddell divides the species *C. ovata* into four varieties, namely, *C. ovata genuina*, which according to Howard contains 1·06 per cent. of aricine and 0·08 per cent. of cinchonine, but, notwithstanding, does not give Grahe's reaction;* *C. ovata vulgaris*, with 2 to 2½ per cent. of quinidine (cinchonidine?); *C. ovata pallescens* and *C. ovata palalba*.

Manzini named the alkaloid obtained from his bark "cinchovatine." For its preparation, he treated the bark with acidulated water, precipitated the filtered liquid with excess of lime, and withdrew the alkaloid from this precipitate by means of alcohol. Upon the cooling of the brown solution beautiful crystals of cinchovatine were formed. The mother liquor was freed from the greater part of the spirit; the dark residue was dissolved in hydrochloric acid and treated with common salt, whereby the colouring matter (? quinoidine) was thrown down. The cinchovatine, on the contrary, remained in solution, from which it could be precipitated by ammonia. This purification was repeated until the cinchovatine appeared of a straw colour, which was only removed by repeated crystallizations from boiling alcohol.

In 1839 Bouchardat† examined this same bark, and not only confirmed the discovery of Manzini, but declared also that the pretended new alkaloid was perfectly identical with the aricine of Pelletier and Coriol. Winckler, too, arrived at the same result, and also considered that the green colouration which Pelletier's aricine presented was not due to the pure alkaloid, but to an admixture of some other substance unknown to him. Consequently—after that Bouchardat and Winckler, independently of each other, had agreed in recognising the identity of cinchovatine, cusconine, and aricine—the result which A. Delondre obtained in operating upon a large quantity of the bark examined by Bouchardat was surprising, since, instead of the expected aricine, he obtained cinchonine and quinine. The confusion becomes still greater since Howard says that the results of his experiments upon aricine are identical with those which Delondre indicates in his 'Quinologie' (pp. 38 and 39), where the before mentioned description of the Cusco bark occurs. After this, Howard would have generally obtained no aricine in his experiments, and consequently esteemed aricine to be identical with quinine.

Finally, it may be mentioned that Kerner‡ met with a preparation in commerce under the name of aricine, but this was essentially a mixture of cinchonidine and his quinidine (see before). Moreover, Kerner has not been able to obtain any aricine, and is therefore not yet convinced of the existence of this alkaloid.

As Delondre stated that the bark examined by Manzini contained cinchonine, and Manzini did not mention that he eliminated this alkaloid, it appears impossible that a preparation actually free from cinchonine could have been obtained in accordance with the indications of Manzini; so that we may be allowed to speak of this cinchovatine as principally impure cinchonine, and this the more justly, since cinchonine, being asserted to be more difficultly soluble than aricine, must have been contained in the first crystallization. Whether the quinine present in the bark may have any influence upon the formation of cinchovatine I know not; but this I know, that when quinine, containing some of the as yet little understood colouring matter of the bark, is dissolved in dilute sulphuric acid, and the solution, while hot, neutralized with ammonia, upon its cooling a transparent jelly-like mass is deposited, in which gradually small white points are formed, which become the centres of the crystallization of the neutral sulphate. Also, it has been observed that if sulphate of quinine not yet completely purified, be strongly pressed and then placed in cold water, it swells up.

My attempts to prepare the alkaloid in question from cinchona barks have under these conditions remained unsuccessful. One bark, which was said to contain "cusconine" entirely, gave a considerable quantity of cinchonine, but no alkaloid the properties of which recalled those of aricine. Another bark, which was considered identical with the "Quinquina Jaën," plate vi. of Delondre and Bouchardat's "Quinologie," gave me, besides traces of amorphous base, 2·6 per cent. of sulphate of quinine, 1·4 per cent. of cinchonine, and about 8 per cent. of conchinine, but no aricine.

I must therefore consider the question of the existence of aricine an open one.

VII. Paricine.

Paricine, which in 1845 was found by Winckler* in a false cinchona bark imported from Pará, and represented as the bark of *Buena hexandra*, Pohl, and also later in the bark of a true cinchona,†—*C. lutea*, the "lengua de vacca" of the Huanuko district,—occurs not unfrequently, according to my observations, in the East India cultivated *C. succirubra*. As the salts of paricine are precipitated from solutions by nitric acid, similarly to beberine, Winckler thought that both these alkaloids might be identical, and Flückiger‡ sought to base this opinion upon certainty. Following them, I published a paper§ upon this subject, in which I sought to point out what they had previously ascertained respecting the identity of these two alkaloids. My further experiments have finally demonstrated the peculiarities of this uncommon alkaloid.

If the alkaloids are extracted from the bark of *C. succirubra* in the usual manner, and a neutral aqueous solution of the sulphate mixed with moderately concentrated nitric acid, the paricine nitrate will be immediately precipitated in yellow flocks. But if the solution be previously mixed with tartrate of soda and potash, to precipitate the quinine and cinchonidine, it may happen that all the paricine is removed with the precipitate, because the tartrate of paricine is rather difficultly soluble in a solution containing other salts. It depends, therefore, upon the quantity of Rochelle salt used whether the paricine will be found still in the solution, or partly or wholly in the precipitate.

Having thrown down the alkaloid with moderately concentrated nitric acid, and worked up the resinous precipitate with the same acid, alcohol is poured over the mass, ammonia is added to decompose the nitrate, and the solution is treated with hot petroleum ether, which removes the alkaloid with the alcoholic solution. The last solvent, after separating it from the alcoholic solution, is evaporated, and the residue taken up in dilute hydrochloric acid and purified by means of a little animal-black. Upon the addition now of an excess of ammonia, the solution gives a yellowish-white flocculent precipitate of pure paricine. Comparative experiments which I made

§ Brichte der deutschen chemischen Gesellschaft, iii. 232. Through an oversight it is erroneously stated there that Winckler's Pará bark was collected from *C. lutea*; it should be referred to the grey bark which Winckler examined in 1865.

with paricine so obtained, and paricine prepared by Winckler, but still further purified by me, demonstrated the complete identity of the two preparations.

Paricine dissolves readily in petroleum ether and ligroin, whilst the purified beberine is nearly insoluble in them, so that in this manner the two alkaloids can be easily separated. It also dissolves readily in water and alcohol, with difficulty in water and ammonia, contracts somewhat at about 100°C., and finally melts at 116°C into a dark-brown liquid, solidifying upon cooling into an amorphous mass. Beberine, on the other hand, melts first somewhere about 200°C., and even then its fusion is not complete. The melting-points of these two alkaloids, therefore, present a difference of at least 80 degrees, so that under this aspect they cannot be considered identical, although in many other characters paricine has a great resemblance to beberine.

Paricine dissolves in concentrated sulphuric acid with a greenish-yellow coloration, which is changed by heat to a dark-brown. Concentrated nitric acid converts the alkaloid immediately to a dark green resin, which is dissolved by heat, taking a dusky yellow colour. Paricine in acetic acid solution gives, with both nitric acid and nitrate of soda, a flocculent, yellowish-white precipitate of nitrate of paricine, which is more difficultly soluble in water acidulated with nitric acid than in pure water. Chloride of sodium induces in a similar acetic solution of the alkaloid a milky turbidity, and afterwards a yellowish-white precipitate, which is difficultly soluble in a solution of common salt, but easily soluble in water. The alkaloid in acetic solution has also a reaction similar to the foregoing with iodide of potassium. Solutions of the chlorides of platinum, gold, and mercury all produce flocculent precipitates in hydrochloric solution of this alkaloid.

The small quantity of perfectly pure alkaloid which up to the present time I have been able to prepare from bark of *C. succirubra* has hindered me from undertaking an analysis of this base, though I am indebted to the firm of Friedrich Jobst, at Stuttgart, for such a suitable quantity of raw material that I hope soon to be able to make known the composition of this interesting vegetable alkaloid.

(*To be continued.*)

THE VARIOUS PREPARATIONS OF KOUMISS, AND THEIR USE IN MEDICINE.

BY V. A. JAGIELSKI, M.D. Berlin,
Late Physician in the Prussian Army, etc.

(*Continued from p.* 695.)

The two following analyses, one of mare's-milk koumiss, made by Hartier, a chemist of Moscow, and the other of E. Chapman's medium cow's koumiss in London, made by Wanklyn, may be compared :—

	Mare's Koumiss.	Medium Cow's Koumiss.
Alcohol	1·65 per cent.	1·60 per cent.
Fat	2·05 „	0·30 „
Milk-Sugar . . .	2·20 „	4·85 „
Lactic Acid . . .	1·15 „	1·08 „
Casein and Albumen	1·12 „	1·07 „
Ashes or Salts . .	0·28 „	0·75 „
Carbonic Acid . .	0·785 „	1·50 „

Thus we see that the casein in both kinds of koumiss is the same to a fraction; much less is the butter or fat in the medium koumiss, for the simple reason that it is not advisable to send out the koumiss *à longue course* with all the fat contained in the milk, as it decomposes too quickly into butyric acid, which is deleterious to the digestive organs. Further, the lactic acid and alcohol show no difference worth considering; but the lactose in the medium koumiss is twice as much as in mare's koumiss, if Hartier's analysis deserve full credit for correctness, as Wanklyn's does, whose reputation as an analytical chemist is undeniable.

The *Whey Koumiss* (C) is derived from cow's milk completely freed from its butter and casein, so that it merely contains some albumen, lactose, lactic acid, alcohol and the salts. It affords the best proof of showing how wrong all the theories were which proclaimed the casein or even the butter as being indispensable for koumiss-making, and may prove useful as a beverage in disease with even a strong febrile reaction, with copious or excessive expectoration, perspiration, or diarrhœa, either in plethoric or in strong constitutions, which do not require an increase of weight, or in patients with inflammation or fever. We must, however, not forget that in the latter case the treatment becomes more difficult and complicated; and we have to use all our skill to abate the fever by antipyretics, to calm the pain by sedatives and narcotics, and to prevent local inflammations from spreading, etc., according to the nature of the localized disease. According to the more recent school of medicine, whey is only of limited value, as it supplies the body with slight nourishment; and it is obvious that, on this account, whey can never take the place of highly nutritious milk, and therefore can never be applied to the purpose of a proper plastic treatment. The whey koumiss, however, promotes decidedly the appetite and digestion, and as a cooling and refreshing dietetic remedy, calming irritation. The "sparkling bland," a diluted and still more pleasant form of whey koumiss, may, in febrile disease, be used as a refreshing drink, and prove more convenient, as bland will keep for a long time, and is agreeably flavoured with ginger, lemon, or orange, etc.

The *Diabetic Koumiss* (D) contains, according to Wanklyn's analysis, 1·6 per cent. of alcohol, 1·1 per cent. of lactic acid, and not more than 1·0 per cent. of lactose. It is particularly suitable for the treatment of that disorder, to increase weight, to allay thirst, to excite the action of the skin, and to check the loss of sugar and the abundant flow of urine, although it appears to me less important how much urine and sugar are excreted, as long as the patient's weight and strength are increasing; and the confidence created in the remedy is also of much consequence in such a distressing condition. According to Stahlberg, koumiss is, in the treatment of diabetes, of greater value than even Vichy or Carlsbad water; and we need not restrict the diet in the usual severe way. If the skimmed-milk treatment, the buttermilk cure, or Professor Cantani's lactic acid treatment, has given such good results, I do believe that koumiss is of still more value, as it acts as a ferment in decomposing within the body all saccharine matter, and as an easily absorbable and strength-giving plastic nourishment; otherwise I cannot explain its beneficial effects on this disease, even as *ultima ratio*, when the tongue appears parched, and the patient seems skin and bone, and thoroughly exhausted. The complication with lung disease appears a forcible indication for its immediate use, as the life will be prolonged under this treatment.

Muscular exercise in open air, regularly continued every day, is of the greatest importance in the treatment with koumiss generally, but especially during the use of diabetic koumiss, which ought to be about a week old, sour, and well sparkling. It contains fermenting casein in the most favourable condition for digestion and nutrition, and a larger amount of lactic acid than even buttermilk, of which Dr. L. Brunton has spoken highly as a remedy in diabetes in this Journal. Further, the carbonic acid and alcohol in this diabetic koumiss must not be disregarded as powerful remedial agents in the treatment of diabetes. In fact, diabetic koumiss is buttermilk in the state of alcoholic fermentation. It ought to be made the principal or exclusive beverage of a diabetic patient, as soon as he has acquired a taste for it. He may also take it with his meals, chiefly consisting of meat diet. Why Dr. Brunton has so entirely excluded koumiss from his experiments and observations, I do not know; and I sincerely regret it, because his lectures on the subject of diabetes appear to me a *chef-d'œuvre de science*. If glycerine be of

any value in this disease, as recommended by Schultzen, it may more advantageously be given with koumiss instead of with water (four pints per day); and as glycerine is fermentable, according to Berthelot, it may be prescribed as an addition to koumiss, or better in koumiss, in order to prevent nausea and diarrhœa from glycerine. When given at the dose of about an ounce and a-half, I feel sure that the combination of glycerine and lactic acid in koumiss, along with the proper diet, will yield the most satisfactory results.

As to my own experience in the general use of koumiss, I have observed that it exerts a striking remedial power, in chronic gastro-catarrh arising from any cause, but especially from the abuse of alcoholic drinks, the use of tonic astringents, styptics, and sialagogues, or the habitual taking of opium. It stimulates digestion without affecting the head—a fact noticed and expressed to me by patients with the utmost satisfaction and joy. Some extolled its peculiar influence on the brain, it leaving the head clear for brain-work, and generally strengthening memory and intellectual power. In many of the secondary symptoms of diseases, such as dyspnœa, cough, weakness, emaciation, etc., even where they are so strong as not to correspond with the topical process of the malady, koumiss is a prompt and powerful check to development of the morbid process; and many other cases of debility, in consequence of excessive or protracted copious secretion of muco-purulent matter or severe hæmorrhages from any organs, or after operations, childbed, and lactation, find a comforting restorative.

In lung-consumption (chronic form), the first stages are most benefited by koumiss. Through an improvement of the digestive functions, the regulation of the nutrition, and its particular healing effect on all relaxed mucous membranes, the cough subsides, shortness of breath improves, night-sweats disappear, and sleep is induced, and coincidently weight and strength and plumpness of the body augment. But I must repeat, in this connection, that full koumiss, like other nourishing diet, is contra-indicated in the febrile phases of phthisis, and should be replaced by whey koumiss, bland, salines, etc. On the other hand, so long as the bodily temperature is still above normal, or so long as a high temperature may fluctuate several degrees between morning and evening, there is reason to use the koumiss, and expect good effects from it. If in eight or ten days the body do not begin to gain weight, the temperature do not show a declining tendency, the tongue do not clear, the appetite do not improve, then the koumiss will be of as much, or as little, use as any other treatment or medicine, because the prognosis will have turned out *pessima*.

Koumiss is an admirable succedaneum for purely drug substances, and even for cod-liver oil, in cases where the stomach has assumed an aversion to such medicines. At the same time, there are critical phases of disease in which a judicious association of drug-treatment is indispensable; and of this the attending physician will be best able to give proper directions. In all cases of koumiss-treatment, the dinner hour should be about 1 o'clock, and, after dinner, a repose of two hours before recommencing to take the koumiss. The doses should also be discontinued about 7 or 8 o'clock p.m. The presence of albumen in the urine is no indication that the koumiss-treatment should be interfered with by any drug-treatment for that symptom till the general health of the patient has improved; but, as long as the patient has to keep to his bed, the total consumption ought never to exceed two or three pints *per diem*. When the patient becomes able to take active exercise without fatigue, he may increase his doses advantageously according to his appetite.

In chronic pharyngitis, laryngitis, bronchitis, No. 2 or No. 3 koumiss will be found to act beneficially, even when relaxation and general weakness are great; but in ulceration, No. 1 or fresh No. 2 is more advisable. I have found it far superior even to Ems water in those complaints, when accompanied by copious expectoration and emaciation, and in large vomicas; and this corroborates Stahlberg's dictum that "koumiss has the properties of Ems water *plus* a great nutritious power." As to diseases of the mucous membranes of the urinary system, I can say, from my own experience, that its use proved successful in cases of renal colic with sandy deposit in the urine, and also with hæmaturia, but principally in catarrh of the bladder with copious mucous, or even muco-purulent sediment. For vaginal and urethral discharges, Nos. 2 and 3 will be found very useful. It is a physiological property of koumiss to lessen all discharges, but to stimulate the secretion of the urine, and to render it clear; often a kind of pressure or contraction of the bladder is produced, especially at the beginning, which, however, ceases in a few days, when, also, all cloudy, turbid, or dark appearances of the urine give way to a heavy limpid state; during the warmer season, diaphoresis takes the place of diuresis.

When the koumiss is taken only in small quantities, the appetite is always keen, but larger quantities are more satisfying, and preclude the necessity of solid food. For general use, the No. 2 state of the koumiss is to be preferred, as it is neither astringent nor aperient. In relaxation of the mucous membranes, and more particularly in chronic diarrhœa, No. 3 koumiss is indicated. On the other hand, when the secretory functions are impaired, as is often the case in constipation, No. 1 full koumiss must be employed, because of its mild aperient effect. I must note here, however, that this aperient effect can be imparted to the other properties of both Nos. 2 and 3 koumiss by mixing them with one-fourth or one-half of fresh milk at the moment of drinking. The use of bran-bread with salt will also sometimes neutralize the astringent effect of No. 3 koumiss, and counteract nausea. In warm weather, koumiss runs through all the changes very rapidly, and No. 3 koumiss spoils then sooner. As a general rule, fresh koumiss retains its No. 1 condition for two or three days in summer when kept cool immediately after it is bottled; from this time to the eighth day, it is No. 2 koumiss; beyond that period it is No. 3 koumiss, and retains its soundness for several months if kept cold. In the treatment of chronic cases, the use of koumiss should extend from six to eight weeks, *à peu près*. If there should be a recurrence of any of the symptoms, they may be checked at once by a repetition of a shorter course, or even a few bottles only. Previously to commencing the koumiss treatment, the patient should be carefully weighed. A patient on two quart bottles a day, appropriates so much nourishing matter, that his increase of flesh and weight cannot fail to be perfectly perceptible. Of course, there is an increase of weight corresponding to the more or less emaciated state of the patient, even if the koumiss be administered in very small doses; but the most surprising effect can always be observed when emaciation and prostration have been greatest (without fever). Even when the patient remains in bed, a pint bottle a day has shown a rapid increase of strength. The average increase of weight during a course I can state at six pounds, more or less; although, in some cases, twenty pounds and more are on record in eight weeks, or eight to eighteen ounces per day during the first ten days. In cases, however, where the increase of weight has been less marked, a great improvement in the patient's strength, spirits, and appearance will be noticed. Thus, we perceive that where the process of digestion and nutrition has been improved, the consequences are very soon apparent upon the system of circulation by an improved heart's action, better pulse, and freer capillary circulation, especially noticeable in the peripheral parts of the body. Here it produces a pleasant feeling of warmth all over, a healthy action of the skin, when the pores open, the vessels expand, and a healthy moisture and colour reappear. As a general rule, all other drinks, oily, pickled, salted, and smoked food, and all strong condiments, should be avoided during its use.

In conclusion, koumiss, though not a specific for any disease, is a benign agent in medicine, which merits serious consideration and study in both private and hospital practice. By its use the digestive organs are roused into activity, fat is deposited in the subcutaneous cellular tissue, the flesh becomes plump, and the complexion assumes freshness and colour, the dull eye assumes expression, and the depression of spirits gives way to animation; the respiration acquires more depth and regularity, as has been determined by the spirometer. Large doses have the effect of promoting a feeling of laziness and even sleep; but this sleep is of a most refreshing kind.

To give a list of diseases for which the koumiss treatment is applicable, appears to me quite irrational, as I should otherwise be compelled to name almost all diseases, because, generally speaking, nearly every disease may reduce, more or less, nutrition, and in such a condition koumiss is indicated; and more than this, it would even sound quite paradoxical to prescribe koumiss in a fracture of the thigh, although this is quite possible when such a fracture is accompanied or followed by anæmia, loss of flesh, or has become complicated by catarrh of lungs, stomach, etc.

These hints may suffice to show that koumiss is neither a specific nor a panacea, although rationally or logically, and practically or empirically, its use is a very extended and general one.

In order to prepare koumiss in an uniform state of excellence, the place of its manufacture must be quite to itself, so that the tendency of milk to absorb foreign odours and emanations may be free from the least encouragement. Moreover, the operative manager of the process should be a man of experience in the work, and always on the spot, to insure its proper progress. It is, therefore, not possible for a dispensing druggist to make its manufacture a branch of his pharmaceutical business. At the same time, there is no reason why hospitals, requiring large and fresh supplies daily, should not have a special apartment for its preparation, under the constant supervision of a duly qualified *employé*.

THE PRESERVATION OF PLANTS FOR HERBARIA.

In a very interesting series of articles which have appeared in the *Gardeners' Chronicle*, under the title of "Refuge for the Destitute," the following instructions are given for the preservation of botanical specimens and the construction of a *hortus siccus*. If we may judge by the numerous queries that reach us, many of our younger readers will be glad of the information contained in them. We therefore take the opportunity of reproducing them in our pages :—

1. *Method of Preserving.*—Specimens intended to be dried should be gathered on a fine day; if wet with rain they are liable to lose their colour, the great enemy to the preservation of which is *damp*. In readiness there should be at home half-a-dozen pieces of stout millboard, about 20 inches long by 15 in breadth, and a good stock of old newspapers, folded to about the same average dimensions; also a few quires of Bentall's "botanical drying paper," a few sheets of ordinary blotting paper, a few pieces of common tissue paper, cut to the size of one's hand, and half-a-dozen squares of cotton wadding, cut to the same length and breadth as the boards. No elaborate "press" is needed, with screws and pillars, and as for the lattice work ventilators sometimes prescribed they are nothing more than incumbrances. Using a board as a foundation, place upon it a couple of the folded newspapers; then dispose the plant in the middle, letting it fall naturally, but keeping the leaves and other parts as little crumpled as possible; cover it in turn with other newspapers, and thus go on with the specimens till all are safely deposited. The extra boards are to interpose if needful, the tissue paper is to lay, when necessary, over flowers of particular delicacy; the cotton wadding is to employ when the stem of the specimen is inordinately thick, so that a vacuum would be caused if the wadding were not there. A board at the top completes the preparations. Next put the pile in some convenient corner, and on the top of it a weight of several pounds. Folio volumes, a box of fossils, or three or four bricks, separately and neatly tied up as parcels, will serve the purpose. After twenty-four hours' pressing, the specimens will be found quite flat, but limp and full of moisture. Now shift them into the Bentall's paper, interposing blotting-paper or tissue-paper when the parts are very tender; newspapers also as intermediates between the Bentall, and press again. In a day or so the specimens should have a second shift. This time the Bentall, and everything else employed, should be made perfectly dry and warm before the fire, or by placing for a few minutes in the kitchen oven. A third and fourth shift, at intervals of twenty-four hours, again with warm dry Bentall (not moist warm, but dry warm), will ordinarily suffice, and now the specimens will be dry, and their colours perfectly fixed. It is of no advantage to employ Bentall for the commencing process, this being one simply of compression. Drying rarely commences for at least two days. The critical time is from the third day till the end of the week. A good plan, at the end of the week, is to expose the plant for several hours to a warm, dry atmosphere. To lie in damp papers is utter ruin to them. Repeated change into dry and warm ones is the secret of success. When travelling, the requisite pressure (should the house not furnish weights) is obtained by tight tying up with whipcord, across and twice athwart, after the manner of a tradesman's package.

2. *Preservation when Dried.*—When perfectly dry, the specimens should be laid out upon half-sheets of tolerably stiff white paper, and the half-sheets be placed within a whole sheet. The measure of the white paper should be about 22 inches by 16. This is larger than the regulation size adopted at Kew, but scarcely more expensive, and preferable for a reason that I shall have to mention presently. If the specimens are likely to be often handled and examined, or, at all events, by careless persons, it is desirable that they should be mounted. Some people employ horrible transverse straps of gum-paper, and even postage-stamp edgings; others smear and smudge with thin gum arabic; others resort to paste or to gum tragacanth, which is worst of all; some employ carpenter's glue, a cement unobjectionable except for the petals of flowers, and incomparable for thick stems, but very inconvenient on account of so soon becoming cold. The best cement yet devised is Marian's solution of india-rubber in naphtha. It is admirably adhesive, most easily applied, wants no warming before use, and should any be spilled or squeezed out beyond the margin of a leaf, when dry it can be rubbed off and leaves no trace. For cleanliness this cement is the most perfect yet discovered. Sometimes it is preferable to keep the specimens loose. Inferior ones can then be superseded by better; the venation of the leaves can be scrutinized when there is need, and a prodigious amount of labour is saved. At Kew, as soon as mounted, it is customary to wash the specimens with a solution of corrosive sublimate in spirits of wine, with a view to prevent attack by insects. Without offering any opinion as to the necessity of poisoning, I may say that in my own herbarium, scarcely anything in which is poisoned, I have not seen a hurtful insect for twenty-five years. In certain polyandrous flowers, the clematis, magnolia, hypericum, cistus, tulip tree, and a few crucifers, little things that I take to be "thrips" sometimes appear, hatched, I imagine, from eggs left among the stamens, but they soon die out of the way, and give no trouble. I attribute this absence of insects to the original thorough drying by means of hot paper. Unhappily the poisoning often extracts a yellow dye, so that if not performed till after the specimen is mounted, a bruise-like stain is communicated to the paper. This, of course, may be obviated by poisoning before mounting. When mounted, the name, date, and locality where gathered, should be written on the containing paper; if kept loose, the same particulars should be

stated on a ticket, and the ticket be attached to the specimen. As soon as fifty or a hundred are got together, they should be sorted according to their natural orders, a sheet being devoted to every order, with its name in bold writing on the outside. When the orders themselves become well illustrated, the genera should be isolated in similar manner; and when a genus becomes well illustrated, the particular species should have separate sheets. By this means continual expansion is provided for: there is a place for everything, and everything is kept in its place. The nomenclature and arrangement should be according to some published catalogue, the newer the better: a system, of course, is impossible. Finally, the sheets of specimens should be deposited in a suitable cabinet, or if a cabinet be not possessed, they may be wrapped in brown paper, marked outside as to the contents. This preserves them from the ingress of dust, which is often a sad blemish to a *hortus siccus*, where cleanliness ranks next to order and accuracy.

3. *What Plants to Preserve.*—Everything that is interesting in economic botany, useful in medicine, employed in art or science, curious and instructive in relation to structure and physiology, or in any way identified with floriculture. The object of the *hortus siccus* is to illustrate the plant in the most perfect manner possible. Such plants, accordingly, as grasses and ferns, should be procured in every stage, from youngest to oldest. Cotyledons, root-leaves, sprays showing plumules, others showing stipules, autumnal foliage, leaves bearing parasitic fungi, should all be treated as though they were flowers—specimens adequately exemplifying the various structures being laid alongside. Seed-pods likewise, and even berries, the latter dried in wadding, should be introduced, and packets of the ripe seed should be kept in envelopes. Tendril-bearing plants, such as the purple-tufted vetch, and twiners, such as the hop, should be got while clinging to their prop, and the two be dried together. Then we see the mode of life as well as the organs. Series such as indicated illustrate the whole biography of a plant, and this, no matter how common it is, is sure to be interesting. Be not led away by any foolish desire for "rarities," thanking God rather for the world's "common things." A good series of illustrations of a few hundreds of curious common plants is better than an herbarium distinguished only for quantity, and for the damage it has done to the botanical features of a district. Here let me enter my protest against the offering of prizes for collections of rare plants. If the societies who award premiums for diligence in extirpation—for that is what rare plant collecting comes to practically—would foster the preparation of good scientific sets or conspectuses, with dissections of every part, limiting the requisition to some extensive and important natural order, they would do some real service to the cause of botany, instead of simply abetting the selfish and covetous. Products also should be introduced, such as lace bark and the bark of the paper birch, with rice-paper, Broussonetia cloth, Böhmeria cloth, and anything else that lies flat and helps to interpret the plant. To a certain extent the well-prepared *hortus siccus* thus tells its tale, not only of structure and beauty, but of the serviceableness of the plant to mankind. Never be content, except where unavoidable, with a fragment. Every specimen should be large and handsome, and the greater portion of the *hortus siccus* co-extensive with the room given by the paper. Fragments, of course, are better than nothing, but they should be regarded as only specimens *pro tem.*

4. *Introduction of Drawings.*—When the *hortus siccus* has acquired value from the number and merit of its dried specimens, the time has arrived to incorporate drawings. Drawings are absolutely needful to the illustration of certain classes of plants, orchids, for example, irids, amaryllids, cactuses, and even roses and utricularias. In these cases they show the flower, its form, and size, and colour, while the specimen shows the habit, whereas neither is sufficient while standing alone. Yuccas, cycads, etc., likewise require drawings for their proper illustration, and a wonderful charm is given at the same time to one's sprays of oak and beech, walnut and ash, by portraits of the full-grown trees. Of course it is easy to refer to books containing plates, when we wish to interrogate a picture or a portrait, but when laid side by side the whole idea is presented at once. Additional interest is given by the introduction of drawings of great antiquity, those, for example, published by Fuchsius, in 1542. This enables us to see at a glance what is the history of the plant, especially when the oldest are supplemented by the newest—a process not always favourable to the latter, not even when the plates have come from the last edition of the 'English Botany.'

As I am not fashioning the theory or hypothesis of a *hortus siccus*, making believe what *should* be, but describing one that stands only a dozen yards from where I write, I may say, for the encouragement of any who feel disposed to construct a similar one, that a few years' steady work has resulted in the bringing together of some seven or eight thousand different species of plants, many of them exemplified by a dozen different specimens, and that the number of drawings is about the same. The *hortus siccus* I have before me contains illustrations, more or less perfect, of everything botanical that has ever held a place in human interest. It is in the presence of the drawings that the desirableness of a large paper now finds reason, since it holds, without need of clipping them, the folio plates of the 'Flora Londinensis;' those also of the splendid volumes of Ledebour, Pallas, and Jacquin. Even Roxburgh's Coromandel plants require only a single fold.

Such, then, is the refuge I recommend to dwellers in towns, who love flowers, and plants, and trees, but to whom the sweet pastime of their culture is denied. Begin soon enough, and the *hortus siccus* is a life-long exercise in everything implied in order and neatness, accuracy of scientific observation and discrimination, and in exact and logical mental work. It is an unfailing amusement; it is profoundly educational alike to one's-self and to others; it is a commentary on one's tastes, and a history of one's experience.

PRELIMINARY ACCOUNT OF AN INVESTIGATION ON THE TRANSMISSION OF SOUND BY THE ATMOSPHERE.*

BY JOHN TYNDALL, D.C.L., LL.D., F.R.S.

(*Concluded from p.* 734.)

On the 24th, when observations were made afloat in the steam-tug Palmerston, the syren exhibited a clear mastery over gun and horns. The maximum range was $7\frac{3}{4}$ miles. The wind had changed from W.S.W. to S.E., then to E. As a consequence of this, the syren was heard loudly in the streets of Dover. On the 27th the wind was E.N.E.; and the syren-sound penetrated everywhere through Dover, rising over the moaning of the wind and all other noises. It was heard at a distance of 6 miles from the Foreland on the road to Folkestone, and would probably have been heard all the way to Folkestone had not the experiments ceased. Afloat and in the axis, with a high wind and sea, the syren, and it only, reached to a distance of 6 miles; at 5 miles it was heard through the paddle noises. On the 28th, further experiments were made on the influence of pitch, the syren when generating 480 waves a second being found more effective than when generating 300 waves a second. The maximum range in the axis on this day was $7\frac{1}{2}$ miles.

The 29th of October was a day of extraordinary optical transparency, but by no means transparent acoustically. The gun was the greatest sufferer. At first it was barely heard at 5 miles; but afterwards it was tried at $5\frac{1}{2}$, $4\frac{1}{2}$, and $2\frac{1}{2}$ miles, and was heard at none of these distances. The syren at the same time was distinctly heard. The sun was shining strongly; and to its augmenting power the enfeeblement of the gun-sound was doubtless due. At

---

* Communicated to the Royal Society, January 15th, 1874. (Proceedings, vol. xxii. p. 58.)

3½ miles, subsequently, dead to windward, the syren was faintly heard; the gun was unheard at 2¾ miles. On land the syren and horn sounds were heard to windward at 2 to 2½ miles, to leeward at 7 miles; while in the rear of the instruments they were heard at a distance of 5 miles, or five times as far as they had been heard on October 23.

The 30th of October furnished another illustration of the fallacy of the notion which considers optical and acoustic transparency to go hand in hand. The day was very hazy, the white cliffs of the Foreland at the greater distances being quite hidden; still the gun- and syren-sounds reached on the bearing of the Varne light-vessel to a distance of 11½ miles. The syren was heard through the paddle noises at 9¼ miles, while at 8½ miles it became efficient as a signal with the paddles going. The horns were heard at 6¼ miles. This was during calm. Subsequently, with a wind from the N.N.W., no sounds were heard at 6½ miles. On land, the wind being across the direction of the sound, the syren was heard only to a distance of 3 miles N.E. of the Foreland; in the other direction it was heard plainly on Folkestone Pier, 8 miles distant. Both gun and horns failed to reach Folkestone.

Wind, rain, a rough sea, and great acoustic opacity characterized October 31st. Both gun and horns were unheard 3 miles away, the syren at the same time being clearly heard. It afterwards forced its sound with great power through a violent rain-squall. Wishing the same individual judgment to be brought to bear upon the sounds on both sides of the Foreland, in the absence of our steamer, which had quitted us for safety, I committed the observations to Mr. Douglass. He heard them at 2 miles on the Dover side, and on the Sandwich side, with the same intensity, at 6 miles.

A gap (employed by the engineers in making arrangements for pointing the syren in any required direction) here occurred in our observations. They were resumed, however, on November 21st, when comparative experiments were made upon the gun and syren. Both sources of sound, when employed as fog signals, will not unfrequently have to cover an arc of 180°; and it was desirable to know with greater precision how the sound is affected by the direction in which the gun or syren is pointed.

The gun, therefore, was in the first instance pointed on us and fired, then turned and fired along a line perpendicular to that joining us and it. There was a sensible, though small, difference between the sounds which reached us in the two cases. A similar experiment was made with the syren; and here the falling off when the instrument was pointed perpendicular to the line joining us and it was very considerable. This is what is to be expected; for the trumpet associated with the syren is expressly intended to gather up the sound and project it in a certain direction, while no such object is in view in the construction of the gun. The experiments here referred to were amply corroborated by others made on November 22nd and 23rd.

On both of these days the Galatea's guns were fired to windward and to leeward. The aërial echoes in the latter case were distinctly louder and longer than in the former. The experiment has been repeated many times, and always with the same result.

In front of the Cornhill Coastguard Station, and only 1¼ mile from the Foreland, the syren, on the 21st, though pointed towards us, fell suddenly and considerably in power. Before reaching Dover Pier it had ceased to be heard. The wind was here against the sound; but this, though it contributed to the effect, could not account for it, nor could the proximity of the shadow account for it. To these two causes must have been added an acoustically flocculent though optically transparent atmosphere. The experiment demonstrates conclusively that there are atmospheric and local conditions which, when combined, prevent our most powerful instruments from making more than a distant approach to the performance which writers on fog signals have demanded of them.

On November 24th the sound of the syren pointed to windward was compared at equal distances in front of and behind the instrument. It was louder to leeward in the rear than at equal distances to windward in front. Hence, in a wind, the desirability of pointing the instrument to windward. The whistles were tested this day in comparison with the syren deprived of its trumpet. The Canadian and the 8-inch whistles proved the most effective; but the naked syren was as well heard as either of them. As regards opacity, the 25th of November almost rivalled the 3rd of July. The gun failed to be heard at a distance of 2·8 miles, and it yielded only a faint crack at 2½ miles.

Meanwhile this investigation has given us a knowledge of the atmosphere in its relation to sound, of which no notion had been previously entertained. While the *velocity* of sound has been the subject of refined and repeated experiments, I am not aware that since the publication of a celebrated paper by Dr. Derham, in the 'Philosophical Transactions' for 1708, any systematic inquiry has been made into the causes which affect the *intensity* of sound in the atmosphere. Derham's results, though obtained at a time when the means of investigation were very defective, have apparently been accepted with unquestioning trust by all subsequent writers—a fact which is, I think, in some part to be ascribed to the *à priori* probability of his conclusions.

Thus Dr. Robinson, relying apparently upon Derham, says, "Fog is a powerful damper of sound," and he gives us physical reason why it must be so. "It is a mixture of air and globules of water, and at each of the innumerable surfaces where these two touch, a portion of the vibration is reflected and lost." And he adds further on, "The remarkable power of fogs to deaden the report of guns has been often noticed."

Assuming it, moreover, as probable that the measure of "a fog's power in stopping sound" bears some simple relation to its opacity for light, Dr. Robinson, adopting a suggestion of Mr. Alexander Cunningham, states that "the distance at which a given object, say a flag or pole, disappears, may be taken as a measure of the fog's power" to obstruct the sound. This is quite in accordance with prevalent notions; and granting that the sound is dissipated, as assumed, by reflection from the particles of fog, the conclusion follows that the greater the number of the reflecting particles, the greater will be the waste of sound. But the number of particles, or, in other words, the density of the fog, is declared by its action upon light; hence the optical opacity will be a measure of the acoustic opacity.

This, I say, expresses the opinion generally entertained, "clear still air" being regarded as the best vehicle for sound. We have not, as stated above, experimented in really dense fogs; but the experiments actually made entirely destroy the notion that clear weather is necessarily better for the transmission of sound than thick weather. Some of our days of densest acoustic opacity have been marvellously clear optically, while some of our days of thick haze have shown themselves highly favourable to the transmission of sound. Were the physical cause of the sound-waste that above assigned, did that waste arise in any material degree from reflection at the limiting surfaces of the particles of haze, this result would be inexplicable.

Again, Derham, as quoted by Sir John Herschel, says that "falling rain tends powerfully to obstruct sound." We have had repeated reversals of this conclusion. Some of our observations have been made on days when rain and hail descended with a perfectly tropical fury; and in no single case did the rain deaden the sound; in every case, indeed, it had precisely the opposite effect.

But falling snow, according to Derham, offers a more serious obstacle than any other meteorological agent to the transmission of sound. We have not extended our observations at the South Foreland into snowy weather; but an observation of my own made on December 29th, in

the Alps, during a heavy snow-storm, distinctly negatives the statement of Derham.

Reverting to the case of fog, I am unable in modern observations to discover anything conclusive as to its alleged power of deadening sound. I had the pleasure of listening to a very interesting lecture on fog-signals delivered by Mr. Beazeley before the United Service Institution; and I have carefully perused the printed report of that lecture, and of a paper previously communicated by Mr. Beazeley to the Institution of Civil Engineers. But in neither of these painstaking compilations can I find any adequate evidence of the alleged power of fogs to deaden sound.

Indeed, during the discussion which followed the reading of Mr. Beazeley's paper, an important observation in an opposite sense was mentioned by Mr. Douglass, to whose ability and accuracy as an observer I am able to bear the strongest testimony. Mr. Douglass stated that he had found in his experience but little difference in the travelling of sound in foggy or in clear weather. He had distinctly heard in a fog, at the Smalls Rock, in the Bristol Channel, guns fired at Milford Haven, 25 miles away. Mr. Beazeley, moreover, has heard the Lundy Island gun "at Hartland Point," a distance of 10 miles, during dense fog. Mr. Beazeley's conclusion, indeed, accurately expresses the state of our knowledge when he wrote. In winding up his paper, he admitted "that the subject appeared to be very little known, and that the more it was looked into the more apparent became the fact that the evidence as to the effect of fog upon sou d is extremely conflicting." When, therefore, it is alleged, as it is so often alleged, that the power of fogs to deaden sound is well known, the disjunctive *not* is to be inserted before the predicate.

The real enemy to the transmission of sound through the atmosphere has, I think, been clearly revealed by the foregoing inquiry. That enemy has been proved to be, not rain, nor hail, nor haze, nor fog, nor snow—not water, in fact, in either a liquid or a solid form, but water in a vaporous form, mingled with air so as to render it acoustically turbid and flocculent. This acoustic turbidity often occurs on days of surprising optical transparency. Any system of measures, therefore, founded on the assumption that the optic and acoustic transparency of the atmosphere go hand in hand must prove delusive.

There is but one solution of this difficulty: it is to make the source of sound so powerful as to be able to endure loss by partial reflection, and still retain a sufficient residue for transmission. Of all the instruments hitherto examined by us the syren comes nearest to the fulfilment of this condition; and its establishment upon our coasts will, in my opinion, prove an incalculable boon to the mariner.

An account of the observations made during the recent fog will be included in the paper shortly to be presented to the Society. These observations add the force of demonstration to others recorded in the paper, that fogs possess no such power of stifling sound as that hitherto ascribed to them. Indeed, the melting away of fog on December 13th was accompanied by an acoustic darkening of the atmosphere, so great that, at a point midway between the eastern end of the Serpentine, where a whistle was sounded; and the bridge, the sound possessed less than one-fourth of the intensity which it possessed on the day of densest fog.

Thus, I think, has been removed the last of a congeries of errors which for more than a century and a half have been associated with the transmission of sound by the atmosphere.

THE ESTIMATION OF SUGAR BY MEANS OF IRON.*

BY E. RIFFARD.

It is known that tartaric, citric, and malic acids, albumen and sugar, possess the property of preventing the precipitation of salts of iron in alkaline solutions. Peroxide of iron in solution in an acid liquid not containing sugar is precipitated directly that the liquid is neutralized by ammonia; but if the iron and the sugar be present in certain proportions, or if the sugar be in excess, there is obtained, after saturation with ammonia, a sucro-ferric ammoniacal compound of a fine red colour, which remains in solution, provided that the liquid contains none of the alkaline earth metals. Having studied the method based on those principles of estimating tartaric acid indicated by M. Juette, the author sought to apply it to the estimation of sugar.

It is, however, necessary to vary the process according to the state of the peroxide of iron in the solution. If it be in the, as yet, imperfectly understood state known as modified peroxide, which is produced by adding a few drops of hydrochloric acid to a solution of crystallized perchloride of iron, 100 milligrams of iron require, to remain in solution in the presence of ammonia 3·71 grams of sugar. If, on the contrary, the solution is prepared by simply dissolving crystallized perchloride of iron in pure water without any addition of acid, 100 milligrams of iron only require 2·587 grams of sugar to remain in solution. If the solution contain this or a larger quantity of sugar, upon adding ammonia, so as to render the liquid clearly alkaline, after agitating freely, a red solution is obtained which is perfectly and permanently limpid. But if a smaller quantity of sugar be present, then, upon the addition of ammonia in excess, the solution, at first milky, quickly throws down the characteristic precipitate of peroxide of iron.

The soluble compound which is formed when an equivalent or more of sugar is present is permanent in the presence of alcohol and of ether; but it is decomposed by heat or by lime salts, and its precipitation is induced by ammoniacal salts, added in excess. Experiments, however, have shown that the error that might result from precipitation produced by hydrochlorate of ammonia formed in the solution may be neglected. In operating, 25·87 grams, or 37·10 grams, according to the state of the ferric solution, of the sugar to be tested are dissolved, and a few drops of oxalate of ammonia added to precipitate the lime; the solution is then filtered, and completed to a volume of 250 cubic centimetres; 25 cubic centimetres are taken first, and for n per cent. of pure sugar present in the specimen, n per cent. of the 100 milligrams of iron may be added, and will remain in solution. Thus the following results will be obtained:—

With n milligrams of iron . .	Clear solution.
With $n+1$,, ,, . . .	Precipitate.

n being the percentage of sugar which the specimen contains.

The action of inverted sugar is more powerful than that of crystallizable sugar, 0·357 gram of crystallizable sugar inverted by hydrochloric acid being sufficient to retain in solution 100 milligrams of iron in the state of modified peroxide. As certain sugars, principally exotic, contain inverted sugar, which might falsify the results, the author avoids this cause of error by shaking the sugar with cold 95° alcohol and filtering the liquor. The inverted sugar and some organic acid substances pass into solution, whilst the sugar remains undissolved. In numerous experiments the author has found this process to give results identical with those given by the saccharometer.

AMOUNT OF AMMONIA IN THE ATMOSPHERE AT DIFFERENT HEIGHTS.

M. Truchot has recently presented to the French Academy of Sciences a series of determinations on this point. By means of a peculiar aspirator the air was made to pass through acidulated water in quantities of from 5 to 10 cubic metres, and the quantity of ammonia then determined. At Clermont-Ferraud, 395 metres above the sea level one cubic metre of air was found to contain,

* Abstracted from the *Moniteur Scientifique* [3], iv. 831.

August 28th, 1·12 milligrams of ammonia; at the summit of the Puy-de-Dôme, 1446 metres elevation, on August 27th, 3·18 milligrams; and on the summit of the Pic-de-Sancy, 1884 metres high, 5·55 milligrams, on August 29th. At the time when this last determination was made the weather was very cloudy and misty, and another was therefore made on October 6th, when the air was clear, and nearly the same result obtained, viz., 5·27 milligrams in the cubic metre. The general result of the observations was, therefore, that the atmosphere contains a larger proportion of ammonia in the neighbourhood of the clouds than nearer the surface of the earth. In Clermont itself the proportion varied between 0·93 and 2·79 milligrams; the proportion was larger with gentle rain, and especially during mist, than when the air is clear, a result obtained previously by M. Boussingault. The proportion of ammonia appears to vary inversely as that of carbonic acid, the amount of this latter being, at the three elevations named, 0·632, 0·405, and 0·342 milligrams in the litre.

PERIODIC MOTIONS OF LEAVES AND PETALS.

These phenomena, on which much has recently been written in both England and Germany, have been the subject of a fresh series of observations by the German botanist Batalin. He divides the various instances of motion into three groups, viz.: (1) Rapid automatic motions caused by a special motile organ, the pulvinus, at the base of the leaf-stalk; (2) Diurnal motions, not so rapid, but also resulting from a special motile organ; and (3) Diurnal motions belonging to the whole of the leaf-stalk, and partially also to the surface of the leaf, but not connected with the presence of a pulvinus. The third of these classes, to which belong the motions of petals which cause the opening and closing of flowers, were the special subject of Batalin's observations. The ordinary explanation of the phenomenon has been the different degree of tension in the two sides of the leaf caused by a difference in the amount of water contained in them, which explanation has, however, already been shown by Pfeffer not to meet all the cases. Batalin agrees with Pfeffer's conclusions, and considers the main cause of the motion to be unequal growth of the two sides caused by alternating differences in the light, temperature, and turgescence. He believes that the same cause is also one of the most efficient in the other classes of periodic motion connected with special motile organs.

THE PROPOSED PHARMACY BILL FOR IRELAND

On Friday, the 20th February, an influential deputation, representing the apothecaries of Dublin and Belfast, waited by appointment upon the Governor and Directors of the Apothecaries' Hall of Ireland to state their views regarding the proposed Pharmacy Bill. The deputation at some length stated their strong objection to any measure by which the present standard of pharmaceutical knowledge should be lowered; pointed out that in England for years past strenuous efforts had been made by the Pharmaceutical Society to compel those engaged in compounding medicines to be properly educated for that purpose; showed the difference between the two kingdoms in that respect, that while in Ireland for nearly 100 years every person who practised pharmacy was compelled by law to attend a prolonged course of study and undergo a strict examination prior to his doing so, in England and Scotland any person, no matter how unqualified, might keep open shop for that purpose.

It was pointed out that very few apothecaries practised as physicians upon their licence only, they having almost invariably (if practitioners) some other qualification. The Apothecaries' Hall had in itself power to do away with the medical and surgical classes and examinations, and in that case it would become what many of the deputation wished—a strictly pharmaceutical body. They thought that while exceptions might fairly, at first, be made in cases where a person showed sufficient cause, that in general an apprenticeship of not less duration than three years, together with attendance at a course of lectures on chemistry, materia medica, and botany should be enforced. The druggists in Ireland had no reason to complain; no one wished to deprive them of any right or privilege they had heretofore possessed; while the apothecaries who had passed through an extensive and expensive course of study (many of them merely to keep open shop) might fairly do so, were their privileges taken from them. The change was for the advantage of the public or it was not; if the latter, it should not be made; if the former, the apothecaries ought not to suffer.

A member of the deputation called attention to the number of unqualified persons in Dublin who compounded prescriptions, and gave an instance which had occurred a few days previously, in which an ordinary prescription had been compounded by a so-called druggist in a grossly incorrect manner.

Dr. Leet replied to the remarks that had been made, and stated that the Apothecaries' Hall had no wish and no intention to lower the standard of knowledge required for compounding medicines, except in so far as related to medical and surgical subjects. He could not allow the deputation to forget that the apothecaries were by Act of Parliament registered practitioners of medicine, and therefore no change such as that suggested by the deputation could be entertained by the Governor and Directors of the Hall; they were, however, willing and ready to consider any reasonable amendments to the proposed bill, and were anxious to act fairly in the matter. They did not wish to continue the present arrangements, by which, as he believed, many towns in Ireland were deprived of the service of pharmaceutists.

Dr. Collins followed, and objected to the stand taken by the deputation. He strongly supported Dr. Leet, and would not be in favour of lowering the standard of professional attainment at present required by the Apothecaries' Hall. Some change as regards the compounding of medicines in this country should be made, and he thought that the proposed bill, which might be modified, would be a useful measure.

Drs. Wise, Holmes and Ryan (Governor) also took part in the discussion.

The following resolutions, approved of by the deputation, were then read:—

1. That the matriculation examination for the Pharmaceutical Society should be as extensive as that of any Medical licensing bodies.
2. That an apprenticeship of not less than three years should be demanded.
3. That every candidate for the final examination should produce his matriculation certificate, his indenture of apprenticeship, together with certificate of attendance on a course of lectures on each of the following subjects: Chemistry, Botany, Materia Medica and Pharmacy.
4. That a direct and fair representation of apothecaries on the board should be granted.

Some of the deputation objected to a clause in the bill by which for six months after the passing thereof the Governor and Directors of the Hall would have unlimited control over the proposed Pharmaceutical Society, and suggested that six gentlemen chosen by the apothecaries who registered themselves as Pharmaceutical Chemists, with six others to be appointed by the Apothecaries' Hall, should have the management *ab initio* of the new Society.

The deputation having been informed that their views would be carefully considered, thanked the Court for the courtesy shown them and retired.

The Pharmaceutical Journal.

SATURDAY, MARCH 21, 1874.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

PUBLICITY OR PELF?

THE land of the setting sun has long had attributed to it more than a fair share of shams, from wooden nutmegs down to bogus diplomas. But no reader of American newspapers can deny that if the shams do exist the gentlemen of the fourth estate are not sparing in words of indignation against them, at least when their concoctors do not happen to be advertisers. An attempt to curb this license of language has been recently made under circumstances that will present points of interest to many of our readers. A maker of "articles of merchandise, generally and publicly known as Dr. RICHAU'S Golden Remedies," took umbrage that he should have been included in a common paragraph, which appeared in the *American Agriculturist*, under the heading "Sundry Humbugs," with the whole tribe of those who advertise "marriage guides," "female medicines," "eye-doctors," "consumption curers," as well as other "quacks and impostors;" and that, further, some inquiring correspondents should have been roundly informed that the "Golden Remedies" were "nonsensical quackery."

Twenty-five thousand dollars was the estimate of the amount of damage done by this mud-throwing, and Mr. DAVID RICHARDS, the proprietor and manufacturer of Dr. RICHAU'S Golden Remedies went into a law court with a claim for that amount against the delinquent *American Agriculturist*. But, like another claimant, he appears to have ignored the possible results of an artful cross-examination. A "Golden Elixir de Amour [*sic* in two reports], or Elixir of Love," had been advertised as being composed of the most "powerful ingredients of the vegetable kingdom; harmless, but speedy in restoring healthy action." Further, it was described as being "the fountain of youth to old age, the rejuvenator of pristine vigour to the young; to the barren woman of our land it is a special blessing," and so on, *usque ad nauseam*.

Mr. RICHARDS was invited to inform the Court —and the public—as to the names of these "most powerful ingredients," in order to assist in coming to a judgment on the amount of wrong done. But he was evidently of the same opinion as King SOLOMON, that "a prudent man concealeth knowledge," and so he recoiled from becoming a public benefactor, except under the cloak of secrecy and the auspices of the medicine stamp. Nevertheless, his modest diffidence lost him his cause; for upon his refusing to give any other answer than that it was a "secret compound of various ingredients, which possess great medicinal properties," the Court ordered that the complaint should be dismissed with costs. Defeated, but dissatisfied, the plaintiff appealed to the Supreme Court, where he was told that to bring an action of libel for injury alleged to be done to his trade in his medicines by denouncing them as arrant quackery, and at the same time to protect himself against exposure by claiming them to be valuable secrets, was a proposition that could not be maintained.

Probably most of our readers, if they had to pronounce upon this case, would return a verdict of "Served him right," and in our opinion they would not be very wrong. But it should not be forgotten that the question has another aspect. The device of asking the manufacturer of a proprietary article to disclose his secret is not a new one, and it requires no great effort of the imagination to conceive that a remedy entitled to a considerable amount of eulogium might be attacked in a similar manner, and yet that the proprietors might shrink from the publicity that would rob them of a source of revenue. Nevertheless, from failure of even a just cause in a law court, unfavourable conclusions would be sometimes drawn, and it might prove better to—

> "Bear those ills we have,
> Than fly to others that we know not of.
> Thus conscience does make cowards of us all."

ADDITIONS TO THE PHARMACOPŒIA.

WE are glad to be able to state that the long-expected Additions to the British Pharmacopœia of 1867 are now announced. They are thirty-four in number, and are mainly those which have been indicated by Dr. REDWOOD at the Evening Meetings of the Pharmaceutical Society. For the convenience of persons already possessing copies of the British Pharmacopœia, the Additions are published separately at a low price. We hope to have an opportunity to notice these additions in detail in our next number.

AN AFRICAN VESICANT.

IN his new work, 'The Heart of Africa,' Dr. SCHWEINFURTH says that the most remarkable plant found in the islands of the Meshera is the *Adenia venenate*, a climbing passion flower. The plant is remarkable for the large development of its stem, which grows half under the soil, and throws out a protuberance some cubic feet in extent. At the end of this protuberance the stem breaks out into a number of long climbing stalks, which mount up to a considerable height. The leaves are bright green, and are applied by the natives of Central Africa for vesicating purposes. They are, however, poisonous,

and are said to have proved fatal to camels, and thus been an obstacle to the acclimatization of those animals in the country.

POISONING BY CROTON SEEDS.

The Medical Times and Gazette reports that twenty-four persons have been poisoned in the south of Ireland, through eating some seeds of *Croton Tiglium*, which had washed ashore in Tramore Bay, it is supposed from a Dutch vessel that had foundered a few days before. The "nuts" were found by the country people and eaten accordingly: the consequences may be guessed, but fortunately no death is known to have resulted.

HUNTER *v.* FREELAND.

In our "Correspondence" columns will be found an appeal for subscriptions towards assisting the defendant to the above suit, which was reported at p. 565, in liquidating the heavy legal expenses incurred. Although it must be owned that there was a certain amount of carelessness or ignorance exhibited by the servant of the defendant, yet the penalty appears greatly disproportioned to the offence, and some amount of sympathy is due to a man who was avowedly specially punished as "an example to chemists."

INTERNATIONAL BOTANICAL CONGRESS AT FLORENCE.

In connection with the International Exposition to be held this year in Florence, the Tuscan Royal Society of Horticulture has arranged for the assembly of an International Botanical Congress. We are informed that the most illustrous botanists of Europe have already intimated their intention to take part in this Congress.

PRIZE FOR THE DETECTION OF ALCOHOL.

A proposition has been made in the French National Assembly by M. Léon Say to institute a prize of 50,000 francs, for the benefit of the person who shall discover a practical method of determining immediately the presence of alcohol in mixtures. The proposition was ordered to be printed and circulated.

SPECIES OF EUCALYPTUS AT KEW.

The *Gardeners' Chronicle* calls attention to two species of the genus *Eucalyptus* which are now represented in the temperate house at Kew. One, *E. cornuta*, is remarkable for its curious horn-like calyx; the other, *E. citriodora*, is worth cultivating, even as a small pot plant, for its delightful fragrance, which is described as being as powerful as that of the Aloysia, but more delicate.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

March 11th, 12th, 13th, and 18th, 1874.

Present (on the 11th)—Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Cracknell, Davenport, Gale, Hills, Linford, Martindale, Schweitzer, Taylor, and Umney.

(12th and 13th)—Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Cracknell, Davenport, Gale, Hills, Linford, Martindale, Schweitzer, Southall, Taylor, and Umney.

(18th)—Messrs. Allchin, Barnes, Carteighe, Corder, Cracknell, Davenport, Gale, Hills, Linford, Martindale, Schweitzer, Taylor, and Umney.

Dr. Greenhow was present on the 11th on behalf of the Privy Council.

MAJOR EXAMINATION.

Four candidates were examined, and declared qualified to be registered as Pharmaceutical Chemists:—

*Pickard, William.....Yeovil.
*Hetherington, Martin Luther Highbury.
Kemble, James .....St. Austell.
Thompson, Lawrence Joseph ...Thirsk.

MINOR EXAMINATION.

Ninety-three candidates were examined. *Sixty-one* failed. The following *thirty-two* passed, and were declared qualified to be registered as Chemists and Druggists:—

*Coleman, Alfred .....Southampton.
*Gilders, George Pollard .....St. Leonard's.
*Blake, Charles Alexander .....London.
*Whyte, Alexander .....London.
Geldart, William .....Seacombe.
Locke, George .....Aylesbury.
Piper, Walter George .....Norwich.
Equal. Allis, William .....Alford.
Equal. Gostling, William Ayton.....Diss.
Cattell, Thomas Bellamy.....Coventry.
Black, William Jones .....Bangor.
Equal. Howard, Robert .....Clitheroe.
Equal. Morgan, Augustus Kinsey .....Nash, Mon.
Palmer, William Joseph .....King's Lynn.
Equal. Coles, William .....Great Missenden.
Equal. Geldart, John .....Whitehaven.
Equal. Stevens, Richard .....Leeds.
Gibbs, Joseph .....Tunbridge Wells.
Ordish, Thomas.....Manchester.
Equal. Miller, Cecil Bradley .....Wellingborough.
Equal. Wise, James .....High Wycombe.
Evans, Daniel William.....Carmarthen.
Lambert, William Henry.....Hull.
Snow, Arthur Legge.....Ross.
Ness, Thomas Henry.....Boston.
Baxter, Thomas Moore.....Wisbeach.
Smith, Richard Henry .....Leeds.
Stiling, John Edward .....Exeter.
Whewell, William Edmund.....Birmingham.
Booth, William Grounds .....Manchester.
Mitton, Richard .....Embsay.
Crossley, Newbold.....Bury.

The above names are arranged in order of merit.

PRELIMINARY EXAMINATION.

The undermentioned certificates were received in lieu of the Society's examination:—

Certificates of the University of Cambridge.

Ekins, Thomas George.....Huntingdon.
Hobson, Charles, jun. .....Windsor.
Lumby, Fred. .....Nottingham.

Certificate of the University of London.

Jones, George Henry .....Hanley.

Certificates of the College of Preceptors.

Churchouse, W. J. Franklin ...Chard.
Marshall, Frank .....Ely.

* Passed with Honours.

Provincial Transactions.

NORTHAMPTON PHARMACEUTICAL ASSOCIATION.

On February 3rd, a special meeting of the above Society was held to hear a paper on Yeast, which had been sent by Mr. Stott, of Leeds. The paper first traced the derivation of the words barm and yeast, beer and ale, and then described the production, mode of growth, and characters of the *Torula*. The labours of Priestley in the study of fermentation were touched upon, and the various stages in the conversion of saccharine into spirituous and the spirituous into acidulous liquids explained.

On March 16th the monthly meeting was held, Mr. H. J. Masters in the chair. Mr. G. C. Druce having read the minutes and correspondence, it was decided to purchase a copy of 'Hooker's Flora,' so that the apprentices competing for the Herbarium prize might have their choice of floras. As several apprentices had only recently come to Northampton, it was resolved that they should be admitted for the summer session without payment, on condition of their joining as members in October.

Mr. Campling read a paper on Pyroxylin, dwelling more particularly on the explosive form (trinitro-cellulose), showing its superiority over gunpowder in the non-production of smoke and the freedom from "fouling." Having described its preparation and its value in blasting, through its possessing much greater explosive power than gunpowder, Mr. Campling instanced its employment in torpedo warfare. He then referred to the difference between the explosive characters of gun-cotton and gunpowder; the former, if ignited in the open air in an uncompressed state, would simply burn, whilst the latter, treated in a similar manner, would explode.

Mr. H. Kemp then read a paper on the Source of Vegetable Matter. The production of charcoal was first explained, and the average amount of carbon in the vegetable kingdom was stated to be 45 per cent. When the immense extent of the forests in different parts of the world was considered, and particularly in South America, where, according to Humboldt, monkeys might travel hundreds of miles on the tops of the trees, some idea of the gigantic quantity of carbon stored up could be conceived. It might be asked, Did that carbon occur in the soil, and, if not, where else could the 1734 lb. of carbon —contained in 4800 lb. of wheat, the average yield of an acre—come from? Mr. Kemp then referred to the numerous experiments which have been made, the results of which all tend to show that the carbon is derived from the atmosphere, which is again replenished from the animals who live upon the vegetation, and by the direct decomposition of vegetation itself.

The following statistics were given as the treatment for seventeen years of the same piece of land on which wheat was grown:—

	Gross Produce.	Organic Matter.	Carbon.
1. Unmanured land	2434	1963	880
2. Land treated with mineral salts	2912	2347	1052
3. Ditto with ammonia	6394	5149	2308
4. Ditto with farm-yard manure .	6059	4883	2183

Votes of thanks having been passed, after a brief discussion the proceedings terminated.

LIVERPOOL CHEMISTS' ASSOCIATION.

The tenth general meeting of this Association was held at the Royal Institution, on Thursday, February 26th. There was a very good attendance.

