The PRESIDENT : The subject of ventilation, whether of sewers or dwelling-houses, is a large one, and people are apt to forget that arrangements in a particular form, though answering in some circumstances, may be of no use in others. I remember the case of a friend of mine who was at infinite pains to ventilate the sitting-rooms of his house, in order to get rid of the products of the combustion of gas. He attempted to show me how splendidly his plan worked, and how the heated air from the gas was carried off through the ventilator, by putting a candle to it, when the light was blown out by an *in*-draught. I suspect such cases are not uncommon. The alteration of external circumstances has a great deal to do with the result in matters of this character. Meteorologists know how exceedingly difficult it is to account for windage, even where obstructions to currents of air appear to be very trifling.

Mr. NICHOLSON, in reply, said : I have seen ventilation through fire tried in several instances, but I do not think the plan is practicable unless you have frequent centres of ventilation. It has been found that, when fires have been lighted at the bottom of the shafts, a pressure has been caused by which the water has been all drawn out of the traps in the immediate neighbourhood. The only remedy in my opinion is to have as many openings as possible into the open air, and as near the ground as possible.

The thanks of the members were then given to Mr. Nicholson for his paper.

Professor Attfield then read the following :—

PHARMACEUTICAL NOTES.

BY S. R. ATKINS.

The Preliminary Examination.

It is desirable that the certificates of the local examinations of the Universities of Oxford, Cambridge, and Durham, and also of the College of Preceptors, should take the place of our own Preliminary examination, the latter to be abolished.

The argument in favour of such a course may be briefly stated thus :—The design of such an examination is to test a liberal education. Such test would be more appropriately applied by a strictly educational authority—educational I mean in the *literary* rather than in the *technical* sense.

The advantages of such a change would be greater uniformity and accuracy of results, the avoidance of the very possibility of collusion on the part of the examined, or of negligence on the part of local secretaries.

And finally, the certainty of securing that which after much talking and writing we have at length obtained a consensus of opinion upon, namely, that this examination should be strictly *preliminary* to apprenticeship.

The Medical Profession.

The relations existing between medical men and pharmaceutists is a subject destined yet further to engage attention. And not being a matter for legislation, it is one pre-eminently in which a healthy public opinion can only be created by full and free discussion.

No one will dispute the assertion that it is highly desirable a kindly and confidential relationship should exist between the general practitioner and the dispensing chemist. That such a sentiment already largely exists we gladly admit, but chiefly confined to the large centres of population.

Nothing is more common in provincial towns than to find every member of the faculty dispensing his own medicines.

Compromise, in the shape of mutual surrender, is the only solution of the difficulty we can discover. Medical men should entrust to us their dispensing, we, *per contra*, guaranteeing not to poach on their special preserve in the shape of counter-prescribing.

Pharmaceutical Titles.

Ground for inquiry and amendment exists in this particular. The bare statement of the fact should suffice, that the men who entered the vineyard at the eleventh hour have well-nigh the same distinction as those who have borne the heat and burden of the day.

We know the difference in value between the terms "*Pharmaceutical Chemist*" and "*Member of the Pharmaceutical Society*"—the general public unhappily does not.

We most gladly welcome the late comers, and would as heartily have greeted them, had they arrived earlier. Still if pharmaceutical titles are of any practical use in so far as our constituencies are concerned let them distinguish and not confound things that differ.

The PRESIDENT : Each of these subjects is so wide that we might occupy a week in discussing it ; it is for you to say how far it is desirable for us to enter upon them now. We are however bound to send to Mr. Atkins the expression of our thanks. If any gentleman has any remarks to offer respecting the notes we shall be glad to hear him.

Mr. REYNOLDS (Leeds) : I have taken notes of two sentences, "the negligence of local secretaries" and "the possibility of collusion." The duties of local secretaries, —since one day in every quarter has now been fixed, when they must be shut up for three hours with the candidates,—are not specially desirable. In any case it is clear that these duties are important and must be thoroughly discharged. Before any doubts are cast upon the integrity with which local secretaries perform their functions good evidence should be offered. I believe that a much more definite system on the part of those who regulate that duty is needful ; for instance, no instructions now come down with the examination papers. The attention of the Board has been drawn to this matter : it is rather a serious point, for the examinations might become void through any irregularity of a deputy to whom an examination had been entrusted. It was desirable to take many precautions and to avail ourselves of the benefit of the experience of the universities. If, for instance, you are likely to have a larger number of candidates than the room ordinarily used can accommodate, so that the students shall have a sufficient space between each other, a larger room should be engaged.

Further, I think the holding of examinations in private houses should be discouraged. Some public place should be used for the purpose. I think I ought to say on behalf of the local secretaries that some improvements could be made on the present system.

Mr. SAVAGE (Brighton) : I concur in the desirableness of the local examination being conducted in large centres, but at the same time it must be borne in mind that the plan will be attended with expense to young men who can ill afford it. Not only this ; but these University Local Examinations occupy a week, whilst our present examinations occupy but three hours.

Mr. CARTEIGHE : I concur in the general spirit of Mr. Atkins' note. He certainly does treat the matter somewhat curtly ; but I concur in the view that it is desirable as soon as possible to pass over a purely elementary educational examination to an educating body, because I think it would be an immense advantage to the youths who are to be our future apprentices. It is true that the Society since the passing of the Pharmacy Act has decided, I was going to say condescended, to continue the Preliminary examinations in their present form or in some other form to be decided upon hereafter. I am not prepared to say that the examination is on the whole satisfactory either to the local secretaries, or to the examiners, or to the candidates themselves. I speak from some little experience when I assert this. I am not prepared to say that every local secretary, or indeed a large percentage do thoroughly understand the importance of their duty in this respect, on the other hand I am bound to admit that it is rather a serious matter to expect a local secretary to give half a day every quarter to the performance of work for which he does not receive any payment. —a work also which does not appear to carry with it any particular honour. All these are difficulties in carrying out the present system. I know that some local secretaries really object to this part of their duty—it would be invidious to say how many, but there is undoubted testimony to that effect. I would rather go upon the broad principles that examinations of this kind, which are not purely technical, should be conducted by a scholastic examining board. What I take Mr. Atkins to mean is that we should encourage a higher class of apprentices and that as long as we keep holding out a sort of intermediate examination, and one which is considered easier than we should wish it to be, so long are we staving off the time when we shall obtain a higher class of apprentices. It ought to be mentioned for the benefit of those likely to contemplate passing these examinations that the time will very shortly come when medical Latin will be excluded. The only justification of the present form of examination is that it has been found expedient. I protest, as a member of the Conference and as a member of the Society against the notion that it is the duty of the Society to conduct examinations which can be much better conducted by men specially trained for that purpose.

Mr. SMEETON (Leeds) : I am inclined to think that the final middle class examinations might be made useful if they could only have a reflex action on the middle class schools themselves. In many cases a boy of sixteen years is brought to us, who when asked if he has learned Latin will say "yes," and although even from a good school, or one that ought to be good from the charges made, you will find his knowledge, on being tested, to be mediocre. If it should become law to compel these schools to submit their students for examination, the difficulty would be surmounted.

Mr. SCHACHT (Clifton) : It must undoubtedly be admitted that one of the objects contemplated by the Pharmaceutical Society in planning the Preliminary examination was the gradual introduction of a better educated class of men into the ranks of pharmacy, and possibly as far as the examination itself is concerned, it might be more thoroughly conducted by some other bodies than by our own Board of Examiners. But this admission constitutes no argument for the abolition of our "Preliminary," for we have no power to compel a candidate for pharmacy to pass the College of Preceptors' examination, or any other than our own, and at last it comes to this—that we want to apply some test that shall exclude those whose previous training is insufficient to warrant the expectation that they will be able to pursue the studies connected with our calling, and this we must do ourselves through our own Board of Examiners. Moreover, by including these departments of knowledge with those that are more purely technical, I do not think the Board in any way risks its dignity. I may remind the meeting that the various departments of the medical profession conduct examinations of this kind. (A member : "Not by themselves.") Yes, by themselves. I am a registered apprentice of the Society of Apothecaries and when about to be apprenticed to my master, the late Mr. Savory, was taken to the Apothecaries' Hall, and required to pass an examination in Latin and arithmetic. I believe that many other bodies hold such examinations and I do not believe it is any disparagement for them to do so.

Mr. CARTEIGHE : The question is not one of dignity at all, but whether the men appointed by the Pharmaceutical Society are the best men for conducting the examination. With respect to Apothecaries' Hall the facts are as stated by Mr. Schacht, but as regards the College of Surgeons this part of their examination is conducted by the College of Preceptors.

Mr. MARTINDALE : I must confirm Mr. Carteighe as to the College of Surgeons' examination being now conducted by a separate examining body. That society formerly did conduct their own educational examination but they have now transferred that duty to the College of Preceptors. I might mention that if our Preliminary examination be abolished, unless very many more centres are selected for their examinations by other bodies, a hardship will be inflicted. On the other hand there is great objection sometimes on the part of apprentices to have the examination in the houses of competing chemists in the same town, and I have heard of cases in which rather than do so they would travel 100 miles.

Mr. COTTRILL (Shepton Mallet) : I think the clergyman of the parish might undertake an examination of this kind. The original intention was that the examination should be a preliminary one ; it was the case with myself nearly thirty years ago, but there has been a departure from this rule. I trust there will be a discontinuance of the advertising notices we now see in newspapers, to the effect that Mr. So-and-So has passed the Preliminary examination in pharmacy, he having been trained by the Rev. Mr. Bircher, or some other local celebrity. Such notices are disgusting when it is remembered that the examination is of such a slight character.

Mr. WILLIAMS : The question is, whether it would be better to have every young man come up to London for examination *in propriâ personâ*, or have written examination papers put before him under local secretaries. I think there would be a difficulty in accepting the examination of the universities or of the College of Preceptors, our Act of Parliament requiring the examination to be conducted by examiners appointed by the Pharmaceutical Society, and approved by the Privy Council.

Mr. CARTEIGHE : I wish to say a word in explanation. I never meant to imply that the examining board had ever refused to undertake the work entrusted to them, but only intended to convey my opinion that as a matter of expediency and for the good of the candidates themselves it is better that these examinations should be conducted by an independent scholastic board.

ABSENCE OF MORPHIA IN THE PETALS OF PAPAVER RHEAS.

BY PROFESSOR ATTFIELD.

Pereira, treating of the red poppy in his 'Elements of Materia Medica,' states, "It is not improbable that this plant [the whole plant] may contain *morphia* in very

minute quantity." And again, "It probably possesses a narcotic property in a very slight degree, but which is scarcely sensible in the ordinary doses in which this medicine is employed." Garrod, in his 'Essentials of Materia Medica,' says of red poppy petals, "They contain, in addition to the red colouring matter, minute traces of the peculiar constituents of opium." And Bentley, in his 'Manual of Botany' cites Chevallier in support of the opinion that the petal-juice contains morphia. These quotations suffice for showing that the well-known colouring agent, the juice of red poppy petals, is, to say the least, suspected to contain morphia, and, consequently, to be a weak, though no doubt very weak, narcotic. On the other hand Hesse, (*Amr. Pharm. Suppl.* 4, 50; *Amr. Pharm.* 140, 145; *Eng. Trans. Gmelin's Handbook of Chemistry*, vol. xviii., p. 206,) in a research on the red-poppy plant, so thorough as to yield him *rheadine*, a well marked crystalline alkaloid, seems to have detected no morphia. Filhol, however, found morphia in the *capsules* of *papaver rheas* (*N. T. Pharm.* 2, 150,) and Aubergier (*N. Amr. Chim. Phys.* 20, 303; also *Gmelin's Handbook*) is said to have obtained from the red poppy cultivated in Algeria opium containing 10 to 11 per cent. of morphia. These statements, however, still leave undecided the question of the presence or absence of morphia in the petals of the plant, the matter to which attention is invited in this note, and the only one having general pharmaceutical interest, inasmuch as the petals are the only part of the plant used in medicine.

In endeavouring to throw light on this subject it became obvious that no experiments could be deemed conclusive unless made on large quantities of material. I therefore worked on one pound of petals (about 6000 petals or 1500 flowers) in each analysis, and made three separate analyses by three different processes. I also assured myself by experiment that each process would isolate morphia if that alkaloid were present.

Experiment 1.—One pound of the petals was gently warmed with a quart of water acidulated by acetic acid. After digestion for two hours the liquid was separated from the solid portion, and the latter again similarly digested. The operation was once more repeated, and the three quantities of liquid mixed and treated as follows, the exhausted petals being thrown away. The liquid was evaporated over a water-bath, and when only two or three ounces remained acetate of lead added until a precipitate ceased to form. The precipitate *a* was separated and examined for meconic acid, or any acid having analogous reactions, while in the liquid *b* morphia was sought. The precipitate *a*—decomposed by sulphuretted hydrogen, the sulphide of lead removed by filtration, and the filtrate, after removal of sulphuretted hydrogen, tested with neutral perchloride of iron—gave no reaction for meconic acid. The liquid *b* was subjected to a current of sulphuretted hydrogen to remove lead, filtered, the clear filtrate evaporated to a small bulk, carbonate of potassium added in excess, and the mixture well shaken with about twice its bulk of a morphia solvent composed of ether and acetic ether in equal parts. A portion of the residue left by the evaporation of this ethereal solution to dryness giving no reaction of morphia, the bulk of the residue was submitted to processes of purification and again tested. Not the slightest evidence of the presence of morphia was obtained.

Experiment 2.—One pound of petals, within two hours of collection was digested in and exhausted by weak spirit of wine acidulated with acetic acid. A little tartaric acid was added to the tincture, and the latter evaporated to dryness at a low temperature, the residue exhausted by cold anhydrous alcohol, the alcohol removed by evaporation, a little water and some bicarbonate of potassium added to the residue, and the whole shaken with seven or eight times its volume of pure ether containing some acetic ether. The ethereal liquid evaporated gave a residue which neither before nor after subjection to purification afforded any evidence whatever of the presence of morphia.

Experiment 3.—The tincture from one pound of petals was slightly acidulated with hydrochloric acid, and evaporated to the consistence of syrup; the latter diluted with water, set aside for some hours, filtered, and solution of phospho-molybdic acid added, until a precipitate ceased to form; the precipitate washed with water containing phospho-molybdic and nitric acids, then caustic baryta added to neutralize acid and liberate alkaloid; excess of baryta removed by carbonic acid gas, and the whole evaporated to dryness over a water-bath; the residue digested in alcohol; the alcoholic liquid filtered and evaporated; the alcoholic residue faintly acidulated by sulphuric acid, dried, washed with pure ether; water and carbonate of potassium added; the mixture shaken with ether and acetic ether; the latter evaporated, and the residue tested with perchloride of iron, iodic acid, and other reagents for morphia. No reaction for morphia was obtained.

These experiments I offer as confirmatory evidence of the absence of morphia in red-poppy petals. If we admit, as I think we may, the presence of the alkaloid in other parts of *papaver rheas*, the experiments have physiological interest, and suggest (to some of our members in India and elsewhere) an examination of *papaver somniferum* with the view of ascertaining whether or not morphia is contained in the petals of white poppies specially grown for opium. The pharmaceutical interest of the matter has already been adverted to, but the experiments may have pharmaceutico-legal value in the event of some zealous dispenser of justice reading the Pharmacy Act as requiring syrup of red-poppy petals to be placed in the same category as syrup of white-poppy capsules.

The thanks of the meeting were given to Professor Attfield for his paper.

The next paper read was a

Note on the Hydration of Extracts.

BY CHARLES EKIN, F.C.S.

It has occurred to me that Wanklyn's method of limited oxidation by means of an alkaline solution of potassium permanganate might be applied with good results to the assay of such medicinal extracts as are dependent for their activity entirely, or for the most part, on certain alkaloids—all alkaloids yielding a certain portion of their nitrogen as ammonia. Also that it might be made available for the determination of the relative values of the first year's and second year's plant of hyoscyamus, about which a good deal has been taken for granted but nothing yet really proved. And again in the case of conium, to determine which has the greater activity, a tincture made from the fruit or from the leaves. Of course, the difficulty lies in the complete and easy separation of the vegetable proteides of the plant juices, but I am by no means sure that this is not a difficulty that can be overcome, although I regret I have not yet had time to go sufficiently into the subject so as to be able to lay results of any value before this meeting of the Conference. I have had, however, incidentally to determine the amount of water in various extracts, and have thus so far answered question 66 on the blue paper circulated by the Conference, viz., "Is it possible to assign a definite degree of hydration to medicinal extracts with a view to uniformity of strength?"

I believe it is quite possible to do so, certainly with some if not with all extracts.

I find that extracts of fair average consistence for pill making, when subjected to the heat of a water bath, in the cases of belladonna and hyoscyamus lose 20 per cent. of their weight, and in the case of conium, 25 per cent.

The plan I adopted was to spread the extract very thinly on a thin platinum capsule, and dry at a temperature of 212° until it ceased to lose weight. Various experiments with the same extract gave in this way very constant results. At first I operated on quantities of 10 grains at a time, but I found that several hours were then required for complete desiccation, whereas if only one or

two grains were used the time required was little more than half an-hour.

The consistence of extracts varies so much that it would seem advisable to define in the Pharmacopœia the amount of water each should contain, the amount to be determined as I have recommended. When once a standard has been set up there would be practically little difficulty to manufacturers, for I find after a few trials the eye can determine from the consistence of the extract, to less than 1 per cent., the amount of water present.

Mr. SCHACHT: I wish to ask Mr. Ekin whether he has satisfied himself that all the material he lost over that drying process was water.

Mr. EKIN: The question is one I am not surprised should be asked, and my reply is, that it is quite possible the loss of weight on drying may not be entirely due to loss of water, but may represent also an infinitesimal quantity of alkaloid. The estimation, if only approximate, is, however, practically sufficient. Everyone who has observed the varying consistence of extracts as sent out by different houses, at one time as thin as treacle, at another time of fair pillular consistence, must admit the desirability of having some standard to go by, even if it be only a rough one.

Mr. A. H. MASON (Liverpool): Mr. Ekin has alluded to a difference between the extract of hyoscyamus produce from different plants. For some little time past I have been in hopes of gaining information on this subject of hyoscyamus, but as yet have been unable to arrive at any definite results. It seems to me an important question whether the *biennial* plant of first year's or second year's growth should be used. Much larger quantities of the former are used by pharmacists in this country than the latter. The Pharmacopœia is rather indefinite on the point. But in Squire's 'Companion' it is very plainly described that the plant of second year's growth should be used. The question, therefore, is raised, what difference is there between the extract, tincture, etc., of the biennial hyoscyamus of the first year's growth and the same plant of the second year's? Mr. Stoddart * says the microspectroscope will immediately decide whether a tincture has been made from the *annual* or the biennial plant. Five dark bands are distinctly seen from biennial plant tincture which are not visible in that from the annual. It has occurred to me, while listening to Mr. Ekin's paper, whether it would be practicable to have all extracts in powder, provided the strength did not deteriorate; at all events, it would do away with the want of uniform consistency.

The PRESIDENT: There is a considerable difference between the annual hyoscyamus and the biennial plant, and the Pharmacopœia directs that we should only use the latter. I have myself cut one that was several feet high. It is altogether different from the annual plant. Mr. Stoddart's paper went to prove this difference between the two was due to the chlorophyll. But as we do not yet know enough of the value of chlorophyll there must be hesitation on our part in assigning any great amount of significance to that difference. I have read somewhere the suggestion that a portion, at least, of the active matter of our hyoscyamus is mixed up with the waxy chlorophyll. A suggestion has been made that the chlorophyll taken off should not be returned after evaporating for extract. It is evident, however, that if the chlorophyll does contain any alkaloid such a suggestion will fall to the ground. That, however, is a matter to which attention should be given by the microscopist and the chemist.

Mr. MASON: I did not intend to convey the impression that there was no difference between the annual and the biennial plant, but my remark had reference to the possible difference between the first year's growth and the second year's growth of the biennial hyoscyamus.

---

* PHARM. JOURN., May 20th, 1871.

Mr. WILLIAMS: A paper has been published by Merck, in which the writer comes to the conclusion that the alkaloid is not crystalline but liquid; that it has a tobacco-like smell and other properties somewhat resembling conia. These statements require confirmation before they can be taken as proved.

Mr. Ekin having been thanked for his paper, the discussion concluded, and the Conference adjourned till Wednesday morning.

WEDNESDAY, *September* 17.

The Conference re-assembled this morning at 10 o'clock.

THE AMERICAN PHARMACEUTICAL ASSOCIATION.—FRATERNAL GREETING.

The PRESIDENT: The first business this morning, gentlemen, has reference to the telegram which was sent yesterday to our American brethren. Last evening we received a return message. It is to the following effect:—

The President of the American Pharmaceutical Association,
To the President of the British Pharmaceutical Conference.

We return your hearty fraternal greetings.

Another American subject was announced in a letter read yesterday from Mr. Bedford, on behalf of the Photographic Album Committee of the American Pharmaceutical Association. Mr. Bedford stated that the album presented to the Conference had been forwarded from the United States, and I have now to inform the Conference that it arrived last evening, and has been laid on the table for the inspection of members. The album had been conveyed to England by the kindness of Mr. Walter V. Morgan.

ABNORMAL DOSES.

The PRESIDENT: The next business is to consider the report of the committee on abnormal doses.

Mr. HAMPSON then read the report as follows:—

"That this Conference having duly considered proposals for the use of special signs to mark unusual doses on prescriptions, and the great advantages to be derived from them, considers that the bracketed initial letters of the prescriber's signature, written immediately after the unusual dose, is the best suited for the purpose.

"This Conference also respectfully urges upon medical men the importance of the prescriber's full name and address being written on *all* prescriptions, to facilitate communication between the prescriber and dispenser.

"This Conference likewise considers it desirable for the dispenser to retain all prescriptions in which initialled unusual doses are prescribed."

After reading the report, Mr. HAMPSON said: I do not think there can be any objection to the report I have just read, as it embodies all the important points which were under discussion yesterday. I beg to move that the report be received and adopted.

Mr. GREENISH seconded the motion, which was carried unanimously.

The resolution having been passed, a conversation took place as to the best mode of communicating it to members of the medical profession, the President suggesting that a copy might be presented to the members of the Medical Council, and to the presidents of each of the various medical societies.

Mr. CARTEIGHE said: I beg to move that a copy of the resolution be distributed among members of the medical profession at the discretion of the general secretaries.

Mr. GROVES: I really think it would be better to communicate, in the first instance, with the head of the medical profession—the Chairman of the Medical Council. This would save the great expense which the distribution of copies of the resolution must incur. Besides, I think it would have more weight if the copy of the resolution

were forwarded by the President of this Conference to the head of the medical profession, who would be the proper person to disseminate similar copies among his own brethren.

Mr. WILLIAMS: It is questionable whether it would be wise to adopt this step. The resolution will, of course, be published in the medical journals, but I think we shall be departing from our province as a conference if we take the course proposed.

Professor ATTFIELD: It will be quite open for the President of the Conference, I suppose, to send copies of this resolution in the way suggested, or the secretaries might forward them at his request; or some other course may be taken, so long as we give a formal tone to the whole matter. In addition, however, to such a mode of procedure, I presume there can be no objection to the President himself communicating with the presidents of the medical societies on the subject.

Mr. GROVES: My proposal was that the Chairman of the Medical Council should be communicated with.

Professor ATTFIELD: Why not the chairmen and the presidents of the leading medical societies?

Mr. SAVAGE: This is a matter of mere detail, which I think may properly be left in the hands of the Secretary.

With this understanding no resolution was passed.

FURTHER EXPERIMENTS ON NEPAUL ACONITE AND ON THE CHARACTERISTICS OF THE ACONITINES.

BY THOMAS B. GROVES.

The paper on Nepaul Aconite which I read before the meeting of the British Pharmaceutical Conference, at Liverpool, in 1870, has I find, not had the effect of converting continental pharmacists to the belief in two crystalline aconite alkaloids; one aconitine which I exhibited before the Conference at Nottingham, in 1866, when I read a paper entitled 'On Aconite,' and showed how I had extracted the crystalline alkaloid; the other pseudaconitine which I produced at the Liverpool meeting above referred to.

However my facts have not been altogether unsupported. Professor Flückiger, of Bern, writing to me (December 10, 1870), thanks me for the fine crystals of pseudaconitine I had sent him and states with what pleasure he had received them. The experiments he had made with them convinced him that they were truly crystals of pseudaconitine and nothing else, and that in the failure of the usual colour reactions it was best characterized by its ready crystallizability, its little solubility and the absence of bitterness; all which traits had been previously described by its discoverer, Von Schroff of Vienna.

Since then two able and exhaustive treatises on aconite have been published by French pharmacists, one in 1871, by M. Duquesnel of Paris, entitled 'On Crystallized Aconitine and the Preparations of Aconite,' the other in 1872, by M. Patrouillard of Gisors, 'On the Aconites and Aconitine.'

M. Duquesnel, in summing up the results of his research states that the activity of *Aconitum ferox* is due not to its containing a more energetic principle than aconitine, but to its containing a greater quantity of that principle, adding moreover that crystalline aconitine, with its ordinary form and properties had been obtained from that root. I am not sure however that my paper on Nepaul aconite had come under that gentleman's observation.

M. Patrouillard admits the distinction between the German or true aconitine, and the English or pseudaconitine, but endeavours to show that these substances are but more or less impure varieties of a single pure aconitine.

As this battle of the aconitines had been going on for at least twenty years, it was not to be expected that unanimity would at once be obtained. In fact I had foreseen that it would be necessary in order to produce conviction to be able to present to competent experimenters specimens of the different alkaloids for comparison. Accordingly soon after I had succeeded in obtaining pseudaconitine I sent to Messrs. Barron and Co. an order to supply me with fifty pounds of the same sample of Nepaul aconite root as they had previously sent me. I received answer to the effect that what they had purchased had become perfectly rotten, and that they were obliged to have it removed from their warehouse in consequence of its becoming heated.

However I managed to get some from another house (Messrs. Davy and Co.), and this was in excellent condition and presented precisely the same appearance as the roots I had before operated upon.

These I kept in a dry place until March of this year, when I thought I should have found time to work them up.

Mr. John Williams (Hopkin and Williams) very kindly consented to perform for me the preliminary operations which were unsuited to the arrangements of my small laboratory. The fifty pounds of roots, when dried and ground, were reduced to forty-eight pounds. The powder, packed into a percolator, was exhausted in the usual way with methylated spirits.* acidulated with hydrochloric acid in the proportion of two drachms to the gallon. The percolate was mixed with two or three pints of water and distilled to recover the spirit. The residue consisting of a highly coloured fluid with the resinous and oily matters of the root floating on its surface was sent to me. No sooner however had I received it than unforeseen circumstances compelled me to put it aside for a time, first taking the precaution to mix with it half-a-pint of ether, as a preservative. Six weeks latter, at the end of May, I found myself once more in a position to proceed with the work, which I attacked with fear and trembling, lest the long delay might have operated injuriously on the alkaloids.

The six pounds of Nepaul aconite I originally worked upon I had treated by what I may call the iodide of mercury process,† which, though well adapted to the treatment of so small a quantity, was thought too troublesome and expensive for the larger.

The process adopted was the following very simple one. A glass syphon having been inserted into the jar containing the mixed liquids, the lower portion was drawn off perfectly bright, leaving the resins, ether, etc., behind. These were sufficiently washed with water, and the clear fluid added to that removed by syphon. The acid liquid was next alkalized with excess of caustic ammonia, which precipitated an abundance of alkaloid, which by combination with the ether dissolved in the liquid became almost immediately imperceptible. It was, I imagine, diffused in oily transparent drops through the liquid. The alkaloids were now washed out by repeated agitation with ether, the same ether, occasionally reinforced, being used again and again, after having been washed with weak hydrochloric acid. The strong and acid solution of the alkaloids thus obtained was precipitated with excess of caustic ammonia, which produced a semi-solid magma, and from this the alkaloids were obtained in concentrated solution in ether by washing well with that fluid. The residual alkaline liquors, Nos. 1 and 2, were reserved for further observation, and the ethereal fluid, measuring about twenty-five ounces, set aside in a loosely-covered beaker to evaporate spontaneously. I will call this No. 3 for convenience of reference hereafter. I then left home for a holiday. Returning at the end of ten days I found that about two-thirds of the ether had evaporated, and, much to my chagrin, that no crystals had made their appearance. In my first experiment the pseudaconitine commenced to crystallize out half-an-hour after its solution was committed to the beaker; I began, therefore, to fear that the delay already referred to had been as prejudicial as I feared it might be. I nevertheless hoped that I might be

* A duty-free spirit, containing one measure of wood naphtha and nine measures of spirit of wine of not less than 50 per cent. over proof.

† M. Patrouillard supposes that I did not. He probably was misled by using instead of the original paper a translation of it that appeared in the *Bull. Pharm. de Bruxelles.*

mistaken, and that, after all the pseudaconitine had, owing to its less solubility in ether, been left behind, the more soluble aconitine only having passed into solution. I therefore returned to the residual liquors. No. 1 had not deposited a precipitate, No. 2 had thrown down a small quantity of white and partly crystalline substance. Both fluids tested with iodohydrargyrate of potassium showed abundant evidence of alkaloids in solution. The two liquids were therefore mixed, slightly acidulated with sulphuric acid, and precipitated with excess of iodohydrargyrate. The slightly cohering precipitate was washed with water by decantation and transferred to a capacious flask, where heated to about 200° it fused. When cold the water was poured from it, and methylated spirit being added the resinous-looking mass was dissolved by the aid of heat and decomposed, as I have before now explained, by the successive application of sulphuretted hydrogen and acetate of lead. The acid solution thus obtained was freed from excess of lead, evaporated to a small bulk (about eight ounces), water having first been added, precipitated with excess of caustic ammonia, and washed with ether.

This ethereal solution, after several days' evaporation, showed no disposition to crystallize, but deposited a small quantity of a brownish syrup soluble in ether. The remaining ether was therefore chased off by water-bath, at which temperature the residual alkaloid fused, and rectified spirit having been added, the liquid was again set aside to take its chance of crystallizing. This, however, it did not seem inclined to do, so after waiting several days it was exactly neutralized with dilute nitric acid and tried again and again ; but still no sign of crystallizing. I will call this No. 4.

By June 15th No. 1 had become of a syrupy consistence, and the only indication of crystallizing was one small rhombohedron that made its first appearance the day previous. It was then removed to a cool and dark cellar. When I visited it four days afterwards I found that its surface had become leathery, and that underneath, embedded in a dense syrup, were some five or six rhombohedra, and about the same number of spherical aggregations of slender crystals of another character.

The case not being yet hopeless, I determined on trying another solvent. As the mixed material contained not only alkaloids and ether, but also separated water, I chose absolute alcohol, which would reunite the whole. This was added in sufficient quantity, care being taken to avoid breaking up the crystals. Before I had completed washing out the beaker with the alcohol, I observed the solution becoming milky in appearance. Half-an-hour later it seemed decidedly granular, and on taking some to the microscope I was overjoyed to find the change was really due to rapid crystallization, the principal form being the familiar rhombohedron I was so anxious to obtain. In three hours more the fluid had become semi-solid, so that the basin could be inverted without spilling its contents. The mass was then broken up, thinned with rectified spirit, and set aside in order that the crystals might increase in size.

This capriciousness as to crystallizing I observed on several subsequent occasions.

After a few days the magma was thrown on to a cloth, drained, washed a little with spirit, and then carefully and very strongly expressed by a screw. A nearly white cake of crystals was thus obtained. The expressed mother liquor yielded subsequently second and third crops of crystals of the same character. All three crops were now dissolved in rectified spirit and recrystallized. In doing so it showed a great tendency to creep up the sides of the vessel and the crystals produced were very much smaller than those I had obtained in 1870. I attribute both this and the shyness of the alkaloid to crystallize from ethereal solution to the fact that the process adopted did not separate the alkaloids in that state of purity they are obtained in when the iodide of mercury process is followed.

In this way I obtained about one ounce and a half of pseudaconitine, a quantity amply sufficient I trust to convince all the doubters in Europe.

All the cloths, vessels and draining filters were now washed in dilute nitric acid, and to the filtered liquid was added the mother liquors of the pseudaconitine and the alkaloid No. 3. Exactly neutralized with the acid the solution was set aside to crystallize. More than once it was allowed to evaporate spontaneously to dryness, water being used sometimes, sometimes rectified spirit to redissolve it. It never showed the slightest tendency to crystallize.

It was therefore diluted with water to a moderate bulk and to it was added ammonia until its smell was plainly perceptible. The abundant precipitate thus obtained was collected on a cloth, washed a little, and pressed strongly. The cake when dried weighed about an ounce. I shall call it amorphous pseudaconitine.

In my previous experiments I found (see original paper on 'Nepaul Aconite') that 130 grs. of the amorphous substance obtained by evaporating the mother liquor of pseudaconitine, when dissolved in acidulated water, precipitated with ammonia, collected and dried, lost in these operations no less than 43 grains. This I suggested was caused mainly by the solubility of aconitine in water. I strongly suspected however that that was not the only cause of loss. Accordingly I determined on examining the mother liquor of amorphous pseudaconitine.

I found at once that though smelling perceptibly of ammonia it still contained an abundance of alkaloidal matter of some sort which was precipitable by adding a further and very large excess of caustic ammonia.

The mother liquor was therefore neutralized with hydrochloric acid and evaporated to about half a pint. This when cold was treated with a slight excess of ammonia which produced no permanent precipitate. A further addition of the strongest solution of ammonia was then added and an abundant precipitate obtained, which when washed a little and pressed had a semi-resinous appearance and appeared translucent at the edges of the cake.

The mother liquor of this still containing alkaloid precipitable by further addition of ammonia was well washed with ether. The ethereal fluid allowed to evaporate to a syrup showed no tendency to crystallize. It was then subjected to the heat of the water-bath which caused it when dry to fuse, and to it was added the cake before obtained. When the whole was in a state of clear fusion it was removed from the basin and allowed to cool in detached portions on a cold plate. It then had the appearance of resin, was brittle, and easily reduced to powder. It weighed about three drachms. I presume it is Hubschman's napellin, though it differs from it in some particulars. I may mention that it cannot be said to be slightly soluble in ether. Nor is its spirituous solution precipitated by the addition of ether.

The aconite alkaloids, upon some of the characteristics of which I shall now report, are crystallized aconitine and amorphous aconitine, derived from *Aconitum Napellus*, Morson's aconitine, pseudaconitine in crystals, amorphous pseudaconitine, and napellin derived from Nepaul aconite.

I say advisedly Nepaul aconite and not *Aconitum ferox*, leaving the moot question of origin an open one. M. Patrouillard has gone very fully into that question and has collected evidence sufficient to cast considerable doubt upon the original statement of Wallich that *Aconitum ferox* is the sole source of bikh. I must say however that having carefully examined 50 lbs. of the root spread out upon a floor, I could not detect any admixture. They appeared to be all derived from one species.