After the reading of the minutes of the previous meeting, the announcement of some donations, and the opening of the question-box, the first paper was read by Mr. Edward Davies, F.C.S., on "Ozone." He said it was only a short communication with regard to ozone, supplementary to a paper read before the Association some time since. He stated that the existence of ozone in the atmosphere, though very probable, was not absolutely proved, and that the starch papers used for its detection and estimation were useless for both purposes. The papers used by M. Houzeau, prepared by dipping red litmus paper into a 1 per cent. solution of iodide of potassium, were advocated as much more to be relied on. M. Houzeau only finds $\frac{1}{700000}$th part of ozone in the atmosphere as a maximum. Allusion was also made to the supposed connection of deficiency of ozone with epidemic disease, especially cholera; and from statements made in a recent work by Dr. Fox on ozone, it was found that no such connection has been proved, as out of eighteen observations in different places, by various observers, nine tended to show that there was such a connection, and nine were adverse to the opinion. Before endeavouring to prove that the healthiness of a place is due to the large amount of ozone in its atmosphere, it should be shown that ozone is conducive to health. Some experiments by Mr. Dewar and Dr. McKendrick, in which frogs and mice were exposed to the action of ozonized air, were described, and special attention called to the fact that the animals when dead had their blood in a venous state, and that the action was a depressing, instead of a stimulating one, as would have been expected from the oxidizing action of ozone. The conclusions drawn were, that more certain means of detecting and estimating ozone were necessary before any opinions could be of value with regard to its importance as a constituent of the atmosphere, and that all statements with regard to its connection or otherwise with disease were thus rendered perfectly useless. Also, that until experiments had been made with artificially prepared ozone on animal life, using very small proportions of ozone, all statements with regard to it must be regarded as pure assumptions.

The paper resulted in a very animated discussion.

Mr. Alfred H. Mason, F.C.S., then exhibited and made some very interesting communications on "Bergamotte Fruit," which gave rise to some discussion.

Mr. James T. Armstrong, F.C.S., hon. Sec., then read a paper on "The Use of Phosphate of Alumina in Sugar-Refining."

He said that it was acknowledged by those who knew anything of refining sugar, that while there are many advantages, there are also many disadvantages arising from the use of blood in that process, and he thought, therefore, it was well worth the trouble and a little of the time of any practical sugar refiner to give his attention to the following questions:—

1. Whether the use of blood pays for the injurious effects that it produces?

2. If there is anything that will answer the same purpose with less injury?

Starting with the supposition that blood is of use in refining sugars (although not quite clear upon this point), the author said there is no doubt that it is coagulated by heat, and by these means throws down some small particles of mud, which are trapped (in a greater quantity than if blood were not used) in the filter bags, and therefore not allowed to deposit upon the char. It had also a great affinity for the colouring matter in the sugar, and thus produced brighter liquor. But after many experiments he had not yet been able to come to a proper comparison between the good effects and the bad ones produced by the impurities from the blood introduced into the syrup in the process of refining. He believed that phosphate of alumina would produce far better results, with none or very few of the injuries produced by the use of blood. He had found that when blood was used there is always a quantity of salts and much uncoagulated animal matter left in the sugar after it has passed the bag filters, which substances render the sugar solutions much inferior to what they would be if blood were not used. But none or very little of these effects are produced when the phos-

phate of alumina is used. Experiments on this point have shown that, even supposing that the phosphate of alumina and blood are alike in their effects, there is a considerable difference in the weight required of each to produce the desired results. The quantity of phosphate of alumina required for an average sugar would be about 14 or 15 oz. to the ton of sugar at the most; whilst, on the other hand, there would be 17 lb. of blood required. Another great objection to the use of blood is the bad smell that it produces in the low sugars and treacle. This could never occur through the use of phosphate of alumina. Often, too, putrid blood is used, causing the injurious substances contained in it to increase greatly in quantity.

The washings from the char would be much better were phosphate of alumina used instead of blood, for the reason that the blood leaves in solution some albuminous matter which causes fermentation, turning the sugar solution very acid, and thus making a greater quantity of sour water.

In conclusion, the author said that he thought one of the reasons why in sugar refineries, where blood is used, the char lost so much of its power is, that when the sugars treated with blood are first run on the char, a portion of the dissolved albumen and blood salts are so extracted by it as to be beyond the power of either washing or burning to free it again.

BRIGHTON ASSOCIATION OF PHARMACY.

The monthly meeting of this Association was held at 150, North Street, on Friday evening, March 6th, Mr. W. D. Savage, President, in the chair; when Mr. John H. Mathews read a short paper on "Incompatible Mixtures."

In introducing this subject for discussion, Mr. Mathews said that he should confine himself to those forms of extemporaneous prescriptions which were prescribed in the liquid form, and were composed of substances either partially or entirely soluble in water; but which, when brought together in the form of a mixture, decomposed each other, forming new compounds differing entirely from those which the prescriber apparently intended to employ. He said that all precipitates thus formed were not necessarily inert, and he mentioned several cases in which it was intended that decomposition should take place at the time when the ingredients were mixed together, and he did not consider such to be "incompatible mixtures" in the sense in which he used the term; at the same time, he thought that when a prescriber ordered vegetable alkaloids in combination with astringent vegetable infusions, containing such ingredients as tannic acid, that they did not expect to have those alkaloids precipitated to the bottom of the bottle, forming not only an incompatible, but, in some cases, a dangerous mixture, inasmuch as the whole quantity of a poisonous alkaloid might be taken in the last dose. He thought, also, that very often when iron was ordered with these astringent infusions, the prescriber was not aware what a nice inky fluid he was exhibiting. Having shown a number of incompatible mixtures which it had fallen to his lot to dispense, he concluded by saying that he thought it was the duty of the pharmaceutist to assist the prescriber, and that whenever he had presented to dispense a prescription which he considered incompatible, he should, if possible, obtain an interview with the writer, and ascertain if he was aware of the decomposition that must take place, instead of carelessly preparing the medicine and leaving the prescriber to find out his mistake as best he could.

A good discussion followed the reading of the paper, in which Messrs. W. D. Savage, Griffin, Higham, and Haffenden took part.

A cordial vote of thanks having been given to Mr. Mathews for his interesting paper, and to Mr. Savage for presiding, the meeting separated.

LEEDS CHEMISTS' ASSOCIATION.

The fifth monthly meeting of this Association was held in the Library, at the Church Institute, on Wednesday, March 11th, 1874; the Vice-President, Mr. S. Taylor, in the chair. There was a very good attendance.

Mr. Taylor proceeded to explain the object of the last post-card that had been issued by the hon. Secretary. The Committee had thought it desirable to give to the members and associates of the Society the opportunity of bringing forward any subject for discussion which they thought might be of benefit or interest to the trade or the Association. Mr. Abbott had replied to the invitation, and had brought forward a subject for discussion, viz., "The Roots and Stems of the British Pharmacopœia."

The hon. Secretary (Mr. J. W. Longley) then read the minutes of the last meeting, which were duly confirmed. The following gentlemen were then elected members and associates of the Association:—Members: Mr. Thomas Child and Mr. J. C. Reinhardt. Associates: Arthur Wray, Thomas Banks, Tom Pearson, Charles Thomas Judson, Frederick William Kingsley, Alexander Speck, Lund Watson, Ernest Rutter Mewburn, Frederick Cowdery, — Harpham, George Walker, John Edward Parker, John Hallewell. The 'Year Book of Pharmacy' was presented to the library as a donation from the British Pharmaceutical Conference, and on the motion of Mr. Smeeton, seconded by Mr. Thompson, it was resolved that the Secretary write to Dr. Attfield, tendering their thanks for the same. The following books were also added to the library: Thorpe's 'Quantitative Analysis,' Armstrong's 'Organic Chemistry,' the latest edition of Bentley's 'Botany.'

Mr. Jas. Abbott then gave his paper on the subject named, at the close of which a discussion was entered into by several members of the Association.

A vote of thanks was given to Mr. Abbott, moved by Mr. Thompson, seconded by Mr. Brown.

Proceedings of Scientific Societies.

SOCIETY OF ARTS.

At the first of the meetings, on Friday, March 6th, of the special Chemical Section recently instituted by the Society of Arts, the chair was taken by Professor Odling. After an interesting address from the Chairman upon the important services rendered by chemistry to manufactures, a paper was read on—

The Paraffin Industry.

BY FREDERICK FIELD, F.R.S.

In pursuing his celebrated researches upon the tar obtained from the red beech, Reichenbach discovered in the ultimate portion of his distillates a white translucent substance, to which he gave the name paraffin (from *parum* and *affinis*), owing to the comparatively slight action exerted upon it by most chemical re-agents. The tar was submitted to repeated fractional distillations, and the portions passing over last were mixed with strong sulphuric acid and violently agitated. After standing in a warm place for some hours, the paraffin floated upon the carbonized residue in the form of a pale-coloured oil, which, after cooling, solidified, and was pressed between folds of bibulous paper. By frequent crystallizations from boiling ether, it was obtained as a brilliantly white body, highly plastic and somewhat unctuous to the touch, but not greasy. This interesting hydrocarbon for many years was regarded as simply a chemical curiosity, "and so it remained," wrote Reichenbach many years after its discovery, "a beautiful item in the collection of chemical preparations, but never escaping from the rooms of the scientific man." I remember distinctly having a few grains sent me by Professor Abel, carefully enclosed in a glass tube, to add to my collection of treasures when I was

in South America. It is now annually made, as will presently be shown, by thousands of tons.

Before entering into the immediate subject of the paper, viz., "The Paraffin Industry," it may be as well, in a very brief manner, to describe some of the properties of the substance itself. Paraffin is a pure hydrocarbon, having no oxygen whatever, and its analysis has given the following percentage composition:—

	Paraffin from Boghead Coal. Gelletly.	Paraffin from Boghead Coal. Anderson.	Paraffin from Grey Shale, Addiewell. MacIvor.
Carbon . . .	85·2	85·15	85·31
Hydrogen . .	14·4	15·40	14·50

Paraffin, when pure, is perfectly colourless and translucent; after slightly warming, it becomes highly plastic, and can be moulded with the greatest ease. Hence, it differs in some respects essentially from spermaceti, with which it has often been erroneously compared, as well as from stearic acid and other bodies used for the manufacture of candles. From this plasticity, in warm rooms, paraffin candles (if not of a very high melting point) are liable to bend, while on the other hand, those made of sperm or stearic acid, although of a lower melting point, remain erect. Of course, as has been observed, this very much depends upon the fusibility of the substance, and the harder descriptions of paraffin are always selected for candles which have to be subjected to much heat. Liquid paraffin is very mobile, and can be filtered through paper almost as readily as water itself. It is scarcely acted upon, even by fuming sulphuric acid, unless at very high temperatures, so that it can be purified by this means from many other organic substances with which it may have been associated, they being immediately charred by contact with sulphuric acid. When submitted for a length of time to the action of chlorine or bromine, chlorinated or brominated compounds are formed, with disengagement of torrents of hydrochloric or hydrobromic acids. Mr. MacIvor, who has devoted many years to the study of paraffin, says that after this body is acted upon by chlorine, it first becomes a gummy looking solid, afterwards a liquid colourless and transparent, and as the passage of the chlorine is continued, a hard brittle resin is the result. This substance consists of—

Carbon	29·55
Chlorine	66·82
Hydrogen	3·39
	99·76

This gentleman has also remarked that the paraffins having the highest melting point are those which are most easily acted upon by the gas. Iodine dissolves in paraffin, imparting to it a beautiful violet colour, which becomes brown as the paraffin solidifies; but the action of this element upon the hydrocarbon is very feeble, no apparent decomposition taking place after prolonged heating for many hours.

By the action of strong nitric or sulphuric acids, M. Campion discovered a new body, which he calls "paraffinic acid," and describes it as a bright, transparent liquid, of a very inflammable nature. Strong nitric acid yields a series of interesting compounds, lately studied by Schorlemmer and others. Mr. Fordred informed me some years ago that when paraffin is acted upon by sulphuric acid, to which a few crystals of permanganate of potash have been previously added, the action is so violent that light and heat are evolved, and even at times accompanied by explosion. The best way of trying the experiment is to heat up the acid and permanganate in a tube, and drop a small piece of paraffin in the warm liquid. When they are all three placed together in the tube and heated up, the action is not nearly so violent. Success does not always attend the experiment, but it can be tried. The decomposition convinces us that the word paraffin (little affinity) is slightly a misnomer.

Paraffin is insoluble in water, very sparingly soluble in alcohol, even when boiling, more so in ether, and exceedingly in naphtha, sulphide of carbon, and aniline. When heated with sulphur at a moderately high temperature it is decomposed, carbon separates, and abundance of sulphuretted hydrogen is evolved. This fact may be of interest to chemists, as affording a ready source of this indispensable reagent in the laboratory. The two substances, the paraffin being in large excess, are heated together in a flask, when a steady and copious flow of the gas is obtained. We have here a tube containing paraffin and sulphur, and the characteristic action of the gas upon lead salts will be seen by the experiment. With regard to the beautiful translucency of paraffin, which, in spite of certain drawbacks, has made this body such an unusual favourite as a means of light, Mr. MacIvor informs me that if, when melted, it is cooled very gradually, and subjected to a slight and steady pressure, it becomes actually transparent, like ice, but that a blow, or even a scratch, will alter its molecular structure, and cause it to re-assume its normal appearance. As this change is also produced upon re-melting it, however cautiously, that triumph of manufacture in this department of industry, namely, making a transparent candle, is yet in the distance.

The specific gravity of paraffin has been variously stated at ·870, ·852, and ·880, and these discrepancies appear to have arisen from the fact that the experimenters have used different substances in their investigations. Mr. Gelletly has shown that the specific gravity rises with the melting point of paraffin. Thus, paraffin melting at about 90° Fahr. has only a specific gravity of ·823; at 128° Fahr., which may be considered a very good average (rather high, perhaps), it has a specific gravity of ·911; and a specimen of an extraordinarily high melting point (176° Fahr.) was as high as ·940, more than 10 per cent. above that at 90° Fahr.

In attempting to give a sketch of the paraffin industry, which, in the space of time usually allotted must necessarily be brief and imperfect, I must be pardoned if many of the names of those who have done good service in this branch of manufacture are omitted, considering that there have been more than sixty patents taken out during the last few years for the treatment of solid and liquid hydrocarbons. To describe them all would be, it may be imagined, a weary task both for reader and listener.

Dr. Lyon Playfair, in the year 1847, called the attention of Mr. James Young to a dark, oily substance exuding from the cracks in the roof of a coal mine near Alfreton, in Derbyshire. This body was distilled, and yielded a pale yellow oil, which deposited, on cooling, small scaly particles, which proved to be the solid paraffin. An establishment was speedily erected on the spot, and the product from the mine somewhat extensively worked until it was exhausted, or nearly so. In the meantime, Mr. Reece obtained a patent (1849) for distilling paraffin from Irish peat, and works were erected near Ashby, in Ireland, for its production. It may be remembered by some amongst us, that at that time the natural resources of the sister island were the subject of much discussion, and the enormous amount of peat which is found in many localities was supposed to be, when properly treated, a source of unbounded wealth. It was stated that not only solid paraffin and illuminating oils could be obtained by its destructive distillation, but also acetate of ammonia and other valuable volatile products. The idea was very popular. A company was started, and although the promised compounds were produced, the expense of obtaining them, the quantity derived from the original peat being so small, led to a commercial disappointment. The following table may give some notion of the amount of materials obtained from the distillation of peat:—

Watery matters	30·614
Tar	2·392
Gases	62·392
Ashes	4·197
	99·595

The watery matters and tar yielding :—

Ammonia	0·287
Acetic Acid	0·207
Naphtha	0·140
Volatile products	1·059
Paraffin	0·125

So that 100,000lb. of peat would only yield 125lb. of paraffin. Peat from the kingdom of Hanover appears to yield more than that from Ireland, 100,000lb. yielding rather more than 300. Although in a monetary sense the Irish scheme was a failure, great credit must always be awarded to its promoters. It certainly led the way to other discoveries, and excited a wholesome interest in the hydrocarbon industry. The poverty of the original material operated upon appears to be the only cause of the non-success of the undertaking.

Mr. Young having been successful in his experiments at the Derbyshire mine, but finding his stock of available materials drawing to a close, experimented upon nearly every kind of coal which he considered likely to yield solid or liquid hydrocarbons. With his usual sagacity, he imagined that there could be obtained by heating coal gradually by artificial means, such as the application of a low red heat, a product similar to the one naturally produced which he had first experimented upon at Alfreton. A highly bituminous coal procured from Boghead, near Bathgate, in the county of Linlithgow, was found to yield large quantities of oil, and a patent was granted to Mr. Young in 1850, "for treating bituminous coal to obtain paraffin and oil containing paraffin." An establishment was erected, and he was joined in this undertaking by Messrs. Meldrum and Binney. This Boghead coal, or Torbane-hill mineral, proved to be by far the richest source of paraffin and paraffin oil yet discovered, as much as 135 gallons or 50 per cent. of oil having occasionally been obtained as a product of distillation. Previous to the expiring of Mr. Young's patent in 1864, many works were in operation in Scotland for distilling oil from shale. Dr. Steele, of Wisham, erected several stills at Broxburn, which were eventually sold to Mr. Fernie, who again sold the establishment to a company (the Glasgow Shale Oil Company). There were also the West Calder Works, the Uphall Company, the Oakbank, the Levenside Oil Works, a few names amongst many more, but sufficient to give an idea of the extent to which, in so short a time, the paraffin industry had been developed.

In Wales also, this manufacture was commenced about the year 1861, principally from three varieties of coal, namely, Curley cannel, which yields 30 per cent. crude oil, sp. gr. ·875 to ·890 ; Smooth cannel, which yields 16 per cent., sp. gr. ·925 to ·940 ; and Bastard or Common cannel, an inferior variety. At Leeswood, in Flintshire, the beds of cannel in some places were found to be six feet in thickness. Mr. Hussey Jones, of Leeswood, was, I believe, the originator of the paraffin industry in Wales. His works became the property of Messrs. Fernie and Company, who were defendants in the great suit of Young v. Fernie in 1864, lasting thirty-nine days, a trial still fresh in the memory of some of us, and which occasioned perhaps at the time as much excitement in the technical world as a certain great trial at Westminster has recently done among the public at large.

Although many chemists had announced the discovery that oils, etc., could be obtained by the distillation of shale and other minerals (see Christison, of Edinburgh, on "petroline" from Rangoon petroleum in 1831, Butler in 1833, Hompech in 1841, Du Bussey in 1845, &c., and many others even anterior to these), Mr. James Young, who was the first to make this industry a practical success and to establish it beyond doubt as a new means of benefiting mankind, must be regarded as the father of paraffin. "It is true," said Dr. Reichenbach, with the generosity that usually characterizes a great mind, "that the discovery of paraffin is mine, and I have announced it. To Mr. Young, however, belongs the merit of a second discovery, the merit of having elaborated a method which furnishes a comparatively large supply of this substance, and which is sufficiently remunerative to the manufacturer, a result which I have vainly endeavoured to realize." The professor speaks of a comparatively large supply. The table before you will show how enormous this has become ; the figures were given by Mr. Kennedy in his speech at the complimentary dinner to Mr. Hill, late manager of the extensive works at Bathgate :—

Shale used in Scotland	800,000 tons.
Crude oil produced	25,000,000 galls.
Paraffin	5,800 tons.
Lubricating oil	9,800 „
Sulphate of ammonia	2,350 „

To carry out this manufacture about 500,000 tons of fuel were required.

But yet it appears that the credit of first manufacturing solid paraffin on anything like an extensive scale is due to Messrs. William Brown and Co., of Glasgow, and I will read an extract from a letter addressed to the Secretary of Juries of the Universal Exhibition of 1862, by a very eminent London firm :—

May 20, 1862.

Sir,—In reply to your communication received last week, requesting to be informed whether there is any peculiarity in the manufacture we exhibit, to which we are desirous of calling the attention of the jury in Class 4, we beg to submit the following remarks : We have been using paraffin in the manufacture of candles since March, 1855. It was made by Messrs. William Brown and Co., of Glasgow, who were, to the best of our belief, the first makers of it in this country, and by whom we were regularly supplied ; but from the smallness of the quantity produced (only three to four cwt. weekly), and its imperfection, especially in hardness, we abstained from offering candles made entirely from it, and merely employed it as an ingredient with other materials in the manufacture of the better class of candles. So far back as 1851, we had assisted, in becoming shareholders to the Irish Peat Company, in the attempt to obtain paraffin from the bogs of Ireland. It was not until November, 1856, that they were in a position to deliver paraffin, at which time we received supplies; and from this source, and a quantity of Rangoon paraffin, we, in March, 1857, manufactured and put in the market for the first time paraffin candles of English make. The price at which they were introduced was 2s. 4d. per lb.

Mr. Butler has been mentioned as one of those chemists who had experimented upon oils obtained from coal, etc., previously to the patent obtained by Mr. Young, and there is no doubt he found also solid paraffin among his products, as will be seen from the following statement :—Extract from patent granted to Richard Butler, Jan. 29th, 1833 (40 years ago, it must be remembered), No. 6375 : "When the residue of No. 2 distillate is exposed to a low temperature, there will soon appear small flakes of a white, odourless, and light substance, which is a compound of carbon and hydrogen." There can be little doubt, I imagine, that this was paraffin. Nearly all the oil and solid paraffin in Scotland is now made from shale. The last of the Boghead coal was, at the commencement of the year 1872, stacked in a field near Bathgate to the amount of several thousand tons, the greater part of which was destroyed by an accidental fire a few months afterwards.

The following is an outline of the processes employed in Messrs. Young and Company's and other large works for the production of the hydrocarbons :—The shale is placed on the retort and heated, care being taken not to exceed low redness. This is of the utmost importance, as a higher temperature would inevitably produce gaseous products. When all the oil has ceased running the operation is stopped. This crude product, which is highly impure, is re-distilled, producing a certain amount of coke as residue, the distillate being technically known as "once run oil," a specimen of which is before you. This is agitated with strong sulphuric acid (in the original patent its own volume, but experience has shown that this quantity is not necessary), allowed to settle, treated with caustic soda, and re-distilled with steam, the products of distilla-

tion being fractioned. The first portion consists of naphtha, which is run in the general naphtha tank, to be ultimatcly distilled and fractioned to various specific gravities. The second contains the larger portion of burning oil. This is subject to two other treatments with acid and soda, and again distilled and fractioned; thc first portion is placed with No. 1 distillate, and the last portion with No. 3. The third, heavy oil, is cooled and pressed for paraffin scale, of which mention will be made presently, and the expressed liquid treated with sulphuric acid, soda, distilled and fractioned until the desired specific gravity is obtained; and for its ultimate purification is again acidified, allowed to settle, and finally treated with soda. You will see from this that the crude oil appears to consist of three oils, naphtha, burning, and lubricating oil, the heavy oil being the one that contains the valuable solid product, and that these are separated after treatment with acid by distillation. The paraffin scale, which has been pressed from the heavy oil, and still contains much adhering oil and a considerable amount of colour, is mixed with a portion of the naphtha obtained in the process, cooled, and subjected to severe pressure. The oil and softer portions, being more soluble than the solid paraffin, are dissolved, and a cake, diminished in bulk, is taken from the press. This is again subjected to a similar treatment, and if not sufficiently refined for its ultimate purification, undergoes another pressure with naphtha. The loss of this volatile hydrocarbon is somewhat heavy, and to obviate this, Mr. Edward Meldrum patented a process, dated 4th June, 1867, No. 1646, for reducing the impure solid paraffin to a powder, and then introducing or mixing naphtha therewith, after which the mass is subjected to pressure. To give the exact words of the patent, an extract may be quoted:—

"My said invention consists essentially in the purification of paraffin by treating it while in a cold, unmelted state with naphtha, instead, as heretofore, in a melted liquid state. In carrying out my said invention, I reduce the impure solid paraffin to a powder, and then introduce therein sufficient naphtha to make it into a paste or pulp, after which I subject the mass to pressure; or the solid impure paraffin and naphtha may be ground up together, and the mixture may be then subjected to pressure. By repeating three or four times the operation of re-grinding the paraffin to a paste or pulp with naphtha, and then squeezing it in a press, the paraffin can be freed from the heavy hydrocarbon oils with which it is contaminated in its impure state."

This must, it would be thought, save a loss in naphtha; but whether the process has been successful or not, I cannot say.

The cakes thus purified are melted in a still, through which free steam is violently passed, as well as confined steam in a worm at about 25lb. pressure, in order to raise the temperature, until every trace of spirit is evolved and the condensed water contains no trace of naphtha. The product from the still is mixed with from 3 to 5 per cent. of animal charcoal, heat is applied, and the charcoal allowed to settle. Some finely divided particles remain, however, suspended in the supernatant liquid, and these must be separated by filtration. The filter employed in the works of Messrs. Young consists essentially of a jacketed case, kept hot by steam, and lined with a cylinder of wire gauze, which is coated internally with flannel, and to make the filtration still more perfect, filtering paper is introduced, so that the paraffin flows through absolutely free from solid particles, and if pure, as colourless as distilled water. This is run into cakes of various forms and sizes, generally in shallow oblong tins. Messrs. Young, however, prefer the circular shape as more adapted for transport in casks.

In the rapid description of the production and refining of solid paraffin from the oils and impurities with which it is associated, it will have been observed that naphtha or other light spirit was employed in its purification, the object being to wash out the greater part of the colouring matter by means of these solvents, and to render the partially purified substance fit for its final passage through animal charcoal. No process can be more successful, as the beautiful results of many eminent houses abundantly testify. But there is an amount of danger attending the operation which many manufacturers have endeavoured to avoid, and some with considerable success. Two or three of the most important it may be as well to mention, first, the patent of Mr. John Fordred, No. 1858, A.D. 1871.

This gentleman, anxious if possible to avoid the use of naphtha or other inflammable liquid, imagined that by kneading, so to speak, crude paraffin scale in a slightly warm alkaline liquor, the alkali would probably form a species of emulsion with the oleaginous portions of the hydrocarbon, and, the heat rendering the solid part plastic, the oils and colouring matter could be separated by a rough filtration. The earliest experiments were kindly explained to me by the patentee; a little bag was filled with thc crude scale, and after being soaked in warm water for some minutes, was kneaded by the hand exactly as, in lecture experiments, the separation of starch from gluten is effected, in the proximate analysis of flour, the starch representing the oil, the gluten the solid paraffin which remains in the bag. After many experiments the apparatus was devised, which is thus described in the patent:—

"In carrying my invention into practice I proceed as follows:—I take say one ton of crude paraffin, having, for example, a melting-point of 120° Fahr., and melt it carefully in an iron tank, and allow the mechanical impurities, such as tar, sand, and the like, to fall to the bottom; after a few hours' repose I run off the clarified paraffin into a number of flat metal trays, in which it solidifies into cakes, weighing about ten pounds each; these cakes are then placed edge to edge in a long bag of peculiar construction, and submitted to heat in a warm room, or in a bath of warm water till brought into a plastic condition. When this object has been attained, the bag of paraffin is submitted to the action of the kneading machine, which is supplied with a solution of soft soap in water, made in the following proportions:—Soft soap 10 parts, water 10 parts, previously heated to about 100° Fahr. This I call the soap-bath. On the machine being set in motion, the oil and colouring matter contained in the crude paraffin will rapidly combine with the soapy liquor, and form a temporary emulsion. I find that any kind of soap soluble in water will answer for the above purpose, but I prefer to use the soft soap of commerce, and in the proportions named. I do not confine myself to the use of a bath of soap and water only, as I find that various other liquors will act upon the paraffin whilst in a warm and plastic condition, such as solutions of the carbonated and caustic alkalies, mixtures of these with solutions of soap, a solution of rosin in alkali, the residual acid or alkaline liquor deposited from acidified hydro-carbon oils after washing or neutralization, and, for some purposes, even warm water itself is sufficient."

(*To be continued.*)

Parliamentary and Law Proceedings.

Poisoning by a Liniment.

At Wigan, on March 12th, the borough coroner held an inquest on the body of Mary Elizabeth Southworth, a girl 16 years of age, granddaughter of Mr. Edward Carr Duff, the landlord of the Shakspere Inn, Wigan. On the previous Tuesday the deceased complained of great pain in her head. She went to bed and some hot gin was given her. As there was no improvement, Mr. Barnish, surgeon, was sent for, but the girl was dead on his arrival. A few days previously deceased had gone with Mr. Duff to a druggist's, and obtained a lotion for rheumatism, and this was labelled "poison" and kept in the "bar snug." It was feared that Miss Southworth had for some reason taken a small quantity of the preparation.—Mr. Barnish came to the conclusion that death had resulted from aconite, which was contained in the preparation in such a quantity that an ounce would cause death in a person of deceased's age in two hours. No witness called could assign any reason why deceased had taken the poison, or why any one should

have administered it to her, or how, if there had been a mistake, she came to make it.—The coroner said he could only imagine that the deceased had been wishful to taste the mixture in order to ascertain whether or not it was poison. It was not by any means the first time children and young persons had done this, and here the lotion was so deadly that a mouthful would be sufficient to cause death. The jury found that the deceased died from a dose of aconite liniment, but under what circumstances it was taken there was no evidence to show. The jury added that so deadly a poison should not be put in an ordinary drinking bottle, or kept in the house except under lock and key.—*Manchester Courier.*

Poisoning by Arsenic.

An inquest on the bodies of five of a family named Coombes, who died by poison, was held at Thursley, near Godalming, on Tuesday afternoon, before Mr. Hull, county coroner.—Sarah Edgeler deposed that she saw the tub produced in the possession of the deceased. She scrubbed it out, and she had never seen it used before she did so. This was on the Friday. The bucket was afterwards used for domestic purposes, and on Friday Mrs. Coombes was taken ill.—William Enlicknap, a blacksmith, stated that one day last month he put a nail to fix a handle on the bucket produced for Mrs. Coombes. He then observed that there was something like soap-suds sticking round the bottom. It came on his hand and made it smart.—Dr. Stevenson, the county analyst, deposed that, by order of the Home Secretary he had made an analysis of the viscera of Charlotte Coombes and Albert Coombes. He had also examined a spoon, a bucket, and farinaceous food. The report made by Dr. Stevenson stated that in the viscera he detected an irritant poison in small quantities. The appearances presented by the viscera of the woman were quite consistent with the assumption that she had died from the effects of arsenic. In the viscera of Albert Coombes he also detected arsenic. From the bottom of the bucket produced he picked off a brown substance largely charged with arsenic. The produced food was also impregnated with arsenic.—The jury returned a verdict of accidental death by poisoning, with a recommendation that tubs containing such poisonous substances should be labelled or destroyed after being used.

Prosecutions under the Adulteration Act.

adulteration of milk.

At the Wolverhampton Police Court, before I. Spooner, Esq., Charles Evans, a milk dealer, of Ettingshall, appeared in answer to a summons which had been issued at the instance of Mr. J. G. Horder (Inspector under the Adulteration Act), charging him with selling milk adulterated with water.—The purchase having been proved, the defendant stated that pure milk was not asked for.—Mr. Spooner : What an idiot you are. The man asked for milk, and that does not mean skim milk, nor milk and water. The analyst's certificate was to the effect that the sample of milk referred to showed, on analysis, adulteration of 22½ per cent. water.—Mr. Spooner: Twenty-two and a half per cent. ! Nearly one-fourth water.—Defendant : That was never my milk in the world.—Mr. Spooner : I daresay not. Of course you will say so now. But it has been proved, so far as human proof can go, that it was your milk, and I don't see any reason to disbelieve the evidence that has been put before me.—Defendant : I cannot believe that so much water was put in.—Mr. Spooner : But I have to decide the matter, and I believe there was. I am quite satisfied on that point, and a most abominable fraud it is. Here people go with good money to purchase good milk, and you, in order to put an extra profit into your pocket, give them instead, a mixture containing one-fourth water, which they can get for nothing, and put it in the milk, if they like, themselves. I fine you £10 and costs, and if you go on defrauding people in this way, and are brought before me again, I will impose the full penalty of £20, and also cause your name to be advertised, as I have power to do. —Defendant : Can you allow me a week to pay the money: I shall have to sell my cows to do so.—Mr. Spooner : No ; I will not show mercy to such as you. If you don't pay, a distress warrant will be issued ; and if there are not sufficient goods to satisfy the distress, you will have to go to prison for six weeks.—On hearing this, the defendant promptly paid the money, amounting altogether to £11 17s. 6d.—*Midland Counties Express.*

alleged adulteration of lozenges.

At the Southwark Police Court, on Thursday last, Mr. Bernard Duffey, manufacturing confectioner, Old Kent Road, was summoned before Mr. Benson, under the Adulteration of Food Act, for selling adulterated "conversation lozenges."

Dr. Bernays, of St. Thomas's Hospital, said he received the lozenges in January last for analysis. He found then to be manufactured of good sugar, but he found a small quantity of starch and some other ingredients. On using the microscope he discovered that it was blue starch and a small quantity of powdered glass—a ten-thousandth part of the latter and a tenth of starch.

Mr. Benson asked if the addition was injurious to health.

Dr. Bernays replied that it was not, unless eaten to a great extent. Children might suffer from over-eating the lozenges. He believed the blue starch was used with the sugar to improve the appearance of the lozenges.

Mr. Ody, on the part of the defendant, contended that there was nothing deleterious or injurious to health in the composition of the lozenges, and he thought it was paltry on the part of the vestry in taking these proceedings.

Mr. Mander, vestry clerk, informed his worship that the vestry had nothing to do with these proceedings. They were taken on the sole responsibility of the sanitary inspector, who had such authority under the act of parliament, without asking the sanction of the vestry.

Mr. Benson was aware of that, and he had not much respect for those vestries who prevented their officers from performing their duty. Inspectors were justified in bringing all cases of adulteration of food before the magistrates. He dismissed the summons in the present case, and recommended defendant not to use blue starch again.

Review.

Pharmacopœia of the Hospital for Diseases of the Throat. Edited by Morell Mackenzie, M.D., Lond., Hon. Medical Superintendent. Second Edition. London : John Churchill and Sons. 1873.

A second edition of this little work has appeared, in which the editor has made more explicit much of the matter contained in the first edition ; most of the errors have been corrected, and in accordance with our suggestion, in reviewing the previous edition,* a change in nomenclature has been made, the term *pigmentum* being substituted for *collyrium*, as applied to solutions for local application.

In the preface the Editor kindly acknowledges our services in pointing out defects in the previous edition, but we still find such grammatical errors as Syrupus Tolutan*i* and Oleum Origani Pallid*i*, and in the posology we think there is a too rigid adherence to the British Pharmacopœia ; for example, the dose of tincture of nux vomica is given as from 10 to 20 minims, that of the extract ½ to 2 grains, both of which are now viewed by therapeutists as excessive, whereas the dose of iodide of potassium is given as from 2 to 10 grains—the latter being much below the maximum dose met with in ordinary prescriptions. As a key to the somewhat mysterious prescriptions emanating from members of the staff of the Throat Hospital we commend the work to our readers.

* Pharm. Journal, 3rd series, vol. iii., p. 17.

Notes and Queries.

[390.] COMPOUND SYRUP OF CAMPHOR.—In the absence of any recognized formula, perhaps the following may prove useful to M. P. S.—

Tinct. Camph. Co. (double strength and without Ol. Anisi), 1 part.
Syr. Simp., 7 parts by measure.
Mix.

GEORGE BROWN.

[390]. COMPOUND SYRUP OF CAMPHOR.—In reply to M. P. S., March 14th, the above preparation is thus ordered to be prepared by the 'Pharmacopœia of the Bristol Royal Infirmary':—

"*Syrupus Camphoræ Compositus.*

℞	Syrupi Opii	℥j.
	Tincturæ Camphoræ Comp. . .	℥ij.
	Oxymellis Scillæ	℥vj.

Mix. One teaspoonful to be taken occasionally."

The formula for Syrupus Opii, the first ingredient in the above compound, is as follows:—

"*Syrupus Opii.*

℞	Opii	℥iv.
	Sacchari non purificati	lb. 112.
	Aquæ ad cong.	xij.

Dissolve the opium in one gallon of boiling water, and mix with the remainder when cold."—J. T. C.

[391]. LOTION FOR MANGE.—T. P. H. would be glad if any of the PHARMACEUTICAL JOURNAL readers will oblige with a good recipe (lotion) for mange on dogs.

[392]. PLATE POWDER.—Can any reader furnish me with a good recipe for "Non-Mercurial Plate Powder."
—ARGENTUM.

Correspondence.

DECOMPOSITION OF LOZENGES.

Sir,—I was very much interested by Mr. Greenish's "Note on a Decomposed Lozenge," read at the Pharmaceutical Meeting on the 4th inst., and beg to offer a short statement of my own experience, in support of the fungoid theory, the truth of which may be at once made evident to any who may have lozenges so affected, and may possess a microscope of tolerable power.

I have never, since my connection with the business (forty-five years) seen even a single lozenge affected with fungus until about six months since, when I discovered in six or seven different kinds of lozenges, peculiar damp spots that I at first attributed to the continued humidity of the season, and therefore exposed them for some time to a warm, dry atmosphere, expecting to see them restored to their normal condition. I was, however, disappointed, for the spots had not only sunk deeper into the lozenges, but had also become more numerous, and—in painters' phrase—tacky.

Finding I could do nothing to restore them, I sent them up to my lozenge makers, asking them to look to them. In about a fortnight's time they replied that they could do nothing with them, and there, for the time, the matter ended.

You may well suppose, then, that Mr. Greenish's note on the very subject was deeply interesting to me.

Altogether I had about 10 pounds of various lozenges so affected, consisting of digestive tablets, ipecacuanha, cayenne, musk, lavender, lettuce, and ginger lozenges; but peppermints were not in the least affected. I at once forwarded samples of all to Mr. Greenish, hoping that he would, with so large a field before him, be able to carry out his further investigations in this very important matter, with more certainty of result than appeared to have been the case on the evening of the 4th inst.

It would be well for the lozenge manufacturers to be communicated with, so that their experience might be made subservient to the continued inquiry. It is certainly a new form of mischief against the genus *homo*, that should be at once pursued up to its cause, and swept away. Should Mr. Greenish's hypothesis be correct, that dextrin is that cause, lozenge-makers will see the necessity of at once giving up its use. Is there indeed any defence for using it, excepting that its market value is much lower than that of Turkey gum of good quality? If such be the case, then certainly *first class* lozenges ought to be free from such an ingredient, and manufacturers will do well to look to it.

I hope Mr. Greenish's remarks on this subject will elicit very many communications, so that he may be furnished with the fullest evidence possible in his further inquiries.

THOMAS WITHERINGTON.

Worcester, March 17th, 1874.

A SUGGESTION.

Sir,—Antimonium tartaratum is a potent and useful medicine frequently given to children in Vinum antimoniale. But is it not generally allowed that this preparation varies considerably, both from the quality of the wine and from the length of time it has been made?

If not too late for the Supplement to the Pharmacopœia, would not a Pulv. antim. tart. co. be a useful addition, in which the Antim. tart. should be mixed with four or six times its weight of Potass. tart. acid., or, as they are frequently prescribed together, mixed with Potass. nit. Such a compound powder would be very convenient in weighing; the division would assist the solution, even if some of the Potass. tart. acid., if used, were not dissolved; and what is of far more consequence, there would be much more certainty in the dose given. Such a preparation would also be useful as a powder.

W. SYMONS.

26, *Jay Street, Barnstaple,*
Feb. 24th, 1874.

GLASGOWISMS.

Sir,—I used to hold it as an axiom that civilization travelled westward, and although I knew that pharmacy was leaden footed I risked the hope that, when it had wended thither, it would live a purer and freer life. This is apparently not to be the case. For to join those twain children of the mist, Mr. Pil. Philip and Miss Comp. there has arisen another unvenerable western portent, in the shape of "Pil. Albi." These pilular mysteries are carefully prepared and tastefully finished off in some opaque corner of a certain pharmaceutical chemist's establishment, not one mile from our New City Road. I also had a visit from another party, who carried what purported to be a prescription, written by one eagerly claiming respectability, for he drives his gig. But thinking that the worthy M.D. had been amusing an after-dinner hour in sipping his port and transcribing Assyrian hieroglyphics, I handed it back to the party, mildly hinting so. The party, however, declared that it was a real prescription, and that the Doctor had painfully impressed the necessity of having it dispensed at a chemist's near our Great Western Road.

Now, Sir, this state of protection is perfectly unjust, and plainly self-destructive. It allows no free life to pharmacy, but binds it, wholly and servilely, to the wheels of the medical chariot. If this kind of work continue, life will only be passable to those who are so mean as to lard well the medical men with a percentage; and at last, by a process of unbeautiful natural selection, the greatest rogue will have the greatest chance of succeeding in money-making. He only will prosper who can unblushingly rob the public to pay a large bonus to the doctor.

I am perfectly well aware of the unremunerativeness of the medical profession in many cases, and would gladly see their rewards increased. Yet most strongly do I contemn that principle of forming a conspiracy with some servile druggist to filch the patient in a round-about manner, to bleed profusely a purse that, too often, is suffering from extreme anæmia. If medical men want their fees increased, let them take means for that end in open daylight, and do not let them use druggists as tools for their deeds of darkness. No profession can ever be raised to esteem and nobleness when its members practise duplicity and hypocrisy. No wonder that quackery is rampant on the hem of the medical garment, and that medical men must blink like owls at it.

For the rest, it is simply disgraceful for any—especially a pharmaceutical—chemist to truckle so; because the possession of that title presupposes that he has the integrity of his profession at heart; that he will gallantly endeavour to lift it into a freer atmosphere; that he will make it a world-wide brotherhood, of which knowledge and skill are the only passports, and where aught else is free as the sunshine. It is debasing to the best interests of pharmacy when its members sell themselves to such greedy and narrowing practices, or when they encourage quackery in any form.

The chemists and druggists will never lift their profession to a splendidly worthy status till they make the medical men and the public unmistakably understand that they are not toadies, but men, who are doing their day's work in an honest, straightforward, and intelligent manner, for a remuneration sufficient to keep the soul comfortably within the body, and that they have nothing in common with those who desert the ranks of straightforwardness to wend, in a tortuous fashion, through the ooze of servility to an unlovely goal.

Glasgow. DOW.

Cocculus Indicus.

Sir,—I scarcely think the answer of your correspondent, M.P.S., can satisfactorily account for the utilization of the large quantities of Cocculus Indicus imported.

Although I have spent several years in one of the largest farming districts in the West of England, and in a business where there was more than the usual amount of cattle medicine supplied, yet—perhaps I ought to be ashamed to own it—my first sight of Cocculus Indicus was obtained in the museum of the Pharmaceutical Society. We never kept it, nor was it ever inquired for, either for cattle medicine or any other purpose. Amongst our customers were farmers from the North of England and from the Midland districts, who had settled in the West, one or two of these happening to be very much troubled with lice amongst their stock, and, moreover, being very experienced men, tried many things; but amongst them all, Cocculus Indicus never had a place.

I, for one, should conclude that the sale of this drug for use amongst cattle is limited to a few localities only—at any rate, it is extremely questionable whether that explanation is sufficient to account for the disappearance of even a tenth part of the drug imported.

A Young Man from the Country.

Wanted! Chloroform!

Sir,—At 4 a.m. this morning there was a violent ringing at the bell, and a violent customer wanted 1oz. chloroform for a medical man, and when asked the name of the said medical man, after some consideration, said, "Robinson." He threatened violent and continuous agitation of the bell if not supplied, and my assistant threatened police if he did not retire: this was too much for him, and he retired. I suppose this is the customer that was so troublesome to our West End friends; but it is evident he is getting down in social position, or he would not have come so far East as this. I write this, hoping to prevent any of our fraternity yielding to the boisterous importunity of a worthless scamp.

James Slipper.

87, *Leather Lane, March 18th*, 1874.

Hunter *v.* Freeland.

Referring to the report of this case, which appeared in the Pharmaceutical Journal of date 10th and 24th January last, a number of the trade are of opinion that Mr. Freeland should be reimbursed for the heavy expenses, amounting to £267, incurred by him in defending himself in the law-courts.

They consider the action to have been of a most vexatious character, and if druggists throughout the country were compelled to act according to the reasons given by the jury for their verdict, the consequence would be the shutting up of a great number of the druggists' shops in many of the smaller towns in Scotland. The statement by the foreman of the jury was to the following effect:—

"The jury unanimously found for the pursuer, and assessed the damages at £12. The foreman of the jury stated that they had not been guided in their decision so much by the injury sustained, as by the principle that more care should be taken in dispensing chemicals; and they intended it as a lesson to chemists to provide properly qualified assistants to take charge during their absence."

It will be seen from the Journal of date 24th January, that the young man in Mr. Freeland's employment has passed his Preliminary Examination very creditably.

The following gentlemen have kindly agreed to receive subscriptions, and Mr. Kinninmont to act as Secretary, to the fund:—Mr. McDonald, of the Glasgow Apothecaries' Co., 34, Virginia Street, Glasgow; Mr. Greig, Glassford Street, Glasgow; Mr. John Mackay, 119, George Street, Edinburgh; Mr. Kinninmont, 69, S. Portland Street, Glasgow, honorary Secretary.

The following subscriptions have been already intimated:—

	£	s	d
Glasgow Apothecaries' Co.	5	5	0
Messrs. Duncan Flockart and Co., Edinburgh	3	3	0
Mr. John Mackay, Edinburgh	2	2	0
,, Wm. Greig, Glasgow	2	2	0

,, Alex. Kinninmont, Glasgow	1	1	0
,, Geo. Smith, ,,	0	10	6
,, R. C. Rait Parker	0	10	6

W. H.—Bentham's 'Handbook of the British Flora,' published by L. Reeve and Co.

C. L. M.—(1) What is required is, a practical knowledge rather than such as could be acquired from any number of pages in a given book. See Professor Huxley's remarks on p. 735. (2) We believe that specimens of all the drugs likely to be shown to a candidate may be seen in the museum, either in the drawers open to the students or upon application to the curator.

J. S. B.—See a formula given on p. 340 of the present volume.

J. B. S.—You will find the formula you ask for in vol. xi. 2nd series, p. 876.

"*Cerebrum.*"—We are unable to give you the information you require.

W. T. B.—As there appears now to be a disposition to apply the current income of the Fund in the manner you desire, we think it would be injudicious to publish your letter at present.

J. Leay.—The fact of a man being in business has no bearing upon his qualifications as an analyst. If the provisions of the Act were properly carried out, the analyst would be completely ignorant as to the source of the samples under examination.

J. Otley.—Only the Inland Revenue authorities could give a reason for the practice you mention.

"*Justitia.*"—We believe that the Deputy-Superintendents have been appointed upon the nomination of the Superintendents.

W. R. F.—(1) Saponification cannot be effected, but an emulsion may be made. (2) Apply to the Secretary for a copy of the Regulations of the Board of Examiners.

A. Archer.—The result of an analysis of the so-called "Corassa Compound" will be found in vol. ii. p. 309, of the present series of this Journal.

Koumiss.—We do not know of any recognized formula, but a method of producing it was described in vol. ii. p. 981.

A. Mitchell.—Can you mention any place where such a test is referred to?

"*Apprentice.*"—The substance does not appear to be what it is stated to be. You are also referred to the regulation respecting anonymous communications.

J. M. Broad, jun.—We are indebted to you for directing our attention to the quotation from Cooley's Cyclopædia on the subject of Cocculus Indicus. Our object, however, is, if possible, to obtain trustworthy evidence as to what actually becomes of the considerable quantity of the drug *now* brought into the market. An assertion made in a book published nearly twenty years ago contributes but little towards the elucidation of the question, especially when such an assertion is unsupported in the experience of officials whose special business it would be to detect and expose such an adulteration.

C. E. Owles.—We know of no such provision as you refer to, and judging from our experience of the opinions of "plucked candidates," we do not think such provisions would be justified or requisite.

Communications, Letters, etc., have been received from Messrs. Wilkinson, W. Griffiths, R. C. Payne, Archer, M. Burden, W. A. Powell, "Student," "Lamma," "Pharmacist since 1842," Z. Y. X.

VEGETABLE POISONS AND THEIR ANTIDOTES.

BY E. M. HOLMES,

Curator of the Museum of the Pharmaceutical Society.

A knowledge of the action of poisons in the human frame, and of the means by which their fatal effects upon the system may be prevented, may perhaps appear to belong rather to the medical practitioner than to the pharmacist. There are, however, occasionally times when he is not at hand, and the prompt application of remedies being the only chance of saving life, as in poisoning by prussic acid or nicotine, the nearest chemist is called upon in the emergency. A knowledge, therefore, of the most reliable antidotes to use in cases of emergency cannot fail to be valuable to the pharmacist, and rightly forms a branch of his education.

For many poisons, more particularly those belonging to the vegetable kingdom, there are no real antidotes known, and it is therefore a subject which demands the attention of the pharmacist as well as of the physiologist. The derivation or substitution compounds of the vegetable poisons have not been investigated to any extent, and the discovery of the different properties of methyl-strychnia* to those of strychnia, show that there is here a wide field open to chemical discovery. This branch of science may, indeed, be said to have been culpably neglected, seeing that it has not kept pace either with chemical discovery or with the progress of medical science.

No amount of care on the part of the chemist can prevent the occasional occurrence of poisoning, nor can any Act of Parliament hinder the employment of substances in common use for the purposes of suicide or murder. Even if the sale of mineral poisons were entirely forbidden, there are many poisonous plants to be found in our gardens, fields, and hedges.

As an instance of the extent to which poisoning was carried in the 16th and 17th centuries, and therefore could again be carried, unless our knowledge of antidotes is improved, it is said that the manufacturer of the celebrated "acqua tofana" confessed to having been instrumental in the death of no less than 600 persons, and this in spite of the severest measures taken by the Government. It is obvious, therefore, that the best way to render poisoning less frequent as a crime, is to know how to counteract its effects.

The employment of antidotes appears to be of as ancient a date as the use of poisons. Thus we find that from very early times endeavours were made to discover an universal antidote. We read of Mithridates, King of Pontus, taking every morning a dose of an electuary, which was supposed to be an antidote for every kind of poison. It is possible that the opium which it contained may have proved an antidote to such poisons as dilate the pupil of the eye, and it may be owing to this, that it retained a place in medicine for so long a period.

The researches of the ancients, however, like those of the alchemists for the elixir of life and the philosopher's stone, must have sadly disappointed their expectations. To find an antidote for even one poison is a matter of considerable difficulty, for the same drug will, under different circumstances and in different people, produce quite opposite effects. Thus in some persons opium will produce sleep, in others wakefulness, and in some cases it has caused diarrhœa, delirium, or even lock-jaw.* Hemlock also in some instances has produced insensibility and convulsions, while in most cases consciousness is retained and the power of the muscles is paralysed. These results may be owing to difference of temperament, or condition of health at the time. Thus, in tetanus large quantities of opium may be taken without producing any effect. From these facts it would appear that *the symptoms produced are the best guide in the administration of antidotes.*

Many antidotes have, at different times, been brought into notice, some of which remove the poison from the stomach, others render it inert by chemical means, and others again produce a reaction by neutralizing the physiological effects of the poison. It is to the latter class that I would more particularly direct attention, for, although it is necessary to render inert, or to remove the bulk of the poison from the intestines, to prevent its absorption, yet it is only the small portion that is absorbed into the blood which causes death, and the effects of which it is necessary to combat by antidotes. In order to find what will best answer this purpose, it is necessary to investigate the way in which poisons are absorbed into the system; their action when absorbed; the way in which they cause death, and the manner in which they are eliminated by nature in cases which do not prove fatal.

But before investigating these points it is necessary to define what vegetable poisons are. This is, perhaps, not so easy a matter as might at first appear. Plants which are poisonous to some animals are not so to others. Strychnia has no effect upon invertebrate animals, and is said not to poison monkeys. Many of the poisons which destroy the life of man and other carnivora are eaten with impunity by graminivorous animals. Thus, opium does not poison pigeons; tobacco and hemlock do not injure goats; and stramonium, henbane, and belladonna are eaten by rabbits.† Whether this is owing to the difference of digestive apparatus or to the knowledge of an antidote, as is said to be the case with the mungoose, must be at present a matter of speculation. Again several umbelliferous plants, namely, *Cicuta virosa*, *Œnanthe crocata* and *Conium maculatum* are said to be without poisonous effect in Scotland, while in England, Wales, and Ireland they cause death as rapidly and almost as surely as arsenic. It is well known that the roots of hemlock are eaten as food by the Russian peasants. It is possible that coldness of climate may cause this difference, as it is a well ascertained fact that hemp will only yield its intoxicating resin in hot climates. A vegetable poison will therefore be best defined by saying that it is a vegetable production which, in the majority of cases, is capable of destroying human life when administered in small quantities. As poisons of this class are exceedingly numerous, it will only be possible to notice a few of them. Those which are in frequent use in medicine or commerce, and those by which death is most frequently caused, either accidentally or intentionally, more particularly demand our attention; many of the vegetable poisons being only known to, and obtainable by, the few.

On perusing the statistics of poisoning‡ it will be found that in cases of *accidental* poisoning, the root of aconite, the tempting berries of belladonna, the

† PHARM. JOURN. (2), vol. xi., p. 871.

‡ Taylor on "Poisons," p. 237.

peculiar capsules of stramonium, and the tuberous and somewhat agreeable roots of the poisonous umbelliferæ are those which have generally proved fatally attractive to human beings; and the leaves of the yew tree to animals, more especially in the winter season.

In cases of *intentional* poisoning, opium, strychnia, prussic acid, and tobacco have been the drugs generally resorted to; while the ignorant medicinal use of savin, digitalis, lobelia, and black hellebore has often led to unexpected and fatal results. Of the above-mentioned poisons more deaths have been occasioned by opium and its preparations than any other. Strychnia, prussic acid, aconite, and belladonna come next in order, cases of poisoning by the others being comparatively rare. To find antidotes for these poisons in particular is therefore of the greatest importance.

(*To be continued.*)

PANCREATIC EMULSIONS OF SOLID FATS.*

BY RICHARD V. MATTISON.

Emulsions may be divided into those of solid and liquid fats. Since the publication of my former papers upon the subject of pancreatin,† and indeed before they were written, I have spent much time in endeavouring to prepare a perfect emulsion of solid fat which would keep without becoming oxidized, and at the same time form a preparation which would not offend the most delicate palate. This I think is accomplished in the preparation here described.

The great superiority of solid fat over cod-liver oil consists principally in the fact that the former is a body rich in stearin, while cod-liver oil is chiefly olein. In the normal diet a person partakes principally of food rich in the former, hence it is that a similar body must be presented for assimilation. Cod-liver oil usually assimilates more rapidly than other fats, and if it can be continued in any case for some time, rapid improvement generally takes place. To this there is the objection that olein cannot replace stearin in the animal system, and the work is not thorough. Again, fats containing much olein are certainly partially assimilated through venous absorption, and this is the reason why patients so soon tire of the oil. The portal system becomes choked up, cathartics are necessary, and even the good effect produced is frequently lost by the course rendered necessary by these circumstances. This becomes of interest to pharmacists, first, from it being to their interest, in a pecuniary way, to devise something better than cod-liver oil, and, second, as an aid to the physician, pharmacy should select such agents as a clear, sound theory suggests, and, by scientific manipulation, so combine them and mould them that they may be of the most potent remedies in the hand of her sister Medicine.

Thus pharmacy, to prevent the loss of fat which is frequently occasioned by the choking up of the portal system through the administration of too much olein, selects a solid fat which is only absorbed by the lacteals, and thus the amount of fat necessary for perfect nutrition can be administered in the natural manner. The fat formed by the assimilation of this emulsion is of a firmness not readily attainable by the administration of cod-liver oil or other similar elements of nutrition. The administration of cod-liver oil in connection with the emulsion of solid fat, however, probably answers more efficiently than either alone.

The emulsion of solid fat is best prepared in the following manner:—

Take of the fresh pancreas of the pig, one hundred pounds; lard, purified, eighty pounds; water, six gallons.

Dissect off all the fat and other extraneous matter from the pancreas, and comminute finely. A sausage cutter, driven by steam, is one of the most complete pieces of machinery for this purpose. After coming from the cutter it is allowed to drop with the fat into a cylindrical hopper driven by the same power. Into this hopper the six gallons of water are allowed to trickle slowly until a perfect emulsion is formed. From the hopper the emulsion is transferred to the press, in which a strong twilled flannel bag is placed, which should be of two thicknesses of material, and the emulsion is thus rapidly separated from the membraneous areolar tissue of the pancreas.

To this emulsion ether is added, and the mixture allowed to remain at rest, with occasional agitation, for a period of about forty-eight hours. For the above quantity from two hundred and fifty to two hundred and seventy-five pounds of ether are required. At the end of this time the mixture separates into two layers or strata, viz., an ethereal solution of pancreatized fat at the top, and an aqueous solution of the impurities of the lard, etc., at the bottom. This mixture is allowed to stand in a large cedar vat, which has glass plates inserted in the side to allow the operator to observe the point of separation between the ethereal and the watery stratum. Into the side of this vat, which should be tall and narrow at the top, like a precipitation jar, a number of wooden spigots are inserted, through which the ethereal solution of pancreatized fat is drawn off into a filtering apparatus, so arranged as to prevent the escape of the ether. (If allowed to stand long enough, a considerable portion will need no filtration.) This filtered ethereal solution is transferred to a suitable still, and the ether distilled off with gentle heat. This is the most troublesome part of the process, as it requires a considerable length of time to free the fat from the last traces of ether unless the temperature is raised, which results in the decomposition of the emulsified fat.

The pancreatin seems to split up in some manner by heat, leaving the fat in the same condition as it was before, or at least its emulsifying power is very much impaired. At the same time there is a peculiar sulphurous odour developed, reminding one of the presence of onions or garlic, or a trace of allyl sulphide or sulphhydrate.

After the fat has been freed from ether with due regard to the temperature, it is removed from the still, and to every fifty parts of this fat seventy-five parts of distilled water and twenty-five parts of alcohol are added, both being added very carefully; when all the water and alcohol has been taken up, enough of oil of cloves is added to impart a pleasant flavour.

From my experiments made before the publication of my first article in December, 1873, I was led to

* Read at the Pharmaceutical Meeting of the Philadelphia College of Pharmacy, Feb. 17th, 1874 (*Amer. Journ. Pharm.* [4] vol. iv., p. 105).

† PHARM. JOURN. [3], vol. iv., pp. 592 and 675.

suppose that, contrary to the views of eminent physiologists, pancreatin has no power of decomposing fat. These views were expressed at that time, and the following facts elucidated by the practical management of the above process will serve as further illustration of the facts there mentioned.

The first is that the pancreatized fat obtained by evaporation of the ethereal stratum before mentioned, when acted upon by plumbic oxide, yields lead, plaster, and glycerin. This certainly shows that the fatty acids are still held in combination with the oxide of glyceryl, although the fat be pancreatized and emulsified.

Second, the aqueous solution left after the decantation of the ethereal stratum contains no glycerin. This proves the absence of even partial saponification upon the mixing of the fat in the first instance with the pancreas.

A sample of the emulsion of solid fat, prepared as above, was presented to the late esteemed Professor Procter, who regarded it with much favour, and spoke at length upon it in connection with a sample of pancreatic emulsion of cod-liver oil, both of which samples were exhibited to the class upon the evening of his death.

The emulsion prepared by this process should have an acid reaction to litmus paper, and should not separate upon standing. Much care is necessary in the manipulation to prevent this.

When added to a small quantity of water, and stirred until complete mixture is effected, the whole has the appearance of milk, and any quantity of water may be added without disturbing in the least the appearance of the emulsion.

A superior method of administering the emulsion is to add it, little by little, to milk ; to those persons having an antipathy to milk it is easily given in a mixture of arrowroot and water. This proves an excellent method, as the pancreatic emulsion, as well as the pancreatin itself, has a decided action upon amylaceous matter, changing it to glucose ; hence it can be easily seen how important the administration of this in connection with arrowroot is in cases of marasmus and other infantile diseases arising from defective nutrition.

In this paper I intended to present a formula for pancreatic emulsion of cod-liver oil which *would not separate* upon standing, but remain perfectly emulsified. Want of time has prevented me, my experiments not having thus far proved perfectly satisfactory.

THE ALKALOIDS OF THE CINCHONA BARKS.*

BY O. HESSE.

(*Continued from p.* 752.)

VIII. Quinamine.

This alkaloid occurs not unfrequently, with paricine and several other alkaloids, in the *C. succirubra* bark sent from Darjeeling.† The quantity of it in this bark amounts generally to traces only, so that its preparation requires much skill in such work.

The whole of the alkaloids contained in the bark in question are first obtained in the ordinary way, dissolved out in dilute sulphuric acid, and the solution, warmed, neutralized with ammonia. Tartrate of soda and potash is added, when cinchonidine and quinine, if present, separate in the form of neutral tartrate. The solution, filtered from the precipitate, is shaken with some ether, after the alkaloids have been set free with ammonia, which takes up the quinamine and the amorphous substances, including the paricine, but the greater part of the cinchonine remains undissolved. Upon the careful, slow evaporation of the separated ethereal solution in a tall stoppered flask, there appear at first crystals of cinchonine, which are short prisms ; then follow delicate, very long, bent and twining hair-like crystals, which are quinamine ; and, finally, there remains a viscous amorphous mass, which while it is yet fluid is separated as much as possible by decantation. The neck of the vessel is broken off, and blotting-paper applied to the inside to remove yet more of the amorphous portion. The more completely the removal of this amorphous mass is effected, the more easy will be the farther manipulation. The crystalline substance so prepared is next washed with dilute alcohol, the residue afterwards dissolved in dilute hydrochloric acid, and platinum solution is added to this weak acid solution until it no longer produces a precipitate. This precipitate being removed by filtration, the quinamine can now be immediately thrown down by ammonia ; nevertheless, it is preferable first to remove the platinum by means of sulphuretted hydrogen, and then after driving off excess of this re-agent, to precipitate the alkaloid by means of ammonia. By a single re-crystallization of the alkaloid from boiling dilute alcohol it will finally be obtained perfectly pure.

The yield of quinamine from the before-mentioned bark amounts generally only to traces—in rare cases to about 0·1 per cent. I once received a specimen bark which yielded nearly 0·3 per cent. of pure quinamine ; sometimes, however, this East Indian bark gave not the least trace of the new alkaloid.

Quinamine forms long white delicate prisms, extremely similar to those of sulphate of quinine, which do not change when exposed to the air ; neither do they lose weight at 120° C., and therefore they contain no water of crystallization. But if this substance be exposed to 120° C. for some time it is coloured yellowish, and dissolves then in acid with a yellow colour. With an increasing temperature, the decomposition becomes more and more apparent through the colour, until, finally, the substance melts into a dark brown mass. But if it be placed in a capillary tube and the heat rapidly applied, it melts at 172° C. to a nearly colourless liquid, which crystallizes upon cooling. Nevertheless, here also decomposition soon commences in the product, which finally becomes brown and amorphous.