I will first take the *fusibility of the aconitines.*

Pure crystallized aconitine did not fuse or show sign of cohering when boiled in a test tube with water.

Crystallized nitrate of aconitine dissolved in a small quantity of water and precipitated with ammonia to a coagulum and then heated in a test tube to boiling did not fuse but became quite brittle.

Amorphous aconitine when treated as above behaved similarly.

Morson's aconitine (amorphous) when boiled with water in a test tube fused and stuck to the glass.

Crystallized pseudaconitine boiled with water did not fuse. Dissolved in dilute nitric acid, precipitated to a coagulum with ammonia and then heated to boiling, did not fuse but became aggregated and plastic when pressed with a glass rod, showing a tendency to fusion.

Amorphous pseudaconitine boiled with water fused and stuck to the side of the tube. When touched was sticky.

Napelline (?) is also readily fusible.

Heated destructively in the bottom of a test tube all these preparations gave off acid vapours of the same odour as the pyroligneous acid used for curing hams.

The vapour given off by quinia and strychnia under the same circumstances was alkaline.

The aconitines heated with hydrate of soda gave off ammonia. These reactions seem to indicate an extremely high molecular weight—the acids formed by rearrangement of the carbon, hydrogen, and oxygen being more than sufficient to neutralize the ammonia formed by help of the nitrogen.

Solubility in Ammoniacal Water of the Aconite Alkaloids.

The solution of ammonia I usually employ in my laboratory contains about 5 per cent. of the alkali. Of this solution I took one measure and diluted it with three measures of distilled water, forming the "stronger solution of ammonia;" the "weaker solution" was of half that strength.

The method adopted was the following. Half-a-grain of the alkaloid (air dried) was dissolved by the aid of one drop of dilute nitric acid in about a drachm of distilled water. The small beaker containing the solution, and a small pipette for dropping it was then balanced in the scale-pan. One hundred grain measures of the ammonia solution were then measured into a beaker of fitting size, and into it was dropped, by means of a pipette, the solution of the alkaloid until a slight permanent cloudiness was arrived at. The beaker containing the solution of alkaloid and the pipette was then taken back to the balance, and the loss it had sustained was noted. This was repeated so long as the solution permitted, and finally, the beaker and pipette having been carefully washed and dried, the weight of the residue that had not been used was ascertained. From data so arrived at I deduced the following numbers. I may, perhaps explain, to avoid misconception, that the water in which the alkaloid was dissolved was always added to the one hundred grain measures of the ammoniacal water before making the calculation. The nitrate of aconitine was employed without deducting anything for the nitric acid it contains. The salt being anhydrous the nitric acid was set against the hygroscopic water of the other samples. The method was found sufficiently accurate to enable one to draw a broad line of distinction between the several specimens.

One grain of alkaloid soluble in	Stronger ammonia water.	Weaker ammonia water.
Crystallized Nitrate of Aconitine .	520	589
Amorphous Aconitine	1005	860
Crystallized Pseudaconitine . . .	2674	2500
Amorphous Pseudaconitine . . .	1489	1372
Morson's Aconitine	881	684

It will be observed that crystallized aconitine is not only by far the most soluble of the series, but that it alone is more soluble in the stronger than in the weaker ammonia water.

That the amorphous aconitine approaches in character the pseudaconitines, being less soluble than aconitine, and more soluble in the weaker than in the stronger ammonia water.

The very much diminished solubility of crystallized pseudaconitine distinguishes it at once from the aconitines with which it has persistently been confounded. It is also slightly more soluble in the weaker than in the stronger ammonia water.

Morson's aconitine is reputed to be a hydrate containing 20 per cent. of water. Making allowance for this its solubility is almost precisely the same as that of amorphous aconitine of *Aconitum Napellus*. But then it is fusible at 212°, whereas my amorphous aconitine is not fusible at that temperature.

The action of heat on these ammoniacal solutions is equally characteristical.

Ammoniacal solution of *crystalline aconitine* became turbid on first application of heat, the turbidity increasing with the temperature. On arriving at the boiling point the alkaloid crystallized out in well-defined microscopic crystals.

Amorphous aconitine, similarly treated, became turbid on the first application of heat, the turbidity increasing with the temperature. On arriving at the boiling-point, however, the liquid became clear, and did not become again turbid on cooling. When on arriving at maximum turbidity the heat was withdrawn from the liquid, and it was allowed to stand in the cold for some hours, the turbidity was gradually dispersed and the liquid became clear.

Crystallized pseudaconitine, under the same circumstances, gave with heat a marked turbidity, which disappeared when the liquid arrived at the boiling point. If, however, the heat were removed at the maximum of turbidity and the liquid allowed to rest, on cooling the greater part of the alkaloid was deposited in crystalline tufts, only recognizable as such by means of a ¼-in. objective.

Amorphous pseudaconitine, treated in the same manner, passed through the series of changes, with this exception, that no precipitate, and consequently no crystals were obtainable.

A strong solution of *Napellin* alkalized with ammonia, when heated to near boiling, deposits a portion of the alkaloid in globular resinoid masses.

Morson's aconitine, so treated, gave at first a turbid fluid, which on arriving at the boiling point, became nearly transparent and ultimately completely so.

Crystallized aconitine was the only one of these alkaloids that deposited crystals on the slow evaporation of its ammoniacal solution.

The difference in the degree of permanence of these solutions was very marked.

Crystallized aconitine, after twenty hours, was much diminished in strength. Ten hours later the alkaloid had entirely disappeared. The test used to ascertain this was iodohydrargyrate of potassium applied to the solution slightly acidulated.

Amorphous aconitine was much more stable, the alkaloid had not entirely disappeared after sixty hours.

Crystallized pseudaconitine was even more disposed to permanency. A lapse of nearly a week showed it little diminished in strength.

Amorphous pseudacontine proved nearly as stable.

Morson's aconitine also was very slowly decomposed. It approached in permanence the pseudaconitines. In fact, I feel disposed to think that it is pseudaconitine, with its apparent solubility increased by a large admixture of napellin. That it contains the latter alkaloid is readily ascertained by adding ammonia in slight excess to its hydrochloric solution, filtering, and then adding to the filtrate a little of the strongest solution of ammonia. A second precipitate, having the properties of napellin, is the result.

Of Napellin, in weak alkaline solution, the official liquor potassæ being used instead of ammonia, one grain dissolved in 520 grain measures of the weaker, in 383 grain measures of the stronger. The limit of the reaction in these cases is the first appearance of opalescence, which is difficult to seize. If the alkaloid be added until a decided flocculence appears, this result appears somewhat unexpectedly after

about 200 grain measures, and the flocculi subsequently disappear. This solubility test therefore is not to be relied upon, nor is it needed. Were it desired to be ascertained either the sulphate or acetate should be used, from either of which combinations the napellin is removeable by ammonia. From the muriate it is not precipitable; nor from the nitrate when moderately diluted. Solution of potash does not appear to injuriously affect the alkaloid.

The colour reactions of these alkaloids may be dismissed in a word. There are "none." As for the phosphoric acid reaction producing a blue colour, I have never succeeded in obtaining it. It is probably due to some accidental impurity, and I believe Dr. Flückiger has arrived at the same conclusion.

All these alkaloids, when boiled with solution of ammonium chloride, liberate ammonia; that is especially the case with the pseudaconitines.

The crystalline salts of crystallizable aconitine are numerous. I prepared and exhibited at the Exhibition of 1862 the sulphate, nitrate, and muriate, as well as the pure alkaloid.

No crystalline salts of pseudaconitine have I been able to prepare. Their solubility, both in water and spirit, is too great. They arrive at the state of syrup, and pass from that to a transparent glass, which when it becomes absolutely dry, cracks up into scales, which might deceive the unwary. The deposit obtained by precipitating the spiritous solution with ether is not crystalline.

The same must be said of napellin.

The true figures of the aconitine salts would need a crystallographer to describe accurately. I will therefore not attempt it. The crystals of pseudaconitine are not for a moment to be confounded with those of aconitine. They are entirely dissimilar.

A good deal might be said on the subject of names. It seems to me probable that there are in truth two series of allied alkaloids—the one furnished by *Aconitum Napellus*, the other by *Aconitum ferox*, or some other Indian aconite. Each species seems to furnish its crystallized aconitine, its amorphous aconitine, its napellin. Should my supposition be correct it is obvious that the term napellin should be abandoned. Then again why should the alkaloids of the Indian aconite be stigmatized as pseud, or false? The prefix Ind. would be better, or if the name napellin be abandoned, nepallin might without danger of confusion be applied to pseudaconitin. To any one reading the treatise of M. Patrouillard, it must be evident that he has been misled by the similarity of the names.

As for attacking in detail the battalions of mistakes that have arisen from the feebly marked characteristics of these alkaloids and mainly from the difficulty or impossibility of getting them to assume a crystalline form, I must beg to be excused a labour that after all would, it seems to me, be profitless.

The purely chemical as well as the physiological relations of these alkaloids will have to be considered at a future time by competent experimenters.

The PRESIDENT: Year after year we have been indebted to Mr. Groves for his very valuable researches; and I feel sure I express the feeling of the Conference in tendering to him our acknowledgments for his continued observations on these aconitines. We hope yet to hear from him the results of further researches on the same subject. I fear but few of us are able to discuss this subject; but there may be some who wish to ask for further information, or to make remarks respecting the paper.

Mr. WILLIAMS: I can only express the strong admiration I feel for the important researches of Mr. Groves. This is a matter which has greatly interested me for many years—I may say for no less than twenty-five years. During this period I have more than once attempted to carry out a series of researches such as those in which Mr. Groves has succeeded; but I am sorry to say that my own researches have not been perfect enough for publication. In fact, the difficulty that has always occurred to me is this: If I ever made a series of experiments on aconitine I could not repeat the experiments with the same results. There was always a difference between the results of the second research and those of the first. I could never obtain the alkaloids in a perfectly definite state. The whole subject is one of great interest and importance, and I trust that it will be kept before us, and that these researches will be continued. They are not yet complete. Chemists have to determine what is the real atomic weight of the alkaloid aconitine, and also of the various kinds which Mr. Groves has clearly proved to exist. It is obvious that it would require some quantity of the alkaloids in order to get at anything like a proper and true result, and that it would be necessary to form salts, double salts, and even substitution compounds, before we could really say what the atomic weights really are. I can only repeat the expression of my strong feeling of gratitude, as well as admiration, for the success which has attended these most important researches instituted by Mr. Groves.

Mr. GROVES: So far as pseudaconitine is concerned, I could furnish an ounce-and-a-half—enough to poison the inhabitants of Weymouth twice over. That, I think, would be quite a sufficient quantity to work upon in settling the question as to the atomic weight. As regards crystallized nitrate of aconitine, I have about fifteen grains only, which is insufficient to determine its molecular constitution. I shall be glad to hand over samples of the pseudaconitine to members of the Conference, as I am desirous that the question should be thoroughly cleared up.

(*To be continued.*)

AMERICAN PHARMACEUTICAL ASSOCIATION.

The Twenty-First Annual Session of the American Pharmaceutical Association commenced at Richmond, Virginia, on Tuesday, September 16th, under the Presidency of Professor Albert E. Ebert, of Chicago. The meeting was held in the Virginia Opera House and there were present about one hundred members.

Professor Ebert, in opening the proceedings, alluded to the fact that the British Pharmaceutical Conference was at the same time meeting at Bradford, and the Austrian Apothecaries' Association at Vienna. He announced that he had received a message of greeting from the President of the former Society, to which he had telegraphed a suitable reply.

Mr. Keiley, mayor of Richmond, was introduced to the meeting, and in an eloquent speech welcomed the Association in the name of the citizens; after which fifty-one new members were proposed and elected.

Professor Procter presented a report from the Committee on the Editorship of the Report on the Progress of Pharmacy, recommending that an officer be appointed with the title of Reporter on the Progress of Pharmacy, and an annual salary of 250 dols. The committee nominated for the new office Professor C. Lewis Diehl, of Louisville. The report was adopted.

Mr. Thomas S. Wiegand read the report of the executive committee, giving an account of the business of the Association during the year and announcing the deaths of six active and three honorary members.

The President next read a long and interesting report reviewing the operations of the officers during the past year and making suggestions as to the best means for advancing the objects of the Association. This report was referred for publication.

The session was then adjourned until the next morning at nine o'clock.

On Wednesday morning, September 17, Professor Markoe, secretary of the nominating committee, submitted a report recommending the election of the following officers for the year 1873-74: *President*, John F. Hancock

(Baltimore). *Vice-Presidents*, William Saunders (London, Ont.), John T. Buck (Jackson, Miss.), Paul Balluff (New York). *Treasurer*, C. A. Tufts. *Permanent Secretary*, John M. Maisch (Philadelphia). *Executive Committee*, T. S. Wiegand, G. Lies, Charles L. Eberle, H. J. Meninger, and John M. Maisch. The report was adopted.

The President-Elect not being in the room at the time, the first Vice-President, Mr. William Saunders, of London, Ontario, was called to the chair. Afterwards Mr. Hancock was introduced and returned thanks for his election.

The Report of the Committee on Adulteration and Sophistication, written by Dr. Charles Rice, of New York, was afterwards read and adopted, as also was the Report of the Committee on the Progress of Pharmacy.

A letter from the retiring President, Professor Albert E. Ebert, of Chicago, enclosing a sum of five hundred dollars, was read. It expressed the writer's wish that the money should be properly invested by the executive committee and the annual interest therefrom appropriated for conferring a suitable prize for the best essay or written contribution containing an original investigation of a medicinal substance, or information respecting improved methods for the preparation of chemical or pharmaceutical products. A vote of thanks was presented to Professor Ebert for his gift and it was resolved that it should be accepted and called the "Ebert Fund," and the prize given from it should be called the "Ebert Prize."

Professor Diehl, in behalf of the committee on centennial celebration, presented a report detailing a full plan for a congress of pharmacists of all nations at Philadelphia during the centennial celebration, and recommending that the meeting of the Association in 1875 should be held in Boston, in order to have a large attendance of members, and to prepare for the centennial. The report was adopted.

The following papers were then read :—

On the Preparation of a Permanently Flexible Gelatine Plaster, prepared by some addition to the isinglass used, which will prevent the tendency of the plaster to curl and irritate the skin mechanically : By Henry F. Rittenhouse, of Philadelphia, in reply to Query 1.

On the Easiest Plan of Making "Sapo Viridis" vel "Sapo Mollis" from Olive Oil and Liq. Potassæ ; By P. Fred Lehlbach, of New York, in reply to Query 7.

Dr. Squibb read papers on Alcohol and Distilled Spirits, Rhubarb, and another on Physician's Pocket-cases.

Professor Markoe read the Report of the Committee on Pharmacopœia.

P. W. Bedford, of New York, read a paper in reply to Query 10, in which he showed that balsam of tolu cannot be rendered emulsionizable like copaiba.

On the Merit of Petroleum Benzine as a Solvent for the Extraction of Oleo-resinous Drugs like Buchu, Chenopodium, etc. : By Joseph P. Remington, of Philadelphia, in reply to Query 12.

On the Proportion of Sugar and Honey in the Officinal Process for Pil. Ferri Carbonatis : By Edward D. Chipman, of Philadelphia, in reply to Query 15.

On the Actual Value of Orange-coloured Window Glass as a means of Preventing the Chemical Action of Light on Volatile Oils : By William Procter, junr., of Philadelphia, in reply to Query 18.

On the Material and Workmanship of Cheap Ointment Boxes : By Mr. J. P. Remington, Professor Markoe and others, in reply to Query 20.

On the Correct Time to Collect the Leaves of Biennial Plants like Lobelia, Hyoscyamus, and Digitalis : By Professor J. M. Maisch, of Philadephia, in reply to Query 21.

On the Method of Preparing Cucumber Ointment : By William Procter, junr., of Philadelphia, in reply to Query 24.

On the Improvement of Graduated Measures by which Greater Uniformity can be Attained : By Dr. W. H. Pile, of Philadelphia, in reply to Query 26.

On Labelling Shop-furniture, Stock-bottles, and Vials, in view of permanence, regularity, and safety, and on a Label-case to faciltate the finding of the same : By George H. Schafer, Fort Madison, Iowa, in reply to Query 28.

Mr. George W. Kennedy, of Pottsville, Pennsylvania, read a paper on the Presence of Berberina in the Root of *Frazera Walteri*.

A letter from the Medical Society of Virginia was read, expressing sympathy with the objects of the Association.

At 7 p.m. the session was adjourned until Thursday morning.

In the basement of the building there was an exhibition of pharmaceutical objects. Amongst those which appeared to attract most attention were pyramids of morphine (valued at 1400 dollars) and quinine (valued at 500 dollars), exhibited by Power and Weightman of Philadelphia. There were also sugar-coated pills, "that children cry for, and would swallow by the dozen."

The third day's proceedings were commenced by the presentation of a report on the President's address, and Louisville, Kentucky, was fixed upon as the place, and the second Tuesday of September, 1874, as the time, for the next annual meeting of the Association. Mr. Emil Schafer, of Louisville, being elected local secretary.

In the course of the sitting Dr. Squibb stated that the time of the Association was usually greatly encroached upon by propositions on behalf of their hosts to participate in excursions, feasts, and other entertainments of the whole body. He thought a resolution should be passed declining all such for future meetings.

Professor Markoe thought that all discussion of this subject was time lost; that the majority of the Association always had been and always would be in favour of accepting whatever hospitalities might be offered. He would suggest that the subject be dropped. His suggestion was concurred in.

Prof. J. M. Maisch, of Philadelphia, submitted the report of the committee on legislation, showing that attempts to improve the pharmacy laws have been made in several States, and have generally proved beneficial and successful.

Professor Bedford submitted an elaborate and able report upon the condition of the drug market during the past year.

Prof. Ben. Lillard, of Nashville, Tennessee, read a paper on the subject of homœopathic pharmacy.

Dr. S. S. Garrigues, of Michigan, submitted samples of American gall-nuts from oak trees.

Dr. Squibb said that gall-nuts from the oak as well as from the sumac tree had been for many years used by Dr. Smith in the production of gallic acid.

Papers were also read by Dr. Squibb on a General Apparatus-stand, Upright Condenser, Pinch-cock, and Burette-stand, with illustrations, and on Ergot and its Preparations.

Professor William Procter, jun., of Philadelphia, read a paper on the constantly-recurring query of beginners, who are confused by the mass of books presented to them as the source of knowledge they need.

A paper on the Best Means of Protecting Sound Drugs from the Ravages of Insects, and on the Means of Destroying them when already in the Drugs, was presented by Professor William Saunders, of London, Ontario.

Henry J. Rose, of Toronto, Canada, read a paper on the Purity of Commercial Tartaric Acid, and the Normal Percentage of Moisture.

On motion, it was resolved that all incorporated pharmaceutical colleges that have not done so be requested to nominate members to be added to the Committee on Pharmacopœia.

After the appointment of committees, the Association adjourned until Friday.

Upon the adjournment of the Association, the members, accompanied by the Mayor, members of the City Council and the press, and other guests invited by the

druggists of the city, steamed down the river. As the boat neared Dutch Gap Canal, a handsome collation, spread under the auspices of the Reception Committee, was partaken of.

The time upon the return from Dutch Gap was mostly occupied by speeches, but an hour or more was spent in listening to some songs splendidly sung by a quartette of Richmond amateurs organized on the spot. The barge arrived at the wharf about half past eight o'clock in the evening, and the excursionists found omnibuses and carriages ready to take them to their hotels or homes. Not one incident occurred to mar the happiness of the occasion. Not a word was uttered that grated harshly upon either Northern or Southern ears, though the war was constantly talked about, as the boat passed by the battle-grounds of some of the greatest struggles of the late war.

The fourth day's proceedings were commenced by the Report of the Committee on the Exhibition, made through Dr. A. W. Miller, of Philadelphia.

Papers, in reply to queries, were read by J. F. Judge, of Cincinnati, Ohio; Dr. E. H. Squibb, Charles F. Fredighe, of Chicago; Professor Maisch; and B. F. Stacy, of Charlestown, Massachusetts; and a volunteer paper on Physicians and Apothecaries, by A. T. Moith, of Fishkill, New York, was read and referred.

Professor Diehl stated that the number of queries responded to, and the number of volunteer papers offered at the present session of the Association, was thirty-six. Professor Diehl also read a list of queries that had been accepted, to be replied to at the next meeting of the Association.

Professor Maisch stated that his attention had been called to the fraudulent substitution of muriate of cinchonia for sulphate of quinia. The fraud is principally practised upon the southern interior towns. The former is worth about fifty cents an ounce, and the latter about 2·50 dollars.

A vote was passed of hearty thanks to the pharmaceutists and citizens of Richmond for the cordiality with which the Association had been received on its first visit to the South. Thanks were also tendered to the Richmond press for their faithful reports of the proceedings, Dr. Squibb remarking, in reference to this point, that although reporting correctly the proceedings of the Association was a very difficult task, he had never during twenty years that he had attended the sessions of the Association, seen better or more accurate newspaper accounts of it published.

The Association then adjourned to meet at Louisville, Kentucky, on the Second Tuesday in September of next year.

Some of the members will go on excursions to Mount Vernon and the Greenbrier White Sulphur Springs.

Provincial Transactions.

NORTHAMPTON PHARMACEUTICAL ASSOCIATION.

On September 15th a meeting was held for the purpose of making the necessary arrangements as to the classes for the winter session, and to fix a night for the election of the new Council. Mr. C. Hester (President) said he trusted that the members would make frequent and attentive visits to the classes, and this would benefit themselves and make the coming session equally successful with its predecessors.

The Secretary, Mr. G. C. Druce, announced donations of £1 from Mr. Abington, of Ringstead; some materia medica specimens from Messrs. Horners and Sons; and French prescriptions from Mr. Sandall. He moved that the PHARMACEUTICAL JOURNALS should be bound, and that Ganot's 'Physics' and Proctor's 'Pharmacy' be purchased.

After discussion, it was arranged that the classes should meet every Monday, Friday, and alternate Wednesday, from 8.30 to 10 p.m.

The Journals were ordered to be bound, and the meeting adjourned. On Wednesday the following Council was elected:—Mr. H. J. Masters, President; Mr. G. C. Druce, Secretary and Treasurer; Mr. O. Wallis, Mr. J. Moore.

On Friday a meeting was held, Mr. H. J. Masters in the chair, when the Secretary, after formal business, read a paper on the indigenous Ranunculaceæ—descriptive of their properties, uses, and peculiarities—illustrating his paper by dried specimens of the different plants mentioned.

Mr. Evans proposed a vote of thanks to Mr. Druce, which was seconded by Mr. Masters, and carried unanimously.

It is a source of pleasure to the Council that, except those who have not passed the Preliminary, all in the town have joined the Association.

ROCHDALE CHEMISTS' ASSOCIATION.

The committee of this association presented its first annual report on Wednesday, October 1st, 1873.

After congratulating the members on the satisfactory state of the association, both as regards the number of subscribers and the balance in the hands of the treasurer, it drew attention to the many questions which are likely to arise and demand attention and united action. It appealed to the younger members of the trade not to allow the valuable specimens of materia medica to remain unused.

With the election of officers for the ensuing session the proceedings terminated.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The first General Meeting of the Association for Session 1873-74 was held in Anderson's University, on Wednesday, October 1st, at 9 p.m. Mr. John Currie, President, in the chair.

The President gave a short address on education connected with the profession, touching upon the profession now as compared with what it was thirty years ago. He urged assistants and apprentices to be assiduous in their duties not only to their employers, but in connection with their studies. He was not in favour of evening classes, and thought that employers should be induced to allow their assistants to have an hour or two in the morning, as a man who had been ten or twelve hours at work was not in a fit state for study. Some conversation as to the formation of a library afterwards took place. Several new members were elected, and the meeting dissolved.

Notes and Queries.

[355]. LIME JUICE AND GLYCERINE.—I think *X. Y. Z.* will find this a very good form for a preparation that will not separate upon standing:—

℞	Sol. Boracis	(℈ j to ℥ j) ℥ iv. ℥ vj.
	Ol. Amygd. Dulc.	℥ xxvj.
	Liq. Potassæ	℥ iij.
	Ess. Limonis	℥ j.
	Ol. Citronell.	♏ xx.

Place the Sol. Boracis in a Qt. Bl., then add gradually the Ol. Amygd., next the Liq. Potassæ, and lastly the perfume, taking care to shake well after each addition.—W. W.

Local Secretaries and the Preliminary Examinations.

Sir,—I am spending the morning, as Local Secretary, in charge of students undergoing the Preliminary examination. The opportunity of quietly reading your report of the last meeting of Council is therefore welcome, and its discussions possess more than ordinary interest for myself and those Local Secretaries who are called upon by the Society to serve it in this way. Perhaps it is a little depressing to read in a public print that the Board of Examiners, on whose behalf we are acting, regard such service with a feeling very different from favourable appreciation, and that we are taking part in doing what is much worse than nothing. It may also seem a trifle unkind that our obscurity should be so publicly paraded, as it was, by a distinguished Councillor, who spoke of the "Local Secretaries, the great mass of whom were totally unknown to all the members of the Council. There might be one here and there who was known, but he should like to have the whole list of names read, and see how much the Council really knew of the great majority of them."

But the energetic policy of some members of the Council dispels any sentimental feeling, and the attempt to settle the matter by writing *sus : per coll :* over the list of Local Secretaries suggests that a trial should precede and not follow the verdict.

I have hitherto avoided entering into any public correspondence upon the proposal to abolish local centres for the Preliminary examinations after December 31st, 1874. It seemed preferable to communicate to the Board of Examiners my opinions as to improvements in the system of conducting the examinations, and I did this some months since. But as the matter has been pressed forward to the administrative stage, public discussion is forced upon us. Upon one point there must be no misunderstanding. As to the *integrity and absolute identity of conditions of examination*, the advocates of provincial centres are not a whit behind the most ardent centralist. Besides sharing every consideration influencing their opponents as members of the Society, their personal honour is at stake. Any suggestion that the bodies whose certificates are received in lieu of examination have taken the work out of our hands, or will speedily do so, is quite futile. To prove this, it is only necessary to observe how small a percentage of candidates enter by this gate. Local centres of examination have become incorporated in the system of modern education, and their convenience and equity are too well understood to permit them to be lightly abolished. That which has been practised for many years by the three English Universities and the Science and Art Department, and applied to a score of subjects of various grades, is not to be denied to chemists and druggists, or at least not on the present imputed ground of the impossibility of getting assessors possessed of common sense and common honesty. The Incorporated Law Society regularly holds one of its examinations in certain provincial centres, a fact less widely known than those referred to above.

It is to be remembered that before the Pharmacy Act of 1868 was obtained, the Society was committed to the favourable regard of provincial centres for the higher examinations, although it was well known how carefully such a scheme must be drawn. Surely the possession of power will not now justify it in disregard of all individual convenience about the Preliminary examinations.

But one cannot avoid asking oneself whether a serious question of privilege has not arisen, and who are the bold men who would set their wishes against all provincial feeling.

Two or three London members have committed themselves to this sweeping proposal, but no country representative has been found to defend it; on the contrary, the representatives of popular opinion have condemned it unhesitatingly. Has the courtesy of consultation with any country members of the Society been shown? So far as it is known, it certainly has not. We must take the proposal as being serious enough, and recognize the fact that two opposite ideas have met, and that one of them will have to give way. These are the rival ideas of bureaucratic centralization on the one hand, and that of local responsibility and decentralization on the other hand. The system of local centres of examination has not been found perfect—granted—therefore sweep it away! Precisely the same reason exists for destroying the municipal institutions of England, which in spite of much bungling serve the country better than many a centralized department, and without a tithe of its jobbery.

It is perhaps as well that the question is to be referred to a conference between the General Purposes Committee and a deputation from the Board of Examiners, although the more logical position was taken by the large minority who refused to recognize a *primâ facie* case for the action proposed.

But let the Board of Examiners be boldly told that it cannot maintain the somewhat irresponsible position of prompting members of Council to such motions. Let it be told that it has set up a system of examination which is perfectly free from suspicion when in the hands of many other bodies of men, but from their lax want of direction, and apparently from ignorance of men and things as found in the provinces, this system, as applied to chemists and druggists, has been faulty. How can charges of "neglecting candidates to serve customers" be brought against secretaries who conduct the examinations in public rooms, as is the case in our chief towns? Who is to blame for irregularities when the examination questions have for a long while been sent without any scrap of directions as to the mode of conducting the examination? Whose business is it to lay down clear and definite rules as to the necessary arrangements—the room, the space between candidates, and, above all, to decide what towns should become recognized centres? Why should not the Board appoint one or two assessors to visit, without previous notice, any examination in progress? That grouping of the smaller towns around centres is reasonable would be granted by nearly all, and although the Board would find a little trouble in such mapping out, this would soon be accomplished. Finally, let the Board be told that the record is changed, and that it is not now in the position of accuser, but stands at the bar of public opinion, charged with responsibility for any irregularities that have happened, and that if it longer fails to reform these, it will lay itself open to the further charge of permitting their existence in order that they may serve as arguments for demolishing the present system.

But one thing is *not* a matter for reference to a committee, like questions of detail, and that is the great principle of centralization or the opposite. The Society itself will take care of great principles, and a matter involving the privileges of four-fifths of its members would be a very intelligible one upon which to take their opinion at an election of Council. There is little doubt that the result would confirm the wisdom of the Society's founders, when they established the Pharmaceutical Society—not of a single city, however important, but—of Great Britain.

Unusual Doses in Prescriptions.

Sir,—There appears to be a general consent upon two points in connection with the late inquest at Ramsgate, viz. :—

1st. That Mr. Fisher was right in refusing to dispense an extreme dose without express assurance of the prescriber's intention.

2nd. That it would be for the convenience of prescribers, dispensers, and patients, if there was some recognized mode by which prescribers might indicate a conscious purpose when extreme doses are ordered.

But it seems to be almost tacitly admitted that if *the prescriber's intention* has been sufficiently ascertained nothing remains for the dispenser but the duty of implicit obedience—an admission most injurious to the self-respect of our calling; and one of your correspondents quotes a

prescription* as only requiring to be thus authenticated to ensure its being dispensed as a matter of course. I can only say that I should refuse to dispense it, even if it were authenticated by the corporate seal of the College of Physicians, for I know of no ethics which permits a man to shift the responsibility of his acts upon another, and I acknowledge no etiquette which compels me to become consciously party to homicide.

I think there has been some little confusion manifested in the correspondence which has been going on as to the proper province of technical or professional etiquette on the one hand, and moral responsibility on the other; and it is to protest against the exaltation of artificial ethics above the solemn obligations of the decalogue that I trouble you with these observations.

Dr. Collis Browne is reported to have given ink to some extreme opinions upon this subject. If this is the gentleman known as manufacturer of chlorodyne, he is probably too much absorbed in pharmaceutical operations to incur much risk from being taken at his word in respect of the "strict obedience of physicians' orders"; but I will tell him what happened years ago to a physician who was no wiser than himself, within a mile of the spot where I now write.

The doctor roughly chid a chemist for some departure from the letter of his prescription, and refused to accept the explanation that it was done to carry out his supposed intention. He was indiscreet enough to say that it was the chemist's business to fulfil his directions, right or wrong, and that the responsibility of error rested with him alone. Some time after, the doctor prescribed in error a poisonous dose of corrosive sublimate.† The chemist knew it to be a poisonous dose, but he supplied it on the doctor's responsibility, sending him, however, a note to that effect. The note came to hand too late, the medicine was swallowed, and the patient died.

Now, it does not concern us greatly to know what Dr. Collis Browne might say to this, but it might concern us very nearly to know what a coroner's jury would say; whether they would ascribe the manslaughter which was undoubtedly committed to the doctor or the chemist. Probably the ends of justice would be met by hanging both.

RICHARD W. GILES.

Sir,—In reference to the case of Mr. Fisher, of Ramsgate, allow me to say that a similar case came under my notice some time since, in which a medical man of this town prescribed for a patient suffering from *delirium tremens* as under:—

℞

Tinct. Digital . . . . ℥j
Aq. Menth. pip. ad. . . ℥ij

M. Half to be taken at once and the remainder in four hours if he does not sleep.

I ascertained that this quantity was intended and the prescription was of course dispensed.

As an instance of the *in*fallibility of medical men I may mention the following:—

℞

Hyd. Bichlorid. . . gr. vj

Ft. pulv. statim sumend.

I need scarcely say that my pen passed through the "Bi" and the prescription was dispensed without a remark to the patient.

Cheltenham, Sept. 7th, 1873. X. Y. Z.

*** We would suggest that in any future discussion of the subject of unusual doses in prescriptions, the principle recommended at the Conference meeting should be adopted, and that it should be dealt with as an abstract question, without reference to any past occurrences affecting individuals.—ED. PH. JOURN.

---

* ℞

Ext. Belladonn. . . . . gr. 80
Aquæ . . . . . 4 oz.
A table-spoonful three times a day.

—PH. JOURN., p. 200.

N.B.—I have known half a grain (single dose) produce alarming poisoning symptoms.—R. W. G.

† See similar case quoted, PH. JOURN., p. 199.

ALLEGED DISPENSING MISDEMEANOUR.

Sir,—Few things are more easy than for an individual "whose name does not transpire," to appear before a magistrate, and bring a wholesale charge either of criminal carelessness or of wanton wickedness against a single person or an entire body of professional men. Such a case occurred the other day before Mr. Woolrych, when a "medical gentleman," in the garb of the anonymous, brought a charge against a chemist, practising at Hammersmith, of substituting a deleterious drug not mentioned in the prescription for a drug of a harmless kind that was mentioned, and adding, as a matter of course, "*that it was the practice of chemists, when they had not the expensive articles required, to use other things in their place.*"

With regard to the first part of the indictment, I have only to suggest that the unfortunate "chemist" labouring under it, should, if he is in a position to do so, come forward and discarding the anonymous, give the lie direct to his accuser. I can scarcely imagine an individual, and a member of a liberal profession, calmly resting under so cruel a calumny, and not coming forward to avenge himself of the insult.

With regard to the latter portion of the charge (the words in italics), it appears to me that the Pharmaceutical Society is bound in the interests of its multitudinous members, for the sake of the honour due to its professions, and, more than all, on behalf of the public, whose protector it assumes itself to be, to demand the name of that "Medical Gentleman" who, under the guise of an anonymous accuser, has dared to come forward, and in a court of justice has brought so sweeping and cruel a libel against a class of men who, one and all, are totally incapable of resorting to the shameful practice he has so recklessly imputed to them.

I say it advisedly, that the "chemist" who could resort to such a practice, would be scouted from the profession, of that fact the "Medical Gentleman" is no doubt perfectly aware.

Let, then, the Society obtain and publish the name of this anonymous accuser, and let it be held up to scorn and reprobation, and, if possible, let its unenviable possessor be brought under the condign punishment of the law.