Only traces of quinamine are dissolved in cold water, 1 part of alkaloid requiring 1516 parts of water at 16° C. for its solution, but it is much more soluble in boiling water. Strong alcohol dissolves quinamine very readily, especially when boiling ; but dilution with water lessens its solvent power. Thus 1 part of the alkaloid is dissolved in 105 parts of 80 per cent. alcohol at 20° C., and in 32 parts of ether at the same temperature. It dissolves very readily in boiling ether, and crystallizes out on cooling. Petroleum, ether, ligroin and benzine also dissolve at their boiling temperatures considerable quantities of quinamine, the greater part of which is deposited again in crystals on cooling. Solution of potash and of ammonia do not dissolve it more than water, and consequently precipitate it from solutions of its salts. The precipitation is at first milky, but afterwards forms small colourless prisms. Concentrated sulphuric acid dissolves quinamine in the cold without colouration, but the application of heat gives it a yellow to a brown colour. On the contrary, strong nitric acid added to the base without heat gives at once a yellowish colour, which becomes afterwards an orange-red, and finally a bright yellow. Perchloride of iron has no reaction on quinamine.

Although quinamine alone has scarcely any bitter taste, it gives with acids a markedly bitter solution. In alcoholic solution it colours red litmus paper blue,

---

* Translated from the 'Vierteljahresschrift für praktische Pharmacie,' vol. xxii. p. 366.

† *Berichte der deutschen chemischen Gesellschaft*, v. 265.

and neutralizes acids completely. When an excess of acid is present, the solution does not, like other cinchona alkaloids, present any fluorescence. Its hydrochloric solution is coloured yellow upon the addition of solution of chloride of lime; and if now an excess of ammonia be added, a yellowish amorphous precipitate of the changed alkaloid is produced, but no green colour, as with quinine and its isomers under similar circumstances. In acid solution, quinamine decomposes very readily, and then gives rise to an amorphous alkaloid, that probably has the same composition as quinamine itself, for which the formula of $C_{20}H_{26}N_2O_2$ has been constructed.

Experiment gave with—

I. 0·2032 gram dried at 100° C., 0·5487 CO_2 and 0·1525 H_2O.

0·1452 gram dried at 100° C., 0·011847 N.

II. 0·2018 gram dried in an exsiccator, 0·5425 CO_2 and 0·1505 H_2O.

	Calculated for $C_{20}H_{26}N_2O_2$		Experiment. I.	Experiment. II.
C_{20}	240	73·62	73·64	73·31.
H_{26}	26	7·97	8·33	8·28.
N_2	28	8·59	8·16	—
O_2	32	9·82	—	—
	326	100·00		

The result of the estimation of nitrogen differs, however, considerably from the relative calculations, though, I believe, that this difference is purely conditional, because during the heating of the alkaloid with soda-lime, a volatile oily substance was formed, a small portion of which escaped from the combustion, although it had to pass through a long layer of soda-lime. Moreover, the equivalent number of 326 was confirmed by an analysis of the hydriodate of quinamine.

This salt was first prepared by saturating the base with hydriodic acid, and recrystallizing the crystals obtained from a little boiling water (Analysis I.); a gently warmed acetic aqueous solution was mixed with solution of iodide of potash, from which the new hydriodate crystallized upon cooling, and was in this case also recrystallized from a little boiling water (Analysis II.).

It gave with—

I. 0·3355 gram dried at 100° C., 0·173 AgI.

II. 0·2795 gram dried at 100° C., 0·145 AgI.

	Calculated for $C_{20}H_{26}N_2O_2$.	Experiment. I.	Experiment. II.
I.	27·96	27·85	28·03

The hydriodate contains no water of crystallization. It forms small colourless prisms, which are easily soluble in boiling water, difficultly soluble in cold water, and very slightly in solution of iodide of potassium.

The *hydrochlorate* of quinamine is a neutral salt, extremely soluble in water and alcohol, which is left in an amorphous residue on the evaporation of its solution. After a long time, however, it will crystallize out.

The neutral sulphate crystallizes, but with much difficulty, in hexagonal scales and short prisms; it also dissolves very readily in water.

Acetate of Quinamine.—When the base is dissolved in a slight excess of acetic acid, and the solution evaporated by a gentle heat, there remains finally a semi-crystalline mass, which is a mixture of free base in crystals and the easily soluble amorphous acetate.

Neutral tartrate of quinamine is obtained by saturating an alcoholic solution of the base with tartaric acid. This solution upon concentration gives an amorphous residue of the salt, which is neutral in reaction and dissolves easily in water. The *acid tartrate* is likewise amorphous, readily soluble in water and in alcohol, but insoluble in ether.

Hydrochlorate of Quinamine and Mercury.—Solution of corrosive sublimate added to a concentrated aqueous solution of quininamine produces a white amorphous precipitate of the above-named double salt, which is entirely soluble in a small quantity of water, so that in a moderately dilute solution no precipitation takes place. This property of quinamine I have sometimes made use of to free this alkaloid from the greater part of the other alkaloids accompanying it, which give with solution of sublimate a precipitate rather difficultly soluble in water.

Hydriodate of Quinamine and Mercury is a yellow amorphous precipitate, which a solution of iodide of mercury in iodide of potassium produces in an aqueous solution of hydrochlorate of quinamine. It dissolves with difficulty in cold water, freely in alcohol, and melts at about 90°C. to a yellow liquid, without any loss of weight. 0·505 gram of the substance dried at 100°C. gave 0·1174 gram, HgS and 0·3625 gram AgI, or 20·04 per cent. Hg and 38·80 per cent. I. These figures do not allow of the deduction of any simple formula, so that this precipitate is probably a mixture.

Hydrochlorate of Quinamine and Platinum is distinguished from all the corresponding salts of the other cinchona alkaloids by its great solubility in water. Only in quite a concentrated solution of the hydrochlorate does the platinum solution produce a yellow flocculent precipitate, but this is again immediately dissolved upon the addition of a little water. As, moreover, the salt is easily decomposed upon the concentration of its solution, I have been compelled to abandon its preparation for the purpose of analysis.

Hydrochlorate of Quinamine and Gold is formed as a yellowish white precipitate when gold chloride is added to solution of the hydrochlorate. But this compound is decomposed immediately; it turns purple, and deposits metallic gold, whilst the supernatant fluid assumes a beautiful red colour.

With respect to the rotatory power of this alkaloid it may be mentioned that for $p = 0{\cdot}8378$ in alcoholic solution and $l = 200$, $\alpha = +1{\cdot}79°$ was obtained, whence is calculated $\alpha\, j = +106{\cdot}8$. It belongs, therefore, to the dextrogyrous class of cinchona alkaloids. Further, it accords in many respects with paytine and has also some similarity to physostigmatine.

IX. Paytine.

Paytine was discovered by me* in a white bark imported from Payta, which, as Flückiger has since shown, agrees entirely in anatomical structure with the cinchona barks. But the particulars of the derivation of this bark are not yet known, and therefore it is not yet certain whether it is from a true cinchona.

The composition of this alkaloid is represented by the formula $C_{21}H_{24}N_2O_2$. It reduces equally with quinamine the gold solution, and like it forms with hydriodic acid a difficulty soluble salt. The effect of paytine upon polarized light differs from that of quinamine, since in alcoholic solution, with $p = 0{\cdot}4542$ (anhydrous) and $l = 200$ it gave a rotation of $-0{\cdot}45°$, which is represented by $a\, j = -49{\cdot}5°$

Possibly paytine, as well as quinamine, is derived from conchinine, the paytine, through an addition of an atom of carbon, but the quinamine through an addition of two atoms of hydrogen. Should this conjecture be confirmed, we might venture to conclude that through the introduction of two atoms of hydrogen, the optical rotatory power is reduced about 154°, but double that amount by the addition of one atom of carbon. This difference in the optical power would consequently represent the value of the above-mentioned alkaloids.

(To be continued.)

PYROGALLIC ACID AS A REAGENT.†

BY M. SCHLAGDENHAUFFEN.

The action of pyrogallic acid upon the alkalies and the alkaline earths is well known. It forms, with the caustic

* *Annalen der Chemie und der Pharmacie*, vol. cliv., p. 287.

† *L'Union Pharmaceutique*, vol. xv., p. 5.

alkalies, dark-brown coloured compounds, and with lime water a splendid violet solution, which finally deposits a black product by a decomposition not yet investigated. With the carbonates and bicarbonates analogous results are obtained. A few drops of a ten per cent. solution of pyrogallic acid, added to bicarbonate of magnesia or bicarbonate of lime in sufficiently dilute solution to remain at first uncoloured, gives, after six hours, an abundant black deposit. This reaction the author has made use of in the examination of alkaline mineral waters, a yellow colouration being produced at once in the waters most impregnated with carbonates, followed, after ten or twelve hours, by a plentiful black precipitate, whilst a negative result, amounting to only a yellow or feeble brown colour, has been found to indicate the absence of soluble carbonates. The presence of calcareous carbonates in potable waters may be detected by adding a small quantity of pyrogallic acid in aqueous or alcoholic solution to a few cubic centimetres of the water to be examined.

The alkaloids have also the property of colouring pyrogallol brown, or at least a deep orange yellow, but the reaction is not manifest in less than a dozen hours. This character distinguishes the organic bases from neutral crystallizable bodies and the glucosides, the latter remaining perfectly inactive in the presence of pyrogallic acid; the heat of a water bath increases the depth of colour. Alcoholic solution of mercuric chloride, added to the coloured liquid containing the alkaloid, causes immediately a black deposit, but a pyrogallic solution containing a glucoside or neutral crystalline body is not coloured by the addition of the bichloride.

Some experiments, based upon this reaction, were made to define the relative alkalinity of the alkaloids. A gram of pyrogallic acid dissolved in 10 c.c. of alcohol, added to 2 c.c. of a saturated alcoholic solution of mercuric chloride, was used as the reagent. Two or three drops were placed in a porcelain capsule, and a few crystals of the substance to be examined added. In some cases the crystals were blackened immediately upon contact; others at first took a light tinge, and became more coloured after a few minutes; whilst some alkaloids only became coloured after a slight elevation of temperature. The following represents the results of the experiments:—

	In the cold.	With heat.
Atropine	Black, immediately	Black.
Veratrine	,, ,,	,,
Codeine	Brown, immediately	,,
Quinidine	,, ,,	,,
Cinchonidine	,, ,,	,,
Thebaine	Pale yellow; brown after ¼ of an hour	,,
Narcotine	Ditto ditto ditto	,,
Papaverine	,, ,, ,,	,,
Brucine	No change at first; brown after ¼ of an hour	,,
Strychnine	Ditto ditto ditto	,,
Delphinine	,, ,, ,,	,,
Morphine	,, ,, ,,	,,
Quinine	,, ,, ,,	,,
Cinchonine	,, ,, ,,	,,

In operating with neutral crystallizable bodies and glucosides, and heating the mixture, the black coloration was never obtained, and even the residue never presented a colour darker than that produced by a mixture of the body with the bichloride or pyrogallol used separately.

Picrotoxin, phlorizin, salicin, santonin, esculin, coumarin, amygdalin, meconin, and digitalin, in no instance resembled the alkaloids in their behaviour. It would therefore appear that the pyrogallo-mercuric, like the guaiaco-mercuric test, can be used to distinguish the glucosides and neutral crystallizable bodies from organic bases, and thus facilitate analytical research.

In replacing the mercuric chloride by ferric chloride analogous results are obtained. The solution of pyrogallate of iron used by the author in his experiments contained only a minimum quantity of metallic salt, the addition of a trace of ammonia or caustic alkali to which gives rise to a deep-blue violet colour. This very delicate reaction of the salts of peroxide of iron, recently indicated by M. Jacquemin, can also be used to recognize the presence of alkalies. The solution which gave the author the best results was composed of—

Pyrogallic Acid	0·50 gram.
Water	5 c.c.
Alcohol	5 c.c.
Perchloride of Iron	0·0001 gram.

The pyrogallate of iron so prepared colours blue crystals of strychnine, brucine, morphine, codeine, and all the other alkaloids. Crystals of narcotine are coloured difficultly, and those of narceine acquire only a scarcely appreciable violet tint, but upon heating them in a water-bath they both yield a very deep bluish violet residue. The glucosides and neutral bodies give no coloration in the cold, and in the heat no deeper tint than pyrogallate of iron heated separately. A solution of cupric chloride added to pyrogallic acid gives analogous results, the coloration in that case being a nearly black brown.

The author considers that all these reactions are explained by the oxidation of the pyrogallic acid under the influence of various metallic oxides. The addition of an alkali, alkaline salt, or free alkaloid to one or other of the foregoing solutions, produces, in the presence of a metallic chloride, a double decomposition; there is formed an alkaline chloride or an hydrochlorate of an alkaloid, and a more or less decided coloration, resulting from the oxidation of the pyrogallic acid by the metallic oxide at the moment when the double decomposition takes place.

NOTES ON SOME NORTH AMERICAN DRUGS.*

BY JOHN M. MAISCH.

Cranesbill appears to be used very extensively in some sections of the United States, while in others it is comparatively unknown—at least as a domestic remedy. In July, 1872, I received a plant from the region of the Blue Ridge, in the State of Virginia, which proved to be *Geranium maculatum*, Lin. The letter accompanying it stated that *it* (whether the rhizome alone or the entire plant was not mentioned) has a great celebrity there as a cure for dysentery, diarrhœa, and all kinds of bowel complaints. It seems probable, however, that the herbaceous portion of the plant is not employed for the purposes mentioned, since it has merely a faintly bitter taste and is nearly devoid of astringency.

Antidote to Snake Poison.—In August last the root and radical leaves of a plant were received from Mr. T. D. Reed, of Meridian, Miss., which, the letter stated, "is said to be a specific for snake-bite, and, in fact, the country people use no other antidote in cases of snake-bite." Unfortunately, the letter gives no information whatever in regard to the part employed for the purposes stated, or to the manner in which it is used. The plants sent contain neither stem nor flowers, but from the black colour of the dried plants and the character of the leaves, were at once referred to the genus *Gerardia*, and by comparison with herbarium specimens were recognized as *Gerardia* (*Dasystoma*, Benth.) *quercifolia*, Pursh. It belongs to the sub-genus *Dasystoma*, which comprises perennial plants with rather large yellow flowers, with the leaves, particularly the lower ones, more or less pinnatifid or cut-toothed, and opposite, on the stem, the floral leaves being often alternate; it is very difficult to preserve the green colour of the plants, all the species readily turning black on drying. The genus belongs to the order of *Scrophulariaceæ*.

The species in question resembles and is closely allied to *G. flava*, Lin., and *G. integrifolia*, Gray, and is distinguished from both by the plant being smooth and glaucous

* *American Journal of Pharmacy* [4] vol. iv., p. 103.

the lower leaves being usually twice pinnatifid, and by the peduncles attaining about the length of the calyx, they being shorter in the other two species named.

Most probably the subterraneous portion is the part employed, and it is not unlikely that, like several other so-called snake roots, the black colour which it assumes on drying may have first attracted attention to it for the purpose named. It consists of a short and rather thin upright rhizome, sending off from eight to twelve rootlets, which are about six inches or more in length, nearly simple, when dry slightly furrowed longitudinally and readily breaking transversely. The fracture is even, somewhat granular, exhibits a thick cortical portion of a dark gray colour, surrounding a thin ligneous centre, of a yellowish colour and a rather irregular shape. As far as can be judged from the taste, the root probably contains a principle analogous to saponin.

Verbena bracteosa, Mich.—Branches of this plant were received last August from Mr. Buntin, of Terre Haute, Ind., who states that it is used there by physicians in the form of infusion, with marked success, in the treatment of scrofulous affections, particularly in scrofulous sore eyes, and that its alterative properties are claimed by some to be more potent than those of iodide of potassium. The plant is abundant in the neighbourhood of Terre Haute, and the specimen received agrees in every respect with the specimens in the College herbarium coming from Kentucky.

The plant is procumbent and widely spreading, with its stems branching to the length of from 12 to 18 inches. It is covered with spreading whitish hairs, the leaves are narrowed at the base into a short petiole, broadly lanceolate in outline, deeply cut-toothed, or the lower pinnatifid and the teeth rather acute. The small blue or purplish flowers are collected in dense spikes terminating the branches, the numerous bracts being longer than the flowers, lance-linear in shape or the lower deeply three-cleft. Its hoariness and its dense long bracted and squarrous spikes are quite characteristic for this species, which possesses a gradually developed but lasting bitterness.

I have not been informed of the strength or dose in which the infusion is given. The plant appears to merit some attention, particularly with the view of isolating the bitter principle and determining its value as an alterative.

California Opium.—I have received from Mr. J. H. Flint, of Marysville, Cal., a handsome specimen of opium, in regard to which the following information was given :

"The opium was raised in Sutter county, on the Sacramento River, about fifteen miles from this city. The expense attending the cultivation of poppy and the collection of opium does not warrant the outlay of sufficient capital to produce large quantities, although the soil and climate are admirably adapted to that purpose. I obtained 7¾ per cent. of morphia from a specimen *recently collected.* It yielded 52 per cent. of soluble matter to boiling water, and lost 17 per cent. of moisture after drying at 212° F. What I have used seems to answer quite as well as the imported article."

From this statement it appears that the opium was assayed in its crude undried state ; if an allowance is made for the 17 per cent. of moisture, Mr. Flint's assay would give (100—17) : 100 : : 7·75 : 9·34 per cent. morphia in dry opium, or nearly the strength of opium as directed by the pharmacopœia. The high price of labour in California, it may be supposed, renders the cultivation of the poppy solely for the production of opium, unprofitable ; but the seeds contain a large percentage of a bland fixed oil, and after its expression are valuable as feed for cattle ; poppy culture may, therefore, notwithstanding the drawback of high wages, not prove unprofitable.

The opium received was more homogeneous in texture than Smyrna opium, of a good strong narcotic odour, and unexceptionable in its physical properties.

Oregon Balsam of Fir.—Under this name an oleo-resin has appeared in our commerce during the last year, which is rather suspicious in appearance. As far as could be ascertained, it comes from New York, and the writer has not been able to trace it beyond that city. It is a thick liquid, perfectly transparent, of a bright brownish colour and a distinct terebinthinate and aromatic odour. On rubbing a little of it between the fingers, different odours become quite evident, the last one remaining being that of nutmegs. It has the appearance of being merely a solution of common resin in oil of turpentine, flavoured, perhaps, with a little of the oil of *Eucalyptus globulus* and a somewhat larger quantity of the volatile oil of nutmegs. Is such an article known on our Pacific coast, and if so, what is its source and how is it obtained ?

Adulterated Serpentaria.—Recently a rhizome with its rootlets was handed to me, with the statement that several bundles of it had been found in a bale of serpentaria obtained from a Western State. The adulteration was promptly recognized as the underground portion of *Cypripedium pubescens*, Lin. (not *C. parviflorum**). This differs so considerably from *Aristolochia serpentaria* and *reticulata*, that the former can never be mistaken for the latter, and the adulteration can therefore be practised successfully only when Virginia snake root is sold in bulk. The rhizome of the latter is quite thin, rarely exceeding one-tenth of an inch in diameter, the remnants of the over-ground stems are invariably projecting as short branches from the rhizome, which terminate by a scarcely concave scar. The rhizome of Cypripedium is much coarser, the stems die off to the rhizome, leaving large deeply cup-shaped scars, the older ones penetrating deeply into the rhizome. Cypripedium, moreover, is a monocotyledonous plant, while serpentaria is dicotyledonous, and the difference in the characteristic disposition of the ligneous bundles is quite evident.

CHEMICAL FOOD.

A correspondent of the New York *Druggists'* Circular, sends to that Journal the following formula, which he asserts will produce a more permanent compound syrup of phosphates than is afforded by the method recommended by the late Professor Parrish :—

Take—	
Freshly precipitated phosph. iron . .	128 grs.
Freshly precipitated phosph. lime . .	256 grs.
Phosphate of soda	128 grs.
Phosph. of ammonia	128 grs.
Syrupy phosphoric acid	12 fl. dr.
Water at 212° (boiling)	4 oz.
Syrup sufficient to complete	16 oz.

Dissolve the soda, lime, and ammonia phosphates, and six drachms of syrupy phosphoric acid in the boiling water. Mix the syrupy phosphoric acid with one ounce of syrup, and rub with the iron until it is dissolved ; add the solution of the lime, soda, and ammonia, and sufficient syrup to make a pint. The advantages of this method over the usual one is the use of pure tribasic phosphoric acid (which should always be made directly from phosphorus, that made from the glacial acid being unsatisfactory) instead of the monobasic acid now employed; the phosphate of ammonia is a better preserver of the solution of iron than the potassic phosphate, and possesses more remedial power over pulmonary diseases, and is inferior to it in no case that I can imagine. The great trouble with *Easton's syrup and chemical food*, as prepared in the United States, is the use of heat, monobasic acid, and too much atmospheric exposure in making those preparations. The best test with which I am acquainted of pure tribasic dilute phosphoric acid is, that it forms a perfectly permanent solution, without precipitate, when mixed with equal parts of the tincture of the ferric chloride. For this test I am indebted to the Messrs. Rosengarten of New York, as also for much valuable information on phosphoric acid and the phosphates. Whenever I have used phosphoric acid made

* For a description of these rhizomes refer to *American Journal of Pharmacy*, 1872, p. 297.

directly from phosphorus by nitric acid, I have found it would stand this test ; but every specimen made from the glacial acid gave more or less precipitate of the phosphate sesquioxide of iron. I think the difficulties heretofore encountered in phosphatic preparations are thus explained. The syrupy phosphoric acid, s. g. 1500, is decidedly superior to either the glacial or dilute solution, for all pharmaceutical puposes ; and if standing the tribasic test with the argentic nitrate, will produce quite permanent solutions of iron, manganese, lime, and zinc, when preserved with sufficient sugar.

THE NATURE AND PHYSIOLOGICAL ACTION OF SNAKE POISONS.*

BY DRS. BRUNTON AND FAYRER.

The terrible subject of poisonous snake bites appears to have always exercised a fascination over the human intellect, akin to that which the serpents themselves are said sometimes to exercise over their victims. Hardly is there a country in which it has not been studied ; the three kingdoms of nature have been ransacked for antidotes ; the homœopathic virtues of theriaca were vaunted a couple of millenniums since ; and the claims of innumerable other remedies have since been put forward down to ammonia and guaco in our own days. Nevertheless, the startling fact is vouched for by official documents that twenty thousand human lives are still lost annually from the bites of poisonous snakes in India alone !

With the hope of diminishing this mortality, Dr. Fayrer, in 1867, began a systematic investigation of the subject, and in a work entitled the "Thanatophidia of India," has recently published a description of the venomous snakes found in British India, with an account of a series of experiments upon the lower animals, conducted for the purpose of studying the nature of the poison, its *modus operandi*, and the value of the remedies that have been from time to time reputed as antidotes. Since then, he has in conjuction with Dr. T. Lauder Brunton communicated to the Royal Society two papers containing a report of further experiments expressly devoted to ascertaining the nature and physiological action of the virus on life and the application of such knowledge in the treatment of those poisoned. Of these papers it is intended here to give a a brief *résumé*.

Estimated by a rough classification of the deaths according to the snakes which inflicted the wound, the cobra (*Naja tripudians*) in India occupies the first place in order of destructiveness ; the Krait (*Bungarus cœruleus*) the second. There is apparently some analogy between the nature of the action of cobra virus and that of curara, death in both cases being induced by arrest of respiration through paralysis of the respiratory apparatus. It has been shown that in the case of curara this is due to paralysis of the peripheral distribution of the motor nerves, that if artificial respiration be kept up until the elimination of the poison from the system the patient may recover. The result implies that the integrity of the parts of the nervous system is not impaired, whilst under the influence of this poison. Recent experiments confirm the opinion that death from cobra poison is due to its action on the nerve centres, to which it is conveyed by the blood with terrible rapidity when the injection takes place into a large vein like the crural or jugular. But whether its action is localized in the nerve centres or is extended to other parts of the nerve apparatus, and whether its effect is permanent or transitory is not yet known. In some cases of cobra poisoning life has been prolonged by artificial respiration, and without committing themselves to any opinion the authors do not abandon the hope that it may, as in the case of curara, even save it altogether.

Passing by the secondary effects of the virus upon the blood, and dealing only with its immediate and deadly neurotic effects, the subject resolves itself into three points of inquiry : (1) Is the nature of the virus such that we may hope to find any agent capable of overtaking, neutralizing and rendering it harmless and inert ? (2) Does the virus exert only a temporarily pernicious action on the ultimate structure of the nerve apparatus ? or (3) Does it so modify the nerve elements as to render them permanently incapable of resuming their functions after the poison has been eliminated ?

With regard to the first proposition the authors have arrived at the conclusion that a complete and satisfactory means of resisting, antagonizing, or eliminating the poison and of saving life is still unknown. Much virtue has been recently attributed to one of the oldest and most trusted of all antidotes—ammonia ; but the authors point out that a century ago Fontana, after repeated experiments, came to the conclusion that its injection into the veins as well as its internal administration and external application, is powerless in this respect, and state that such has been the result also of all the experiments made with it in India.

Cobra poison, when fresh, in a transparent, almost colourless fluid, of a somewhat syrupy consistence, and not unlike glycerine in its appearance. When quickly dried it forms a transparent mass of a yellowish-brown colour, resembling some kinds of gum arabic. The poison may be kept for some months in a fluid state without undergoing any change, but after a certain time it decomposes, giving off carbonic anhydride, and acquiring a dark brown colour and disagreeable odour. The dried poison may be kept for a much longer time without undergoing any apparent change.

The chemical composition of the poison has been examined by Dr. Armstrong. He has not been able to separate from it any crystalline principle. It is partially coagulated by heat ; mineral acids produce in it a gelatinous precipitate ; absolute alcohol throws down a white gelatinous precipitate ; a drop of it evaporated with a little sulphate of copper solution, and then treated with caustic potash, gives a violet coloration. These reactions show that the chief constituent of the poison is an albumenoid body. In an ultimate analysis very little difference was found between the fresh poison, the alcoholic precipitate, and the alcoholic extract. The following are the results, the albumen being given for comparison.

	Crude Poison.	Alcoholic Precipitate.	Alcoholic Extract.	Albumen.
Carbon .	43·55	45·76	43·04	53·5
Nitrogen .	43·30	14·30	12·45	15·7
Hydrogen	.....	6·60	7·00	7·1
Sulphur .	.....	2·5	.....	.....
Ash . .	.....	Traces.	.....	.....

But although there is little difference between the composition of the alcoholic precipitate and extract, there is an immense difference between their physiological action, the extract being a virulent poison, the precipitate almost inert. This is notably different from what has been stated by Dr. Weir Mitchell respecting the poison of the rattlesnake, namely, that the alcoholic precipitate is active whilst the extract is inert.

Coagulation of the cobra poison by boiling, however, does not destroy the activity of the poison ; but a portion which was boiled for more than half an hour under pressure corresponding to a temperature of 102° C, had no effect when injected into the thigh of a lark. Dilution appears to have no effect in lessening the activity of the venom, except so far as it retards obsorption. Admixture with liquor ammoniæ and liquor potassæ does not alter the effects of the poison.

In experiments made with the coagulated poison, death seemed invariably to be caused by paralysis of the spinal cord, the motor nerves being little affected, while in those made with the dried venom, sometimes the action on the cord predominates sometimes that on the nerves. In this

* Abstract of two papers read before the Royal Society *Proceedings*, vol. xxi., p. 358, and vol. xxii., p. 68).

respect, as also in some of the symptoms it produces, cobra poison agrees very closely with conia. That alkaloid, as Drs. Crum-Brown and Fraser, have shown often contains a mixture of true conia and methyl conia. Conia alone paralyses the motor nerves without affecting the spinal cord; but when mixed with methyl conia, sometimes the one is affected first, sometimes the other. When the dose is small the motor nerves are usually paralysed before the reflex function of the cord; when it is large the cord is paralyzed before the nerves. Methyl conia also affects both; but a small dose of it paralyses the cord before the nerves, while a large paralyses the nerves first.

The local effects of the poison are partial paralysis of the bitten part, occasionally pain in it, ecchymosis around the spot where the poison has been introduced, and sometimes in other and distant parts, and if the animal survives for some hours, infiltration and, perhaps, incipient decomposition of the tissues and hæmorrhagic discharge. The general symptoms are depression, faintness, hurried respiration, exhaustion, lethargy, nausea, and vomiting. In guinea-pigs and rabbits peculiar twitching movements occur, which seem to represent vomiting in them, and occasionally, in fact, guinea-pigs do vomit. Dogs vomit, are salivated, and present an appearance as if the hair had been rubbed the wrong way. As the poison proceeds paralysis appears, sometimes affecting the hind legs first and seeming to creep up the body and sometimes affecting the whole animal nearly at the same time. Hæmorrhage, relaxation of the sphincters and involuntary evacuations, not unfrequently of a sanguineous or muco-sanguineous character, often precede death, which is generally accompanied by convulsions.

Snake poison is essentially a neurotic, acting by absorption, and when it takes full effect, it appears to kill by annihilating the source or distribution of nerve force. It is also an irritant, and to certain extent a septic, for if the bitten creature survive, the wound and parts about it are apt to slough and induce septicæmia. The blood itself is affected by the poison. It generally presents a dark colour, as if death were due to failure of the respiration and not of the circulation; but it readily assumes a florid colour when exposed to the air. Coagulation usually occurs in ths blood of animals killed by cobra poison, while it is frequently absent from the blood of those killed by *Daboia* venom. Just as the *Naja tripudians* (cobra) may be regarded as among the most virulent of the colubrine snakes, the *Daboia Russellii* is probably as venomous as any of the viperine snakes. Experiments on pigeons and guinea-pigs tended to show that the general symptoms produced by the *Daboia* venom are nearly the same as those of the *Naja*. The local symptoms are greater extravasation of blood and effusion into the areolar tissue.

The bite of venomous serpents, such as the cobra, *Daboia*, and *Bungarus*, has been found by the authors, in numerous experiments, to be generally fatal to the innocuous serpents, but not always so. The occasional escape of the latter, however, is thought to be probably due to the quantity of poison absorbed having been small either absolutely or relatively to the size of the bitten snake. On the other hand venomous snakes were not generally affected, either by their own poison or that of another kind of snake. Small venomous snakes have, however, occasionally been killed by large individuals belonging either to the same or to a different species. The authors think that in some of these cases death may possibly have been due to other causes, especially in the case of a *Daboia* bite, where the fangs are so large that the wound and internal hæmorrhage might cause death; but it was remarked that the symptoms preceding death were similar to those occurring in innocuous snakes. Possibly the immunity which poisonous snakes enjoy from the effects of their own poison or that of another species (an immunity not shared by small individuals of a venomous species poisoned by a large quantity of venom) may be due in some measure to a power of excreting the innoculated venom through their own poison glands, which are modified parotid glands.

One popular belief has been proved by the author's experiments to be unfounded. It has long been supposed that the mongoose (*Herpestes griseus*) is unaffected by the poison of venomous snakes, either on account of some peculiarity in the constitution of the animal, or, as the story used to run, on account of its knowledge of some herb which it eats as an antidote. If fairly bitten, however, the mongoose succumbs like any other creature, as proved by experiments in India. Its great activity and vigour enable it to elude the snake, and generally when it is wounded it is merely scratched, not pierced by the fangs. But if the fangs be thoroughly embedded the animal dies.

Usually there is a correspondence between the size of the animal and the intensity of the effects of a given quantity of the poison; but there are some exceptions to this rule, for a cat will resist the action of cobra poison, as much as, or more than, a dog five or six times its size.

Like rattlesnake poison, cobra poison does not prevent the germination of seeds, but appears to interfere with and retard it, especially when the poison is strong.

In studying the means of preventing death from the bites of venomous snakes, the manner of its excretion from the system is of great importance. From data afforded by their own experiments and observations of others, the authors consider that the poison is excreted by the kidneys and mammary glands, and probably also by the salivary glands and mucous membrane of the stomach. A case has been reported in which an infant, suckled by its mother after she had been bitten by a snake, but before any marked symptoms had shown themselves, died in two hours after it had partaken of the milk. Excretion of the venom from the kidneys appears to be shown by an experiment in which the urine of a dog poisoned by the bite of a sea-snake (*Enhydrina bengalensis*) killed a pigeon twenty-two hours after being hypodermically injected. Some saliva obtained from the submaxillary gland of a dog poisoned by cobra venom had no effect when injected under the skin of a lark's thigh; but one drachm of the greenish liquid which flowed from the mouth of a dog similarly poisoned killed a pigeon in two hours.

It is evident that the lethal action of any poison depends upon the relative rapidity with which it is absorbed and excreted. If absorption goes on more rapidly than excretion the poison accumulates in the blood, and exercises its deadly action; while the quantity in actual circulation may be reduced to an infinitesimal amount if the excretion can keep pace with or go on more rapidly than the absorption. In the case of curara all the bad effects usually following its introduction into a wound may be prevented by applying a ligature between the wound and the heart and only loosening the bandage occasionally for an instant or two at a time. In this way only a little of the poison is absorbed each time the ligature is slackened, and this is excreted by the kidneys before another quantity is absorbed. The same obtains in snake poison, but here much will depend upon whether the nerve tissue is decomposed or left in a condition to resume its functions upon the removal of the poison.

With regard to artificial respiration, which the authors had found in some cases to prolong life, the following experiment was performed under the superintendence of a committee appointed by Government to investigate the subject. A dog bitten by a sea-snake appeared to die two hours afterwards in convulsions. Artificial respiration was commenced, but four hours afterwards the application of a galvanic current caused no muscular contractions; the eyes were dry and glazed, and the body was cold. Next morning, about sixteen hours after the apparent death of the animal, reaction commenced: the galvanic current caused movements of the body and expulsion of urine, and the bowels acted spontaneously. In five hours more the animal seemed as if it would recover: the eyes lost their glazed appearance, tears were secreted, and a greenish fluid flowed from the mouth; reflex action became re-established, the eyelids closing when the cornea

was touched. Attempts to swallow were made, when water was poured into the mouth ; the body showed sensibility to pain, and the eyelids twitched when the finger was merely brought near to the eye. The heart, however, became weaker, and the animal died 24 hours and 35 minutes after its first apparent decease. Although from the symptoms hopes may be entertained that the poison does not act as a ferment in decomposing the tissue, it is evident that its excretion proceeds very slowly. It was at one time thought to quicken the excretion by the employment of diuretics and sialogogues, but this hope having been much lessened by the discovery that the poison paralyses the nerves of secretion, the authors are inclined to think that perhaps the readiest means of removing the poison from the body may be to allow it to flow out with the blood in which it is circulating, and to supply the place of the poisoned blood thus withdrawn by transfusion.

With regard to the mechanical methods of preventing the entry of the poison into the circulation after a bite, Drs. Brunton and Fayrer think that the speedy application of an elastic cord (such as is used in bloodless operations) round the limb, combined with the application of cups attached to an exhausting syringe or pump, may be of service.

INFLUENCE OF VEGETATION UPON MALARIA.*

BY C. A. GORDON, M.D., C.B.

In an interesting paper on the "Hygiene of Malaria," published in the *Medical Press and Circular*, the author has the following remarks upon the influence of vegetation upon the prevention or extension of malaria :—

The power exerted by forests and woods in preventing the extension of malaria deserves a special notice. The advantages of having a belt of forest between barracks and a malarious swamp have been acknowledged from ancient times. We learn that the Romans, whenever practicable, established their camps under the shelter of woods. In India it has from time immemorial been the custom of the natives of malarious districts to form villages in the denser parts of the jungles, where, according to recent observations, they are relatively exempt, not only from intermittent fever, but from cholera. In America, the Dismal Swamp, where ague is never met with among the inhabitants, is covered with evergreen trees of large and lofty stature ; whereas, on the other hand, there are numerous instances of districts having become unhealthy by the forests that had covered them being removed. Among such may be enumerated St. Stephano and Campo Salina in the Pontine Marshes. American writers observe that encampments on land, the wood of which had just been cut down, are, of all others, the most unhealthy, and add, "it is perhaps from this cause that new countries are generally fatal to the first settlers," a remark which I specially commend to the attention of those about to emigrate to the Far West. Dr. Cleghorn, writing of the Forests of Southern India, makes somewhat similar allusion to the influence of woods upon health, and expresses his belief that the greater degree of sickness at Wellington than at Coonoor, although only a couple of miles distant, is attributable to the scarcity of wood at the former place as compared with the latter. It seems almost unnecessary to observe, that in order that woods and forests may prove beneficial as guards against malaria, it is necessary that they are composed of trees which are themselves in a healthy state, and are not of the description known to produce injurious manations.

With regard to water as a vehicle for ague-producing malaria, not only that which is stagnant, but in some instances that of rivulets impregnated with vegetable matter, fresh or decaying, may convey the poison, and there are numerous instances recorded of streams in India having this property. That of stagnant pools and marshes has ever had a similar reputation, and in some instances it has been found that although health may not suffer in residents in such localities so long as they refrain from making use of the water, yet they become affected immediately they neglect this precaution, the ready explanation being, that although malaria may not be given off by soil so long as it remains submerged, the overlying water may itself become saturated with the poison.

If, however, there are plants the presence of which in water renders it deleterious, there are many others which act as purifiers, and render that which otherwise would be deleterious, wholesome ; among such are *Hydrocharis*, or frog-bit, *Stratiotes*, or water soldier, *Macrophyllum*, *Vallisneria*, and *Anacharis alsinastrum*, which, since 1834, when it is believed to have been introduced from North America, has flourished abundantly in marshes and canals in England. Among other plants which have a similar action are *Sagittaria*, or arrow-head, *Alisma plantago*, or water plantain, *Butomus umbellatus*, or flowering rush, *Lemna*, or duckweed, *Pistia*, or *gigantic* duckweed, *Montia*, *Potamogeton*, or brookweed, *Callitriche*, or starwort, *Hippuris*, or marestail, *Equisetum*, or horsetail, besides various rushes, carices, grasses, flags, and cresses ; while *Œnanthe*, although itself poisonous, purifies water in which it grows. Nor is the list complete with all these, and the enumeration shows, if any argument be necessary to do so, how essential is a measure of botanical knowledge on the part of the army medical officer, in order that he may efficiently fulfil the functions of his position in this as in many other respects. Notwithstanding the undoubted acrid properties of the natural order *Ranunculaceæ* generally, there are at least four genera whose presence in water is beneficial, namely, the *R. aquatilis*, *Nelumbium*, *Victoria*, and *Nymphæa*, as are also the members of the natural orders *Ceratophylleæ* and *Podostemaceæ*, and some of the *Algæ* among the cryptogamic plants. Some of these plants being provided with leaves which float upon the surface of the water, directly decompose the otherwise noxious vapours under the influence of the solar rays, and in their stead produce respirable air ; others, more submerged, themselves give out a supply of oxygen, thus purifying the water and rendering it fit for the support of life.

Vegetable matter, whether in the fresh or dried state, exerts various effects in the propagation, absorption, or destruction of malaria. According to Dr. Hammond, he contracted intermittent fever from inspecting musty hay, and symptoms of pyrexia from examining old books. Dr. Salisbury considers that measles and some other affections are readily conveyed by means of straw, and that epidemics may thus be propagated among troops in camp. Plants in a state of decay or decomposition give rise similarly to malaria, or at any rate produce in man the diseases usually attributed to such a cause. Old trees undergoing the process of *dry rot*, and some vegetables, more especially cruciferæ, and those generally of a succulent nature, have this effect. Dense vegetation, as low jungle, especially containing trailing plants and of a nature to interfere with free perflation of the locality, is conducive to the concentration of malaria.

Under other circumstances trees and growing plants are valuable as protectives against malaria. The existence of a belt of trees between a barrack and a pestiferous marsh is fully acknowledged, and the circumstance of planting a marsh with evergreen trees has, in many instances, converted a malarious into a healthy locality ; while, on the other hand, as in the case of St. Stephano and Campo Salina in the Pontine Marshes, places have become unhealthy by the forest upon them being cut down. The precise process by which these and some other plants exert their destructive effect upon the poison is as yet unascertained. Others, however, are known to cause a large increase of ozone during sunlight, and thus to purify the atmosphere. The toolsee plant, or *Thymus capitatus*, is in India held to exert this power to such a degree that it has become sacred to Vishnu, that is, the preserving principle. Other plants have more or less the same character, as the cherry laurel (*Cerasus lauro-cerasus*), although both its

* From a paper on the "Hygiene of Malaria," published in the *Medical Press and Circular*, March 4 and 11, 1874.

flowers and fruit contain, as is well known, a poisonous principle; so also with cloves, lavender, mint, lemon, heliotrope, hyacinth, and narcissus, although the odour from the latter is, under certain circumstances, capable of producing unpleasant effects. Certain prepared perfumes, similarly exposed to the sunshine, add further to the atmospheric stock of ozone—the well-known eau-de-Cologne, for instance, oil of bergamot, extract of mille-fleurs, essence of lavender, and some of the aromatic tinctures. The oxidation of certain essential oils obtained from plants and flowers, such as the oils of nutmeg, aniseed, thyme, and peppermint, is likewise indicated as a source of ozone, though the supply of this aërial condiment is, in the case of these, less considerable. Perhaps, indeed, the influence of such natural destroyers of malaria are less studied and willingly recognized at the present day than they were in former times. In past ages there appear to have been instances of a sort of instinctive resort to certain plants as disinfectants. Herodian relates that during a plague in Italy, in the second century, strangers crowding to Rome were directed by the physicians to retreat to Laurentum (now San Lorenzo), a place so-called from the abundance of *Laurus nobilis*, or sweet bay tree, which then grew there, and by inhaling the odour of which they would in a certain measure be guarded from infection. And long before the time alluded to the disciples of Empedocles had been accustomed to plant aromatic and balsamic herbs in the neighbourhood of their dwellings, in the confident belief that by so doing they were providing means of defence against fevers, etc. To this day we have the name of "feverfew" as the appellation of one of the strongest scented compositæ, with traditions of its abounding febrifugal powers; and it may be added, "if we are wise we shall imitate the citizens of Laurentum, and promote the growth of bay trees wherever the soil and climate will allow them to flourish." Besides all these, some resin-yielding and aromatic plants have the reputation of destroying malaria. There is reason to believe that several species of the natural order *Myrtaceæ* possess this property besides the *Eucalyptus globulus*. Of late years this plant has obtained a high reputation for its assigned power, and some writers have recommended its introduction with a similar object on the Gold Coast. Various examples of its success in Algeria are recorded. At Pandook, on the banks of the River Hamyze, fever was extremely prevalent. In 1867 several thousand plants of the eucalyptus were introduced, with the immediate result of rendering the locality healthy. A similar result was obtained at Ben Machydon and Gue de Constantine, in the island of Corsica, in Cuba, in the Australian Colonies, at the Cape of Good Hope, and other places. Probably other trees which yield aromatic gum resins would have a similar effect, and it is not known that malarious diseases prevail in places where trees of the natural order Coniferæ grow abundantly.

Various other plants have obtained a reputation as being capable of destroying "malaria," or at any rate rendering that influence innocuous. Thistles had rendered some parts of the campagna near Rome healthy, and on the plants being cut down, those districts became again "malarious." Sunflowers appear to have been first planted for a similar purpose in America, and in that country they are said to have been so successfully. Baron von Alsten, whose property was situated on the banks of the Scheldt, and liable to be flooded by that river, planted several patches of the sunflower (*Helianthus*) near his house, and with the result that for ten years his family continued exempt from fever, while in other properties, where no similar precaution was taken, this disease continued to prevail. The plant has of late years been sown in the Mauritius for a similar purpose, and in further recommendation of its good qualities, the observation has been made that it yields 40 per cent. of good oil; that the leaves from it are excellent fodder, and the stems being rich in saltpetre, make good fuel. Marshes may also be rendered healthy by the presence of other plants. Among those that conduce to this happy result is the *Pistia Stratiotes*. In India, the West Indies, and Africa, the power exerted by this plant in absorbing the deleterious gases of muddy marshes is well known, and probably it is on this account that in the latter country the plant is held sacred. The *Pistia* is believed to possess this power in a greater degree than any other plant, being capable in a few days of rendering stagnant water sufficiently pure for fish to live in; although it by no means follows that the water is thus rendered suitable for use by man. The contrary is indeed the case. In Jamaica, water in which this plant grows, acquires so acrid a character as to give rise to intestinal fluxes in those who use it.

Some trees and tree-like plants have, with greater or less reason, the reputation of themselves evolving malaria, and consequently the natives of the countries where they grow avoid sleeping or resting under them at night. Those that give off their branches at an inconsiderable distance from the ground, or the foliage of which is dense, have this reputation in the highest degree, and among them the tamarind and *neem* trees (*Melia azadarachta*). A similar influence is said to arise from the papaw tree (*Carica papaya*), and Dr. Livingstone states that in East Africa, near the Zambesi River, tracts are covered with the plant *Pœderia fœtida*, a member of the *Guettardæ* group of the Rubiaceæ. Many people suffer inconvenience in various ways from odours arising from certain plants, although the effects are not in the nature of disease of recognized malarial origin. In these cases the matter evolved, so far from being an invisible *aura*, is a substantial exhalation. Thus, besides the unknown effects of ipecacuanha in inducing sickness in certain persons, even when brought no nearer to them than an adjoining room, and flowering plants, in producing "hay-asthma," nausea, sickness, and even death, has been attributed to the odours of some, as the *Narcissus* and the *Cheiranthus*, or wallflower, not to mention the fraction of truth there no doubt is in the story of the upas tree (*Antiarus toxicaria*). The manchineel tree (*Hippomanæ mancinella*, N. O. *Euphorbiaceæ*) of the West Indies, and certain American and Chinese species of *Rhus* (N. O. *Anacardiaceæ*) not only produce severe irritant effects upon the skin, but affect very severely such persons as are predisposed to suffer from malaria. The flowers of the *Daphne Mezereum* also evolve odours which are more or less injurious to particular persons, and a similar property is attributed to the oleander (*Nerium Oleander*). The mangrove, or *Rhizophora*, has ever had an unenviable notoriety, on account of the malaria-producing properties assigned to it. As a rule, probably without exception, localities where this plant flourishes being for the most part marshes and low lying tracts, liable to inundation, are notoriously unhealthy, but in all probability this reputation arises altogether from paludal causes rather than from the plant itself.

ABSORPTION OF AMMONIA BY THE AËRIAL PARTS OF PLANTS.

A point of considerable practical importance to agriculturists has recently been investigated by M. Adolf Mayer, of Wiesbaden, viz., whether the aërial parts of plants have the power of absorbing ammonia or not. He carried out a series of experiments on plants, which were grown in such a manner that access of ammonia through the roots was prevented, while the leaves were subjected to the influence of this substance in either a gaseous or dissolved condition. The upshot of his experiments was that a variety of plants subjected to these conditions all had the power of absorbing carbonate of ammonia by their aërial parts, both in the gaseous and the dissolved state, and of employing it in the building up of their tissues. The plants, however, did not appear to thrive when all access of ammonia through the roots was prevented. The experiments did not indicate that plants belonging to the order Leguminosæ have any special aptitude for absorbing ammonia through their aërial organs, nor for assimilating the combined nitrogen of the atmosphere.

The Pharmaceutical Journal.

SATURDAY, MARCH 28, 1874.

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

ADDITIONS TO THE BRITISH PHARMACOPŒIA OF 1867.

IN announcing last week the publication of a reprint of the British Pharmacopœia, together with the addendum to which reference has several times been made in this journal, we contemplated entering upon a critical discussion of the new additions to the Materia Medica as well as the preparations of the Pharmacopœia, but having in the meantime learnt that this matter was to be specially brought forward at the evening meeting of the Pharmaceutical Society next week, under conditions most likely to ensure a thorough discussion of the various features of interest, we shall at present confine our remark to a bare enumeration of the articles and preparations included in the "Additions to the Pharmacopœia." The subject is to be brought before the Pharmaceutical Society, next Wednesday, with the advantage of practical illustration by specimens of all the preparations, and it does not appear to be advisable to attempt to forestal in any way the free expression of opinion on that occasion by practical pharmacists upon a book in which they are so largely interested.

The first addition on the list is another ether, Æther Aceticus, as being one of the most agreeable compounds of its class. Then Ammoniæ Nitras, as a source of nitrous oxide; Amyl Nitris, and Aqua Chloroformi follow. The claims of Chloral Hydras are recognized by a place, and it is stipulated that it shall be in colourless crystals, a form in which it is now prepared in considerable quantities on the continent. There is also a Syrupus Chloral. There are as many as four phosphorus preparations; two hypophosphites, Calcis Hypophosphis; and Sodæ Hypophosphis, Oleum Phosphoratum, a solution of phosphorus in almond oil and Pilula phosphori, in which the excipients are balsam of tolu and yellow wax. A precipitated peroxide of mercury is added under the name Hydrargyri Oxidum Flavum; as well as oxide of bismuth, Bismuthi Oxidum, prepared by precipitating subnitrate of bismuth with caustic soda.

A solution for hypodermic injection now makes its first appearance among the official formulæ, in the shape of Injectio Morphiæ Hypodermica, containing one grain of the acetate in twelve minims of the injection. Three new suppositories bring the total number of these preparations up to seven; the new comers, are Suppositoria Acidi Carbolici cum Sapone, Suppositoria Morphiæ cum Sapone, and Suppositoria Acidi Tannici cum Sapone. The first of the three are entirely new to the Pharmacopœia, and are to be made with curd soap and starch; the latter two resemble those previously official, the vehicle of lard, wax, and theobroma butter being replaced by one of glycerine of starch, curd soap and starch, the introduction of soap being intended to obviate the inconvenience hitherto experienced by the soiling of linen by the melting of the fat. This has necessitated the introduction of another soap, Sapo Animalis, or curd soap, which is also ordered in a new pill, Pilula Scammonii Composita, that has been introduced to supply the want of an authorized formula for a purgative pill without aloes. Curd soap is also recommended in the place of hard soap in Linimentum Potassii Iodidi cum Sapone. A Charta Sinapis brings in its train Gutta-percha and Liquor Gutta-percha. There is an Extractum Glycyrrhizæ Liquidum, containing one-ninth of its volume of rectified spirit, and also a Pulvis Glycyrrhizæ Compositus, composed of powdered senna, liquorice, and sugar, differing from the analogous preparation in the German Pharmacopœia in the absence of fennel and sulphur. Another powder is Pulvis Elaterii Compositus, in which one part of elaterium is diluted by nine parts of sugar of milk. Two more juices are added, Succus Belladonnæ and Succus Hyoscyami, similar to the juice of hemlock, previously in the Pharmacopœia. The Liquor Magnesiæ Citratis is quite a novel feature, and contains 200 grains of citric acid with 100 grains of carbonate of magnesia and 40 grains of bicarbonate of potash to the half-pint.

There are three fresh additions to the vegetable Materia Medica—Areca, the seed of the betel-nut tree, which is introduced as a vermifuge; Aurantii Fructus, required in the preparation of Tinctura Aurantii Recentis; and Laricis Cortex, the bark of *Larix Europæa*, D.C., deprived of its outer layer, of which a Tinctura Laricis is to be made with rectified spirit. Another new tincture is Tinctura Quiniæ Ammoniata.

Finally, there is now an official formula for the preparation of Pepsin. It is described as a preparation of the mucous lining of a fresh and healthy stomach of the pig, sheep, or calf. It consists of the viscid pulp which is to be obtained by scraping the cleansed mucous membrane with a suitable instrument, then spread upon a glazed surface and dried at a temperature not exceeding 100° F.

In speaking of these additions to our national Pharmacopœia above enumerated, the *Lancet* expresses the tolerably safe opinion that they at least afford a promise of comprising some valuable matter. With equal discretion, it adds that if the practical knowledge and judgment displayed in preparing the previously published part of the work have also been exercised in this part of it, the profession will be

indebted to the Medical Council, and to the Pharmacopœia Committee for their labours in this direction.

The *Medical Press and Circular* does not think much of the additions, and is not impressed with their importance. As regards most of them it has nothing to say, but it condemns phosphoretted oil as being a bad mode of administration, and as to the phosphorus pill, it has doubts whether the formula will be liked, or whether prescribers will not prefer the products of those who have made these pills popular.

The comments are sufficiently meagre, and the other medical journals have as yet said nothing on the subject.

THE SHOP HOURS REGULATION BILL.

A HOBBY horse always appears to be an awkward steed to dismount from, and therefore it will not occasion much surprise to hear, thus early in the session, that Sir JOHN LUBBOCK is announced to be ready with a successor to the Shop Hours Regulation Bill, so ignominiously shelved last year without even a second reading. On this occasion, Sir JOHN is stated to have "taken counsel with some of the parties on whom the proposed law would operate, including a number of the retail tradesmen of the metropolis." If this be so, it would be interesting to know upon what principle of selection these representative tradesmen have been chosen, for, although the step itself might be a wise one—even if rather tardy—the alleged result is startling, namely, that with certain exceptions, "especially in reference to the provision trade," the Bill will require that all shops shall be closed at eight o'clock in the evening!

Whether the wisdom of the concoctors of this latest specimen of "harassing legislation" will include dispensers of medicines amongst the certain exceptions in the provision trade, or will give them a special exception of their own, we scarcely care to inquire, for the innate absurdity of such a system of special exceptions is obvious, in view of the composite nature of many businesses in country districts. Either an "excepted" shopkeeper will be able to sell any article in his shop after the hour at which his neighbour is compelled to close, and thus give rise to endless evasion of the law, or else he will require a legal adviser constantly at his elbow to caution him as to tabooed articles.

The object of the Bill—the shortening of the hours of labour—is one which has our hearty sympathy; and it is because we wish to see this movement go forward that we are anxious to see nipped in the bud compulsory legislation that would bear such disastrous fruit. Much has already been done, without compulsory legislation, towards earlier closing, and we believe that with a more confident reliance upon the good feeling of the public much more might be done in this respect. An appeal recently put forward by the Early Closing Association, based on the assumption that the people of this country have generous instincts, and would not consciously be guilty of cruelty, is sound in principle, and one that might be more generally asserted. At any rate, now that the country has pronounced so decisively against the professional promoters of this kind of legislation, it ought to be possible to deal summarily with all such amateur attempts.

AMONGST the bills which have been introduced into the new House of Commons, is one to consolidate and amend the law relating to Juries, brought in by Mr. LOPES, which is set down for second reading on Wednesday, April 22nd. Mr. NORWOOD has also again brought in a bill to provide for the registration of certain firms carrying on business in the United Kingdom.

A CORRESPONDENT informs us that a new kind of spurious sovereign, made of platinum and electroplated with gold, is being put into extensive circulation. This spurious coin bears the date of 1856. It is not deficient in weight, but gives a dull, heavy ring, by which it may be distinguished from the genuine sovereign.

REFERRING to a statement made at the commencement of Dr. WATT'S lecture on Ozone (reported at p. 723) we are informed by Dr. J. E. DE VRIJ that the Teyler Museum is not to be found at Geneva, but in Haarlem, a town in North Holland, celebrated to English tourists for its organ and a fine collection of pictures.

ON Saturday last a petition was presented in the House of Commons from Darlington, praying that restrictions might be placed on the production of Opium in India.

THE last Evening Meeting of the Pharmaceutical Society, during the present session, will be held on Wednesday next, April 1st. On that occasion specimens of preparations in the Additions to the British Pharmacopœia will be placed on the table by Mr. C. UMNEY, and discussion thereon will be invited. The following papers are also announced:—'Dispensing Note on Chloromercurate of Morphia,' by Mr. W. MARTINDALE; and 'Some Notes on Materia Medica,' by Mr. E. M. HOLMES, the Curator of the Society's Museums. Dr. J. E. DE VRIJ, who intends visiting London, will make some observations on Tincture of Perchloride of Iron. We think it matter for congratulation that the efforts of the President have resulted already in so great an improvement in the list of subjects announced previous to the meeting. The Chair will be taken as usual at half-past Eight o'clock.

NOTICE.—In consequence of the occurrence of Good Friday in the ensuing week, it is necessary that the next number of the PHARMACEUTICAL JOURNAL should be published on Thursday. As this will require our going to press on the previous day, it will not be possible to publish the reports of the meeting of the Council and the Evening Meeting until the following week.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN EDINBURGH.

March 17th and 18th, 1874.

Present (17th): Messrs. Buchanan, Gilmour, Kemp, Noble, Tait, and Young.

(18th): Messrs. Ainslie, Buchanan, Gilmour, Kemp, Noble, Tait, and Young.

MAJOR EXAMINATION.

One candidate was examined, and declared qualified to be registered as a Pharmaceutical Chemist:—

*Graham, William Woodrow ...Dalbeattie.

MINOR EXAMINATION.

Twenty-three candidates were examined. *Fourteen* failed. The following *nine* passed, and were declared qualified to be registered as Chemists and Druggists :—

*Mackay, James Bunyan L. .....Edinburgh.
*Murray, Robert Dalzell .....Edinburgh.
Farquhar, James .....Aberdeen.
Wells, William .....Chorley.
Dunlop, Thomas Hall .....Newcastle-on-Tyne.
Macdonald, Alexander.....Edinburgh.
Keen, Nimrod .....Birmingham.
Allan, William ....Edinburgh.
Foster, John .....Crieff.

The above names are arranged in order of merit.

MODIFIED EXAMINATION.

Two candidates were examined. *One* failed. The following passed, and was declared qualified to be registered as a Chemist and Druggist :—

Little, Robert .....Carlisle.

Provincial Transactions.

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

A conversazione of the members of the above Society and their friends was held in the Art Museum, Nottingham, on the evening of the 27th of February, by invitation of the President (Mr. Fitzhugh), and council.

The magnificent suite of rooms, containing rare and beautiful objects of art, partly local and partly from the South Kensington Museum, was well filled during the evening, upwards of 300 ladies and gentlemen being present, including a considerable number of the members of the medical profession.

A number of microscopes were kindly lent by members of the Society and others, which added much to the brilliancy of the scene and to the amusement and instruction of the guests.

Arranged on tables and cases in convenient places, in the rooms were some magnificent specimens of drugs, chemicals, and chemical and pharmaceutical apparatus kindly lent for the occasion by friends and well wishers to the Association.

The most attractive of the numerous specimens exhibited were a fine collection of rare chemicals, and rare specimens of Materia Medica, from the Museum of the Pharmaceutical Society, kindly lent by the Council.

A beautiful case of models of genus, by Dr. Attfield.

An album of photographs of eminent pharmacists in America, from Dr. Attfield on behalf of the Pharmaceutical Conference.

Some fine specimens of drugs, from Messrs. Barron, Harvey, and Messrs. Hearon, Squire and Francis, London. In the collection of the latter firm were fine specimens of true and false pareira root.

Beautifully mounted chemicals, and a set of Chinese pictures, illustrating the career of an opium smoker, by Messrs. Morson and Son.

Chemical and Pharmaceutical preparations, from Messrs. Hopkin and Williams.

Beautifully mounted specimens of the Platino-cyanides and other rare chemicals.

Collection of platinum vessels and instruments, by Messrs. Johnson, Matthey and Co.,

Fine collection of true and false cinchona barks and alkaloids, with a number of bottles of sulphate of cinchonidine for distribution amongst medical men.

Also beautiful crystals of borax, citric and tartaric acid, by Messrs. Howard and Son.

(These specimens have been kindly presented to the Museum of the Association, by Messrs. Howard and Son.)

A large number of medical and pharmaceutical appliances, by Messrs. Maw, Son and Thompson, and Lynch and Co., London.

A rotary pill machine, Mr. Robert Jackson.

Model of Goodall's grinding and sifting apparatus, Mr. H. Goodall.

Chemical apparatus, Messrs. Mottershead and Co.

Many fine specimens of drugs and chemicals from the Museum of the Nottingham and Notts Chemists' Association.

Besides the objects provided for the intellectual amusement and instruction the more material interests of the guests were not neglected. Mr. Lomas, excelled himself in his admirable supply and conduct of the refreshment room.

A fine band added to the delight of the largest assembly of chemists and their friends ever held in Nottingham.

* Passed with Honours.

Proceedings of Scientific Societies.

NEW YORK COLLEGE OF PHARMACY.

At the meeting of the New York College of Pharmacy, on February 12, 1874, a lecture was delivered on—

The Application of the Microscope in Pharmacy and the Drug Trade.

BY FREDERICK HOFFMANN, PH.D.

I have been invited to address you this evening on the usefulness of the microscope in pharmacy and the drug trade. As so vast a subject cannot be treated in a single lecture, to any satisfactory extent, I have concluded to confine myself to the most important application of the microscope in our profession, viz., to its use in the examination of crude drugs, and to illustrate this less by a lecture than by the exhibition of specimens of a number of microscopical preparations. Before doing so, I deem it proper to offer a few remarks on the causes which have brought the microscope more and more into use in the drug trade.

It is a well-known fact that the achievements of the physical sciences, and their practical application to the pursuits of industry and commerce, have caused remarkable changes in many branches of the arts and trades, and that they also have exerted a considerable influence upon the scope and drift of the drug trade and of pharmacy. The pharmaceutical laboratory of yore has gradually passed away, and in its stead the establishments of the manufacturing chemist have risen to supply the medicinal chemicals and most of the pharmaceutical preparations; the pharmaceutist is not any more a manufacturer but mainly a dispenser, the responsibility only for everything that he dispenses is left to his share, and consequently the duty of critical scrutiny and discrimination of the preparations of the chemical manufacturer, and of the products of nature as supplied by the commerce in drugs.

These gradual changes in the sphere of his occupation have naturally exercised a correspondent alteration in the practical and scientific requirements of the pharmaceutist. Although one of the most interesting parts of his former practice has been taken out of his hands, the pharmaceu-

tist has not lost ground in the compass of his attainments; it is the critical exercise of knowledge and skill in the direction of scrutiny and discrimination which forms the pre-eminent requisite of the modern pharmaceutist, and which extends his professional qualification and efficiency; or, in other words, it is nowadays of less importance to the pharmaceutist to acquire a practical skill of manufacturing medicinal chemicals, or to know exactly the therapeutical action of drugs, than to have a precise knowledge of their characteristic properties and the ability of ascertaining their identity and qualities.

This change in the pursuit of the pharmaceutist is also evident in pharmaceutical literature. The number of treatises on chemical, as well as on pharmacognostical and microscopical examinations, increase from year to year; while those treating of the methods of manufacture lose in ratio and pre-eminence. Moreover, the most advanced pharmacopœias of the present day have ceased to describe or to prescribe the methods of preparing medicinal chemicals, and confine themselves to concise descriptions of the characteristics of medicinal substances, and of the modes of establishing their identity and ascertaining by approved tests their quality and purity.

The consequence of these changes in the province and drift of pharmacy is the obvious fact that analytical chemistry and pharmacognosy, and the application of the microscope, have taken a foremost rank among the necessary attainments of the pharmaceutist, and have also largely engaged the interests of the druggist, so that the test-tube and the microscope are becoming more and more indispensable implements in every well-conducted pharmacy and druggist's establishment.