JAMES A. PROVOST.

94, *Terminus Road, Eastbourne,*
2nd October, 1873.

*** We have received from the medical man concerned in the case referred to in the foregoing a letter in which he gives an account of the circumstances which induced him to make application to the police-court magistrate. Unfortunately, we cannot from want of space publish his letter this week, but will do so in our next issue.—ED. PH. JOURN.

"*Iris.*"—(1) *Eupatorium cannabinum.* (2) *Inula dysenterica.* (3) Probably *Daucus Carota.* All Umbelliferous plants should have fruit and leaf on the specimens sent. (4) *Centaurea nigra.* (5) *Calamintha officinalis.* (6) Bentley's Handbook of the British Flora: Illustrated.

Mr. Alexander Kinninmont is thanked for his communication.

"*Juvenis*" (Newton,)—See Mr. D. Hanbury's Paper on Pareira Brava, *ante*, pp. 81, 102.

F. A.—Rub the oxide of zinc with the glycerine, adding gradually the oil, afterwards the water, and lastly, the spirit of rosemary. The oil should be free from rancidity, else the danger you mention will be greater.

G.—The plant is probably *Allium vineale;* but it is impossible to say with certainty without seeing the flower.

B. B.—(1) The name you mention is not on the Register of Pharmaceutical Chemists, nor on that of Chemists and Druggists. (2) In our opinion we should say there is no right to trade as indicated by your enclosure. (3) You should communicate with the Registrar on the subject.

Williamson, Professor A. F. Marreco, Dr. Scoffern, Dr. J. M. Crombie, Mrs. L. Stocks, the Editor of the *Garden*, Dr. W. H. Griffiths.

CHINESE RHUBARB.

The following notes on Chinese Rhubarb are from a recent report on the trade of Hankow. The writer first refers to the paragraph in Colonel Yule's 'History of Marco Polo's Travels,' where it is said that "over all the mountains of this province"—meaning Tangut, the modern Kansuh—"rhubarb is found in great abundance, and thither merchants come to buy it, and carry it thence all over the world." The best rhubarb it appears is still produced in Kansuh, but one of the principal marts for the sale of the drug is Sanyüan, in Shensi, in which province also rhubarb is grown to a considerable extent. The cultivation in both provinces has, however, been seriously affected by the Mohammedan rebellion. Much of the rhubarb which comes hither is from Szechuan. It is generally of very common quality, and is quoted in the market at from 5 to 8 taels per picul; the kind known as Shensi being usually quoted at from 15 to 50 taels. A Chinese informant says that the moist heat of the province of Szechuan is injurious to the preparation of the root. In both provinces—Kansuh and Szechuan—the rhubarb is grown in mountainous districts. The plants, when grown, are cut down and thrown in heaps, they are then taken to the farmer's house, where the roots are pared or scraped. In Kansuh, the roots are then tied together and hung up from poles covered with matting, but in Szechuan the roots are obliged to be dried in the sun, and, as a consequence, they are not, like those of Kansuh, of firm substance throughout. The following information on the quality and prices of the different kinds of Chinese rhubarb was furnished by a Hankow merchant :—

1. Province of Kansuh, Sining; average of value, say 80 taels.
2. Same province, Liang-chow, very nearly as good; 75 taels.
3. Szechuan, Mien-chow, 30 per cent. worse; 55 taels.
4. Kansuh, Kiaichow, 50 per cent. worse.
5. Kansuh and north-west border of Szechuan, 60 per cent. worse; if well made, 40 taels; if common, 20 taels.
6. Szechuan, Kuan Hien, 60 per cent. worse; better quality, 30 taels; common, 20 taels.
7. The very common, at 5 to 8 taels per picul, comes, as has been said, from Szechuan.

Rhubarb does not come to Hankow from Sining and Liang-chow at present. Very little comes from Mien-chow; the other districts supply the requirements of the market.

The value of the rhubarb exported in 1872 was about £20,600; namely, Shensi, 2267 piculs, value 61,931 taels, and Szechuan, 899 piculs, with a value of 6048 taels.

THE ANNUAL SUPPER OF THE MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION.

At the conclusion of the annual meeting of the above Society (see p. 305) those present adjourned to the Blackfriars Hotel, where about forty members and friends sat down to supper. After the removal of the cloth the usual loyal toasts were proposed by the chairman, Mr. Brown, and drunk with becoming loyalty.

Mr. G. S. Woolley then proposed, "The Pharmaceutical Society of Great Britain." He alluded to the early days of the Society,—to the efforts of many distinguished men, especially Jacob Bell, "of glorious memory," to induce the trade to unite for purposes of education and in the endeavour to raise their calling above the level of a merely commercial occupation. This union being effected and efforts in the direction of improved education continued, the result was the incorporation of the Society by Royal Charter; the completion of the splendid building, now the home of the Society, with every means and appliance at command for the education of those able and willing to avail themselves of them; and finally the Pharmacy Act of 1868, which although not perfect, still owed its many advantages and the smallness of the number of its defects to the untiring energy and devotion of the President and Council who were at that time at the head of affairs at Bloomsbury Square. To this union of the leading men in the trade pharmacists owed the position held to-day—a position immensely above that held thirty years ago, and standing firmly upon it as they did, it depended solely on their own exertions whether or not they proved themselves worthy of a still higher place amongst the educated professions.

Mr. W. S. Brown in responding said: I presume that as by the favour of my fellow-members of the Pharmaceutical Society I hold a position on the Council of that body I am called on to reply to this toast rather than our esteemed friend Mr. Wilkinson, the Local Secretary. Mr. Woolley has referred in feeling and appropriate terms to the honoured names of many of the founders and early friends of the Pharmaceutical Society. Thirty years since, when an attempt at legislative interference with our privileges called together a meeting in London, the wise judgment of some, and foremost the late Jacob Bell, saw that after accomplishing the first object of their association the opportunity to initiate a movement of a more enduring character presented itself, and they laid the foundation on which has arisen the noble institution which is, and ought to be, a gratification to the whole body of chemists in the kingdom. All honour to those who thus laboured, and the results of whose efforts we are reaping in improved position and in the development of education. The Pharmaceutical Society has some of its early friends still in its ranks, and many good and true men have risen up and are now connected with it. We look with satisfaction to the central institution, with its excellent equipment for teaching, and hope that our provincial Association may keep pace with the growing importance of the public requirements. The Pharmaceutical Society has a high duty to perform, and its recognition by the State and its increasing influence throughout this and other countries promises a bright future. The approval and cordial co-operation of the members must ever strengthen and sustain the governing body; and the good wishes of this assembly, as expressed in the toast, I have much pleasure, speaking on behalf of my fellow-members, and in the name of our much respected President, in gratefully acknowledging.

Mr. J. T. Slugg, in proposing "The Medical Profession," said he was glad to know that they were honoured by the presence of several members of that profession. This was an indication of two things; first, of the estimation in which they held that profession, or they would not have invited them; secondly, of the estimation in which the profession held pharmacists, or they would not have accepted the invitation. He ever regarded the medical profession as a very high and a very holy one. It had been said that in the world were two large heaps, one of misery and one of happiness; and it was every man's duty to diminish the heap of misery and augment the amount of happiness. Now the sole occupation of a medical man was to do this. Hence, he said, it was a high and a holy calling. Having resided in Manchester for nearly forty-five years, he was sufficiently acquainted with its medical men, past and present, to be able to say that in no provincial centre did the members of that profession devote themselves to their duties with greater zeal or ability than in Manchester. He had pleasure in proposing the toast of "The Medical Profession," coupled with the names of Dr. John Tatham, Medical Officer of Health for Salford, and of Dr. Brierly.

Dr. Tatham expressed the pleasure it gave him to be

present, and thanked the company for the hearty reception they had given to the toast.

Dr. Brierly also responded.

Mr. J. Blyton proposed "Success to the Manchester Chemists and Druggists' Association." He said that he felt quite unable to do justice to a toast of so much importance as that which the President had entrusted to him. Fortunately, it was a toast in which they were all interested, and it would not require any words of his to commend it to the cordial acceptance of that meeting. Their presence there, and the heartiness of their proceedings, showed the interest they felt in the success of this energetic and prosperous Association. He had been familiar with chemists' associations in various parts of the country for twenty-five years, but they were often societies established principally for *trade* purposes—such as regulating prices, the hours of closing, and other matters of interest to the trade. They owed it to the enlightened public spirit of the Manchester Chemists' Association, led by their excellent President, Mr. Brown, to have marked a great advance upon this old purpose of a chemists' association. The Manchester Society was organized and kept up principally as "a school of pharmacy," and its object was to teach the young men and apprentices the scientific part of their business—an advantage which he hoped the rising generation of chemists and druggists in the neighbourhood would continue to avail themselves of. He felt that not only Lancashire but the whole country ought to be proud of this Association, for the worthy aims and noble purposes it had set before it. Mr. Woolley had given them an interesting account of the rise and progress of the Pharmaceutical Society's School in London. Although this local Association was not officially connected with the parent society, he felt that it ought almost to be ranked with it, or at any rate be looked upon as an important adjunct to it. Its objects were the same, viz., to provide a sound technical education for the rising generation of pharmacists, and to send forth into the world a body of men in every way qualified for the high and responsible duties that they might be called upon to perform, in the laboratory as well as in the shop. He felt that an association with such aims deserved success, and he had great pleasure in proposing the toast "Success to the Manchester Chemists and Druggists' Association."

Mr. W. Wilkinson (Vice-President) responded. He said he did not anticipate being called upon to reply to this toast, and felt quite unable to do justice to the subject. He had always taken great interest in the prosperity of the Association, and was glad to think that it was in a fairly satisfactory condition, and was to a great extent fulfilling the object for which it was established, namely, that of helping apprentices and assistants to acquire the knowledge required to pass the Pharmaceutical Examinations. He thought he might say that the classes had been most successful. He wished the same could be said of the monthly meetings, and of the interest the employers took in the Society. Like many similar associations, they started with a goodly number of members, and a considerable amount of enthusiasm, but in a year or two subscriptions began to fall off; some could not, or would not, attend the meetings, and therefore declined to renew their subscriptions; some did not see what they got for their money; others did not see the good of the Society; and all sorts of reasons were given to avoid paying the subscription. Now he thought this arose from a mistaken notion as to the objects and purpose of the Association. He took it that the Association was *not* formed for their personal benefit, or for anything that they were to get by it, but to supply the means whereby their assistants and apprentices might acquire the knowledge to enable them to pass the examinations required by law. He believed every one would admit that it is the duty of those who take apprentices to teach them what is needed, or at any rate, see that they are taught. Now, for many reasons, very few of them were able to do this themselves, and he thought it the interest as well as the duty of every one who had an apprentice to support an Association which did for him what he could not do, or do so well, himself. The report told them that they had that year spent £20 more than their income, and though they had a balance in hand from previous years that would soon be exhausted unless some of their old friends renewed their subscriptions or new members joined. The principal part of the work devolved on a few members, but it could not be carried on without funds, and those who gave their time to the affairs of the institution should not be expected to find *all* the money too.

Mr. Siebold, in proposing "The British Pharmaceutical Conference," said he could not but think it unfortunate that so important a toast as that of the British Pharmaceutical Conference had not been entrusted to a better speaker than himself, but if they would kindly pardon his shortcomings he would withdraw the word "unfortunate" and say that he was most happy to propose it, and that of all the toasts that had been drunk that night it was precisely the one he should have selected if he had had the choice. They were well aware that the great object of the Conference was the advancement of pharmacy, by stimulating its members, and through them, the members of the whole profession, to scientific activity. It had not been aided in its educational efforts by Acts of Parliament or compulsory measures of any kind, and its influence might therefore not have been so widely felt as that of the Pharmaceutical Society, but it had told, and was telling with ever-increasing effect, on those who have a genuine desire for knowledge for its own sake, and who require but a good example to rouse their own energy. If they bore in mind the amount of useful work already done, and how the number of members had increased from 21 to 2000 within ten years, they could not resist the conviction that the British Pharmaceutical Conference would exercise an important and most beneficial influence on the future of pharmacy. Nothing was so sure to raise pharmacists from their present position to a higher rank in its social scale as their more general participation in scientific pursuits. Original research must not be looked upon as the calling of a gifted few, but as the duty of everybody who had it in his power to contribute a share, however small it might be, to the great store of knowledge; and should their efforts not be successful they would at least be conscious of having honestly striven to serve a noble cause. He need not remind gentlemen of the encouraging and stimulating effect which the yearly meetings of the Conference must have upon its present and future members. Pharmacy would ultimately, and let them hope before very long, attain that high and honourable position which it so justly deserved, and he felt sure that that result will be greatly due to the efforts of the body whose health he then had the honour of proposing. He had the utmost pleasure in coupling with the toast the name of Mr. Benger, one of the general secretaries of the Conference.

Mr. Benger, in responding, briefly referred to the history and aims of the Conference. Alluding to the recent meeting at Bradford, he said that in spite of the efforts of hotel proprietors to keep people away, it had been a decided success, regarded either from a social or scientific point of view. The hospitality of local members had been unbounded. No one present would be surprised to hear that amongst the most important papers read at the meeting were the contributions of Mr. Louis Siebold, a gentleman whose services in connection with the Manchester School of Pharmacy had been inestimable. The work of the Conference was of course on a comparatively humble scale, but it was a cheering thought, as Herbert Spencer had said, that, throughout the universe, the grandest results had been brought about by the slow accumulation of minute actions. This should encourage all to feel that however little they could do, that little was worth the doing.

"The Manchester Chemists' Assistants' Association" was proposed by Mr. Hermann Woolley, and replied to by Mr. Lane. "The Visitors" and other toasts followed, and a very agreeable evening was spent.

The Pharmaceutical Journal.

SATURDAY, OCTOBER 18, 1873.

Communications for this Journal, and books for review, etc.' should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE ALLEGED DISPENSING MISDEMEANOUR.

THE letter which we publish this week in reference to the case of incorrect dispensing reported in several of the daily papers a fortnight since, and commented upon by two correspondents in this Journal, will serve to give some idea of the facts of the case. As the statement is *ex parte*, we purposely abstain from giving the name of the druggist implicated, especially since there seems to be a prospect of further legal action in the matter. It will not, however, be out of place to express our satisfaction at Dr. SCOFFERN'S disclaimer of that general condemnation of the practice of dispensing druggists which was attributed to him in several newspaper reports of his application to the Hammersmith Police Magistrate. He could scarcely have done otherwise than disclaim a statement so unfounded and slanderous, but, without attempting to enter into the merits of the case one way or the other, we cannot avoid thinking that when the report appeared in the papers Dr. SCOFFERN might reasonably have taken some pains to contradict it at once. His explanation of the apparently anonymous application to the police magistrate is certainly feasible, but when he saw himself made the authority for such a grave accusation of a respectable body of men, the least he could have done would have been to correct the error of the reporters. In that respect, however, his sense of justice has been but tardily exercised, and it was not apparently until the *Daily Telegraph* criticised the "occult" medical gentleman that he was moved to offer any explanation of his part in the affair.

Our contemporary, the *Daily Telegraph*, has earned the thanks of the trade by the manner in which it has come forward to defend them from the imputation of tampering with prescriptions entrusted to their care. It is satisfactory to find a general paper appreciating the qualifications and trustworthiness of druggists, and it is encouraging to find such a public recognition of their services as is shown by the sensible and well-timed remarks of our contemporary.

As regards the mitigated form of Dr. SCOFFERN'S accusation, that it is the practice of certain druggists to substitute one ingredient for another in dispensing prescriptions, or leaving it out wholly when the thing prescribed is a little expensive or out of the way, we must, with all due respect to Dr. SCOFFERN, confess to some considerable incredulity as to this being really the case. But we are as certain that the commission of such a misdemeanour would be most stringently condemned by the great majority of the trade, as we are that no respectable member of our body would in the slightest degree lay himself open to the charge of having committed such a breach of faith.

FLOWERING OF JALAP PLANTS IN FRANCE.

IN a recent number of the *Revue Scientifique*, Professor BAILLON states that there has been an abundant flowering of the jalap plants growing in the garden of the Faculty of Medicine at Paris. Both jalap and scammony have frequently been cultivated in botanic gardens, but have rarely flowered. The present occurrence has allowed of the verification of the fact that the jalap plant belongs to a species of the genus *Exogonium*, for its corollas are remarkable for a limb perpendicular to the axis of a very long and narrow tube, and its anthers are exserted. Professor BAILLON considers that the specific name should be *E. jalappa;* because the plant was first designated under the name *Ipomœa jalappa*, by the American botanist NUTTALL, whilst the epithet, "*purga*," now generally employed, was later by several months. It should be remembered, however, that the plant differs entirely from the *Convolvulus jalappa*, which does not produce the true tubercular jalap used in medicine, but an enormous root, not employed in Europe, and much less active.

The tubercles of the true jalap grown at Paris have been well developed, having attained the size of a small turnip. It has thus been possible to trace their growth, and to ascertain their true origin. They are produced upon subterranean roots in the form of slender cords that very much resemble the so-called roots of couch-grass. Here and there the subterranean axes develop for their nourishment adventitious roots which descend vertically into the soil. Some of these roots remain slender and cylindrical, and seem to be only organs of absorption. Others gradually increase in size and become napiform; their upper portions become reservoirs of juices, and are gorged, amongst other things, with the purgative resinous principles.

APPOINTMENTS UNDER THE ADULTERATION ACT.

THE following further appointments of analysts under the provisions of the Adulteration Act have been announced:—As Medical Officer of Health, and also to act as Public Analyst for the Port and Borough of Sunderland, Dr. HENRY JOHN YELD, at a salary of £500 per annum. At Leicester, Mr. YOUNG, Pharmaceutical Chemist, has been appointed public analyst for the borough, it being understood that at the next Quarter Sessions he will be appointed to the same office for the county also, at a joint salary of £100 per annum, to which the county will contribute £60, and the borough £40. In London, Mr. SEPTIMUS PIESSE has been appointed public analyst for the Strand district.

EXAMINATIONS IN LONDON.

October 10*th*, 1873.

Present—Messrs. Allchin, Barnes, Bottle, Carteighe, Cracknell, Davenport, Gale, Linford, Martindale, Schweitzer, and Umney.

Dr. Greenhow was also present on behalf of the Privy Council.

MODIFIED.

Twenty-three candidates were examined. *Sixteen* failed. The following *seven* passed, and were declared duly qualified to be registered as Chemists and Druggists :—

Gibson, George Henry.....Brigg.
Hardcastle, Alfred Wright .....Birmingham.
Macdonald, John .....Ellesmere.
Miller, Thomas .....Leicester.
Watts, Edward .....Saffron Walden.
Wavell, William John .....Brighton.
Wright, John Walter .....Stockport.

PRELIMINARY.

The undermentioned certificates were received in lieu of this examination :—

Certificate of the University of London.

Stacey, Henry George .....London.

Certificates of the University of Cambridge.

Cottman, Frederick .....Salisbury.
Jerrett, Samuel Ernest.....Devonport.

Certificate of the University of Oxford.

Walgate, Septimus .....Hull.

Certificate of the University of Edinburgh.

Pattinson, Joseph.....Carlisle.

Certificates of the College of Preceptors.

Harston, John Frederick.....Lincoln.
Jones, Nathaniel S. .....Fulham.

Certificates of the Royal College of Surgeons.

Alden, Ebenezer Wenham .....London.
Gallatly, George Frederick .....Chertsey.

Certificate of the Faculty of Physicians and Surgeons in Glasgow.

Tichborne, Charles Robert Clarke...Dublin.

PRELIMINARY.

The undermentioned certificates were accepted by the Board in Edinburgh in lieu of the Society's Examination :—

Certificate of the Royal College of Physicians and Surgeons in Edinburgh.

Haycroft, Henry Robert Howell...Glasgow.

Certificate of the University of Edinburgh.

Tweedie, John Jackson .....Carriden Bo'ness.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

ANNUAL MEETING, SESSION 1872–73.

The Annual Meeting (twenty-fourth session) was held at the Royal Institution, September 25th, 1873. The President, Mr. E. Davies, F.C.S., in the chair.

In the absence of the Secretary, the Chairman read the annual report:—

"*Report of the Twenty-Fourth Session of the Liverpool Chemists' Association.*

"At the close of the twenty-fourth session of the Liverpool Chemists' Association, your Council present their annual report of the state of the Association in the various branches of its active life. Though perhaps not marked by much progress the session has not been one of retrogression, and your Council trust that it may only indicate a resting place from which with renewed energy the Association may advance in the path of usefulness so long trodden by it.

"During the session twelve members and six associates have been elected, and after deducting nine names which by death, removal, or other causes have been struck off the roll, the number at present on the books is 14 honorary members, 119 members, 21 associates. The evenings of our ordinary meetings have been well filled up ; papers of interest have been read, and discussion has been more animated than formerly. One important subject, namely, Pharmaceutical Education, occupied two evenings.

"A recommendation from one of the meetings, that your Council would take active steps to bring about early closing, was carefully considered by them. It was resolved by a considerable majority that whilst your Council sympathized most heartily with the desire that earlier closing should be practised, they did not think that such active interference came within the province of the Association. They trust that their endeavours to keep free from trenching on matters not distinctly included in the aims of the Association will meet with the approval of the members.

"During the session the experiment of having a box for the reception of questions has been fairly tried, and has been successful in eliciting from members much information which might not otherwise have been brought forward. It bids fair to be a most useful addition to our educational machinery.

"The chemistry class was conducted as usual during the winter. A botany class could not be formed, as a sufficient number of members did not come forward. Arrangements have been made for a chemistry class during the coming session, particulars of which have been forwarded to all the members.

"Your Council would call the attention of the younger members who are contemplating entering into the practical working of pharmacy that changes of considerable importance have been made in the bye-laws of the Pharmaceutical Society, especially in Section 10, Clause 16, to which the following addition has been made :—'After the 31st day of December, 1874, no person shall be admitted to the Major or the Minor examination who shall not have attained the full age of twenty-one years, and after the 31st day of December, 1876, no person shall be allowed to pass the Major or the Minor examination unless he shall satisfy the examiners that for three years he has been registered and employed as an apprentice or student, or has otherwise for three years been practically engaged in the translation and dispensing of prescriptions.'

"The Minor examination in chemistry will be made more stringent by requiring a knowledge of qualitative analysis and chemical physics, and your Council urge students to at once avail themselves of opportunities for practical work which alone can give information of value in these departments.

"The Library and Museum do not present any changes calling for notice. The Library has been fairly used by the members both for borrowing and reference. A large number of periodicals have been bound, and thus presented in a more accessible form. In accordance with an invitation from the Pharmaceutical Conference your Council appointed Messrs. Shaw, Sumner, and Mason as delegates, all of whom attended the meetings.

"Messrs. Davies, Murphy, Sharp, and Symes retire from the Council by rotation, but are eligible for re-election.

"Your Treasurer will present a Report of the Finances of the Association, which shows a credit balance of £6 2*s*. 7*d*."

The Treasurer read the financial report :—

Examined and found correct, Sept. 25th, 1873,

R. SUMNER,
JAMES T. ARMSTRONG, } Auditors.

Mr. Sumner moved: "That the Report, as read, be adopted, and, together with the Transactions of the General Meetings, the Laws and Bye-Laws, the Catalogue of Books in the Library, and the List of Members, be printed and circulated among the members."

Mr. Armstrong seconded the resolution, which was carried unanimously.

The next proceeding of the meeting was the election of four members of the Council in the place of Messrs. Symes, Davies, Sharp, and Murphy, who retired by rotation. All the retiring members were re-elected except Mr. Murphy, whose place was filled up by Mr. Armstrong.

The following resolution was then moved by Mr. Parkinson: "That the best thanks of this meeting be given to the donors to the Library and Museum, and to the authors of papers during the past session."

The motion was seconded by Mr. Rigby, and passed.

Mr. Williams moved: "That the best thanks of this meeting be given to the Officers and Council for their services during the past session."

Mr. Robinson seconded the motion. Carried *nem. con.*

Mr. Davies, the President, and Mr. Shaw, the Treasurer, then thanked the meeting for the manner in which it had acknowledged their services.

The Society had the pleasure of the presence of an honorary member, who had, in days gone by, worked as hard as any for the welfare of the Society, viz., Dr. Edwards, of Montreal; he was welcomed by the meeting. Dr. Edwards then rose and thanked the members for their welcome, saying he had always the welfare of the Liverpool Chemists' Association at heart, and hoped that the present session might be as useful a one as any the Association ever had.

The meeting then separated.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION AND SCHOOL OF PHARMACY.

The Fifth Annual Meeting was held in the Rooms of the Association on Friday evening, Oct. 3rd, 1873, Mr. W. S. Brown, President, in the chair.

The Secretary, Mr. F. Baden Benger, read the following Annual Report, and the Treasurer, Mr. G. S. Woolley, the Statement of Accounts:—

"*Fifth Annual Report of the Manchester Chemists and Druggists' Association and School of Pharmacy.*

"In presenting their Fifth Annual Report, your Council are glad to express satisfaction on some points in the condition of the Association, and notably on the success which attended the courses of lectures delivered by Mr. Siebold.

"One of the primary objects of your Association, and one ever kept prominently in view by your Council, has been to provide in this district opportunities for education in the higher branches of pharmaceutical science. During five years efforts to establish a School of Pharmacy have been renewed; sometimes with cheering results, but often in the face of evident coolness and indifference on the part of those for whose benefit these efforts have been made. Last session, however, three courses of lectures were given for the first time in your own rooms, and were attended by large and diligent classes. Thirty-six students attended the Chemistry course; thirty-one the Materia Medica course; and twenty-nine that on Botany; amounting to a total of ninety-six entries, and Mr Siebold's report, published at the end of April, was of a most satisfactory character.

"Encouraged by these hopeful signs, and feeling assured that they are serving the best interests of the younger members of the trade by again securing the services of Mr. Siebold, your Council have arranged for the delivery of three courses of lectures by this gentleman during the coming session. Particulars of these have been forwarded to every chemist and druggist whose name appears in the Manchester Directory; and through the courtesy of the respective editors of the *Pharmaceutical Journal* and the *Chemist and Druggist*, the announcement has received full publicity.

"Four lectures and papers were given by members at the Ordinary Monthly Meetings: 1st. On the Tests for the Alkalies, by Mr. Pidd; 2nd. On our Planet: its Weight, Size, Shape, Past History, and Present Condition, by Mr. J. T. Slugg, F.R.A.S.; 3rd. On Pharmaceutical Education, by Mr. Louis Siebold; 4th. On Telegraphs, by Mr. F. Baden Benger. The attendance at these meetings was fairly good. It has been gratifying to see so many associates present and interested in the proceedings. The merely nominal annual subscription of 2*s.* 6*d.* places the advantages of associateship—viz., the use of the reading-room, library, and museum, within the reach of all. The rooms have been open every evening from seven till ten o'clock, except Saturdays and Sundays, but as some persons find this time inconvenient to leave business, facilities have been afforded to students to visit the rooms at any other hour of the day by applying to the Secretary for the keys.

"The extended knowledge of these privileges has resulted in a considerable increase in the list of associates, but as this class is essentially a migratory one, it is most desirable that members of the trade should feel it their duty to inform their assistants and apprentices of the existence of the Association, and the Secretary will at all times be glad to give information to new comers. The enlarged and continued support of members is, however, urgently needed. The present income of the Association is insufficient to cover the ordinary working expenses, and entirely inadequate to warrant the Council in carrying out their original intention of adding a laboratory to the School of Pharmacy, or to enable them to extend the usefulness of the Association in any of the many directions which suggest themselves. The direct advantage of membership should be apparent to all engaged in the trade in this district, and it is remarkable that so little public spirit should be evinced in the support of an Association the objects of which cannot but be approved by all.

"The following donations have been received during the year:—The PHARMACEUTICAL JOURNAL, weekly, from the Society; 'The Year Book of Pharmacy for 1872,' from the British Pharmaceutical Conference, and a number of valuable specimens of Materia Medica from Messrs. Hodgkinson, Stead, and Treacher. Some important additions have been made to the Library by purchase, and the reading-room has been supplied with several medical, chemical, and other scientific periodicals as published.

"By the death of Mr. Halliday, the Association has

lost an active member of the Council, and a contributor to the monthly meetings."

THE TREASURER IN ACCOUNT WITH THE MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION.

The Chairman, in moving the adoption of the report and financial statement, said that at the last annual meeting he expressed the hope that, seeing they then had got their new rooms, and great pains had been taken by the Council in effecting the necessary arrangements, he should be able to congratulate them at their next meeting on having a very large increase in the number of members. He was very sorry that he could not do that, but at the same time he must express his gratification that they had been able to hold their own. It could not be too often impressed upon members of the trade that it was only by joining such an association that they could assist in making those educational arrangements which were necessary for the advancement of the younger members of the trade. He earnestly hoped that members of the trade would see their way clear to join the Association. There was no direct profit accruing from membership ; the sole object of the Association was the advancement of education, and it deserved greater support than was at present received.

Mr. Marsden seconded the adoption of the report, which was unanimously carried.

Votes of thanks were passed to the retiring officers, and the following gentlemen were elected for the ensuing year :—President—Mr. W. S. Brown ; Vice-Presidents—Mr. J. T. Slugg, F.R.A.S., and Mr. W. Wilkinson ; Treasurer—Mr. G. S. Woolley ; Hon. Sec.—Mr. F. Baden Benger ; Council—Messrs. Barnaby (Oxford Street), Blain (Bolton), Bostock (Ashton), Botham (Higher Broughton), Hargraves (Oldham), Hughes (Victoria Street), Kay (Stockport), Mumbray (Broughton), Payne (Piccadilly), Robinson (Pendleton), Hermann Woolley (Market Street), J. Waterhouse (Ashton).

HALIFAX CHEMISTS AND DRUGGISTS' ASSOCIATION.

The Annual Meeting of the above was held at the Old Cock Hotel, on the evening of October 9th, 1873, under the presidency of Mr. Jessop. Having partaken of the good things provided by the host, the business of the meeting commenced by the election of the officers for the next twelve months, viz., Mr. Jessop, President ; Messrs. Shott and Hebden, Vice-Presidents ; Mr. Brierly, Treasurer ; and Mr. Brook, Honorary Secretary ; with Messrs. Dyer, Farr, Shaw, Pollard, and Wood, as the Committee. The report of the Honorary Secretary alluded to the opposition of the Society against Sir John Lubbock's Shop Hours Regulation Bill ; the formation of a small library of books of reference for the use of the members ; the reduction of the freight of drugs from London by the railway companies ; and a general annual holiday for the trade at Midsummer.

Mr. Hebden proposed the "Pharmaceutical Society." Mr. Stott, in replying to the toast, said that he gloried in the fact that he was one of the founders, being connected with it from the very first, and although some might consider it to have been rather too selfish and grasping, yet he considered its tendency had been to exalt the status of the trade and promote the cause of education. It was in vain the physician prescribed for his patient unless he be properly supported by the druggist.

The other toasts comprised, "Town and Trade of Halifax," "Kindred Trade Societies," and the "President and the Officers of the Association." A hearty vote of thanks to the Chairman brought a cheerful and harmonious evening to a conclusion.

BRISTOL PHARMACEUTICAL ASSOCIATION.

The first meeting of the session was held at the Museum and Library, Queen's Road, on Friday, October 10th. The President, Mr. G. F. Schacht, delivered the following inaugural address :—

ADDRESS TO THE MEMBERS AND ASSOCIATES OF THE BRISTOL PHARMACEUTICAL ASSOCIATION. SESSION 1873-74.

BY THE PRESIDENT, MR. G. F. SCHACHT.

Ladies and gentlemen,—

I must ask all visitors who are honouring the Bristol Pharmaceutical Association with their presence to-night to be good enough to remember that my duty, as President for the year, is to address the members and associates of our Society ; and I must beg them, if my remarks at times present a somewhat over-technical aspect, to bear with them generously.

Physic, I am aware, is not usually supposed to be a very cheerful thing to contemplate ; but it is (to use a homely phrase) our "bread-and-butter," and "we do not quarrel with it." But we think it both pleasant and useful now and then to spread a little jam or ginger, or other delicacy over the plain every-day dish, and the present occasion is by some regarded as one of those supreme moments.

Of course, all who have come with much expectation of enjoyment will be disappointed, for sweets and spices enter but to a small extent into the composition of the organization that has now to address you ; but (if I may venture to quote a great man on a small occasion) "such as I have I give," and must hope, at any rate, to escape the charge of having bored you.

I should like, then, gentlemen, in commencing my first duty for the year, to make one personal observation and to be forgiven. It is that I highly appreciate the honour of being elected the President of this Association. I should have been quite content to have continued to serve as joint honorary secretary with my friend Mr. Pitman, but as my colleagues on the Council appeared to think that my time had come to occupy this more ornamental post, I hesitated but little to accept it, hoping, by a ready compliance, to furnish an argument that might have weight with others when my term of office shall have expired ; for I know well that the Association includes amongst its members many who will make most excellent presidents, and I sincerely hope we may all live to enjoy the full advantage which their occupation of this chair will necessarily bring.

It is the duty of each one of us, as it appears to me, cheerfully to assist in upholding an association whose prime object is "the promotion of scientific pharmacy," and to be ready for this high end, to serve either in the ranks or in office, according to the exigencies of the moment.

I rejoice in the thought that this feeling pervades the whole body of the Council, and that the pharmacists of Bristol generally desire, with more or less zeal, to co-operate for the furtherance of our good cause.

These considerations entitle me to think that at the

commencement of our session, 1873-74, we are in as fair a position for doing good work as at any period of our history.

And in what direction shall we look this time next year for the evidence of good work having been done? Principally, I think, in this—to the numbers of students that have attended our courses of instruction, and to the signs of benefit thereby acquired. And if this conviction constrains me to address the chief part of my remarks to the younger portion of my audience, I hope their seniors will not think I am heedlessly neglecting other important matters.

For instance, I do not attempt to give you, as some may have expected that I should, a statement of the present outlook of pharmacy, or even a *résumé* of its last year's history—for these matters have been so recently undertaken and so exceedingly well done by my friend Mr. Brady in his presidential address to the British Pharmaceutical Conference, that my efforts would necessarily be but a feeble echo of his, and would result in a simple waste of your time;—and again, during our recent canvas of the trade so much cordiality and good feeling was manifested by our *members*, that with this expression of grateful acknowledgment I prefer to leave *them* to their own excellent devices;—and I elect to address the bulk of my remarks to our *associates* and other junior candidates for pharmacy.

It is perhaps a little dangerous to say anything that may even appear unduly to exalt in our young friends the idea of their especial importance in this world or in our Society—youth is sufficiently prone to conceit without any such assistance—but I must trust to their good sense in the present case not to pervert my confidence, because I wish them to know that but for them and our interest in their professional wants, this Society would most probably not exist. A few other topics in which we are professionally interested may occasionally present themselves for discussion, but the creation and development of the taste for science amongst our assistants and apprentices, and the provision of opportunities for its systematic culture constitutes the real object of our work and is the process, I had almost said the only process, by which we hope in any appreciable degree to achieve the progress of scientific pharmacy.