While chemical analysis is particularly adapted to the examination of the products of chemical industry, and to the estimation of the value of the drugs, the microscope renders great service in the investigation and identification of all organized substances. We ascertain by chemical tests the value of cinchona barks, of opium, of nux vomica; they furnish a sure evidence of the presence and the proportion of the alkaloids in those drugs, and of organic acids, of sugar and the various vegetable principles in other drugs, but they fail to disclose their nature and structure. Now it is precisely in this branch of investigation that the microscope affords much aid, and the advantage of prompt application and speedy results; it discloses at once the anatomical structure of a drug, the peculiarity of any kind of starch, and thereby the plant from which it was derived; it indicates directly if the bark which is offered to the manufacturer of quinine is really cinchona bark, and, consequently, if it is worth the trouble of a chemical assay for the percentage of alkaloids. It decides promptly the derivation and genuineness of sarsaparilla, of ipecac, of jalap, and of most barks, roots, and vegetable drugs, and the quality of all those powdered substances which are liable to adulteration with starchy flours. The microscope, therefore, is an invaluable aid in their examination and in the discovery of adulterations, and, as indicated with the cinchona barks, it may also frequently be made to serve as an auxiliary to chemical researches. While chemicals are always uniform and the same in composition and properties, many of the crude drugs greatly vary, not only in appearance and form, but also in their qualities, resulting from their derivation, from the conditions of growth or cultivation, from the modes of their gathering and preparation for preservation, and other natural or incidental causes.

These few remarks will be sufficient to introduce to you the true significance and the value of the microscope; they will at the same time indicate the important influence which this instrument has exercised upon the progress of pharmaceutical materia medica, and to what an extent it has contributed to a better knowledge of crude drugs, and to correcter methods in their discrimination. The more or less vague, empirical criteria of mere external appearances, in their recognition and estimation, have lost ground by the microscopical methods of investigation, and in their stead the nature and relation of the internal structure and constitution have furnished a rational and scientific foundation for the classification of drugs and for the science of pharmacognosy, which stands to materia medica about in the same relation that chemical analysis bears to general chemistry.

It will be my aim to endeavour to demonstrate these facts, as far as possible, by illustrations of a selection of microscopical preparations; they will best explain the nature and the character of this mode of examination of drugs. In order, however, to understand these illustrations, and to avoid explanation in each particular instance, I had better describe, at the outset, in few words, what and how we observe through the microscope, as applied to our purposes. It is principally the anatomical structure of plants, and those parts of plants which furnish drugs, that now engage our interest and investigation, inasmuch as it affords the general as well as the special criteria for the discrimination and determination of the vegetable drugs.

Although vegetable architecture, in regard to its elementary organs, is the same in all plants, yet it shows in the nature and order of its structure differences so great that they are the ultimate causes of the almost infinite varieties in size, form, and appearance which we observe in the vegetable world; they also afford the basis and the principal features for the science of structural botany, and for the classification of plants.

Plants, as is well known, are built up by minute elementary organs called cells; they consist of an outer transparent and colourless membrane, or wall, composed of a substance called cellulose, which envelops the cell contents, mostly semi-liquid or liquid fluids that contain in suspension various substances formed by the physiological processes going on in the living plant—for instance, chlorophyll, oil-drops, starch, crystals, etc. Although the cell walls have no pores which admit the circulation of the alimentary saps, yet in obedience to a physical law, the sap permeates the cell walls, and insures in this way the vital circulation and the assimilation of the nourishing fluid throughout the cellular tissue and the body of the entire plant.

In the processes of growth and accumulation the cells experience different changes and transformations; they propagate by multiplication or partition, and are not only accumulated to build up the cellular tissue, but also frequently enlarged and transformed into tubes, fibres, and vessels, forming vascular and woody tissue. The primitive as well as such modified cells and vessels continue during the vital processes to increase and to thicken the substance of their membranes by inward deposits of cellulose, either in a continuous lining or in interrupted layers around the cell walls. In the first instance the cell walls in older parts of plants become more or less substantial and harder. Such cellular or woody tissue appears, upon a cross-section, under the microscope, as a uniform, often almost solid, skeleton; in the second instance the section, especially in a longitudinal direction through the body of the plant, shows the cells or vessels with markings of different appearances, in the shape of annular or spiral rings or bands, or of dots or apparent pores; they arise from the unequal distribution of these secondary deposits, and are portions of the cell walls which are either thinner or thicker than the rest, and which lay often apart from the cell wall, and protrude when this is broken.

As the life phenomena of the plant are the sum of the physiological processes of the cells and vessels which compose it, so is the strength and substantiality of the cellulose skeleton the cause of the different degrees of cohesion and density, of tenderness and hardness, of elasticity and brittleness, which we meet in infinite variety in vegetable structures. Although all these differences of organization and construction are more or less manifest to the unaided eye, yet their minute structure becomes in a far higher degree visible when observed through the microscope.

Since, however, only transparent objects admit a distinct observation by transmitted light, only thin, flat sections of the substance or body of specimens can be submitted to microscopical examination. These cuttings may be made in different directions, either perpendicular or parallel to the axis of the plant, or parts thereof. In the first instance we obtain transverse, in the latter longitudinal (radial and tangential), sections.

Such microscopical objects are best observed when immersed in a drop of water upon a glass slide; by using glycerine or other antiseptic fluids, instead of water, such preparations may be preserved as standard objects for future reference or comparative observation; they are in that case covered with thin glass covers, the edges of which are cemented upon the slides with varnish.

In this way the specimens are mounted. They are in their natural condition, and are thus best adapted to scientific observation and study. The appearance and contour of such specimens can, however, readily be made more conspicuous by the application of dyestuffs, such as aniline dyes, tincture of fernambuc or of iodine, ammoniacal solution of carmine, oxalic acid, solution of Prussian blue, etc.

The lecturer now demonstrated the structure of the fruit (carpels) of the parsley family (Umbelliferæ) and exhibited upon a screen by the aid of an oxyhydrogen microscope illustrations of transverse sections of a number of fruits of that family, and explained the characteristics which furnish the criteria for discriminating these fruits from each other, and of ascertaining at once the species from which they are obtained; among them were cross-sections of the fruits of fennel, anise, caraway, parsley, water hemlock, spotted poison hemlock, etc.

The transverse sections of a number of medicinal seeds were exhibited and explained; among them seeds of almonds, flax, mustard, poppy, colchicum, nutmeg, coffee, nux vomica, etc. In several of them, as for instance with mustard, the lecturer called attention to the absence of starch granules in their cellular tissue, which fact furnishes prompt evidence of the purity of their powder from any adulteration with starchy flours.

These were followed by the seeds of the grass family, which are not only the principal supply of vegetable food for men and the domestic animals, but whose flour and starch have, to the pharmaceutist and druggist, the additional interest of being occasionally met with as adulterants of powdered drugs. The lecturer illustrated and explained the general structure of the fruit (caryopsis) of the grass family, and the special characteristics in the anatomical structure of their seeds, and in the shape and size of the starch granules of the most important cereals; beside transverse sections of all the grains most used in domestic economy, he exhibited microscopical illustrations of their flour and starch. The epidermis of most of the grains of the cereals is coated with an exceedingly thin silicious cuticle, which protects the grain greatly against the access of air and humidity, and to which coating the fact must be attributed that unbroken grains of wheat, rye, barley, and other cereals withstand the action of the gastric juices in the processes of digestion, and that wheat grains are said to have been found in the dry air of Egyptian tombs, undecomposed, after the lapse of thousands of years.

Transverse sections of the seeds of beans, peas, and lentils were also illustrated, and microscopical specimens of their flour. These were followed by illustrations of the different starches which furnish arrowroot, as well as of those which have been found as substitutes or adulterants. The magnifying power of the stereopticon, however, was insufficient to bring out the starches with enough distinctness, and failed to disclose the nucleus or fissure, and still less the delicate concentric layers or markings which in many starches surround them, and are peculiar and characteristic to the starch granules of various plants, and which indicate the mode of their formation, and, in common with the shape and size of the granules, furnish the criteria for their distinction and derivation.

In connection with starches, the sporules of the club moss (*Lycopodium clavatum*, L.) and another adulterant of the same, *Pinus* pollen, were exhibited and briefly described, and subsequently the glands of the strobiles of hops and of the capsules of kameela.

In passing to microscopical specimens of medicinal roots, woods, barks, and parts of the central axis of plants, the lecturer gave a concise and lucid exposition of the anatomical and structural organization, and of the growth of the phanerogamous plants, and of the fundamental differences which form the principal characteristics for their division into two great classes, the inside growers or Endogens (Monocotyledons), and the outside growers, or Exogens (Dicotyledons). The descriptions were illustrated by transverse sections of an endogenous and exogenous stem.

Subsequently a number of medicinal roots and their substitutes and adulterants were exhibited and explained in transverse, radial, and tangential sections; among them liquorice, burdock, belladonna, seneka, dandelion, chicory, rhatany, valerian, several of the snake roots, ipecac, and the root of *Psychotria emetica*, the tubers of *Aconitum napellus* and *Aconitum stoerkianum*, and Russian or Turkey rhubarb, and Chinese or East India rhubarb.

During the illustration of the microscopical specimens of the roots, the protector, and subsequently one of the lenses of the stereopticon, broke, by the continuous and intense heat of the calcium light, and in consequence the lecturer confined the further portion of his lecture to a brief statement of the subjects which composed the remainder, and which he had prepared and arranged for illustration and description, namely, ten specimens of sarsaparilla roots as met with in American and European commerce; specimens of a number of medicinal barks, and of a series of twenty-one cinchona barks, all in transverse, radial, and tangential sections.

The lecturer then said that he had confined the subject matter of his lecture to the application of the microscope in the examination of crude drugs only, but that in concluding he would not pass by without referring briefly to another important use of the microscope within the sphere of the pharmaceutist, namely, to its application, in urinary and similar pathological examinations, as well as in forensic investigations, and the discovery of trichinæ spiralis in animal muscular tissue, especially that of pork.

He continued—I stated in my introductory remarks that the microscope has added an important method of scrutiny and research, and thereby greatly extended our knowledge of crude drugs, and that it is destined to have an increased usefulness in pharmacy, and still more in the drug trade. I trust that these few illustrations, however inadequate my explanations have been, have sustained the truth of that assertion, and that they have demonstrated to you the nature and the value of microscopical investigation, and at the same time the fact that this instrument, which has so largely contributed to the extent of human knowledge, and to a fairer conception of the constitution of the organic world, has lost to the pharmaceutist and the druggist the mere capacity of occasional usefulness and interest, and that in the examination of drugs, and many articles of commerce and domestic economy, it is an indispensable implement, and is second in importance only to the test-tube, the burette, and the balance.

I hope these illustrations may tend to secure a greater appreciation of the value and usefulness of microscopical examinations, and to invite your interest to a closer study of the most interesting branch of materia medica, to pharmacognosy, which now is the fundamental science of the druggist. The time is not far off when the more general application of the microscope in the service of pharmacognosy will place the principles and methods of the wholesale drug trade of our country upon a more scientific basis, and raise it beyond the level of a mere empiric

business of routine. In consideration of this fact it is, therefore, with a sense of appreciation and good-will that I avail myself of this opportunity to urge, upon druggists in particular, a practical application of the subject-matter of my lecture. Notwithstanding all its commercial interests and relations, the wholesale drug trade participates also largely in the results of science, and has derived during the last decades a beneficial impulse from the progress and the achievements of chemistry and the microscope. It cannot have a better guide in the problems which it has constantly to meet in the contingencies and fluctuations of commerce and industrial competition. Moreover, as the resources of knowledge widen, and facilitate the means of deception and imposition of every kind, they afford, on the other hand, the certain safeguard to protect the purity and the character of the drug market, and to secure and maintain its high standard.

It is, therefore, a growing necessity of our time that the drug trade should more and more raise the requirements and the range of its pursuit, and embrace and utilize the resources and the power which science abundantly offers. Even those who feel but little interest for science, and encounter it with the commonplace questions, "Of what good is it?" "Does it pay?" cannot but admit that scientific attainments are a profitable investment nowadays.

The tendency of our time is largely in favour of science and knowledge, as the most rational foundation for all pursuits of human labour and enterprise. They will, in our calling likewise, maintain their undisputed prerogative, as the certain guide to ascendency and victory over empiricism.

CHEMICAL SOCIETY.

Thursday, 19th March, 1874. Professor Odling, F.R.S., president, in the chair. After the ordinary business of the Society was completed, the President called on Professor Dewar to deliver his lecture on Dissociation. The lecturer premised that as he had but little that was new to tell, he must content himself with condensing and epitomizing the results of others. After briefly referring to the theories of Priestley and Hutton, he described the famous experiments of Sir James Hall, who obtained a substance identical with marble, by fusing carbonate of lime, under pressure. He next noticed Grove's discovery that water was decomposed at a lower temperature than that produced by the union of oxygen and hydrogen, and then explained the masterly researches of Deville on the effect of heat in causing the dissociation of carbonic anhydride, carbonic oxide, water, etc. After this, the lecturer showed that in dissociation the tension of the vapour evolved is constant for a given temperature, and independent of the mass, illustrating it by Debray's experiments, on the decomposition of carbonate of lime at a regulated heat, and the evolution of water from certain hydrated salts. The lecture, which was illustrated with diagrams of various curves of tension, concluded with some remarks on the dissociation of the compound of hydrogen and palladium, and with a description of an apparatus devised by the speaker for ascertaining the temperatures produced by the explosion of a mixture of oxygen and hydrogen under various pressures. The meeting then adjourned until Monday, 30th March, the Anniversary Meeting. The next General Meeting will be on Thursday, 2nd April, when the following papers will be read:—1, "On Sulphocyanide of Ammonium and Sulphocyanogen," by Dr. T. L. Phipson; 2, "Note on a Reaction of Gallic Acid," by Mr. H. R. Procter; 3, "On the Cobalt Bromides and Iodides," by Mr. W. N. Hartley; 4, "On the Distillation of Sodium Ricinoleate," by Mr. E. Neison; 5, "On the Solubility of Plumbic Chloride in Glycerine," by Mr. H. Piesse; 6, "On Ozone, as a Concomitant of the Oxidation of Essential Oils," by Mr. C. T. Kingset; and three papers by Dr. D. Tommasi, on the Action of Benzyl Chloride on Camphor, and on the Alcohols, and on the Preparation of Organo-metallic Bodies of the Olefine Series.

SOCIETY OF ARTS.

The Paraffin Industry.

BY FREDERIC FIELD, F.R.S.

(*Concluded from page* 765.)

A second patent granted to R. M. Letchford and W. B. Nation, No. 890, A.D. 1872, comprises, say the patentees, two objects, first, economy in the materials and labour employed, and secondly, the freedom from danger arising from the use of paraffin oil in the usual methods of refining.

The process is conducted in the following manner:—

"We provide a tank, say about 12 ft. by 6 ft. and 2½ ft. deep, divided by cross partitions into V form cells 2½ inches wide at the top and 2 inches at the bottom. The cells are open at the bottom, as the partitions stop short at 2 inches from the bottom of the tank; their upper ends are 9 inches from the top of tank; there is a space of about 1 inch between cell and cell; there is a perforated lid or grating to fit into the tank resting on the top of the partitions. A grating with bars 1½ inches apart is suitable. We fit steam pipes (free or closed) into the tank below the partitions. In using this apparatus we run water into the tank to the depth of 6 inches and fill crude paraffin into the cells of the tank, and then secure the lid or grating to prevent the paraffin floating. We run more water into the tank to within 2 inches of the top, and turn on steam until the temperature of the water is within about 10° Fah. of the setting point of the paraffin under manipulation; then we shut off the steam to allow the heat time to permeate the material. In about one hour we increase the temperature, raising it gradually for about four hours to within 2° of the setting point of the paraffin that was put into the tank; then we shut off the steam and take off the soft portions which have floated to the surface of the water. This being done, we run the water off to the top of the divisions, then melt the remaining paraffin in its cells, and let it stand to cool all night. In the morning the steam may be turned on again to repeat the operation, which is done as often as necessary to obtain the purity and hardness required. It is rarely necessary to do so more than four times; or the process may be conducted by first melting the paraffin in the cells and then cooling to 2° below the setting point of the material. We then secure the lid, add more water, and float out the soft portions. In either way we finally remove the lid and take out the paraffin from which the low melting portions have been extracted; the low melting portions which have been removed are to be again treated like the crude.

"For obtaining fine degrees of whiteness, when the foregoing operations have been carried far enough, we remove the clean paraffin to a steam-jacketed pan, adding thereto about 7 per cent. of commercial ivory black in powder, and keep it melted for four or five hours, until the whole of the ivory black is precipitated. We then cast into cakes in the usual way; the ivory black may afterwards be used advantageously in making blacking."

There is one more patent which may be mentioned among a host of others (No. 3241, A.D. 1871, granted to Mr. Hodges):—

"The crude paraffin having, if desired, been first separated from rough impurities, is cast into cakes and allowed to cool slowly, so as to form into well-developed crystals. The cakes are then placed on a bed of absorbent or porous material, and are while thus placed exposed to a warm temperature, sufficient to render fluid the more easily melted portions with which the crystallized paraffin is mixed, but insufficient to melt the paraffin. The fluid and more easily melted portions then flow out from between the crystals of paraffin, and into, or into and through, the absorbent or absorbent and porous materials on which the cake rests. The cake—thus freed from the fluid, or fluid and more easily melted portions—may then be treated in any usual method to render it white, or as much lighter in colour as may be practicable; or the process may be repeated until the separation of the harder from the softer portions has been effected as completely as is desired, and then any requisite process for whitening the product may be adopted if needed."

It will be seen that all these processes have for their object the removal of the liquid from the solid hydrocarbons. It would be out of place to give one the preference

over the the other. Each of the patentees considers, doubtless, that his idea is the best.

The partially purified paraffin is by no means colourless, and upon closer examination will be found still to possess considerable smell. One method for its further purification may be thus described. Let us take, for example, this material obtained according to the patent of Mr. Fordred. After being melted by free steam to separate any water or alkali which may be machanically retained, it is poured into a tank and agitated by means of air, with from five to ten per cent. of strong sulphuric acid, the sulphurous acid evolved resulting from decomposition, is conveyed away by a suitable apparatus. The agitation is carried on for some hours, very much depending upon the nature of the paraffin, and the experienced manufacturer can easily tell when the desired result is effected. Here are various specimens before us of acidified cake, as it is termed, both before the tarry mass has subsided and after remaining at rest for some hours. It will be observed that that which is immediately drawn off is darker in appearance than that which has been allowed to rest, containing as it does a large quantity of black specks, an aggregate of which is seen in the sample of tar in this dish. The best of these products is still, however, far from white, and the acidified paraffin has yet to undergo a further treatment. Animal charcoal, the substance previously mentioned as a bleaching agent, is generally employed. The paraffin is warmed and digested with the charcoal for some hours ; the latter is allowed to subside, and the liquid, if not quite bright, is passed through a filter kept warm by a steam jacket. But lately, other bleaching agents have been used which are deserving of notice.

A patent was granted to Messrs. Fordred, Lambe, and Sterry, in A.D. 1868, No. 610, for the use of fuller's earth as a decolourizer of paraffin and other bodies, an extract of which may be quoted—

"Fuller's earth we also use for finishing the bleaching of paraffin in lieu of animal charcoal, whatever the previous process of purification may have been. In that case about twelve per cent. powdered Fuller's earth is added to the melted paraffin, which is manufactured at a temperature of about 230° Fah., and well agitated, and after subsidence the clear paraffin is run off. We find that in all our processes, where we have mentioned Fuller's earth as the agent to be employed, we can replace that substance in great part or wholly by marl clay, or other readily-attainable natural substance of like character. The Fuller's earth or analogous substances used in place thereof in any of the ways stated above, may be re-used, and the paraffin remaining adhered may finally be recovered from it by washing with agitation or by other suitable means."

This process is so simple and expeditious that it may be shown as a lecture experiment, and while the earth is being added, and the paraffin brought to the required temperature, and the particles allowed to settle, I will proceed to notice another method of bleaching lately patented by Mr. Arthur Smith and myself, which in many respects obviates certain disadvantages that accrue from the use of Fuller's earth. Fuller's earth and many other natural silicates are undecomposible even by strong acids, although certain silicates of lime or magnesia on both these bodies are decomposed when the acids are concentrated, forming a gelatinous residue of silica and solutions of the basis. It occurred to us that, by forming artificial silicates and employing them, instead of the natural, as proposed in the previous patents mentioned, these compounds might be employed, and the paraffin or other hydrocarbons separated by the addition of very weak acidulated matter. We experimented with the silicates of lime, magnesia, manganese, iron, and some others, and although all answered admirably, we came to the conclusion that the magnesia salt was the best, a less amount being required to ensure the full bleaching action required. At the first glance, any of these substances, even the lime salt, seems too costly to admit of practical application, but this is not the case.

It is very important to mention that the success of this process depends upon the purity of the salt and the manner in which it is dried. If the gelatinous mass in that beaker were simply desiccated without previous washing, and the soluble saline body (in this case sulphate of soda) retained the porous structure, or whatever it may be of the silicate, would be, so to speak, stopped up, and all bleaching action impeded. And if the washed product were heated to redness, its decolourizing power would also be destroyed. It must be dried at 212° and no higher, and thus the far cheaper and simpler operation of fusing silica with dolomite is inadmissible; the resulting silicates would be valueless. Fuller's earth, which is simply ground, contains naturally a large quantity of water, and this substance also, if heated to redness, is of no avail in paraffin refining. And yet a more singular fact is this, that although we must have a hydrated compound, no bleaching action takes place until the water is separated. Melted paraffin, as far as my own experience extends, may be agitated either with fuller's earth or artificial silicate for any length of time, without any perceptible action, at a temperature slightly higher than its melting point. The colour seems to disappear when the water is driven off, as if it took its place, and could not be dissolved from the hydrocarbon, however long the operation might be extended. By this time, it may be hoped, you will be enabled to see the bleaching action of the Fuller's earth in the experiment which was prepared a short time back, and is now awaiting completion.

It must not be supposed that the bleaching action of the two substances that have just been discussed is confined to solid hydrocarbons. Paraffin oil is rendered water-white by digesting it at a moderate temperature, with either Fuller's earth, or an artificially prepared silicate. In conclusion, a few of the applications of this beautiful substance may be briefly enumerated. Independently of its chief employment as a source of artificial light, through the medium of lamps and candles, it has been advantageously applied for other purposes. It has been proposed to saturate gunpowder with melted paraffin, in order to retard its explosive action, if required; it having been ascertained that a smaller sized grain might be substituted for a larger, when subjected to this treatment. The powder is digested with the paraffin, and the excess of the latter is removed by steam heat. It is a non-conductor of electricity, and has been used extensively as an insulator, in electro-telegraphic science. It has also been employed, when dissolved in naphtha, as a preservative of stone and brick-work permeating the interstices of the mass, and repelling the action of wind and rain. When melted with india-rubber, it produces a good water-proof compound, which can be applied to wearing apparel. It has been used advantageously for polishing cloths, giving them a fine and smooth surface. Dr. Lawson Tate has made use of paraffin in surgery, employing it as a covering for splints in fractured limbs, with very considerable success. The laundress has discovered that by rubbing a small piece of paraffin on a warm flat iron, a beautiful gloss is imparted to linen, and the humble manipulation is much lighted by the ease and celerity with which the iron travels over the clothes, at the same time leaving no greasy stain in its track. The horticulturist has also found that paraffin, when mixed with bees-wax, can be excellently applied in the budding of roses, or the grafting of fruit-trees. Mr. Veally has shown that it is most useful in the preservation of beer barrels, preventing them from becoming foul ; and it would be difficult, at the moment, to narrate its many applications, or to speculate upon its future. As paraffin will not dissolve the aniline colours, it may be asked how the beautiful tints are produced which serve to embellish the candles you see before you. The colours are dissolved in stearic acid, which is afterwards diluted with the paraffin, the colour remaining in a mechanically suspended state. If a candle, slightly tinted, is melted, and the liquid passed through bibulous paper, the filtrate is white, and the dye remains on the filter.

The insolubility of certain colouring matters, especially

those from aniline, may be employed successfully in determining the freedom of paraffin from stearic or other fatty acids.

Petroleum and the mineral ozokerit, both closely identified with the paraffin industry, would each demand a separate lecture, and however pleasant it would be for me to speak about these interesting bodies, I feel that I have exceeded the time allowed me, and that your kind attention has already been exercised too long.

Parliamentary and Law Proceedings.

The Charge of Manslaughter against a Chemist and Druggist.

At the Devon Lent Assizes, in his charge to the Grand Jury, Mr. Justice Quain referred to the case of Samuel Goss, who was charged with the manslaughter of a woman named Yeo (see before, p. 193). His Lordship said that this was a case that required very careful investigation at their hands. It seemed that the prisoner was a chemist, carrying on business at Braunton, and he presumed that he was not a properly qualified medical practitioner. The woman Yeo had been suffering from a cancerous wound on her breast, and on consulting the prisoner as to what she ought to do, he appeared to have prescribed for her some solution with which he instructed her to rub the wound. She continued to apply the preparation for a considerable time up to within a short period of her death, and it afterwards transpired that the solution was a strong preparation of sulphate of zinc. The medical evidence was the only evidence that he had got before him, that having been taken at the coroner's inquisition. As far as he knew the case had not come before the magistrates, and the only testimony, therefore, that would be placed before the Grand Jury, would be that contained in the dispositions taken at the coroner's inquest in August last. In order to prove that the prisoner was guilty, it was not sufficient to prove that he had no medical qualifications, but it must be established that he had been guilty of criminal negligence in recommending to this woman a preparation which was most unfit for her under the circumstances. They must be satisfied that the preparation was a grossly improper preparation to apply to a wound of this kind, and upon that subject the evidence before them was silent. There was no medical evidence that went to that extent. In addition to that they must come to the conclusion that there was gross negligence—criminal negligence, arising from gross ignorance in treating such a case; nothing short of that would justitfy them in returning a true bill. The Grand Jury ignored the bill.

Obituary.

Notice has been received of the death of the following:—

On the 26th February, 1874, Mr. George William Sharples, Chemist and Druggist, of Central Beach, Blackpool. Mr. Sharples had been a member of the Phamceutical Society since 1870.

On the 26th January, 1874, Mr. John Carrick, Chemist and Druggist, of St. Mary's street, Edinburgh.

On the 8th February, 1874, Mr. William Wey, Chemist and Druggist, of Stonehouse, Devon.

On the 9th February, 1874, Mr. Michael Russel McLeod, Chemist and Druggist, of South College street, Edinburgh.

On the 6th March, 1874, Mr. Matthew Francis Jubb, Chemist and Druggist, of Chariot street, Hull.

On the 17th March, 1874, Mr. Edmund Temple, Chemist and Druggist, of Bristol.

On the 18th March, 1874, Mr. John Jackson, Chemist and Druggist, of Southampton Row, London.

On the 20th March, 1874, Mr. Frederick Pegler, Chemist and Druggist, of Lower Norwood, Surrey.

Review.

Adulterations of Food, with Short Processes for their Detection. By Rowland J. Atcherley, Ph.D., F.C.S. London: H. S. King. 1874.

There is still the want existing of a standard work which could be relied on by a chemist, who, conversant with ordinary mineral analysis, has undertaken the by no means facile task of the detection of food adulteration. The sorry scenes which have occurred of late between the analysts appointed under the Food Adulteration Act and their opponents are not to be wholly charged to want of capacity, but rather to the absence of an unanimity of opinion as to which methods of examination are best suited for adoption as standard tests. It is folly to disguise the fact, that this disagreement is mainly due to the small amount of attention that has hitherto been given by the majority of chemists to such investigations.

The small volume now under our notice is addressed to the consumer, the dealer, and to the professional analyst. But, although most of the adulterations in food are treated of, yet it is in a manner rather profound for the reader ignorant of chemical science, but scanty indeed for the analyst, to whom, also, Dr. Atcherley addresses himself. The analyst, we cannot help thinking, is regarded as ignorant of elementary chemistry, and the consumer and dealer must become acquainted with chemical technicalities to find the work of service to them.

The misconception as to the amount of knowledge that is essential to the analyst does not lie only with those in authority; here, in the preface, the author writes that "a carefully compiled description of volumetric solutions and their applications, specially bearing on the subject, has been added for the benefit of the professional chemist." It will suffice to show the scope of the volume if we give the list of these carefully described solutions: Standard oxalic acid; standard nitrate of silver and permanganate of potash with description of titration; the preparation of a copper solution, and estimation of sugar with the same. It would seem, then, that the author considers it necessary to instruct the professional chemist in the preparation and use of these simple reagents, of which a tyro in practical chemistry would blush to be ignorant. But little exception can be taken to most of the author's statements, however we may differ from him in a few particulars. Credence is given to the long ago exploded notions as to chalk and starch in milk and picric acid in beer. Dr. Atcherley evidently believes in the existence of the last as an adulterant to beer, for in his preface he states that he has adopted a new method for its detection by the conversion of the acid into "chloropicrine." On page 13 we are informed that 160 parts peroxide of iron are equal to 308 parts of the protosulphate, and on these data to base the quantity of sulphate of iron; on page 16 1 part of alumina is said to be equal to 9·027 parts crystallized alum; on page 3 we are told that 1 part sulphate of barium is equal to 0·5958 parts sulphuric acid, H_2SO_4; and on page 55, under the heading "Lard," there is this statement:—

"Salt is almost sure to be present, and is indicated by forming a precipitate when treated with a solution of nitrate of silver, but it must not be looked upon as an adulterant unless it be present in undue proportion. *Chloride of Calcium is likewise precipitated by nitrate of Silver and might be confounded with Salt.*"

We doubt not that the non-scientific readers addressed by our author will take this in its literal reading and to their confusion. The plan is to be condemned of attempting in the same work to satisfy totally distinct requirements, even if there be the desirability, which we do not counsel, of any other than the professional analyst occupying himself with that which at the best can only be unsatisfactorily done by the non-scientist. Although it might from this work appear that Dr. Atcherley has had

experience, and considers himself sufficiently authoritative to give expression to that opinion in a comprehensive book on the subject, we consider he has nevertheless yet to fulfil that task.

BOOKS RECEIVED.

THE BIRTH OF CHEMISTRY. By G. F. RODWELL, F.R.A.S., F.C.S. With numerous illustrations. (*Nature* Series.) London: Macmillan and Co. 1874. From the Publishers.

ANNUAL REPORT OF THE BOARD OF REGENTS OF THE SMITHSONIAN INSTITUTION, showing the Operations, Expenditure, and Condition of the Institution, for the Year 1871. Washington, 1873. From the Institution.

HANDBOOK OF NATURAL PHILOSOPHY. By DIONYSIUS LARDNER, D.C.L. Hydrostatics and Pneumatics. New Edition. Edited and the greater part Re-written by BENJAMIN LOEWY, F.R.A.S. With 236 Illustrations. London: Lockwood and Co. 1874. From the Publishers.

Notes and Queries.

[391]. LOTION FOR MANGE. — Replying to T. P. H., March 21st, I beg to offer him the following form for the above :—

℞.	Ol. Olivæ	Oj.
	Acid Carbol. (No. 2)	℥iiss.
	Ol. Petrol.	℥iiss.
	Sulph. Nig.	℥ss.

Mix.

MATTHEW CREWDSON.

[391]. LOTION FOR MANGE.—In reply to query of T. P. H., I beg to enclose recipe for mange in dogs, which after a large and varied experience amongst dogs of all breeds, I can with confidence commend to his notice :—

℞.	Hyd. Perchlor.	℈j.
	Spt. Vin. Meth.	℥iv.
	Sulphur Pur., P.B.	℥vj.
	Aq. Calcis ad	Oj.

Mix.

GEO. F. GUEST, A.P.S.

[392.] PLATE POWDER.—I know of nothing better than Prepared Silica. It produces a beautiful polish ; in fact, a burnish.—W. B. FITCH.

EXTERNAL APPLICATIONS OF CHLORAL HYDRATE.—In the *Bulletin Thérapeutique*, Dr. Dujardin Beaumetz, gives some formulæ of the application of chloral hydrate for external use. The simple aqueous solutions are of all strengths, those most commonly used being 1 part of chloral to 100 of water, and 1 part of chloral to 50 of water. M. Martineau, not finding these solutions to possess sufficient disinfecting power, combines the alcoholate of essence of eucalyptus as follows :—

Aqueous Solution of Chloral Hydrate (1 per cent.) . .	1000 grams.
Alcoholate of Essence of Eucalyptus	4 or 5 table spoonfuls

The formula for the above alcoholate is—

Essential Oil of Eucalyptus .	10 grams.
Alcohol	1000 „

Dr. Dujardin Beaumetz employs in certain cases the chloral hydrate dissolved in glycerine, applied as a topic for wounds or in injections. The following are the proportions :—

Chloral Hydrate	10 grams.
Glycerine	50 „

M. Martineau dresses the sloughs of the sacrum, in patients suffering from typhoid fever, with a 1 per cent. solution of chloral hydrate. He washes the wound with the liquid, then covers it with a pledget of charpie saturated with the solution.—*L'Union Pharmaceutique.*

BENEVOLENT FUND.

Sir,—I have just received an urgent appeal from the Secretary of the Society to further assist in augmenting the Benevolent Fund which certainly (considering the number of persons in the trade) is very small and inadequate indeed, so much so as to be quite a scandal to the trade. As I have already given my usual subscription I think I am not called upon to give a second till I see the whole of the trade combining and doing something more than has yet been done. If only each member of the trade would give 10*s.* a year (about 2¼*d.* a week) it would produce an amount which would be of real service, and put a stop to these oft-repeated appeals which are anything but dignified.

It has been said over and over again by various members that they did not subscribe because the money was invested, and the interest only applied to the use of the fund, but if the Council would only at once apply the subscription to the current relief of applicants, then we should see money pour in as fast as we could desire. By the report I have just received I see the amount paid direct to the relief of members last year was only £350 15*s.*, which I take for granted is about the amount subscribed under these new arrangements, so that little has been done after all.

I think it would, however, be satisfactory to the old subscribers to know how many of the persons relieved by the fund were subscribers, and also of the large number admitted into the Society under the Act of Parliament, how many have been, and are at the present time, subscribers to the fund, the benefit of which they can now claim.

ROBERT PALMER.

Sir,—What is the principle on which the new scale of subscriptions is based? I find I can have one Vote for Five Shillings, but if I am now liberally inclined and extend to two or four votes, I have to be taxed with an additional amount to the extent of 5 per cent. The guineas also cease in regard to Legacies of £50 or £100.

Would it not be more uniform to drop the guinea in every case.

E. M. BURDEN.

38, *Duke Street, Grosvenor Square.*

DECOMPOSITION OF LOZENGES.

Sir,—I enter on the discussion of this subject with some diffidence, seeing that I have handed it over to Mr. Greenish; but finding from the letter of Mr. Witherington that this fungus disease is more common than I thought, the matter becomes of greater importance, and the desirableness of finding out the cause, so as to remedy it, is much to be wished. I trust therefore I may be permitted to make an observation or two respecting it.

That the cause of this peculiar decomposition is a fungus, there is no doubt. Where it originates is a more difficult question to answer. But what it feeds upon is more within the range of our knowledge. If a lozenge be made of sugar, starch and gum, or dextrin, what supplies the nitrogen, for the life and growth of the plant? This question, I think, suggests an answer: That there is most probably a nitrogenous substance added in small quantity, such as gelatine.

If the subject interests any of your readers, I shall be glad to furnish them with specimens.

F. M. RIMMINGTON.

Bradford, March 23.

In reference to the above subject, Mr. J. M. Cornish writes :—

Sir,—"If I remember rightly, ginger yields over 25 per cent. of a fine white starch, which may be obtained by the ordinary process of elutriation practised in preparing arrow-root. Query—Is it the acidulous extractive of the ginger, or a foreign acid, acting on the ginger starch, which has been observed by Mr. Greenish? I am further inclined to partially attribute the decomposition of the ipecac lozenge to its own starch, and extractive ipecacuanha (according to Pelletier, 1817) contains 42 per cent of starch and 16 per cent. *deliquescent* extract."

Dr. Voelcker's Lecture on Milk.

Sir,—There cannot be two opinions as to the interest and value of the lecture of Dr. Voelcker, of which a report appeared in the Pharmaceutical Journal for March 14th, but some of the statements contained in it are so misleading in their nature, that I think it right to point them out, lest, having been made by so high an authority as Dr. Voelcker, they should be assimilated and become part of the future faith of rising chemists.

It is with reference to Dr. Voelcker's observations on the detection of milk adulteration that I desire to write, and I may say here that he will have the sympathy of all respectable chemists in his denunciation of those gentlemen who profess to determine the proportion of water added to the second place of decimals.

Of course, no analyst of experience supposes that milk has great constancy of composition, but I think they must have been somewhat startled to learn, on Dr. Voelcker's authority, that the average milk from a whole herd of cows could be so poor. By half-starving the cows, it appears that they can be made to give milk as much as 2 per cent. poorer in solid matter than has ever been observed before, and Dr. Voelcker is careful to point out that "as the milch cows were kept entirely for the use of the college, there can be no question as to the genuineness of the supply." There is no doubt that Dr. Voelcker is best able to form an opinion as to the possibility of the college authorities having been systematically cheated by their dairyman; but he certainly ought to have been very sure that no tricks were played before he placed on record results which were obtained a good many years ago, and which, I believe I may say, are at variance with the experience of all other chemists.

But there are other statements contained in the report of Dr. Voelcker's lecture to which I am in a position to give an unqualified contradiction. Dr. Voelcker says that "milk purposely watered yields only 5 to 6 per cent. of cream, and has invariably a lower specific gravity than 1·025." Now, as a matter of fact, the gravity of adulterated milk as sold, frequently reaches 1·027 to 1·029, and has rarely a less density than 1·024 or 1·025. It may be asked how I know that such milk was adulterated. My answer is that the milkmen in many instances pleaded guilty, and submitted to the fine. This being so, what is the value of Dr. Voelcker's conclusion, that "within certain limits the specific gravity is the most trustworthy indicator of quality?"

Dr. Voelcker goes on to argue that the presence of an unusual quantity of cream cannot lower the density of milk to the same degree as the addition of water, and immediately below he gives a table of his own results, from which a diametrically opposite conclusion is deducible.

Taking the per-centage of cream on the milk as 10 per cent., which Dr. Voelcker says is about the average, it appears that the process of skimming raises the density from 1·0314 to 1·0337, so the addition of 10 per cent. of cream would lower the gravity to the same extent; that is, it would cause a diminution in the gravity of 0·0023, while Dr. Voelcker's table shows that the addition of 10 per cent. of water would only alter the gravity by 0·0019, which is less than the alteration produced by cream.

The table also shows that milk adulterated with 10 per cent. of water has an average density of 1·0295, which is lowered to 1·0257 when 20 per cent. of water has been added, unless part of the cream has also been removed, in which case still more water would be required to bring the gravity down to the same extent.

It appears, therefore, that Dr. Voelcker ignores all adulteration unless it exceeds 20 per cent., so as to bring the gravity below his limit of 1·025. As far as my experience goes, the proportion of water added to milk before the Adulteration Act came into active operation, was usually about 15 per cent., and was very rarely more than 25 per cent.—an adulteration which Dr. Voelcker would scarcely detect.

On the other hand, I think few analysts whose opinion is of value, would like to swear to 5 per cent. of water in milk, but there is no difficulty when the amount reaches 10 or 12 per cent.

I may mention that I am in the habit of taking the gravity of the whey (by a bottle), and I find the results obtained by this plan exceedingly useful, and far more trustworthy than estimations of the density of the original or the skimmed milk. I also estimate the cream (and sometimes the fat), the solids, and take the original gravity.

Sheffield, March 21. Alfred H. Allen, F.C.S.

Cocculus Indicus.

Sir,—In asking "What becomes of the Cocculus Indicus?" one touches somewhat delicate ground, which, for obvious reasons, is not likely to be approached otherwise than very gingerly by those who are really able to supply the required information.

Little light having been, as yet, thrown upon this obscure matter, I offer the result of a brief experience in the traffic of the drug. Some twelve years ago, I commenced my career of assistant in an important town of the Midlands, where, amongst divers other unwonted wares, we not unfrequently sold a pound or so of Cocculus. Coincident with this fact the town curiously enough enjoyed a repute for its strong ale! Every inn-keeper there, with few exceptions, brewed his own beer, which, for the most part I can vouch for it was exceptionally pleasant to the eye and palate, withal "sleepy stuff," and of unquestionable potency in muddling the brains of its votaries; but, having perhaps supplied some of the mystic berry shortly before, I might have judged the liquor in advance.

More I cannot say. I never broached the subject with my employer, for it always appeared to me invested with a halo of mystery not lightly to be disturbed; but I had small doubt in my own mind what became of the Cocculus Indicus,

Walter A. Powell,

5, *Castle Street, Swansea.*

Obscure Formulæ.

Sir,—Can you tell me where to find formulæ for the following articles:—

Sp. Calorific, and
Tinct. Calorific Co.

They are prescribed in prescriptions presented to me to-day, written by a physician residing in George Street, Hanover Square, and have been dispensed by a chemist and druggist residing at Notting Hill.

I suppose this is a near relative of Miss Comp.

P. T.

Bridgewater, March 16*th*, 1874.

F. C. Mumford.—A formula for syrup of lacto-phosphate of iron and lime was given in the Journal for January 31st last, p. 610.

"*A Pharmacist since* 1842."—Unfortunately the cases are not analogous. If the feeling described by you is generally prevalent, the better way would be to memorialize the Council. Meanwhile, it ought not to be presumed that that body has ignored the question.

"*Lamina.*"—Digest the leaves in rain-water placed in a sunny spot, until the parenchyma is sufficiently decomposed to allow of its removal with a soft brush; then bleach with chloride of lime or sulphurous acid.

H. Humphrey.—It is a proprietary preparation, the London agents of which are Messrs. Savory and Moore.

H. L. Brothwood.—Any sulphur present would be in suspension and could be separated by filtration and detected in the residue by the usual tests.

H. Butler.—Some information respecting the strength of the preparation mentioned will be found in the Pharm. Journ., 1st ser., vol. xii., p. 253. We do not think it would be justifiable to make the substitution suggested.

Z. Y. X.—The General Order of the Inland Revenue Board, dated 9th August, 1866, states that the use of methylated spirit, or any derivative thereof, in the manufacture or preparation of any article or substance "*capable of being used* as a beverage, or *internally as a medicine, is illegal.*"

Errata.—We are requested to make the following corrections in Mr. Wellborn's note on oxide of tin:—Page 750, col. i., line 6 from bottom, for "solution" *read* "soluble;" col. ii., line 19 from top, *for* "oxide of lead" *read* "oxide of tin."

In the Registrar's Report, p. 639, the number of Pharmaceutical Chemists on the Register at the end of last year should have been 2374, and the number of Chemists and Druggists 10,842, making a total of 13,216.

Communications, Letters, etc., have been received from Mr. Garside, Mr. F. Balkwill, Messrs. Cadbury Bros., R. C.

THE BRITISH PHARMACOPŒIA ADDENDUM.*

BY C. UMNEY.

Discussions upon the nomenclature, the weights and measures, the preparations, and other matters connected with the British Pharmacopœia, have on many occasions during the past three or four years, occupied the members of this society at their evening meetings.

Although the repeated invitations of the president, to have subjects of pharmaceutical interest brought forward for discussion, have not been as heartily responded to as he and other well-wishers to pharmacy could have desired, still, it is beyond dispute that when opportunities have occurred for the interchange of ideas upon such topics as have been presented at our evening meetings, good has invariably resulted.

During the past year pharmaceutical research has, it is to be regretted, flagged considerably; it can hardly have been caused by the announcement that the Supplement or Appendix to the British Pharmacopœia was to be published at an early date, for one would have imagined an announcement from Professor Redwood that such a publication might be expected, would have stimulated pharmacists to have brought forward all matters that deserved the attention of the Pharmacopœia Committee.

To those who have worked to amend the errors of the 1867 edition, as well as to those who have bestowed thought and labour upon the preparations now added to our national pharmacopœia, our thanks are due.

As you well know, after some considerable delay, the addendum has made its appearance, and it has the good fortune to be associated with a volume of which pharmacists are justly proud, and with which the medical profession is evidently satisfied, as was shown by the *Lancet* in a recent article upon the British Pharmacopœia, the closing paragraph of which might be here reproduced with advantage:—

"It will be seen that there is at least a promise of some valuable matter in these additions to our national Pharmacopœia, and if the practical knowledge and judgment displayed in preparing the previously published part of the work have been equally exercised in this, the profession will be indebted to the Medical Council and the Pharmacopœia Committee for their labours in this direction."—(*Lancet*, March 21, 1874.)

My object in addressing you this evening is not so much to bring my preparations (placed upon the table) specially under your notice, but rather to have them before us as illustrative of the 34 new remedies and substances used in the preparations of medicine contained in the supplement, while we discuss their relative merits.

I must acknowledge that I have had no special experience of many of the matters before us other than that I have gained, by way of experimenting, during the past few days; I ask, therefore, your indulgence for any errors of judgment that I may commit, in my haste to bring so important a matter before you.

Let us in this discussion, be mindful of the fact that the compilation of a work is a much more difficult task than a criticizm; also, on the other hand, that criticism fairly carried on must, in the end, be to the benefit of those criticized.

Let us turn then to the Supplement, and take the preparations *seriatim*.

Acetic Ether.—This body, although not new to the chemist, is a body with which pharmacists are but little familiar. All will remember the characteristic and pleasant odour so often noticed in preparations containing alcohol and acetic acid, and notably in the officinal tincture of acetate of iron, in which acetic ether is unmistakably formed, much to the detriment of the tincture, not so much from its presence as from the loss of acetic acid, and consequent deposit of a basic salt (which, by the way, may be obviated to a degree by having about 5 per cent. free acetic acid present in the tincture). This ether, we have been told, has more especially been introduced with a view to its use subsequently when the pharmacopœia is more generally altered.

The special objects in its introduction may have been for flavouring certain preparations, and also to have a more perfect solvent of cantharidin when making blistering fluid.

The Pharmacopœia does not pretend in all cases to give minute directions to manufacturers, but general remarks for their guidance, it therefore merely states that this ether may be made from dry acetate of soda, rectified spirit, and sulphuric acid. A better form could hardly have been given, as the more anhydrous the two liquids the more quickly and abundantly do they produce the compound ether.

Chloride of calcium is directed to be used to dry the ether when produced, by digestion with half its weight, and final rectification.

Here I cannot help noticing one omission of great importance, which may lead to confusion, viz., the non-rectification of the product from a solution of carbonated alkali, to remove free acetic acid of which considerable quantity will always be present.

Under "characters and tests" we have the specific gravity described as 0·910 and the boiling point 166°. In Gmelin's Chemistry, we find the specific gravity described as ·888, and the boiling point as 165° (74° C.)

Miller also very nearly corroborates this, for he names ·890 as the specific gravity, and 164° as the boiling point.

But upon reference to Watts' Dictionary of Chemistry, this ether is described as having a specific gravity at 0° C. of ·910 (Kopp) and a boiling point 74·3° (166 Fahr.).

In the face of this conflicting evidence by good authorities, it is difficult to decide at any rate the specific gravity of acetic ether, unless by actually working out the matter for oneself.

I had my suspicions, that if I could find a specimen in pharmacy that would answer to the pharmacopœia tests, I should in all probability find free acetic acid as an impurity, I also thought that some specimens might be contaminated with ordinary sulphuric ether.

Accordingly I examined three, with results as under:—

	Specific gravity.	Boiling point.	Free Acid.
a	·890	160°	none.
b	·889	158°	,,
c	·915	164°	16 per cent. of monohydrated acetic acid.

Washed with an equal volume of water while *a* lost 3·5 per cent. *c* lost 10 per cent.

* Read at the Evening Meeting of the Pharmaceutical Society, April 1, 1874.

I find that the acetic ether of the French Codex is directed to be rectified from a small quantity of potassic carbonate, but not from chloride of calcium.

The resulting ethereal liquid would not, although deprived of acid, be thoroughly desiccated, and would contain (probably 10 per cent.), of *either* water, alcohol, or sulphuric ether; even all might be present.

It would therefore appear that the text in the addendum, to be strictly accurate, must in some way be modified, and at least direct the rectification of the product over carbonated alkali, to ensure the absence of free acetic acid.

I should imagine that the French Codex preparation would be preferable; but this remark at the present time is premature, for I am not fully aware whether almost anhydrous acetic ether would not be required in some preparations.

I purpose further investigating certain points connected with this liquid as soon as possible.

Nitrate of Ammonia is so well known to us, as the source of laughing gas, that it seems almost unnecessary to bring it before you.

The tests of the Pharmacopœia have been framed with great caution, and anyone carefully following these cannot fail to select a good specimen of the salt now so largely used for the production of nitrous oxide for use by the surgeon dentist.

It would be well here to call attention to the presence of chlorides in some commercial specimens which must, upon being fused, produce a gas much contaminated with the irritating vapour of ammonium chloride.

Nitrite of Amyl.—This powerful medicine, although known since 1844, when it was discovered by Balard, has been but little used. We are indebted to Guthrie* for having first observed in 1858 the remarkable and powerful action of this liquid on man. Its physiological properties have been investigated by Drs. Richardson, Brunton, Talfourd-Jones, Anstie, and others, and have formed the subject of more than one paper for the meeting of the British Association. To those reports and to other journals† I must refer anyone desirous of becoming further acquainted with the medicinal properties of this liquid.

Pharmacists, here and in America, seem to have given some attention to the production of this remedy in a state of purity.

Maisch‡ prepares it by the action of nitric acid direct, upon amylic alcohol, and reserves that portion of the liquid for final purification which distils between 96° and 100° C.

Tanner§ takes advantage of Redwood's process for spirit of nitrous ether (the British pharmacopœia process), and prepares the amyl nitrite in this way. Other processes have also been suggested, which I should recommend to your notice.

The chief points in the production of this body in a state of either absolute or even medicinal purity, first and foremost hinge upon the thorough fractional distillation of the fousel oil, until the amylic alcohol selected for use has a constant boiling point of 132° C. The crude nitrite, prepared by either of the processes indicated, must be washed with caustic soda, to remove prussic acid formed during the process, and nitrous compounds, and finally rectified over potassic carbonate.

That portion only is reserved for use in medicine which distils between 96° and 100° C.

The boiling point, as given in the Pharmacopœia, is not, I presume, intended to be the boiling point of absolutely dry and pure amyl nitrite, indicated by Guthrie, as 99° (210° Fahr.), but rather an average boiling point of good medicinal nitrite, ranging through some eight or ten degrees of Fahrenheit's scale.

The specific gravity, as represented in the Pharmacopœia, is, I believe, for medicinal purposes, sufficiently accurate. Some three years since,* I found that some specimens I then examined were not amylic nitrite, but were contaminated with nitrites of radicals much higher in the series than amylic alcohol.

Chloroform Water is, perhaps, one of the best of the introductions into the Pharmacopœia. All, at some time or other, have been inconvenienced by the sparing solubility of chloric ether, when ordered in a mixture in such quantity as to be only partially dissolved, which difficulty has been considerably aggravated by the variable strength of chloric ethers as compared with the officinal spirit of chloroform.

The water, containing one-half per cent. (fluid) of chloroform, seems to be, as far as I have observed, a fully saturated solution.

Areca nuts, as they are termed in commerce, are introduced as a vermifuge.

It has been urged that this remedy to exert its maximum anthelmintic force, must be in a certain state of division, and not prepared as a fine powder.

My opinion is, that this is more imaginary than real, and that, in all probability, when a specimen has been pronounced inert, it was due either to partial destruction by an insect of the betel seed before powdering, or to the powder having been stored for a considerable period previous to administration.

Aurantii Fructus is introduced for the fresh peel, directed to be used in the preparation of Tinct. Aurantii Recentis. Fruit merchants consider the fruit in perfection in the months of February, March, and April; pharmacists should therefore prepare their stock of tincture for the ensuing year as soon as possible.

Bismuthi Oxidum is introduced with a view to its use in subsequent Pharmacopœias. Solution of citrate of bismuth and ammonia is the preparation for which it is, no doubt, intended by a manipulation very similar to that given by Wood (Pharmaceutical Journal, 16th September, 1871). A liquor thus prepared is free from the impurities common in the present officinal solution, which process is seldom if ever resorted to, by manufacturers. This oxide can be obtained by boiling basic nitrate with caustic soda solution, 80 parts being produced from 100 of the nitrate.

Calcis Hypophosphis and *Sodæ Hypophosphis* are already in considerable use in medicine; they may be said to have forced their way into the Pharmacopœia, from the fact that their medicinal value is acknowledged on all sides.

We shall doubtless in forthcoming editions hear more of these, in the form of syrup or other convenient modes of administration, and if not of these, probably of a ferruginous syrup with hypo-

* *Journal of Chemical Society*, vol. xi. 1859.

‡ Pharmaceutical Journal, April, 1871, p. 865.

§ Pharmaceutical Journal, Nov. 25, 1871, p. 421.

* Pharmaceutical Journal, Nov. 26, 1870, p. 422.

phosphorous acid (syrupus ferri hypophosphitis). This latter is now in demand, and may most rapidly and advantageously be prepared by Wood's process (PHARMACEUTICAL JOURNAL, vol. ix, p. 461).

While we are speaking of acids of phosphorous, I should like to draw attention to the advantages in using a phosphoric acid of greater strength than the 10 per cent. solution now officinal, for the manufacture of a certain class of preparations now in considerable demand, with a view of introducing it into the Pharmacopœia on a future occasion. I would employ a 50 per cent. solution at least (specific gravity, about 1·500) as described by Carteighe (PHARMACEUTICAL JOURNAL, 26th March, 1871).

I am tempted to again dwell upon a preparation containing the element phosphorus, which seems to be playing, you know, an important part in the medical treatment of the present "high pressure" days.

The preparation to which I would refer, perhaps, will be thought by some to savour of quackery, but still it is in enormous demand The public, who are generally keen observers of the value of such remedies, attach great importance to it, but whether their views are wholly corroborated by the medical profession, I am not prepared to say. It will be sufficient to remark that it is one of those compounds which are dubbed by our American cousins (the *Lancet* styles some of the addendum preparations in the same way) as "elegant pharmacy." The compound syrup of the phosphates, known popularly as Parrish's Syrup, is the preparation to which I refer, and my own view is, the sooner we have an official formula for it the better. Why not this, as well as citro-tartrate of soda, which was introduced to imitate a well-known preparation, and to keep pace with the public taste for physic?

Charta Sinapis.—Mustard leaves, as they are termed in trade, were made officinal in the last United States Pharmacopœia; our process is almost identical with the American, and both are imitations of Rigollot's mustard leaves, which have been in considerable demand.

It will require dexterity and practice before one can make the elegant leaves of the French manufacturer.

The American Pharmacopœia directs the spreading of the solution of gutta-percha and mustard with a brush, while the British Pharmacopœia, with the same viscidity of the gutta-percha solution, directs the passing of the paper on one side over the mixture.

Chloral Hydras.—Although known to the chemist from the earlier days of Liebig, still it was not until some four years since that it was brought forward as a remedial agent. It has been in large demand (not in the quantities the newspapers stated), and although perhaps less is used now than a year since, still my own observation convinces me that it is maintaining its ground. At first our market was wholly supplied from the Continent, but eventually, thanks to the enterprise of an English firm of manufacturing chemists,* it was produced at home.

Its import in considerable quantity was viewed with a jealous eye by the Customs, who attached a duty of fifteen pence per pound to it.

For a considerable period the chloral hydrate of pharmacy was wholly found in masses; now, however, detached crystals, ranging from the size of large crystals of sulphate of magnesia to those of chlorate of potash, are met with; but these are wholly of continental manufacture. I am informed that English makers, presuming that these are now required by the description given in the addendum of chloral hydrate, are quite prepared to undertake their manufacture.

The Pharmacopœia Committee does not undertake to be a manufacturer's encyclopædia, still it would, I think, have been advisable to state the particular liquid, from which chloral hydrate may be crystallized.

The characters and tests enumerated are ample to decide the purity of good chloral hydrate, the boiling point of 205° and Wood's quantitative chloroform test (PHARM. JOURN., March 4th, 1871) being those chiefly to be relied upon.

Extractum Glycyrrhizæ Liquidum is certainly a preparation of which both prescribers and dispensers stood in need.

When it was first introduced to our notice within these walls by Professor Redwood, who at the same time brought forward other United States' Pharmacopœia preparations, we were told that glycerine and proof spirit would be the liquids by which the fluid extract would be preserved, and that the starting point would be extract of liquorice, and not liquorice in powder as there directed. It appears, however, to have been decreed that we shall not be afflicted with "the glycerine mania" prevalent on the other side of the Atlantic, for the glycerine has been discarded, the extract of liquorice replaced by the root, and the spirit only retained, and that in very small quantity.

That a fluid extract shall be made from the root direct is certainly more like "artistic pharmacy" than dissolving the extract in water. That there will be no lamentation over the rejection of the glycerine few will question, but that the preservative action of 11 per cent. of rectified spirit will be sufficient to prevent acetous fermentation I much question. Time and observation only will decide this matter. Experiments I have made with this fluid extract give the following results from 100 parts:—

Dried Liquorice Root	100 parts.
Solid Extract (B. P.)	26 „
Extract Fluid (sp. gr. 1·160) . . .	56 „
Extract Glycyr. Liquid, B.P. . . .	61 „

This latter, when complete, has a specific gravity of 1·130, which information might have been appended with advantage to the Pharmacopœia description, thereby giving one an opportunity of determining what the density of the completed extract should be.

Gutta-percha is a body with which pharmacists hitherto have not had experience. I would call attention to the impurity of much of the gutta-percha of commerce, and the variation of 100 per cent. in price.

Hydrargyri Oxidum Flavum is a preparation with which we have been for some time familiar, not only for use in ointments, but as the mercuric oxide used in the preparation of the valuable oleates of mercury.

These latter, perhaps, may find favour on a future occasion, when they have been more extensively tried, and when the oleic acid of pharmacy is other than the rough oleic acid of the candle factories.

Injectio Morphiæ Hypodermica is a preparation of which various solutions have from time to time been used, the weakest being probably the officinal

* Foot, Barrett & Temple, Battersea.

solution, and the strongest one of ten grains to the fluid drachm. This latter is the one prescribed in Squire's work on hospital formulæ, and has perhaps been more generally used than any other. The preparation now officinal has a strength of five grains to the fluid drachm.

I confess I am an admirer of the method by which this solution is directed to be made ; it is practically and theoretically sound and likely to produce uniform results, provided always that its preparation by a good manipulator can be ensured.

I have, however, my misgivings on this point, and imagine that frequently such good results will not be obtained as might have been expected had the solution been directed to be prepared from acetate of morphia direct, even with all its faults, and more especially if required hurriedly, which will doubtless often be the case.

I had almost made up my mind that at any rate for all things new in medicine, we should count by ten and not twelve ; had we done so in this instance, we should have had a solution of one grain in ten minims, the continental pharmacist would then have been able to almost "run and read," as it were, and dispense easily his decigramme of morphia salt to his c.c. of solution when an English prescription was presented.

Laricis Cortex is ordered for the production of tincture of larch bark, not altogether unknown in pharmacy. At the present time two or three spurious larch barks are to be found in trade. I have not had an opportunity of comparing them, but Mr. Holmes, has kindly done so, and reports that the specimen (B) closely corresponds with that in the Society's Museum.

Liquor Gutta-percha.—This solution is introduced as a vehicle for the powder of black mustard in making the Charta Sinapis.

The formula is identical with that given in the recent edition of the United States Pharmacopœia. If gutta-percha is of good quality and thinly cut, as the Pharmacopœia directs, its solution is most easily effected.

The carbonate of lead acts as a mechanical purifier, and answers the purpose excellently well.

Had benzol been officinal, doubtless it would have replaced chloroform in this preparation.

Liquor Magnesiæ Citratis is introduced as a preparation containing true citrate of magnesia, and is made by a modification of the French Codex process for purgative lemonade. The carbonic acid is generated from acid carbonate of potassium ; the Codex directs the use of the corresponding soda salt. The water thereby charged with carbonic acid is under less pressure than in the ordinary lemonade of trade, which contains generally when filled from a machine 2·5 atmospheres of gas. This liquor would not contain more than 1·5 atmospheres in addition to the quantity dissolved by the water. There is just sufficient to make it grateful, and not too much to prevent it from being easily taken as a draught. I should have preferred to have seen half a fluid ounce of simple syrup with half a drachm of tincture of fresh lemon peel, ordered for each half-pint bottle, rather than syrup of lemon, which has, to my palate, a mawkish taste.

Oleum Phosphoratum is made with almond oil, which is first directed to be heated to 300° Fahr., and maintained at that temperature for fifteen minutes. Now, in some cases such treatment of the oil may be necessary, but I have not noticed either water or albuminous matter in the almond oil with which I have experimented. Almond oil readily takes up the phosphorus when the required temperature of 180° (Fahr.) is maintained. The oil now officinal differs in strength from the phosphorated oil of the Codex, which contains 2 per cent. Presuming the specific gravity of almond oil to be ·920, then ·74 will be the percentage of phosphorous. Surely a one per cent. solution would have been preferable. I do not consider the description of "colourless" as correct for this liquid. I should describe it as straw-coloured.

Pepsin.—At last this preparation is made officinal, and a standard published by which the value of medicinal pepsin can be determined.

How much of the pepsin of trade will come up to the officinal test, is a matter of speculation.

I have prepared pepsin from fresh rennets, but have not yet had an opportunity of experimenting upon pepsin, either from pigs' or sheeps' stomachs.

It is imperative that the directions of the pharmacopœia as to washing, be strictly adhered to ; and I should say, profiting by a failure I had on the first occasion, the scraping even of the stomach is a matter of importance, for a material point seems to be the sufficiently light scraping in order that the fatty matter be not removed with the viscid pulp, which is finally converted into a solid form by desiccation at a temperature of 100° Fahr. The powdering of the gelatinous-looking pellicles is a matter easily to be accomplished, the result being "a light yellowish-brown powder, having a faint, but not disagreeable odour, and a slightly saline taste, without any indication of putresence."

The determination of its value by its solvent action upon fifty times its weight of coagulated egg albumen aided by a minute quantity of hydrochloric acid is, I believe, in the main, correct. That the albumen will dissolve there can be no question ; the time mentioned, viz., four hours seems to me for, at any rate, pepsin from the stomach of the calf to be rather too short. The experiment I made took a longer time ; it is, however, just possible that pepsin made from a pig's stomach may have a more rapid action upon albumen.