We can do but little to change the fully formed man, but we may hope to do something with the forming pharmacist. Social change is, in its very nature, gradual and slow. One fancies that it well nigh requires the passing away of a generation for each step. The child is father of the man. What he is at the beginning he pretty much remains to the end of his career. What you, young men, make yourselves now in the time of your pupilage, that you will make pharmacy when your day of action arrives.

And in passing I would say for your encouragement, that in my opinion you may in that day compel a more correct public recognition of its just claims. I say its *just* claims, nothing more and nothing less than its due, that is, what you make it to deserve. Depend upon it (and this observation is by no means new) the world estimates a man very much at his own valuation, not perhaps at what he sometimes *says* he is worth but at what he shows that he *knows* he is worth. If the so-called pharmacist is willing to comport himself as a mere huckster, to descend to the dishonest or semi-honest tricks of low-trading, to treat his fellow-labourers in pharmacy with systematic suspicion; if, in fine, he declines to manifest respect either for himself or for his class, how can he possibly expect the public to do so! But on the other hand, if his rule be scrupulous honesty and intelligent work at his own home and, as a necessary result, the assumption of the same rule at his neighbour's, who amongst the public would dare to doubt him! It is because I believe that examples of the former class are becoming rarer and rarer that I am hopeful for our future. I feel persuaded that our business is much more intelligently and much more honestly done than it was some years ago, and I am equally sure that the disposition to regard the neighbour chemist rather as a fellow-labourer than as a rival is more and more upon the increase.

If I am right these are pleasanter greetings for you young men than were those that met some of us at the commencement of our career, and I would have you appreciate them at their full value. If the difference is in any way due to the efforts of those that have preceded you, I am sure that all the show of gratitude they ask at your hands is, that you accept the benefit frankly and turn your improved opportunities to the best account.

I said that the creation and development of a taste for science amongst our juniors, and the provision of opportunities for its culture, constituted the chief object of our association, and I must now remind you that, prompted by that doctrine, we have to the present time provided those opportunities mainly in two directions—systematic courses of lectures on botany, chemistry, and materia medica—and occasional lectures in this room on some subject of general science.

There seems to be little occasion to urge any abstract arguments in favour of the benefits that attach to systematic teaching in the form of regular courses of lectures. These are almost universally admitted; and I can honestly assert that the teaching we are fortunately able to offer you is very good. You may search all England through and you will find it a difficult matter to discover three better teachers than Mr. Coomber, Mr. Leipner, and Mr. Stoddart; and I am quite sure that with common industry you may attain such proficiency in the three sciences as will enable you not only to pass your examinations with credit, but also to gain a hearty love for those sciences for the rest of your lives.

I hope therefore I may assume that we are agreed as to the usefulness of these courses of lectures, and that a good many of you will attend them during the coming session.

The other process, however, by which we attempt to create and cultivate this taste for science—I mean the provision of *occasional* lectures in this room—does not apparently command such universal approval. It is sometimes questioned, both by lecturers and students, whether much good results from isolated discourses.

The difference in the two cases appears to consist chiefly in the fact that whereas in the former the lessons, being offered in a continuous and consecutive order, the various phenomena are presented in a way that enables the mind of the hearer to appreciate them with the least possible effort of his own—in the latter it becomes necessary for the hearer himself to assign the place in his intellectual system wherein to stow away the fresh goods. This is not always the easiest thing in the world to do, and its difficulty is in proportion to the unpreparedness of the individual mind for such a duty.

I ventured upon an occasion somewhat similar to the present to urge upon all pharmaceutical students the usefulness of preliminary mathematical training in the after acquisition of scientific knowledge. I now repeat the opinion that the more our knowledge is stored upon the basis of real method, the more is it likely to become so much part of ourselves as to be available for our own and others' good, and that to be altogether without mental method would merely illustrate mental chaos.

Upon this point however I do not now wish to enlarge, but I desire to suggest an idea which if you will thoroughly take it to your minds and nurse it kindly might for ever redeem the isolated lecture from the charge of uselessness.

It is the idea that no phenomenon of nature can pos sibly stand alone.

Every natural phenomenon consists of matter under the influence of force. One cannot conceive of force but as having an accession or a subsidence—a coming, a doing, or a going; in other words, every phenomenon must have a history, it must be connected with antecedent and subsequent operations from which it cannot be philosophically

dissociated, and which we may be sure are as worthy of thought and study as that which appeared for the moment to be the central object in the field of view.

But more than this, not only is every phenomenon of nature related to its immediate before and after, but also to a group of operations of which it is perhaps one out of many illustrations.

It is this latter half of the idea to which I especially wish to draw your attention, for, if I am not much mistaken, it lies very near the root of that which leads to discovery in science, and to so-called creation in art.

Let me try and illustrate my meaning.

If an intensely heated non-volatile body be brought into a dark room it will emit what is called white light. If this be analysed by a prism it will appear as an uninterrupted band of various colours, known as the spectrum. In its constant place between the red and the blue will appear the yellow portion of the light. Now, if between the ignited body and the prism we contrive to interpose a quantity of the vapour of the metal sodium, the spectrum is no longer a continuous band of varied colour, but in the place normally occupied by the yellow colour we now have no light at all; on the contrary, a dark band appears. The sodium vapour, though transparent to all the other colours, is opaque to yellow. On the other hand, let the sodium itself be heated in the absence of other light until its vapour becomes intensely luminous, and the only colour it will then emit is this very yellow which it refused to let pass in the previous part of the experiment.

Again, a moderately heated body, placed at one end of a tube and a delicate thermometer at the other, the tube being filled with dry air, it is found that the heat radiates through the air to the thermometer with but little loss. If carbonic acid gas be substituted for the air, much more heat disappears, if olefiant gas be used, still more. Now for the converse. If a mass of air be heated it radiates but little; if carbonic acid gas be heated it radiates much more; olefiant gas still more.

Once again. If I stand by a pianoforte and with my voice or other instrument sound a certain note, say C, I find I have immediately set vibrating all the C strings in the piano. If I were to arrange a screen of C strings before me, and run my voice up the scale of G, you on the other side of the screen would hear G A B—D E ♮F G, but the C would be stopped; strike those strings and C only would be heard.

Now, here we have three phenomena which might be very correctly assigned to three distinct departments of physics—to light, to heat, and to acoustics. Yet who can contemplate them for one moment in juxtaposition without detecting their close parallelism, and at once yielding to the suggestion that they may be but modified manifestations of the same fundamental operation? Viewed by the light of this suggestion, the parallelism appears still more complete.

That vibrations through some conveying medium accompany the phenomena of sound is not a difficult idea to realize. Our eyes can see these vibrations in the strings of sounding musical instruments, and our very skins can feel the vibrations in the air produced by the deep notes of an organ. It is tolerably easy, therefore, to comprehend the explanation that when the vibrations that accompany the sound of my voice reach the screen, these C strings take up and absorb all those waves that produce C sounds, and commence corresponding (though, perhaps, inaudible) vibrations, whilst the other waves that do not coincide with the C waves are allowed to pass.

Now, see how beautifully these same explanations fit the corresponding phenomena of heat and light. The heated body, like the sounding voice, produces vibrations in the surrounding media, a mixed series of waves of different heights, and, so to speak, of different musical pitch. Of these a screen of carbonic acid gas absorbs those with which its own molecules can be set vibrating and lets the others pass.

Once more, the incandescent glowing substance that I first imagined, from the impulse of its own internal molecular vibrations, evokes in the surrounding ether vibrations and waves of all varieties of intensity that produce impressions not only of heat but of light also. Certain of these waves produce red light, others yellow, others blue. The interposition of the screen of sodium vapour arrests and absorbs the vibrations that convey the yellow light and lets the others pass.

This sifting, as it were, of the vibrations and waves produces, in the one case, silence; in the second, cold; and in the third, darkness.

You see then, I hope, that these three phenomena, though very different in their sensible manifestations, are closely related in the probable intrinsic nature of the processes by which they exist, and this observation once made suggests many trains of thought. One of the first would probably lie in the direction of inquiry as to what other *already observed* facts might, with similar liberty of variation, be grouped with them as owning a kindred origin, and soon perhaps would follow the attempt to find in some special department of natural operations, phenomena *not yet observed* but deemed probable from the knowledge of corresponding manifestations in other departments.

Am I imagining a case? By no means; I am simply telling the history of every science, and pointing to one of the chief agencies in scientific progress.

The highest minds amongst us revel in these suggestive parallelisms, and the grand generalizations and orderings of an otherwise chaotic mass of facts that characterize modern science are the natural issues of this happy intercourse.

Let me remind you yet once again of the oft-told tale of Sir Isaac Newton and the falling apple. Many, many times must this phenomenon have happened before eyes that could see yet saw not—let us even say, before eyes that saw, yet saw not all. Let us willingly admit that many open, thoughtful minds lived before Newton, and read the lesson according to their lights. A falling apple had doubtless given the cue to many a moralist and to many a preacher, as he taught gravely and wisely how the time of fairest show and seeming bloom may be but the message of a fall, and how this fate must come to all who hang alone upon material support. This is something of what I meant in saying that much of what was called creation in art might find its secret in a keen appreciation of parallelisms and similitudes in nature. How easy to believe that the poet had some such fact before him when he wrote—

> "This is the state of man: To-day he puts forth
> The tender leaves of hopes, to-morrow blossoms,
> And bears his blushing honours thick upon him:
> The third day comes a frost, a killing frost;
> And,—when he thinks, good easy man, full surely
> His greatness is a ripening,—nips his root,
> And then he falls . . . . ."

These and many other reflections, noble and ignoble, may, I say, have been suggested by this home-side incident, but it was reserved for the splendidly-trained genius of Newton to take from it the hint that led to the grandest generalization of the facts of which it was a trifling illustration that the world has ever seen.

I cannot, I trust, be wrong, then, in submitting this idea for your careful consideration, and in urging upon you this thoughtful, reasoning, scientific method of receiving everything. It has been aptly said that talking of science is not necessarily scientific talk, so let me add—listening to science is not the same as scientific listening. The one may be what we all agree in designating waste of time, the other is what we hope you will give to all the teaching we can offer you. Again, it has been said—and I find myself often quoting these clever words—"the eye sees only that which it brings with it the power of seeing." You and I must cultivate this open scientific vision that takes in all, and takes it in aright, and then every phenomenon, though apparently isolated, from the falling of an apple to the appearing of a new world, will bring to us a valuable lesson.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

(*Continued from page* 296.)

ERRATUM.—Through an accident, the paragraph on p. 292 representing Mr. Brady's remarks respecting hyoscyamus was passed without correction. It should read as follows:—

The PRESIDENT said: I do not think that it is generally understood how great a difference there is between the annual and biennial varieties of *Hyoscyamus niger*. In its second year the latter is a large ornamental plant from three to five feet high. In reply to the suggestion that has been made that the chlorophyll, which is separated at an early stage in making the extract, should be rejected, I should just like to say that it is possible that a portion at least of the active matter is associated with it. Mr. Stoddart's researches showed clearly that the absorbtion bands of the tinctures of the annual and biennial plants are quite distinct, and it is at least a collateral fact that chlorophyll under different circumstances gives two or more distinct spectra; and this is a subject still under investigation. Until we are sure that the waxy chlorophyll does not retain any part of the hyoscyamine the present process for making extract may be regarded as a good one in principle.

A NEW TEST FOR MORPHIA.

BY LOUIS SIEBOLD.

In conducting a series of experiments on organic alkaloids, I discovered a new test for morphia, which greatly exceeds in delicacy the tests hitherto known for that substance. If it is to be applied for the detection of opium in food, the contents of stomachs, etc., in poisoning cases, it is of course necessary to separate the alkaloid from the other substances in the usual manner. The test is then performed in the following way:—

Heat the substance which is believed to be, or to contain, morphia, gently with a few drops of pure sulphuric acid, add a very small quantity of pure perchlorate of potassium. The liquid immediately surrounding the perchlorate will at once assume a deep brown colour, which will soon spread and extend over the greater part of the acid. Warming increases the delicacy of the test. 0·0001 gramme of morphia can be distinctly recognized in this way and no other alkaloid is acted upon in a similar way by the substances named. It is indispensable however for the success of the experiment that the perchlorate of potassium be absolutely free from chlorate; if it is not, it must be heated with successive portions of pure hydrochloric acid until the latter remains colourless and ceases to give off chlorine. After removing the HCl completely by washing with water, the perchlorate must be dried at 212°, and it is then ready for use. I feel justified in strongly recommending this test to the attention of the chemical profession.

[Some time after I had forwarded the above report to the Secretary of the Conference, another equally delicate new test for morphia was published by Mr. R. Schneider. One drop of pure sulphuric acid is placed on a porcelain slab, and a mixture of one part of morphia and six parts of sugar added; the mixture will at once assume a purplish red colour, which remains unaltered for some time. Codeine and aconitine, if treated in the same way, produce a similar reaction.]

Professor ATTFIELD: I am glad Mr. Siebold has called attention to the use of perchlorate of potassium as an oxidizing agent. The colour it gives with alkaloids differs from the colour obtained with some other oxidizing agents; and as it is not a very common chemical in laboratories generally, I think it is as well that attention should be drawn to the fact set forth in the paper we have heard, not only for its own sake, but because it suggests that many new tests might probably be found, if gentlemen would endeavour to ascertain the reactions of perchlorate of potassium mixed with acid on the large number of alkaloids and other organic principles.

Mr. GROVES: With regard to the detection of minute quantities of poison, say in the stomach of animals, for my own part, I certainly should feel some hesitation in giving decided evidence as to its presence unless a physiological as well as a chemical test were applied.

NEW DERIVATIVES FROM MORPHINE AND CODEINE.

BY C. R. A. WRIGHT, D.SC.

Lecturer on Chemistry in St. Mary's Hospital Medical School.

Since the last meeting of the Conference the following additional results have been obtained, partially in conjunction with Mr. E. L. Mayer, of Glasgow.

By acting on morphine with sulphuric acid diluted with its own bulk of water at 100°, two polymerides are formed, corresponding in physical properties with the tricodeine and tetracodeine obtainable from codeine by similar treatment, and described in last year's paper; these are hence termed *trimorphine* and *tetramorphine* respectively; *dimorphine* does not appear to be obtainable in this way, although dicodeine is plentifully obtained from codeine thus. The physical characters of the four series of polymerides may be thus summarized:—

Mono- series (ordinary bases, not polymerized).—Bases crystalline. Salts, crystalline.

Di- series (polymerized bases).—Bases amorphous. Salts, crystalline.

Tri- series (polymerized bases).—Bases amorphous, and soluble in ether. Salts, amorphous.

Tetra- series (polymerized bases).—Bases amorphous, and insoluble in ether. Salts, amorphous.

On account of these physical properties, the bases hitherto designated as "apomorphine," "deoxymorphine," and "deoxycodeine," are regarded as belonging to the di- series.

Trimorphine and tetramorphine differ much from morphine in physiological action; the former produces excitement and salivation, but no vomiting; the latter is a more powerful emetic even than "apomorphine." Not being crystalline, its salts do not form quite as elegant a preparation as "apomorphine hydrochloride"; they can be administered readily by hypodermic injection, or internally as a pill or otherwise.

The substance described as "sulpho-morphide," by Arppe, and by Laurent and Gerhardt, and viewed by the latter as a kind of amide, is found to be only the sulphate of tetramorphine.

Hydrochloric acid has no action on tetramorphine, in which respect it resembles tetracodeine; trimorphine, on the other hand, gives rise to a chlorinated derivative, containing two proportions of hydrochloric acid to three of morphine; this reaction, therefore, confirms the formula attributed to trimorphine, *i.e.*, proves that it is the *treble* polymeride. Tricodeine is acted on by hydrochloric acid differently, the elements of water being removed and a non-chlorinated base resulting.

Tricodeine, $\overline{C}_3 = 6H_2O + (\overline{C}_3 - 6H_2O)$.

Trimorphine, $\overline{M}_3 + 2HCl = 2H_2O + (\overline{M}_3 + 2HCl - 2H_2O)$.

The action of hydrochloric acid on morphine appears to give rise, firstly, to chlorinated bases derived from non-polymerized morphine, thus: a mixture of $(\overline{M} + HCl)$, $(\overline{M} + HCl - H_2O)$, and $(\overline{M} + 2HCl - 2H_2O)$ is produced: and secondly, to "apomorphine" and a chlorinated tetra base $(\overline{M}_4 + 2HCl)$ produced by the further alteration of these first-formed substances.

Similarly, the first action of hydrochloric acid on codeine gives rise to bases—$(\overline{C} + HCl)$ and $(\overline{C} + 2HCl - 2H_2O)$; this latter is the "chloro-codide" of Matthiessen

and the author; as its formation is preceded by the production of ($\overline{C}$ + HCl), and as it yields ordinary codeine (not polymerized) by the action of water, it results firstly that the chlorinated bases produced by the first action of hydrochloric acid on codeine (and hence on morphine) belong to the *mono-* series of derivatives; and, secondly, that codeine is represented by the formula $\overline{C} = C_{36}H_{42}N_2O_6$, and not by the half of this formula, as supposed at the commencement of these researches (and hence that morphine $\overline{M} = C_{34}H_{38}N_2O_6$, and not $C_{17}H_{19}NO_3$).

In just the same way, the first action of hydrobromic acid on codeine gives rise to ($\overline{C}$ + HBr), "bromocodide" or ($\overline{C}$ + 2 HBr—2 H_2O) being subsequently formed.

The further action of hydrobromic acid on bromocodide has been formerly shown to be different from that of hydrochloric acid on morphine, described above; at 140°-150°, in sealed tubes, the action of hydrochloric acid on chlorocodide was found by Matthiessen and the author to be different again, "apomorphine" (identical with that from morphine) being produced, together with methyl chloride. At 100°, however, a different reaction takes place, methyl chloride is formed and water eliminated, but instead of "apomorphine," a base where the elements of water are less completely eliminated is produced. This base is, like "apomorphine" (tetrapodimorphine), a member of the di- series, and resembles "apomorphine" greatly; its physiological action, however, is much less energetic, and its composition is expressed by the formula ($\overline{M}_2$—2 H_2O), "apomorphine" being ($\overline{M}_2$—4H_2O), it may hence be conveniently termed *diapodimorphine*.

Simultaneously with diapodimorphine, a base isomeric therewith, but belonging to the tetra- series, is produced; the composition of this being (M_4—4H_2O), it may conveniently be termed *tetrapotetramorphine*.

A comparison of the physiological action of the various "apo" derivatives of di- and tetramorphine leads to the singular result that the emetic action of the derivative is the more marked in the di- series, the more the elements of water are subtracted, whilst in the tetra- series the emetic action becomes less and less the more water is abstracted, thus:—

Di- Series.

Name of Base	Relation to Morphine.	Physiological Action.	Observer.
Dimorphine (hypothetical)	$\overline{M}_2$	?	?
Diapodimorphine ...	$\overline{M}_2$—2H_2O...	Produces profuse salivation but no vomiting (cats).....	Dr. J. G. Blackley.
Tetrapodimorphine (apomorphine) ...	$\overline{M}_2$—4 H_2O...	Moderately powerful emetic (cats). Very powerful emetic (man)	Drs. Gee and Stocker.

Tetra- Series.

Tetramorphine ...	$\overline{M}_4$	Very powerful emetic (cats) .	Dr. Stocker.
Diapotetramorphine	$\overline{M}_4$—2 H_2O ..	Powerful emetic (cats and dogs)	Dr. Stocker.
Tetrapotetramorphine ...	$\overline{M}_4$—4 H_2O ..	Produces profuse salivation but no vomiting (cats).....	Dr. Blackley.
Octapo tetramorphine ...	$\overline{M}_4$—8 H_2O ..	Produces neither salivation nor vomiting (cats)	Dr. Blackley.

The last mentioned base, *Octapotetramorphine*, is obtainable as the end product of the action of zinc chloride and hydrochloric acid on morphine at 180°, at lower temperatures, or with a shorter time of exposure, treatment with zinc chloride forms "apomorphine," the base ($\overline{M}$ + HCl—H_2O) belonging to the mono- series, or a tetrabase ($\overline{M_4}$ + HCl—4 H_2O) according to circumstances.

The derivatives of the mono-, di-, tri-, and tetra- series of polymerides appears to be sharply distinguished from one another in their physical characters, and, in many instances, by their physiological actions; in chemical reactions no less difference appears to exist. Thus, when a derivative of dimorphine (diapodimorphine, tetradimorphine, or "deoxymorphine") is dissolved in excess of caustic potash and the solution exposed to the air, a liquid is obtained which, on supersaturation with an acid and agitation with ether, communicates a magnificent purple tint to the ether. The colouring matter thus produced has been isolated and examined; it is an indigo-blue powder, exhibiting traces of crystalline structure; in alkalies it dissolves with a bright green colour; in water containing ammoniacal salts, with a pure blue tint; in ether, benzene, chloroform, alcohol, and bisulphide of carbon, it dissolves, forming liquids of tints varying from violet-blue to magenta-purple; the tint is different with each solvent, even when the same quantity of material is dissolved to the same bulk. On analysis, the substance gives numbers agreeing with the formula $C_{40}H_{34}N_2O_7$.

Neither mono-, tri-, nor tetra- derivatives of morphine are capable of yielding this substance by this treatment (if perfectly free from di- derivatives, a point difficult to ensure).

Again, if monomorphine derivatives (hydrochlorides) be heated to 150°-180°, they swell up and partially decompose; the residue, when distilled with potash, yields methylamine and *pyridine*; when tetra- derivatives are treated in the same way, *methylamine* only seems to result, whilst a di- derivative, "apomorphine," when treated thus, gives rise to *no volatile base at all*. The nitrogen, therefore, would seem to be differently related to the other elements present in these different series of polymerides.

The numerous derivatives of codeine and morphine (upwards of 40 in number) obtained during the last few years may, with only one or two inconsiderable exceptions, be included in one or other of the formulæ—

$$(\overline{C} \pm Hp)x + m\,HX—nH_2O.$$

$$(\overline{M} \pm Hp)x + m\,HX—nH_2O.$$

Where p has values varying from 0 to 8.

Where x = 1, 2, 3, or 4, forming the mono-, di-, tri-, and tetra- series respectively.

Where m varies from 0 to 4.

Where n varies from 0 to 12.

And where X denotes either Cl, Br, or I.

Tables illustrating the compositions of these derivatives, formulated and arranged on this principle, are given in the *Journal of the Chemical Society*, 1873, p. 228, and the *Chemical News*, xxvii., p. 287, or in the *Berichte der Deut. Chem. Ges.*, v., p. 1111, and vi., p. 268.

The author again desires to express his obligations to Messrs. Macfarlan and Co., of Edinburgh, for their great kindness and liberality in presenting him with the alkaloids necessary for these researches.

The PRESIDENT: There are probably few present to whom the whole, at any rate, of Dr. Wright's paper is quite intelligible; but there can be but one opinion as to the value of such researches as those he has for so many years been engaged upon both in their chemical and physiological aspects.

The President called upon Mr. Williams.

Mr. WILLIAMS: The subject is so overwhelming in its character, that I feel sure you will pardon me if I do not now attempt to deal with it. Its wide character may at once be understood by the simple statement that there are upwards of forty derivatives from morphia and codeia, and that the whole question is still in a complicated state. It is possible to condense the molecule of morphia, and also of codeia, even twice or three times, and you may thus obtain an infinite variety of products. The researches of Dr. Wright are most interesting and elaborate, and how he finds time to perform so many analyses and so many experiments is most surprising, knowing as we do that he has the labours of a professorship and other important duties to discharge. For his great industry and its successful fruits, I think pharmacy and chemistry generally are deeply indebted to Dr. Wright.

Professor ATTFIELD: I think that Dr. Wright has set all gentlemen engaged in chemical researches a most excellent example. As a rule, when chemists discover from time to time new substances, the matter rests there, so far as any physiological action of the substances is concerned. Then some wonderful combinations are produced by therapeutists, but the chemical interest in them being very small those researches excite little interest among chemists. Now Dr. Wright, though only a chemist I believe, is not content in giving us the results of his researches, which are of a purely chemical character, but he has enabled us by various means to judge of the physiological action of the substances discovered, a service which seems to me to be of the greatest value both to the medical profession and to pharmacy.

Mr. SIEBOLD: The difference in the physiological action of the various derivatives of morphia, as explained to us by Dr. Wright, is so remarkable as to demand further inquiry, especially on the part of medical practitioners. I believe the physiological action and chemical nature of alkaloids generally, and their derivatives, are little understood; and I am, therefore, all the more glad to see that they have been made the subject of such excellent research on the part of Mr. Groves and Dr. Wright, as shown by the results they have placed before the Conference to-day. It is to be hoped that these researches will be continued not only by the same gentlemen, but also by other chemists and pharmacists to whom they have set such a good example. I have very little doubt but that at the end of the second decade of the British Pharmaceutical Conference we shall be discussing organic alkaloids made artificially from inorganic constituents.

ON THE ESSENTIAL OIL OF ORANGE (PORTUGAL).

BY C. R. A. WRIGHT, D.SC. (LOND.),

Lecturer on Chemistry in St. Mary's Hospital Medical School.

A brief preliminary notice on this subject by the author and Mr. C. H. Piesse was read before the Conference two years ago; since then a large number of experiments have been made, of which the following is a synopsis:—

Proximate Constituents.—The great majority of the oil (97·2 per cent.) distils below 180°; a small quantity of an oxidized constituent boiling near 220° is contained, possessing the composition $C_{10}H_{16}O$; and a non-volatile soft resin is also contained giving numbers on analysis agreeing with the empirical formula $C_{20}H_{30}O_3$, together with another oxidized substance of high boiling point, a portion distilling at 240°-250°, agreeing with the empirical formula $C_{40}H_{64}O_5$.

The oxidized constituent $C_{10}H_{16}O$ is possessed of the property of becoming altered by heat forming an isomeric liquid of higher boiling point, and finally becoming a non-volatile resin, no change in its composition being thereby produced: in this respect it resembles an analogous (or identical ?) substance contained in oil of nutmegs.

The portion boiling below 180° yields, on distillation over sodium, a hydrocarbon, $C_{10}H_{16}$, boiling constantly at 178°, and apparently consisting of one homogeneous substance, no trace of cymene being apparently present. Many other natural terpenes (*e.g.*, the terpene of turpentine oil and that of nutmeg oil) are not pure terpenes, having been found to contain cymene, $C_{10}H_{14}$, as well as a $C_{10}H_{16}$ hydrocarbon.

When two equivalents of bromine are cautiously added to the terpene of orange oil (*hesperidene*) combination takes place with evolution of heat; the product breaks up on distillation, forming hydrobromic acid and cymene, thus—

$$C_{10}H_{16}Br_2 = 2\,HBr + C_{10}H_{14}.$$

The cymene thus formed is identical with that contained in cummin oil and with that obtainable from camphor, yielding on oxidation terephthalic acid and acetic acids without admixture with isophthalic acid or higher homologues of acetic acid; the original hydrocarbon, *hesperidene*, when similarly oxidized, gives acetic acid, but no trace of terephthalic acid.

If the oxidation be not carried to its limit, the action of chromic acid on hesperidene gives rise to a small quantity of a substance, $C_{10}H_{16}O$, which resembles in all respects save odour the body of that composition contained in the original oil; probably therefore that body is formed by the spontaneous oxidation of the hydrocarbon; or possibly the hydrocarbon is produced by the natural deoxidation of this oxidized substance.

Action of Nitric Acid on Hesperidene.—This action is very energetic, the resulting substances being carbon dioxide and nitrous red fumes, oxalic acid and a new body, *hesperisic acid*, being formed: this hesperisic acid forms a lead salt insoluble in water, and a calcium salt soluble in water and precipitated by alcohol from aqueous solution; its barium salt is soluble in water. The acid is obtained by treating the purified calcium salt with sulphuric acid and ether; on evaporation of the ether the acid is left as a honey-like mass which gradually becomes crystalline. It is hexabasic and has the composition $C_{20}H_{26}O_{17}$, $2H_2O$, the $2H_2O$ being lost at 100°.

Action of Hydriodic Acid on Hesperidene.—Hydriodic acid combines with hesperidene, forming a liquid compound partially decomposed by distillation. Attempts to synthesise an acid containing eleven proportions of carbon by acting on this hydriodide with cyanide of silver, etc., met with little success: it was also found impracticable to add hydrogen on to hesperidene by the joint action of phosphorus and hydriodic acid, a polymeride boiling about 250° being the sole product.

Professor Attfield also read a paper which had been prepared by Dr. Wright, "On the Essential Oil of Nutmegs," as follows:—

ON THE ESSENTIAL OIL OF NUTMEGS.

BY C. R. A. WRIGHT., D.SC. (LOND.),

Lecturer on Chemistry in St. Mary's Hospital Medical School.

Proximate Constituents.—Pure nutmeg oil was found to contain about 2 per cent. of a non-volatile soft resin, agreeing with the empirical formula, $C_{40}H_{56}O_5$; substances distilling at 260°-280°, and 280°-290°, having compositions approximating to $(C_{10}H_{13}O)n$; an oxidized constituent (the myristicol of Gladstone) boiling near 212°, but altering by the action of heat in the same way as the constituent $C_{10}H_{16}O$ contained in orange oil (Gladstone attributed to this substance the formula $C_{10}H_{14}O$, but the analytical numbers agree better with $C_{10}H_{16}O$, a formula shown to be correct by the decompositions of the sub-

stance); and a mixture of at least two hydrocarbons, one a terpene, boiling at 163°, the other ordinary cymene. This last was extracted by treating the mixture of hydrocarbons with sulphuric acid, whereby the terpene became resinized. On distillation with water, cymene passed over unaltered: when purified this was found to be identical with all the other known varieties of cymene.

By the same process cymene has been extracted from ordinary oil of turpentine, which is thus shown to be a mixture and not a single body.

Decompositions of Myristicol.—When heated with zinc chloride, myristicol partly splits up into water and cymene, thus—

$$C_{10}H_{16}O = H_2O + C_{10}H_{14}.$$

A portion, however, becomes converted into a non-volatile resin, of composition intermediate between cymene and myristicol, thus—

$$2n\ (C_{10}H_{16}O) = n\ H_2O + (C_{20}H_{30}O)_n.$$

When treated with phosphorus pentachloride myristicol gives rise to a chlorinated product, $C_{10}H_{15}Cl$, formed thus—

$$C_{10}H_{16}O + PCl_5 = POCl_3 + HCl + C_{10}H_{15}Cl.$$

On heating, this chlorinated product splits up into hydrochloric acid and cymene. Thus—

$$C_{10}H_{15}Cl = HCl + C_{10}H_{14}.$$

The cymene thus produced from myristicol by these two reactions is in each case identical with the cymene produced from other known sources.

Oxidation products of Nutmeg Hydrocarbons.—Fractional distillation does not completely separate the cymene naturally present from the terpene contained in nutmeg oil, even when carried on over sodium for six weeks, hence the oxidation products of cymene (viz. toluic and terephthalic acids) are mixed with those of the terpene.

Chromic acid gives rise to acetic acid and a constituent, $C_{10}H_{16}O$, much resembling myristicol, and boiling at about the same temperature; probably this is identical with myristicol, as the only difference lies in the odour. Ordinary terephthalic acid is also found in small quantity (from the cymene present).

Nitric acid gives rise to carbonic and oxalic acids, and also to a peculiar acid, *myristisic acid*, much resembling hesperisic acid, obtained similarly from hesperidene; in addition, ordinary toluic acid, and also terephthalic acid, is found in small quantity (from the cymene present). Myristisic acid is hexabasic, and is expressed by the formula $C_{20}H_{26}O_{16}$, $2\ H_2O$, the $2\,H_2O$ being lost at 100°. It much resembles hesperisic acid, from which it only differs by one proportion of oxygen, hesperisic acid being $C_{20}H_{26}O_{17}$, $2\ H_2O$.

Production of Cymene from Nutmeg Terpene.—By adding two equivalents of bromine to the nutmeg terpene, combination takes place; the resulting dibromide splits up on heating into cymene and hydrobromic acid, just as hesperidene dibromide does. The resulting cymene constitutes about 55 per cent. of the hydrocarbon taken (about 10 to 12 per cent. of cymene being originally contained as such); the rest becomes converted into a resinous substance. This cymene is identical with all the other known forms of that body.

When the action of heat on the dibromides of turpentine (Oppenheim), nutmeg terpene, and hesperidene, are compared with the boiling points of the three hydrocarbons (160°, 163°-164°, and 178° respectively) it is noticeable that the first-mentioned terpene yields little cymene by heat alone; the second about half its weight, and the third nearly the theoretical quantity. It is also noticeable that hesperidene evolves much less heat on combination with a given weight of bromine than the nutmeg terpene, the same being true for the resinizing action of sulphuric acid; it hence appears probable that the boiling points and other physical properties of isomeric bodies and their chemical properties are inter-connected in this way, that the body of highest boiling-point is produced by the expenditure of the greatest amount of force in performing the combination of the constituent elements, and consequently possesses the least amount of what may be termed "intrinsic chemical energy." It is proposed to examine questions of this kind experimentally; but the practical difficulties in the way are in many cases very great.

A hearty vote of thanks was accorded to Dr. Wright for his researches.

Report on the Purity of Commercial Specimens of Officinal Acids.

BY LOUIS SIEBOLD.

The title of this paper shows that I wish to deal, not with the crude acids of commerce, but with those products which are sold *as pure* for dispensing and analytical purposes. That these so-called pure acids are in many cases far from pure is a fact well known to every chemist who takes the trouble of testing the chemicals supplied to him. To dwell upon the impurities contained in such acids, the means of detecting and removing the same, and the best methods of preparing acids of perfect purity, is the object of this paper.

Hydrochloric Acid.—If this acid is prepared in strict accordance with the pharmacopœia process and from perfectly pure materials, it will always be obtained free from sulphuric acid, sulphurous acid, arsenic, iron and free chlorine which are the main impurities found in the commercial article. If the sulphuric acid used contains arsenic, the hydrochloric acid made from it will of course contain the same impurity; if oxides of nitrogen are present in the former, free chlorine will inevitably occur in the latter, whilst organic matter either in the H_2SO_4 or in the NaCl generally cause the formation of a little sulphurous acid. I need hardly remind you that free chlorine and sulphurous acid destroy one another, and that for this reason they can never occur together. There appears to be hardly any difficulty in obtaining from wholesale dealers and manufacturers hydrochloric acid quite free from sulphuric acid, from sulphurous acid and also from appreciable quantities of iron (very small traces of iron can be detected in nearly every sample), but arsenic and free chlorine are very frequently found in acids sold as pure; and as arsenic is undoubtedly a most objectionable impurity, however small its quantity may be, it should be carefully searched for, and if found, the acid containing it should be rejected as unfit for dispensing and even more so for analytical operations where its use might lead to very serious mistakes. Boiling a little of the acid with a piece of *pure* copper foil is a very convenient test and is therefore generally resorted to, but it is not delicate enough for the detection of very small traces of arsenic. I have often been unable to detect it in hydrochloric acid by the copper test when a careful examination with sulphuretted hydrogen proved its presence most unmistakably.

It does not, however, suffice to add a solution of H_2S, but the gas must be conducted through the acid until the latter is completely saturated with it. After twelve hours' standing the precipitate which will in any case be formed must be filtered, washed, dried, and fused with carbonate and nitrate of sodium; the fused mass dissolved in water, filtered, mixed with pure nitric acid in excess, boiled and then tested with ammonia and nitrate of silver or with sulphuretted hydrogen. It is impossible to judge of the absence of arsenic from the light colour of the precipitate. By the method just described, arsenic will be found in many samples of hydrochloric acid which, if tested according to the directions of the pharmacopœia, would seem to be quite pure.

Sulphurous acid is readily detected by the pharmacopœia test, or by iodized starch, the colour of which would be destroyed by the least trace of H_2SO_3. For detecting free chlorine, solution of indigo appears to me preferable to a mixture of iodide of potassium and starch, as the formation of blue iodide of starch might be caused by per-

chloride of iron which is often present in hydrochloric acid, and which might thus be mistaken for chlorine.

On the strength of numerous experiments which I have made I can recommend the two following methods as the best for preparing perfectly pure hydrochloric acid from the crude commercial article. The first of the two methods yields an acid of low specific gravity (1·120 to 1·125) which though very suitable for analytical purposes, does not come up to the pharmacopœia standard of strength. By the second method which was proposed by A. Bettendorff about two years ago, and which I cannot recommend too strongly, a pure acid of 1·16 sp. gr. can be produced with very little trouble indeed.

1st method.—Dilute the crude acid with sufficient water to reduce the specific gravity to about 1·12; saturate it with sulphuretted hydrogen gas, allow to stand for fully twelve hours, decant the clear liquid from the precipitate, drive off the sulphuretted hydrogen by heat and distil after adding a little chloride of sodium.

The sulphuretted hydrogen removes not only the arsenic, but likewise the free chlorine or the sulphurous acid, whichever of the two may be present.

2nd method.—Mix the crude acid whose specific gravity should be between 1·16 and 1·18 (not lower than 1·16) with a small quantity of a solution of stannous chloride in hydrochloric acid of the same strength and allow to stand for twenty-four hours. Any arsenic present will thus be precipitated in the shape of a brown powder (which consists of metallic arsenic with a variable amount of tin). Sulphurous acid if present produces a precipitate of stannous sulphide and is therefore removed along with the arsenic. The filtered acid now only requires to be distilled from a little chloride of sodium, as in the previous process. But as hydrochloric acid of so high a specific gravity parts with a great deal of hydrochloric acid gas on boiling, it is necessary to place a little water into the receiver for its absorption. This method also removes free chlorine if present.

About four years ago a new method of making pure hydrochloric acid from the commercial was published by P. W. Hofmann. According to this one volume of crude hydrochloric acid is to be mixed gradually with $3\frac{1}{2}$ volumes of strong sulphuric acid in a tubulated retort, and the HCl gas disengaged by the heat produced by the addition of each successive quantity of H_2SO_4 is to be conducted through distilled water in the usual way. Fresenius has proved this method to be quite useless, as neither arsenic nor chlorine can be removed by the same.

In reference to the above method of purifying with stannous chloride, I wish to add that I only recommend it for removing, but not so much for detecting arsenic, as the presence of H_2SO_3 in the hydrochloric acid might lead an inexperienced worker into errors.

Sulphuric Acid.—The chief impurities for which this substance must be tested before it should be used for medicinal or analytical purposes are arsenic, lead, and oxides of nitrogen. Arsenic is best detected by Marsh's test, lead by sulphuretted hydrogen, and oxides of nitrogen by ferrous sulphate. An acid free from arsenic and nitrogen oxides, but containing lead, calcium, iron, etc., may be easily purified by distillation, but if the first-named impurities are present mere distillation will not suffice. In that case it is necessary to mix one volume of the acid with six or seven volumes of water, and to saturate the mixture with H_2S. After forty-eight hours the clear acid is decanted from the precipitated sulphides of lead and arsenic, evaporated in a retort until fumes of H_2SO_4 escape and then distilled. What passes over first is too weak, and is rejected until an acid of 1·84 sp. gr. distils, when the receiver is changed. To assure a quiet boiling of the acid, and thus to prevent the cracking of the retort, it is extremely useful to conduct a slow current of air, by means of an aspirator, through the acid during distillation. Though sulphuric acid purchased as pure from the most respectable houses is sometimes found to contain impurities, this is by no means the case to the same extent as it is with hydrochloric acid, which it is almost impossible to purchase in a state of absolute purity, whilst there is not much difficulty in obtaining a supply of perfectly pure sulphuric acid.

Nitric Acid.—This preparation can be obtained in a state of the utmost attainable purity by distilling commercial acid of 1·42 sp. gr., and of good quality, with a little absolutely pure nitrate of potassium, from a glass retort. What passes over first must be rejected, until an acid distils which, if diluted with water, forms a perfectly clear mixture with solution of nitrate of silver, remaining clear, too, after standing for ten minutes. Not less than two drachms of the acid should be subjected to this test. When thus quite free from every trace of HCl, the receiver is changed, and the distillation carried on until only about one-eighth of the original bulk remains in the retort. If carried on still further the purity of the product would be endangered, as traces of sulphuric acid might pass over with the nitric. Another method of purifying nitric acid consists in removing the HCl by the addition of solution of nitrate of silver to the somewhat diluted acid, decanting from the precipitate and distilling the clear acid with a little perfectly pure nitrate of potassium, until about seven-eighths have passed over. The method is good but is only applicable for preparing an acid of low specific gravity (1·25).

The first method, I feel sure, is the best of all that can be recommended for preparing pure nitric acid of the pharmacopœia strength, and as it presents no difficulties whatever it is, I believe, the one generally applied. The fact, therefore, that it is almost impossible to obtain perfectly pure nitric acid by purchase seems all the more surprising. It is easy enough to get it free from solid impurities, as mere distillation is sure to remove these; nor is there any great difficulty in procuring it free from HCl, but H_2SO_4 is always present, no matter from whom it has been obtained. Many samples of nitric acid sold as perfectly pure may be quite good enough for medicinal use, but the trace of H_2SO_4 present is always a source of annoyance in medical laboratories where the acid is required for accurate scientific investigations. Whoever requires this preparation absolutely free from H_2SO_4 is obliged to make it for his own use. To detect very small quantities of this impurity in nitric acid, the application of the pharmacopœia test, consisting in the addition of a solution of barium chloride to the diluted acid, is altogether insufficient. About four ounces of the acid to be tested must be evaporated on a water bath until a few drops only are left; the residue is then mixed with a little distilled water and a few drops of solution of chloride of barium. A precipitate will thus be obtained from any commercial specimen of pure acid. If nitric acid containing small traces of H_2SO_4, which do not show on the mere addition of a solution of $BaCl_2$, is neutralized or nearly neutralized with pure carbonate of sodium (quite free from sulphate), the mixture will then turn cloudy on the addition of a solution of a barium salt. It is on this account that the presence of even very small traces of H_2SO_4 is often very annoying to the analyst. The reason that manufacturers do not succeed in producing nitric acid of perfect purity by the method described is that they do not reject enough of the acid passing over at the beginning, and that they carry on the distillation too far towards the end, and, finally, that they use impure nitrate of potassium. Howard's pure nitrate of potassium, generally considered as a very pure preparation, still contains appreciable quantities of chloride, which must be removed by recrystallization (stirring the solution well during crystallization, so as to prevent the formation of large crystals) before it can be used for the manufacture of pure nitric acid.

Hydrocyanic acid.—In a preparation like this, the strength must of course be a far more important feature than the purity. The traces of sulphuric acid frequently present seem to me very little, if at all, objectionable in a preparation, the medicinal dose of which is so very small, and which, moreover, is not required in a perfect state of

purity for scientific purposes. But the great disparity in the strength of different specimens of this acid is most objectionable and serious, considering its powerful nature. The pharmacopœia requires it to contain 2 per cent. of the anhydrous acid HCN, but my experience tells me that the hydrocyanic acid used for dispensing in druggists' shops varies from two to about a quarter of a per cent., and even less. I know of cases in which 2 drachms and half an ounce of the acid labelled Acidum hydrocyanicum PB. have been given to dogs without bringing on the least indisposition. The reason of this is, that the preparation is kept in bottles, the stoppers of which do not fit tightly, so that HCN is continually escaping, and can be distinctly noticed by smell without moving the stopper. This is the case with nearly all the common 1 and 2 oz. stoppered blue glass bottles in which the acid is generally kept by retail chemists. How very necessary it is to keep it in bottles with well fitting ground stoppers, and tied over with bladder or gutta percha tissue, and how very great a change it undergoes even in a short time, may be seen from the following:—I purchased a 2 oz. bottle of the pharmacopœia acid, freshly made, from a very respectable wholesale house, and at once estimated its strength by volumetric analysis. It contained 1·6 instead of 2 per cent. It was kept in the same bottle without being tied over, and the escape between stopper and neck was noticeable at some distance. After twenty-four hours it contained 1·2, after two days hardly one per cent., and after a month it contained only traces of HCN. This explains the great disparity in the effect upon animals produced by samples of the acid procured from different retail establishments. Chemists should therefore either prepare their own hydrocyanic acid, or, at any rate, they ought to test its strength by volumetric analysis or by ponderal analysis with nitrate of silver (taking the specific gravity is altogether insufficient); they should keep it carefully closed, and examine its strength again from time to time, as this preparation may lose in strength however well it is kept.

In performing the volumetric test, it is important that not more solution of caustic soda should be used than is necessary to produce a distinct alkaline reaction, as any large excess would lead to an inaccurate result, too much of the solution of $AgNO_3$ being then required for the formation of a permanent precipitate.

Not desiring to give this report any undue length, I reserve the consideration of phosphoric acid, sulphurous acid, and acetic acid for a future occasion.

Mr. Hasselby (Goole): I should like to ask whether it is possible to substitute a definite salt, such as the crystallized cyanide of potassium, for an equivalent quantity of hydrocyanic acid. The solution of one would be as valuable as the solution of the other. I too have noticed a depreciation in strength when acids are kept in stoppered bottles; and it has more than once occurred to me whether some of those members of the Conference who have sufficient knowledge of chemical and medical practice could not find a definite salt as a substitute for a preparation so indefinite as the hydrocyanic acid of commerce is.

Mr. Moss: I can confirm what Mr. Siebold says regarding the difficulty of obtaining nitric acid free from traces of sulphuric acid. I had occasion, some little time ago, to use such nitric acid for oxidizing purposes, and was quite unable to obtain it, though I applied to one of the first houses in London. I was not able to detect sulphuric acid by the ordinary Pharmacopœia test, but found it without any difficulty by the method of evaporating a quantity, diluting, and adding a solution of barium salt.

The President: The suggestion with regard to the use of cyanide of potassium is too important to be overlooked. Some years ago cyanide of potassium was sent out in bottles labelled with a formula for the preparation of hydrocyanic acid by the addition of tartaric acid to its solution.

Mr. Groves: A physician, of Weymouth, was in the habit of ordering cyanide of potassium in this manner. On one occasion he ordered half-grain doses. I remarked that it was a dangerous dose. His reply was that he had prescribed it before. Upon inquiry I found out that the stuff really used was the common fused cyanide. The use of a salt so deliquescent and easily alterable as cyanide of potassium is not, in my opinion, to be recommended. The cyanide of zinc, on the other hand, is perfectly stable, readily yields up its hydrocyanic acid to the acid juices of the stomach or to dilute mineral acids, and is, I think, deserving of attention, if not to a place in the next Pharmacopœia.

Mr. Williams: Pure crystallized cyanide of potassium is much more permanent than Mr. Groves seems to think. It is somewhat deliquescent, and should be kept in a well-stoppered bottle. The use of cyanide of potassium is a very old idea, but I believe has been nearly given up by medical men. At first sight, it appears a very feasible plan. By adding an equivalent of tartaric acid a bitartrate of potassium is formed and a solution of hydrocyanic acid is obtained. While I am speaking I should like to allude to the question of arsenic. A process lately recommended for detecting arsenic is by means of hypophosphite of potassium. I have found that a slight addition of hypophosphite of potash or soda to hydrochloric acid containing arsenic, and then boiling, gives a brown colour, the arsenic being, in fact, reduced to a metallic state. The author of this test recommends that we should take advantage of it to produce pure hydrochloric acid by using the hypophosphite and then distilling the acid. He says that by adopting that method we can obtain a perfectly pure acid, and, for my part, I think that is not an unlikely result. I can corroborate the statement made with respect to the difficulty of separating sulphuric acid entirely from nitric acid; I have found great difficulty in doing it completely. Mr. Siebold seems to speak of it as being a comparatively easy process. So it is, if the distillation is conducted on a very small scale, and very slowly, but if the distillation is conducted at a comparatively rapid rate—a rate at which the manufacture of it must proceed in order to make any quantity, I think it will be found that some sulphuric acid nearly always passes over. I have found it so myself, and I should be glad if a mode could be devised of separating entirely sulphuric from nitric acid.

Mr. Siebold: The complete separation of sulphuric acid from nitric acid is not difficult with an acid of high specific gravity (say 1·4), the boiling-point of which is very high. At that temperature, if the distillation is carried on too far, or if too little KNO_3 is used, some traces of sulphuric acid invariably pass over; but if we are satisfied with an acid of lower specific gravity suitable for most analytical purposes (say 1·25 or thereabouts), then we can always succeed in producing a nitric acid perfectly free from sulphuric acid. I succeeded in preparing it in either way, but I have not succeeded in obtaining it of higher specific gravity than 1·42. As to removing arsenic from hydrochloric acid, I think you will find that hypophosphite is not so suitable as stannous chloride. This will remove every trace of the arsenic from the acid, and as a test for arsenic it is a very delicate one. With respect to hydrocyanic acid, an extremely diluted acid keeps much better than a strong one. For this reason hydrocyanic acid is rarely used in Germany. Aqua laurocerasi is used instead of it. If you examine this preparation from time to time, you will find that the strength of it hardly varies at all. It seems to be a pretty constant preparation, but we should take care that we get the right thing. A great deal of aqua laurocerasi sold to us is made from essential oil of bitter almonds with magnesia in the manner so well known to us, therefore we should test this article in any circumstances; but in repeating the test from time to time you will find that the aqua laurocerasi changes very little indeed, the extent of the change being nothing as compared to those of the changes which take place in the stronger acid.

Mr. F. M. Rimmington (Bradford) : I have observed that the bottle itself is frequently the cause of the decomposition of the acid. If the glass contains an excess of alkali it is sure to destroy the acid in a short time. I have made it a practice to test the bottles before filling them. In this way I wash carefully with distilled water, put them to dry on a sand bath, or hot plate, in order to ascertain whether there is any portion of salt left on the side of the bottle. Or you may test them with test paper if more convenient to adopt that method. If they show any alkalinity it is sure to destroy the acid.

Mr. Williams : I should like to mention one thing with respect to the hydrocyanic acid, and that is the advisability of adding a mineral acid. For it is impossible that hydrocyanic can be kept when absolutely pure for any length of time. It is essential that a mineral acid should be added to the pure hydrocyanic acid. I have pointed this out on a former occasion to Dr. Redwood and other gentlemen who have to do with producing the British Pharmacopœia ; and I strongly urge that a quantity of hydrochloric acid, equal to the quantity of hydrocyanic acid present, should be ordered to be added, to preserve the hydrocyanic acid. I think you may safely add two per cent. of hydrochloric acid to two per cent. of hydrocyanic acid solution. In this way the acid can be preserved much longer than in any other way.

Professor Attfield : In reading the paper I noticed that Mr. Siebold quarrelled with an old favourite of mine, namely, the copper test for arsenic. It is so extremely convenient to use copper to get out arsenicum when organic matter is present, that one does not like to give it up because it is supposed to be a little less delicate than the others. I myself think that it is not inferior in delicacy to any of the tests, and that the reason why analysts sometimes fail with the test in endeavouring to detect very small quantities may be found in the fact that they use the ordinary test-tube in heating the strip of copper. Even in the hands of a student, I have found that if a fair piece of copper be heated for a considerable time with the acid liquid, and if, after boiling, washing, and drying, it be cut into strips and placed in a test-tube, narrow on the whole, but at the bottom of which there is a considerable sized globe or bulb, then the whole of the bulb heated in the flame, and the test-tube held almost horizontally the arsenic will crystallize in the narrow part of the tube in a pretty little ring.

Mr. Groves : I think the plan I practise is more simple than that. I put the copper into the bottom of one test-tube, and then drop another closely fitting tube into the first one, I then place a little water in the second one, and, upon heating it, the arsenious acid is deposited on the bottom of the cold tube in a beautiful bloom. I have succeeded in obtaining arsenic thus with the third of a drop of liquor arsenicalis B. P., and verifying it by the usual tests.

Mr. Siebold : I quite agree that the copper test is exceedingly handy, and, if carefully performed, very delicate ; but I am convinced in my own mind that, for the detection of very small traces of arsenic in so-called pure hydrochloric acid, it is inferior to the test I have mentioned. Traces of arsenic which escape observation by the most careful application of the copper test may be detected in the manner described, as may be seen by mixing impure HCl with ten or twenty times its volume of perfectly pure acid, and submitting this mixture to the two tests.

Mr. Siebold having been thanked for his communication, the Conference then adjourned for luncheon.

Upon re-assembling the first paper read was on

Alchemy, and Its Bearings on Pharmacy.

BY W. D. SAVAGE.

Dr. Johnson calls alchemy "the more sublime and occult part of chemistry, which proposes for its object the transmutation of metals and other important operations." Shakspeare, in 'Julius Cæsar,' alludes to alchemy ; and in 'King John' he says :—

> "To solemnize this day, the glorious sun
> Stays in his course, and plays the *alchemist ;*
> Turning, with splendour of his precious eye,
> The meagre cloddy earth to glittering gold."

Our friend Professor Attfield tells us at the time the name was given it had little more for its object than the transmutation of the baser metals into gold. Whatever may have been the original object, there can be no doubt, in the efforts used to ascertain the combination of the metals, that the experience thus acquired tended to promote the science of chemistry, which we are told by modern lexicographers, "Is the science which determines the constitution of bodies, and investigates the laws which regulate the combination and mutual action of their elements" ; let us then briefly consider some of the circumstances which have contributed to the building up our present pre-eminent position. Alchemy was not always followed by its professors with the purest motives ; it has been designated as "An art without art, originating in falsehood, and proceeding through labour to beggary" ; still we have much in the dark and mysterious gropings of the ancient philosophers to be grateful for, in aiding to develop practical chemistry.

The origin of alchemy is somewhat doubtful, for whilst some contend that it was known to the priests of the Egyptians, others again, with some reason, affirm that it was unknown till about the eleventh century, supporting their views by reference to Herodotus and Pliny, who they say were not likely to overlook so important a matter, if it had been known to the Egyptians. It would appear that the first Greek or Roman writer that refers to the subject is Suidas (in his Lexicon occurs *Chemia*, the conversion of silver and gold), but Dr. Thompson says that if the art of *making silver and gold* implies alchemy (or al-chemia), the chemistry of chemistries, it originated with the Arabians when they began to turn their attention to medicine. In the Book of Exodus, we are told that Moses caused the molten calf to be burnt in the fire, ground into powder, and strewed upon the water, and the Israelites made to swallow it ; if this was effected by chemical agency, we are not aware of the means ; it is not likely that they knew anything about the perchloride, but rather that a miracle was performed to impress the astonished multitude. We must, however, pass over much that is interesting, and come to consider *alchemy* as illustrated by the erratic Paracelsus, a native of Zurich, and born in 1493. His father was a physician, and instructed him in *alchemy*, *astrology*, and *medicine*. With a large amount of knowledge and experience he combined an inordinate amount of self-esteem. He is said to have been the first who ever held a Professorship of Chemistry in Europe, having been elected, in 1527, to the Professor's Chair at Basle ; but he was so conceited that he burnt with great solemnity the writings of Galen and Avicenna because they did not agree with his views, and it was no wonder that they did not, when he publicly declared that if God would not impart the secrets of physic, it was not only allowable, but even justifiable, to consult the devil. He was a dissipated wandering empiric, who professed to have a panacea which was capable of curing all diseases in an instant, and even of prolonging life to an indefinite length. Alas ! for the fallibility of human nature,—a few hours' illness terminated his life, when but forty-eight years old, at Salzburg, in Bavaria. Chemistry does not seem to owe so much to him as to the influence which he had on others. He did not scruple to denounce the schools and systems of others, whilst he had no well-arranged plan of his own. We are told that he adopted the *three elements*, of Basil Valentine, of *salt*, *sulphur*, and *mercury*. With respect to mercury, he was the first to administer it internally, and gained some celebrity by curing syphilis with it. About the same time (1540), a a physician of Paris (Antoine Lecoque) acquired con-

siderable reputation by curing the same complaint by the administration of gold, but in what form is not mentioned. It is curious to observe the union which existed betwixt the early chemist and the physician, and how often this combination forwarded the usefulness of both. However, this connection has not always been productive of good, for the early chemists were too much disposed to attribute the source of all disease to the presence of some hostile acid or alkali, or some deranged condition in the chemical composition of the fluid or solid parts; so they conceived all remedies must act by producing chemical changes in the body. On this hypothesis, a fever which raged at Leyden, in 1699, was treated by absorbents and testaceous medicines, to counteract the pernicious influence, as they thought, of some prevailing acid. The consequences proved most serious, as two-thirds of the population of the city found an untimely grave.

The Arabs seem to have been the great promoters of the school of poly-pharmacy. The '*Summa Perfectionis*' of Gebir, in the eighth century, the earliest work on chemistry, is said to be such a strange production that Dr. Johnson believes the word *gibberish* to be derived from the name of the author. These gropings in the dark, however, to discover the means of attaining perpetual youth and boundless wealth by the philosopher's stone, have not been unattended with advantage to science, although it seems a mystery, viewed in the light of modern knowledge, how two such opposite results could be obtained. The assimilation of gold by the precipitate from mercury, or, as it was termed, the "*Mercurius precipitatus per se*," was sufficient to impose on the credulous. This, I say, after all is not so wonderful, but the *perpetual youth* anticipated from the discovery is not so easily explained, unless indeed that wealth, being all-powerful, was used metaphorically to imply freedom from care and, as a sequence, longevity. Alchemists believed the metals were composed of sulphur and mercury, the differences in their properties resulting from the differences of the degrees of combination—gold, for instance, was formed of pure mercury, united with a small quantity of sulphur, also very pure; copper was formed of mercury and sulphur of almost equal proportions, and so on; but the sulphur and mercury, mentioned by the alchemists as performing such an important part in metallic combinations, were not always the common articles known by these names now. The *Mercurius* represents the metallic element, cause of ductility and brightness of metals, whilst *Sulphur* represents the combustible element, then known as "Phlogiston." The problem, therefore, was to change the proportion of the elements—acquired only by much experience and careful manipulation—so as to effect the respective changes, and as the mass of the people knew nothing of the simplest results of chemical combination, they were easily imposed on. An instance of this kind is related of one Bragadino (*alias* Count Manugnaro), who assured his dupes that by travelling much in the East he had become initiated into the secrets of alchemy; his public exhibitions *seemed* to justify his pretensions, and when his patrons failed to produce the same results it was their bungling,—for had he not *publicly* shown them *what* could be done? His secret was simply the employment of an amalgam of mercury and gold. His acquisition of wealth gave him a position which proved his downfall, for in 1590 he exhibited before the Court at Munich, when his cheat was detected, and he was hung. Previous to this he had gone about Germany with two immense black dogs, proclaiming that Satan himself was subservient to his power. Another class of empirics may be mentioned —those who secreted gold-dust in charcoal and disguised it by amalgamation with silver and other metals. Some few years ago we had analagous cases of imposition practised in London and many of the large towns, by pretending to extract payable quantities of gin from bread. In Brighton a large concern was started, expensive machinery erected, and the products of distillation carefully stored, but the yield of spirit was so little that it would not pay. It was generally believed that the experiments showing favourable results were effected by the fuel being first impregdnated *with spirit*. Scientific roguery was not confined to our ancestors—every day reveals some new scheme of modern alchemy, requiring neither the exhibition of the crucibles with false bottoms nor *golden coloured* metals to obtain dupes.

But recurring back to our history, Roger Bacon claims a prominent place as a philosophical alchemist. He was a native of Somerset, born in the year 1214. He became a Cordelier Friar,—pursued his studies as privately as possible; notwithstanding, he was accused of magic and suffered ten years' imprisonment. He is said to have written nine works on chemistry and alchemy, but the only printed one, Dr. Jebb states, was the 'Speculum Alchemiæ.' It is said that he invented gunpowder; this has been doubted. At any rate, his description of thunder and lightning—produced from a mixture of sulphur, nitre, and charcoal—would lead one to believe that its composition was known to him, and to a certain extent its effects; but he very judiciously says—you must know the method of mixing them! The next name suggested in the order of succession is Raymond Tully, a friend and scholar of Bacon's, born in Majorca in 1235. He it was who introduced those hieroglyphical figures or symbols which are so strangely, and, in most cases, inappropriately used to ornament the globes in our shop windows. Tully (according to Gmelin) was acquainted with carbonate of potash, for we are told he *distilled* cream of tartar, burnt the residue, and obtained a deliquescent salt. He was acquainted with nitric acid, which he produced from saltpetre and green vitriol. He mentions its power of dissolving mercury and other metals. His aqua regia was made by adding sal ammoniac, or common salt, to nitric acid, and he was aware of its power to dissolve gold. Spirit of wine was known to him as aqua vitæ ardens, and he knew how to make it stronger by using dry carbonate of potash, and that he could prepare vegetable tinctures from it; he also mentions alum from Rocca, marcasite (bismuth), white and red precipitate of mercury. He first obtained oil of rosemary from the plant by distillation. He made a lute with flour mixed with white of egg and spread on linen, and although the writings of Raymond Tully are mixed up with a good deal of jargon, yet in considering the progress of chemistry five centuries ago, much merit is due to the efforts of this wonderful man.

Arnoldus de Villa Nova, a native of a village of Provence, is said to be the author of a work entitled "Rosarium" intended as a complete work of alchemy of the time. Like most of those who preceded him he considered *mercury* was the constituent of metals. He professed a knowledge of the "philosopher's stone." Gold and gold water were in his opinion the most precious of medicines. He employed mercury in medicine, and prepared a mixture of oil of turpentine, oil of rosemary, and spirit which afterwards became famous as "Hungary water." His distillations were made in glazed earthen vessels with a glass top and helm.

In the middle ages alchemy became a favourite pursuit in many European countries. Edwards I. and III. were believers in it; indeed in the reign of the last-named monarch a proclamation was issued for the apprehension of two famous men who knew how to make silver by the art of alchemy, and who "may be profitable to us and our kingdom."

Basil Valentine, a Benedictine monk of Erford in Saxony, born in 1394, was a distinguished alchemist, and the first to suggest the method of preparing antimony, and his experiments with it on his brother monks resulted in his killing several and injuring others. The everlasting pill of the ancients consisted of *metallic* antimony, which, Dr. Paris says, being slightly soluble in the gastric juice, was supposed to exert the property of purging as often as it was swallowed. Strange theory! Just imagine *one* pill for the repeated use of a whole family for their

lives; can modern homœopathy boast of anything equal to this?

Valentine has the credit of discovering the volatile alkali and its preparation from sal ammoniac. He used the mineral acids as solvents and noticed the production of ether from alcohol. He is said to have given iron as a tonic, and a fixed alkali made from vine twigs cut in the beginning of March, for the cure of gout and gravel. He thought the metals were compounds of *salt*, *sulphur*, and *mercury*, and that the philosopher's stone was composed of the same ingredients; that a great similarity existed in the mode of purifying gold and curing the diseases of men, and that antimony answers best for both. He was acquainted with arsenic, knew many of its properties, and mentions a red compound which it forms with sulphur. Zinc and bismuth were known to him, and he was aware that manganese was employed to render glass colourless. Many of the preparations of mercury, such as the nitrate, bichloride, and red oxide were known to him. He also was acquainted with acetate of lead as saccharum saturni.

A subject of such vast importance, extending as it does over centuries, cannot possibly be compressed in the small space allotted to me. I must therefore content myself with a summary, applying in the best way I can its bearing on pharmacy, although its natural affinity is chemistry. In taking a retrospective view of Paracelsus and his doings, we cannot help observing a large amount of mysticism and error mixed with truth. For instance, he says the fundamental force of a thing is a *star*, and defines alchemy as the art of drawing out the *stars* of metals. According to Dr. Thompson he had two *laudanums*; one was red oxide of mercury and the other consisted of 1 oz. chloride of antimony, 1 oz. hepatic aloes, ½ oz. rose water, 3 oz. saffron, and ℥ ij ambergris, mixed together; and in one case it is related that three drops effected a cure, and in another, three pills killed the patient. As to what menstruum was used to make either of the above into drops we are left in ignorance. His elixir of life was said to be a solution of common salt. He had a strange conception that a power which he calls *archæus* (nature) presided over the chemical operations of the stomach, separating poisons from nutritive food. That *tartar* is the principle of all the maladies proceeding from a thickening of the humours, the rigidity of the solids or the accumulation of earthy matter, so that medical men are enjoined to discover the *tartar* before they try to explain the affections. As *tartar* is deposited at the bottom of the wine cask, so in the living body is it deposited on the teeth. When we employ vegetable substances for the cure of diseases we are to consider their harmony with the constellations. The doctrine of signatures, as it was called, supplied another means of knowing how far the nature of the disease was indicated by colour of the remedy—thus, saffron and turmeric were good for jaundice, and in the animal kingdom the lizard is said to have the colour of malignant ulcers and carbuncles, and therefore a suitable remedy. Polygonum persicaria (dead or spotted arsmart) was an infallible remedy against all the effects of magic. However, with all his strange conceptions, Paracelsus was a great reformer, and representing *chemistry* as he did, an indispensable art in the preparation of medicines, he effected great good by getting rid of the objectionable, and in many cases, disgusting decoctions and syrups, by substituting *tinctures*, *essences*, and extracts, and it is said that he was the first to introduce *tin* as a remedy for worms; mercury, arsenic, zinc, and bismuth were known and used by him, and as sulphate of potash is called by Oswald Crollins, of Hesse, *specificum purgans paracelsi*, we may infer that he was in the habit of using it.

Crollius added some valuable remedies. The binoxide of mercury he calls *arcanium corallinum*; the chloride of silver was *Luna Cornea*, and calomel he called *Mercurius dulcis*. Passing over many names more or less important in the history of alchemy, we must not omit, however, altogether *John Baptist Van Helmont*, a physician and chemist of Brussels, who was distinguished by alternately adopting and rejecting the art of magic, as practised by the Jesuits, the doctrine of the Stoics, the sacred books of mysticism, etc. An accident, we are told, induced him to devote his attention to the practice of medicine, and its reformation. Happening to take up the glove of a young lady who was suffering from the disease, he caught the *itch*, and the Galenists whom he consulted, according to their usual practice, assigned the cause as combustion of bile and the saline state of the phlegm, and after reducing him to great weakness by a course of purgatives, without effecting a cure, he determined to study medicine for himself, and he took the degree of M.D. (1599), travelled through France and Italy, and we are told performed many cures by the way. It is foreign to our purpose to follow him in all his curious proceedings. He tells us the *Archæus* of Paracelsus draws all the corpuscles of matter to the aid of fermentation, that *water* is the true principle of everything which exists; and he illustrates this by drying 200 lbs. of earth and planting in it a willow weighing 5 lbs. The earth and plant were kept moist with rain-water, and at the end of five years, notwithstanding the earthen pot in which the willow was planted was covered with a perforated tin plate to keep out the decayed leaves of autumn, the willow weighed 169 lbs. 3 oz. The earth having been again dried, was found to have lost but 2 oz. of its original weight, so that 164 lbs. of wood, bark, and root was produced from water alone (air?) But we must pass over much that is interesting, and briefly refer to some of the things more immediately connected with ourselves. Van Helmont knew the properties of carbonic acid gas under the name of *gas sylvestre*. Sal ammoniac, he says, may be distilled alone, and so may aqua fortis, but if mixed together so much *gas sylvestre* escapes as to burst the vessels, unless it has a means of escape. He was evidently aware of the evolution of gas in mixing the solution of carbonates and metals in acid, but he was unable, as we are, to collect and distinguish the kind of gas. It is said that he swallowed some henbane; that in two hours he had the most disagreeable sensation in his stomach, and having no longer the free use of his mental faculties, he believed the seat of the understanding to be in the stomach, of volition in the heart, and of memory in the brain. He seems to have known the gastric juice, which he calls an acid liquor for dissolving the food, but under the mysterious influence of the Archæus. The *tartar* so vaguely described by Paracelsus is much more clearly defined by Van Helmont, who says it is a crystallized salt, but he retains his belief in the mythical *Archæus*, when he says mercurials, antimonials, opium, and wine are agreeable to it in a state of delirium from fever. His mercurius diaphoreticus is supposed to have been calomel; his *golden sulphur* would appear to be sulphurated antimony; and his antimonium diaphoreticum seems analogous to our P. Antimonalis, but not so pure. Opium he used as a *fortifying* and *calming* medicine. Whatever that may mean (seeing that he considered it to contain an acid salt and a bitter oil) may be guessed rather than defined.

I might enumerate many other distinguished names who have contributed more or less to the alchemists' creed, but enough has been said to connect the ancient professor of alchemy with the modern chemist, and the efforts of both to promote pharmacy; and whatever may have been the motives of those who early practised the art, much valuable information has been elicited. We may smile at their processes. Perhaps our successors may smile at our *allotropic* and *molecular* theories. One thing is quite certain, that we are not behind the alchemists in our efforts to *procure gold*; indeed we go far beyond them, for we try to convert not simply the inferior metals, but *everything* into gold. We may wonder at men being foolish enough *to pay* for a knowledge of a secret which, did the owners possess, would render future efforts unnecessary. Are we much wiser in this age of enlightenment? Does not the promised 50 per cent. of the underground never-ending calling up capital of the Borough Mining Company

suggest something like it? But I will conclude with one of Æsop's fables. A certain man bequeathed to his sons a treasure which was buried in his vineyard. They dug and dug, but no treasure could they find. There was, however, a treasure in store, for the future crops revealed the wisdom of their father; and it is just this that the alchemists did for us.