Pilula Phosphori. Phosphorous is not one of the most manageable bodies to convert into a form suitable for administration and easy dispensing. We must not, therefore, be surprised if some complaints are made upon the practicability of the method for preparing this mass. My experience in making phosphorous preparations has been limited. I will therefore merely say that, as far as I can judge, the directions accompanied with considerable care and patience give a very satisfactory result. To make the wax thoroughly incorporate with the balsam of tolu and phosphorous is the part of the process that seems most tedious. Upon a quantitative experiment I have made I find when operating upon about half a pound of the ingredients that the weight is finally increased about 13 per cent. on account of the water absorbed by the mass during the immersion and manipulation. This hydration, therefore, will give an amount of phosphorous present in the completed product equal to about 1 per cent.

Pilula Scammonii Composita is the non-aloetic cathartic mass promised to be inserted in the Appendix. It is to be supposed that the curd soap here ordered will replace the olive oil soap in most preparations in which the latter is now prescribed in

all future editions of the Pharmacopœia. The use of spirit as a solvent, combined with strong tincture of ginger, leaves little to be desired as far as the production of an elegant mass is concerned; but the process is rather an expensive one, and the essence of ginger might have been replaced by the oleo-resin of ginger (or gingerine as it is called in trade), now officinal in the United States' Pharmacopœia, which would in this case have answered the purpose exceedingly well.

Pulvis Elaterii Compositus commends itself immediately as a safe and ready means of dispensing elaterium.

Pulvis Glycyrrhizæ Compositus is somewhat different to the compound liquorice powder we have been accustomed to see prescribed latterly, which was that of the Prussian Pharmacopœia, containing, in addition to the British Pharmacopœia ingredients, sulphur and fennel fruit; doubtless those in charge of the work have strong reasons for rejecting the sulphur.

Sapo Animalis.—The introduction of this soap into the Pharmacopœia is a wise step, even if only to authorize a practise common with manufacturers, who have been fully cognizant of the objections to the olive oil soap of the Pharmacopœia for some years. The remark, that "this soap may with advantage be substituted for the hard soap made with olive oil in preparing Linimentum Potasii Iodidi cum Sapone" is not in the least too strong, for it is absolutely necessary, if anything approaching a good liniment be required, that the officinal olive oil soap be discarded. How manifest is the disadvantage under which the compilers labour in having to publish an appendix only, without revision of the text of the old work; for a parallel can be found for this remark upon the soap over and over again in looking through the Pharmacopœia and comparing it with the work of pharmacists upon certain subjects to which they have given their attention since the 1867 edition was introduced, but which cannot appear because of material alteration that would be necessary in the text.

Succus Belladonnæ belongs to a class of preparations which have for years been in some demand; they are really valuable, and as a rule are much more to be relied upon than solid extracts. Of course a hard and fast rule cannot be laid down as to the relative equivalent value of this or other juices as compared with the original plant or with the extract, but the following, I think, will nearly express the average ratios:—

Belladonna Herb, fresh . . .	100 parts.
Expressed Juice	60 „
Solid Extract	4·7 „

Succus Hyoscyami, the same remarks apply as to the preceding juice, but, perhaps, here to a stronger degree upon the greater objection to evaporation, for I am of opinion that expressed juice of henbane suffers considerably in evaporation for the production of the solid extract.

The relative equivalent values of herb, juice, and extract, will probably be as under—

Henbane Herb, fresh . . .	100 parts.
Expressed Juice	70 „
Solid Extract	4·4 „

These expressed juices seem to have a specific gravity of about ·990 to ·997

Suppositories.—My experience in the manufacture of suppositories is very small. Martindale, Gerrard, and other practical men can speak more authoritatively upon the subject than I can; doubtless they will give us the benefit of their observations in manipulating the three soap suppositories.

The irritant nature of the soap upon surfaces with which it comes in contact, is purely a medical question, and does not concern us.

The *Carbolic Acid and Soap Suppository* does not work well, the quantity of moisture being alone derived from the carbolic acid seems to me insufficient, at any rate it will not admit of starch being used. To make these easily I should take equal parts of curd soap and curd soap in powder.

The *Suppository of Morphia and Soap* is easily manipulated, the quantity of starch added being sufficient to make the suppository finally weigh 16½ grains.

The *Suppository of Tannic Acid and Soap* is also easily made, the amount of starch added being sufficient to make the suppository weigh upwards of 23½ grains.

The two latter suppositories on exposure to damp air, might be expected to become slightly adhesive from the use of the hygroscopic body glycerine.

Syrupus Chloral.—The administration of hydrate of chloral in the form of a syrup has been general during the past two or three years. When it was first used in this form the variously flavoured syrups were numerous, amongst them might be enumerated orange-peel, orange flower, peppermint, tolu, ginger, chloroform water. It would have been well if at the evening meeting some two or three years since, when it was proposed to settle the question of the best vehicle for its administration that the matter had been decided; the syrup would not then have been sent through the country broadcast made from half a dozen different formulæ, but a recipe would have appeared in the Journal as having had the approval of the meeting, and would consequently have carried some weight with it. It would seem that this difficulty beset the Pharmacopœia Committee, for they have finally settled upon simple syrup, hoping by its adoption to prevent all chance of giving offence to one or other who have held that such and such a flavouring was the most elegant.

All this is very good, and under the circumstances is, perhaps, the best solution of the difficulty that, could have been devised, and I admire it. I cannot say as much for the elegance of the syrup itself, for to a pharmacist's eye, it is anything but a syrup.

The formula given contains too much water for the solution of the hydrate before the simple syrup is added, the resulting compound being thin and certainly unparalleled in density by any other officinal syrup. When prepared according to the Pharmacopœia formula the spec. grav. will be 1·218. I should certainly suggest that when an opportunity occurs for revision, we should be directed to dissolve the hydrate in about its own weight of water and then add simple syrup, thus—

Hydrate of Chloral . .	80 grains.
Water	1½ drachms.
Syrup to	1 fluid ounce.

The spec. grav. of such a syrup would be 1·320 and would be an improvement, at any rate pharmaceutically, upon the now officinal syrup. It may be that there are some who are so fastidious that they object to the taste of sugar—if that be the case let a solution in water only be made officinal—of an equivalent strength to 10 grains to the drachm.

Tinctura Aurantii Recentis is an old friend, for grey-haired pharmacists will remember that a tincture from the fresh peel, although not of equivalent strength to the present, was officinal in the 1824 pharmacopœia, and was discarded for reasons best known to the compilers of the 1836 edition. We are certain they did not then cherish the now popular notion of conservatism, or they would have retained the formula for the present race of pharmacists, who, perhaps, wish they had done so, rather than they themselves should be accused of retrograde pharmacy. The subject was revived before this Society at an evening meeting, by Haselden, as one worthy of attention. (PHARM. JOURNAL, Nov. 9th, 1872.) The discussion upon his paper, in which Bland, Brown, Greenish, Groves, Sandford and Umney took part (PHARM. JOURNAL, Nov. 9th, 1872) went to show as follows :—

Bland.—"*That tincture of dried peel was a bitter, while tincture of fresh was a flavour only.*"

Brown.—"*That upon no account would he use rectified spirit.*"

Greenish.—"*That Continental pharmacists used dried peel and double strength.*"

Groves.—"*That he had experimented upon all peels, and finally came back to the recently dried by preference.*"

Sandford.—"*That he used a tincture approximating to the* 1824 *tincture.*

Umney—"*The difficulty there would be at certain times in procuring fresh Seville orange peel.*"

The result of this discussion apparently would not have been the introduction of this tincture if these pharmacists had a voice in the matter. Symes (PHARM. JOURNAL, Nov. 9th, 1872, p. 381) also remarks upon this tincture, and suggests the addition of as much water as with the water in the peel, would bring the spirit to proof strength, but none of these experimenters seem to have fallen into the error the British Pharmacopœia has in the manipulation there directed.

We are told to macerate the 6 ozs. of orange peel in one pint of rectified spirit for a week with frequent agitation. Then press the dregs, mix the products, and make up the measure to one pint with rectified spirit.

The introduction of the word "pint" into the text is evidently an error, and seems to have crept in inadvertently, for we are directed only a few lines previously to take a "sufficiency" of spirit, which remark would have been unnecessary, or at any rate contrary to custom, if a pint had been intended. I have had an opportunity of making this tincture during the past fortnight, and have found rather than spirit being required to make up any deficiency resulting from loss, there is actually a gain of about 10 per cent. by volume. The formula should, therefore, be amended thus :—

Take of—

Bitter Orange .	A sufficiency.
Rectified Spirit	18 fluid ounces, or a sufficiency.

Carefully cut from the orange the coloured part of the rind in thin slices, and macerate six ounces of this in 18 fluid ounces, etc., etc, Finally, add sufficient spirit to make one pint.

I would remark that my observations confirm those of Haselden and Symes, that fresh peel is to dry peel as 100 : 33·3.

Tinctura Laricis has previously been but little used ; when it has, the tincture has generally been made with proof spirit. With the bark in a proper state of division, percolation is admirably adapted for the production of this tincture. The loss of spirit I have noted in making it by the officinal method is about 10 per cent. by volume.

Tinct. Quiniæ Ammoniata has been seldom heard of previously. The formula given is one that has appeared in the PHARM. JOURNAL, and has doubtless been adopted by those who have had occasion to prepare the solution. The specific gravity noted is ·936. One fluid ounce of this tincture, when evaporated to dryness over a water bath, re-dissolved in one fluid ounce of water, and ammonia cautiously added in slight excess, will give a precipitate, which, when dried until it ceases to lose weight, will weigh not less than 5·6 grains.

Two preparations are conspicuous by their absence. I refer to the acetum and oxymel of ipecacuanha. These were introduced to us by Dr. Duckworth, and working processes given by Carteighe, and over and over again they were said to be destined for the addendum.

What has become of them? Is it possible that they kept perfectly up to a certain time, and then suddenly went the way of all ipecacuanha preparations. I imagine that this must have been the case, for we heard of them at every meeting at which the additions to the Pharmacopœia came under discussion, and finally they are shut out.

I would submit that if these have been found unstable, an aceto-alcoholic fluid extract be prepared and investigated, with a view to its use in future editions, either as fluid extract, or more generally for a syrup, by dilution of the fluid extract with simple syrup.

In conclusion, I would now review the first page, entitled, "Corrections made in 1874 in the Reprint of the British Pharmacopœia of 1867."

The only important correction is the specific gravity of the strong solution of perchloride of iron, which was formerly stated to be 1·338, now to be 1·440, which is, I believe, nearly accurate.

The tincture made by diluting this liquor with rectified spirit, and for which a specific gravity was named in the previous print, has been deemed either accurate or unworthy of correction.

The list in the main consists of the proportions of active ingredients in various more or less potent preparations. Up to the present time I have not had an opportunity of checking these calculations.

I would, however, point out one anomaly in which ipecacuanha and opium, both of which are in the ratio of one in ten in Dover's powder, are said to be respectively as one in twenty-four and one in twenty-three and a half, nearly, in compound pill of ipecacuanha and squill.

While I sympathize with the compilers in the difficult task they have had in making corrections without disturbing the text of the old print, to which point I have previously alluded, still, I cannot refrain from expressing my humble opinion that as corrections, almost the whole of which are immaterial, have been made, while more important points have been allowed to remain unassailed, it would have been better had that list never been published.

When the novelty of this book has passed away, we shall look forward to a new edition of our National Pharmacopœia, which will doubtless bear a decennial revision. In the meantime, let it be not only the ambition, but the bounden duty of every pharmacist to make some research, no matter in what direction,

if it bears upon pharmacy, and give this Society the benefit of his observations; by this, and this only shall we be enabled to keep pace with pharmacists on the Continent and in the United States, and what is of more importance, show to the medical profession that we are fully alive to the responsibilities of our calling.

Laboratory, 40, *Aldersgate Street, E.C.*

THE ALKALOIDS OF THE CINCHONA BARKS.*

BY O. HESSE.

(*Concluded from p. 772.*)

X. The Amorphous Bases.

Cinchona barks contain more or less considerable quantities of amorphous basic substances, the quality of which depends upon the nature of the alkaloids which occur normally in the respective cinchona barks. We may therefore consider these substances to be decomposition products of the two cinchona alkaloids, and this the more so because they may be obtained from the latter artificially, and are often formed from them unintentionally during their preparation.

If the crystallizable alkaloid give no green colouration with chlorine and ammonia the accompanying amorphous alkaloids, as a rule, behave in a similar manner; but if the crystalline bodies give this green colouration, so does also the amorphous portion of the bases. It may, therefore, be conjectured that in the first case the amorphous substance arises from cinchonicine, in the latter from quinicine. But if the bark contain at the same time quinine and cinchonidine, or conchinine and cinchonine, it may be concluded that then the amorphous substance is a mixture, with which are associated in a few cases, as in the bark of *C. succirubra*, small quantities of paricine and amorphous quinamine. Upon the ground of this experience, therefore, I cannot share in the opinion of De Vrij, that in the above-mentioned bark, the amorphous substance contains a special alkaloid. Moreover, I have been able, by successive precipitations with ammonia and re-dissolving in ether, to separate the amorphous portion of the alkaloid of this bark into two parts, of which one gave no green colour with chlorine and ammonia, but the other gave that colour quite distinctly.

It has often been suggested that this amorphous modification of the cinchona alkaloid is formed through the influence of light. When crystallized sulphate of quinine is exposed to direct sunlight, it is in fact coloured yellow; but this operation, even if it last for a year, is confined to the surface of the mass. If the surface exposed to the sunlight be protected with black paper, which does not let the light pass through, the sulphate of quinine under this paper remains for a long time unaltered. The protecting cover, which is here represented by the black paper, is represented in nature by the chlorophyll coloured cellulose, so that the influence of the sun can only so far operate upon the quality of the alkaloids as the latter are directly struck by the sun's rays. This explains how it is that the bark, even in the form of the finest powder, when exposed for a long time to the sunlight suffers but little damage to the crystallizable alkaloid.

But quite a different result appears if the alkaloid in acid solution be exposed to the sunlight. In such cases not only the sunlight penetrates the solution, but through the unequal heating of it currents are engendered, and thus continually fresh particles are led to the spot where the influence of the sun is the strongest. This can be illustrated by an example. I have, for instance, divided a solution in water acidulated with sulphuric acid, of such alkaloids as are obtained from the best Calisaya bark, into two equal portions, and exposed one of these to the sunlight; but the other part I placed in a closet, and in addition, by pasting black paper over the vessel sought to protect it from the influence of light. After seventy-three days the latter solution had the original yellow colour, and exactly the same amount of alkaloid as before the experiment. On the other hand the solution exposed to the sunlight became brownish red and contained now a red substance which was amorphous, dissolved readily in ether, and did not neutralize sulphuric acid. Of the quinine only 0·54 per cent. was still present, whilst the amount of that alkaloid was originally 3·72 per cent. Instead of quinine a considerable quantity of an amorphous substance was obtained, which corresponded with quinicine. The small quantity of cinchonine and conchinine, which were originally in the solution, could afterwards no longer be detected.

Under the influence of light, therefore, a red substance is formed from quinine, which indeed is still an alkaloid, but is not capable of neutralizing an acid. As such a substance is not met with in the cinchona barks, it appears to me as if light generally has not so much influence upon the formation of the amorphous bases as there is at present a disposition to believe. Rather must an influence of quite a different sort operate in determining the quality of the cinchona alkaloids. We have to take into consideration that the cinchona alkaloids are only met with in the bark, and indeed in the cellular layer situated next to the sap wood, the so-called bast layer, but not in the wood* nor probably in the leaves, flowers, seed-capsules or seeds. Probably it would be right to consider them an excretion which, through imperfect nourishment or other vital process of the plant, becomes absorbed in the further development of the plant, and thereby undergoes an alteration in character.

The amorphous bases, moreover, are formed in the manufacturing preparation of sulphate of quinine, and remain dissolved in the mother liquor. From this mother liquor David Howard† obtained what he at first took to be a new alkaloid. If, therefore, quinicine be formed in the working up of barks containing quinine, it might well be expected that when barks containing cinchonine and cinchonidine are employed cinchonicine would be obtained.

Both substances dissolve easily in ammoniacal salts; but, nevertheless, the latter cannot be used to separate them from the crystallizable bases, because these are equally soluble therein. To this may be added, that when quinoidine is boiled in an aqueous solution of an ammoniacal salt—such as oxalate of ammonia—it readily adheres together, so that but small contact takes place between the solvent and that which is to be dissolved; hence it appears to me that the process of quinine purification given by De Vrij‡ is more suited to the lecture-desk than the laboratory.

When the crystallizable cinchona alkaloids are heated for a long time with acids, they are converted, as Pasteur first pointed out, into their amorphous modifications. Quinicine is thus formed from quinine, and cinchonicine from cinchonidine, by which the specific rotatory power is diminished. It may probably be assumed that the decomposition product which Zorne§ obtained from the sulphates of quinine and cinchonine, by heating them with hydrochloric acid, were not derived directly from the quinine and cinchonine, but from their amorphous modifications, quinicine and cinchonicine. These latter sub-

* Translated from the 'Vierteljahresschrift für praktische Pharmacie,' vol. xxii. p. 366.

* Broughton has noticed an extremely small trace of the cinchona alkaloids in the wood as well as in the leaves of *C. officinalis* and *C. succirubra*; De Vrij also believes that he has detected traces of the alkaloid in the leaves of *C. succirubra*. These traces may probably owe their existence to some accident that escaped observation. At all events, in a careful experiment with twenty pounds of leaves, Howard has not been able to meet with a trace of alkaloid. Also an experiment which I undertook with the wood of *C. succirubra* yielded no alkaloid.

† Pharmaceutical Journal, [3] vol. i. p. 845.

‡ Jahresbericht für Chemie, 1866, p. 472.

§ Journal für prakt. Chemie, [2] vol. iv. p. 44.

stances are, moreover, also formed without the addition of acids, if the bases be exposed with glycerine to a temperature of 180° C., or preferably, 210° C. The glycerine is then coloured red, a red substance, not neutralizing acids, being formed in it, and the amorphous modification of the respective base is produced besides.

Arrived at the conclusion of this memoir, I would yet remark that in the interest of the subject it is very desirable that some of the pretended aricine should be sent to me (at Fuerbach, in Stuttgart) for examination, since I assume that some may be met with in one collection or another. With respect to quinidine (p. 613) I hope to make a further communication, the results of which must be awaited. Consequently, of the cinchona alkaloids, if we leave out of consideration the modifications of them, and Schutzenberger's* two nameless alkaloids ($C_{21}H_{28}N_2O_2$ and $C_{18}H_{22}N_2O_2$), only the following can be safely named as discovered: quinine, cinchonidine, cinchonine, paricine, quinamine, paytine, and conchinine. The first three of these alkaloids are well known as commercial articles; but conchinine is mostly met with in commerce under the name of "quinidine." The latter three alkaloids—quinamine, paytine, and conchinine—appear to form a group together. They might probably, under the influence of cell-life in the respective plants, be transformed one into another, and this might be the reason why in the bark of *C. succirubra* no conchinine is met with, but quinamine is.

HYDRATE OF CHLORAL.†

Dr. Oscar Liebreich has recently published a paper in the *Berliner Klinische Wochenschrift*, in which he calls attention to the important subject of the purity of chloral hydrate, and the effect which its deterioration may produce on the patients to whom it is administered, and on its reputation as a remedy. The case, he says, is different from that of such a substance as quinine, the adulteration of which will only reduce, but will not pervert, the proper action of the drug. With chloral and other substances prepared by analogous chemical processes, the result of the manufacture may be the formation of compounds which, if administered, produce an altogether different result from that intended. The process of manufacture is one which requires great care; and it seems that it is at least difficult to ensure the purity of chloral, if made in large quantities. Liebig himself, who discovered it, never attempted to make more than a few grammes at once; and Dr. Liebreich was so convinced, when he brought it into notice as a medicinal agent, that purity was necessary for success, that the first supplies were made under his immediate superintendence. At present, it is manufactured in various places; and the result is that, in some parts of the continent, notably in Saxony and Switzerland, it has fallen into disrepute. Dr. Liebreich has made a collection of specimens of the drug used in cases where it has failed to produce its proper action, and possesses, he says, some horrible chemical compounds which he would not venture to give to a human being. He prefers the crystallized form of chloral hydrate as the most stable. It may contain hydrochloric acid; this is no disadvantage if the proportion remain the same; but, if it increase, it indicates that the formation of dangerous compounds may be going on. Sometimes the hypnotic action is increased; this he attributes to the production of chlorine compounds, which are more readily changed into chloroform than chloral itself is. An acid reaction, arising from the formation of trichloracetic acid, does not show that the chloral is unfit for use, though it weakens its action. In pure chloral, this action is limited; while impure chloral is liable to the constantly increasing productions of acid compounds—not trichloracetic acid—of a deleterious nature. Dr. Liebreich remarks that the German *Pharmacopœia* is in error in fixing the boiling point of chloral hydrate at 95 cent. (203 Fahr.). This, he says, is correct for anhydrous chloral; but the boiling point of chloral hydrate is not constant.

JERVIA IN VERATRUM VIRIDE.*

BY CHAS. L. MITCHELL.

Since the discovery and isolation of two alkaloids in *Veratrum viride* by Mr. Charles Bullock in 1865, no additional researches seem to have been made. Simon obtained jervia from *Veratrum album* some ten or fifteen years ago, but notwithstanding the fact that *Veratrum viride* is so similar in almost every respect, up to this date, I can find no record of any attempt having been made to prove the presence of jervia in the latter root.

While recently preparing specimens of the *Veratrum viride* alkaloids according to the process given by Mr. Bullock, my attention was drawn to the circumstance, that when the precipitate produced in the acetic solution by sodium carbonate was treated with warm diluted sulphuric acid, a considerable amount of a granular, whitish powder separated on cooling. I at first supposed it was sulphate of calcium, but a closer examination revealed the fact that it was of organic composition, and after several different trials, I succeeded in proving it to be an alkaloid identical with the jervia of Simon. It may be obtained in its pure form by the following process:—

Veratrum viride finely powdered is thoroughly exhausted with stronger alcohol, the tincture distilled to a small bulk, acidulated with acetic acid and precipitated in water. The resin is then separated by filtration from aqueous solution of the alkaloids and the filtrate concentrated by evaporation and rendered strongly alkaline with solution of carbonate of sodium. The precipitate thus obtained is drained, dried, boiled with strong alcohol until nothing more is taken up, the alcoholic solution evaporated to dryness and digested in very dilute sulphuric acid.

The granular powder which deposits on cooling is sulphate of jervia. This is separated, well washed and drained, and then boiled for some time with a strong solution of carbonate of sodium. By this treatment the sulphate of jervia at first formed is decomposed, the jervia separating as a granular powder, which is washed until free from alkali, dissolved in acetic acid, precipitated with ammonia, well washed and dried.

Jervia thus obtained is a light, white powder, capable of crystallizing from an alcoholic solution, tasteless, inodorous, and of a feebly alkaline reaction. It is insoluble in water, but very soluble in boiling alcohol, from which it is almost entirely deposited, on cooling, in white flakes. It is freely soluble in chloroform, but is only slightly soluble in benzin. With acetic and phosphoric acids it forms very soluble salts; with sulphuric, hydrochloric, and nitric acids, it yields salts, sparingly, soluble in alcohol and water, and precipitated from the more soluble acetate and phosphate.

Potassa, soda, and ammonia, precipitate jervia from its solutions in white, rather gelatinous flakes, insoluble in an excess of the precipitant. With reagents it gives the following reactions: Perchloride of gold, curdy, yellow precipitate; sulphocyanide of potassium white precipitate; bichloride of platinum, granular, yellow precipitate; iodohydrargyrate of potassium, curdy, white precipitate.

The most characteristic test for jervia is its reaction with sulphuric acid. When a minute fragment of it is moistened on a glass slide with a drop of concentrated sulphuric acid it immediately changes, first to a straw yellow and then gradually to a green colour. This reaction is quite delicate.

Concentrated nitric and hydrochloric acids dissolve jervia to a colourless solution, which when boiled becomes of a

* *American Journal of Pharmacy* for March.

straw colour; when heated it melts to a clear oil; at a little above 400° Fahrenheit turns brown; and when the temperature is raised still higher, it burns with a smoky flame.

Thinking that it would be well to compare this alkaloid with the jervia from *Veratrum album*, I subjected some of the latter, which I had previously prepared, to the same tests, with precisely the same results. I do not feel as yet able to state exactly the proportion in which jervia exists in *Veratrum viride*, but am pursuing a series of investigations on both this and *Veratrum album*, the results of which I trust shortly to be able to make public.

LACTO-PHOSPHATE OF LIME AND COD LIVER OIL.*

BY C. G. POLK.

The cry of "Eureka," which has ascended so loudly over the new hobby, lacto-phosphate of lime and cod liver oil, it seems has almost led the enthusiastic members of the medical profession to hope that the great specific for all the ills to which flesh is heir had at last been found. The long high-sounding name seems to invest it with solemn import, and leads us to regard it with respect and confidence. It seemed to be the very thing for a proprietary medicine, and consequently it did not take very long to secure it a copyright.

The errors of the combination, outside of the quackery into which it has been run, however, immediately concerns us, and to point them out I am prompted to indite this.

In the first place, the syrup of lacto-phosphate of lime will not combine without the addition of adjuvants with cod liver oil and form a homogeneous mixture. To secure a perfect admixture, other substances must be introduced, and these usually are acacia, tragacanth, and alkalies. Against such a compound, when freshly made, there is, perhaps, no pharmaceutical objection. The relative amounts of cod liver oil and lacto-phosphate of lime are, however, not so uniformly required under the varying phases of disease, age, sex, and temperament, so as to enable the pharmaceutical chemist to prepare a preparation uniformly adapted to every case or one as well adapted to secure the best remedial effect of the agents as when proportioned by an intelligent physician to meet each individual case. This can be done by using an emulsion of cod liver oil; the one suggested by Mr. Rice is a good formula, to which the syrup of lacto-phosphate of lime may be added in whatever amount desired. Thus we should always get the article fresh, free from rancidity if good oil is used, and have an article preferable to much of that now dispensed. The more I have examined the syrup of the lacto-phosphate of lime and cod liver oil, the more I have become convinced that the preparation is an unfortunate one. Cod liver oil rapidly becomes rancid and unfit for administration in the presence of the phosphate, lacto-phosphate, and hypophosphite salts of lime. It seems to me that it would be a much better plan to use the oil and lacto-phosphate alternately, than to mix them together; I always do, and often find the result very gratifying. Lacto-phosphate of lime, it seems to me, is more especially adapted to the period of convalescence from acute diseases than chronic ones. As is well known, during the progress of fevers and inflammations, the waste of the phosphate of lime is great and requires a resupply, which is nicely afforded by the lacto-phosphate. But in such cases the cod liver oil is not by any means indicated. In scrofulous diseases of children, the class in which the syrup of the lacto-phosphate of lime and cod liver oil has been very extensively used, and in which no doubt it has given good results, a better preparation would be obtained by extemporaneous combination. As a rule, fixed medical formulas, combining several ingredients, are objectionable. Dover Powder is an established fact, and the combination of iron, quinia, and strychnia in Easton's syrup is a splendid preparation incapable of extemporaneous formation as required in the usual routine of pharmacy. A few more instances perhaps might be cited, but the rule still holds good. Lactic acid, it is well known, plays an important part in rheumatism; what result may then accrue from the continued use of the lacto-phosphate of lime in chronic diseases?

* *American Journal of Pharmacy* for March.

ON COPPICING CINCHONAS.

The following letter upon this subject, from Mr. John Eliot Howard, appears in the *Gardener's Chronicle* for March 28:—

As all information connected with the cultivation of the cinchona is important for those engaged in this branch of industry, I will ask space for a few remarks in reference to the plan of coppicing advocated in an extract from the *Agricultural Gazette of India*, and copied in a recent number.

It is well that the owners of the Sikkim plantations find the results of their cuttings "most satisfactory," but it is important to observe that this satisfaction does not extend to those who would desire from thence a supply of material for the extraction of quinine, and, consequently, that it would be a mistake to recommend this plan for general adoption.

The bark of coppiced oak is, I believe very abundant in tanning material. Certainly, I know that the corresponding bark of the cinchona, and especially of the *C. succirubra*, abounds in the astringent principles which are an annoyance to the chemist in the above manufacture. It is equally a matter of notoriety that the bark of small branches, such as would be supplied by this plan, is comparatively barren in quinine. In my 'Quinologia' (*sub voce C. magnifolia*, p. 8) will be found a table from the researches of Dr. de Vrij, showing that kinovic acid abounds in the inverse proportion to quinine, so that the bark of small branches (called *canutillos* in South America) may be very useful as a tonic, and very bitter, but useless for the extraction of quinine.

It is certain that the latter is never found in quantity till the bark has attained a certain thickness. The reason for this is, probably, that the alkaloids are not formed in the leaves and carried downward by the descending sap. A theory that such was the case used to be entertained, but is negatived by the examination of the leaves, such as I have communicated to the PHARMACEUTICAL JOURNAL, and by Mr. Broughton's researches in India. On the other hand I have sought to show that the alkaloids are formed in the cellular tissue of the bark, commencing more especially with the cambium (see 'Quinology of the East Indian Plantations,' p. 28). When the bark is renewed, after being stripped from the tree, the new portion presents a very unique appearance; such as I have represented in the last work, and which I call lax cellular tissue. This is specially rich in alkaloid (see plate iii.), and I have found the singularly radial appearance of this structure exactly reproduced in some renewed succirubra bark of good quality which I have recently examined.

I compare this in my own mind to the peculiar cellular tissue of the gall-nut, produced through the puncture of the cynips, and therefore in a similar abnormal manner. This tissue, as everyone knows, is very rich in the (chemically) characteristic product of the tree.

I am indebted to M. Moens, of Java, for the following confirmation of my opinion (which will not be without interest to your Ticehurst correspondent on grafting vines, p. 311). M. Moens says:—"Some years ago Mr. V. Gorkom had grafted two C. Calisayas upon two C. Pahudianas. The grafts succeeded very well, and I now took the bark for examination. This showed that the Calisaya, as well as the Pahudina, kept their alkaloids as if they had grown separately. I think this is an experiment of considerable interest, and we shall repeat it, if possible, with (C.) micrantha and Calisaya Ledgeriana. I think the result most agrees with your idea that the alkaloids are formed in the cellular tissue of the bark."

I wish it to be understood that I do not pledge myself to any particular mode of cultivation. I have grave doubts of the possibility of carrying out the plan of renewing the bark with commercial success. Let every plan have a fair trial and time will decide; but, as I think, the verdict will not be in favour of the coppicing system.

It may interest your readers to learn that the introduction of a new sort of Calisaya (called Ledgeriana) into Java, has greatly added to the value of the plantations, and the prospects of success are of a marked character.

In India, also, Mr. McIvor has found a new variety of great promise—the sample of its bark sent me having yielded not less than 11 per cent. of crystallized sulphates of the two alkaloids, quinine and cinchonidine. These kinds I have referred to in an article, now publishing by the Linnean Society, on the genus Cinchona.

This week has seen a large consignment of bark of C. officinalis from the Nilgherries of excellent quality for the extraction of quinine, of course fetching a high price.

ASCENT OF SAP IN THE BARK OF TREES.

M. Faivre has recently performed a series of experiments on the mulberry, hazel-nut, and cherry laurel, which he considers goes far to prove the fact that the substances which supply the food of plants have an ascending motion in the bark. For this purpose he made perfect or imperfect annular incisions through the bark, or detached pieces of the bark, to which buds were attached, or removed entire cylinders of bark from the trunk. The result of the experiments was that the buds always continued to develop when the communication remained uninterrupted with the lower portion of the trunk; while, when this communication was completely destroyed, the buds invariably withered away. If the bud was separated by a perfect annular incision, it withered the more slowly the greater its distance from the incision; and in these cases the starch disappeared entirely from the portions of the wood above the incision between it and the bud. When entire cylinders of bark with buds on them were removed, the buds continued to develop, and even produced branches bearing leaves.

FOURTH REPORT OF THE ROYAL COMMISSION ON SCIENTIFIC INSTRUCTION.

In the above report which has just been published, are contained some important recommendations with respect to the natural history and scientific collections belonging to the nation, and also with respect to the establishment of courses of scientific lectures in the great centres of population. The recommendations are thus summarized :—

With regard to *the Natural History collections of the British Museum*, it is recommended:—That the occasion of the removal of these collections to the new buildings now being erected at South Kensington for their reception be taken advantage of to effect a change in the governing authority and official administration of that division of the museum. That a director of the national collections should be appointed by the crown, and should have the entire administration of the establishment, under the control of a minister of State, to whom he should be immediately responsible; and that the keepers of collections, should be responsible to the director. That the appointments of keepers and other scientific officers should be made by the minister, after communication with the director and with the board of visitors (herein after referred to). And that the director should prepare the estimates, to be submitted, after consultation with the board of visitors, for the approval of the minister. That the present superintendent be the first director. That a board of visitors be constituted. That the board be nominated, in part by the crown, in part by the royal, and certain other scientific societies of the metropolis, and, in the first instance, in part also by the board of trustees; the members to be appointed for a limited period, but to be re-eligible; and that the board of visitors should make annual reports to the minister, to be laid before parliament, on the condition, management, and requirements of the museum, and should be empowered to give him advice, on any points affecting its administration.

With regard to *the Museum of the Royal College of Surgeons*, it is recommended :—That, should the fund at the disposal of the college, owing to changes in medical legislation, or from any other cause, prove inadequate for the efficient maintenance and continued extension of the museum, it should receive support from the State, as an institution intimately connected with the progress of biological science in this country.

With regard to *the National Botanical Collections and Gardens* it is recommended that the collections at the British Museum be maintained and arranged with special reference to the Geographical distribution of plants and to palæontology; and that the collections at Kew be maintained and arranged with special reference to systematic botany. That all collections of recent plants made by Government expeditions be, in the first instance, sent to Kew, to be there worked out and distributed, a set being reserved for the British Museum; and that all collections of fossil plants made by Government expeditions be sent to the British Museum. That opportunities for the pursuit of investigations in physiological botany should be afforded in the Royal gardens at Kew.

With regard to the *Scientific Collections of the South Kensington Museum*, the commissioners recommend the formation of a collection of physical and mechanical instruments; and they submit for consideration whether it may not be expedient that this collection, the collection of the patent museum, and that of the scientific and educational department of the South Kensington Museum, should be united and placed under the authority of a minister of State.

With regard to *Provincial Museums*, it is recommended that, in connexion with the science and art section of the education department, qualified naturalists be appointed to direct the collection of specimens in order to supply whatever deficiences exist in the more important Provincial museums; and, also, in order to organize typical museums, to be sent by the department of science and art into the provinces to such science schools as may be reported to be likely to make them efficient instruments of scientific instruction. That a system of inspection of provincial museums be organized with a view of reporting on their condition, and on the extent to which they are usefully employed, and whether the conditions of the loan or grant from the department of science and art have been fulfilled.

With regard to *Public Lectures*, it is recommended that courses of lectures be given in connexion with the collection of physical and mechanical instruments, the establishment of which we have proposed, the object of these lectures being to illustrate the progress of scientific and mechanical discovery and invention. That the establishment of lectures on science, accessible to all classes on the payment of a small fee, should be promoted by the Government in the centres of population. That, in the first instance, with the view of carrying out the preceding recommendation, the system of instruction of this kind, which has already been established by the government in the metropolis, should be developed by the institution of courses of lectures on the principal branches of experimental and natural science. That the proposed lectures be of two kinds. First: Lectures of an elementary character on the general principles and most important facts of science. Secondly: Lectures specially intended for the working classes on the application of science to the arts and industries ot the country.

The report and recommendations are signed by the Duke of Devonshire, Sir John Lubbock, Sir J. K. Shuttleworth, W. Sharpey, T. H. Huxley, G. G. Stokes, Henry J. S. Smith, and B. Samuelson.

The Pharmaceutical Journal.

SATURDAY, APRIL 4, 1874.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE REGISTER OF CHEMISTS AND DRUGGISTS AND THE CALENDAR OF THE PHARMACEUTICAL SOCIETY FOR 1874.

LAST year we took the opportunity afforded by the publication of the Register of Chemists and Druggists and the Pharmaceutical Society's Calendar to place before our readers some comparative statistics gathered from those official records which it was thought might have some interest as a contribution to the history of the progress of pharmacy in this country. As the Calendar and the Register for 1874 have now been published, we avail ourselves of an early copy placed at our disposal to continue the comparison.

The total number of Chemists and Druggists on the new Register is 13,216 against 12,757 in 1873, being an increase of 459. Of these 2374 are Pharmaceutical Chemists, or 17·96 per cent. on the whole number. This is an increase on the actual number of Pharmaceutical Chemists of 7; but it is a slight decrease on the relative percentage of 1873, which was 18·56. However, since the removals from the Register of Pharmaceutical Chemists include the names of both examined and unexamined persons, whilst the additions are the names of persons who have all passed the Major examination, it is interesting to note that the number of examined Pharmaceutical Chemists is now 1179, or 8·92 per cent. of the whole number of registered Chemists and Druggists, a percentage almost identical with that of last year.

The number of persons whose names are on the Register of 1874 by virtue of their having passed the minor examination is 1400, or 10·59 per cent. of the whole, this being an increase of 397, or 2·72 per cent. The foregoing figures may be compared thus :—

	1873.			1874.		
	Number.	Per cent.		Number.	Per cent.	
Pharmaceutical Chemists :—						
Non-examined	1229	9·63		1195	9·04	
Examined . .	1138	8·93		1179	8·92	
	2367	18·56		2374	17·96	
Chemists and Druggists who have passed the Minor . .	1003	7·87		1400	10·59	
Remainder, including those who have passed the Modified . .	9380	73·57		9442	71·45	
Total	12,750	100·00		13,216	100·00	

Next, as to the proportion which the number of names on the Calendar of the Pharmaceutical Society bears to the number of names on the Register of Chemists and Druggists. Of the 2374 Pharmaceutical Chemists on the Register, 2119 or 89·25 per cent. against 86 per cent. last year, are members of the Pharmaceutical Society. Of the remaining 10,842 Chemists and Druggists on the Register, 781 are connected with the Pharmaceutical Society as Chemist and Druggist Members, and 1193 as Associates. This gives a total of 4093, or 33·97 per cent. of the whole number of registered Chemists and Druggists who are connected with the Society, being a relative increase of more than one per cent. during the year. The Registered Apprentices of the Society have increased from 764 to 811. These figures may be tabulated thus :—

	1873.		1874.	
	No.	Per cent.	No.	Per cent.
Pharmaceutical Chemists, Members of the Society	2027	86	2119	89·25
Other Registered Chemists and Druggists connected with the Society . . .	1695	...	1974	...
Total number of Registered Chemists and Druggists connected with the Society	3772	29·77	4093	30·97
Registered Apprentices of the Society	764	...	811	...

For the information of those readers who are not acquainted with the Calendar of the Pharmaceutical Society it may be as well to mention that besides the lists of members associates, etc., the new Bye-Laws, the Pharmacy Acts, and the new Regulations of the Board of Examiners, it contains a full abstract of all the legislative enactments in which Chemists and Druggists are especially interested.

THE ADDITIONS TO THE PHARMACOPŒIA.

THE time occupied by the reading of Mr. UMNEY's paper on the additions to the Pharmacopœia did not admit of any discussion being entered upon, and it was consequently resolved, on the motion of Mr. BLAND, that the meeting should be adjourned until the first Wednesday in May.

The VICE-PRESIDENT, however, directed attention to the fact that there seemed to be two issues of this official publication, differing very much from one another, and although both bearing outside the same title and the date 1874, one of them was dated inside on the title-page 1873.

Professor REDWOOD, on being appealed to for information, declared himself unable to account for the circumstance.

It would almost seem as if, by some unaccountable accident, the proof sheets circulating among members of the Pharmacopœia Committee, while the additions were still under consideration, have been bound up in mistake for the perfected impressions of the work. This would certainly be a serious matter, and immediate steps will be necessary to ascertain the extent to which this has taken place.

THE SOCIETY OF CHEMISTS AND DRUGGISTS IN IRELAND.

It is with satisfaction that we note that notwithstanding the obstacles which the above Society appears to meet with in attaining the special object for which it was formed, namely, a Pharmacy Bill admitting the chemists and druggists in Ireland under certain conditions to the privileges of dispensing, it is turning its attention to the diffusion of useful scientific information amongst its members. A valuable course of popular scientific lectures, illustrated with diagrams and experiments, has been organized, to be held in Molesworth Hall, Molesworth Street, Dublin. The programme is as follows:—

March 30th—"The Secrets of Modern Pharmacy." Professor Charles R. C. Tichborne, Ph.D., etc.

April 13th—"Terrestrial Distribution of Heat." George Porte, Esq., M.R.I.A., etc.

April 27th—"Some Phenomena of Light, and their Relation to Practical Chemistry." Henry Draper, Esq., F.C.S.

May 11th—"Adaptations in Plants." Professor Robert M'Nab, M.D.

May 18th—"The Microscope." Joseph H. Woodworth, Esq.

May 25th—"Crystallization and Crystalline Forms of Pharmaceutical Products." Professor J. Emerson Reynolds, L.K. and Q.C.P.

June 8th—"Adulteration of Food and Drugs." Professor Charles Cameron, L.K. and Q.C.P., City Analyst.

The tickets are 6*d*. each; or 2*s*. 6*d*. for the course, and the members are admitted free.

CONVERSAZIONE OF THE FACULTY OF PHYSICIANS, AND SURGEONS OF GLASGOW.

This Corporation held a conversazione on the evening of Thursday, the 26th March. Between 300 and 400 medical practitioners from all parts of Scotland, including counties so wide apart as Inverness and Aberdeen on the one side and Peebles and Dumfries on the other. The company was received in the large hall by Dr. Ebenezer Watson, the President, who gave a short address of welcome, and briefly indicated the various objects of professional interest in the different apartments. Mr. John MacMillan, Glasgow, and Messrs. T. and H. Smith and Co., Edinburgh, exhibited, in one of the apartments, specimens of drugs, admirable both as to extent and arrangement, and including most of the new preparations. In addition to the display of pharmaceutical specimens, Mr. MacMillan exhibited a considerable number of instruments and apparatus connected with pharmacy. Messrs. Smith showed a complete series of opium principles, two of them, thebolactic acid and cryptopine, their own discoveries. The specimen of meconine was the product of 1000 lbs. of opium. They also showed large specimens of crystallized salts of morphia—including the meconate of this alkaloid, introduced by them for hypodermic treatment, and soluble in three or four parts of water,—cantharadin, caffeine, aloin, ergotin, jalapin, scammonin, etc. The exhibition attracted, as it deserved, much attention during the evening.

Transactions of the Pharmaceutical Society.

NORTH BRITISH BRANCH.

The fifth meeting of the session was held in the Society's Rooms, St. Giles Street, Edinburgh, on Thursday evening, 26th March, at half-past eight o'clock. Mr. J. R. Young, President, in the chair.

There was a full attendance.

Dr. Stevenson Macadam read a paper on the quality of milk supplied to towns. This paper it is intended to publish next week.

After some remarks by the Chairman, Mr. Mackay, and Mr. Baildon, a very cordial vote of thanks was awarded to Dr. Macadam for his very interesting communication.

Mr. Baildon then read the following descriptive papers in reference to eight cases of specimens presented to the Pharmaceutical Society's Museum in Edinburgh, by Robert Jamie, Esq., of Singapore. Communicated by Mr. H. C. Baildon:—

Early in December of last year I received two letters from my friend Mr. Jamie, of Singapore, intimating that he had sent to my care eight cases of various specimens to be presented by me, in his name, on their arrival, to the North British Branch of the Pharmaceutical Society of Great Britain. They were consigned to the care of Messrs. Langton, Scott, and Edden, of London, with instructions for them to pass them through the Custom House, and to forward them, carriage paid, to my address. As mischief is frequently done by the rough usage of the Custom House officials, I requested Messrs. Langton to use their influence to have these cases passed unopened, as they contained nothing liable to duty. This they kindly succeeded in doing, and upon their being unpacked in our rooms, in Mr. John Mackay's and my presence, almost all the specimens were found perfect. I beg now to read from a private letter to myself from Mr. Jamie, of date 1st November, 1873, in reference to these specimens.

"Long ere this I hoped to have answered your kind favour of 5th and 11th Dec., 1872, conveying to me the thanks of the Pharmaceutical Society for what you read of my letter at the meeting, but, circumstances over which I had no control prevented me till now. The chief and principal cause being an attack of Dengue fever, which I got in the beginning of this year. Though only confined to my room by the fever for four days, yet the pains which accompany this fever were so excruciating and continued so long that it was months before I felt myself again. I never experienced so much pain from any of my previous attacks of fever (aguish) which I have occasionally had. The doctors said that it resembled rheumatic fever. Though treated properly with iodide. potass. etc., the pains were in no hurry to leave, so at last I left nature to work a cure. The fever was epidemic, and all classes suffered more or less severely. I could be at business daily, but to do the least thing, even writing, was exquisite agony. I had before my illness begun to make a collection of coral, etc., for the Museum, but it was only the other day that I got it completed. I shipped the whole (8 cases) to London in the 'Ivy' consigned to Langtons, Scott and Edden, who will get their agents to pass them through the custom house and forward on to you free of charges. I enclose a list of the various specimens sent, but before saying anything more about them, I shall go over the paragraphs in your letter requiring answering."

It will be recollected that Mr. Jamie had on a previous occasion taken great pains to prepare an essential oil from Champaka flowers and the following is in reference thereto:—

"The Champaka flowers of either kind could not be manipulated according to the French method, for the simple reason that there are so few trees, and they again are so far apart: the flowering is so very irregular and seasons uncertain. Steaming without doubt is the more preferable mode for extracting the oil. I have scarcely

seen a flower of the white kind for a year. The tree is not a rapid growing one or it might have been worth one's while to have planted a few acres for experiment.

"I am very sorry to hear that the orchids have made so little progress with you. The weather I hope has been more favourable this season for them, and that many have flowered. My own collection has suffered very much from the attacks of a small insect (a weevil), which burrows into the centre of the plants which kills them: it is really heartrending to look at the destruction they have made amongst my fine large plants—not a leaf on them—and it disheartens one from continuing increasing stock even though comparatively cheap here. Some few months ago I got over from Borneo 1000 plants of a kind (*new* Phalænopsis) and now there is not a single plant remaining. Fifty dollars gone besides the trouble of sticking and looking after them, and many thousands of other kinds I am not the only sufferer here; others who cultivate them have suffered also. In Burmah, one of the greatest fields for them, they are dying also from the same cause.

"We have had the most extraordinary season I ever remember since I came here; very hot, with little or no rain, sometimes a month would pass and not a single drop of rain fall. So long did that state continue that we consider the outbreak of cholera, which we had for some time, originated from this cause. It carried away daily some 20 or 30 natives; they in fact were the principal sufferers; very few Europeans died, and those who did were of intemperate habits. From the papers I observe, that cholera has been very general over the habitable globe; it certainly has not been carried from place to place at all these places mentioned in the papers, but in many must have been generated *de novo*, brought about by high temperatures, bad drainage, bad water, swampy ground, and, perhaps, though last not least, the state of the individuals' health, caused by low living and want of proper clothing; this latter applies more to Eastern than Western nations. In case I forget I may as well mention now, that in the No. 5 case you will find a long stick which I present to yourself to make a walking stick of. You will appreciate it the more when I tell you that it is a fine piece of the most rare and valuable wood *Aloexylon agallochum* — lign aloes—from Cochin-China, which, when of fine quality, is more precious than gold amongst the natives. I myself roughly polished and rubbed it with oil, to make it look well. I have enclosed £2 which will pay for washing the coral which the Society may keep, as I do not expect they will care for so much as I have sent or even any. The rest can be given to whom you think fit; it was collected before I took ill, and before I could again pay attention to it, got dirty, and as it is packed in sawdust will take some time to free it, and the best way in my opinion to do that will be to put it in a running stream of water, using a brush, at the same time putting out in the sun to dry, when it ought to look beautifully white. One washing and bleaching may not do, it ought to be done till perfectly white, when it will be ready for putting under glass.

"In reference to this I may mention that I have had great pleasure in presenting to the Museum of Science and Art, through my friend Professor Archer, a selection of specimens not already in the museum, and that we are indebted to Dr. Traqquairn for naming most of the kinds kept for our own cabinets.

"The three white ants' nests, they probably do not care for keeping them all, one might be given to Professor Archer with a queen ant if he cares to have them; and one to Dr. Macadam, to give you an analysis of for a lecture at one of your evening meetings. If any manufacturing chemist, such as T. and H. Smith or Macfarlane and Co., would like to try making the alkaloid of the *Menispermum crispum* I shall most willingly collect and forward them a cwt. or so of it. I have written you another letter with a sort of running commentary on the most of the different articles sent, which you can read as it is, or if you think necessary, supplement from your private letter any extract which I have omitted that bears on any of the subjects. Many of the Gamboge leaves, are tied with silver wire to the cardboard, as I found that with the least shaking, they fell from the twigs. I am not satisfied with my attempt at pressing; next lot I trust will be still better, which I hope to present to Herbarium at the Society's Rooms, London.

"Professor Christison or Professor Balfour will now, from the leaves, male and female flowers, and fruit, be able to definitely class, or rather name, the gamboge tree of Siam."

I will now read Mr. Jamie's letter, which is more especially connected with his presents:—

"Singapore,

"Nov. 3rd, 1873.

"At the first Pharmaceutical meeting you have the pleasure of attending, return my grateful acknowledgments for the cordial vote of thanks which you so kindly conveyed to me. And now, will you, in my name, present to the Society the botanical, mineral, and natural history specimens which I have forwarded to your care, and which are as per enclosed list.

"Four cases containing specimens of varieties of coral found here, among which are two pieces of red coral. Singapore has no limestone, and is consequently dependent on coral for making lime for building purposes, the burning of which, and of sea shells (for lime) is a large trade amongst the Chinese. Putrid coral—by that I mean the dead animal—is a great source of disease, and no one can doubt this if they only walk over a coral reef at low water under a tropical sun. Sailors frequently catch fever from having such in their sleeping bunks. In No. 5 case there is a fine specimen of the snout of the saw-fish (*Pristus cirratus*) which was caught off Malacca; the teeth are very perfect and in good condition. In No. 6 case there is a specimen of a coralline tree, from which the natives make ornaments. It is not brittle, but tough, and can be bent into any shape without breaking, by the aid of heat, and is capable of a fine polish. A small piece of a branch of the true Gamboge tree of Siam, polished roughly at the ends to show the hardness of the wood, a piece divided lengthways, a piece with a small branch with leaves, and showing the exudation of the gum resin. These were cut from the tree at a time when the ground was exceedingly dry, no rain having fallen for a month previous, which accounts for the very small quantity exuded; and a large skin of what the natives call 'Ikan pari-pari' with which they polish smooth wood, etc. In No. 7 case you have a large specimen of the galena from the mines at Patani on the east coast of the Malay Peninsula; it is rich in silver, running from 64oz. to 80oz. per ton; a bag with galena very poor in silver, if any, from near Freemantle, Australia; gold quartz, with arsenical silver pyrites, from the Clin-drap mines, near Malacca, yielding 4½oz. to 6oz. pure gold per ton; a piece of ironstone which has been under tidal influence, giving it a coppery appearance; and a piece of limestone rock with fossil shells from near Penang.

In the last case, No. 8, are three white ants' nests and their queens. None of the queens have arrived at maturity, though their nests are full-sized. Each queen is built in and cannot by any means get out again; her principal occupation is laying eggs, her food being brought to her. There must be some particular virtue in white ant's nests, as the Chinese pay high prices for them to mix in certain kinds of porcelain which they make. These ants' nests are found inside of a large hillock of similar earth, which is quite impervious to rain, however heavy the shower may be, and so hard that it is some time before a chunkel (literally a pricker), a large hoe, makes any impression on it. I think of all known insects the white ants are the most destructive, and a constant battle it is between man and them who shall be masters of the house, for if once in, thousands of dollars may not put them out. Those persons who wish to know

more about their habits and the benefits(!!) they confer directly or indirectly on those who do battle with them, I would refer to Kirby and Spence's 'Entomology.' A piece of *Menispermum crispum*, which, when freshly collected, is exceedingly bitter, and is used by the natives in place of quinine in cases of fever (see Lindley's 'Flora Medica.' The leaves I omitted to send, for which I am very sorry. My next contribution, I trust, will contain them. Two Bezoar stones, whether got from porcupine or deer I know not, a Parsee here gave them to me ; iron pyrites from Macassar, the same being very common all over the islands round about ; other minerals from Macassar and elsewhere ; a lump of very pure cinnabar ; also a piece of limestone rock, showing the cinnabar *in situ*, found in Borneo. There the Borneo Company (Limited) have erected large premises for its distillation. Copper ore, also from Borneo. Part of a petrified claw, found amongst the ironstone of this island, remarkable as being one of the very few fossils discovered; from the size of the claw, the bird must have been of some considerable size. A piece of mineral from the Pellew Islands. Rock crystals from Johore. A bottle with oxide of titanium with a trace of silver, which can be got in shiploads full near to Singapore. Two of these most wonderful and lovely *Euplectilla*, from Manilla. Mounted on a fine piece of white coral, and put under a glass shade, they will make a beautiful ornament for the Society's rooms. A copy of a colloquial Chinese dictionary used at Canton; a few pieces of the soldier ants' nurseries; when newly taken out of the ground they smell somewhat like rye bread. Specimens of coralline ornament —a bracelet and a mounting for a riding whip, roughly done. A few pens made from the common bracken as used by Parsees for writing. The same kind of bracken I have seen growing as high as twenty feet in certain favourable parts of the jungle. A small specimen of tin ore from the Carimons quite close to Singapore. A card with specimen of the young leaves of *Ficus lasiophylla*. A card with specimens of back and front view of the leaves of what I was told was a species of *Comarius*, with a packet containing a few of the seed pods, and probably seeds inside some of them. The beauty of the venation on the back of the leaves drew my attention, and I thought they were worthy of being included. Several cards with specimens of Gamboge leaves (back and front view of them) and fruit. A glass tube with small branches (twigs) with male flowers in spirit ; a glass tube with small twigs on which are the female flowers of the Gamboge tree ; a tube with male flowers *only* as cut off the twigs, preserved in spirit, and a tube with them also, but colour abstracted by repeated washings of spirit, showing the amount of colouring matter when the two are put side by side. The trees from which these specimens are taken are true gamboge trees, having been sent down by the King of Cambogia to Sir Joze de Almida, of Singapore, some thirty-three years ago. These and many other fruit trees are now in the possession of the writer. They are evidently slow growing trees, as now they are only 19½ feet high, one foot from the ground 38 inches round the girth, and the circumference of the lateral branches are as near as possible 76 feet. The trees are remarkable for the number of short branches which spring from the lower part of the trunks, and spread to some distance laterally, being in that respect different in their habits and appearance from other trees near them. The veins or ribs in the leaves are not very distinctly defined, and there are intermediate rudimentary ribs but faintly marked. Many of the leaves, and more especially those of the female trees, are indented at their apices, and the leaves from both trees vary very much in size and shape, as may be seen by looking at the specimens. I unfortunately omitted to send a specimen card of indented leaves. The flowers on the twigs of the male tree are pedicellate, and those of the female sessile. The ovary sits quite close on the twigs, style very short and of a pale green colour, stigma mammillated, or what will, perhaps, still better convey my meaning, looked like a bunch of beautiful white heath flowers, but solid instead of being hollow. To see the pistil in all its beauty, the thin membrane surrounding the style with stamen looking formations must be cut away. Dissections were made from the freshly expanded flowers, as well as from unexpanded, magnification, 20 diameters, colour of male and female flowers, like a lemon colour. The shape of the mature fruit is generally square, though different forms and in all stages of maturity may be seen on the same tree ; no pulp inside ; four seeded, though three seeded fruit are met, and very frequently one of the four is smaller than the other three. If eaten without removing the integuments, purgative, and if taken off, harmless, they are tough and horny between the teeth and astringent to the taste. On one of the cards I have laid open the testa of a seed, showing a beautiful deposit of the gum between it and the tegmen. The fruit on the cards have shrivelled up very much in drying, and are only now one-third their original size. The anthers of the male flowers are not peltate, but circumsessile ; when freshly cut and immediately examined under the microscope the circumsessile anthers are very distinctly seen, surrounding the stamens as a belt extending from near the base to the very apex. Examined after being kept in spirit their position is much altered, being more in the shape of a cord round the stamens, and the stamens being somewhat contracted. Would not glycerine be much better for such delicate organs ? It is just quite possible that very many of the anthers may have come off by the action of the spirit and motion together, which will alter their appearance under the microscope. I had hoped to have been able to have sent you the mode of collecting the gum, but I have been disappointed in obtaining the information in time."

Since then I have received another letter from Mr. Jamie, dated, 25th December, giving a full and most interesting account of the process, which I will now read :—

"Singapore,

"25th Dec., 1873.

"My dear Mr. Baildon,—

"I trust you have got all the cases per 'Ivy,' and found their contents in good order.

"I hope the flowers of the Gamboge tree reached you in perfect condition, and more especially the leaves, as I omitted to put in along with them a few bits of gum camphor, to prevent the insects attacking them. When I wrote you regarding their dispatch, I was not in a position to inform you how, when and where the gum resin was chiefly collected and prepared for the European market ; but now I am glad to say,—thanks to friends in Bangkok, who got a Chinaman, acquainted with the *modus operandi* of pipe or bamboo gamboge, to wait on me as he passed through to Malacca,—that I can give you the information which, as described by him, is considerably different from any account that I have seen in works on Materia Medica, etc. But first allow me to say a few words as to the locality of the gamboge tree, and time of collection of the gum. Neither Siam proper nor Cochin-China proper ever produced gamboge. The Siamese and Cochin-Chinese, at various times, wrested from the Cambogians portions of their territory ; and it is from those conquered portions of Cambogia (as well as Cambogia) that the gum resin is prepared for exportation, Saigon and Bangkok being the principal places now of export, though, in former years, the greater part of, if not all, came from some seaport of Cambogia. At present Kâmpoh is the only seaport left to the Cambogians, and what little they now export comes from it. Cambogia, then, is the native place of the gamboge tree, and there it may be said to be indigenous, for the trees there flourish most luxuriantly, without attention or cultivation, in the dense jungles ; they must be propagated by means of birds, monkeys, musangs, and such-like animals, for no trees are ever planted. The best time for collecting the gum resin is a little time after the wet season is over (that season is from about the

middle of June till the middle of October), say from February to the end of March, but it extends more frequently till after April, as March and April are very hot months, and the exudation from the trees is not so watery then. When the trees are fit for wounding,—and they are so when their trunks vary from the size of a man's thigh and upwards, the larger the better,—they are wounded by means of a parang, or chopping-knife, in various parts of the trunk and large branches, when prepared bamboos are inserted between the wood and the bark of the trees, to hold the juice as it flows from the wound. After tying the bamboo cylinders to the trees, for they are tied as well as inserted, they are left there and examined daily till filled, which generally takes from fifteen to thirty days, and sometimes longer, the length of time filling depending on the flow of juice and the size of the bamboo cylinder. When no more is seen exuding, the cylinder and its contents are removed, a fresh wound made in some other part of the tree, and the cylinder reinserted and tied as before; the same process is repeated till the bamboo cylinder is filled, when it is taken to a fire, over which it is gradually rotated till the whole of the water in the gum resin is evaporated, and it gets sufficiently hard to allow of the bamboo being torn off, when it is ready for the commercial world, and, as thus prepared, shows the striated appearance of the bamboo very distinctly. The present value of the gum in Singapore, at this mail's rate of exchange, is 1*s.* 10*d.* per lb., or say, 58 dollars per picul. The bamboo cylinders are made as follows:—Cutting the bamboo at its nodes makes a closed hollow cylinder, which will vary in length and thickness, accordingly as the bamboo is well-grown; but generally cylinders are made from an inch to three inches in diameter, and from four to eight inches and even more in length; then one of the nodes is entirely cut off at an angle of 45° or more, after which it is thinned all round by paring off the outside, leaving only a thin casing, thus completing the operation, and fitting it for insertion. The gamboge that comes from Siam is considered the best by our merchants here, being cleaner and freer from woody particles and bark. I hope these few remarks on the mode of preparing the gamboge gum will reach you in time to be read with what I have already communicated about the tree, leaves, etc., but should they not, then I hope you will kindly read them at the most convenient time for yourself, if you think them worth communicating to the Society.

"Yours very truly,

"R. JAMIE."

I now revert to Mr. Jamie's letter of the 3rd November:—

"I send for the museum specimens of Kayn Gharn from Cochin-China and from Sumatra. The latter piece you will observe is very much like one or two pieces of the Cochin-China, but amongst the Cochin-China lot there is one very fine piece, very dark, heavy, and full of resin, which is the odoriferous source, and according as it contains more or less resin, so is its value. The Chinese use it along with sandal wood to burn as incense, and make it into ornaments which are valued at fabulous prices. A sort of head ornament worn by mandarins, consisting of 108 beads, made for hanging round the neck, is valued at 100 to 1000 dollars (!!) according to the quality of the wood. The Parsees and Khugs burn it with gum benzoin. The kinds used for burning here are generally the common kinds. Make a match or two of the Sumatra kind, and ignite them at the gas, and if full of resin it will burn not unlike a pitch torch, giving off a very large amount of carbon, with a perfume *sui generis*. Asiatics are extremely fond of the smell of this wood. The Arabs hang their clothes over it when burning, to disguise the smell of their stinking garments, which they seldom or ever wash or change, wearing them as long as they will hold together. When smouldering, the aroma is of an acetous odour, certainly not much like benzoic acid. To give you some idea of the cost I shall mention what I paid for these pieces sent. The Sumatra kind cost 5 dollars and the Cochin-China 9 dollars. Also I give you the export and import values to and from Singapore for the year 1872:—

IMPORTS.

	Piculs.	Value.
China	9	1.710dols.
Malay Peninsular	49½	9.085
Nederlenno, India	522	3.262
Siam	7 74/100	2.104
		16·161

EXPORTS.

	Piculs.	Value.
China	212	9.021dols.
Arabia	4½	900
British India	16 70/100	800
Hong Kong	143	7.682
Jeddah	20½	3.792
		22·195

From the above it will be noticed the price varies much, just as the quality of the wood. Regarding the tree or trees which produce the Kayn Gharn (the common name by which all natives know it), for two or three different trees are said to produce it, not much for certain is known. It is thought to be the *Aloexylon agallochum*, producing the Aloes of Scripture, and I regret that I can add nothing to elucidate the subject. The Sumatra and Cochin-China samples, under the microscope, are identical in structure. In Kitto's Biblical Encyclopædia, under the article "Ahalim" the best description of its source is given. Its use in medicine is *nil*. One day polishing a very big piece for a walking stick with sand paper, the fine particles of the wood, floating in the air, being carried into my mouth, tasted as if I had taken the least bit of Barbadoes aloes. It has a very slight aloetic taste when taken in powder. Thinking it might be purgative, I, on two different occasions, swallowed thirty grains, but did not experience the slightest action on the bowels. It is only fit for masticatories, pastilles, cachou aromatise, and perfumery, for all of which it is admirably adapted. Though Europeans put no faith in it as a medicine, the natives again extol its virtues very high. Fearing that I have taken up too much of your valuable time reading my desultory letter, I shall finish by wishing success to your museum."