Mr. GROVES: Having devoted my attention in some degree to archæology I have not forgotten to study the archæology of chemistry, and I have consequently read many of the ancient chemical works to which Mr. Savage has referred in the course of his paper. In one, of which Glauber was the author, it is asserted that there is an intimate connection between the metals and the stars, and now we have some reason to believe that the metallic veins in the earth were produced probably by electrical currents, and that those currents were induced by the action of the stars and chiefly by that of our great star the sun. It just occurs to me to suggest that the gold of the golden calf which Moses caused to be burnt and ground to powder, referred to by Mr. Savage, must have been Mosaic gold!!

Mr. HAMPSON: The alchemists used saffron. We use that article also, but I think it might be usefully expunged from our pharmacopœia as a relic of alchemy.

A vote of thanks to Mr. Savage for his paper was passed.

(To be continued.)

Parliamentary and Law Proceedings.

ADULTERATION OF MILK.

At the Glasgow Central Police Court on September 30th, Alexandri Russeli was charged with having sold a quantity of milk, the same having been mixed with water. After evidence had been taken as to the purchase—

Dr. Thorpe, Professor of Chemistry in Anderson's University and City Analyst, deposed: I remember a sample of milk being brought to me by the sanitary inspector and the preceding witnesses on 9th September. I took a portion of the milk and analysed it, and on the 12th ult. gave the following certificate:—"Found that the sweet milk which I received on the 9th of this month was mixed with water to the extent of 10·6 per cent. The cream was only 5·6 per cent." I thought a portion of the cream must have been removed, it was so low. I have seen a poorer sample of milk. The water had been added after it came from the cow. I have the means of ascertaining that by determining the soluble matter the milk contains.

Cross-examined by Mr. Lang: Could you, by any analysis whatever, tell when the water had been put into the milk?—No. Supposing that the milk comes from the Mearns, passes into the hands of the wholesale dealers in Glasgow, then into the hands of retail dealers, and you find water mixed with the milk in the hands of the retail dealers, can you tell whether the water was put in in the Mearns, at the wholesale dealers', or at the retail dealers'?—No. I am not aware of any possibility of telling. Milks vary a little as they come from cows. The component parts of milk are fats, sugar, salts, and water. The water in different samples of milk varies. I determine the addition of water in two ways; in the first place, from the specific gravity of the milk, and in the next from the total solid matter which it contains. Average milk contains about 12½ per cent. of solid matter. It is never less than 11½ per cent., and very seldom less than 12. In this particular quantity of milk I found the total solid matter was 10·4 per cent. The average amount of cream in Glasgow milk is about 8½ per cent. I have determined this point by examination of upwards of 200 samples of the milk sold in Glasgow, collected by myself and my assistants. This particular sample of milk had 5·6 per cent. of cream. By the two methods I make out that the added water is 10·6 per cent. I examined a sample of milk handed to me by Mr. Cossar on the 29th September, and gave him a report to the effect that the specific gravity was 1032 before creaming, and 1033 after creaming; that the cream was 6¼ per cent.; that the total amount of fat and cheese-forming matter, sugar, and salts was 11·92 per cent. Then I say:—"These results appear to show that this milk is free from any sensible amount of added water—that skimmed milk is present, but in inconsiderable quantity." The specific gravity of defendant's milk was 1030 before the creaming, after creaming 1031. The amount of cream was 5·6 per cent., and the amount of solid matter 10·4. There are various modes of testing milk. One method extensively used, especially in France, consists in determining the opalescence of the milk—that is to say, one looks through a disc of milk and determines how far one can push a tube containing milk before the object becomes opaque. Of course one can see further through thin milk than through thick. Another test consists in a full analysis of the milk, determining it into its several constituents. In this case I did not have a full analysis, nor did I determine the opalescence.

The Procurator-Fiscal: Would a full analysis of the milk have given you any other result, so far as the presence of water is concerned?—No. The French method is seldom used, because its results are not considered reliable.

The evidence for the prosecution having been closed, an application was made on behalf of the defendant that the remainder of the milk should be placed in the hands of another chemist for analysis, and after some discussion it was agreed that it should be sent to Dr. Thomas Anderson, Professor of Chemistry in the University of Glasgow. An application was then made on behalf of Dr. Thorpe that a portion of the milk should be obtained from Dr. Anderson on the seal being broken, that it might be placed in the hands of another chemist for analysis. This gave rise to a long wrangle. On the one hand, it was contended that the case for the prosecution being closed, it would not be allowable for the procurator-fiscal to produce additional evidence, and that therefore there would be no utility in the third analysis to check Professor Anderson. On the other hand, it was urged that as no objection was raised as to Dr. Thorpe's analysis while the evidence was being given, the defendant was not entitled to a fresh analysis, or if this were granted, that the prosecution was entitled to offer rebutting evidence in the event of Professor Anderson's report being contradictory to Dr. Thorpe's. To this latter view the presiding baillie appeared to incline, but there does not seem to have been any definite order made other than that the sample of milk preserved should be sent to Dr. Anderson for analysis. The case was adjourned to the 14th inst.

Two other similar cases were heard, in each of which there was a conviction, and the mitigated penalty of 10*s.* was imposed.—*From the Glasgow Herald.*

POISONING BY CREOSOTE.

On Thursday, October 2nd, an inquest was held at the General Hospital, Belfast, before Dr. Dill, Borough Coroner, on the body of a child named Hugh M'Neill, who was poisoned by drinking a quantity of creosote on the 28th September last.

Rose M'Lean deposed that deceased was about three years old, and on the day above stated was heard screaming, and was found in bed with a bottle in his hand which had recently contained creosote. Some water was applied to the child's lips and throat, which were severely burned by the creosote, and he was immediately removed to the General Hospital. The creosote was used by a man who lodged in the house who suffered from toothache. The bottle was produced, and bore no label.

James M'Lean said he found a label under the bed, and on it was printed "Creosote; from Moorhead and Company, 202 and 204, North Street," "Poison" not marked on the label.

The jurors at this stage of the proceedings were desirous of seeing the Act of Parliament regulating the sale of medicines, drugs, poisons, etc.

It was found that creosote was not included in the list of poisons specified in the Act 33 and 34 Vic., cap. 26, section 1.

The evidence of the house-surgeon went to prove that the child was admitted into the hospital on the 28th of September last, labouring under symptoms of irritant poison, his lips, mouth, and throat being badly burned, and died from its effects four days afterwards, and that the said poison was creosote. The child had taken a large quantity, and his suffering was intense.

The jury returned the following verdict :—"That the said Hugh M'Neill, in the General Hospital, in the Borough of Belfast, on the 2nd day of October, 1873, came to his death by accidentally imbibing a quantity of creosote, which was incautiously laid in his way, on the 28th September, 1873 ; and the jurors do further say that it would be highly advisable (having regard to the medical evidence disclosed at this inquest) that owing to the frequency in which creosote was used by the general public it should in future be labelled 'Poison,' and that means should be used to have it placed on the list of poisons included in the Act of Parliament, 33 and 34 Vic., cap. 26, section 1 ; and the jurors do further wish to urge upon the press the necessity of making known to the public the facts as unfolded at this inquiry—viz., that creosote is an irritant poison, and should be used with extreme caution." —*The Belfast Northern Whig.*

Obituary.

Notice has been received of the death of the following :—

On the 18th August, Mr. Morgan Jones, Chemist and Druggist, of Swansea.

———

On the 3rd October, 1873, Mr. Richard Finden Jones, Chemist and Druggist, of High Street, Oxford.

Notes and Queries.

[362.] COCHINEAL COLOURING.—In reply to E. Nicholson, I beg to say that if the following be carefully manipulated with the best and pure articles, it is excellent :

Take of	Cochineal (the best quality),	
	Salts Tartar,	
	Cream Tartar,	
	Alum	āā 1 oz.
	Distilled Water. . . .	8 oz.
	White Sugar.	4 oz.

Boil the cochineal (powdered) and salts tartar in the water in a large vessel ; then add the cream tartar and alum (powdered fine) and strain through muslin. Afterwards filter and make up to 8 oz. Add the sugar, and dissolve by means of gentle heat. Some use S.V.R. (℥ ss. to ℥ j) instead of sugar, but I much prefer sugar.—J. B.

The Preliminary and Prize Examinations of the Pharmaceutical Society.

Sir,—It is with considerable regret that I find the mode of conducting some of the examinations of our Society (notably the Preliminary and sundry prize examinations) has been made a subject of discussion at the Council table. Had it rested there I should have consulted some of my late colleagues in preference to stating my views through the medium of the Journal, but seeing that some members of the Pharmaceutical Conference have, as it were, made stock of the question, and publicly opened the case, any reticence upon my part is not required ; as an ex-member of the Board of Examiners my experience may be worth something, and being unattached I may write if possible with more than my usual independence. Without any desire to find fault with individual opinions, I may be permitted to state what I believe to be just and desirable. There are three definite opinions which have been expressed as to the future of these examinations—1st. That they should be conducted in London or Edinburgh ; 2nd. That the Preliminary should be turned over to almost any legally qualified examining board rather than our own ; 3rd. That they should still be conducted by ourselves. To this last opinion, as I have ever done, I still adhere. I will in the first place endeavour to show that my opinion is in accordance with the Charter and Act, and then having stated the principal objections of those who are of a contrary opinion, will attempt to refute them. I believe that in accordance with the intention and spirit of the Charter and Act it is the duty of the Society to examine all who present themselves, or perhaps in plainer terms, that candidates can demand to be examined by the examiners appointed by the Society and not to be sent about to other institutions—see line 205 etc., of the Charter of Incorporation, clause viii. of the Pharmacy Act, 1862, and clause vi. of the Act, 1868. Thus much for what I deem to have been originally the spirit and intention of the law. It is also clear that the Council of the Society can alter any bye-law for the appointment of Professors or others as examiners, and may make such regulations as to time or place or otherwise as may be considered convenient or desirable. Now this convenience applies as well to the examinee as the examiner. When the examinations were voluntary every reasonable facility was afforded the candidates. Why not so now? The candidates for the Preliminary have the option (let it remain optional) of passing (in lieu of our own) the Local Examinations of the Universities of Oxford, Cambridge or Durham, the examinations of the College of Preceptors, or those of any legally constituted examining body previously approved by the Council, *provided Latin and Arithmetic be included in the subjects.* Still the candidates prefer coming to their own in spite of the large percentage of failures and the sometimes assertion that the examination is too stiff (occasionally that it is not stiff enough). The reasons advanced by those who desire a change are—1st. That the Preliminary would be better performed by a scholastic examining board. 2nd. That sufficient attention has not been given by those appointed to superintend the writing of the answers. 3rd. That the candidates assist each other. To the first I simply say, knowing how much or how little is required, if, out of the twelve or fourteen gentlemen constituting the Board of Examiners, some cannot be found conscientiously and satistactorily to perform that duty, I weep. To the second I do not, and I never did, believe in the wilful negligence of the Local Secretaries. Occasionally an unavoidable irregularity has occurred, but it has been stated somewhat in extenuation that the printed regulations for the guidance of the superintendent have not been always enclosed with the questions. Here, then, are two possible sources of error which are easily remedied, and do not prove the system bad ; it is only irregularity on the part of those entrusted with certain duties. It cannot be expected that the members of the Board of Examiners will undertake to see mere office work done, whether in Bloomsbury Square or elsewhere, and is it to be supposed that such irregularities never happen to other examining

boards of even longer standing? As I stated at the annual meeting, the remedy for such would be to arrange for the writing of answers to take place at different large towns throughout the country, the most convenient for candidates from the smaller places to attend. Besides the Local Secretary, let one other gentleman be appointed, so that in the event of one being unable to superintend, the other might still be available. If necessary, hire a room for the occasion, and if required, pay the superintendent. Like other things which have been said and written, I cannot bring myself to credit that gentlemen are not to be found willing and able to devote three or four hours once in three months for the benefit of their Society and the convenience of the rising generation of pharmacists. Do any think this a hardship? If so, let them remember how many days, and sometimes a portion of the night, Members of Council and others devote to the service of the Society, and for honour and conscience' sake as their recompense. For the third reason, that candidates assist each other, the little knowledge I possess of human nature, as exhibited at competitive examinations for prizes, forbids my acquiescence upon such occasions to the statement made. At the Preliminary such might be attempted, but I think the percentage of failures is sufficient to prove that little comes of it beyond the blind leading the blind. That a great similarity in the words employed and the answers given by candidates in the same town should tend to the opinion that they had copied from each other is reasonable, but I have generally yielded to the more charitable construction, that they have been coached by the same person. It would be decidedly hard upon the present race of pupils or students to compel all to come to London or Edinburgh, or to send them to pass the Preliminary at particular Local Examinations only. Some of my fellow-workers seem to ignore one grave and serious fact, that dispensing chemists, and those intending to become such, are not as a rule rich men, and that every extra expense is a pull, often borne with patience, but not lovingly. It is possible to expect too much education, and to carry it to such an extent as to extinguish the really useful assistant. Judging from a mercantile or trading point of view, I have known the trade for many years, and I see a scarcity of good useful assistants, and those who were co-assistants with myself know it but with increased expenditure and a large diminution of profit. But to return to the Preliminary, there is yet another point from which it may be viewed. A fee of five guineas, as the matter now stands, covers the Preliminary and the Minor. By sending the candidates away from the Society the trouble and the expense of the Preliminary would be removed from the Society and transferred to the candidate. The gentlemen who form the Council cannot, I am confident, have considered the question from this aspect, and I sincerely hope that no Council of a wealthy Society like the Pharmaceutical will ever sanction such a step.

In concluding my remarks, let me add that I have neither seen nor heard sufficient reason for accusing ourselves and the continued thirst for changing our arrangements. A misty dream, picturing the Council applying to the Local Government Board or the Committee of Council on Education, has once or twice disturbed my peaceful repose. May it never be realized, at least in my day!

A. F. Haselden.

18, *Conduit Street*, 13*th Oct.*, 1873.

The Alleged Dispensing Misdemeanour.

Sir,—Relative to the late case of wrongly dispensing a prescription, concerning which a letter appeared in your last week's number, followed by an editorial postscript to the effect that you had in vain endeavoured to find out particulars, I feel constrained to write to you as a matter of public duty, and also to make an explanation.

Having no desire to make a police court subservient to my own publicity, I, in asking for a summons, simply handed my card to the magistrate. As little did I wish to indicate unnecessarily the name of the dispenser who so grossly violated his duty.

This reticence has been misinterpreted. On the one hand a morning newspaper has called me, in a leading article, "the occult" medical gentleman. On the other, a number of conscientious dispensers are pressing on me the need of exculpating them.

Allow me to state that if the Editor of the *Telegraph* had (as was only just to have done) published a letter of full explanation, in reply to his leader, all would have been cleared up. In that letter explanation was made that my practice is wholly conducted by way of prescriptions dispensed at chemists and druggists, hence I could not, and did not, state "that chemists and druggists were in the habit," etc. What I said was that *certain* chemists and druggists were in the habit of substituting one ingredient for another, or leaving it out wholly, when the thing prescribed was a little expensive or a little out of the way.

My prescription was as follows *verbatim et literatim* :—

℞ Syr. papav. alb. . . ℥ ij.
Calcis sulphitis . . gr. xx.
Pulv. tragac. co. . . gr. xv.

Aq. anethi ad ℥ iss. M. ft. mist. quarum capt. coch. min. j post singulas sedes liquidas, vel omnis 2^{s} horis.

The sulphite of lime had been wholly omitted, and lime water substituted—lime water to a child, very delicate, æt. 8 mo., and voiding blood! My little patient is dead. She had been attended by the delinquent for a fortnight anterior to my being called in. What he might have administered I do not know, but I do know he had scarified her gums most cruelly. *I* would not have done it at all.

Permit me to add that this occurrence will originate a civil action against Mr. ——, and, to subscribe myself

Your obedient Servant,

J. Scoffern, M.B., Lond.,

Formerly Professor of Forensic Medicine and Chemistry at the Aldersgate College of Medicine.

Upper Westbourne Park, October 5.

Remuneration of Chemists.

Sir,—A few days ago the following prescription was left here to be dispensed :—

℞

Chloroform		℥ v.
Ti. Opii		ss.
Ol. Olivæ		ij.
Lin. Saponis	ad	℥ ij.

M. ft. Lin.

The price charged was 1*s.* 3*d.*, which we at the time considered low; you may feel assured that when the gentleman called for it we were somewhat surprised when he informed us that he could get it made up for 1*s.* by a house of position and repute not many miles from Oxford Circus. We are of course aware that they have co-operative societies, medical halls, etc., to compete with; but still at the same time I think we ought to be fairly remunerated for our labours, as they entail more than any other class of tradesmen—care, expense, and trouble—and, in order to show our independency and dislike against such a degrading system of cheapness, our prices should be accordingly. There is no doubt but what they do us great harm in sundry articles, such as patent medicines, etc. It therefore behoves our Society, in order not to deprive poor chemists of their legitimate trade, to keep a sharp look out, and try to put down as much as lies in their power all that which interferes with the chemist's welfare.

Sensitive.

520, *Oxford Street, London, Oct. 7th*, 1873.

"Cappa" and "An Inquirer."—The preliminary portion of the operation should be conducted at the ordinary temperature of the atmosphere.

M.P.S.—A table of official tests for impurities in preparations of the British Pharmacopœia will be found in the Appendix to Attfield's 'Manual of Chemistry.'

J.H.—The following is Fehling's formula for preparing the cupric solution, as given in his paper on the "Determination of Sugar by Sulphate of Copper" (see Pharm. Journ., 1st series, vol. ix., p. 419):—"40 grams of pure crystallized sulphate of copper are dissolved in about 160 grams of water, and this solution is gradually added to a solution of 160 grams of neutral tartrate of potash dissolved in a small quantity of water, mixed with from 600 to 700 grams of caustic soda lye of 1·12 specific weight; I then dilute the whole to 1154 4 cubic centimetres at 15° C."

Communications, Letters, etc., have been received from Messrs. Lasham, Provost, Abraham, Tuson, "One who has Known the Drug Trade more than Thirty Years," C. S.

GLYCERATE OF SUCRATE OF LIME AND ITS EMPLOYMENT IN THE PREPARATION OF CHALK LINIMENT.*

BY M. LATOUR.

A recent explosion at Mont Valérien, the victims of which were treated in the military hospital of Saint-Martin, where the author is pharmacien principal, gave him an opportunity on a large scale of profiting by a rapid method of preparing an oleo-calcareous liniment, which he has practised for some time with satisfactory results. It is specially when it is necessary to prepare such a compound quickly and in considerable quantities that he considers the process presents real advantages. The new ingredients also that he introduces give to the compound special qualities, which he thinks would render it suitable for employment in a great number of cases,—such as severe burns, erythema, erysipelas, variolic eruptions, chilblains, etc.—where the skin is the seat of more or less inflammatory symptoms.

At first, M. Latour employed the solution of sucrate of lime ; but in order to avoid the formation of carbonate of lime through the absorption of carbonic acid from the air, he tried the addition of glycerine. This led him to study the solubility of sucrate of lime in glycerine, and finally to construct a formula representing nearly the limit of this solubility and furnishing a dense product of constant composition, to which he has given the name of saturated glycerate of sucrate of lime. This, in a certain state of dilution, he uses to prepare his new chalk liniment.

Solubility of Sucrate of Lime in Glycerine.—Sucrate of lime is very soluble in glycerine and the addition of water and heat hastens the solution. The temperature may be raised to the boiling point without fear of the coagulation of the monobasic sucrate of lime, which is prevented by the glycerine. The following two experiments had for their object to compare the solubility of sucrate of lime in water and in glycerine, separately :—

(*a.*) Fifty grams of dry sucrate of lime, in fine powder, were treated with 100 grams of distilled water, at from 75° to 80° C., the liquor filtered, and the proportion of lime determined by an alkalimetric operation. Ten grams of the solution gave 0·4958 gram of lime corresponding to 3·646 grams of sucrate of lime. The solution was coagulated by heat.

(*b.*) One hundred grams of dry sucrate of lime, in fine powder, were treated with a mixture of equal parts of water and glycerine (100 grams of each), at a temperature of 75° C., and the liquor filtered. The filtration was slow. An alkalimetric estimation showed that 10 grams of liquor contained 0·5161 gram of lime, corresponding to 3·756 grams of dry sucrate of lime. In this case heat did not cause the monobasic sucrate of lime to coagulate.

In comparing these results it must be admitted that the solubility of sucrate of lime is nearly equal in water and in glycerine. The slight difference is due to a peculiarity that is worth mentioning. During the evaporation of the sucrate of lime to obtain that compound in a dry state there is formed a small quantity of carbonate of lime. If the sucrate be treated with water traces only of the carbonate formed go into solution, whilst in the mixture of water and glycerine the whole is dissolved. In fact, if a few drops of hydrochloric acid be added to each of such solutions there is a notable disengagement of carbonic acid from the glycerate, but only a very feeble one from the aqueous solution. This would explain the slight difference in the two experiments.

Saturated Glycerate of Sucrate of Lime.—Without having recourse to the use of dry sucrate of lime, and in order to shorten the operation, a nearly saturated solution of sucrate of lime may be obtained by adopting the following formula :—

Slacked Lime	200 grams.
Powdered Sugar	400 „
Water	2 kilograms.
Glycerine	400 grams.

Mix the sugar and lime thoroughly in a mortar ; add the water in small portions, so as to obtain a clear pulp without lumps. Put the mixture into a stoppered flask. After contact for twenty-four hours, filter, and add the glycerine to the solution, then evaporate until it is reduced to one litre. It is essential not to add the glycerine until after the filtration of the solution of sucrate of lime, or the filtration will be retarded.

The glycerate of sucrate of lime thus prepared has a density of 1·280 at 15° C. It is not coagulated by boiling ; but coagulation takes place if it be diluted with four times its volume of water. It contains, by volume, in 100 cubic centigrams, 7·716 grams of lime, corresponding to 56·55 grams of dry sucrate of lime ; by weight in 100 grams, 6·720 grams of lime, corresponding to 49·42 grams of dry sucrate.

Applied to the skin, this glycerate of sucrate of lime forms a kind of varnish, which under the influence of transpiration is detached in the form of lumps ; upon inflamed surfaces it produces a feeling of coolness and comfort. More decided drying qualities may be imparted to it by dissolving in it, with heat, about 3 per cent. of gelatine.

Dilute Glycerate of Sucrate of Lime.—Preparation of Chalk Liniment.—For the preparation of chalk liniment with the glycerate of sucrate of lime it is preferable to use a dilute solution, such as exists before the mixture is concentrated, as directed in a preceding paragraph. It then has a density of 1·144 at 15° C., and contains, by volume, in 100 cubic centigrams, 3·512 grams of lime, corresponding to 26·05 grams of dry sucrate of lime ; by weight, in 100 grams, 3·289 grams of lime, corresponding to 24·19 grams of dry sucrate.

The formula for the liniment of the glycerate of sucrate of lime is as follows :—

Ground Nut Oil	200 grams.
Dilute Glycerate of Sucrate of Lime.	100 „

Mix in a vessel having a large mouth.

By substituting oil of sweet almonds, a mixture is obtained that is a little less solid. In certain cases, where it is desired to combat the odour which is given off from the profuse suppuration of severe and extensive burns, the simple oil may be replaced by camphorated oil.

Dr. Lagarde, who used this preparation in the treatment of the soldiers injured in the before-mentioned explosion, reports that it fulfils the principal requisites sought for in application to burns ; that it efficaciously protects the injured surface from contact with the air, does not adhere to the wound, diminishes the pain, modifies the suppuration, and hastens and controls the cicatrization. It is easily used, and may be renewed without causing pain to the patient. Dr. Muller has also used the liniment in the same hospital, in cases of erysipelas of the face.

NOTE ON LIATRIS ODORATISSIMA.

BY JOHN R. JACKSON, A.L.S.,

Curator of the Kew Museums.

Under the name of wild vanilla the leaves of *Liatris odoratissima*, Willd., are sometimes used in North America as a substitute for true vanilla. The plant belongs to the Compositæ and grows to a height of three or four feet with an erect annual stem, terminated by a corymb of beautiful purple flowers; the odour of the leaves is very perceptible when bruised, and this odour has been referred to the presence of the principle coumarin. It is said that many of the flavouring fruit essences, perfumes, etc., are produced in America from the leaves of this plant, and they have also been occasionally employed to give a pleasant fragrance to tobacco and cigars. This application has been largely extended of late, and the leaves are brought to market in small bales. They are mostly selected from the lower part of the plant, and are about six inches long by three broad. The smaller and less perfect leaves are used for fillers of cigars, while the large and sound ones are used for wrappers.

The plant is said to be very abundant in Florida, and it has been suggested that if it were submitted to cultivation and the stalk cut back so as to induce the development of large leaves it might be improved in quality and value. The flavour that these leaves impart to tobacco is approved of by many persons and it has the advantage of having no deleterious properties. Another use to which the leaves are put is for the purpose of protecting woollen cloths from the attacks of moths. Other species of *Liatris*, such as *L. scariosa*, *L. squarrosa*, and *L. spicata* are considered to have medicinal properties; the former is employed in making a gargle for sore throats, also in gonorrhœa, and it has a reputation for the cure of snake bites. The root of *L. squarrosa* is acrid and pungent, and yields a balsamic substance in alcohol. *L. spicata* is called button snakeroot and has some reputation as a stimulant, diuretic and expectorant. It is used in the form of a tincture or decoction made from the root.

THE OLEO-RESIN OF THE SUNFLOWER.

(*Helianthus annuus.*)*

BY M. CHARDON.

Among the known oleo-resins, the turpentines, properly so called, appear to form a group specially characteristic of some genera of Coniferæ. It is easy, however, to connect with them a product yielded by the flower of a plant far removed from the conifers, namely, the *Helianthus annuus*, so well known under the name of the sunflower. Whether this product is peculiar to the plant grown in Algeria, where the author has observed it, or whether it is developed in the plant when grown in any other climate, he is unable yet to determine, but in all those which he has found in Algiers and its neighbourhood he has been able to verify the following facts.

As soon as the capitulum of the sunflower is laid bare by the opening of the foliaceous involucre, before even the florets have given to the flower all its splendour by their expansion, transparent and colourless drops appear on the extremities of the projecting paleæ or bracts. These are more abundant in proportion as the growth of the stalk is more vigorous, which excludes the idea of their origin in a diseased state of the plant. In proportion as the florets expand the production seems to disappear.

This substance has been collected, and, upon examination, presented the following characters:—Its consistence was semi-liquid and pitchy; its odour much resembled that of the product of *Pinus maritima*, with which it might easily be confounded. Although that which was collected contained animal and vegetable *débris*, it was perfectly transparent. Its burning and aromatic taste was persistent because of its insolubility, and was not at all sweet. It did not reduce Fehling's liquor when heated with it, and when exposed to the air in a thin layer it dried on the surface, and ceased to adhere to the fingers after two or three days. Heated carefully by itself, it gave off an essential oil, its odour was increased, and the residue was a hard matter, brittle when cold, which could be compared better to nothing than to colophony. In boiling water also it hardened and left a white opaque resin. Its solubility in alcohol was complete.

It would be certainly interesting to know more of this substance, but the small quantity collected would not enable the author to carry his investigation further. The observations were made upon a score of plants, some of which, from want of water, were sickly and yielded nothing to the collection, although the production of the substance in them was quite visible.

* Read before the Société d'Emulation pour les Sciences Pharmaceutiques (*Répertoire de Pharmacie* [N.S.], vol, i., p. 537).

THE ESTIMATION OF PHOSPHORUS IN FATTY MIXTURES.*

In order to separate phosphorus from articles of food, vomits, and other matters containing fatty substances, in such a state of purity that it may be unfailingly recognized by characteristic properties, and produced in court as evidence, D. A. von Bastelaer gives a process already found of advantage in several judicial inquiries, which is based essentially on the solubility of phosphorus in ether, and its almost perfect indifference towards solution of ammonia if in contact with it for only a short time. If the substance from which phosphorus is to be separated is not fluid, *e. g.*, phosphor paste, it is first reduced by addition of water to the condition of a sufficiently thin pap, in order that it may be thoroughly mixed with ether by agitating for some seconds. Not only the weight of the original substance taken, but also that of the added water is noted. After the reduction, about 100 grams, or any other suitable weighed quantity of the fluid mass is taken, mixed with as much ether, and left in contact therewith in the cold for four or five hours, during which period the mixture is to be violently shaken at frequent intervals. The ether being now decanted, is replaced with an equal quantity of fresh ether, and these operations are repeated about three times. The united ethereal liquids, protected from dust, are allowed to evaporate spontaneously at 15°-20°C in a shallow dish. At this point some water is added, that the phosphorus may be protected from the action of the air after evaporation of the ether. If what remains after removal of the ether be gently warmed to 50°-60°C, the phosphorus unites itself with a portion of the fat, forming a fluid globular mass under the water, whilst the remainder of the matter taken up by ether rises to the surface as a thin film. The globule containing phosphorus is now treated with about 10 to 15 grams of strong aqueous ammonia in a small flask and violently agitated. This treatment is repeated a few times. Lastly, if the adhering ammonia be removed by washing first with water acidulated with sulphuric acid, and then with pure water, the phosphorus remains behind, certainly somewhat soft in consistence, but otherwise exhibiting all the physical and chemical properties which characterize it. It may be brought in a little glass tube and handed to the judge as *corpus delicti*.

The Pharmaceutical Journal.

SATURDAY, OCTOBER 25, 1873.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

CINCHONA CULTIVATION.

THE prevailing scarcity of quinine and the consequent high price that it now commands will be sufficiently familiar to pharmacists to invest with more than ordinary interest any fresh information respecting the various attempts that have been made to promote the cultivation of cinchona, and thus provide a more abundant supply of the raw material from which that invaluable drug is obtained.

As our readers are aware, one of the places where cinchona cultivation has been established is Java, and the Dutch Government has devoted considerable attention to this enterprise. By the courtesy of Mr. HOWARD we are enabled to place before our readers some account of the results obtained in the latest examination of the barks from these plantations, and it will be satisfactory to learn that there are evident signs of progress. We learn from Dr. HASSKARL'S late report that the plantations in Java have been considerably extended, nearly 30,000 young trees having been planted out during the second quarter of this year, making a total of 1,800,252 plants. The weather has also been exceedingly favourable to the growth of the cinchonas, and as much as 7000 kilos of bark has been prepared for delivery.

As regards the yield of these barks in alkaloid the results are also very good, some samples of calisaya bark yielding as much as 10 and 11 per cent. of quinine, while many others yield from 4 to 6 per cent. of that alkaloid. This fully justifies the opinion expressed some months since by Mr. HOWARD that the main object of the introduction of cinchona cultivation into Java, viz., the obtaining a rich source of quinine, has not failed.*

In other respects Dr. HASSKARL'S report, which we regret being unable to publish *in extenso* this week, confirms what has been previously said on the subject. It is worth, however, noticing that the calisaya yielding the very high percentage of quinine differs from the typical calisaya of WEDDELL in its small white flowers and very small capsules.

Another feature of note is the comparative scarcity of quinidine in the barks of calisaya, consistently with the remark of Mr. HOWARD in the article already referred to. In the red barks analysed by Dr. HASSKARL there was an extraordinary preponderance of cinchonidine, and the total of alkaloids in those barks exceeded that in almost all the other kinds of bark.

It has been shown that in all probability it was cinchonidine that cured the COUNTESS OF CHINCHON, and hence it is no wonder that when bark alone was given, the red bark should, if it contained a large amount of this alkaloid, have obtained such renown in the hands of Dr. SYDENHAM and subsequent practioners, until the worthless bark of Mutis was introduced to baffle their skill.*

Among other points of interest in the report here referred to we learn that a number of samples of Java bark have been sent to the chemists attached to the Cinchona plantations in British India for comparative examination, and we trust there may soon be from our own colonies as gratifying accounts of the progress of Cinchona cultivation as those we are receiving from Java.

FLOWERING OF THE SCAMMONY PLANT.

SCAMMONY (*Convolvulus Scammonia*) sown in the garden of the Faculty of Medicine in Paris a year since has germinated, and passed through a relatively mild winter in the open ground, this season has been covered with flowers. By its leaves and its corollas of a creamy-white colour, with five pale, dingy rose bands on the outside, it recalls the appearance of *Convolvulus arvensis*. The anthers are remarkable for the rapidity with which, at the moment of opening, they turn outwards their lines of dehiscence, which are primitively introrse. The flowers are at the end of a rather long peduncle, and are sometimes solitary, and sometimes disposed in few-flowered cymes.

AT a *soirée* lately given at Blackheath by the Council of the West Kent Natural History, Microscopical, and Photographic Society, the President, in the name of the Council and members, presented to the hon. secretary, Mr. E. CLIFT, pharmaceutical chemist, of Lewisham, a set of elegant mantel ornaments, consisting of clock and pair of vases. The clock bears the following inscription :—

"Presented to Edward Clift, Esq., by the members of the West Kent Natural History, Microscopical, and Photographic Society, in recognition of his able and courteous discharge of the duties of Honorary Secretary during a period of Fourteen Years.

"J. JENNER WEIR, President.

"*Blackheath 13th May*, 1873."

THE *Times*' correspondent at Naples writes that the dry weather has much damaged the yield of oil both in quantity and quality. In that neighbourhood the olives have fallen from the trees as dried, hard berries, and the few that remain are being shaken or beaten down before the rain comes. The consequence is that oil has risen to fabulous prices, and those who have stored it are making little fortunes.

DR. J. E. DE VRIJ, who is so well known by his labours in connection with the chemistry of cinchona bark and its alkaloids, has been elected a Foreign Correspondent of the French Academy of Medicine.

Transactions of the Pharmaceutical Society.

SPECIAL MEETING OF THE COUNCIL.

Wednesday, October 22nd, 1876.

MR. THOMAS HYDE HILLS, PRESIDENT.
MR. ALEXANDER BOTTLE, VICE-PRESIDENT.

Present—Messrs. Atherton, Betty, Robbins, Sandford, Sutton, Urwick, and Williams.

This Special Meeting of the Council was held for the purpose of reading a third time the proposed new Bye-law, previous to submitting it to a Special General Meeting of the Society.

The PRESIDENT moved that the proposed new Bye-law be read a third time.

The motion was seconded by the Vice-President, and carried unanimously.

The proposed new Bye-law was accordingly read a third time.

THE JUNIOR BELL SCHOLARSHIP.

The PRESIDENT announced that Mr. E. J. Thring had written to resign the Junior Bell Scholarship, as he found himself unable to take advantage of it, his employer declining to release him from the remaining portion of his apprenticeship term.

Mr. WILLIAMS said he had made inquiries and found that Mr. Thring had accepted the scholarship under some misapprehension, thinking that he might be allowed to attend the lectures, etc., on two mornings a week, or something of that sort. Mr. Williams and the Secretary had called on Mr. Thring's employer to see if he could be induced to relinquish his claim on the young man's services, but that gentleman stated that he was not able to do so. They were therefore obliged to advise Mr. Thring to resign, which he had accordingly done. Mr. Williams suggested that it would be well if in future care were taken to ascertain that the candidates for the Bell Scholarship thoroughly understood the conditions before competing.