At the close of the descriptive papers the various specimens were viewed with much interest by the meeting.

The Chairman, in proposing a hearty vote of thanks to Mr. Jamie for his very valuable contributions to the museum of the Society, said he was glad to know that Mr. Jamie had been for some years engaged with Mr. Baildon as his principal assistant, and had left Edinburgh with an earnest desire not to forget its pharmaceutical interests. He understood that Mr. Jamie had passed his Minor examination a good many years ago, and evidently retained a strong desire that the rising generation of chemists and druggists should have every opportunity of benefiting by a good museum. He hoped that in the event of any of the young men now present going abroad, they would bear in remembrance the good example shown by Mr. Jamie, and if opportunity offered, enrich from time to time the cases of the museum belonging to the Society.

Mr. Tait seconded the vote of thanks, and stated that Mr. Jamie had also been in the employment of his firm, Duncan, Flockhart, and Co., and that he was proud to know Mr. Jamie had so handsomely and substantially remembered the Society.

The vote was passed with loud acclamations, and Mr. Baildon, in replying, agreed to convey to Mr. Jamie the thanks so warmly given, when writing to Singapore.

The Secretary then announced, in name of Mr. Baildon,

as a presentation to the library of the Society, the following volumes:—

'Dr. Copland's Dictionary of Practical Medicine,' parts 4, 5, 6, 10, 11, 12; 'Gout and Rheumatic Gout,' Dr. Garrod, second edition; 'The Science and Practice of Medicine,' Dr. Aitken, vols. i. and ii.; 'Constitutional and Local Diseases Medical Geography Essays, Political, Economical, and Philosophical,' vol. i.; 'Practical Observations on Diseases of the Lungs and Heart,' by Archibald Billing, M.D., A.M., F.R.S.; 'Principles of Medicine,' by Dr. Billing; 'A Treatise on the Diseases of Children, with Directions for the Management of Infants from the Birth,' by Dr. Underwood, vol. i., ii., iii.; 'Gibb, on the Throat and Windpipe;' 'Arbuthnot on Air;' 'On Scarlatina and its Successful Treatment by the Acidum Aceticum Dilutum of the Pharmacopœia,' by Isaac B. Brown; 'Dr. Yeoman on Consumption;' 'Dr. Yeoman on Cough, Influenza, Asthma, etc.;' 'Elliotson's Principles and Practice of Medicine;' 'Copland's Dictionary,' vols. i. and ii.;' 'The Diseases of Children.' J. M. Coley, M.D.; 'Observations in Medicine,' Dr. Marshall Hall; 'Yearsley on the Throat;' 'Hydropathy or Cold Water Cure;' 'Priestley on Air,' vols. i., ii., iii.; 'Rumford's Essays,' vols. ii. and iii.; 'Monk's Agricultural Dictionary,' vols. i., ii., iii.; 'Thomson's Conspectus of the Pharmacopœias, London, Edinburgh, and Dublin.'

Last month's number of *Pharmacist*, from Chicago, and No. 8 of the *Pharmaceutical Journal*, from Toronto, were also laid on the table as presentations to the library.

Proceedings of Scientific Societies.

SOCIETY OF ARTS.

At the Ordinary Meeting of this Society on Wednesday, March 11, 1874, the following paper was read on—

Cocoa and its Manufacture.*

BY JOHN HOLM, F.R.C.S., EDINBURGH.

The subject, the consideration of which will occupy our attention this evening, and which I have the honour of bringing before you, namely, "Cocoa and its Manufacture," is one of considerable importance, treating as it does of one of the most valuable foods which man derives from the vegetable kingdom.

The cacao or chocolate tree, which yields the cacao—cocoa—or chocolate-nut, belongs to the natural order *Byttneriaceæ*. Linnæus bestowed on it the name *Theobroma*, derived from the Greek words θεὸς (God) and βρῶμα (food); which is stated to have been given to the plant in consequence of that great botanist's delight in the food-drink prepared from its seeds, in which it is stated he largely indulged and somewhat ideally regarded as "food fit for the gods." Of the species of *Theobroma*, there are nine individuals mentioned by botanists, of which the *Theobroma cacao* is the most important, and yields the best and finest fruit.

Varieties of the Cacao Tree.

Name.	Country.
Theobroma Cacao (*Sativa*) (Linnæus)	West India Islands.
Theobroma ovalifolium (De Candolle)	Mexico (Soconuzco).
Theobroma angustifolium (De Candolle)	Mexico.
Theobroma Guyanense (Aublet)	Guiana.
Theobroma bicolor (Humboldt)	Brazil and New Granada.
Theobroma speciosum (Wildenow)	Brazil (Para).
Theobroma sylvestre (Martius)	Brazil and Jamaica.
Theobroma microcarpum (Martius)	South America (wild species).
Theobroma glaucum (Kusten)	

The cacao tree is indigenous to tropical America, and is there found in its wild state. The range of latitude in which it grows may be placed as between the seventeenth parallels, in which area it flourishes best; its cultivation has, however, been extended with success as far as the twenty-fifth parallels; its range of altitude extends from a few feet to 1760 feet above the level of the sea. Mexico appears to be the original home of this tree, from whence it gradually extended into South America and the West India Islands. At the time of the discovery of Mexico by the Spaniards, it was almost the only plant in the cultivation of which care was taken; it was grown in large quantities, and great pains were bestowed upon it, it being regarded by the natives as the most valuable product of their country. The tree was called by the Mexicans "Cacava quahuitl," and also "chocolatl;" while the preparation made from its seeds was named "chocolatl," a name said to be derived from the noise made by crushing the bean between two stones. It is from this native nomenclature that we derive the words cacao and chocolate, the former of which has been corrupted into the better-known word cocoa, applied generally both to the seeds of the plant and the preparation derived from them.

The cacao tree is an evergreen of very beautiful appearance, and has been likened in height and form to the cherry tree. It is taller in its wild than in its cultivated condition, in which the height is curtailed. The height of the adult tree ranges from fifteen to forty feet. The wood is porous and light, but capable of taking a high polish. The bark is of a cinnamon colour, becoming deeper as the age of the the tree advances. The foliage is profuse, the leaves being of a green colour, varying in shade according to the species and nature of soil. They are smooth and glossy, lanceolate in form, with plain edges. In size they vary from 7 to 10 inches in length, and from $2\frac{1}{2}$ to $3\frac{1}{2}$ inches in breadth, growing principally at the top of the tree. The flowers are very plentiful; they are small and clustered, and spring directly from the larger branches and the trunk itself, and according to Humboldt, even from the roots of the tree if these are left uncovered. They are of a saffron and sometimes a pink colour, and are devoid of scent. The buds are similar to cherry stones in size and form, and of a whitish-pink or green colour. Large numbers of the flowers fall before attaining maturity, and thus the yield of the fruit is greatly less than the number of the blossoms put forth; not more than one pod being usually produced from each cluster of flowers.

The cacao fruit, or pod, is an elliptical ovoid shape, and pointed at the end; it varies considerably in form in the different species, and measures from 7 to 10 inches in length, and 3 to $4\frac{1}{2}$ inches in breadth. The surface is somewhat rough, with deep, longitudinal furrows. In colour the surface is green, but as it ripens it becomes of a bluish-red colour, gradually deepening to a decided purple; or else, in certain varieties, it becomes of a delicate yellow or lemon colour. The rind of the seed pod is about half an inch thick, is tough, and requires some force to break it. The pod is divided into five compartments, in each of which is ranged a row of five to ten seeds, lying in a gelatinous pulp. A single pod thus yields from twenty to forty seeds. It is these seeds which form the raw cacao, or cocoa of commerce, from which the various preparations of manufactured cocoa and chocolate are made. I shall now pass on to give a brief description of the general mode adopted in the cultivation of this valuable plant, merely premising that slight differences of method obtain in different countries and districts.

In the selection of ground on which to form a cacao

* Reprinted from the *Journal of the Society of Arts*.

plantation, it is necessary to choose a spot in which the soil is rich and loose to a considerable depth. It should also be near a stream, so that efficient means of irrigation may be ensured. The tree is found to flourish best on hilly slopes which face away from the quarter whence the cold winds which prevail may blow. The young plants should be reared in nursery grounds, where the seeds are sown in small mounds placed at short distances from each other. In each of these two seeds are placed, but when both germinate it is usual to destroy the weaker of the two plants. In ten or twelve weeks these should have attained a height of fifteen to eighteen inches, and are then fit for removal to the plantation. The ground has here been previously prepared, and as the cocoa tree requires protection from both the sun and wind, banana and coral-bean trees, the latter called "madre di cacao," are planted at intervals between the spaces allotted for the cocoa trees, which are placed in rows at regular intervals, varying according to the nature of the soil, from fifteen to thirty feet. When the tree has attained the age of two years, it puts forth several branches, and the flowers now shortly begin to appear, but are removed, that the strength of the tree may not be impaired. About the fifth year the tree is very rich in foliage and strong enough to bear, and the blossoms are now allowed to mature. It is not, however, until the eighth or tenth year that it yields a plentiful crop. It then continues prolific for thirty or forty years.

One of the peculiarities of this tree is that the leaves, flowers, and unripe and mature fruit may be seen growing plentifully at one and the same time. The fruit therefore has to be gathered when ripe throughout the year, but there are two periods at which the produce is most plentiful; these are the months of June and December, which are regarded as the harvest months of the cocoa plantations.

In gathering the cocoa crop the workman whose duty it is to select the pods (this requires great care and experience) is armed with a long, wooden fork, with which he disengages the fruit from the tree. He is followed by others, who collect the fruit into heaps and carry it into sheds, where the pods are opened and the seeds taken out. Each tree will yield from one pound and a quarter to eleven pounds per annum. The seeds have now to undergo a peculiar process, called "curing," before they are fit for use by the manufacturer. This process is one of great delicacy, and requires much experience and skill to conduct it successfully. Upon it depends in a very great degree not merely the preservation of the cocoa, but the development in it of a fine flavour. There are two modes of conducting it. The simpler one is merely to place the cocoa seeds, when taken from the pods, in heaps in the sun, and these are stirred at intervals. A sufficient quantity of the pulp in which the seeds are imbedded adheres to them to supply enough moisture to give rise to a moderate amount of fermentation, which ceases when the nuts are sufficiently dry to be packed. The other mode is by "claying;" that is, the nuts are placed into holes or trenches dug in the ground, and covered with clay or sand; they are stirred at intervals, and great care is taken to prevent the fermentation which arises from proceeding too violently. When it has reached its proper point, the nuts are spread upon a platform or upon mats until perfectly free from moisture, when they are placed in bags.

The use of cocoa as a food by the Mexicans, at the time of the discovery of that country by the Spaniards, is the first knowledge we have of it. With them it was esteemed the most valued product of the country, and Prescott informs us the Emperor Montezuma took no other beverage. The seeds were also used as coins, a fixed value being attached to them, and this custom Humboldt tells us was in existence in his time. The Spaniards did not at first appreciate the virtues of chocolate, and one of their earlier travellers describes it as a "drink fitter for a pig than a man;" but this feeling speedily changed, and their love of this beverage became almost a passion.

The method of the Indians was followed by the Spaniards, whose process is thus described by Simmonds:—

"The kernels are roasted in an iron pot pierced with holes; they are then pounded in a mortar, and afterwards ground between two stones, generally of marble, till they are brought to a paste, to which sugar is added, according to the taste of the manufacturer. From time to time, as the paste assumes consistency, they add long pepper, arnatto, and lastly, vanilla. Some manufacturers vary these ingredients, and substitute cinnamon, cloves, aniseed, and sometimes musk and ambergris."

The introduction of cocoa into Europe may be placed at 1520, when Columbus brought home samples of the nut. Spain, however, for some time depended on the colonies for the manufactured article, but when the art of preparing it was conveyed there, the raw material was also imported. The Spaniards, by jealously guarding as a secret the mode of manufacture, were able to retain the monopoly of all trade in chocolate for many years.

The value of chocolate was speedily appreciated by the physicians of Europe, and Hoffmann, wrote a monograph treating of it, entitled "Potus Chocolati," in which he recommends it in many diseases, and instances the case of Cardinal Richelieu, who, he states, was cured of general atrophy by its use.

It was probably more than a century after the introduction of cocoa into Europe before the English became acquainted with it. According to my late partner, Mr. Hewett, the earliest mention of its use appears in a newspaper called Needham's *Mercurius Politicus*, dated the 16th of June, 1659. For many years England continued to import all the chocolate she consumed in its manufactured state; but I believe about the commencement of last century several persons commenced the manufacture in this country. There is very strong reason to believe that a knowledge of the mode of preparation was brought into England by Sir Hans (then Dr.) Sloane.

Before considering the modes of manufacture which have been adopted in this country, it will be convenient to notice the characters and chemical composition of the cocoa beans. In shape these are something like an almond, but rather thicker; they vary both in size, shape, and quality, the various growths having distinct characteristics. Our principal supplies are drawn from Trinidad and the Spanish Main, which yield the best qualities, and from Ecuador and Peru, the Island of Grenada, and Guiana. The following is a list of the cocoa-growing countries:—

Country.	Commercial name of growth.
Trinidad	Trinidad.
Mexico	Soconuzco.
Spanish Main:—	
New Granada	Magdalena.
Venezuela	Maracaybo.
	Caraccas.
Guatemala	Central American.
Ecuador	Guayaquil.
Peru	
Grenada (Island of)	Grenada.
Guiana	Surinam.
	Berbice.
Cuba	The name of each island.
Guadeloupe	
Martinique	
St. Croix	
St. Lucia	
Dominica	The name of each island.
St. Vincent	
Jamaica	
Brazil	Para.
	Maranham.
	Bahia.

Guinea (Western Africa) .	African.
Bourbon	The name of country; yield quite unimportant.
Philippines	
Mauritius	
Madagascar	
Australia.	

I would now recall to your minds the manner in which the cocoa nuts or seeds are contained in the cocoa pod. If we examine the seed as imported we find that it is enveloped in a husk or shell of its own. When this is removed, the surface of the nut is seen to be marked by slight grooves, which divide it into irregular portions. These depressions mark the position of a fine membrane, which penetrates into the substance of the seed and divides the cotyledons from each other, and also each of these into several lobes. It is these irregular segments of the cotyledons which, when broken down, forms cocoa nibs.

(*To be continued.*)

Parliamentary and Law Proceedings.

The Unrestricted Sale of Poisons by Grocers' Boys.

At the last County Galway assizes a grocer's boy was indicted for manslaughter. It appeared that the prisoner obtained employment, only two days before the poisoning took place, as a shop-boy in the establishment of Mr. Harpur, who, amongst other matters, sold drugs. The deceased lived with her mother, and feeling ill, sent a little girl to Mr. Harpur's shop for a pennyworth of jalap. The prisoner went to a drawer which was not labelled, and gave her a yellow powder, which he believed was jalap. This was given to deceased, when in a few minutes she complained of a burning pain in her stomach, and her mother having gone back to the shop, it was found that the prisoner had given hellebore in mistake for jalap; she died in a few hours after. Dr. Emerson Reynolds proved that the drug which deceased had taken was white hellebore. The jury, being unable to agree, were discharged, and the prisoner bound over to stand his trial at next assizes.

The *Medical Press and Circular*, in reporting this case, remarks, "We venture to inquire why it is that the shopkeeper who keeps hellebore in an unlabelled drawer, and keeps a boy of two day's experience to retail it to little girls, does not stand in the dock in company with his poor ignorant servant?"

Prosecutions under the Adulteration Act.

ADULTERATED MUSTARD.

At Wolverhampton, G. Carter, a small shopkeeper, of Willenhall, was charged before Mr. Spooner with selling mustard which was adulterated. Mr. Cartwright appeared to prosecute, and Mr. H. B. Hill defended. Samuel Toye proved that on the 24th January he went into the defendant's shop, and purchased a certain quantity of mustard, stating at the time that he was going to have it analysed. He did not notice that there was a printed label on the can—"Warranted free from any injurious ingredient, but not pure mustard." A certificate from Mr. Jones, the analyst, was produced, stating that the sample delivered to him consisted of 39 per cent. of wheaten flour and turmeric, and 61 per cent. of mustard. Mr. Spooner (to Mr. Jones): Well, tumeric is a very simple and harmless ingredient.—Mr. Jones: Quite so, but it is an adulteration.—Mr. Hill: The public don't care about having pure mustard.—Mr. Spooner: I should think that the public are not such donkeys as to buy an adulterated mixture for the genuine article.—Mr. Hill: But they don't care about having the genuine article. This is Keen's London mustard, and it is sold as stated on the label, as a mixture, but it does not contain any ingredient that is at all injurious to health.—Mr. Jones said that a few years ago it was difficult to obtain pure mustard, but of late years the quantity of pure mustard sold had greatly increased, and the public had begun to appreciate the benefit of getting the real article.—Mr. Spooner: If the defendant would always state to his customers what there is printed on the label, viz., that it is not genuine mustard, he would be all right. It is certainly not a case in which a penalty should be imposed.—The learned Stipendiary then ordered the defendant to pay the costs, and advised him, in future, to tell his customers what was on the label.

At Marlborough Street, on Saturday last, Mr. Roberts, grocer, Cleveland street, was summoned before Mr. Knox for selling mustard as pure which was adulterated.—Dr. Whitmore, analyst to the parish, proved that the mustard was adulterated with tumeric and flour to the extent of one-third.—Mr. Berkeley urged on behalf of the defendant that it was an act of oppression not to take out a summons until three months after the alleged offence.—Mr. Knox, after remarking that three months was certainly a long time before a summons was taken out, added that he did not consider it a bad case—certainly not one for a fine of £20, or even £1, but he did for a fine of 5s. and costs.

ADULTERATION OF COFFEE.—A SERVANT FINED.

On Tuesday, March 31, at the Marylebone Court, Walter C. Barker, grocer, of Wigmore Street, Cavendish Square, was summoned for selling coffee which had been adulterated with chicory to the extent of 50 per cent. Mr. Beard, for the defendant, asserted that his assistants had orders to label each packet, stating that there was an admixture of chicory. The summons against Mr. Barker was dismissed, but his assistant was ordered to pay a fine of £1 and £2 9*s.* 6*d.* costs.

ADULTERATED BUTTER.

At the same court, Mr. George B. Cox, of Wigmore Street, Cavendish Square; Peter Keevil, Edgware Road; and John Gorman, of Carlisle Street, Portman Square, grocers and provision dealers, were summoned for selling adulterated butter. Each case was proved, and it was contended by the defendants that they sold the butter as they received it from the wholesale merchants; but it was proved in the case of Keevil that the butter sold was an admixture of lard and palm oil; in fact, there was hardly any butter in it at all. Mr. D'Eyncourt said he did not think the defendants Cox and Gorman intended to defraud the public, but they would each have to pay £2 and 10*s.* costs; and Keevil would have to pay, as it was a bad case, £10 and £3 3*s.* costs.

Review.

Elements of Chemistry, Theoretical and Practical. By W. A. Miller, M.D., L.L.D., revised by Herbert McLeod, F.C.S. Part II., Inorganic Chemistry. London: Longmans, Green, Reader, and Dyer. 1874.

If "teaching" a science be taken as meaning something more and better than merely stuffing the head of the student with verbal statements (more or less unintelligible to him) of facts or theories (more or less irrelevant in *themselves* to anybody outside the profession) then, of all sciences, chemistry, perhaps, is the one most difficult to teach. The first difficulty we encounter is, that the very things we have to speak about, and the order of phenomena we have to consider, are virtually new to the pupil and lie outside the sphere of daily experience and observation. It is not a refutation of our statement to object, that, say, air, water, charcoal, iron, quicklime, as *things*, and the calcining of chalk, the slacking of lime, the burning of charcoal, as *phenomena*, are as familiar in general, to the chemical, as, say, the falling of a stone, the motion of a pendulum, or the pressure of steam against the piston of

an engine, to the physical tyro. In every day life, it is true, we constantly meet with chemical substances and chemical processes like those referred to; but ordinary experience does *not* teach us to look upon the things as definite species, nor upon the phenomena as transmutations, of matter. Vide the history of the science of the process of combustion. Chemists had long been in possession of a most admirable theory to account for the evolution of heat and light, before they had the remotest notion, for instance, of carbonic acid! To say it again: the strangeness, to the mind of the pupil, of the fundamental notions of chemistry is the great difficulty which we must first of all clear away, before we can think of systematic teaching, and the only correct way of doing this, let us now add, according to our opinion, is the one recommended by *Arendt* (in his excellent book: 'Die Organisation des Chemischen Unterrichts;' Leipzig: Voss) who says that, in the school or college boy's *first course* of chemistry the subject should not be treated as a real science at all, but, mainly at least, like a branch of natural history. What he recommends is to begin by showing to the pupil a well selected and arranged series of such substances as ordinary metals, oxides, salts, and to acquaint him with their mechanical, physical, morphological and some of their chemical properties, especially such as are not accompanied by deep-going material changes; in case of the salts, for instance, their property of dissolving in water and, under certain circumstances, separating out again from the solutions in crystals, should come first, and be very fully illustrated by experiments, while of the chemical changes proper, only a few of the simplest, such as the elimination of the metal of a salt by another metal, should be taken in at all. On the occasion of the study of the behaviour of metals when heated in *air* the teacher will of course not miss the opportunity of telling the pupil, or rather extracting from him, something about the constitution of the atmosphere; but, on the whole, says *Arendt*, your chief aim should be to sharpen his powers of observation by familiarizing him with the *things* chemistry has to deal with, and, if the resources of the school admit, to teach him to use his hands.

After such a preliminary course the student is prepared for attending with real benefit to himself, an elementary series of *scientific* lectures on chemistry and reading an elementary book of the order, say, of *Roscoe's* excellent 'Lessons.' This second course being completed, what text book should one recommend to him, who, for one reason or other, wants to take a deeper dive into the subject? Well, ten or twelve years ago, *our* answer would have been: *Graham and Watt's* 'Elements' and speaking to an intelligent foreigner we should have added: learn English to be able to read that book. It really is a pity that Mr. Henry Watts has not, it seems, the time for re-editing this excellent work and bringing it up to the present state of the science. Perhaps he will do so one day, or another of the few men competent will do it for him. In the meantime *Mr. McLeod's* new edition of the second volume of *'Miller'* is, perhaps, the best available substitute, in English for the Graham of the future. Let us at once admit that the book is not an unworthy brother to the one we should have preferred. It is very carefully compiled, not from other books, but from original memoirs, and the editor has shown good tact in the selection of matter. Not the least merit of the book is that it duly places the facts and the methods of the science in the foreground, and does not give more of theories than is required for the summing up of the former, and as a basis for the latter. What we also feel bound to give Mr. McLeod special praise for is that he nowhere inflicts upon us exasperating graphic formulæ. On opening the book we were quite prepared for pictorial respresentations of the 'constitutions' of the Zircones, Garnets, of Meerschaum, etc., etc., and the sense of relief we enjoyed in *not* finding these, is more than we can express in words.

Another good feature in the book is that it not only calls itself on the titlepage, but *is*, as far as can reasonably be expected, really a handbook of *practical* chemistry. All the more important processes of manufacturing chemistry (including metallurgy) are fully described (some, perhaps, too fully); and so likewise are the laboratory methods for the preparation of the ordinary reagents and other practically important chemicals. Analysis, also, and its applications to practical "assaying," are not forgotten; in fact we almost feel inclined to say that the editor has devoted a little too much of his space to this branch of the subject. Those who take a special interest in the more purely scientific parts of chemistry will be glad to find in the book a *résumé* of the more important results of recent researches in thermo-chemistry—which *résumé*, however, we beg to submit, would have been all the better for the addition of an *aperçu* of the bearings of these results on the laws of chemical action.

What the appendix on *organic* chemistry—in vol. ii. of a book, of which vol. iii. is to be entirely devoted to this branch—is meant for, we are at a loss to make out.

Obituary.

JOHN WHEELEY LEA.

We regret to announce the death on Monday, March 23, of Mr. John Wheeley Lea, formerly of the firm of Lea and Perrens, Worcester, at the age of 83 years. Mr. Lea was a member of the Pharmaceutical Society from its foundation in 1841 until he retired from business in 1857. In 1850, 1851, 1855 and 1856, Mr. Lea was elected a member of the Council of the Society.

Notice has also been received of the death of the following:—

On the 23rd March, 1874, Mr. Henry Bannard, Pharmaceutical Chemist, of Epsom. Mr. Bannard was a member of the Pharmaceutical Society.

Correspondence.

**** No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

Live and Let Live.

Sir,—The inquiry concerning Cocculus Indicus has engrossed the attention of chemists and druggists lately. One subject, however, obviously more important, seems to be entirely neglected.

The Pharmacy Act was passed in 1868 by the strenuous exertions of the Pharmaceutical Society. This Act, doubtless with the best intentions, was designed mainly for the protection of the public; it should have gone further, and by restricting the sale of drugs to chemists and druggists, afforded protection to those who have, by means of hard work and hard cash, succeeded in qualifying themselves by passing the examinations. Measures are freely passed for the protection of birds, animals, etc., but that unfortunate biped, the chemist, with his meagre returns and arduous labours has to contend against ceaseless and unfair competition; the country grocers sell all kinds of drugs except laudanum, corrosive sublimate, arsenic, and such things as, on account of the responsibility, druggists do not care to sell, and not only do they sell drugs, but undersell us whenever opportunity offers; stationers, too, vend patent medicines to any extent, and the co-operative stores, by having a qualified man to manage the drug department, add the last straw to break the camel's back.

One of the said stores has just been established in Exeter; it is supplied with drugs by a wholesale firm in Exeter, and by a well-known wholesale firm in London. I wonder that those who have a reputation like that of the houses I refer to, should, in this manner, forfeit the confidence of the whole retail trade. They neither deserve nor can expect to receive the support of chemists when they do their best to uphold a system of trading so totally foreign to our English ideas of fair play. Our small returns will not allow us to lower

our prices, so we must struggle on in anticipation of the good time coming.

I hope the Pharmaceutical Society will step in on our behalf, and as we are required to qualify ourselves for our calling, assist us to gain a living by it.

JOHN N. PLACE.

DECOMPOSITION OF LOZENGES.

Sir,—From the numerous communications I have received on this subject it is evident that the evil is of more general occurrence than I had previously anticipated. I am still pursuing my investigations, and hope to have the opportunity of resuming the subject at a future evening meeting. It would materially assist me in this inquiry if those who have observed similar changes in their lozenges would send me specimens, with full particulars as to age, condition of keeping, etc. In reply to Mr. Cornish's suggestions in last week's Journal, I may observe that the granules of ginger starch are so very different in their form to those of the potato or maranta that a practised eye would not be likely to err on this point. Again, the starch grains which exist in the cellular portion of the Minor Striated Ipecacuanha are so very characteristic that there could be little difficulty in determining their presence, and if these play any part in the decomposition it is not a primary one, and can only occur in ipecacuanha lozenges. I have little doubt but that the change is due to some substance common to most, if not all lozenges.

PHYTOLOGY: ON THE PROPERTY POSSESSED BY CERTAIN BULBOUS ROOTS OF ADAPTING THEMSELVES TO THEIR PROPER DEPTH IN THE EARTH.

My attention was first drawn to this, thirty years since. In a garden at Pontefract I made several alterations, one effect of which was to disperse and bury, twelve inches under the surface, a bunch of snowdrops (*Galanthus nivalis*). At their usual season several of them duly sent up their leaves and flowers. As soon as the foliage began to decay I took them up, with the view of planting them again in a cluster.

I was surprised at finding the old bulb at twelve inches deep in the ground, entirely *perished*, excepting the skin and stalk. Upon the latter a new bulb had formed, about four inches under the surface of the soil. This proved to be the case with all that I dug up. The circumstance had escaped my memory until last year, when (thinking I should leave my present house and garden) I dug up my tulip roots. I found that some of them had been raised above their proper depth in the earth, and some upon the surface. The latter bulbs showed a skin the size of the original, but contained merely a small offset, about the size of two wheat-corns. A sap-root had struck down, from which, at four to five inches below the surface of the earth, strong, healthy bulbs were thrown off.

I have nowhere seen or read of this phenomenon of self-arrangement, but I think it may be useful to the botanist and nurseryman, and also afford a field for amusement and instruction to many. It is desirable to ascertain what bulbs obey this law. I have tried the crocus, but the results were ambiguous.

COCCULUS INDICUS.

Sir,—The letters recently appearing in the Journal anent Cocculus Indicus, remind me of one or two incidents, which may possibly interest some of your readers. Some 30 years ago, when a young man just commencing business, I was wont to experience, after my midday meal—when possibly I had done deglutition to some 10 or 15 ounces of the contents of the "9 gallon," which I got from a neighbouring brewer—a very unpleasant oppression across the forehead, and my brains certainly felt less clear *post* than *ante prandium*. One day when pouring out my usual beverage, I observed something pop from the jug into the glass; a glance at this sufficed for the unmistakable recognition of the half capsule of a *cocculus indicus* berry. It certainly was curious, that that solitary half capsule, should have escaped the meshes of the brewers sieve, got safely from the kin into my 9 gallon, from thence through the narrow passages of the tap, and again be brought to dry land in my little back room.

It might have got into almost anybody else's glass in the place—possibly even to that of the village surgeon, without the "illustrious stranger" being recognized.

The brewer's clerk passing my door *ter in die* to his meals, I put "the stranger" into a pill box, and posting the clerk up, as to the road by which he had arrived, begged him to inquire of his employer, with my respects, if he could tell me who he (or what it) was? I had to ask the clerk for the reply. "Oh, M——— thought it was only a hop leaf" (!) The clerk was loyal to the master whom he served. Years after he had left his employ on my making reference to the singular "hop leaf" he confessed that he never in his life, before or after, saw his master blush such crimson, or look so confused, or betray such extreme vexation as when he introduced my stranger to him. Had *he* known *what* the pill box contained, he would not have ventured to be the bearer of it.

Since the charge some years since made against the Burton brewers of bittering their ales with strychnine, and their indignant and emphatic denial of using anything beyond malt and hops, and their freely inviting inspection of their process, I was under the impression that all brewers of any note eschewed such vile malpractices as poisonous adulteration, but scepticism on this point is haunting me. Until very recently I had for some while been drinking a certain bitter ale, brewed in the neighbourhood of London, and I had suffered a good deal from giddiness, especially experienced when suddenly turning round. As the sensation was not felt at any particular time, I did not attribute it to diet, but since happening to change the bitter ale for London stout—the giddiness has apparently gone with the former: and I have since recollected that the giddiness became worse about the time that the price of every thing, including malt, hops, and labour so suddenly rose.

One more anecdote connected with beers and brewers and I have done. Some years since there resided in the town from which I write, a well-known "character," who kept "a public," one that is known as "a brewer's house;"—he was bound to sell beer only that his landlord brewed. One day he told the brewer he had something he wished particularly to show him. The publican brought out a locked casket, containing a packet which had as many envelopes, as that with which the late Wizard of the North was wont to amuse his audiences, at last the innermost one was reached, when, with the gravest of grave faces, he solicited the brewer's opinion as to the nature of the small object it contained. "Why," replied the brewer, "there can be no doubt as to what it is—it is a hop leaf." "Well," he rejoined, "I thought it was, but do you know I found it in *your* beer!"

"*An Old Pharmacist.*"—There is nothing in the Pharmacy Act to prevent an unregistered person selling drugs which are not poisons within the meaning of the Pharmacy Act; but it does prohibit such person from assuming any style or title implying that he is a chemist and druggist. You are also referred to the rule respecting anonymous communications.

"*Syrupus.*"—Your questions 1, 2 and 3, indicate the need of a course of study in a chemical laboratory. You can learn the price of such a microscope as you require from the makers, who constantly advertise in the papers, etc.

A. Y.—(1) Apply to the Secretary for a copy of the pamphlet entitled 'Hints to Students.' (2) We are informed that there is no formula for a "Lotio Zinci Sulphocarbolatis" in the Pharmacopœia of King's College Hospital, but we have been kindly supplied with the following formula for an "Injectio Zinci Sulphocarbolatis," as being probably what you require:—

℞.	Zinci Sulphocarbolatis. . .	gr. xl.
	Aquæ	Oj.

M.

F. P. Balkwill.—Vanilla (cut small), 2 oz.; rectified spirit, 1 pint. Digest for a fortnight. See a paper by Mr. Moore in the second volume of the present series of the PHARMACEUTICAL JOURNAL, p. 748.

COMMUNICATIONS, LETTERS, etc., have been received from R. T. Gould, A. Stathers, J. M. Cornish, "Fructus," "Hampton," L.

DISPENSING NOTE ON THE CHLORO-MERCURATE OF MORPHIA.*

BY WILLIAM MARTINDALE, F.C.S.

The more definite and certain action produced by injecting medicinal agents hypodermically, and their more rapid therapeutic action upon the system, have led surgeons to administer perchloride of mercury in this manner in certain forms of syphilis. This salt, when given by the mouth in large doses, frequently disorders the stomach and causes diarrhœa without producing the requisite mercurialization. When injected hypodermically, as might be supposed, by its corrosive nature and chemical action on albumen, it causes great pain, a hard lump is formed, and rigidity of the part where applied. To lessen the pain in the case of a patient who was very sensitive and not readily influenced by mercury, Mr. Berkeley Hill thought a combination of it with morphia would be of service, and asked me to prepare for him the following solution :—

R Hydrarg. Bichlor.	gr. 8
Morphiæ Hydrochlor	gr. 4
Aquæ Destill..	℥j.

Make a solution for subcutaneous injection; six minims contain gr. $\frac{1}{10}$ Hydrarg. Bichlor. and gr. $\frac{1}{20}$ Morphia.

I added the two salts to a little water in a test tube, and dissolved them with the aid of heat. On filtering and cooling, although there was more than four times as much water ordered than was necessary to hold either salt in solution separately, I was surprised to find a large deposit of silky acicular crystals. This I at once perceived was due to the formation of a double salt of mercury and morphia, which, on reference to Watts,† I found was described as the choromercurate of morphia. It is prepared by mixing solutions of equivalents of the two salts, hydrochlorate of morphia and perchloride of mercury, and has the composition of $C_{17}H_{19}NO_3 \cdot HCl \cdot 2Hhg''Cl_2$. There are nearly corresponding iodo- and bromo-compounds of mercury and morphia. Double chlorides in combination with mercury are, as is well known, very numerous. *Liquor hydrargyri perchloridi*, as I have shown,‡ contains the double chloride of mercury and ammonium, in which case the mercury salt is rendered much more soluble; but, in the case before us, the peculiarity is that it is rendered much less soluble.

With the sanction of the prescriber, I temporarily got over the difficulty by using a mixture of seven parts of water and five of glycerine as a solvent; but even out of this it crystallized in a few days, and I was informed that it neither lessened the pain nor the inconvenience which an ordinary solution of perchloride of mercury would have caused.

I suggested and prepared for use in its place a solution of the alkaline chloro-albuminate of mercury, from the formula of M. Staub, given in the "Year Book of Pharmacy," for 1873, p. 293, but more concentrated. In this solution an excess of chloride of sodium and chloride of ammonium are dissolved together with the perchloride of mercury, and added to a mixture of white of egg and water. The alkaline chlorides, it is stated, prevent the combination of the mercury salt with albumen. This it did for a time, at any rate, but, probably, as mine was a more concentrated solution than M. Staub's, after a while it became curdy. Mr. Hill, therefore, left off using it, but he informed me that this solution caused less pain, and entered more readily into circulation than when the simple solution of perchloride of mercury was used. He has kindly given me the following notes of the case in which he used these solutions :—

Memorandum of Injections of W. C. R.

1874—March 9th, 10th, and 11th. Two daily of solution of $HgCl_2$ in distilled water = $\frac{1}{10}$ gr. in ℥ vj with ℥ j of solution of morphia = $\frac{1}{6}$ gr. The separate solutions were mixed in the syringe.

March 12th, 13th, and 14th. Two daily of solution containing morphia and $HgCl_2$ in glycerine and distilled water. The morphia and mercury crystallized out in a few days.

March 15th, 16th, and 17th. Two daily of Staub's albuminated solution. In a few days this solution became curdy.

March 18th, 19th, and 20th. Two daily of $HgCl_2$ gr. $\frac{1}{8}$ in distilled water ℥ vj.

The same bulk of fluid was used in all — ℥ vj.

The localities chosen were nearly always on the arms, and generally over the triceps. Four injections were made into the front of the thighs.

Effect 1. If the point was not well sharpened, pain, at the time and afterwards, was complained of a good deal. Latterly the point was sharpened almost daily on an agate hone, and the pain of the puncture was very slight.

2. The subsequent pain felt an hour or two after the injection varied much, even when the same solution was employed. Very little difference was felt with those having morphia and those having mercury without morphia. The least painful form was the albuminate. The most painful the solution of $\frac{1}{8}$ grain in ℥ vj.

3. Hard swellings formed round each of the punctures, which lasted two to three days, were very tender, and greatly impeded by their painfulness the movements of the limbs. For this reason the thighs were only used a few times, and the right arm less than the left arm.

On March 20th patient was so crippled by pain that the injections were discontinued. No abscess, however, resulted, and in four or five days the lumps had disappeared and the pain also.

4. Two signs only indicated the effect of the mercury.

(*a*) Improvement in the condition of the syphilitic sore. It grew smaller and less hard.

(*b*) The breath became mercurially fœtid about March 18th.

The gums, the bowels, and the patient's general condition showed no appreciable sign of the drug being absorbed. During the second week of injection the patient took a grain of calomel three times daily, or other mercurial pill.

March 28th. He does not yet betray any further sign of mercurialization than those detailed. He is the second case that Mr. Hill has observed which has been only very slightly influenced by subcutaneous injection. In all the rest mercurialization has been speedily produced. As a rule the gums are tender and swollen, and the syphilitic affection rapidly disappears when $\frac{2}{10}$ grain of bichloride have been introduced.

March 29th. Injections were recommenced; $\frac{1}{8}$ grain of $HgCl_2$ dissolved in ℥ xii of distilled water, at the rate of two per diem. The pain has not been appreciably less than was felt with the more concentrated injections, but the hard lump formed round the point of insertion has been smaller and less hard.

Diarrhœa began March 31st, consequently injections were discontined on April 1st.

MATERIA MEDICA NOTES.*

BY E. M. HOLMES,

Curator of the Museum of the Pharmaceutical Society.

Koegoed.

At the Brighton meeting of the British Pharmaceutical conference in August, 1872, a paper was read by Mr. Keyworth of Hastings, upon a drug called Koegoed, the botanical source of which was said to be unknown. Having had occasion lately to turn to Dr. Pappe's Medical Flora of the Cape of Good Hope, I found that the same name, although spelt in a slightly different manner, was applied by the Hottentots to the *Mesembryanthemum tortuosum* a plant belonging to the nat. ord. Ficoideæ. Not having been able to detect any leaves in a specimen given to me by Mr. J. Moss, I wrote for a further supply to Mr. Keyworth, who courteously complied with my request. In the parcel forwarded to me by that gentleman I found a few leaves of an oblong-ovate shape which exactly corresponded in appearance with those of a specimen of the *Mesembryanthemum tortuosum* in the British Museum. Dr. Shaw, who is well acquainted with the Flora of South Africa, happened to be in the British Museum while I was engaged in comparing the specimens, and immediately recognized the Koegoed as the form in which that plant is used by the Hottentots, remarking that he had seen it growing in Bushmanland, but considered it to be rather a rare plant. There can be no doubt, therefore, that the Koegoed is the produce of *M. tortuosum*, of which it is probably the root and procumbent stem.

Three other species of *Mesembryanthemum* are used medicinally by the Hottentots, but these have leaves of a different shape to those of the Koegoed, the leaves of the *M. edule* and *M. acinaciforme* being scimitar shaped, and those of *M. crystallinum*, which is well known in this country as the ice plant, being broadly ovate and amplexicaul. The expressed juice of the first two species above mentioned is extensively used in the South of Africa in dysentery, as a gargle in malignant sore throat, and in the form of a lotion for burns and scalds.

The Koegoed, besides being used as stated by Mr. Keyworth, as a sedative for cattle, is chewed by the Hottentots as an intoxicating agent, and appears to possess narcotic properties which deserve further investigation.

Some Adulterations of Crude Drugs.

Cascarilla.—Notwithstanding the great care which is exercised by most wholesale buyers in selecting good samples at the drug sales, and in the examination of all parcels which enter into stock in their warehouses, spurious drugs are occasionally overlooked and find their way into the retail trade. This spurious cascarilla (of which a sample is upon the table) presents an instance in point. It was imported from the port of Nassau, in the Bahama Islands. A lot of cascarilla, consisting of four serons selected from a fine sample, was purchased by one of the first London houses. Of these serons, three contained the true bark; but the fourth, which appeared to contain unusually fine specimens, and which were sent out as such, was afterwards found to consist almost entirely of the spurious bark.

At first sight this bark strongly resembles cascarilla in appearance, but may be distinguished thus:—The periderm or outer layer of bark does not readily peel off, and is of a fawn colour—not white. On the inner surface the bark is of a reddish tint and is furnished with a number of straight, closely packed, raised lines, which give it a striated appearance, the inner surface of cascarilla being smooth. The taste is not aromatic but astringent, and almost without bitterness. The colour of the bark is also of a more reddish tint than that of cascarilla. From the general appearance and microscopical structure of the bark it seems probable that it may belong to a plant of the same genus as the cascarilla.

Most of the species of croton occurring in the Bahamas appear to have aromatic barks, but in the excellent paper published in the Pharm. Journ. by Dr. Daniell upon the cascarillas of the Bahama Islands, one species described under the name of *Croton lucidum*, L. is said to have in the fresh state a slightly bitter and somewhat astringent bark. It further resembles the spurious bark in the "dull red colour of the cortical layers." It is said to be used by the negroes of New Providence to mix with the bark of the true cascarilla, under the idea that it improves the curative powers of the latter, and it is known by the name of the false sweetwood bark, sweetwood being the name applied by them to the true cascarilla. Hence this bark may have been mixed with the cascarilla, by those who collected it, for the above-mentioned purpose. From the fact of its occurring only in one seron, however, it appears more probable that it was an intentional adulteration. Unfortunately there are no specimens of the bark of *Croton lucidum* either at Kew or at the British Museum, so that I have not been able to ascertain with certainty (as might be done by the use of the microscope) the identity of this bark with that of the *Croton lucidum*, L. I trust, however, in the course of the year to receive further information concerning it from Jamaica.

With regard to its medicinal properties, the bark appears to cause sickness without produciug other disagreeable effects.

Mr. A. H. Squire, who first brought this bark under my notice, has examined its behaviour with various reagents, and finds that the infusion and tincture are darker in colour than those of cascarilla; that tincture of galls gives a scarcely perceptible cloudiness, and that tincture of perchloride of iron turns the tincture almost black, while the infusion is only slightly deepened in colour by it, and that acetate of lead gives an abundant precipitate with both tinctures. The tincture of cascarilla is not altered in appearance either by tincture of perchloride of iron or tincture of galls.

Arnica Root.—In a specimen of arnica root which was recently sent to me for examination (by Messrs. Wright, Sellers, and Layman), I found only 50 per cent. of the genuine root, and in a second sample only 1 per cent. of arnica. In both samples there were two or three different kinds of roots, but the chief adulterant in both cases was the same.

The physical characters of this spurious arnica are so strongly marked that it is not difficult to recognize it. For the sake of comparison, before giving the distinctive characters of the spurious drug it may be well to recall the description of arnica.

What is commonly known as arnica root consists of a slender rhizome or prostrate stem having a

* Read at the Evening Meeting of the Pharmaceutical Society of Great Britain, Wednesday, April 1st, 1874.

number of rootlets arranged almost in a line along the under surface. In a transverse section the cortical portion is found to be hard, and of a yellowish white colour, while the central portion or meditullium is soft, and of a dirty greyish or brownish-white colour. The odour is distinctive, and the taste has a peculiar acridity and an after flavour which may be likened to the odour of rancid cocoa-nut oil.

The spurious drug may be at once recognized by the fact that it is not a rhizome, but a root which evidently descends vertically into the soil, as it is surrounded on all sides by rootlets. In size it varies from that of arnica to five or six times as large, in some pieces appearing præmorse, and in others suddenly narrowed and elongated. The cortical portion resembles that of arnica in colour, but the meditullium, or central portion, is of a purple tint, and presents a discoid appearance, two characters which I believe are met with in but few roots. When the root is soaked in water the purplish meditullium swells up and loses its discoid appearance. The taste is astringent and somewhat aromatic, faintly resembling that of cloves. Thinking it possible that the root might belong to some plant having leaves like those of arnica, and that it might have been gathered in mistake for arnica, I examined several species of *Hieracium* which grow in similar situations, and resemble arnica in having composite flowers and entire leaves, but in none of them had the meditullium a purple colour. The astringent taste of the spurious arnica then led me to suspect that it might be the root of a rosaceous plant, and the clove-like flavour seemed to indicate the root of *Geum urbanum*, an indigenous plant well-known to herbalists in this country, under the name of Avens, or Herb Bennet. Having procured specimens of the latter from Covent Garden, I found that the appearance, structure and taste were identical, and have therefore no hesitation in referring the spurious arnica root to that plant. The other kinds of root were present only in small quantity, and appear to have been accidental. One is a slender rhizome of a paler colour than that of arnica, and has a white discoid meditullium, and a bitter taste; another is evidently that of a species of *Vaccinium;* a third looks very like valerian, but is odourless; a fourth closely resembles bistort root.

From all the spurious roots the leaves have been carefully removed, while an unusual quantity of arnica leaves are mixed with the roots, evidently for the purpose of producing the impression that the root is genuine arnica. That the adulteration is an intentional one is also evident from the fact that the leaves, flowers, and general habit of the two plants are totally distinct; arnica having entire leaves, a simple stem, and composite flowers, while *Geum urbanum* has lyrate pinnate leaves, a branched stem, and simple flowers.

Belladonna Root.—A sample sent to me for examination contained 50 per cent. of a malvaceous root, which I believe to be that of *Malva sylvestris;* the remainder consisted of small pieces of belladonna root. Externally, the two are very much alike, especially when the belladonna is in small pieces; but internally the appearance and structure will be seen to be very different, belladonna having a very large meditullium and a small cortical portion, while in the mallow the two are nearly equal. The fracture of belladonna also is short, while in the mallow it is distinctly fibrous.

This adulteration, although easily detected, is of considerable importance, seeing that it would in this proportion reduce the strength of the preparations of belladonna by one-half. Both the arnica and belladonna were imported from Germany.

Whether these adulterations are to be taken as an indication that arnica and belladonna are becoming scarce in Germany, or whether they are the result of a demand for cheap drugs, is not very evident, but their occurrence does point to the necessity for a very careful examination by the pharmacist of all crude drugs which enter into stock, and to the importance attaching to a thorough acquaintance with the appearance and structure of all articles of materia medica. They show also that adulterations may occasionally occur where they would be least suspected.

[*The discussion on this paper is printed at p.* 821.]

THE QUALITY OF MILK SUPPLIED TO TOWNS.

BY DR. STEVENSON MACADAM, F.R.S.E.,
*Lecturer on Chemistry, etc., etc.**

The recent prosecutions in Edinburgh and other cities and towns, in reference to the adulteration of milk, have proved that there is great necessity for more full information regarding the chemical composition of genuine or normal milk. Consequently, having been professionally engaged in some of the cases of alleged adulteration, and having acquired a mass of results regarding the analyses of milk, I have thought it right to give publicity to these researches, in the hope that they may tend to afford greater certainty to future analyses of milk, and thus be of public service.

In carrying on the analysis of milk, the special points which may be determined are—

(1) Specific gravity of the milk.
(2) Percentage of cream by volume.
(3) „ „ solids by weight.
(4) „ „ solids not fat „
(5) „ „ fat or butter „
(6) „ „ ash in solids „

Where it is possible, all these points should be determined. Some chemists attempt to despise the specific gravity and cream tests, and stand by the solids and fat only; whilst others hold, and correctly so, that the specific gravity and cream determinations are excellent guides when they are properly carried out. Necessarily, when all the points are determined—the specific gravity as well as the solids, and the cream as well as the fat—both parties must be satisfied, as the one affords a check to the other, and double certainty and accuracy of results are obtained.

The *specific gravity* is best taken in the ordinary specific gravity bottle, holding 1,000 grains of water at 60° F. The milk should be agitated previously, so as to mix the fat or cream thoroughly throughout, but care must be taken that the agitation is not so violent as to incorporate air bells with the milk. The temperature of the milk at the time should be 60° F. if possible, but, if slightly above or below that temperature, then an allowance of two-tenths may be made for every degree above or below, being added to the weight when the temperature is above 60° F., and being abstracted from the weight when the temperature is below 60° F. The hydrometers which are supplied with the ordinary lactometers are seldom correct, and, moreover, there is greater uncertainty in reading off the exact figure on the stem indicative of the specific gravity. I always employ the specific gravity bottle. Taking genuine milk derived direct from the udders of the cows belonging to three large dairies in the

* Read before the Pharmaceutical Society (North British Branch) at the meeting on the 26th March, 1874.

neighbourhood of Edinburgh, I find the specific gravity to range from 1028·4 to 1035·7 ; the average of forty-four trials with different milks being 1032·20 (water=1000·00). The variations in the specific gravity of the milks ranging over 7 degrees undoubtedly indicate a difference in the composition of the milks and in the quantities of the respective components.

The *cream* is determined in an elongated vessel of uniform width, and graduated at the upper part so as to indicate accurately from 1 to 25 per cent. of the whole capacity. The precautions necessary for the uniform and accurate estimation of the proportion of cream obtainable from milk by this creamometer are (1) that the vessels should be of similar size, so as to admit of the fat globules rising to the surface with equal facility ; (2) that the milk should be taken as fresh from the cow as possible, or that, in contrasting the relative qualities of samples of milk, they should be taken about the same length of time from the cow ; (3) that the milk should be well agitated before being placed in the graduated vessel ; (4) that the temperature of the milk should be about 60° F. ; (5) that the temperature of the room be kept about 60° F. ; and (6) that the respective milks be allowed to remain in the creamometers for the same length of time, say twenty-four hours. Working in this manner, I find that genuine milk throws up a proportion of cream ranging from 5 to 11¼ per cent. by volume, whilst the average of forty-four trials gave 7·8 per cent.

The *total solids* in milk may be readily estimated by evaporating a given weight of the milk in platinum vessels heated on a water bath. A convenient and excellent bath may be constructed from a common iron pot, about eight inches wide and four inches deep, covered with a sheet of copper-plate about ten inches square, which can be kept in its place by a band being cut out at each side and bent down to embrace the pot. Four circular openings are cut in the copper cover, which admit of four flat platinum basins, about two inches in diameter, being set in the bath. The square corners of the copper cover form a hot plate when the bath is in working order. The milk to be tested having been agitated, a portion is poured into one of the platinum basins and weighed. The amount should run from 80 to 100 grains. The basin and contents are then placed on the water bath, and the water kept briskly boiling for at least two hours. Probably to ensure the thorough drying of the residue, three hours should be taken in all trials, so as to have uniformity in mode of working and greater accuracy in result. The basin and contents are then re-weighed, and the total solids from the given amount of milk are obtained. A calculation then gives the percentage of total solids by weight, and I find that genuine milk gives from 10·57 to 14·54 per cent., the average of forty-four trials being 12·04. There is thus a difference of 4 per cent. in the amount of solids obtainable from samples of genuine or normal milk.

The *solids not fat* are estimated by taking the total solids contained in the platinum basin, and extracting the fat by ether, at the same time heating gently over a vessel containing hot water. On settling for a minute, the ether may then be decanted off into a small weighed beaker. The ether treatment of the total solids should be repeated other three times, so that the solids are acted upon four times by the ether. On drying up the residue in the platinum basin, and re-weighing, the proportion of *solids not fat* in the amount of milk employed is obtained, and a calculation will give the percentage. Genuine milk gives from 8·74 to 11·23 per cent. of the solids not fat—the average of forty-four trials being 9·62 per cent.

The *fat* may be determined in two ways, either by the loss in weight of the total solids as compared with the solids not fat, or by the evaporation of the ethereal solution and weighing the fatty residue. I do not find the evaporation method so accurate as the estimation by loss. There is apparently some of the fatty matter which escapes over the side of the vessel even when the evaporation is conducted in glass beakers. The difference in weight between the total solids and the solids not fat gives always a higher result and one which I consider is more accurate. Taking, therefore, the loss in weight due to the extraction of the fat from the total solids by the ether, I find that genuine milk gives a percentage of fat ranging from 1·56 to 3·32, the average of forty-four trials being 2·44.

The *ash* in the solids is estimated by burning off the organic constituents and weighing the residue. In genuine milk the ash ranges from 0·62 to 0·76 per cent., the average being 0·69 per cent.

In carrying on these researches, genuine milk was obtained in every instance direct from the udder of the cow. My assistant, Mr. William Jack, went to three large dairies and personally took the samples. He inspected the pails before the milking was commenced, saw all the cows milked, and sampled every milk himself.

From dairy A there were altogether 16 samples taken from 14 cows, 12 of the samples were from the entire runnings of milk from 12 cows, whilst two of the samples were the first of the runnings and the remaining two samples were the last of the runnings from the remaining two cows. The first five and the last five of the 16 samples were fully analysed, and the results are given in the following table:—

No. of Cow.	Specific gravity of milk.	Cream per cent. by vol.	Total solids per cent. by wght.	Solids not fat, per cent. by wght.	Fat per cent. by wght.	Ash in solids per cent. by wght.
1*a* first of runnings	1032·9	7	11·57	9·32	2·25	0·71
1*b* last of runnings	1031·2	10	12·32	9·30	3·02	0·68
2 whole runnings	1033·4	5½	11·39	9·52	1·87	0·72
3*a* first of runnings	1034·1	5	11·25	9·28	1·97	0·69
3*b* last of runnings	1029·4	11¼	13·66	9·32	4·34	0·70
10 whole runnings	1030·4	6	10·57	8·74	1·83	0·67
11 ,,	1032·7	5	11·42	9·70	1·72	0·70
12 ,,	1031	6	11·51	9·55	1·96	0·69
13 ,,	1031·1	9	12·62	10·04	2·58	0·74
14 ,,	1028·4	10	11·96	9·18	2·78	0·70
Average of the 10 samples	1031·46	7½	11·827	9·395	2·432	0·70

From the above table it will be observed, that, taking the whole runnings, the specific gravity of the milk ranged from 1028·4 to 1033·4, the cream from 5 to 10, the total solids from 10·57 to 12·62, the solids not fat from 8·74 to 10·04, the fat from 1·72 to 2·78, and the ash from 0·67 to 0·74 ; whilst the average of the ten experiments gave specific gravity 1031·46, cream 7½, total solids, 11·827, solids not fat 9·395, fat 2·432, and ash 0·70.

The samples of first runnings were markedly inferior in quality, whilst the samples of last runnings were as markedly superior in quality ; in No. 1 cow the proportions of cream being 7 to 10 and fat 2·25 to 3·02, whilst in No. 3 cow the variation in cream was 5 to 11¼, and the percentage of fat 1·97 to 4·34. It may be stated that the cows, Nos. 1, 2, 10, 11, 12, 13, and 14, were of the "cross" breed, whilst No. 3 was an "Ayrshire" ; that Nos. 1 and 2 had calved in January, No. 3 in November, Nos. 10 and 11 in June, No. 12 in December, and Nos. 13 and 14 in July ; and that the cows were fed three times a day, viz., at 7 a.m. mash of draff, oilcake, and boiled turnips ; at 12 noon draff and raw potatoes, and at 7 p.m. mash, raw turnips and hay.

From dairy B there were 22 samples of milk taken, 18 of which were from the whole runnings of 18 cows, whilst two samples were the first runnings, and two samples were the last runnings of milk from other two cows. All of these samples were fully analysed and the following results were obtained :—

No. of Cow.	Specific gravity of milk.	Cream per cent. by vol.	Total solids per cent. by wght.	Solids not fat, per cent. by wght.	Fat per cent. by wght.	Ash in solids per cent. by wght.
1*a* first of runnings	1033·6	5	10·47	9·15	1·32	0·67
1*b* last of runnings	1030·5	12	12·94	9·17	3·77	0·73

2 whole runnings	1032·5	8	12·57	9·88	2·69	0·74
3 „	1033·7	7	11·75	10·19	1·56	0·71
4 „	1031·4	8	11·91	9·32	2·59	0·68

6*a* first of runnings	1033·4	5	10·57	9·03	1·54	0.62
6*b* last of runnings	1029·0	14	14·09	8·99	5·10	0·59
7 whole runnings	1032·9	7½	12·17	9·93	2·24	0·65
8 „	1032·5	7½	11·97	9·70	2·27	0·67
9 „	1031·5	7½	11·52	9·23	2·29	0·62
10 „	1032·8	6	11·24	9·55	1·69	0·71
11 „	1032·8	7	11·84	9·73	2·11	0·72
12 „	1030·8	9½	11·66	8·94	2·72	0·64
13 „	1030·6	9	11·98	9·37	2·61	0·68
14 „	1033·5	8	12·33	9·95	2·38	0·72
15 „	1031	6	11·48	9·52	1·96	0·73
16 „	1033·4	6	11·37	9·73	1·64	0·70
17 „	1032·7	6	11·29	9·54	1·75	0·75
18 „	1029·6	8	11·41	8·85	2·56	0 69
19 „	1034·0	10	13·85	10·79	3·06	0·76
20 „	1031·3	11	12·48	9·16	3·32	0·68
Average of the 22 samples	1032·14	8	11·95	9·50	2·453	0·69

Taking the above analyses and leaving out the special experiments on the first and last of the runnings of the two cows, Nos. 1 and 6, it will be found that over the whole runnings given by each cow, the specific gravity ranged from 1029·6 to 1034·0, the cream from 6 to 11, the total solids from 11·24 to 13·85, the solids not fat from 8·85 to 10·79, the fat from 1·56 to 3·32, and the ash, from 0·62 to 0·76, whilst the average of the whole 22 analyses gave specific gravity 1032·14, cream 8·0, total solids 11·95, solids not fat 9·50, fat 2·453 and ash 0·69. The samples of first runnings were again much inferior in cream and fat to the last runnings, thus in cow No. 1 the difference was in cream 5 to 12 and fat 1·32 to 3·77, whilst in cow No. 6, the variation in cream was 5 to 14 and in fat 1·54 to 5·10. In this dairy the cows Nos. 1, 7, 8, 9, 10, 11 and 12 were English, Nos. 2, 3, 4, 5, 6, 13, 14, 15, 16, 17, 18, and 20, were Ayrshire, and No. 19 was a cross; and the calving of the cows had taken place in January for Nos. 1, 8 and 9; October for Nos. 2, 3, 4, 5 and 6; December for Nos. 7, 10, 11, 12 and 13; August for Nos. 14, 15 and 18; September for Nos. 16 and 17; June for No. 19, whose milk was nearly out, and February for No. 20, whose milk was only two weeks old. All the cows were fed three times a day on draff and raw turnips.

From dairy C, 12 samples of milk were taken from 12 different cows, and gave the following analytical results :—

No. of Cow.	Specific gravity of milk.	Cream per cent. by vol.	Total solids per cent. by wght.	Solids not fat, per cent. by wght.	Fat per cent. by wght.	Ash in solids per cent. by wght.
1. whole runnings	1031·5	9	12·92	9·94	2·98	0·72
2. „	1031·6	10	12·73	9·71	3·02	0·69
3. „	1032·6	9	12·94	10·15	2·79	0·73
4. „	1034·8	6	11·96	10·22	1·74	0 65
5. „	1034·4	6	11·88	10·04	1·84	0·68
6. „	1031·9	6	10·92	9·16	1·76	0·62
7. „	1032·9	6	11·04	9·34	1·70	0·64
8. „	1035·7	11	14·54	11·23	3·31	0·73
9. „	1030·4	8	11·93	9·37	2·56	0·69
10. „	1031·8	8	12·22	9·69	2·53	0·70
11. „	1034·4	10	13·33	10·02	3·31	0·71
12. „	1034·3	6	11·93	10·07	1·86	0·69
Average of the 12 samples	1033·0	8	12·36	9·91	2·45	0·69

The above results show that in Dairy C, the milk also varied much in all the testing qualities. Thus, the specific gravity ranged from 1030·4 to 1035·7, cream from 6 to 11; total solids from 10·92 to 14·54; solids not fat, from 9·16 to 11·23; fat, from 1·74 to 3·31, and ash from 0·62 to 0·73; whilst the average of the whole 12 samples gave specific gravity 10·33, cream 8, total solids 12·36, solids not fat, 9·91, fat 2·45, and ash 0·69. In this dairy, the cows, Nos. 1, 2 and 9 were Ayrshire; Nos. 3, 4, 5, 6, 7, 8 and 12 were cross; and Nos. 10 and 11 were English; and the food consisted of draff, turnips, and oilcake at 5.30 a.m.; draff and turnips at 12 noon, and draff, turnips, and oilcake at 6 p.m.

The average quality of the milk supplied to Edinburgh by the three dairies may be better observed by placing the averages side by side and then striking an average of the whole samples derived from the 40 different cows. This average of the whole trials may then be contrasted with the lowest and highest results obtained from the whole samples in specific gravity, cream, total solids, solids not fat, fat and ash. The following table exhibits these points :—

	Specific Gravity of Milk.	Crm. per cent. by vol.	Total Solids per cent. by wght.	Solids not fat per cent. by wght.	Fat per cent. by wght.	Ash in solids per cent. by wght.
Dairy A average	1031·46	7½	11·827	9·395	2·432	0·70
„ B „	1032·14	8	11·95	9·50	2·453	0·69
„ C „	1033·00	8	12·36	9·91	2·45	0·69
Average of three dairies, representing forty cows' milk . .	1032·2	7·8	12·04	9·60	2·44	0·69
In all trials—						
Lowest . . .	1028·4	5	10·57	8·74	1·56	0·62
Highest . . .	1035·7	11¼	14·54	11·23	3·32	0·76

These latter figures show that the specific gravity of milk of undoubted genuine quality may range from 1028·4 to 1035·7, or more than 7 degrees, the cream from 5 to 11¼, or more than double; the total solids from 10·57 to 14·54, or 4 per cent.; the solids not fat from 8·74 to 11·23, or 2½ per cent.; the fat from 1·56 to 3·32, or more than double, and the ash from 0·62 to 0·76.

These results prove conclusively that milk taken from different dairies varies in chemical composition, and that milk taken from different cows in the same dairy varies still more in chemical properties, notwithstanding that the cows are housed in the same way, fed at the same time and manner, and milked at the same hours. No doubt the quality of the milk must be influenced not only by the food but by the water in the food, the temperature of the byre, the season of the year, whether summer or winter, as well as probably the breed of cow, age, time of calving, and exact state of health of each cow at the time of milking.

The beneficial effects of improved feeding are apparent in several trials which I have made since the foregoing results were tabulated, on the milk of four of the cows belonging to dairy C. The milk was taken from the cows during the day when it is generally supposed that the milk is richer; but besides that, the dairy man stated that he had commenced to give his cows more nutritious food. The analytical results of the testing of these latter samples of milk were as follows :—

No. of Cow.	Specific gravity of milk.	Cream per cent. by vol.	Total solids per cent. by wght.	Solids not fat, per cent. by wght.	Fat per cent. by wght.	Ash in solids per cent. by wght
1. whole runnings	1032·5	12	14·41	10·47	3·94	0·73
2. „	1033·6	7½	12·64	10·41	2·23	0·71
3. „	1033·3	10	14·21	11·05	3·16	0·75
4. „	1030	10	12·91	9·70	3·21	0·74
Average of the 4 samples	1032·3	10	13·54	10·41	3·13	0·73

These results show a decided increase in the proportion of the several ingredients in the milk, due apparently to the better feeding of the Cows.

(*To be continued.*)

PREPARATION OF NITRATE OF SILVER FOR USE AS A CAUTERY.*

BY E. BOUILHON.

Although crayons of nitrate of silver are in such frequent use, they are far from consisting always of a definite salt, and are often met with of different colours and very varying composition. Sometimes they are black, containing oxide of copper ; sometimes grey, because the salt has been partly decomposed during the fusion, and metallic silver produced ; sometimes bluish, because ordinary nitric acid has been used to dissolve the silver, and there has been formed a small quantity of chloride of silver, which has been affected by the light. These crayons are frequently very brittle, which is a serious inconvenience when they are required for use in the throat or uterus. The white pencils are still more impure, as many makers, under the pretext of giving them solidity, and obtaining them less coloured, use nitrate of silver containing more or less nitrate of potash. This mixture, in fact, resists heat better and gives a less friable product, but the potash salt is an addition that ought not to be permitted ; for, putting aside all question of adulteration, the action of the crayons so obtained is weakened by an inert substance, whilst pure nitrate of silver itself is but a moderate caustic.

Treatises on chemistry and pharmacy are rather indefinite on this subject ; they simply direct melting of the nitrate of silver and the running of it into moulds, but they say nothing of the crystalline texture of the crayon. The Codex, losing sight of the fact that this salt is easily reduced by organic matters under the influence of heat, recommends the greasing of the moulds, in order probably that they may be emptied with more facility. It recommends also that the salt be kept a long time fused, a proceeding as illogical as its preservation in organic substances such as linseed.

In carefully studying the reactions that are produced during the preparation of the crayons, the author has noticed that fusion modifies not only the physical properties, but also the composition of the salt. Thus, the crystallized nitrate of silver is neutral, or even sometimes slightly acid ; but that which has been melted is basic, and as much more so in proportion to the time it has been kept in fusion. The problem, therefore is to melt the salt without rendering it basic, and the author states that he has attained this object by operating in the following manner :—

Twenty grams of pure nitrate of silver are put together with five or six grams of distilled water and one gram of pure nitric acid into a porcelain capsule of sufficient capacity ; this is placed upon a narrow fire, so as not to overheat the sides, which would cause the decomposition of a portion of the nitrate and the blackening of the mass. The water and acid evaporate, the salt becomes dry, and as soon as the fusing-point is reached begins to melt. At this point it is necessary to conduct the operation very carefully, to heat very moderately, and to detach from the sides of the vessel with a glass rod the crusts of dry salt which do not run into the liquid. When about three-fourths of the nitrate is melted it is to be run immediately into a perfectly clean copper mould, not containing any organic matter. Crayons are thus obtained which are of a dead-white colour, and of irreproachable solidity.

The scrapings and debris of any crayons that might be defective can be again placed in the capsule, either alone or with fresh nitrate, distilled water and pure nitric acid added, and the operation recommenced. The precaution must always be taken, however, only to melt a portion of the salt, in order not to go beyond the temperature of its fusing point, and thus to avoid rendering it basic.

* Abstract of paper in the *Répertoire de Pharmacie*, vol. ii., p. 134.

THE SPONGE TRADE OF RHODES.

According to a report on the trade of Rhodes, including the Islands of the Sporades, we learn that the chief exports to Great Britain are sponges and valonia. The sponge fishing industry is actively carried on. The apparatus is exclusively imported from England and France, and though there is no difference in the construction of the English and French machines, nor in the depth to which they can attain, nor the length of time a diver can remain under water—the two main conditions of success in regard to sponge fishing,—still it is said that the English made machines generally prove stronger than the French and that of this fact the islanders are thoroughly conscious. The air-tubes of the British apparatus have, however, hitherto laboured under the disadvantage of being heavier than the French, thus tending to impede the free movements of the diver, as the tubes are caught on rocks. In consequence of this their use has not been greatly in favour. Latterly, it is satisfactory to hear that a great improvement has been introduced into the English apparatus in this respect. The sponge fishery is the principal branch of industry in the Islands of the Sporades. It is estimated that the annual average crop of sponges amounts to £120,000, and of this quantity about £50,000 worth are sent to England. Formerly France used to absorb a large portion of the yield, the exports to that country being large ; but since the last war, Austria, Germany, Italy, and especially England have been the chief customers for these sponges, and have taken the yield almost entirely. With regard to the mode in which the business is conducted, it is interesting to note that the native speculators themselves generally take the sponges to England for sale, and having disposed of them satisfactorily invest the proceeds in articles of British manufacture, which they convey to their own country, and doubtless dispose of with an equally good profit to themselves. They certainly show no lack of enterprise in the management of the business.

It is anticipated that the depreciation in the value of sponges, caused by the large stocks existing in Europe through the more abundant crops consequent upon the introduction of diving apparatus, together with the increasing taxes imposed on the fisheries, will tend to restrict this industry in the Rhodes district, and will induce the divers to seek a more remunerative and less dangerous mode of earning their livlihood. The fishery, indeed, appears to be a very dangerous employment, and numerous accidents occur every season, mostly owing to the divers, in their anxiety to get a good haul, exceeding the prescribed depth. At the present time all sponges sent to England contain about 8lbs. or 10lbs. of sand to 1lb. of sponge—certainly a large proportion ; but it is mentioned that the English merchants, being accustomed to buy the article with as much sand as may be introduced into the sponge, decline to pay a proportionately higher price for those which contain a less quantity of sand. Formerly the same system was adopted in France, but there experience has shown that it is preferable to purchase the sponges just as they are fished. In order to provide for this, agents are sent to Rhodes, the centre of the trade, to purchase them from the divers or from owners of fishing apparatus. By this means they succeed in obtaining the sponges at first hand, and can rely on their not being weighted with sand. The same system, it is believed, will be shortly adopted in England, as an English firm in Rhodes comtemplates the experiment of sending a large number of unsanded sponges to the English market. The attempt at first may probably meet with some discouragement, but there is no reason why it should not be ultimately successful.

The Pharmaceutical Journal.

SATURDAY, APRIL 11, 1874.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

CO-OPERATION AND THE SHOPKEEPER.

To judge from the recent utterances of Professor GOLDWIN SMITH, who, we believe, aims rather at the position of a prophet, it might be supposed that the last days of the retail trader are near at hand, and that before long the co-operative system, of which he is so ardent an admirer, will have swept this class of the community out of existence. In his address to a meeting held last Saturday evening, at Heckmondwicke, in connection with the Co-operative Congress at Halifax, the learned Professor commenced by lamenting that some of those whom he held to be the best friends of the working classes, who had done most of late years to animate and guide the movement by which the working man's condition has been raised, had, as he expressed it, been "cast out of the councils of the nation" because they promoted the co-operative movement. Such a course, he held, would be destructive of Parliament, which would thus come to be a mere mass of mediocrities, without any opinions of their own, enjoying only the distinction of being either perfect cyphers or else a class of "sneaks," founding their opinions upon all public questions mainly on what they thought would bring them a vote.

It would appear that the learned Professor, in giving vent to this lamentation, had in his mind the notion that the "casting out" of the objects of his admiration had been in some way brought about by the agency of retail traders, who had a grudge against the promoters of the co-operative system; for, after having elicited the cheers of his audience by the remarks we have quoted, he straightway went on to repudiate any desire to speak with want of sympathy or feeling for the case of the retail trader. But however this may be the Professor had no doubts about what that case was; no contingency seemed to disturb his conviction that the retail trader will soon be classed with extinct species, and that he will in this respect become the next successor of the dodo. For, said the Professor, the world moves on; the old gives place to the new, and the imperfect to that which is more perfect, and though this progress often involves great hardship to classes, it is in his opinion quite evident that co-operation must come.

It may well be that the vigour of these assertions were properly adapted to the audience addressed by Professor GOLDWIN SMITH, and had he confined himself to that mode of treating the subject, we should have merely translated what he said into language suited for other circumstances and considerations which it was not the Professor's business to give much prominence to in his address.

But the Professor was not content with that, and he unfortunately went on to give reasons for what he announced to be his convictions. Those reasons are curious, and therefore we reproduce them here. They were to the effect that retail shops can only be kept open on three bad conditions. First, great waste of human labour, because each shopkeeper must be idling half his time; secondly, undue profits, for without undue profits no man could live upon a very small trade; and, thirdly, the credit system.

Now these are mere assumptions, and they tend to show that however ably the learned Professor may theorize about political economy he knows little of the facts of practical shop-keeping. The credit system, although wide-spread, is certainly not universal, nor is it an institution always favoured by the seller, whilst it will be news to the shopkeeper that the time not actually occupied with his customers is necessarily wasted in idleness. The fact is that there are other services involved besides the mere act of selling—such as buying, storing, dispatching, etc.—and, as has been pointed out, the buyer at a co-operative store attempts to economize by performing part of this work, especially the porter's share, for himself. Such attempts, however, must eventually be affected by the market value of the labour performed. The upper and even the middle class patrons of the co-operative stores will probably not always care to compete for the wage of the warehouseman and porter; and as to skilled services and professional work, they are commodities that will not very readily lend themselves to the necessities of co-operation.

For our own part we do not believe any good can result from one-sided denunciations of the evils, real or imaginary, of retail shops or of co-operative trading. Both are facts, the existence of which must be mutually recognized, and it is only by vigorous competition that we can hope for a solution of the problem which has now for some time perplexed tradesmen. Protective legislation cannot be hoped for, even if it were worth having, and although the trial will probably be severe and irritating, the sooner it is faced the better. As the *Times* points out, in a recent article, it was under the impression that prices were exorbitant and the quality of the goods inferior, that customers took refuge from the shops in "stores," precisely as customers of another class were driven from hotels to clubs half a century since, and precisely, we may add, as in the present day they are being driven from clubs back to hotels. But there can be little doubt that the majority of people will prefer to be supplied

by the shopkeeper to supplying themselves, and—in spite of Professor Goldwin Smith's philosophy—there is no reason why in the future the shop should not still be an institution advantageous to customer and shopkeeper alike.

THE ANNUAL DINNER.

Many of our readers will be glad to learn that arrangements are now being made for the Third Annual Dinner of the Members of the Pharmaceutical Society and their friends. It is proposed that it shall take place at the Crystal Palace, on Tuesday, May 19, the day before the Annual Meeting of the Society. As it is necessary that a list of the Stewards should be published forthwith, gentlemen who are desirous of acting in that capacity are requested to send their names at their earliest convenience to Mr. Richard Bremridge, 17, Bloomsbury Square, or to Mr. M. Carteighe, 172, New Bond Street.

THE SOCIETY'S MUSEUM.

With reference to the question of admitting visitors to the Museum of the Pharmaceutical Society at a later hour than hitherto, which has been the subject of correspondence in this Journal, it will be seen by our report that the Council, upon the recommendation of the Library, Museum, and Library Committee, has decided that the Museum shall in future be open during the same hours as the Library, namely, daily (except Saturdays) from 9 a.m. until 5 p.m., and from 7 p.m. until 10 p.m.; Saturdays, from 9 a.m. until 2 p.m.

ANALYSIS OF BREAD.

The *Medical Times and Gazette* states that in consequence of the unsatisfactory circumstances attending the evidence in some recent prosecutions for the adulteration of bread with alum, and especially those at the Greenwich Police Court, the master bakers of Deptford, acting in self defence, have made a request to the Greenwich District Board of Works that in all purchases of bread made for the purpose of analysis the inspectors may be allowed to leave a portion of such bread under seal with the vendors so as to permit of an independent analysis being made. Our contemporary remarks that this request, which the Board has refused to grant, is only a reasonable one after what has occurred. We fail, however, to see what guarantee such a regulation would give additional to that provided in 3rd section of the Act of 1860, namely, that the purchaser shall inform the seller of his intention of having the article analysed, and give the seller the opportunity of accompanying him to the analyst in whose presence samples are to be taken and sealed for future reference if necessary.

Mr. James Wick, who, in 1866, was elected an annuitant on the Benevolent Fund, died on Tuesday last, at the age of 72 years.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL,

Wednesday, April 1st, 1874.

MR. THOMAS HYDE HILLS, PRESIDENT.

MR. ALEXANDER BOTTLE, VICE-PRESIDENT.

Present—Messrs. Atherton, Baynes, Betty, Brown, Frazer, Greenish, Hampson, Owen, Radley, Robbins, Sandford, Savage, Stoddart, Sutton, Urwick, and Williams.

The minutes of the previous meeting were read and confirmed.

The North British Branch.

Mr. Williams drew attention, as a matter arising out of the minutes, to the removal of the North British Branch to new premises in Edinburgh, as announced at the last meeting. He was much astonished that such a step had been found necessary so soon after the new premises had been entered upon, and still more so that no intimation had been conveyed to the Council of the intention to take this step. He had no doubt that if Mr. Mackay were present he could explain the circumstances.

Mr. Frazer regretted he could not give the Council any definite information on this subject, not having been present at the meeting in Edinburgh when this course was decided on. He could only suppose that some practical obstacles had been found which rendered it desirable to change. Mr. Mackay had informed him that he should not be able to attend the present Council meeting, but hoped to attend that of next month.

After some remarks by Mr. Brown and Mr. Hampson, it was decided that the Secretary should write to the Secretary of the North British Branch, asking him to favour the Council with an account of the circumstances which had led to the recent change of premises.

The late Mr. Morson.

The President read a letter from Mr. Thomas Morson, acknowledging in very cordial terms the receipt of the letter of condolence from the Council respecting the death of his late father. Mr. Thomas Morson also begged to be allowed to present to the Society an oil portrait of his father, to be executed by an artist who had long enjoyed his intimate acquaintance.

The letter was ordered to be entered on the minutes, and on the motion of the President, seconded by the Vice-President, it was resolved that Mr. Morson's offer to present the Society with a portrait of his father be gratefully accepted.

The following being duly registered as Pharmaceutical Chemists were respectfully granted a Diploma, stamped with the seal of the Society:—

Graham, William Woodrow.
Hetherington, Martin Luther.
Kemble, James.
Pickard, William.
Thompson, Lawrence Joseph.

An associate was restored to his former status in the Society, on payment of the subscription for the current year and a fine of five guineas.

Elections.

MEMBERS.

Joseph Cockshott, an associate of the Society from 1842, was elected a member of the Society,

Pharmaceutical Chemists.

Graham William Woodrow.....Dalbeattie.
Kemble, James.....Lostwithiel.
Pickard, William .....London.

Chemists and Druggists.

Cummock, John .....Troon
Fay, Cyrus.....Stockwell.
Morley, George..... .....Wainfleet.
Thacker, William .....Richmond, Surrey.

ASSOCIATES.

The following having passed their respective examinations, and being in business on their own account, were elected "Associates in Business" of the Society.

Minor.

Beach, Tom Clarke .....Gloucester.
Blackmore, Peter Ludgate .....Stratford.
Dunn, Frederick Edwin .....Sudbury.
Lee, William Walter .....Wandsworth.
Ransford, William ....Bristol.
Roberts, Joseph Elliott .....Harrow Road, W.
Stephens, Henry Isaac.....Liverpool
Storey, John Charles.....Hull.
Sutton, William .....Lavenham.
Watson, Joseph Henry.....Shipley.

Modified.

Fletcher, Francis Bagshaw .....East Retford.
Hudson, Thomas Frederick.....Mile End, E.
Jones, Joseph .....St. John's Wood, N.W.

The following having passed their respective examinations, were elected "Associates" of the Society.

Minor.

Bettle, Joseph Alfred .....Bedford.
Blake, Charles Alexander .....London.
Booth, William Grounds.....Manchester.
Brooks, Charles.....Wandsworth Road, S.W.
Coles, William ....Great Missenden.
Dampney, Richard Shepherd...Chard.
Dutchman, Walter .....London.
Geldart, John .....Whitehaven.
Gilders, George Pollard .....St. Leonards.
Gordelier, William Gibbs.....Sittingbourne.
Gostling, William Ayton.....Diss.
Heath, Frederick Devon.....High Wycombe.
James, Joseph .. ..Hanley.
Keen, Nimrod .....Birmingham.
Knights, James West .....St. Ives, Hunts.
Mackay, James Bunyan Lillie...Edinburgh.
Miller, Cecil Bradley .....Wellingborough.
Murray, Robert Dalziel .....Edinburgh.
New, Thomas Cheney .....Evesham.
Ordish, Thomas.....Manchester.
Owen, Samuel .....Leominster.
Palmer, William Joseph .....King's Lynn.
Scobie, James .....Perth.
Taylor, George .....Kendal.
Whyte, Alexander.....London.

Modified.

Althorp, Henry.....Chester.
Little, Robert..... .....Carlisle.

APPRENTICES OR STUDENTS.

The following having passed the Preliminary Examination, were elected "Apprentices or Students" of the Society :—

Bennett, Isaac Booth .....Stockport.
Clark, Robinson Urwin .....Jarrow.
Josling, Alfred .....Chelmsford.
Priestley, Walter Herbert .....Barnstaple.
Rumsey, James Window .....Criekhowell.
Smith, George .....Sunderland.

HONORARY MEMBERS.

Mr. SANDFORD nominated Professor Robert Bentley, and, in the absence of Mr. Schaeht, Dr. Porter Smith, as Honorary Members of the Society. In accordance with the regulations, the names of these gentlemen will be suspended in the Library for a month, and be voted upon at the next meeting.

NOMINATIONS FOR COUNCIL AND AUDITORS.

The SECRETARY reported that there had been 42 nominations to fill the 14 vacant seats, and the following 26 gentlemen had signified their readiness to accept office if elected :—

Atkins, Samuel Ralph, Market Place, Salisbury.
Baildon, Henry C., 73, Princes Street, Edinburgh.
Baldock, John Henry, 3, High St., South Norwood, S.E.
Bottle, Alexander, 37, Townwall Street, Dover.
Bower, William, 96, Tottenham Court Road, London, W.
Broad, John, Rise House, Hornsey Rise, N.
Chipperfield, Robert, 50, Oxford Street, Southampton.
Fowler, Stanley, 36, Elgin Crescent, Notting Hill, W.
Frazer, Daniel, 113, Buchanan Street, Glasgow.
Freeman, Richard, 70, Kennington Park Road, S.E.
Hampson, Robert, 205, St. John Street Road, E.C.
Hills, Thomas Hyde, 338, Oxford Street, W.
Mackay, John, 119, George Street, Edinburgh.
Owen, John, 51, Holloway Road, N.
Preston, Joseph Classon, 88, Leadenhall Street, E.C.
Rimmington, Felix Marsh, 6, Ivegate, Bradford.
Robbins, John, 372, Oxford Street, W.
Sandford, George Webb, 47, Piccadilly, W.
Schaeht, George Frederick, 7, Regent's Place, Clifton.
Shaw, John, 24, Great George Place, Liverpool.
Stacey, Samuel Lloyd, 300, Holborn, W.C.
Stoddart, William Walter, 9, North Street, Bristol.
Sutton, Francis, Bank Plain, Norwich.
Thomas, Richard Wheeler, 10, Pall Mall, S.W.
Turner, Charles Ernest, 63, Great Russell Street, W.C.
Williams, John, 16, Cross Street, Hatton Garden, E.C.

The following sixteen members declined to accept office if elected :—

Andrews, Frederick, 23, Leinster Terrace, Hyde Park, W.
Bell, William Henderson, 96, Albany Street, Regent's Park, N.W.
Bland, John, 51, Penton Street, Pentonville, N.
Burden, Edward, 38, Duke Street, Grosvenor Square, W.
Constance, Edward, 37, Leadenhall Street, E.C.
Faulconer, Robert Stephen, 270, Walworth Road, S.E.
Gulliver, William, 6, Lower Belgrave Street, S.W.
Guyer, James Brett, 11, Strand, Torquay.
Hanbury, Cornelius, Plough Court, Lombard Street, E.C.
Hills, Walter, 338, Oxford Street, W.
Morson, Thomas, 124, Southampton Row, W.C.
Palmer, Robert, 35, Ovington Square, S.W.
Savory, Charles Harley, 143, New Bond Street, W.
Sharpe, George Young, 34, High Street, Notting Hill, W.
Urwick, William Walker, 60, St. George's Road, Pimlico, S.W.
Yarde, Giles, 60, Lambs Conduit Street, W.C.

Several members of the Council expressed their surprise and regret at Mr. Urwick's decision to withdraw his name.

Mr. URWICK desired to thank his colleagues for their kind expressions, but said he was unable at present to spare the time necessary for attending to the duties of the Council.

The Secretary reported that the following five members had been nominated for election as auditors in May next, and had declared their willingness to accept office if elected.

Andrews, Frederick, 23, Leinster Terrace, Hyde Park, W.
Barron, Frederick, 2, Bush Lane, Cannon Street, E.C.
Hodgkinson, William, 127, Aldersgate Street, E.C.
Horner, Edward, 20, Bucklersbury, E.C.
Squire, William, 5, Coleman Street, E.C.

FINANCE.

The report of this committee was read, and various accounts were ordered to be paid. The balance-sheet and departmental accounts were also presented, and the report of the auditors. The latter stated that they had not signed the departmental statement of accounts, because they were unable to vouch either the due allocation of receipts and expenses to the various accounts, or the estimated values of the copyright of the Journal, lease of premises, etc., which had been introduced.

Mr. STODDART inquired what the item of £1600 due to the Society represented.

The SECRETARY said it was the amount due by Messrs. Churchill on the Journal account.

After some further conversation the report of the committee was received and adopted, and the financial statement as audited was ordered to be published with the annual report.

BENEVOLENT FUND.

The report of the Benevolent Fund committee was read and adopted.

The PRESIDENT read a letter from Mr. Thomas H. Wyatt, architect, offering to present the Society with an old engraving, which had lately come into his possession, representing Bloomsbury Square in the year 1787, and showing the premises of the Society. The letter was ordered to be entered on the minutes, and it was resolved that the engraving be accepted, and that the thanks of the Council be conveyed to Mr. Wyatt.

LIBRARY, MUSEUM, AND LABORATORY.

The report of this committee recommended the purchase of the following books for the library :—

Tuson's 'Veterinary Pharmacopœia,' second edition ; Lockyer's 'Spectroscope and its Applications,' second edition ; Rodwell's 'Birth of Chemistry ;' Griffith's 'Universal Formulary,' third edition, by Maisch.

The librarian reported that during the month of February books had been supplied to 19 members in the provinces : the average attendance in the library had been 15·37 during the day and 5 in the evening, showing an improvement.

Professor Bentley reported that he had 30 students attending his second course of lectures, 13 of whom had also attended the first.

Professor Redwood reported that he had 32 students now attending, of whom 14 had attended his first course.

Professor Attfield stated that he had had 71 entries since the commencement of the session, 38 students being now at work.

Specimen sheets of a catalogue of the specimens in the museum were presented by the curator, one with explanatory notes and one without. The committee recommended that the former be adopted, and also that the English synonyms should be added where practicable. The curator also applied for a microscope to be used in the museum, and the committee recommended that one be provided at a cost of £10 to £15. With regard to the question of opening the museum in the evening, the committee recommended that a trial should be made, they being of opinion that no attendant other than the hall porter would be required.

Mr. ATHERTON asked what had become of the two microscopes which the Society already possessed.

Mr. WILLIAMS said the Society had two valuable microscopes, but they were in almost constant use by the professors, who he did not think could very well be asked to surrender them.

Mr. GREENISH said there could be no question in the mind of any one as to a microscope being a matter of necessity to the curator of a museum such as the Society's, and he ought to have one in constant use. Everyone engaged in the examination of different substances connected with materia medica must be aware that it is on the microscope he mainly depends for the identification of many articles, and for the detection of substitution or adulteration in others.

Mr. SANDFORD said the specimen sheets of the catalogue which had been submitted by the curator did him great credit, and would be most useful.

The report and recommendations of the committee were then received and adopted.

PARLIAMENTARY.

This committee had held one meeting, when it was determined to postpone the consideration of the objectionable parts of the Adulteration Act until the meeting in May, but if in the meantime any amendments or alterations were announced, the committee would meet to consider them.

The VICE-PRESIDENT said the Juries Bill was set down for the 22nd of April ; he should like to know if the attention of the committee had been called to it.

The SECRETARY said the Bill had not yet been printed. As soon as he could get copies he would send one to each member of the committee, and, if necessary, a meeting would be called.

SPECIAL COMMITTEE ON THE LETTER TO THE COUNCIL FROM THE BOARD OF EXAMINERS IN SCOTLAND.

The report of this committee stated that a deputation from the Board of Examiners in Scotland, consisting of Messrs. Tait and Gilmour, accompanied by Dr. Maclagan, the Government visitor, had attended the examination in the month of March. The questions for consideration had by this visit been very materially reduced, inasmuch as the practice of the London Board had shown the North British Examiners that certain regulations which they had objected to were not of the character they had supposed. These gentlemen having become conversant with the practice of the London Board were satisfied that the same arrangements might be carried out in Edinburgh, and the committee had, therefore, much pleasure in reporting that the divergence between the two boards was now removed, and that their practice would in future be identical. This was regarded as another proof of the necessity for more frequent interchange of personal communication between the two examining boards. Discussion had arisen as to the amount of time that should elapse before rejected candidates were allowed to present themselves again for examination. On account of the number of failures which had taken place it was unanimously resolved by the Committee of the Council, the London Board of Examiners, and the Deputation from the Scotch Board to recommend that after October next candidates who failed should not be admitted to subsequent examination until after an interval of three or six months at the discretion of the Board of Examiners. It was also recommended that the two boards should communicate to each other from time to time the names of unsuccessful candidates to insure this regulation being enforced.

Mr. BAYNES said there was a very important suggestion in the report, namely, that the term of three or six months interval should be at the will of the examining bodies. He would a great deal rather determine at once that a rejected candidate should not come up again for six months, or for any other term which might be decided upon if three months were too short, unless some special circumstance induced the examiners to make an exception in his favour ; but he objected to the proposed alteration, and also to a correspondence between the two bodies, as being mischievous and troublesome.

Mr. SANDFORD said the practice hitherto was that when a man failed he was sent back for three months ; but the examiners were of opinion that that time was not in all cases sufficient, and they therefore desired the power of referring some candidates to their studies for six months. The object of the communication between the two boards was that if A. B. failed at an examination in London he should not be allowed to present himself in Edinburgh before the expiration of the term fixed.

Mr. HAMPSON said there was an important principle involved here which he must object to. The examiners wished to have the power of restricting candidates from presenting themselves at the termination of three months. It was quite possible that many came up unprepared, but if they were rejected that was quite sufficient. He did not think the examiners should have the option of fixing an arbitrary period as to the time at which the candidates should present themselves again. Sometimes a candidate from some unforeseen circumstance utterly failed to pass, yet he might have resolution, talent, and opportunity sufficient to prepare himself in three months, and he should therefore have the right of representing himself if he thought proper.

Mr. BETTY agreed with Mr. Hampson. They ought to look at this matter in all its bearings, and though the number of failures for the minor examination had been very great recently, it was pretty well understood that that number was exceptional and arose from reasons which were generally known, and he objected to legislate for exceptional circumstances. He also demurred to the names of the rejected candidates being published in the way proposed. He did not believe such a practice was adopted by any similar body and should be sorry to see it introduced.

Mr. SANDFORD said the two boards were really the two boards of one Society—they were virtually the same.

Mr. BETTY remarked that if a young man failed to pass an examination at the London College of Surgeons he could go to Edinburgh and pass there. Practically the case was the same. He objected to the name of any one who had failed being sent out of the establishment.

Mr. GREENISH did not think the alteration ought to be made under present circumstances.

Mr. RADLEY said he knew of two cases, if not three, of young men who had come up for the first time, and being exceedingly nervous had failed, but in three months they had presented themselves again, and passed very creditably.

Mr. WILLIAMS said he was both astonished and pained that so much opposition should be made to this proposal, and thought the Council ought to have some consideration for the Board of Examiners. They were men who practically came in contact with the candidates, and their opinion, which was very strong upon this subject, ought to be taken. They believed that six months was in many cases quite short enough, considering the ignorance which many of the candidates displayed, and that therefore they ought to have the power of preventing those candidates from re-entering for examination at a shorter interval. Already the report that such a step was in contemplation had been noised abroad, and he understood that some of the gentlemen who undertook to prepare candidates for the examination at a certain fixed amount had made up their minds to double their fees. In fact, if this three months system were altered, he believed it would tend to break down the cramming system of which they had heard so much lately. With regard to sending the names of rejected candidates, it was agreed upon all sides that it was most essential that the young men who failed in London should not have the opportunity of going to Edinburgh and presenting themselves for examination, or *vice versâ*. The only way to check such a practice would be to insist upon the names of rejected candidates being communicated between the two boards. He hoped the report would be adopted.

Mr. SANDFORD then moved and Mr. WILLIAMS seconded a resolution that the report and recommendations of the special committee be received and adopted.

Mr. BROWN thereupon said he must move an amendment to the effect that the recommendation, whereby the term of three months prescribed before re-examination might at the discretion of the examiners be extended to six months, be not agreed to by the Council. That was the only part of the report which was objected to, and it appeared to him there was no evidence before them, and he had not heard any arguments from the previous speakers, to show why this power should be given. After full consideration the time of three months had been fixed upon as the interval that ought to elapse, and he did think it would be very injurious to invest the examiners with such a discretionary power. He did not see that what had been reported with respect to the cramming system had anything whatever to do with the question, and certainly it was beneath the dignity of the Council and the professors to talk so much about cramming as they had done. The examiners of the Society were either competent or incompetent to discriminate between those who came up to be examined and to decide who were proper to be entrusted with the responsibility of business. If they did not take sufficient time, or had not sufficient facilities afforded them to properly test the candidates, some alteration should be made in that respect. But in many cases it would be a serious injustice if the discretion were left to the examiners to remit a young man for six months to his studies, when perhaps he had only failed in one subject. He did not suppose that young men were so foolish as to present themselves a second time without having made something like proper preparation, and he did not believe it was the fact that candidates were constantly presenting themselves every three months without being prepared.

Mr. SAVAGE suggested that instead of a direct negative being given, the question should be postponed *sine die*. He wished also to say that he did not believe some of the gentlemen who had been alluded to by Mr. Williams, who prepared young men for the examinations, deserved all that was sometimes said about them. From what he could gather they paid a great deal of attention to their pupils, and insisted on their attending closely to their studies, not only during the lecture hours, but at home.

Mr. HAMPSON seconded the amendment, thinking it would be very unwise to accede to the proposition of the Board of Examiners.

Mr. GREENISH said it was within his own knowledge that a most able young man had failed to pass the first time, but came up in three months and passed with honours.

Mr. SUTTON observed, with regard to the "cramming" question, that if men were determined to cheat they would do it somehow, and he really did not think the proposed alteration would affect it, because if the candidates were sent back for six months, and wished to cram they would not cram the whole of the six months, but simply for a short time at the end of that period.

The PRESIDENT thought the examiners were treated rather more hardly than they deserved, for they had as much consideration for the young men that came up as any gentleman present. They did all they could to ascertain what knowledge the candidates possessed, and if it were possible to pass them with satisfaction to themselves and honour to the Society they would do so. He himself had frequently recommended young men not to come up again for six or even twelve months, and it was not proposed to prevent those coming up earlier who might reasonably expect to be prepared. He hoped that the Council would agree to the recommendation, feeling certain it would save a great deal of time to the examiners and money to the candidates. At any rate, if they did not agree to it they might refer the matter back to the committee.

Mr. BROWN thought it most important there should be one fixed rule. If three months were not long enough they might make it six, which he should much prefer to the plan now suggested; perhaps giving the examiners discretionary power to reduce the time.

The VICE-PRESIDENT said he had referred to the regulations for the examination of the College of Physicians, the College of Surgeons, and the Society of Apothecaries, and he found nothing indefinite there with reference to the period for which young men should be referred to their studies if they failed to pass the examinations. For the College of Physicians, if they failed in the first examination they were sent back for three months, but at the second examination they were sent back for six months, and the same applied to the other bodies he had mentioned. There was no discretionary power. It did occur to him that they might meet the matter by resolving that a candidate who failed in two subjects should be sent back for three months, while one who failed in three should be sent back for six months. He suggested that the amendment should be altered so as to refer the matter again to the committee.

Mr. BROWN said he could not do so. The more he thought about it the more was he convinced of the necessity for the amendment, and the more opposed was he to

granting a discretionary power. No one was prepared to pay greater respect than he to the efforts of the board, and to the fairness with which they carried out the examinations, or the consideration which they extended to candidates; for when he was vice-president he attended very frequently, and was very much satisfied with what he had learnt on those occasions. Nevertheless, he was decidedly of opinion that it would be a mistake to give the discretionary power now asked for.

On the amendment being put, the following voted :—

For—Messrs. Atherton, Baynes, Betty, Brown, Frazer, Greenish, Hampson, Owen, Radley, Robbins, Savage, Stoddart, Sutton, and Urwick.

Against—The President, Mr. Sandford, and Mr. Williams.

The Vice-President was present, but did not vote.

On the amendment being put as a substantive motion, Mr. Sandford suggested an amendment, that the matter should be again referred to the committee, but this was subsequently withdrawn, and the substantive motion was carried.

The report of the committee was then adopted with the exception of the portion referred to in the above amendment.

Additional Scholarships.

The committee appointed to consider this question reported that they had met, but as neither Mr. Schacht or Mr. Mackay were able to be present they decided to postpone the discussion.

Deputy-Superintendents of Examinations.

The following were appointed Deputy Superintendents of the Society's examinations :—

Rev. E. Hutchinson .....Darlington.
Mr. William Gethen .....Hereford.

Conversazione.

The Committee appointed to make arrangements for the forthcoming Conversazione reported certain arrangements which had been made and some which were still in progress. The report was adopted.

The Secretary stated that the new wing of the museum would be thrown open on the evening in question.

General Purposes.

This committee reported that they had held a meeting on that morning to receive the reports of Professors Redwood and Bentley respecting the examinations at the termination of the first course of their lectures. It appeared that the attendance had been very good and the examinations satisfactory. The committee recommended that in addition to the bronze medal which it had been announced would be given to the most successful candidate, two certificates should also be awarded to those who attained a certain proportion of marks.

Mr. Robbins said he believed it was considered by the committee that the professors had to a certain extent compromised the matter by leading the students to understand that these certificates would be given, and therefore, though several members objected to a departure from the regulations which had been already published, they ultimately consented to this recommendation.

Mr. Urwick said his feeling was that the matter was so strongly recommended by Professor Redwood that it would be better to err in the direction of generosity.

Mr. Frazer said his opinion was that they should give the bronze medal which had been announced, and nothing else.

Mr. Williams was of the same opinion, and thought giving so many certificates would only tend to reduce and degrade the honour which it was intended to convey.

Mr. Urwick said that it was generally known to the students before the examination took place who were likely to be successful in obtaining prizes, and others did not care about competing. It was to encourage the latter class that these certificates were desired.

Mr. Frazer said he objected to the certificates being given, if only out of justice to those who had not competed. Many might have done so if they had known that certificates would be awarded, but who, relying on the published regulations, had not come forward.

Mr. Urwick said he believed the students had been given to understand generally that there would be certificates.

Mr. Greenish had always advocated two certificates being given. It was quite true, as had been said, that the students were under the impression that these certificates would be awarded. His desire would be to induce all young men, as soon as they entered the business, to commence attendance on the lectures; but those who did so while still in business could not be expected to compete successfully with young men who were at work in the laboratory, devoting their whole time to study, and consequently they would not enter the competition. Therefore he thought it would be well to award two certificates to those who were not able to obtain the only bronze medal.

Mr. Sutton observed that these remarks applied almost exclusively to the case of Londoners, whereas young men in the country might be quite as deserving, but from not having an opportunity of attending the lectures they would not be able to obtain the certificates.

Mr. Betty said he recollected when the subject of the silver and bronze medals and certificates was thoroughly discussed, the professors being present. As he understood, the question was then decided, and it ought not to have been brought forward again. It was then settled according to the terms of the advertisement which had appeared since in the Journal, every word of which was most carefully considered both by the Council and by the professors. He did think, therefore, they were bound not to depart from the course which had been thus laid down. If their decision was a wrong one, let it be reconsidered at a future time, and fresh regulations made; but so long as they were in force they ought to be adhered to.

Mr. Sandford said at the time the discussion took place to which Mr. Betty had referred, it was arranged that a bronze medal should be given at the end of each five months' course, and a silver medal at the end of the ten months' session, when certificates would also be granted.

If they now agreed to give certificates at the end of five months there would be two at the end of each course and two or three others for the whole session, so that confusion would be likely to arise, and being so many, their value would be lessened. He was decidedly of opinion therefore that they should adhere to the rules already laid down, and he could not agree that the students had been led to expect any certificates would be awarded beyond the certificate of attendance given by the professors.

Mr. BAYNES thought the recommendation of the committee should be supported.

Mr. GREENISH said the matter was of great importance, not only with regard to this examination but to the number of young men entering in future. He thought they ought to endeavour to get at least half the young men attending the lectures to compete at the examinations. This would never be the case unless certificates were awarded in addition to the bronze medal.

Mr. WILLIAMS said he had suggested to the committee that a compromise might be effected by giving certificates of merit only, not certificates of honour.

The VICE-PRESIDENT could not believe it was the intention of the Council to depart from the published statement in the calendar of the prizes to be awarded; what was the use of printing a new calendar, with certain regulations and then adopting fresh ones?

Mr. FRAZER then moved an amendment—that the proposal to award certificates of merit at the end of each course be not agreed to. This was seconded by Mr. Williams, and, on a division, carried by 8 to 4.

With this exception the report was agreed to, and the Bronze Medals for the successful competitors in the examinations at the conclusion of the first lecture course of the present session were awarded to—

James Kemble, Chemistry and Pharmacy.

William Ayton Gostling, Botany and Materia Medica.

PHARMACEUTICAL MEETING.

Wednesday, April 1st, 1874.

MR. THOMAS HYDE HILLS, PRESIDENT, IN THE CHAIR.

The minutes of the previous meeting having been read and confirmed, the following donations were announced, and the thanks of the Society awarded to the donors:—

For the Library—'Throat Hospital Pharmacopœia,' from Dr. Morell Mackenzie; 'Ueber die Bukublätter,' from Professor Flückiger; 'Les Eaux Thermales de l'Ile de San Miguel (Açores),' from the Portuguese Legation; 'On the Geometrical Isomorphism of Crystals and the Derivation of all other Forms for those of the Cubical System,' by the Rev. W. Mitchell, M.A., from the Victoria Institute.

For the Museum—Specimen of congœ or kungee oil, pods, and seeds, from Mr. Thomas Buck. A specimen of *Arachis hypogœa*, for the herbarium; from Mr. George Nicholson.

The thanks of the Society were voted to the donors.

DISPENSING NOTE ON CHLORO-MERCURATE OF MORPHIA.

Mr. W. MARTINDALE then read a Dispensing Note on Chloro-Mercurate of Morphia, which will be found on p. 809.

MATERIA MEDICA.

Mr. E. M. HOLMES furnished some further information respecting Koegoed, a South African plant, which was brought under the notice of the British Pharmaceutical Conference at Brighton. He also gave details respecting some cases of admixture of other substances with cascarilla, arnica, and belladonna roots. The paper is printed on p. 810.

Mr. HANBURY asked if the spurious arnica was mixed with the other or whether it came in a separate state.

Mr. HOLMES said that one sample contained about one-half arnica and half *Geum* and other roots; another sample, however, had only 5 per cent. of real arnica.

Mr. HANBURY said that about two months ago he was shown a sample of a drug sold as arnica which did not contain any arnica at all, but consisted entirely of some other root which he could not identify. Such a thing could hardly be called adulteration, because it was a complete substitution.

TINCTURE OF PERCHLORIDE OF IRON.

Dr. J. E. DE VRIJ said that he had intended to bring the subject of Tincture of Perchloride of Iron before the meeting at some length, but having that day seen for the first time a paper read by Professor Attfield ten years since, he found that much of what he had to say had been anticipated. His attention had been called to the subject by a paper contributed by Mr. Hustwick to the Pharmaceutical Conference at Brighton in 1872, in which Mr. Hustwick favoured the substitution of the liquor for the tincture whenever the latter was ordered. Dr. De Vrij said that in his opinion such a step was not justifiable; for, notwithstanding all that had been objected, physicians still ordered the tincture, and probably would continue to do so. He thought that the principal point in the preparation of tinctura ferri perchloridi was to first obtain a really neutral solution of perchloride of iron. This could be prepared by passing chlorine gently through a solution of ferrous chloride as long as any was absorbed, and afterwards driving off excess of chlorine by exposure to a temperature not exceeding that of the water-bath. When the alcohol was added to such a solution, a tincture was produced, which, contrary to what was usually stated, remained bright and clear if exposed to the sunlight, but yielded a precipitate if kept in the dark. Dr. De Vrij exhibited two specimens illustrating this fact.

Professor ATTFIELD said this communication might be divided into two parts, that which related to a preparation of a neutral solution of perchloride of iron in water and that which related to the tincture. Dr. De Vrij made a clear addition to their knowledge when he said that a pure neutral solution of the perchloride, made by passing chlorine into a solution of ferrous chloride, might be quite freed from the excess of chlorine by exposing it over a water-bath. He there went beyond the point which he (Professor Attfield) had reached when he read the paper to which reference had been made. Since that time he had been accustomed in the laboratory to prepare a solution of perchloride of iron pretty much in the way mentioned by Dr. De Vrij; but they had made what he thought a little improvement by passing a steady current of air through the solution, thus enabling free chlorine to be driven off somewhat more rapidly, and so reducing the chance of the solution of perchloride of iron becoming altered. With regard to the tincture, he understood Dr. De Vrij to say that if it were made by the addition of the alcohol to that solution of neutral perchloride of iron and then exposed to the light, no deposition of precipitate occurred, but that a clear solution resulted. He could quite confirm that observation, but he could not agree that there was thereby produced a solution of perchloride of iron with spirit only. No doubt Dr. De Vrij was perfectly aware that while the tincture was exposed to the light a reaction was going on, and the ferric chloride was being reduced into ferrous chloride, and ethereal compounds containing chlorine were produced at the same time. If it were exposed for a sufficient length of time the tincture would become green, and was then no longer tincture of perchloride of iron at all, but ferrous chloride entirely with some ethereal bodies. It was quite obvious if the tincture of perchloride of iron were made according to directions, namely, by adding alcohol to the aqueous solution, that instead of preserving the compound, which was generally the reason for adding alcohol, it decomposed it, and therefore there could be no doubt that this addition was a great mistake, and that a simple aqueous solution of perchloride of iron was much to be preferred. His own idea was that the alcohol was simply wasted, but still there was no doubt that if conservative

physicians continued to order the tincture, as they doubtless would for a long time to come, pharmacists must continue to make it. It should, however, be understood by all that when this tincture was ordered that which was dispensed would be a tincture which might contain perchloride of iron, but it might also contain ferrous chloride and chlorinated ethereal bodies, and therefore was not a definite preparation. The aqueous solution could be kept for any length of time without spoiling.

Dr. De Vrij said the tincture Professor Attfield had alluded to was a tincture much used on the continent. It was made by the addition of alcohol to the perchloride of iron, and when exposed to the light became not only green, but, at length, quite white ; though very curiously, if kept in the dark, it turned a beautiful yellow colour, like gold, so that probably the ferrous chloride became ferric chloride again. From possessing this yellow colour it was generally described in the books as "golden drops." With regard to the practice of physicians in these matters he could only say that sometimes when you told a physician of the chemical action which took place in these compounds, the reply given was that the human body was not a retort.

Professor Attfield said he recognized quite plainly in the tincture which Dr. De Vrij had prepared, the presence of the chlorinated ethereal bodies he had referred to, and Mr. Groves (sitting next) also thought a considerable amount of decomposition had occurred in the specimen.

Additions to the Pharmacopœia.

Mr. C. Umney then read a paper on the 'British Pharmacopœia Addendum,' which was illustrated by specimens of the new preparations. The paper was printed at p. 789 of the Journal of last, and gave rise to the following discussion :—

The President, in offering Mr. Umney the best thanks of the meeting for his interesting and elaborate paper, regretted that there was so little time left to discuss it.

The Vice-President said Mr. Umney had called attention to the Addendum to the Pharmacopœia, which bore date January 24th, but as there were two versions of that Addendum, probably some gentlemen would refer to one and some to the other, which would very likely lead to confusion, as there were considerable variations between the two. Only last week he purchased a copy at Messrs. Churchills, but on examining it he found that the body of the work did not correspond with the Index, since the latter referred to page 24 for the Tincture of Ipecacuanha, but on turning to that page there was no such subject. On obtaining from the Library a copy of the Addendum which had been placed there, he found upon a very brief comparison that there were many variations between the two, and in the course of half an hour he had jotted down some of these discrepancies, which were as follows :—

December, 1873.	*January*, 1874.
Corrections—p. 166, *for* $16\frac{1}{2}$ *read* $23\frac{1}{2}$.	"*For* $16\frac{1}{2}$ *read* 24."
Index—Omitted.	"Areka."
,, Omitted.	"Laricis Cortex."
,, "Pilula Jalapæ Comp."	Omitted.
,, Omitted.	"Pilula Phosphori."
,, Omitted.	"Pilula Scammonii Comp."
,, Omitted.	"Pulvis Glycyrr. Comp."
,, "Tinct. Ipecac.," which does not appear in the book.	Omitted.
Index—Omitted.	"Tinctura Laricis."
,, Omitted.	"Tinctura Quiniæ Ammon."
Page 13 — Calcis Hypophosphis, dose 2 to 5 grs.	Dose 5 to 10 grains.
Page 14—Extm. Glycyr. Liquidum, made from hard extract.	Made from root.
Page 18—Ol. Phosphoratum.	Formula varied and dose altered.
	Pulvis Glycyrr. Comp., differing from Phar. Prus.
	Sodæ Hypophosphis, dose increased.
Page 23—"Syr. Chloral."	Syr. Chloral, formula varied.
,, Tinct. Aurantii Recentis.	Made up to the pint.
,, Omitted.	"Tinct. Laricis."
,, Omitted.	"Tinct. Quiniæ Ammon."

With these two varying books, both dated 1874 on the cover, but one bearing date December, 1873, inside, and the other January, 1874, they ought to know which they were discussing before they began. Perhaps Professor Redwood could explain how these discrepancies arose.

Mr. Bland suggested that the discussion should be adjourned, as it was already late, and the subject was of such importance.

Professor Redwood regretted he was unable to give any explanation how the different variations got into circulation, but it was evident some mistake had been made either by Mr. Bottle or by the bookseller who supplied him. There was no doubt the Addendum to the Pharmacopœia, proposed to be made by the committee of the Medical Council, was in print even in the early part of 1873, and was circulated amongst the members of the Council and their friends. It was also true that there were the differences which had been pointed out between it and the work which had just been published, but he entirely denied that there had been any publication of the work until very recently in the present year. Besides, as now published, the title was "Additions to the Pharmacopœia," whereas the copies which had been circulated amongst the Medical Council for something like twelve months were entitled "Addendum." Those had been circulated in order that members of the Medical Council might get all the information they could from their medical and pharmaceutical friends, and consequent upon such inquiries the corrections which Mr. Bottle had pointed out had been made in the revised edition. He could only account for one of the former having been published on the supposition that some of the sheets had got mixed at the printers, and by inadvertence had been sent to the bookbinders and issued with the revised edition. The Addendum had never been sent out at all except for private circulation. He should like to make some observations on the Additions, but should much prefer before doing so to hear the observations of practical men who had been engaged in making the various preparations, and should therefore be very glad if the discussion were adjourned.

It was then agreed to adjourn the discussion until the first Wednesday evening in May, and the proceedings terminated.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

The anniversary meeting of the Chemical Society was held on the 30th March, Dr. Odling, F.R.S., President, in the chair. The President, in his sketch of the history of the Society during the past year, stated that there had been an increase of 51 in the gross total of members. He read short biographical notices of the following who had died :—Baldwin Francis Duppa, Frederic Crace Calvert, Henry Bence Jones, William Husskisson, jun., Charles Davy, William John Hay, and Daniel Stone. The only foreign member the Society had lost was Justus von Liebig, to whose memory the President paid a graceful tribute. It was proposed that early next session Dr. Hofmann should deliver the third Faraday lecture, the subject being "A Discussion of the Early Work of Liebig." During the past year 51 papers had been read, besides four lectures, against 22 in 1872 and 58 in 1873.

Dr. Odling called attention to the fact, which did not appear to be generally known, that the Society made small grants to assist experimental chemists in the prosecution of original research.

After the reading of the Treasurer's report, which showed a satisfactory condition of the finances, the following officers and other members of the Council were elected for the ensuing year :—

President.—W. Odling, M.B., F.R.S.

Vice-Presidents who have filled the office of President.—Sir B. C. Brodie, F.R.S. ; Warren De la Rue, Ph.D., F.R.S. ; E. Frankland, D.C.L., F.R.S. ; A. W. Hofmann, D.C.L., F.R.S. ; Lyon Playfair, Ph.D., C.B., F.R.S. ; A. W. Williamson, Ph.D., F.R.S. ; Col. P. Yorke, F.R.S.

Vice-Presidents. — J. H. Gladstone, Ph.D., F.R.S. ; A. Vernon Harcourt, M.A., F.R.S. ; G. D. Longstaff, M.D. ; H. E. Roscoe, Ph.D., F.R.S. ; Maxwell Simpson, Ph.D., F.R.S. ; A. Voelcker, Ph.D., F.R.S.

Secretaries.—W. H. Perkin, F.R.S. ; W. J. Russell, Ph.D., F.R.S.

Foreign Secretary.—H. Müller, Ph.D., F.R.S.

Treasurer.—F. A. Abel, F.R.S.

Other Members of Council.—J. Attfield, Ph.D. ; H. E. Armstrong, Ph.D. ; Dugald Campbell ; J. Dewar, F.R.S.E. ; A. Dupré, Ph.D. ; G. C. Foster, F.R.S. ; M. Foster, M.D., F.R.S. ; Peter Spence ; Hermann Sprengel, Ph.D. ; Thomas Stevenson, M.D. ; R. Warington ; C. R. A. Wright, D.Sc.

Thursday, April 2nd, 1874 ; Professor Odling, F.R.S., in the chair. After the transaction of the usual business of the Society, papers "On Sulphocyanide of Ammonium and Sulphocyanogen," by Dr. T. L. Phipson ; and a "Note on a Reaction of Gallic Acid," by H. R. Procter, were read by the secretary. Mr. Procter finds that a mixture of gallic acid and potassium arsenate when exposed to the air acquires a beautiful green colour. Mr. W. Noel Hartley then read a memoir "On Cobalt Bromides and Iodides," in which he described the method of preparation and properties of these compounds. They closely resemble the corresponding chlorides. Fine specimens of the different salts were exhibited by the author. Mr. E. Neison read a paper on "The Distillation of of Sodium Ricinoleate," and Mr. C. H. Piesse a "Note on the Solubility of Plumbic Chloride in Glycerine;" Mr. Kinzett had a voluminous communication "On Ozone as a Concomitant of the Oxidation of the Essential Oils"—Part I.; and from his experiments he infers that the compound produced during the oxidation of oil of turpentine is neither ozone nor hydrogen peroxide, but a hydrated oxide of turpentine. The last paper was on the "Action of Chloride of Benzyl on Camphor"—Part II., by Dr. D. Tommasi.

The meeting then adjourned until Thursday, 16th April, when communications will be read "On Isomeric Terpenes and their Derivatives—Part IV.: Oil of Cajeput," by Dr. C. R. A. Wright ; and "On the Constitution of Urea," by Dr. D. Tommasi.

SOCIETY OF CHEMISTS AND DRUGGISTS OF IRELAND.

The first of a course of popular scientific lectures, in connection with this Society, was delivered on Monday evening, March 30th, in the Molesworth Hall, Dublin. The attendance was considerable.

On the motion of Mr. J. T. Holmes, the chair was taken by Mr. John Brooks.

The lecturer was Professor C. R. C. Tichborne, and the subject of his discourse, "The Secrets of Modern Pharmacy." He explained a difficult subject very lucidly, and elicited frequent applause. The topics treated of were the Decomposition of Water, illustrated by electricity and the lime-light ; fermentation ; and dissociation in connection with fluids, to the investigation of which he had himself devoted a great deal of attention. The lecture was illustrated by various chemical experiments of an instructive and interesting character, carried on by means of a well-constructed apparatus, which rendered the subjects most intelligible to the audience.

At the conclusion of the lecture, Mr. Esson, J.P., moved a vote of thanks to the chairman and Mr. Tichborne. Mr. W. Hayes, the honorary secretary, seconded the motion, and took occasion to express a hope that at the rest of the course the attendance of ladies might be greater than he observed it was at present. He was convinced that ladies would derive much profitable instruction from the lectures, which they could advantageously apply to domestic cookery and other domestic purposes.

Professor Tichborne, in responding, referred to the remarks made by Mr. Hayes on the subject of the attendance of ladies, and suggested that the profession of pharmacy was especially adapted to ladies, on account of their superior neatness of manipulation as compared with men. Probably it would be some years before such a result would be attained by ladies in this country, although on the Continent it was at present by no means a rare thing to find ladies engaged in the practice of pharmacy. At any rate pharmacy was much more suitable for ladies than surgery and anatomy.

The monthly meeting of the above Society was held at 44, Molesworth Street, on the 6th inst., the chair was taken by J. A. Ray, Esq. Being Easter Monday there was a limited attendance, and after transacting routine business the meeting adjourned.

Parliamentary and Law Proceedings.

Strange Case of Poisoning.

The *Liverpool Daily Albion*, of April 2nd, reports that on the previous Tuesday morning, Miss Elizabeth Chalmer, an elderly lady, who has kept a young ladies' boarding establishment at Hayman's Green, West Derby village, died from the effects of poison which she had taken by mistake. On Monday evening she was in good health when she retired to bed about eleven o'clock. Shortly after that hour she came to the room of her assistant, and, complaining of being unwell, said she had taken something which did not agree with her. On the assistant following her to her room, the deceased lady pointed to a bottle on the mantelpiece and said she had taken something out of it which had occasioned the pain from which she suffered. Dr. Parke, who lives close by, was immediately sent for, and on his arrival he examined the bottle from which the liquid had been taken, and found that several drops which remained were poisonous. Miss Chalmer, after suffering great agony, died, having exhibited the symptoms which accompany death from poisoning. It appears that the bottle from which the liquid was taken was a small one that had originally contained a draught prescribed for toothache, and the supposition is that for convenience deceased had transferred to it, from a larger bottle, a quantity of a poisonous liquid which was directed to be used outwardly for rheumatism and similar complaints. It is stated that she suffered from toothache on Monday evening, and, doubtless, had drunk the contents of the small bottle, imagining at the time that it contained the soothing draught. An inquest on the body was held yesterday before Mr. Driffield, county coroner, at the Sefton Arms, West Derby village, when the jury returned a verdict to the effect that the decease met her death by taking poison inadvertently and by mistake.

Prosecutions under the Adulteration Act.
Two Convictions for Selling Adulterated Scammony.

At the Central Police Court, Glasgow, on Friday,

April 3rd, Mr. Robert Martin, "Druggist,"* 14, London Road, was summoned before Bailie Walls, charged with having on the 18th of March sold to two of the Sanitary inspectors 3 drachms of powdered scammony, which was adulterated with flour or other substance.

He pleaded not guilty, and was defended by Mr. Stevenson.

Alex. Johnston Walker, sanitary inspector, deponed to having bought the article. It was not stated that it was adulterated. He paid 1*s.* 6*d.* for 3 drachms, which was at the rate of 4*s.* per ounce or £3 4*s.* per pound.

Dr. Thorpe, city analyst, found that the scammony in this case had been mixed with 23·6 per cent. of flour. The amount of the true resin contained in the sample was only 46·01. There was 26·73 per cent. of other substances—vegetable tissues, such as cellulose and other matters natural to the plant—and 3·66 per cent. of ash. The 3·66 per cent. and 26·73 per cent. were necessary ingredients in the gum. An author from which he quoted gave 80 or 90 per cent. as the proper proportion of the gum. This sample contained 46·01 per cent.

By the Court—There were very great differences in scammony as imported. It was, he believed imported in an impure as well as in a pure state. He had had samples passing through his hands which contained 80 to 90 per cent. of the resin.

By Mr. Stevenson—Only some three or four cases of scammony had passed through witness's hands. Two of these were pure and two impure. All the samples were in powder. Dr. Hassall said that he could tell whether the adulteration with starch took place in Smyrna or here by examination with the microscope. If the granules of starch adhered it was mixed in Smyrna, and if not it was adulterated in this country. The starch granules in this case did not adhere, but he did not on that account go the length of Dr. Hassall, and draw the inference.

James M'Donald, manager of the Glasgow Apothecaries' Company, Virginia Street, said that Dr. Martin had got scammony from them in August, 1872. It was what was usually sold as Aleppo scammony. There was no such thing as pure scammony to be had. It was usually mixed with starch. They did not mix it. Druggists almost invariably bought it in powder. As they knew that the ordinary article as sold in Smyrna was often adulterated they added some virgin scammony when grinding it. The only way in which a medical man could make the adulterated article effective was by increasing the dose.

Bailie Walls—Does not that make it a very difficult matter for a medical man when prescribing?

Witness—They know that it is adulterated.

The Fiscal—If a prescription is sent to you at the Apothecaries' Hall do you know whether it is the adulterated or pure article that is wanted?

Witness—We always dispense the pure article.

The decision in this case was adjourned till the evidence in that following was taken.

Robert Couper, chemist, 176, Castle Street, was accused of selling half an ounce of scammony which had been adulterated with flour and mineral matters.

The sanitary inspectors deponed to having bought the article and paid 2*s.* for the half ounce.

Dr. Thorpe had analysed the sample. It contained 29·5 per cent. of flour; 5 per cent. of mineral matter, consisting mainly of chalk (besides the normal 3 per cent. of ash); 47·96 per cent. of the gum or resin of scammony; 14·35 per cent. of vegetable tissues.

Hugh Dykes, town traveller to Hatrick and Co., wholesale chemists, shown invoice for half a pound of powdered scammony sold by their firm to accused for 32*s.*, deponed that was a fair price for Aleppo scammony.

Dr. Wallace, analytical chemist, had made a report on scammony, which he got from Mr. Couper. His analysis showed that it contained 45·6 of resinous matter, which dissolved in ether; 40·2 per cent. of other organic matters; 7·8 per cent. of ash or mineral matters, and 6·4 per cent. of water. An examination by the microscope showed the presence of a considerable quantity of wheaten starch. The sample was not pure scammony, but contained a considerable amount of adulteration. It did not, however, by any means follow that the vendor was responsible for any of the adulterants. It was not likely that he was. It was almost impossible to get the drug free from adulteration. Dr. Letheby, in his report before the committee of the House of Commons, said that there were many adulterations of this drug practised abroad. It was practised by the Jews at Smyrna, who prepared it for the English market. Chalk and starch were put in in the course of this preparation, to prevent it undergoing decomposition. Dr. Hassall, in a similar report, said that out of 13 samples as imported only one was genuine, yielding 79·6 per cent. of resin. The amount of adulteration varied from 8 to 75 per cent. of added substances. One sample was entirely factitious, containing no scammony at all. The adulterating ingredients were mostly carbonate of lime or chalk, wheat, flour, gum, and a considerable proportion of woody fibre. Of 17 samples of powdered scammony purchased from various druggists in London, one only was genuine, yielding 76·4 per cent. of resin. The adulterants varied from 18 to 65 per cent. The proportion of resin varied from 27·2 to 65·6 per cent. Wheat flour, frequently some chalk, and occasionally sand or some other substance were the adulterating ingredients. Couper's might be accepted as an average sample.

The Fiscal said he thought the evidence both for the prosecution and for the defence showed that it was a general practice to adulterate scammony—a practice which should be put down.

Mr. Stevenson for both of the accused, said that these drugs were purchased in the usual way of highly respectable druggists, and the article was that ordinarily sold in the town. He thought it was hardly a case to impose a fine.

The Assessor had no hesitation in saying that the charges must be found proven in the sense that the scammony was sold as unadulterated, and was found to be adulterated. If the adulterated article was to be sold, then intimation must be given to the purchaser.

Bailie Walls then fined each of the accused 20*s*, with 20*s.* expenses in each case.—*North British Daily Mail.*

* Although in various newspaper reports, Mr. Robert Martin is described as a "druggist," there is no person of that name residing in Glasgow who is a registered chemist and druggist. In the Medical Directory for 1874 is the following entry: — "Martin, Robert, 14, London-rd., Glasgow. — L.R.C.P. Edin. and L.M. 1872; L.F.P.S. Glasg.

Obituary.

HENRY DEANE, F.L.S.

It is with profound regret that we have to announce the death of Mr. Deane, of Clapham, which occurred on Saturday, the 4th inst., at Dover, where he had been detained for a day or two by stress of weather, on his way to visit his son in Hungary. Walking from his hotel to the boat he was arrested by a sudden pain in the region of the heart, and in a few minutes ceased to exist.

Thus suddenly passed away the noble spirit of one whose name must be familiar to all readers of the PHARMACEUTICAL JOURNAL; a name in the foremost rank of that band of enlightened pharmacists who felt the thick darkness surrounding them thirty years ago, and resolved to dispel it; a name honoured throughout the kingdom for the work he had done in the Pharmaceutical Society to advance pharmacy and pharmacists, and held in deep affection by those who had the privilege of his private friendship.