The SECRETARY said a similar difficulty occurred last year in the case of Mr. Plowman, but that gentleman's employer after some persuasion was prevailed upon to set him at liberty three months before the expiration of his time.

Mr. WILLIAMS remarked that next year Mr. Thring would be ineligible to compete for the Junior Scholarship, as he would be over age, and as this was likely to occur very often, most young men being apprenticed for a term expiring at their twenty first birthday, there seemed a little hardship in the present regulations which might require reconsideration.

The SECRETARY stated that in accordance with instructions he had written to Mr. A. P. Luff, the candidate next on the list, to inquire if he would be prepared to take advantage of the scholarship, and had received an affirmative reply, both from Mr. Luff and his father, the latter stating that he was quite willing that his son should devote the whole of his time to study.

It was moved by Mr. WILLIAMS :—

"That the Junior Bell Scholarship for the Session 1873-4 be awarded to Arthur Pearson Luff, the present holder, Edmund John Henry Thring, having resigned the Scholarship through inability to avail himself of it."

The motion was seconded by Mr. SANDFORD, and carried unanimously.

APPOINTMENT OF AN EXAMINER.

The SECRETARY read a letter from the Privy Council approving the appointment of Mr. Octavius Corder, of Norwich, as a member of the Board of Examiners for England and Wales.

INSURANCE OF THE SOCIETY'S PLATE GLASS.

On the motion of Mr. WILLIAMS, it was resolved to insure the plate glass belonging to the Society, both in the windows and in the glass cases in the Museums, in the National Plate Glass Assurance Company.

The Council then adjourned until after the Special General Meeting had been held, the report of which appears below.

On reassembling, the Secretary drew the attention of the Council to that portion of the letter from the Privy Council of July 31st which suggested the desirability of requiring an interval of three years to elapse between the passing of the Preliminary examination and that of the Major or Minor.

The SOLICITOR stated that in his opinion the Society would hardly be warranted in making such a regulation, looking to the provisions of the Pharmacy Act.

After some conversation a draft letter was settled for transmission to the Privy Council, to accompany the new Bye-Law when submitted.

CONVERSAZIONE AT SHEFFIELD.

In accordance with the request of Mr. Radley, of Sheffield, permission was granted to lend certain specimens from the museum for exhibition at the Conversazione of the Pharmaceutical and Chemical Association, at Sheffield on Friday.

SPECIAL GENERAL MEETING.

A Special General Meeting of the Members of the Pharmaceutical Society was held on Wednesday, October 22nd, 1873, at twelve o'clock, at 17, Bloomsbury Square, Mr. Thomas Hyde Hills, President, in the chair. The attendance was very limited.

The SECRETARY having read the notice convening the meeting,

The PRESIDENT stated that the Privy Council having objected to the new Bye-law, sec. 10, clause 6, as formerly approved by the Society, the one now submitted had been prepared. It had been read at three Council meetings, and in accordance with the rules, he would now move that the General Meeting approve and confirm the new Bye-law.

The clause referred to and the proposed new clause are as follows :—

PRESENT.	PROPOSED.
SECTION 10.	
Clause 6.	*Clause* 6.
After the first day of January, 1871, no person shall be appointed an examiner who at the time of appointment is, or who during one year prior to the time of appointment has been, a Member of the Council, other than the President or Vice-President; and the election of any examiner to be a Member of the Council shall vacate his appointment as an examiner.	No person shall be appointed an examiner who at the time of appointment is, or who during one year prior to the time of appointment has been, a Member of the Council; and the election of any examiner to be a Member of the Council shall vacate his appointment as an examiner.

The VICE-PRESIDENT having seconded the motion,

Mr. MEE inquired what was the object of the new Bye-law, the necessity for which he could not understand.

Mr. SANDFORD and the SOLICITOR explained the necessity of framing the new Bye-law, in order to meet the views of the Privy Council.

Mr. MEE still protested that he could not see the need of the Bye-law, the matter being, in his opinion, quite clear before. He must therefore oppose it.

The PRESIDENT appealed to Mr. Mee to allow the motion to pass unanimously, as it was simply intended to put an ambiguous point beyond all doubt.

The motion was then put and carried with one dissentient, and the proceedings terminated.

EXAMINATIONS IN EDINBURGH.

October 14th, 15th, and 16th, 1873.

Present—

(14th.) Messrs. Ainslie, Buchanan, Gilmour, Kemp, Kinninmont, Noble, Tait, and Young.

(15th.) Messrs. Buchanan, Gilmour, Kemp, Kinninmont, Noble, and Young.

(16th.) Messrs. Ainslie, Buchanan, Gilmour, Kemp, Kinninmont, and Young.

Professor Maclagan was present each day on behalf of the Privy Council.

MAJOR EXAMINATION.

Two candidates were examined. *One* failed. The undermentioned passed, and was declared duly qualified to be registered as a Pharmaceutical Chemist :—

Modlen, Robert.....Edinburgh.

MINOR EXAMINATION.

Thirty-one candidates were examined. *Ten* failed. The following *twenty-one* passed, and were declared to be duly qualified to be registered as Chemists and Druggists :—

*Brown, John Macdonald.....Dunfermline.
*Grant, Donald .....Elgin.
*Robinson, George Carr.....Edinburgh.
McNaught, Andrew.....Belfast.
White, Thomas Lee .....Edinburgh.
Clark, William Inglis .....Edinburgh.
Riach, Charles Beverley .....Aberdeen.
Lambie, Hugh .....Glasgow.
Lawler, Hugh .....Edinburgh.
Attwood, Henry Ernest .....Edinburgh.
Buchanan, David .....Arnprior by Stirling.
Equal. Fraser, Andrew .....Aberdeen.
Equal. Hunter, John Carswell .....Glasgow.
Clark, William Coltart.....Dalbeattie.
Brown, George .....Edinburgh.
Donald, David .....Perth.
Steele, John Cockburn.....Greenock.
Anderson, David Smith .....Musselburgh.
Campbell, Colin .....Dumbarton.
Frater, Mark W. .....Morpeth.
Forewell, Henry .....Edinburgh.

The above names are arranged in order of merit.

MODIFIED EXAMINATION.

Six candidates were examined. *Two* failed. The following *four* passed, and were declared to be duly qualified to be registered as Chemists and Druggists :—

Kitchen, James.....Glasgow.
Marshall, John .....London.
Milburn, Walter Edwin .....Tollerton.
Wallace, William .....Glasgow.

EXAMINATIONS IN LONDON.

October 15th, 16th, 23rd, and 24th, 1873.

Present on the 15th and 16th—Messrs. Allchin, Barnes, Bottle, Carteighe, Corder, Cracknell, Davenport, Gale, Linford, Martindale, Schweitzer, and Umney.

Present on the 22nd and 23rd—Messrs. Allchin, Barnes, Carteighe, Corder, Cracknell, Davenport, Gale, Hills, Linford, Martindale, Schweitzer, Southall, and Umney.

Dr. Greenhow was present on the 15th, on behalf of the Privy Council.

MAJOR EXAMINATION.

Six candidates were examined. *Four* failed. The following *two* passed, and were declared duly qualified to be registered as Pharmaceutical Chemists :—

Leake, Thomas Whaplate .....London.
Harrison, William Hopper .....Barnstaple.

* Passed with Honours.

MINOR EXAMINATION.

Ninety-nine candidates were examined. *Fifty-six* failed. The following *forty-three* passed, and were declared duly qualified to be registered as Chemists and Druggists :—

*Hearne, Frederick .....Strood.
*Holt, George Alfred .....Douglas.
Equal. *Bibbings, John Henry .....Exeter.
Equal. *Carlton, Arthur .....Horncastle.
*Harding, William .....Bristol.
Brown, Robinson .....Stockton-on-Tees.
Fuller, Thomas.....Fallowfield.
Equal. Read, William .....Havant.
Equal. Savage, John Welch .....Wells.
Equal. Row, George Commins .....Braintree.
Equal. Wills, George Sampson Val. ...Hay.
Moore, John Ernest.....Southampton.
Baxter, John Newsome .....Rotherham.
Ingham, Thomas Whittaker ...Rawtenstall.
Huggett, Sydney .....Lancaster.
Chamberlain, Arthur Garratt...Leicester.
Style, John William.....London.
Equal. Rogers, William Sexton .....Southsea.
Equal. Symonds, Henry .....Norwich.
Lewis, Edward Prosser .....Tenby.
Simpson, Allwood.....Stalybridge.
Equal. Fiddick, Thomas .....Camborne.
Equal. Leslie, John Morison .....Port Elizabeth.
Peacock, Percy .....Chelsea.
Kirkby, Robert .....Ulverston.
Welcher, Robert Mitchell .....Chatteris.
Smith, Charles .....Sleaford.
Pidgeon, Joshua David .....Brighton.
Robinson, Stanley.....Stalybridge.
Equal. Equal. Hilton, Howard Christopher ...Whitefield.
Equal. Equal. Reeve, Thomas Lewis .....Hastings.
Equal. Appleton, Thomas Alfred .....West Brompton.
Equal. Booth, George Samuel.....Heckmondwike.
Equal. Southwell, John William.....Scarborough.
Chapman, Joseph John .....Chertsey.
Equal. Kershaw, Edward.....Manchester.
Equal. Soutter, David .....Grimsby.
Lathbury, Charles John .....Worcester.
Somers, Robert Walter.....Guildford.
Carson, Robert .....Manchester.
Equal. Holyoake, Francis.....Wandsworth Road.
Equal. Myott, Frederick .....Oldham.
Lee, William Walter .....Wandsworth.

The above names are arranged in order of merit.

PRELIMINARY EXAMINATION.

The following is the result of the examination held on the 6th instant :—

England and Wales.

Two hundred and eighty-six candidates presented themselves for examination, of whom *one hundred and fifty-seven* failed. The following *one hundred and twenty-nine* passed, and have been duly registered as Apprentices or Students :—

FIRST DIVISION.

Equal. Greenleaf, Alfred William .....Ipswich.
Equal. Sangster, John Graham .....Southsea.
Roe, Robert .....Lancaster.
Equal. Osmond, John Hooper .....Heywood.
Equal. Wallis, George .....Ryde.
Payne, John Woollard.....Liverpool.
Walsh, Peter Henry.....Blackburn.
Equal. Thompson, Arthur .....Buxton.
Equal. White, William Thomas .....London.
Equal. Wise, Joseph Norman .....Carlisle.

* Passed with Honours.

Equal. Clower, John.....Nottingham.
Equal. Leivers, George Edward .....Eastwood.
Equal. Needham, Francis David .....Dublin.
Equal. Pollard, George Frederick .....Burnley.
Equal. Cornish, James Mitchell .....Penzance.
Equal. Kent, Edward ... .London.
Dusting, Abraham Tong .....Penzance.
Equal. Alcock, Frank Harris .....Burslem.
Equal. Broadbent, John .....Stretford.
Equal. Bromley, Eugene Frank ....Woolwich.
Equal. Chotin, Victor Frederick.....Guernsey.
Equal. Morton, Henry .....London.
Equal. Taberham, Frederic William ...Wells.

SECOND DIVISION.

Collis, Arthur Frederick .....Cheadle.
Equal. Barfoot, John Richard Doughty. Chesterfield.
Equal. Parkes, Harry Charles.....Fareham.
Equal. Williams, Thomas Henry .....Plymouth.
Cox, John Henry .....Kingston.
Equal. Edmondson, William ... .Morecambe.
Equal. Hurst, Walter ..... Manchester.
Equal. Lingwood, Edgar Henry .....Colchester.
Equal. Vaughan, Sidney Herbert ..... London.
Equal. Jackson, William .....Bridgend.
Equal. Jones, Charles .....Ashton-under-Lyne.
Equal. Roberts, George Constable .....London.
Equal. Temple, Frederick Staveley.....Hull.
Humphreys, Arthur .....Nottingham.
Equal. Horton, Thomas .....Peterborough.
Equal. Nelson, Harry .....York.
Equal. White, Woolmer Rudolph Donati...Landport.
Hay, Richard Mayman .....York.
Equal. Marsh, Gideon William Barker. Dover.
Equal. Powell, Walter .....Clevedon.
Equal. Stevenson, David Archibald ...Chertsey.
Clayton, Christopher.....Market Rasen.
Browne, Frank S.....Norwich.
Equal. Buckley, James Julian .....Eastbourne.
Equal. Kent, George Dugan .....Landport.
Equal. Welford, Richard .....Blackburn.
Richardson, Peter George .....Conndon.
Equal. Jones, Edmund.....Hanley.
Equal. Little, Charles Arthur.....Manchester.
Equal. Winch, John Miller .....Colchester.
Equal. Equal. Cant, Hemington .....London.
Equal. Equal. French, Montague Robert .....Gosport.
Equal. Equal. Higginbottom, Walter Harold ..York.
Equal. Palmer, George Smith .....Lincoln.
Equal. Stahr, Victor Emanuel.....London.
Equal. Fry, Samuel .....Bishop's Waltham.
Equal. Page, Robert Steele .....London.
Equal. Pratt, Edward Jonathan .....Great Yarmouth.
Equal. Watson, Joseph Edmund.....Bristol.
Kelly, Francis Charles .....Great Yarmouth.
Equal. Equal. Griffiths, William .....Neath.
Equal. Equal. Wright, John Charles .....Wolverhampton.
Equal. Cowan, Richard Hamilton .....Southsea.
Equal. Harding, Christmas .....Denbigh.
Equal. Nowell, Barnes .. ..London.
Davidge, Henry Ernest Frederick...Lynn.
Smale, John Edward .....Landport.
Equal. Heaton, Wilmer Everard.....Colne.
Equal. Hoyle, Richard Ashworth .....Rawtenstall.
Equal. Hucklebridge, Philip .....London.
Equal. Pell, John .....Market Harborough.
Equal. Wyborn, Edward .....Reading.
Patterson, James .....Landport.
Equal. Cooper, Herbert .....Rye.
Equal. Gimblett, William Henry .....Swansea.
Equal. Haden, Walter Edward .....Lichfield.
Equal. Urwick, Charles .....London.
Equal. Beesley, John .....Liverpool.
Equal. Harmer, James Dorkin .....Kingston-on-Thames.
Equal. Wilks, Charles Frederick.....York.
Allkins, Walter .....Tamworth.
Baxter, John .....Manchester.
Blayney, John Hartley.....York.
Bowman, Samuel .....Durham.
Bright, Frederick ..... Taunton.
Christopherson, Cornell .....Ipswich.
Cridland, Francis Ed. John.....Devizes.
Crompton, John Clayton .....Manchester.
Curnby, George .....Loddon.
Déqué, Laurent Joseph .....Derby.
FitzGerald, John Anthony .....London.
Fowler, George .....London.
Fowler, William .....Sunderland.
Greaves, Edward Harrison .....Bristol.
Greenough, Hugh Fairhurst ...Manchester.
Griffith, Philip .....Weston-super-Mare.
Hallas, David William .....Manchester.
Harrison, John William .....Leeds.
Hayton, Peter Bamlett .....Leeds.
Holway, John M.....Swansea.
Hope, Arthur Peach.....Uppingham.
Hughes, William David .....Liverpool.
Equal. Jones, Charles William .....Manchester.
Equal. Jones, Hugh .....Abergele.
Equal. Lickiss, Charles.....York.
Equal. Lomas, James Wright .....Sunderland.
Equal. Lugg, James Harvey .....Penzance.
Equal. Matthews, Walter Thomas .....Bristol.
Equal. Mewburn, Ernest Rutter.....Ilkley.
Equal. Mitchell, George .....London.
Equal. Niblett, Frederick John .....Stroud.
Equal. Palmer, Edwin Thomas ..... Hammersmith.
Equal. Poock, Joseph Thomas.....Weston-super-Mare.
Equal. Reed, Walter Sherwood .....Sunderland.
Equal. Reeves, Alfred .....London.
Equal. Ridley, Edward Henry.....Manchester.
Equal. Tadd, James .....Polruan.
Equal. Tapson, Alfred Edward .....Bristol.
Equal. Thompson, William .....Bradford.
Equal. Waite, James .....Bolton.
Equal. Walker, Frederick William.....Halifax.
Equal. Warburton, William.....Haslingden.
Equal. Ward, Smith.....Batley Carr.
Equal. Wardale, Herbert Faulkner.....Hull.
Equal. Wilkins, Edward .....Reading.
Equal. Williams, Frederick Lloyd .....Llandovery.

SCOTLAND.

Twenty-five candidates presented themselves for examination; of these *seven* failed. The following *eighteen* passed, and have been duly registered :—

FIRST DIVISION.

McVean, John Duncan .....Stirling.
Currie, Alexander.....Portsoy.
Mitchell, Andrew.....St. Andrews.
Reid, William .....Aberdeen.

SECOND DIVISION.

Ramsay, David R. .....Dundee.
Equal. Jack, William .....Lochgilphead.
Equal. Turnbull, Edward Hardy.....Edinburgh.
Curle, David .....Partick.
Raffan, John .....Portsoy.
McDonald, Donald Fraser .....Edinburgh.
Henry, Claude F. .....Edinburgh.
Frater, J. Irvine .. ..Aberdeen.
Smith, William.....Chester.
Gamley, David .....Edinburgh.
MacPherson, Colin Allen .....Edinburgh.
Swan, William Duncan .....Stirling.
Alexander, Alexander .....Aberdeen.
Ligertwood, Charles Riddel.....Aberdeen.

ADDENDUM.—In the list published on p. 304 the following should have appeared among the *Certificates of the College of Preceptors*, received in lieu of the Preliminary examination :—

Beck, Albert Neve .....St. Leonard's.

The following is a list of the Towns at which the Examinations were held, with the numbers of Candidates annexed :—

ENGLAND AND WALES.

	Candidates.				Candidates.		
	Examined.	Passed.	Failed.		Examined.	Passed.	Failed.
Altrincham	1		1	Ipswich	4	2	2

The questions for examination were as follows :—

Time allowed: Three hours.

LATIN.

Translate into English two of the following sentences :—

1. Quod improviso unum pagum adortus esset, quum hi qui flumen transissent suis auxilium ferre non possent, ne ob eam rem aut suæ magno opere virtuti tribueret aut ipsos despiceret : se ita a patribus majoribusque suis didicisse ut magis virtute quam dolo contenderent aut insidiis niterentur.

2. Hi neque vultum fingere neque interdum lacrimas tenere poterant : abditi in tabernaculis aut suum fatum querebantur, aut cum familiaribus suis commune periculum miserabantur.

3. Detur imprimis uncia una et interpositis tribus vel quatuor horis, cochleare exhibeatur si fuerit opus, et post duas alias horas repetatur dosis, si alvus antea non moveatur.

4. Coque simul lento igne, assidue movens, donec Oleum et Oxidum in Emplastri liquefacti crassitudinem coeant. Oportebit autem paululum Aquæ ferventis adjicere, si ea fere omnis, quæ in principio adhibita est, ante finem coctionis fuerit absumpta.

5. State the comparative and superlative degrees of the following adjectives—malus, multus, nequam, superus.

6. Decline "vis" and "domus."

7. Parse "Dulce et decorum est pro patriâ mori."

ARITHMETIC.

8. From $64\frac{1}{4}$ take $\frac{2}{3}$ of $\frac{3}{4}$.

9. Divide ·00281 by 1·405, by 1405, and by ·001405, proving the truth of each result by fractions.

10. One year being equivalent to 365 days and 6 hours, find how many seconds there are in 27 years and 245 days.

11. Find the value of 3 tons, 0 cwt., 3 qrs., 26 lbs. of sugar at £1 4*s.* 6*d.* per cwt.

12. If 20 men can perform a piece of work in 12 days, how many men will accomplish another piece of work which is six times as great in a tenth part of the time ?

ENGLISH.

13. Parse the following :—

"On either side the river lie
Long fields of barley and of rye."

14. Write from fifteen to twenty lines on *one* only of the following subjects :—

Music.
Diligence.
Railways.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The first general meeting of the twenty-fifth session was held at the Royal Institution, Colquitt Street, on the 9th October last, the president, Dr. Charles Symes, in the chair.

The Secretary announced that the following gentlemen had been elected officers for the present session, viz. :— President, Dr. Charles Symes ; Vice-President, Mr. Alfred H. Mason, F.C.S. ; Honorary Treasurer, Mr. John Shaw ; Honorary Secretary, Mr. Jas. F. Armstrong, 17, The Willows ; Council, Messrs. E. Davies, F.C.S., J. Abraham, Charles Jones, Joseph Hallawell, A. Redford, Charles Sharp, R. Sumner, and Alfred E. Tanner.

Messrs. R. Mumford, John Alexander, George G. Halliburton and Dr. Cook were elected members.

Mr. E. Davies, F.C.S. exhibited specimens of the different sorts of new burners as invented and sold by Mr. R. Wallace, Manchester, and gave a full description of the different ways of using them. The burners are made with one to twenty-four flames, and give a temperature of 3000° F., and will melt almost any metal.

After some discussion on the source, and the best means of obtaining oil of rhodium, the president, Dr. Symes, delivered the following—

INAUGURAL SESSIONAL ADDRESS.

"It has pleased your Council to appoint me a position in your midst which I have with some reluctance accepted,

and that for the following reasons:—Firstly, my personal inability to fill the office in the very perfect manner in which it has been done by your late president. The amount of ability which he has displayed; the happy combination of firmness in holding to points he felt to be right, with the kind and courteous manner to those who differed from him in opinion, has engendered a good feeling toward him from all, and an indebtedness which it will be difficult to repay.

"Secondly, my business being situate somewhat distant from our sphere of operations and requiring much personal attention, there will be a difficulty in placing so large an amount of time at your disposal as has been done by Mr. Davies, who has always been on the spot to lend a willing ear and give his sound advice. And thirdly, that the reins of an association like this involves a responsibility for which I feel myself quite unequal; but then I know I shall have your help and guidance, and if we are all moved by a spirit of progress and endeavour to keep pace with the times, relying on the active co-operation of our Council and Secretary, together with that of the members of the Association, we may be sure that we shall have as profitable a session as ever we have had.

"I should indeed be sorry to see this Association mixed up with trade disputes, or working for the interests of any party; but we might go too far in ignoring the legitimate claims of trade. Science will fare but badly at our hands if our business is not well cared for; our daily wants are a stern reality, and it is but a poor philosophy that does not teach a man first to provide these.

"The Pharmaceutical Society is a kind of Pharmaceutical Parliament, and there are many trade questions which it would be impolitic for such a body to take cognizance of; if we were just the Liverpool *branch* of that Society our sphere of operations in this direction would be equally circumscribed, but as we happen to be an independent body we must strike out for ourselves a line of conduct suited to meet the requirements of the chemists and druggists of Liverpool and its vicinity. When challenged with the questions, What good is there to be got at the meetings of the Association? or, What good does it do? we must be prepared to point to some real and substantial good, to show that the time spent here is not spent in vain.

"We find other associations dealing with trade questions which promote the interest of pharmacy, and prospering; most of you have seen the Midland Counties' price list issued by that Association—the Manchester list also.

"Do you think there would be anything discreditable to this Association in calling a general meeting to consider the desirability of curtailing our hours of business? I will not press this point too closely, as it has already been dealt with and, to my regret, dismissed, but anyone who gives the matter a moment's thought must see that as a large number of chemists do not close their places of business till we close our proceedings they cannot possibly attend, and that if we value our numerical strength it is incumbent on us to take the initiative in promoting early closing.

"And now I must say a word to those who hold themselves aloof, and regard us only with dissatisfaction.

"To the student I would say—We cannot possibly provide you a royal road to a knowledge of your business, or to passing your examinations; these have to be arrived at by study,—yes, just what you are pleased to call *dry* study,—and there is no substantial substitute. You are called to a somewhat higher standard of qualification than formerly, but scarcely commensurate with the requirements of the age, and you have every facility afforded you for acquiring that necessary knowledge.

"This Association and its school of pharmacy are amongst them—do you duly seek the advantages it offers?

"To the man of business I would say—We cannot come into your pharmacy and arrange your stock, post your books, or provide you with good customers; but we can offer you facilities for keeping up your knowledge of pharmaceutical progress; we can offer you interchange of opinion on matters in which we are mutually interested, and by your assistance can demonstrate the truth of the proverb "unity is strength"; our united efforts could overcome many difficulties and anomalies which frequently occur in our daily vocation. To the public who do not understand the nature of the difficulties we have to contend with, these anomalies must often appear ridiculous. Instances are familiar to us all.

"It certainly would be a discredit, collectively and individually, to the chemists of this neighbourhood if we had no association. Surely pharmacy has not reached so low a level here as to have no honest pride in such a matter! The pride I would ask is not that of a penurious descendant of ancient nobility, but that of emulation, which will not allow us to be in the rear; a jealousy, not of a neighbour who happens to be doing better than ourselves, but for the cause of pharmacy, its advancement, its social and intellectual position.

"Our business is often spoken of as intermediate between a trade and a profession, I would rather say it is a blending of the two. In the manufacture of our finer chemical and pharmaceutical preparations, in testing the purity of those purchased, in analysis and in dispensing, as much knowledge and skill, of its kind, is required as in any of the learned professions; in selling an ordinary retail article we are strictly tradesmen. It is clear, however, that pharmacy, in its present acceptation of the term, was not practised in the days of Æsop. In his fable of the "Besieged Town," he tell us that each tradesman thought no other calling like his own, winding up by the currier declaring "there is nothing like leather." How rarely do we hear a pharmacist declare "there is nothing like physic!"

"As a rule, we feel our sphere of operations very circumscribed; the profits of the largest establishments form no very handsome income as compensation for the care, attention, and responsibility involved in conducting them.

"I confess to having felt this as strongly as anyone could possibly do, but let us hope that there is something that can be looked on as making up this deficiency in pecuniary compensation.

"Do you think that one per cent. of the medical men in this country ever get compensated in a pecuniary sense for their services? I do not; they need no eulogium from me—'*Virtus per se splendet semper.*'

"What higher or nobler aim can a man have than the alleviation of human suffering? What could induce a medical man to go through a single year's active practice, unless he felt his life of labour to be one of love? Called from his warm bed on a cold winter's night, it might be to visit the haunts of wretchedness, or the mansion of the great, but what to witness? Not mirth, but sadness; not pleasure, but pain. To cool the fevered brow, to soothe the agony of the sick or dying. This is indeed a sacred office, and he who faithfully discharges its duties can look with confidence for a higher than his pecuniary compensation. Now the calling of a pharmacist is closely allied to that of the medical man, and to the full extent to which he participates in these offices of kindness will he participate in the never-failing reward.

"Toward the close of last session the U.S. Pharmacopœia was published, a book of considerable interest to the British pharmacist. Two series of papers on it have already been published in the PHARMACEUTICAL JOURNAL, and although somewhat elaborate, they are by no means exhaustive; many practical hints are entirely overlooked. Several of its improved preparations appear well worthy our attention. Its liq. ferri citratis would be a decided improvement on our scales, which make a very unsatisfactory mixture, being usually but partially soluble; its infusions of cinchona with the addition of aromatic sulphuric acid necessarily contain a larger amount of alkaloids than our simple infusion. They might merit a place beside, although not as substitutes for it, ammonia being often

prescribed with infusion of bark in this country. The method of preparing vin. ant. tart. by first dissolving the salt in a little boiling water, economizes time and produces quite as good an article. The linimentum cantharidis prepared by digesting the powdered flies in ol. terebinth. is doubtless an excellent rubifacient. I will not, however, occupy your time with further details, as I trust during this session we shall have at least one paper on the work.

"It is probable that in the early part of 1874 an appendix to the B. P. will be published. I think this is a step in the right direction. New drugs, chemicals, and preparations are constantly being brought under the notice of the medical profession, and by them are prescribed syrups, tinctures, liquors, etc., which, if dispensed at half-a-dozen pharmacies, might have nearly as many strengths. Ten years is too long for such a chaos to accumulate without any attempt at reducing it to order. An appendix is the proper thing to accomplish this. Many of the preparations it is intended to introduce have already been brought before your notice.

"Important changes have recently been made in the bye-laws of the Pharmaceutical Society and in the School of Pharmacy. These have been published and freely discussed in the PHARMACEUTICAL JOURNAL and *Chemist and Druggist*. Time alone can prove whether the results will be as satisfactory as the promoters of the changes anticipate, but when we see a new bye-law created to deal deadly blows at what has been called 'cram,' and a change in the school which has every appearance of fostering the intended victim, we might be pardoned for wondering whether these gentlemen are not attempting to blow hot and cold with the same mouth.

"And now I must bring this short address to a close. Thanking you for your kind attention, let me again ask you to put forth your energies to make this session a successful one—let us feel at its close that we have done something for the advancement of pharmacy."

A cordial vote of thanks was proposed by Mr. Sumner and seconded by Mr. Sharp, who said he was quite sure, from his experience of the Liverpool Chemists' Association, that it was quite equal to any emergency that would ever take place.

The President then made some more remarks in reference to his paper, after which the meeting separated.

LEEDS CHEMISTS' ASSOCIATION.

The annual meeting of the Society was held in the Clergy Room of the Church Institute, on Wednesday, October 15th, 1873. The President, Mr. E. Brown, in the chair.

The minutes of the last meeting having been read and confirmed, the following gentlemen were unanimously elected members and associates:—

Member, Mr. Thomas Iredale, North Street.

Associates, Messrs. E. A. Barber, B. Parker, Worfolk, E. A. Hanson, Thomas Wallas, and I. Laycock.

The Hon. Secretary (Mr. J. W. Longley) then read the

REPORT.

"In presenting this, the Eleventh Annual Report of the Leeds Chemists' Association, your Committee have great pleasure in congratulating its members on the state of the Association, both numerically and financially, and though they must confess to some amount of disappointment at the comparatively small numbers who attend the meetings and lectures the Committee hope that the great advantages they offer will induce a better attendance at lectures, and an increase of its members. That the meetings are so poorly attended is to be deplored, seeing that *one* of the objects of the Association is 'for the better scientific education of assistants and apprentices.' The number of members at present is 34, being a decrease of one from last year, and the number of associates is 47, being an increase of 11, showing an increase in the annual subscriptions of 17*s.* 6*d.*

"Your Committee have pleasure in stating that there is at present a balance in favour of the Association in the Treasurer's hands of £14, and in the Secretary's hands of £1 0*s.* 10½*d.*

"Your Committee have to announce that they have accepted the resignation of Mr. E. Yewdall as Hon. Sec., he having held that post since its foundation, during which time he has faithfully discharged the duties imposed upon him with an amount of zeal and energy deserving of the highest commendation. Your Committee feel that they cannot adequately express the valued importance of the services rendered by Mr. Yewdall to the Association.

"Some interesting papers have been read during the year, and your Committee tender their thanks to those gentlemen who have assisted the Association with their instructive papers:—'Some Leeds Worthies in Science,' by Mr. R. Reynolds, F.C.S.; 'The Chemistry of a Piece of Coal,' by Dr. Parkinson, Bradford; 'Bone, its Functions in the Animal System, and Uses in the Arts and Agriculture,' illustrated by experiments, by Mr. Thos. Fairley, F.C.S.; 'Mineralogy and Crystallography,' illustrated by numerous beautiful specimens, by Mr. O. Pegler, Associate of the Royal School of Mines; 'British and American Pharmaceutical Notes,' by Mr. E. Brown; 'Our Society,' by Mr. E. Yewdall.

"Four members of the Committee attended the British Pharmaceutical Conference at Bradford, in September last, as delegates from our Association.

"The following books have been added to the library: Fownes' 'Manual of Chemistry,' latest edition; Fresenius' 'Qualitative Analysis,'; 'Supplement to Watts' Chemistry'; Ten Vols. of the 'Journal of the Chemical Society'; the 'Pharmacopœia Germanica'; 'Transactions of the American Pharmaceutical Association'; Proctor's 'Lectures on Practical Pharmacy.' The 'Year Book of Pharmacy' has been presented to the Association as a donation to the library from the committee of the Pharmaceutical Conference. Cases for reading PHARMACEUTICAL JOURNAL, *Chemist and Druggist*, and other periodicals, have been added.

"Not having had a librarian for some time who could give the measure of attention required to the library, a very accurate statement cannot be rendered. However it may be interesting to members and associates to know that there are at present on the shelves of the library about 220 volumes; that upwards of 120 volumes have been out on loan during the year, and in addition to the periodicals taken in by the Association, many new books have been added, a list of which has been read.

"Seven students from our Association attended Mr. Abbott's class on botany, and six presented themselves for the examination of the Science and Art Department. One obtained 1st class certificate, three 2nd class, and two failed.

"Fourteen chemist's apprentices and assistants have attended Mr. Ward's class on chemistry, during the last year, seven of whom passed the examination of the Science and Art Department, two in the advanced, and five in the elementary stage in inorganic chemistry, and two in the elementary stage, organic chemistry. The attendance of the students and their application to study was, on the whole, highly satisfactory. Your Committee have great pleasure in announcing that they have made arrangements with Mr. Abbott to give a course of lectures on Materia Medica, which will comprise twenty-four lectures, and will be illustrated by diagrams and specimens. An examination will take place at the close of the course, and two or three prizes will be awarded. An arrangement has also been entered into with Mr. Louis Siebold, Manchester, who has kindly consented to give a lecture on 'Fermentation.'

"Your Committee have to announce that they have engaged the room next to the library as a lecture-room, so that no inconvenience may be caused to the members and associates who wish to use the library on lecture nights.

"Your Committee earnestly request the associates to make every endeavour to attend Mr. Abbott's class, as

well as those given by Mr. Ward, at the Mechanics' Institute, in connection with our Association, on Chemistry, and also request the members to use their influence with those who are at present non-attendants, urging them to join, and respectfully point out the difficulty of upholding such an Association as ours without the aid of its members and associates."

Proposed by Mr. T. B. Stead, and seconded by Mr. F. Reynolds, that the report be adopted. Carried unanimously.

Proposed by Mr. E. Yewdall, and seconded by Mr. Stead, that a vote of thanks be presented to Mr. C. Pierson for his diligence in collecting the subscriptions without remuneration. Carried unanimously.

Mr. E. Brown announced that a sub-committee had been formed to inquire into the desirability of engaging rooms at the Trevelyan Hotel, for the usual social gathering, to be held next month, and he had pleasure in announcing that the inquiry was satisfactory.

It was moved by Mr. E. Yewdall, and seconded by Mr. T. B. Stead, that Mr. J. Day be requested to give his paper on "Percolation" during the present session. Carried unanimously.

The following gentlemen were then elected officers for the coming year :—

President, Mr. F. Reynolds ; Vice-President, Mr. S. Taylor; Honorary Secretary, Mr. J. W. Longley; Librarian, Mr. T. Wilson; Sub-Librarian, Mr. E. O. Brown ; Curator, Mr. Payne. Committee—Messrs. T. B. Stead, E. Brown, E. Yewdall, Richard Reynolds, William Ward, and William Smeeton.