He was one of its earliest members, and in 1844 was appointed an Examiner. He was a member of the Council for many years, and served as Vice-President in 1851-2 and 1852-3, as well as President in 1853-4 and 1854-5. No man could be better qualified to perform the duties of an Examiner. Possessing, by nature, an inherent love of

science, and convinced by keen observation of the necessity of a scientific training for those who were to be entrusted with the responsible practice of dispensing, as well as of the wisdom of applying all energy in acquirement of the knowledge of things necessary for a man's daily avocation, he brought to his office the very spirit essential for the initiation of the Board, and it may be fairly said that he did much to advance the system of examination to the sound practical condition in which it now exists. To his latest days he took especial interest in the proceedings of the Examiners, and not a month ago, in a conversation we had with him on the progress of the work of which he had seen the commencement, he spoke warmly of his old colleagues for their untiring zeal in the cause, dwelling specially on the practical energy of Mr. Squire.

Mr. Deane was for nearly twenty years member of Council, and was President during a somewhat troubled and difficult period in the existence of the Society. His services on the Pharmacopœia Committee will be remembered by those associated with him at the time; and although the College of Physicians, at whose instigation the committee was formed, had not the opportunity of utilizing the practical information obtained thereby, the labour was not thrown away, for many preparations of the British Pharmacopœia, issued by the Medical Council, bear traces of it.

It should not be forgotten that Mr. Deane was the first President of the British Pharmaceutical Conference, and the fact of his being chosen for that office is testimony of the high estimation in which he was held by the leading pharmacists of the kingdom.

Simple in his habits, indomitable in pursuit of knowledge, thoroughly practical in matters of business, too high-minded to stoop to anything mean or dishonourable, Mr. Deane was possessed of that sound practical sense which teaches that a man should never shirk his duty, that it would never be the duty of a man to perform a dishonourable act, and that consequently there is never any excuse for neglecting duty.

Some three or four years ago the *Chemist and Druggist* published an autobiography of Mr. Deane, which, as a plain unvarnished story of his life so completely portrays his character, that we close our article with a reprint of it from our contemporary.

"I was born at Stratford, in the parish of West Ham, Essex, near London, on the 11th of August, 1807. My parents, Moses and Elizabeth Deane, being members of the Society of Friends, I was brought up in that persuasion, and continued a member thereof until my marriage in 1843. For nearly the first eleven years the only sound instruction I received was from my beloved parents. Although I was sent to what was considered a good day school, in the immediate neighbourhood, I have a most distinct recollection of its utter inefficiency as a place for communicating even the merest rudiments of knowledge, and it was not until my father sent me to a large Friends' school at Epping, conducted by Isaac Payne, that I had the slightest idea of what it was to be systematically taught, and to know the value and pleasure of learning. Unfortunately, my father's means were not such as to enable him to keep me long at school, and I was removed at Midsummer before I was fourteen years old, and just at a period when I began to like and understand my daily task. In after years I have felt how much was lost to me by this early removal from mental training. Nevertheless, during this time seed was sown and friendships formed which materially influenced my after life.

"Amongst my schoolfellows were Henry and Edwin Doubleday, who have since attained a world-wide notoriety as entomologists. Their father was fond of collecting birds and insects, and the sons happily followed his tastes; they in their turn communicated the same to many of their companions, myself amongst the number. Moreover, I was occasionally favoured with an invitation to go home with them to tea, occasions which were highly prized as affording opportunities for seeing their collections and illustrated books of natural history. From collecting insects, collecting plants and drying them—without regard to names, but for their intrinsic beauty—seemed naturally to follow. Thus habits of observing the beauties of creative wisdom were early fixed in my heart, and I often look back with thankfulness to that now far distant day when my friends the Doubledays sowed that seed which was to keep out many temptations to evil, and prove such a lasting source of pure enjoyment. I have ever since advised all my young friends to adopt a hobby calculated to improve the mind, and, by acting as a counterpoise to our natural tendency to indulge in sensuous pursuits, to keep the devil at a respectful distance.

"From the time I left school, in 1821, I was four years in a state of untraining. My father's business was neither suited to my taste nor physical constitution, and I did but little in it. This state promised to be ruinous to my best interests in life, and perhaps would have been so but for the close friendship my father held with John Gibson, one of the firm of Howard, Jewel, and Gibson (now Howards and Sons), whose eldest son and I were great friends and constant companions. I had the run of their laboratory and premises, and thus gained a predilection for manufacturing chemical pursuits. My investigations were a frequent source of annoyance to our maid servant, whose proper domain was invaded by experiments with explosive compounds and fetid gases.

"When I was about sixteen years old my kind friend, John Gibson, gave his son, myself, and another youth, who was our frequent companion, tickets for a series of lectures on Natural and Experimental Philosophy, which were delivered by a once assistant in the house of Allen and Hanbury's, at Plough Court, at the Mathematical and Philosophical Society's rooms, in Crispin street, Spitalfields. This course comprised the elements of physical science as then known, including mechanics. The latter I have ever since looked upon as the best foundation of all other knowledge, and I should like to see it form a part of our regular Pharmaceutical curriculum. The lectures were admirably delivered and illustrated, and sank so deeply into my mind that I can, at this distant day, recall most of the beautiful illustrations placed before us. This was one great saving and turning point in my life, which led to an increasing thirst for knowledge. Parkes's Chemical Catechism was placed in my hands, which I read through two or three times to my permanent advantage, as I soon practically discovered.

"At the age of eighteen I was apprenticed, for three years, to a chemist and druggist at Reading, Joseph Fardon, who had served his time to my uncle Shillitoe, of Tottenham, and who afterward lived three years with John Bell and Co., in Oxford Street. This well-known pharmacist was a kind, indulgent, considerate friend and master, and while with him I learned to powder alum, ginger, and nutgalls; to grind and mix paints; polish the shop scales, counter and bottles; open and shut shop, and many other things now, unfortunately considered *infra dignitatem* in this generation. I had to open shop, summer and winter, at six o'clock in the morning, a practice which I continued with my own hands for many years after I came to Clapham *without losing the respect or confidence of any one of my customers*. To me activity was a necessity, and I rather liked these tasks than otherwise, and I saw no indignity in performing duties required by my master, which were in their nature not only honest, but calculated to improve me in the knowledge of my business. For while grinding prussian blue or powdering roots and seeds, I pondered over their physical constitution, and afterwards read up their natural history in, my then incomparable book and best friend, Thomson's 'Dispensatory.' This habit of doing anything that was required of me was not only of immediate benefit to myself, but in after years probably rendered me more apt in teaching those placed under my care, and certainly gave me an idea of the nature and requirements of our trade in country places, such as London itself could not afford.

"From that time my motto has been—as I believe it ever was in practice—"There is nothing beneath the dignity of a man that is not dishonourable." Not unfrequently have I had to carry a dozen or two of soda water to a distance of one or two miles on a hot summer's day, and these occasions afforded opportunities for looking after plants. I shall never forget on one of these excursions finding a fine plant of henbane, a plant I had never seen before, but which I recognized at once from the description read in Thomson's 'Dispensatory.' I took it home and made some extract much to my own satisfaction, but my master would not have it used, it was so unlike the black stuff regularly dispensed; mine was of that pleasant green colour now well appreciated.

"In addition to the real love I had for my business, there was one strong inducement to stick unflinchingly to my duties, which was ever borne in mind. I knew I should have to get my living by an occupation deliberately chosen by myself, and paid for by my father, though with the humble fee he could but ill afford. Both parents would probably grow old, and the day might come when it would be my duty and privilege to provide for their declining years. An amount of honest pride was also a strong stimulant to exertion in acquiring knowledge. When I first entered on my duties behind the counter I was a tall fellow six feet high, and could look over the heads of my master and his assistant. Consequently, many of the customers presumed I knew more in proportion to my size, and asked me questions about things of which I had never heard, and which made me blush in utterest confusion. This state of ignorance was most distasteful, and I resolved to have an answer ready for the next inquiring customer. Thus I soon gained a reputation for more knowledge than I felt I deserved. My master's small library was soon exhausted, and my shilling a week pocket money and other small pecuniary presents were chiefly devoted to the purchase of such standard works, directly or indirectly relating to pharmacy, that my limited means would reach. At that time there was nothing in the English language published for the benefit of those following our particular business. This was very remarkable, seeing that Fellows of the College of Physicians were entirely dependent on the chemists and druggists as dispensers of their prescriptions, and for their success in practice. However, in London, and some large towns in the country, a few of the most intelligent chemists did the larger portion of the dispensing, to the exclusion of those who would not or did not take sufficient pains to acquire the right kind of knowledge, or who could not resist the temptation to use inferior or sophisticated drugs compounded according to formulæ well known at that date, but now rapidly becoming obsolete.

"I ought, perhaps, here to bear testimony to the exertions of the late Thomas Herring, who was the first, I believe, to introduce pharmaceutical preparations of such excellence and elegance as had never before been offered to the trade. In fact, they were a rapid stride in advance, and by many druggists were looked upon with suspicion. Ultimately the old system was broken down by his innovations; and we, of the present day, have much for which to thank him.

"After I was out of my time, at Reading, I was fortunate enough to get a situation at John Bell and Co.'s, in Oxford Street, when I soon found that I was unacquainted with the practical duties of a large business, and I sometimes wished the floor to open and swallow me up, so ashamed was I that such a big fellow should know so little. However, "*Labor omnia vincit*," I stuck to my early resolution of never allowing anyone to feel dissatisfied for want of a proper answer, and I read a variety of useful books at every opportunity, carefully avoiding politics and novels. All this was heavy work with my average daily labour of fourteen hours. I was much encouraged by the friendship of both the late Jacob and Frederick Bell; to them, or rather to their memory, I owe a deep debt of gratitude for their many acts of consideration for my faults, and the opportunities placed in my way for improvement. One inestimable boon I must specially mention—their allowing me to attend a course of lectures, at the Royal Institution, by Faraday and Brande. This was a great privilege, and not one to be slighted. Never shall I forget the clear and impressive manner of both those great men. They were perfect each in his own way; but Faraday cannot ever be forgotten for his simple eloquence and unfailing success in all his experiments. His kindly, earnest, and impressive manner, conveying in every word the evidence of truth, made an indelible impression on my mind and all who heard him.

"Between my first entry into the establishment in Oxford Street, and my ultimately leaving it, there was an interval of about two years, during which I was at home endeavouring to manage and improve the business of my father, who had become paralysed, and incapable of attending to it. There I continued some time after his decease. I was in Oxford Street altogether about five years, and had become greatly attached to it, both on account of friendships formed and the many privileges enjoyed, when a circumstance occurred which rendered it needful for me to leave. John Bell had an excellent library which was accessible to the assistants; but as yet there was nothing specially written for chemists and druggists, and this want was the frequent subject of conversation between Jacob or Frederick Bell and myself, and we more than once suggested the formation of a society adapted not only for mutual improvement, but with a view to the general improvement of the whole body of chemists and druggists. It was not, however, till some time after I had left, and was in business on my own account, that Mr. Hawes's Bill stirred up the general body, and gave rise to the formation of the Pharmaceutical Society.

"In the autumn of 1837 I took the business now occupied by me at Clapham, assisted by several friends, but more especially by the late Richard Hotham Pigeon, whose large pecuniary aid, afforded in the most liberal and trusting spirit, was supplemented by the advice of a judicious parent. This step was looked upon as certain failure, but my friend Pigeon and the minority encouraged me with better hopes. Besides, had I not my dear mother and sister with me entirely dependent on my success? My own mind never wavered; I was not afraid of work, and I knew how to live on bread and cheese with no stronger drink than a cup of tea or a glass of water. Providence favoured me in a most wonderful manner, and my best hopes were more than realized, so that in a very few years I was out of debt, and prospering to my heart's content.

"In 1841, on the establishment of the Pharmaceutical Society, I became one of its first members, but took no active part in its formation. In 1844 I was requested to become one of the Board of Examiners. After a little hesitation I accepted the honourable post, a step which I have never regretted. It afforded me large means of self-improvement and at the same time brought me in contact with men, the value of whose friendship I cannot express in words. The same may be said of my connection with the Council, upon which I was elected in 1851. In 1840 the Microscopical Society was formed, and my friend Frederick Bell and I joined it on the foundation. I invested £10 in a microscope, and began work investigating and mounting objects with great ardour. This instrument did not long please me, and I got the basis of a better and more complete one, with which in 1845 I made the remarkable discovery of the existence of Xanthidia and Polythalamia in the grey chalk of Folkestone, a bed below the common white chalk. It is well-known that the white chalk is chiefly made up of the *débris* of the shells of Foraminiferæ—a fact first brought to my notice by the late Dr. Pereira—and that the layers of flints, supposed with strong reason by Dr. J. S. Bowerbank to be the fossilized condition of ancient sponges, contained a great variety of the organisms called Xanthidia and Polytha-

lamia. I looked carefully in the chalk itself for the Xanthidia without success, but found them freely distributed in some portions of the grey chalk in which flint in layers, like those of the white chalk, do not exist, but in which occur occasional masses of chert, showing abundant evidence of the structure of sponges without, so far as I could detect, any evidence of Xanthidia. The Polythalamia in this grey chalk were in a very remarkable condition, showing what appeared to be the investing membrane of the shells and the bodies in a truly fossilized but not silicified condition. The species seemed to be identical with those found in the white chalk. Another curious fact seemed to me to be brought out, namely, the mode of distribution of the silica in these two kinds of chalk. In the white chalk it chiefly exists in the form of layers of flint; in the other it is distributed in minute grains or crystals. I also discovered in a Fucus (?) prepared as an article of diet in China or Japan, an abundance of a beautiful silicious organism occasionally found in Ichaboe guano, and which, in a notice read to the Society, I named *Arachnoidiscus Japonicus*, forming the basis of a genus of great beauty, and deservedly popular amongst amateur observers with the microscope.

"The distribution and exchange of these and other objects of interest with members of the Society led to the most friendly intercourse with many excellent men, to whom I am greatly indebted for kindly feeling, and for hints in the art of observing and mounting objects, thousands of which I have had intense pleasure in distributing. It is almost invidious to name one good friend without naming others, but it would be unjust not to mention Mr. Bowerbank's open weekly evening meetings at Islington, where any one with a desire for knowledge was ever welcomed, with or without personal introduction. Frederick Bell and I went thus, were kindly welcomed, and had our first lesson in observing with a good microscope. So began what little skill I possess in the use of an instrument which for full thirty years has afforded me an inexhaustible source of elevating and unalloyed pleasure. My microscope led to a most friendly intercourse with the late Dr. Pereira, and some of the illustrations in the edition of his 'Materia Medica,' in progress, and unfinished at his decease, were made from objects prepared and mounted by myself.

"The first meeting of the new Society that I attended was at 338, Oxford Street, when I read a short and very indifferent paper on "Displacement,"* as a method of preparing tincture, etc.; yet poor as it was, I believe it set many chemists experimenting and working at that method of preparing tinctures and extracts. The process has since that time become more completely understood, and consequently more successful. My next contribution was "Experiments on Senna,"† noticed by both Dr. Pereira and Dr. Royle, subsequently many smaller ones of no great value until those on opium preparations and extract of meat, the chief merit of which is due to H. B. Brady, without whose ready pen and pencil their interest would have been very small.

"When I took my place at the Board of Examiners, I found that very efficient arrangements had been made for conducting the examinations (I believe by Mr. P. Squire, of Oxford Street); and although not so efficient as they afterwards became under energetic care and ordering, they were fully up to the acquirements of the students. The tables were well supplied with specimens of all kinds, fresh plants, drugs, and chemicals, but as yet there was no practical dispensing. I am quite satisfied that although not so systematically conducted as they are at present, the Examiners arrived at a correct estimate of the qualifications of those who presented themselves. One striking fact was constantly noted for many years, that the larger number of the best qualified men were those who had acquired their knowledge in the country, without those special advantages afforded to those who attended the lectures and laboratory at the establishment in Bloomsbury Square. This was the case for several years after the institution of examination; but it is notorious that these first men have now taken their proper place as leaders amongst their brethren in pharmacy.

"The examinations for many years did not occupy many hours on each occasion; the number of examiners was small, and they were conducted *con amore* without fee, other than that afforded by a good conscience: "and all for love, and nothing for reward." Of late their onerous duties have wisely been remunerated; and it is the concurrent testimony of all that they are discharged with strict impartiality.

"I was elected on the Council in June, 1851, and almost before I had taken my seat, Mr. John Watts, of the Edgeware Road, proposed me as Vice-President, which extraordinary proposition was at once carried, and I was enthroned at the lower end of the table. Thomas Herring was President. The following year, 1852, Mr. Joseph Gifford was elected President, and I again Vice-President. In 1853 and 1854 I was President, and underwent the severe ordeal of the prosecution by Mr. Dickenson, from which the Society ultimately emerged victor.

"In 1854, the College of Physicians applied to the Council of the Pharmaceutical Society for aid in the preparation of a new Pharmacopœia, and a committee was formed to assist in this object. As President I was chairman of the committee, and at the special request of the chairman of the Pharmacopœia Committee of the College of Physicians, Dr. F. Farre, I retained that position, as the medium of communication between the two bodies until the Royal Medical Council was appointed, and took proceedings to form a national Pharmacopœia. Our services were no longer required; but I may state that when we entered upon our duties we resolved to do what we could to promote the formation of a national Pharmacopœia, and for this object Mr. Squire's admirable book, 'The Three Pharmacopœias,' afforded a means of comparison, and a basis of operation.

"Dr. Redwood was our efficient Secretary, and performed many experiments as circumstances suggested. I made many hundred of experiments between the meetings, which were seldom held oftener than once a month. Once a week would not have been too frequent, but council, committee, and examinations already occupied a large amount of time, which few of us could afford to sacrifice. I can safely say that during the six years I held these responsible positions, one fourth of the time was entirely taken up in the service of the Society.

"This service of twenty-six years has been a service of love, a kind of second bride, and during that time, being fully aware of my deficiencies, I trust I have laboured with some degree of success to promote the great object set on foot by my late valued friend, Jacob Bell, to stimulate the mental energies of our young men, and to institute a system of education which should fill the void which had hitherto existed. How far my colleagues and I have been successful it is not for us to know, but another generation will develope the truth and pronounce a verdict."

The remains of the deceased were removed from Dover to the house where his wife's parents lived and died, at Coglinge, near Shorncliffe. On Thursday they were interred in the neighbouring village of Cheriton. Amongst those who were able to pay the last tribute of respect by being present at the funeral were the President of the Pharmaceutical Society, Mr. T. H. Hills; the Vice-President, Mr. A. Bottle; the Treasurer, Mr. J. Williams, and the Secretary, Mr. E. Bremridge; the President and Secretary of the Pharmaceutical Conference, Mr. T. B. Groves, and Professor Attfield; Messrs. Morson, F. J. Hanbury, and numerous friends from Clapham, Dover, and the neighbourhood. The service was conducted by the Rev. Edwin Grice, a friend also of the deceased.

Analysis of Milk.

Sir,—I observe in the Pharmaceutical Journal for 14th March, 1874, a paper which Dr. Voelcker is reported to have read to the Farmers' Club. The paper is entitled, "Milk: its Supply and Adulteration," and in it I read some amusing, but not very wise comments upon a little 'Manual of Milk Analysis,' which I have recently published. The Doctor says one might as well talk of a 'normal potato,' or a 'normal cabbage,' or a 'normal pig,' as of normal milk.

Doubtless this is very funny, but it is neither happy nor true. Potatoes vary greatly in size and weight; some are ten times as big or as heavy as others, but even among the Doctor's own analyses we look in vain for examples of the percentage of milk solids having doubled. After having indulged in such comparisons, it was hardly to be expected that the Doctor should say precisely what it is that I maintain is so very constant in milk. I maintain that the percentage of "solids not fat" is a very constant quantity; and, notwithstanding the generally unsatisfactory nature of his analyses, Dr. Voelcker's results do not entirely conceal this constancy.

Those who are familiar with the subject will know that no such irregularities as Dr. Voelcker mentions in his paper were observed in Sweden, and that there is the most cogent evidence in favour of there being certain regularities in the composition of milk.

It is obvious also that irregularities of composition would be simulated by defective analyses. The drying up of milk solids was, until recently, a most tedious and uncertain operation, but with the modifications introduced by myself it has now become one of the easiest and most accurate operations which the chemist has to perform.

I have very little doubt that the extraordinary irregularities described by Dr. Voelcker depend upon defective analysis, and not upon real differences in the samples.

In the Doctor's paper he gives a tabular statement of his Cirencester results. From this we gather that the evening milk in October contained 3·76 per cent. of milk-sugar; and that in November the evening milk contained 5·68 per cent. of milk-sugar. Equally curious was the percentage of ash in this wonderful milk, viz., 0·58 in October and 1·15 per cent. in November.

For my part, I cannot accept these results as true, and regard them as merely affording evidence of the badness of the analyses.

J. Alfred Wanklyn.

117, *Charlotte Street, Fitzroy Square.*
April 7th, 1874.

The March Examinations.

Sir,—An advertisement appears in the Pharmaceutical Journal of April 4th, stating that at the "*last*" Major and Minor Examination "*all the honours fell*" to students in the South London School of Pharmacy.

I am not a student in the above school, nor have I ever been.

George P. Gilders.

8, *Osborn Place, Blackheath.*

Sir,—I was rather surprised to read an announcement in your advertisement columns to the effect that all the honours in each examination last month fell to the students of the South London School of Pharmacy. Now, as I was fortunate enough to obtain honours I think I may be allowed to speak in the matter. I most emphatically deny ever having had anything whatever to do with Dr. Muter or his system, and I have not even seen either him or his establishment.

I am able also to state, on reliable authority, that five out of the six candidates who gained honours in the examinations last month did not receive their training at his hands.

In conclusion, I may, perhaps, venture the remark that it would be better for the credit of the establishment where "systema omnia vincit" if its conductors adhered more strictly to the truth in their advertisements.

W. Pickard.

205, *St. John Street Road, April 7th*, 1874.

The Society's Conversazione.

Sir,—In reading the account of the recent conversazione, held by the Nottingham and Notts Chemists' Association, I was glad to see South Kensington in the provinces, but must confess (without wishing to disparage our pleasant gatherings therein) that somewhat an envious feeling came over me that the association in question was able to afford, in addition to the attractions of music, etc., matters of interest connected with the profession.

Is it quite inadmissible under present circumstances to infuse more of this element into the conversazione at South Kensington? I feel assured the distinguished members of the medical profession, and others who attend our annual May gathering, would feel none the less gratified by its introduction, while to the pharmacists themselves the value of this large meeting would be vastly enhanced. Hoping this suggestion may be favourably received, I am, etc.,

Jno. Lasham.

Romford, March 31, 1874.

"*Live and Let Live.*"—In reference to the letter of Mr. J. N. Place, of Exeter, we have received a communication signed by Messrs. A. Evans and Company, George Cooper, and Matthew Husband, wholesale druggists in Exeter, requesting us to notify that they emphatically deny having supplied the co-operative stores in that town, and stating that they have refused to do so.

A. P. S.—The address of Messrs. Winsor and Newton is Rathbone Place, Oxford Street, London.

"*Fructus.*"—There is a considerable proportion of henbane seed present.

"*Quærens.*"—Mayne's 'Vocabulary of Medical Terms,' published by Messrs. J. and A. Churchill, price 8*s.* 6*d.*

E. Yewdall.—Your letter has been handed to the Secretary.

T. P. B.—The article referred to was published in vol. i. of the present series, p. 167.

F. C. Clayton.—The preparation in question is a proprietary one, respecting the composition of which we are unable to give you any information.

"*Amateur Microscopist.*"—We are unable at present to say what the specimen may be, but hope to be able to furnish you with the information shortly.

"*Llandudno.*"—The information asked for will be given in an early number.

"*Hampton.*"—(1) Butler and McCulloch, Covent Garden. (2) Vide Pharm. Journ. [2] vol. x., p. 590; also Pharm. Journ. [2] vol. ix., p. 58. By insane root was probably meant *Atropa mandragora* or belladonna. The latter grows near the locality of the scene mentioned. Shakespeare is not known to have been a botanist, and probably alludes to some tradition extant at the time. The exact plants meant by insane root, cursed hebenon, etc., have long been matter of conjecture, and will probably remain so.

"*Theta.*"—The candidates either pass or do not pass, and there is no part of the arrangements of the Board of Examiners to allow candidates to pass piecemeal.

J. F. Brown.—We know of no book better suited for the purpose than the one mentioned, nor do we think it would be found dry by any Student really desirous of acquiring a thorough knowledge of the subject.

Mr. George Delves (Exeter).—The subject you refer to is a frequent source of perplexity to us as well as to others; but careful consideration has led us to conclude that no good would be done by any such public discussion as you suggest. With much of what you say we entirely agree, but it must be remembered that there is at the present day little ground to hope for legislation protective of classes. The act you refer to was not in any way of this nature but merely one to secure the safety of the general public.

Communications, Letters, etc., have been received from Messrs. Leach, Broad, J. Abraham, J. Z. Holmes, Fairlie, Bell, "Brunswick."

EXPERIMENTS ON SOME VARIETIES OF CAMPHOR.

BY PROFESSOR FLÜCKIGER.

The interesting investigations on the Ngai Camphor due to Mr. Plowman * induced me to submit several camphors of my collection to the following experiments. They refer to the common camphor of *Cinnamomum Camphora* F. Nees et Eberm, and to the following other kinds :—

1. *Ngai camphor* in the crude state, as mentioned by my friend Daniel Hanbury, † to whom I am indebted for this sample as well as for those described under 2 and 3.—This sample consists of whitish crystallized granules.

2. *Ngai camphor* in the pure state, forming flattish colourless pieces, highly crystalline, yet not exhibiting well developed crystals.

3. Camphor of *Dryobalanops aromatica* Gärtn., *Borneo camphor*, also called *Malay camphor*, in the crude state, given by Prof. de Vriese to Mr. Hanbury ; the sample came from Sumatra.

4. Camphor of *Dryobalanops aromatica* Gärtn., as met with in the London market by Mr. J. E. Howard in 1850 under the name of "Native Camphor."

5. *Crude camphor* from Hong Kong, presented to me as well as the last by Mr. Howard, and presumed, on account of its peculiar odour, to be different from common camphor. It occured in the London market in 1864.

It will be observed, that only the Ngai camphor (2) consisted of pure crystals ; I thought it not advisable to purify the other samples for fear of losing too much of the substances, of which I had no considerable quantities at my disposal.

It is well known by the researches of Des Cloizeaux, ‡ that common camphor crystallizes in forms belonging to the hexagonal system. They exhibit in polarized light brilliant colours like other crystals not belonging to the cubic system. This is easily demonstrated by examining a clear splinter of camphor under the polarizing microscope, or by melting a little camphor between two slips of glass and examining it in the same way. Hexagonal crystals are evident in every bottle in which ordinary camphor is kept for some time, and camphor dissolved in alcohol of about sp. gr. 0·89 separates on cooling in crystalline tufts exactly resembling the crystals which are slowly formed in winter time on the surface of water. The crystals of camphor are unable to deviate the ray of polarized light, but their alcoholic or other solutions turn the plane of polarization to the right hand.

The crystals of the camphor of Borneo, derived from *Dryobalanops*, according to Des Cloizeaux, § belong to the cubic system. I can fully confirm the assertion that, examined in the way just stated, the crystals of my samples 3 or 4 of this substance, as well as several others, do not display any action on polarized light ; it is well known that cubic crystals, that is to say regular cubes and all allied forms, are devoid of that optical power. The alcoholic solution of Borneo camphor, on the other hand, possesses, as showed long ago by Biot, a dextrogyre power a little inferior to that observed in common camphor under the same circumstances.

Now, the crystals of *Ngai camphor*, 1 or 2, which I examined by means of the polarizing microscope, proved likewise to belong to the *cubic system*.

As to Mr. Howard's camphor, mentioned under 5, it seems to consist of a cubic camphor, accompanied by a certain amount of another camphor doubly refracting in polarized light like common camphor. It is well worth noticing, that the presence of the latter would scarcely be revealed by any other means than the microscope, for the odour and optical behaviour of this sample is on the whole that of Malay or Dryobalanops camphor.

Mr. Plowman has well ascertained the leading chemical and physical characters of the Ngai camphor. I have but a few remarks to add. On the surface of water it turns as rapidly as common camphor ; the same applies to Borneo camphor.* Both these varieties are able to swim on water owing to adhering air, for they sink if deprived of that air.

There is another curious fact concerning camphor. Common camphor and chloral hydrate, about the same weight of each, both in perfectly dry and large pieces or crystals, kept for some hours in a carefully dried and closed vessel are liquified, as recently pointed out by J. F. Brown.† I have found that this is the case with Borneo camphor and with Ngai camphor likewise.

Mr. Plowman's researches tend to show that the latter differs but slightly from Borneo camphor, both being of the same composition, and exhibiting the same general behaviour. My observations just alluded to point out a few characters more, equally possessed by both these forms of camphor. Yet there is a well-marked difference, inasmuch as the *Ngai camphor* in alcoholic solution *deviates the ray of polarized light to the left hand.*

As to my optical researches, I used Wild's polaristrobometer, and observed the deviations in monochromatic light afforded by a flame coloured by means of a salt of sodium. (I prefer the borate.) The results are summarized in the table on the next page, which shows the numbers as observed directly. The starting-point of the observations being 47°·7, this number is to be deducted from those given in the table in order to get the dextrogyre deviations, the latter answering to numbers exceeding 47°·7. The numbers inferior to 47°·7 point out a levogyre power, the amount of which is found by deducting the number directly observed from 47°·7. The table thus shows for instance that the solution 6 of common camphor, in a column of 50 millimetres long, deviated 57°·5 — 47°·7 ; that is to say, 9°·8 to the right hand, whereas the *levogyre* power of a similar column of solution 2 of Ngai camphor is 47°·7 — 40°·3 = 7°·4.

The true deviation of Ngai camphor is represented by the figures under 2; the sample 1 contained a certain amount of impurities, its solution showed therefore a weaker action. In working with the alcoholic solutions of sample 1, as well as of sample 2, I was struck with the very peculiar odour of the Ngai camphor, which seemed to me rather suggestive of ambergris than of wormwood. I cannot agree with

* And likewise, according to Chautard, to the stearoptene of feverfew, *Chrysanthemum Parthenium* Persoon, which will be mentioned hereafter.

† PHARM. JOURN., 14th March, 1874, 729. This extremely curious liquefaction is also produced by dry crystallized carboli acid.

Mr. Hanbury's statement that the odour of 2 is scarcely distinguishable from that of ordinary camphor. An alcoholic solution of Ngai camphor exhibits a very well-marked difference if it is allowed to evaporate on the hand. The odour of the Ngai camphor, especially of 1, seemed to me to agree with that of Borneo camphor, yet to be decidedly *stronger*.

Under 3 and 4 my table presents not quite the full deviation of Borneo camphor, my samples being too small to allow of purification. The numbers are nevertheless sufficient to manifest the great difference between the Ngai camphor and that of Dryobalanops; they confirm also that the rotatory power of ordinary camphor is stronger than that of Malay camphor.

TABLE SHOWING THE DEVIATIONS OF THE FOLLOWING SOLUTIONS OF CAMPHORS AS OBSERVED IN WILD'S POLARISTROBOMETER.

Starting Point: 47°·7.

	Millimetres. = 25	Millimetres. 50	Millimetres. 100
1. Crude Ngai camphor, dissolved in its equal weight of absolute alcohol	43°·6	38°·5	
2. Pure Ngai camphor, dissolved in its equal weight of absolute alcohol	43·8	40·3	
3. Dryobalanops camphor, De Vriese's, dissolved in its equal weight of absolute alcohol	52·0 51·6	56·6	
4. Dryobalanops camphor, Howard's, dissolved in its equal weight of absolute alcohol	51·2	55·0 56·0	
5. Crude comphor from Hong Kong, dissolved in its equal weight of absolute alcohol	52·1	56·6	
6. Common camphor, dissolved in its equal weight of absolute alcohol	52·4	57·5	68·5
7. Common camphor, 1 part in 9 parts of absolute alcohol	48·3	49·9 49·3	51·0
8. Common camphor, 1 part, alcohol 0·8185 sp. gr. 6 parts, and 3 parts of water		49·7	
9. Common camphor, in its equal weight of chloroform	54·5 54·8	62·4	
10. Common camphor, in its equal weight of bisulphide of carbon	54·4	62·0	
11. Common camphor, in its equal weight of acetone	52·7 53·0	58·7 58·3	
12. Common camphor, in its equal weight of methylic alcohol	52·2 52·4	57·5	

Being engaged in these experiments I was curious to know whether the polaristrobometer would afford the means of estimating the percentage of camphor in solution. The experiments under 7 and 8 prove that the rotatory power of somewhat dilute solutions of camphor decreases too rapidly to allow such a quantitative method. Moreover, there is another fact still less in favour of such an estimation. The table gives in many instances two different numbers for one and the same observation; it is in fact not always possible to meet with an undoubtedly exact number of deviation. I am not able as yet to explain this uncertainty, which is sometimes very troublesome, whereas in other cases the observation can be performed with all desirable exactness.

Another question, well worthy of examination, concerns the influence of different solvents on the optical properties of camphor. I have not thoroughly investigated this point, but the few facts ascertained under 9 and 10, show that influences of that kind exist; the rotatory power of ordinary camphor is increased by dissolving it in chloroform or bisulphide of carbon. It would be a matter of interest to examine, in that respect also, the other varieties of camphor mentioned in these notes.

From the above observations it follows, that the new camphor from the Ngai plant, *Blumea balsamifera* DC., of the order *Compositæ*, crystalizes in the cubic (regular) system, like that of Borneo from *Dryobalanops*. Both, according to Mr. Plowman, agree with the formula $C_{10}H_{18}O$, but my experiments prove that the Ngai camphor in alcoholic solution is as much levogyre as the solutions of Borneo camphor are dextrogyre. The camphor of *Blumea* has therefore very correctly been termed by Professor Attfield* the *twin-brother* of the famous product of *Dryobalanops*, the Borneo or Malay camphor.

There are two other camphoraceous substances forming optically indifferent crystals of the cubic system, namely, *Terecamphene*, $C_{10}H_{16}$, and the monochlorhydrate $C_{10}H_{16} + H\,Cl$ of the oil of turpentine of *Pinus Pinaster* Solander, and other pines. Both these substances have been prepared and examined in 1862 by Berthelot. The alcoholic solution of the latter appears to possess nearly the same levogyre power as that of our Blumea or Ngai camphor. The rotation of the solution of terecamphene is twice as considerable.

These two substances are in composition widely different from the camphor of *Blumea*, but there is another camphor agreeing with the latter in that as well as in other respects. In 1856 Jeanjean† examined the products of the fermentation of the sugar contained in madder, the root of *Rubia tinctorum* L. One of these is a camphor having the composition of Borneo camphor, but possessing exactly the same rotatory power as our Ngai camphor. It seems to me, after all, very likely that camphor of *Blumea* and camphor of *Rubia*, as produced in the fermentation of sugar of madder, are but one and the same substance. I am indeed sorry that I am not in possession of the latter in order to prove the correctness of this view. Jeanjean attributed to it a peppery odour.

This chemist has not examined the nature of the crystals of the Rubia camphor; by boiling them for a short time with nitric acid he obtained the compound $C_{10}H_{16}O$, agreeing in composition with ordinary camphor, but differing from it by deviating the ray of polarized light as much to the left as common camphor does to the right hand. I need scarcely mention that this refers to the alcoholic solutions of these camphors.

I devoted to a similar treatment the small quantity of Ngai camphor, sample 1, still at my command after the foregoing experiments. I obtained crystals which were entirely devoid of the peculiar odour of Ngai camphor and rather reminded one of ordinary camphor. The quantity of that camphor of sample 1 being too small for further exact investigations, I could only ascertain that its alcoholic solution was levogyre, without estimating the amount of deviation. But what is more interesting is the fact, that the polarizing microscope proved the crystals of the camphor

* PHARM. JOURN., 7th March, 1874, 722.

† *Comptes Rendus* 42 (1856) 857; also Gmelin's *Organic Chemistry*.

under notice not to belong to the same system as their mother substance; they displayed, indeed, brilliant colours, showing that there was no longer any question of the cubic system.

It is very remarkable that, according to Chautard,* the oil of feverfew, *Chrysanthemum Parthenium* Pers., on cooling, or by treating it with nitric acid, yields a levogyre camphor $C_{10}H_{16}O$, which in all probability is identical with that prepared by Jeanjean as just stated from Rubia camphor. It would consequently, likewise, agree with that which I obtained by oxidizing Blumea camphor, a question which requires more material for investigation than I had at hand.

I need scarcely remark that the camphor $C_{10}H_{16}O$, which may be obtained by oxidizing the Malay camphor, is absolutely identical with ordinary camphor. By treating the small remaining quantity of sample 4 with nitric acid, I quickly succeeded in getting it. The crystals, after washing and drying, were examined under the polarizing microscope, where they proved most brilliantly not to belong to the cubic system but to the hexagonal. The microscope thus enables us to demonstrate very manifestly the transformation of the optically indifferent crystals of Dryobalanops camphor into Laurel camphor, even in the smallest fragment.

Mr. Hanbury has pointed out† how much Ngai camphor is esteemed in China; it is curious, from a historical point of view, that the Chinese possess in their own country a variety of camphor so very closely allied to the Malay camphor. Why have they imported, from time immemorial, the latter from the Archipelago? Why do they still appreciate Malay camphor so enormously higher than even Ngai camphor? And not the least curious is the fact that they appear to be well aware of physical differences, which we in Europe have been endeavouring to fix more precisely by the implements of modern science.

We have proved that *Blumea balsamifera* DC., the Ngai plant of the Chinese, yields a camphor $C_{10}H_{18}O$, which forms crystals of the cubic system; these are optically inactive, but afford alcoholic solutions which deviate the ray of polarized light to the left hand. These crystals can be transformed into a camphor, agreeing no doubt with the formula $C_{10}H_{16}O$, whose crystals no longer belong to the cubic system. Their alcoholic solution is levogyre. This latter camphor appears to occur in feverfew.

Malay camphor from *Dryobalanops*, equally in cubic crystals devoid of optical power, and having the formula $C_{10}H_{18}O$, affords alcoholic solutions which possess the same rotation as those of Ngai camphor, but to the right hand. The camphor $C_{10}H_{16}O$, obtainable from Malay camphor, belongs to the hexagonal system, its solutions are dextrogyre; it has been met with as yet only in *Cinnamomum Camphora*.

ADULTERATION OF GINGER.

BY THOMAS GARSIDE.

A gross and very obvious sophistication appears to have been quite overlooked. I allude to the whitewash on the so-called bleached ginger. According to the text-books the white appearance is supposed to be imparted to it by the fumes of burning sulphur, or by a solution of chloride of lime. Owing to the very chalky character of a sample which was inspected, a suspicion was raised that the above mentioned methods were not sufficient to account for it.

In order to test the matter, five samples were obtained from different shops. On two of these the easily detached white powder was found to consist of calcium sulphate, in one case with a trace of chloride and in the other without any. The presence of calcium disposes of the supposition that sulphurous acid only was used in the bleaching process. If, however, the ginger had been first steeped in solution of chloride of lime and afterwards exposed to sulphurous acid fumes, calcium sulphite would in all probability be formed, which, on exposure to the air, would become converted into sulphate.

The absence of any notable amount of chloride would preclude this idea.

The powder on the remaining three samples was found to consist principally of calcium carbonate, with smaller proportions of sulphate and chloride. In order to ascertain the amount, an average piece of ginger was taken and the adhering mineral matter separated and weighed.

It was 2·33 per cent. of the ginger employed, and consisted of

Calcium chloride	4·98
Calcium sulphate, with other salts. . .	7·90
Calcium carbonate	87·12
	100·00

The small proportion of chloride here shown, I think, would justify the assumption that the chloride of lime process had not been employed. Moreover, on two out of the three samples containing calcium carbonate, small particles of ultramarine blue were detected; and this, under the name of lime blue, is commonly used to improve the colour of lime washes.

From these facts it would appear that three of the samples had been simply whitewashed, without any attempt at bleaching, but how the other two came to be covered with plaster of paris is not very clear, as this material has not the same "body," nor does it adhere so well as the lime wash, and would scarcely be preferred to the latter if the method of applying it were the same.

Apart from this, however, the fact that a common article of food should contain between two and three per cent. of chalk is so evidently a fraud upon the public that it is to be hoped the practice will cease when attention is drawn to it.

10, *Cross Street, Southport,*
March 23rd, 1874.

THE PRESENCE OF NITRATE OF POTASH IN THE LEAVES OF PLANTS.

BY T. AND H. SMITH.

The observation made by Mr. E. S. Wayne, of the occurrence of nitrate of potash as a natural constituent of the leaves of *Ricinus communis*, in his paper reprinted in a recent number of the PHARMACEUTICAL JOURNAL, confirms the writers in a belief which they have long entertained, that the existence of that salt in the products of the vegetable kingdom is more common than is generally accepted.

Some few years ago Messrs. Smith obtained about two ounces of nitre from a hundredweight of *Cannabis Indica*. It was obtained by evaporation of the watery liquid left in distilling the spirit from the alcoholic solution of the gunjah, in preparing the resinous extract of Indian hemp. On examination

* *Journ. de Pharm.* 44 (1863) 22.
† PH. JOURN., 7th March, 1874, 710.

the crystals proved unmistakably to be nitrate of potash. They have since obtained similar crystallizations from Indian hemp, but have not been induced to carry the investigation further, in order to determine whether, in those cases also, the crystals were those of nitrate of potash.

Although, in the case mentioned, probably the quantity of nitrate of potash obtained may be considerably more than what the spirit of wine could have dissolved, were the solution attempted directly upon the salt, yet the writers look upon this as an instance of what occurs in many similar circumstances. Substances are often unexpectedly found in solvents, of crude organic matters, which the solvent could not have taken into solution unless through the aid of other constituents simultaneously present.

THE QUALITY OF MILK SUPPLIED TO TOWNS.

BY DR. STEVENSON MACADAM, F.R.S.E.,

*Lecturer on Chemistry, etc., etc.**

(*Continued from p.* 813.)

An important point regarding the time and mode of sampling milk requires now to be considered. When the milk is brought into the sale shop, it is generally placed in a large sale can, from which portions are removed by a measure now and again, as demand requires. During the sale of the milk the process of creaming is going on slowly, and as the fat rises to the surface and the sale measure is being dipped in, the milk which is thus removed becomes richer in cream or fat, so that in course of time the milk which is left behind becomes poorer, owing to the floating up and removal of part of the cream or fat originally diffused through it. Milk begins to cream immediately on being set at rest, and the mere disturbance of the upper half of the contents of a vessel will not reintermingle the cream with the whole milk, and thus keep up the original composition.

I have made special trials to determine the effects of the sale "ladling" process on the quality of the remaining milk. In the first experiment the original milk gave 10 per cent. of cream; after a process of sale removals for one hour, the remaining milk only showed 9 per cent. of cream when allowed to stand; and after sale removals for three hours, the remaining milk only gave 7 per cent. of cream. A second trial was made with a mixture of twenty-two samples of milk, and a portion of the original mixture of milk was analysed side by side with another portion, which had been subjected to the ladling process for three hours. The results were as follows:—

	Original Mixture.	Remainder of Milk in sale can in three hours.
Specific gravity	1032	1033·1
Cream per cent. by volume . .	9	6
Total solids per cent. by weight	12·06	11·39
Solids not fat „ „	9·67	9·58
Fat „ „	2·39	1·81
Ash in solids „ „	0·70	0·67

It was thus apparent that during the period milk is retained in a sale can, and successive quantities ladled out from time to time, the remaining milk becomes poorer in quality through loss of cream or fat, and in the space of three hours the proportion of fat is reduced by 25 per cent., or one fourth of the whole.

In endeavouring to fix on a standard for genuine milk, and which might be fairly deducible from the foregoing experimental results, I am of opinion that taking large dairies, where the runnings of a number of cows can be thrown together, so as to equalize the rich and the poor milk and yield an average, the following proportions may be taken as a standard for genuine or normal milk:—

Specific gravity . .	about	1030
Cream	not under	6 per cent.
Total solids . .	„	11 „
Solids not fat .	„	9 „
Fat	„	2 „
Ash in solids . .	„	0·65 „

But we must be prepared for even lower results in individual cases, as in dairies where only one, two, or three cows are kept, and where they are probably not very well fed. Even in the larger dairies, where the milk of the cows is not mixed together, or where probably the milk of every two or three cows is simply placed in a can by itself, there might occasionally be found a sample having a lower composition than the standard given above, and yet the milk be undoubtedly of genuine quality. Any difficulty in this respect, however, would be avoided by the whole milkings of the dairy being placed in a large common vessel, and thereafter the sale or town cans filled from this mixture of the whole runnings of the dairy.

The foregoing experimental results of the analyses of the samples of milk taken direct from the udders of 40 cows belonging to three large dairies, prove that the standard for genuine or normal milk which has recently been put forward for the guidance of city analysts is far too high. The assumed standard declares that normal milk must have 12·5 per cent. of total solids, of which 9·3 per cent. are solids not fat, and 3·2 per cent. must be fat. This so-called standard has been assumed in the face of an analysis of *average country milk*, which is also quoted, and which *average* milk contains actually less than the assumed standard which ought to indicate *minimum* and not *average* quality of genuine milk. According to this so-called standard, adopted in so arbitrary a manner and blindly followed by town analysts, by far the greater number of the samples of milk taken direct from the udders of the 40 cows in the dairies A. B. and C. would be held to be adulterated, either with water or with skimmed milk or with both, and taking the average of the whole of the samples of milk, which shows only 2·44 per cent. of fat, we find that it contains about 25 per cent. less fat than the assumed standard, so that the entire bulk of the genuine milk yielded by the 40 cows, if mixed together in equal quantities would be held to be adulterated with about 25 per cent. of skimmed milk. The results obtainable from the assumed high standard should not therefore be depended upon; and yet by calculation from such data, carried out to the tenths and hundreths of a grain, we find prosecutions taking place and convictions attempted to be obtained and enforced.

The assumption of a definite high standard for milk, and the further assumption that all milk is of equal, or nearly equal, quality, is even directly contrary to all previous researches on the subject, as shown by the great diversity in the composition of milk as given in analyses published in different chemical treatises. Even the amount of fat in cows' milk on which the proportion of adulteration with skimmed milk is based, is authoritatively stated to be sometimes as low as 1·25, 1·4, 2·13, though ranging up to 3·42, 4·56, etc., showing great variations in the amount of this ingredient. Probably the best evidence on this point is given in a Government report, written by Prof. John Wilson in 1866, where the Danish dairy farms are referred to, and where the variations in the amount of fat in milk are observable in the amount of milk required to yield a pound of butter at different seasons of the year. The proportions range in the same dairy farm from 19½ to 33 lbs. of milk, and in another dairy farm from 21½ to 31½ lbs. of milk, which must be employed to yield a pound of butter.

Since the analyses of the samples of milk were made by me, and I was called upon to give evidence in two cases of alleged adulteration, there has been published in the PHARMACEUTICAL JOURNAL, an excellent paper by Prof.

* Read before the Pharmaceutical Society (North British Branch) at the meeting on the 26th March, 1874.

Voelcker, "on Milk, its Supply and Adulteration," in which he gives the results of the analyses of the milk yielded by the herd of cows at the Royal Agricultural College, Cirencester, during eleven months of a year, and shows the great variations which occur in the quality of the milk obtained from the whole herd. The total solids range from 9·3 to 13·8 per cent. and the fat from 1·79 to 4·12 per cent., and, judging from the assumed high standard adopted by some town analysts, the whole runnings of this herd of cows would have been declared to be adulterated for two-thirds of the year.

The Adulteration Act was framed for the protection of the public, and, if properly worked out, would undoubtedly lead to the suppression of adulteration in food, drink, and medicine, and would at the same time be of national service, and a protection to the honest merchant against the dishonest and fraudulent dealer. But if anything is calculated more than another to render the Act inoperative and untrustworthy, it is the framing and setting up of a standard of genuineness which can seldom be reached by the genuine article itself; and by blind adherence to which the majority of the samples of the genuine and unadulterated material must be declared to be mixed and adulterated.

Considering the great variations in the quality of genuine milk and the beneficial effects of the good feeding of the cows upon the milk, it is worthy the attention of dairymen whether they would not sell their milk under a guarantee of quality, say 11 per cent. of total solids, of which 9 are solids not fat and 2 are fat. In large dairies this could be ensured by mixing the whole runnings of the milking of the herd in a common tank, and thereafter filling the sale or town cans from this mixture of the whole milking. Milk could thus be sold with a guarantee which would give certainty to the purchaser that he was obtaining not only genuine milk, but genuine milk of good quality.

Since reading the foregoing paper before the meeting of the society, I have had the opportunity of testing the quality of the milk yielded by the cows in another dairy which supplies milk to Edinburgh. This dairy, which we may call dairy D, contained six cows at the time complaints were lodged against the genuine character of the milk, and I have tested the quality of the milk given by each of these six cows in the morning, at noon, and in the afternoon. My assistants, Mr. William Ivison Macadam and Mr. Charles Edward Bourchier, went to the dairy on each occasion, inspected the milk pails, saw all the cows milked, sampled each milk from the whole runnings taken from the udder of each cow, and brought the samples to me in a locked case. The analyses were made by me in the manner stated before, and the results obtained are given in the following table :—

No. of Cow.	Specific gravity of milk.	Cream per cent. by vol.	Total solids per cent. by wght.	Solids not fat, per cent. by wght.	Fat per cent. by wght.	Ash in solids, per cent. by wght.
Morning milk.						
1. whole runnings	1034·5	6	11·52	9·76	1·76	0·72
2. „	1033·3	5	10·63	9·05	1·58	0·68
3. „	1033·4	6	10·96	9·22	1·74	0·69
4. „	1032·3	8	12·29	9·75	2·54	0·74
5. „	1033·3	6½	11·04	9·18	1·86	0·71
6. „	1034·1	6	10·95	9·21	1·74	0·73
Average of morning milk	1033·5	6¼	11·23	9·36	1·87	0·71
Noon milk.						
1. whole runnings	1033·1	8	12·94	10·23	2·71	0·71
2. „	1030·9	9	12·78	9·66	3·12	0·70
3. „	1032·2	7	11·42	9·26	2·16	0·72
4. „	1030·6	8	11·98	9·37	2·61	0·73
5. „	1030·7	8½	12·66	9·70	2·96	0·70
6. „	1030·9	10	13·73	10·26	3·47	0·72
Average of noon milk	1031·4	8½	12·58	9·74	2·84	0·71
Afternoon milk.						
1. whole runnings	1033·0	7½	12·52	10·08	2·44	0·73
2. „	1031·1	8	12·09	9·33	2·76	0·71
3. „	1030·2	10	13·11	9·86	3·25	0·73
4. „	1028·3	8	11·25	8·62	2·63	0·74
5. „	1031·4	9½	12·81	9·69	3·12	0·70
6. „	1030·8	10	12·84	9·58	3·26	0·72
Average of afternoon milk	1030·8	9	12·43	9·52	2·91	0·72
Total average of morning, noon, and afternoon milk	1031·9	8	12·08	9·54	2·54	0·71

These results prove that, taking either a single cow or the whole herd, the morning milk did not come up to the assumed high standard of 12·50 of total solids, of which 9·30 are solids not fat, and 3·20 are fat ; the noon milk only gave one sample above the standard, whilst the five remaining samples were below the standard; and the afternoon milk gave two samples equal to the standard and four samples below it. Of the whole eighteen samples only three were up to the standard and fifteen were below it, so that the milk of these fifteen cows would have been declared mixed or adulterated with water, or skimmed milk, or with both water and skimmed milk, according to the assumed high standard. Again, taking the whole morning milk, the whole noon milk, or the whole afternoon, separately or together, the entire runnings of this dairy would on the same standard be declared to be adulterated.

The differences in the quality of the milk yielded by the same cow at different periods of the day, and the variations in the character of the whole milk given by the whole herd at morning, noon, and afternoon, are markedly observable in the results obtained from dairy D. It is quite apparent that the morning milk is the poorest, whilst the noon and afternoon milks are decidedly richer. It may be stated that all of those cows were of the Ayrshire breed, that they were fed on draff, turnips, oats, straw, and peas meal ; that No. 1 cow calved in August and the milk was almost out, Nos. 2 and 5 calved in February, No. 3 in January, and No. 6 in September, and the milk of the latter was nearly done.

In conclusion I may mention that out of 66 samples of genuine milk taken from 46 cows, and which have been fully analysed by me, only eleven of these samples came up to the high standard of 3·2 per cent. of fat, of which one sample was of the last runnings of the milk, and three samples were deficient in the high standard of 9·3 of solids not fat; so that only seven samples of the whole runnings of milk came up to the assumed high standard on all points. Neither the average quality of the genuine milk obtained from any one of the four dairies nor the average quality of the genuine milk yielded by all the dairies taken together was equal to the arbitrary high standard assumed by City Analysts.

THE CHEMISTRY OF THE LIVER.

In one of the Croonian Lectures recently delivered on the subject of Functional Derangement of the Liver, and published in the *British Medical Journal*, Dr. Charles Murchison, LL.D., F.R.S., etc., deals at some length with the chemical history of the compounds that are formed in connection with the functions of that organ.

The following is taken from this portion of the lecture :—

In the first place, it is now known that the liver is one of the organs mainly concerned in the process of sanguification. So long ago as 1820, it was shown by Magendie and Tiedemann that the absorption of nutritive matters from the bowel was not limited to the lacteals, but that part was taken up into the blood through the portal vein ; and the researches of subsequent physiologists have clearly established that the liver exercises most important functions in assimilation and nutrition. The most valuable

contributions towards our knowledge of this matter have been the researches of Claude Bernard and other observers, who have shown that the liver has the power of making and storing up for a time within its cells glycogen ($C_6H_{10}O_5$), a substance resembling dextrin ($C_6H_{10}O_5$) in its chemical composition and reactions, and like it capable of conversion into sugar by the action of albuminoid ferments. This substance always exists in the liver in larger amount during digestion than during fasting, attaining its maximum usually about four or five hours after a meal. It does not yet seem certain what the materials are from which it is mainly formed, but there can be no doubt that its amount is increased by the use of starchy or saccharine food. The starch ($C_6H_{10}O_5$) of the food is believed to be converted into grape-sugar or glucose ($C_6H_{12}O_6$) by the saliva and pancreatic secretion, while the cane-sugar ($C_{12}H_{22}O_{11}$) is transformed by the intestinal secretion into grape-sugar and another form of sugar called lævulose ($C_6H_{12}O_6$). The glucose and lævulose are absorbed by the intestinal veins and carried by the portal vein to the liver, where they are converted partly perhaps into fat, but mainly into glycogen, which is stored up in the hepatic cells, and distributed for the nutrition of the tissues during the intervals of fasting. The circumstance, however, of glycogen being formed in considerable quantity in the livers of animals who have been fed for a month or more on flesh alone, and the fact that its quantity in the liver of a dog is always increased after a meal of flesh, show that it can also be produced from albuminous matter. The albumen of the food is converted by the gastric juice into peptone, which is also absorbed by the intestinal veins and carried to the liver, where it is believed to be decomposed into glycogen and nitrogenous products such as leucin ($C_6H_{13}NO_2$) and tyrosin ($C_9H_{11}NO_3$), which are ultimately resolved into urea (CH_4N_2O). The glycogen derived from these two sources does not remain long in the liver, for the large quantity formed after a meal is quickly diminished on fasting. It is not got rid of by the bile-ducts, for bile contains neither glycogen nor sugar. But, either as glycogen, or more probably as sugar, into which it is believed by Bernard and most other physiologists to be reconverted through the action of an albuminoid ferment in the liver or in the blood, or transformed in some other way, it enters the blood by the hepatic veins.

One object of the glycogenic function of the liver is supposed to be that of continuously supplying an easily oxidizable material, such as sugar, which in the presence of oxygen and albuminous matter is readily converted in the lungs into carbonic acid and water, and thus contributes to the maintenance of animal heat. But, although there is still some difference of opinion among those most competent to judge, the bulk of evidence goes to show that a portion only of the glycogen formed in the liver is transformed into sugar to be burnt in the lungs, and that the maintenance of animal heat is far from being its chief use. There are good grounds for believing that it assists in cell-growth ; for, just as in plants the presence of sugar seems to be necessary for the most rapid development of cells, so in animals glycogen can be found wherever cell-growth is actively going on.

But, in the second place, modern research has made it probable that the liver is endowed with a function not suspected by Galen, and which, from a pathological point of view, is even more important than that which we have been considering. Many observations, pathological as well as physiological, point to the conclusion, that the liver is not only a blood-forming, but a blood-destroying or purifying, organ, and that it contributes in a great degree to the destruction of albuminous matter derived from the food and textures, and the formation of urea and lithic acid, which are subsequently eliminated by the kidneys. First, there seems to be little doubt that the albumen and fibrin of the blood become largely disintegrated in the liver. Lehmann and Bernard have shown that, while portal blood contains much fibrin, blood from the hepatic vein contains little or none. Brown-Séquard has calculated that no less a quantity than 2690 *grammes*, or about 86½ ounces, of fibrin is daily lost to the blood in its passage through the digestive organs and the liver. If this be so, we can readily understand that, when anything occurs to interfere with this fibrin-destroying function, there should be a rapid increase of fibrin in the blood, as we know to occur in acute rheumatism and in other diseased states. Moreover, there are grounds for believing that, while white blood-corpuscles take their origin in the liver, the red corpuscles are destroyed there, and that the nitrogenous colouring matters of the urine are partly the result of this destructive process. Gréhaut has ascertained that there is a positive destruction of hæmoglobin in the passage of blood through the liver. Red blood-corpuscles are known to be at once destroyed when brought in contact with a solution of bile-acids of a certain strength (12 per cent., Legg) ; while the researches of our late colleague, Dr. Bence Jones, make it very probable that the various shades of yellow, brown, and pink, presented by the sediments of the urine are due to different degrees of oxidation of the pigment of the bile. Further, there is evidence that the liver is largely concerned in the formation of the nitrogenous matters which are eliminated by the kidneys.

The third function of the liver is the secretion of bile. The composition of this substance is complex, and its uses are not yet sufficiently known. Human bile, as found after death, is usually a dark brown fluid, of tenacious consistence, from the presence of mucin, which it derives from the gall-bladder and bile-ducts ; but, when fresh, as it flows from the liver, it is a thin transparent liquid, of a golden yellow colour like that of yolk of egg, of a very bitter taste, of alkaline reaction, and having a specific gravity of about 1018. It has an unctuous feel, and mixes freely with oil or fat. It contains from 9 to 17 per cent. of solid matters (the proportion being always greater soon after a meal), consisting for the most part of substances peculiar to bile. Excluding the mucin, its principal ingredients are—1. Bile-pigment ; 2. Biliary acids combined with soda ; 3. Cholesterin and fats ; 4. Mineral matter, such as phosphates of soda, potash, lime, magnesia, and iron, chloride of sodium, and traces of copper.

The following analysis of bile, obtained from a man aged 22, killed by an injury, was made by Frerichs.

Water	859·2
Solid residue	140·8
Glycocholate of soda } Taurocholate of soda }	91·4
Fat	9·2
Cholesterin	2·6
Bile-pigment and mucus (of which, mucus about 1·4)	29·8
Salts	7·7

The yellow pigment is now designated *bilirubin* ($C_{16}H_{18}N_2O_3$). On standing, it becomes greenish from oxidation, and is converted into *biliverdin* ($C_{16}H_{20}N_2O_5$), which accounts for the dark colour usually presented by the bile in the gall-bladder after death and in the fæces. Biliverdin is also the principal colouring matter of the bile of the herbivora. Bilirubin is now known to be formed from blood-pigment or hæmoglobin by the hepatic cells, in the passage of the blood through the liver. That this was the source of the bile pigment, was suggested at the end of last century by a distinguished Fellow of this College, Dr. W. Saunders, who observed : "Green and bitter bile, being in common to all animals with red blood, and found only in such, makes it probable that there is some relative connection between this fluid and the colouring matter of the blood, by the red particles contributing more especially to its formation." This view, revived in our own day by Virchow, is supported by the apparent identity of bile-pigment with the pigment-hæmatoidin found in old extravasations of blood, and by the fact that what appears to be bile-pigment can be produced from blood-pigment by the action of chemical reagents ; by the

discovery of Zenker and Frerichs of crystals of hæmotoidin in inspissated bile and in the bile of jaundiced urine; by the observation of Gubler that bilirubin and hæmatin give the same play of colours with nitric acid, except that the green colour is most persistent in the former, and the violet in the latter; by the discovery of Frerichs, Kuhne, and others, that when any substance, such as bile-acids or even water, which has the property of dissolving blood-corpuscles and liberating hæmoglobin, is injected into the veins, bile-pigment (bilirubin) appears in the urine; and by the statement of Grehaut, that there is a positive destruction of hæmoglobin in the passage of blood through the liver. There are, on the other hand, grounds for believing that bile-pigment is in its turn converted into urinary pigment. A substance presenting spectroscopic characters similar to those of urinary pigment can be prepared by deoxidation from bilirubin; and it is believed that, in the organism, bile-pigments are reduced by hydrogen or other reducing agents present in the intestines. It is also a well known clinical fact, that nothing influences so much the characters of the urinary pigment as functional or structural disease of the liver. The liver, then, together with that osmotic circulation constantly going on between it, the blood, and the contents of the intestines, to be referred to presently, appears to be the medium of conversion of blood-pigment into bile-pigment, and of bile-pigment into urinary pigment.

The bile-acids in human bile are two—glycocholic acid ($C_{26}H_{43}NO_6$) and taurocholic acid ($C_{26}H_{45}NO_7S$). Both acids are derivatives of albumen, and contain nitrogen; and taurocholic acid, to which the bitter taste of bile is due, contains all the sulphur of the bile. Both are in bile combined with soda, and both are what are called conjugate acids; that is to say, that they are composed of cholic acid ($C_{24}H_{40}O_5$), which contains neither nitrogen nor sulphur, in combination with taurin ($C_2H_7NO_3S$), which contains both nitrogen and sulphur, and glycocin ($C_2H_5NO_2$), which contains nitrogen, but no sulphur.

Cholesterin ($C_{26}H_{44}O$) is a fatty substance, which crystallizes in colourless rhombic plates, one corner of which is often indented. It is met with in nerve-matter, in the spleen, in blood, and in certain morbid exudations, as well as in bile. An American physician, Dr. Austin Flint, jun., has endeavoured to show that cholesterin is formed for the most part, if not entirely, from nerve-tissue, from which it is taken up by the blood; and that one of the chief functions of the liver is to eliminate this cholesterin, the accumulation of which in the blood, from the liver ceasing to act, is attended by cerebral and other symptoms of blood-poisoning.