In vacating the chair, Mr. Brown gave a brief review of the progress of pharmacy during the past year, touching lightly upon the Bill for the storing of poisons, the fire at Chicago, and the many deaths of celebrated characters that have taken place.

Mr. Reynolds, on taking the chair, remarked on the reluctance he had to take office, believing that there were many more qualified than himself to take the post ; at the same time he was not insensible to the honour conferred upon him, and would at all times endeavour to do his best for the Association. He was sorry to see such a small attendance at the meetings and lectures, and thought that one means of inducing associates to join would be for them to follow the example of the Tyne Chemists' Assistants' Association, for the reading of papers, etc. The first duty he had to do gave him considerable pleasure, namely, to move that a vote of thanks be given to the retiring officers.

It was moved by Mr. Stead, that a vote of thanks be given to Mr. Brown and Mr. E. Yewdall, the retiring officers. It gave him great pleasure to do so, because of the untiring energy displayed by Mr. Brown during the last two years. Of Mr. Yewdall's services he could not speak too highly, and felt great regret at his resignation. He was sorry to see such small attendances at lectures and meetings of the associates, because he agreed with the remark of Mr. Longley that the Association was one for their good ; but he knew that in a large town like Leeds there were so many attractions, that it was with difficulty the young men could be persuaded to join. After a few words of good advice to the associates, the resolution was seconded by Mr. Pierson, and carried unanimously.

Mr. Brown briefly returned thanks, and referred to the able manner in which Mr. Longley had devoted his time and energy to his new duties since Mr. Yewdall resigned.

Mr. E. Yewdall, in returning thanks, said, that although he had resigned, he should still take great interest in the society.

NORTHAMPTON PHARMACEUTICAL ASSOCIATION.

The Council of the Northampton Pharmaceutical Association have issued the following report for the year ending September 30th, 1873.

"The Council have much pleasure in placing before the members the report of their second year's progress, feeling sure that they will view with gratification the success that has been attained at such a moderate expenditure. Classes in botany, chemistry, materia medica, pharmacy, and prescriptions, have been conducted through the winter session with the usual large attendance—averaging ten at each class—great interest being shown in the various subjects, as may be seen from the fact that *four* members passed the Minor, and *five* the Preliminary examination during the year.

"The examinations, which had been conducted by Messrs. Maxwell and Sandall, and for which prizes were offered, acted as a great stimulus to attendance and study ; and though but few assistants competed, yet the experiment was sufficiently successful to warrant the Council in repeating it.

"The Association has been benefited by several donations during the year, and Siebold's herbarium and a fume cupboard of a novel construction have been added to the rooms.

"The botanical ramble to Castle Ashby and Olney was a remarkable success, and, with the two visits to P. Jeyes, Esq., formed pleasant episodes in their course of study.

"At the request of the Council the class conductors have formed a programme of classes for the ensuing session. The Council trust that their trouble may be rewarded by the punctual attendance and close attention of the members.

"During the year the rooms will be open every night for study. In May, examinations in the various subjects will be held.

"The Council thank most sincerely Mr. Barry for his services as Local Secretary to the Pharmaceutical Society ; Mr. Jeyes, for the continued use of the room ; Messrs. Sandall and Maxwell, for acting as Examiners ; Mr. Abington, of Ringstead, for his donation, and the other friends who have so kindly rendered assistance.

"The members' subscriptions this year have covered the expenses of the Association, thus redeeming the promise made last year by the Council of being *self-supporting*.

"Finally, the Council, in returning thanks to the members for electing them, declare that no exertion on their part shall be wanting to prove that the confidence reposed in them has not been misplaced."

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

(*Continued from page* 318.)

NOTES ON THE PRESENCE OF BROMINE, IODINE, AND SILVER, IN SEA WATER.

BY GEORGE ALEXANDER KEYWORTH.

Some years since the writer carried on a long series of experiments in the endeavour to separate these substances

from sea water without heat. Silver was first sought for, which is believed to exist as chloride. Its presence has long been inferred from the alleged increase in silver acquired by the copper sheathing of vessels after long voyages. Although distributed through the ocean with extreme tenuity, the calculated aggregate in such a volume as a cubic mile is very large.

Professor Faraday privately expressed an opinion that the silver might be found by means of the electric battery, and suggested a weak continuous current with platinum electrodes. Various forms were employed, and in one case the battery was in action during four months : among other products iodine as iodide of starch * was obtained, but results were always negative as regards silver. Reminded of the axiom, that when the same result can be gained by chemical or by electrical action, the former is preferable; sulphuretted hydrogen was passed through several gallons of filtered sea water, and then allowed to stand during some months. The precipitate was extremely small and consisted of sulphur. Silver has however been obtained by means of sulphuretted hydrogen, albumen, and heat from a large quantity of sea water, concentrated by evaporation. The sulphide of silver becomes entangled in the coagulated albumen, and the metal can be separated by cupellation. Mr. Steel of Gravesend advertised some time since in the *Graphic* for assistance in carrying out his patent for collecting silver from the sea by means of apparatus to be employed by sailors, with results expected to be lucrative. Inquiry has not elicited anything as to this process.

The search for silver led to experiments for detecting iodine with more success, inasmuch, as the starch reaction was in one instance obtained. It was found necessary to separate the large proportion of lime present in sea water by means of oxalate of ammonia, and to remove also the sulphates by means of baryta water. The addition of chlorine water and hyponitrous acid then set free the iodine, which presented the characteristic reaction with starch. To succeed, however, the process requires extreme delicacy and many precautions. Bromine, however, can be readily obtained, even from so small a quantity as a fluid ounce of sea water. It is best to employ oxalate of ammonia and baryta water as before. On adding a few drops, first of chlorine water, and then of hyponitrous acid, the yellowish tinge is apparent, and the bromine can be readily separated by shaking the phial with a small quantity of sulphide of carbon, which falls down of a fine orange colour. The bromine can then be removed by means of caustic potash in the usual manner.

I would venture to suggest, for the consideration of the committee, that one or more of the above substances so existing, might be profitably taken up by a member, and thoroughly worked out at the cost of some portion of the "Bell and Hills Fund." My own hands are full, but I should be very pleased to give such an investigator any details I may possess (besides those embodied in the paper), and to send him any amount of the raw material.

The thanks of the Conference were awarded to the author for his notes.

On the Examination of Tea for the Detection of Adulteration.

BY ALFRED H. ALLEN, F.C.S.

In my capacity of public analyst (under the Adulteration Act) for the Borough of Sheffield, a considerable number of teas have come under my notice, the majority of specimens having been brought by the tea-dealers themselves as a security against selling tea which if analysed by me officially might be condemned as adulterated.

Like some kindred questions which have lately been prominently before most of us, the examination of tea for certain additions has not yet become sufficiently a matter of routine, each analyst following his own methods, which in many cases have but little system, and thus in one or two notable instances lately, chemists have been found making irreconcilable statements as to the absence or presence of certain adulterants. The only work which professes to deal with the detection of the adulterations of tea is that of Dr. Hassall; but his directions, though somewhat elaborate, are not very definite, and he does not seem to have made any analysis of genuine tea himself. In fact the analyses we have of tea are by no means numerous, and some are so old that they may well be viewed with suspicion.

My object in examining the subject has been more to work out a technical method of testing teas for adultera tion than to establish the actual composition of genuine tea. I have therefore adopted those methods which I have found to give me pretty constant results with the same tea or other genuine samples and have paid less attention to ascertaining facts which, though interesting in themselves, have seemed to have no direct bearing on the question at issue.

The three principal constitutents of tea are tannin, gum, and woody fibre, with smaller quantities of some albumenoid body, theine (the active principle), colouring matters, chlorophyll, essential oil, etc. The proportions of these found by different analysts vary very much, the difference evidently depending on the methods of determination employed.

The estimations of tannin seemed to present the greatest variations, and in many cases were manifestly wrong. Thus, Hassall directs the analyst to exhaust a weighed quantity of the dried tea with hot water (of which about a quart is to be used), and to dry and weigh the residue, which he calls "woody fibre." The infusion is to be evaporated to a small bulk and treated with alcohol, which precipitates the gum, and subtracting the weight of this and the weight of "woody fibre" from the quantity taken, he arrives at the percentage of tannin. This estimation of such an important constituent "by difference" is very objectionable and is doubtless the cause of Frank and Phillips finding upwards of 40 per cent. of tannin in black tea. It is true that Dr. Hassall gives an alternative process by evaporating the alcoholic solution to dryness, which if carried out would probably make the percentage of tannin higher still from its oxidation. But Dr. Hassall also suggests that the tannin should be precipitated from the liquid by a solution of gelatin, and the precipitate weighed, 100 grains being said to equal 40 of tannin. This process again is very unreliable, owing to the large and variable quantity of colouring matter which is carried down by the precipitate of leather. But a modification of this process, in which a volumetric solution of gelatin is used, has given me very concordant and reliable results and has made the determination of the tannin in tea an operation of a rapid and tolerably simple character.

The use of a standard solution of gelatin for the determination of the strength of tannin matters is nothing new, but I believe I am the first to employ the process in the examination of tea.

A short description of the details of the method may be found serviceable and will enable other chemists to obtain results which will bear comparison with those obtained by me when working with genuine teas.

Twenty grains of tea are weighed out and boiled in a flask for half an hour with three or four ounces of distilled water.

The solution is drained off from the leaves, which are boiled again with a little hot water which is added to the main solution, and, after cooling, the whole is made up to a measured quantity. One-tenth of this liquid (= 2 grains of tea) is taken out with a pipette and placed in a beaker with an equal bulk of water, and a standard solution of gelatin is added to it by about five grains at a time with repeated stirring. A precipitate of tannate of gelatin is produced, and when the process is successful it readily sett allowing the operator to judge of the

---

* Colourless iodide of starch was produced in this case.

progress of the operation. When the precipitation is judged to be approaching a termination, a small quantity of the liquid is filtered into a test tube and tested with a small quantity of the gelatin solution. If a further precipitation occurs the test portion is returned to the bulk, and a further quantity of gelatin added. Another test portion is taken and tested as before, and if no further turbidity occurs, a further small portion of the filtered liquid is tested with tannin solution to make sure that the process has not been carried too far. The end of the precipitation being reached, the volume of gelatin solution is noted, and the process is repeated on half of the original tea solution (= 10 grains of tea), the preliminary test enabling the operator to add nearly the required amount of gelatin solution at once, but otherwise the process is conducted as before, except that further dilution of the liquid is unnecessary. If desired the process can be repeated on the remaining portion (= 8 grains) of the tea solution. With a little practice the end of the reaction is readily hit, but it is always well to repeat the estimation on the remaining quantity of the solution.

I believe my estimations of tannin in tea, made by the above process, are right within half of a per cent.

The standard gelatin solution is made by dissolving 40 grains of Nelson's gelatin in 7000 fl. grains (16 oz.) of distilled water, and adding 15 grains of powdered alum (which greatly facilitates the subsidence of the precipitate of leather). The strength of the gelatin solution is ascertained by dissolving five grains of pure tannin in about six ounces of water, and proceeding as with the tea. It does not keep well, so must be reset every few days, or a fresh solution prepared.

By using the above process, I have found in genuine black tea of rather more than average quality, 12·5 per cent. of tannin ; and in green tea about 19·0 per cent.

These numbers present a close agreement with those in the old analyses of Mulder, which I consider the most accurate and complete analyses of tea extant.

According to Frank and Phillips, black tea contains a little over 40 per cent. of tannin. The origin of this mistake is apparent when we add to the tannin found by Mulder, the "extractive matter."

Thus in Mulder's analysis we find :—

	Green (Hyson).		Black (Congou).	
Tannin	17·80		12·88	
Extractive . . .	22·30	40·10	19·88	44·24
„ dark coloured			1·48	

	Frank.	Phillips.
Tannin in unused Black Tea .	40·6	42·5

I consider the estimation of the tannin of the first importance, for if it reaches the normal amount all question of adulteration by exhausted leaves is at an end, and foreign leaves are very unlikely to be present. The only fallacy in such a conclusion would be caused by an admixture of catechu or sloe leaves.

The next point of importance is the percentage of "woody fibre," as it is called by some analysts, and here again I am disposed to think that Mulder's analysis is the only accurate one, as far as a determination of real cellulose is concerned.

He found "vegetable fibre" to the extent of 17·08 per cent. in green tea, and 28·32 in black tea. Frank states the "woody fibre" in black tea at 44·8, and Phillips at 46·8. Peligot found the exhausted leaves in undried green tea came to 43 per cent. of the original weight, and in black tea to 49 per cent.

I have estimated what I hesitate to call "woody fibre," containing as it does much colouring and albumenoid matter, by boiling genuine undried tea of commerce in hot water as long as the water becomes coloured. The solution was strained off, and the exhausted leaves dried.

The "insoluble matter" thus obtained varied from 50·5 to 51·2 per cent. in green teas, and from 58·7 to 60·8 per cent. in black teas. It will thus be seen that the insoluble matter is tolerably constant in amount, and, when largely in excess of the average, an admixture of exhausted or foreign leaves is extremely probable.

The gum I have estimated in two ways. One method is to exhaust the tea with boiling alcohol (methylated spirit will do), re-dry and weigh the residue, and boil with water, and weigh the dried leaves again. The difference between the two weighings, representing the matter insoluble in spirit but soluble in hot water, has been assumed to be gum. I have not found the method very satisfactory, and have now abandoned it for the following :—The solution of the tea in hot water, which was strained away from the insoluble matter is evaporated to a syrup, treated with (re-distilled) methylated spirits, the precipitate of gum washed with spirits, dried and weighed.

The percentage of gum, insoluble matter, and tannin in any sample of tea, considered carefully, will enable the analyst to form a very accurate opinion as to the presence or absence of exhausted leaves, etc.

Analysed by the above described method, a sample of very superior black tea gave the following results, which I have placed in juxtaposition with the numbers obtained after some of the same sample had been infused in the usual manner in the tea-pot,* and the leaves re-dried.

	Original Tea.	Exhausted Tea.
Moisture	9.2	11·1
Insoluble Matter	58·7	87·5
Gum	10·5	3·8
Tannin (by Gelatin) . . .	15·2	3·3

From this it will be seen that infusion in the tea-pot results in the increase of the insoluble matter by nearly 30 per cent., while the gum and tannin are much reduced in amount.

Generally, the exhausted leaves are redried, and made up with gum, which dressing gives them a peculiar glossy appearance, and is detected by excess of gum on analysis.

An inspection of the table on p. 333 shows that genuine green teas are richer in tannin than black teas in about the proportion of 2 to 3. This is no doubt due to the partial oxidation and destruction of the tannin, during the process of fermentation to which black tea is subjected during the process of manufacture. Whether the acknowledged superior strength of green tea is due to the larger percentage of tannin present in it I am not prepared to say. The determinations of theine I have made do not account for the difference, and most analysts have found more theine in black than in green tea. The infusion of green tea is not nearly so strong in colour as that of black tea, though it is half as strong again in tannin, so that the depth of colour cannot be regarded as a proof of strength, though so considered generally. If a solution of carbonate of sodium be added to a weak infusion of tea (strained away from the leaves) a considerable darkening is observed, though certainly the infusion can become no stronger. Thoroughly exhausted tea leaves yield a brown liquid when treated with carbonate of sodium solution. These facts quite explain why careful housewives have a fancy for putting soda in the tea pot, the infusion becoming sensibly darker by the addition, to say nothing of the extra colouring matter extracted from the leaves. Apart from its softening effect on the water (the advantage of which I think is doubtful) there can be no good reason for its addition.

The sample marked No. 5 in the table was evidently a made up article, having a glossy appearance and disagreeable taste. The analysis clearly showed the cause of these characters.

No. 6 consisted largely of tea stalks, but I did not feel justified in reporting it as adulterated, as they are readily perceptible to anyone, and that the purchaser would not

* The exhaustion was not carried to excess, no second quantity of water being used.

Conclusions ...	...	...	...	...	Reported as containing exhausted leaves re-dried and made up with gum.	...	Reported as containing exhausted leaves re-dried and made up without gum.	Reported as containing exhausted leaves, strongly coloured by Prussian blue, etc.		This presents almost the same composition as No. 3, which was obtained from an entirely different source.	Presents a close resemblance to inferior green tea in every respect.	Contained sulphate of iron and foreign and probably exhausted leaves, besides the additional impurities picked out and examined separately.	Contained catechu, starch, magnesia, metallic iron, graphite, sand, etc.

pay so much for tea containing them, and no one would expect to make very strong tea from such a specimen. No. 7 had a peculiar redried appearance, without any gloss on it. The analysis resulted as was expected.

No. 11 shows the close resemblance in composition between sloe leaves and tea, but of course no theine would have been found in the sloe.

The samples No. 12 and No. 13 were bought in consequence of a bill appearing in the grocer's shop-window recommending everyone to "try our rough-flavoured, thick, sappy, moning congou at 2*s.* per lb., equal to 2*s.* 6*d.* tea sold everywhere." On asking for the rough flavoured congou mentioned in the window bill, the tea was taken from a canister but "a good pinch" from somewhere else was added to it. This addition was very different in appearance from the rest of the tea, and thus was readily separated again from the main bulk of the sample, of which it constituted about five per cent. The picked out portion was then analysed separately as No. 13, the result obtained showing it to be a fair specimen of "Lie Tea" made up of catechu, starch, sand, metallic iron, graphite, magnesia, etc.

In the recognition of foreign leaves chemistry cannot be expected to play a very active part, but we must rely on botany and the microscope. The presence of foreign leaves was distinctly recognized in sample 12, and they were strongly suspected to be present in Nos. 5 and 9.

I may suggest the distillation of an evaporated extract with a mixture of sulphuric acid and manganese dioxide as a possible means of detecting foreign leaves in tea. Treated with such an oxidizing mixture, coffee, tea Paraguay tea, holly, and the cinchona plants give volatile

yellow quinovic acid, a highly characteristic body. The sloe, cherry laurel, peach, plum, etc., will yield hydride of benzoyl (oil of bitter almonds). The willow and poplar will yield salicylous acid. I propose to ascertain how far these reactions can be depended on when the leaves are in admixture with tea.

In the methods I have used for detecting facing and colouring there is not much that is new.

On treating the tea with warm water the colours and facings come off, and on straining off the leaves and leaving the liquid at rest they gradually settle to the bottom. If Prussian blue or indigo be present, the sediment has a bluish or greenish colour, and the tests for these pigments must be tried accordingly. Magnesia is often present, both in the free state and as insoluble silicate (steatite). This latter facing I have found lately on several occasions on green teas of peculiarly smooth appearance and slippery feel. It was detected by treating the sediment with hot hydrochloric acid, and then with solution of caustic soda. The residue was ignited and fused with alkaline carbonate, the fused product dissolved in acid, evaporated to dryness, redissolved in weak acid, the solution treated with ammonia and oxalate of ammonium, the precipitate filtered off and the clear liquid tested for magnesium in the usual way by phosphate of sodium, when an abundant precipitate was obtained, proving the presence of magnesium as silicate.

I have taken considerable trouble to devise a rapid and simple process for the estimation of the amount of theine in tea, but have not succeeded as fully as I had hoped, and my experiments in this direction have come to a close since I became convinced that the determination would be valueless for the purpose of detecting adulteration. I have estimated the theine by Peligot's and Stenhouse's processes, and have also used the following method, which would, I think, be the best process when estimations are really desired :—

200 grains of the powdered tea are placed in an apparatus, in which they can be subjected to the action of hot commercial benzol, which becomes coloured of a deep greenish-brown. Arrangements are made for condensing the vapours, and causing the liquid to flow through the tea repeatedly as long as it becomes coloured. By this process of condensation, two ounces of benzol are amply sufficient for the extraction of 200 grains of tea, and nearly the whole of this is regained on distillation. When cold, the benzol is filtered, distilled off by a steam heat, and the residue extracted by boiling water, the solution filtered, and the clear liquid evaporated to dryness on the water bath, and the residue of impure theine weighed. To purify the theine, it is redissolved in hot water, treated with a small quantity of acetate of lead, filtered, the clear liquid treated with sulphuretted hydrogen, the black precipitate of sulphide of lead filtered off, the solution of theine once more evaporated to dryness, and the theine weighed. I have not found it possible to omit the purification, as a variable quantity of colouring matter, etc., is found in the impure product, and thus its weight is not to be depended on.

In conclusion I desire to express my high opinion of the skill and perseverance shown by Mr. Joseph Stapleton, who has assisted me most ably throughout the above experiments.

Mr. Greenish : I think that the method mentioned by Mr. Allen may be a very excellent one for the detection of the presence of exhausted leaves, but I doubt whether it will show when tea has been mixed with very old leaves. There are first, second, and probably later pickings of tea, and if as possibly may be the case, the later—and inferior—pickings contain a larger proportion of tannin, that fact would interfere materially with the results obtained. I have paid a good deal of attention to tea, and I must say that I think it is absolutely necessary that after pouring water over the leaves, they should be separated and examined individually. It is somewhat unfortunate that all the leaves are usually broken up. You do not get the points of the leaves, but find them scattered here and there. The botanical character however can be easily ascertained. There is something very characteristic about the serration and the venation of tea-leaves, the serration only coming half-way down the leaf and the primary venation stopping short of the edge of the leaf, or rather turning off and leaving a distinct space between it and the edge of the leaf. At the apex of the leaf there is a notch instead of a point. [A figure of the tea-leaf, in illustration of these botanical characters was drawn on the black-board by the speaker.] It is very important that these botanical characteristics should be kept clearly before the mind of the person who is examining tea suspected of being adulterated. I have never yet met with a sample of green tea which has not been "faced," usually with a mixture of Prussian blue, turmeric, and china clay. This may generally be seen by the naked eye. When small quantities of the tea are placed in water the "facing" comes to the top of the water ; then if it be floated on a slide and examined with a microscope its various ingredients may be easily detected. Again, if the under cuticle of the leaf be separated, the characteristic distinct space between the two cells of the stomata will be at once perceived. If these tests be applied we can at once determine whether the sample contains foreign leaves. It is important to bear in mind that the Assam tea leaf has its margin biserrate.

Mr. Williams : If hydrate of lime were employed the theine would be produced white and pure at once.

Mr. Allen : I fully admit that microscopic examination of tea will show more clearly than the tests I propose the presence of foreign leaves in tea, but all I proposed to do was to show the actual value of the tea. I do not understand how tannin can accumulate in old tea-leaves. We know that the difference between green and black tea is owing to the latter undergoing a kind of fermentation before it is dried, by which a portion of the tannin is destroyed, and the determinations of tannin I have made bear this out. I should therefore have thought that the older the leaves were the less tannin they would have contained. In some specimens of green tea I have found Prussian blue, china clay, and even French chalk. I have found green tea free from colour, but that was when I was supplied with it specially by a dealer for comparison with other teas. I am quite aware that some adulterations of teas can be easily ascertained by the use of the microscope, but being a chemist I always prefer, where I can, to detect the adulteration by chemical means.

Mr. Greenish : I have always made use of the microscope in examining teas, and I have not been fortunate enough to meet with a single specimen of unfaced green tea. If warm water be poured upon a small quantity of green tea a sort of scum will rise to the surface of the water in which Prussian blue, turmeric, and china clay can easily be detected by the microscope.

Mr. Allen having been thanked for his communication the Secretary read the following paper :—

Contributions to the History of Potable Waters. No. II.

BY M. M. PATTISON MUIR, F.R.S.E.

In a paper read before the Glasgow Philosophical Society in April 1872, I gave a few measurements of the solvent action of various saline solutions upon lead. That the presence of nitrates powerfully influences this action was there distinctly shown.

It is generally supposed that water supplied for domestic purposes, after remaining some time in a cistern in any way connected with, or situated near to the drains which remove the sewage matter of the house, is more hurtful than that water which comes directly from the main pipe. In addition to other obnoxious constituents, water stored in a leaden cistern situated as above described might be

supposed to contain an amount of nitrates which would cause it to exert a marked solvent action on the lead.

In a comparison of cistern water with water supplied from the main, there are three questions which present themselves.

1. Does the cistern water contain a relatively large amount of nitrogenous organic matter?

2. Is the amount of nitrates and nitrites in the cistern water great as compared with the other water? And,

3. If these substances are present in large amounts does their presence influence the solvent action of the water on the leaden cistern?

1. 500 c.c. of water taken from the supply pipe of a dwelling house, all the water in which came through an ordinary leaden cistern situated in the bath room, was distilled after the addition of about one gram pure sodium carbonate; no estimable amount of ammonia was found in the distillate.

500 c.c. of water from the main pipe similarly treated also gave a negative result.

After the addition of about 20 c.c. alkaline permanganate solution, and further distillation, the ammonia in the distillate of No. 1. water was equal to ·07 milligrams per litre or ·07 parts in one million of water.

In the case of the water from the main the ammonia, after the same treatment, was equal to ·08 parts in one million of water.

2. 500 c.c. of the cistern water was evaporated to a very small bulk, a fragment of freshly ignited lime having been previously added. The liquid was filtered and the nitrogen existing therein as nitrates and nitrites estimated by Thorpe's method, which consists in evolving the nitrogen as ammonia by the action of zinc coated with a deposit of spongy copper at a boiling heat. (*Chem. Soc. Journ.* June, 1873.)

In the distillate ammonia was estimated by the addition of Nessler's reagent. It was shown that the amount of ammonia corresponded with that contained in 21·4 c.c. of a standard ammonium chloride solution, each c.c. of which contained ·025 m.gm. of ammonia. The amount of ammonia was therefore equal to ·535 m.gm. which corresponds to ·44 m.gm. of nitrogen. There are therefore ·44 parts per million of nitrogen existing as nitrates and nitrites in this water.

500 c.c. of the water supplied directly from the main pipe, after similar treatment, yielded a distillate in which the amount of ammonia was the same as that contained in 12·7 c.c. of the standard solution, that is, it was equal to ·317 m.gm. This calculated to nitrogen gives ·26 parts per million of water.

3. 300 c.c. of the cistern water was evaporated to the volume of 50 c.c., and the lead estimated, by comparing the depth of colour consequent upon the addition of a measured volume of sulphuretted hydrogen water with that produced, under similar conditions, in an equal volume of pure water to which a known amount of lead in solution had been added.

The standard lead solution contained ·1 gram of lead per litre; 1 c.c. was therefore equal to ·1 m.gm. of lead. The depth of colour produced on addition of sulphuretted hydrogen water to a volume of pure water to which ·7 c.c. of this solution had been added was equal to that produced in the same volume of the water under examination. The lead contained in the 300 c.c. of the water was therefore ·07 m.gm., which is equivalent to ·23 parts per million.

The water from the main, treated as above described, was found to contain ·20 parts of lead per million of water.

These results seem to me to lead to the following conclusions:—

1. The nitrogenous organic matter liable to undergo putrefactive changes is very nearly equal in the two waters. In neither is this amount at all large.

2. There is a very marked difference between the amounts of nitrogen existing as nitrates and nitrites, the proportion being as 1 is to 1·7.

This, taken in conjunction with the fact that the albumenoid ammonia is almost the same in each case, tends to show that the water has really been contaminated with sewage matter, or with gases arising from such matter, but that when the water has found its way through the pipes of the house this nitrogenous matter has for the most part been oxidized.

The evil is, therefore, not so bad as if the added nitrogenous matter remained in that state in which it is most ready to undergo rapid change. Although the nitrates have increased in quantity, yet there is not such an amount of these salts present as would lead one to suppose that the water has undergone any excessive sewage contamination. These results, nevertheless, point very clearly to the fact that the cistern water is less pure than that supplied from the main, and, in our limited knowledge of the action of dissolved organic matter upon the organism it would be unwise to say that no bad effects are likely to follow the continued use of such water. Nor can we foretell what condition of affairs might be brought about in such a water during the prevalence of an epidemic disease. Would it be unscientific to suppose that the disease germs would be more readily carried by a water, a large part of the oxygen of which is occupied in doing work in decomposing nitrogenous matter, than by a water, the greater part of whose oxygen is directly available for the purposes of oxidation?

3. Although water No. 1 contains such a relatively large amount of nitrates yet the amount of lead held in solution by it is scarcely, if at all, larger than that contained in water No. 2.

This may, in all probability, be accounted for by the fact that house cisterns are generally very far from clean; the lead is almost invariably protected either by a coating of an insoluble lead salt or by a deposit of some other matter upon it. And even if the lead were bright and clean, the water contains salts whose action retards the solvent influence of the nitrates present; a very small proportion of carbonates being sufficient (as is shown in the paper referred to) to materially hinder this action.

Organic matter of some kind may also accumulate in the cistern, and the action of the water on the lead be thereby hindered. The influence of organic matter in this respect remains as yet however to be examined, no definite measurements having been made.

This subject, viz., the influence which the means of supply exerts on potable waters, is one requiring a great deal of examination. I can only offer these remarks and measurements as a small contribution towards its solution.

Anderson's University, Glasgow,
September 12th, 1873.

The thanks of the meeting were voted to Mr. Muir for his paper.

Mr. MATTHEWS: My experiments on this subject lead me to believe that the action referred to in the paper just read was due to nitrites rather than to nitrates, and we know that *quasi*-free nitrous acid under certain circumstances by continuous operation will go on dissolving the metal, and that this action goes on even with ice water.

Professor ATTFIELD: If I understand Mr. Muir's paper rightly he has found an extraordinary amount of nitrogen in the form of nitrates and nitrites in cistern water as compared with water taken from the main, the figures being ·44 per million of nitrogen in cistern water as against ·26 per million in water from the main. I think that the water in the cistern which he examined must have absorbed a most unusually large amount of nitrogenous organic matter in the form of sewer-gas to produce such an increase in the nitrates. The statement appears to be of an alarming character, and a considerable number of experiments should be made before such a result could be relied upon as typical.

An Improved Preparation of Kino.

BY GEORGE ELLINOR.

The tincture of kino of the Pharmacopœia is so unstable that it is very little used.

Kino possessing advantages over most of the astringents, having a peculiar action on the mucous membrane of the intestinal canal, it is desirous to have a solution of the drug in a stable form, and miscible with water in any proportion.

In the liquor kino concent. or fortior I now exhibit this is fully accomplished.

This liquor kino fortior, diluted with water to form the relative strength of the tincture, will be found most efficacious and reliable.

Liquor kino concent. or fortior is prepared in the following manner, viz. :—

Kino	℥ j
Glycerine	℥ ij
Water to	℥ iv

Rub together in a mortar the kino, glycerine, and ℥ j of the water, until dissolved, then make up to f ℥ iv by the addition of water.

To the liquor kino fort. one volume by measure mixed with four volumes of water will thus form the liq. kino corresponding with the strength of the tincture relatively, but really stronger, the whole of the kino being dissolved, and this is entirely soluble in water.

I prefer making the liquor kino in the concentrated form because from it can be so readily prepared the representative of the Pharmacopœia.

The whole of the kino is dissolved; the sand and other earthy matter is thrown down after standing a week or so.

I believe this preparation to be very efficacious, and adapted to mixture of chalk, and all diarrhœa mixtures, and with a great amount of saving in the expense of rectified spirit, the cost being less than 6*d.* per Oj. of the preparation as compared with the price of the tincture.

I think it may take a place with the glycerates of the Pharmacopœia.

As far as I have been able to determine, it is far preferable to the tincture in its action and stability.

The President: It was suggested long ago in America that a glycerine solution of kino might be used advantageously, but there are very strong objections to using glycerine with astringents.

Mr. Williams: Is the specimen of the solution produced liable to pectize by keeping?

Mr. Greenish: We ought to be very careful before we venture to suggest any alteration in the method of making tinctures laid down in the Pharmacopœia. I make tincture of kino by percolation which never gelatinizes, even though kept for a considerable time.

Mr. Groves: The pectization of kino depends greatly upon the age of the substance; fresh kino does not pectize, whilst that which is two or three years old probably will do so.

The President: Just to bear out what I stated a moment ago, I may say that I know of one case in which three hundred grains of perchloride of iron dissolved in pure glycerine were swallowed by mistake without any ill effect, whilst a very much smaller quantity dissolved in water must have caused serious results. Again, I know several instances in which medical men have been disappointed in obtaining the full astringent effect they expected from glycerinum acidi tannici, when a strong aqueous solution has answered admirably. Glycerine, I am certain, has a powerful action in weakening the effect of astringents, and its indiscriminate use in pharmacy is much to be deprecated.

Mr. Martindale: I wish to point out that what is called Botany Bay kino is more likely to pectize than the pure Indian kino.

(To be continued.)

Parliamentary and Law Proceedings.

Poisoning by Morphia.

On Thursday, October 16, an inquest was held in Carlisle before the city coroner (Dr. Elliot) respecting the death of Mrs. McLeod, wife of Dr. McLeod, who had been resident in the city during the last few months. The first evidence given was that of servants, who deposed that deceased and her husband had appeared to live together on very affectionate terms. In consequence of one of the children suffering from an attack of typhus fever Mrs. McLeod's rest had been much interfered with.

William Ruston, chemist's assistant with Mr. Joe Todd, deposed: I remember supplying some medicine on Saturday last to 22, Chiswick Street. I supplied a prescription sent by Dr. McLeod, containing chalk mixture, and a plaster as well. I should think it was for an adult, owing to the dose. I have not the prescription with me. I do not think there was any laudanum or solution of morphia in it. Yesterday or the day before I supplied Dr. McLeod with 20 grains of muriate of morphia.—Dr. McLeod (interrupting): No, no, 10 grains; the bottle would not hold more than 10 grains. [The bottle was produced, and Dr. McLaren said at the present time it contained 3 grains.—The Coroner emptied the bottle, and asked if Dr. McLaren would go to the druggist's and get 10 grains into it, and the jury could then see how much it could hold.]—Witness continued: I served it to Dr. McLeod personally. I have no doubt about the bottle. I remember it, and said it was hardly safe with the old label on, and proposed to put a new one on. Dr. McLeod objected, and said the old label had better remain. Dr. McLeod has been in the habit of getting medicine at our shop; but it was in small quantities. I am not aware that he ever got any muriate of morphia before. Had no note in the books of the things he had got, and I can just now remember nothing. [At this stage Dr. McLaren returned with the bottle, apparently at first sight about three-quarters full of morphia.—The Coroner (to witness): It would not contain as much again?—Witness: I would like to shake it before I say that. Witness then shook the bottle well, and the result was that the powder settled down, so as to take up about half of the bottle.—The Coroner: There is no doubt about it. It could contain as much again.—A Juryman: Will Dr. McLaren tell us how much he has got put up in the bottle now?—The Coroner: We will get that afterwards.]—Witness: Dr. McLeod paid 8*d.* for the morphia, and that was the price of 20 grains.—The Coroner: (to witness): You can form a fairly accurate idea of quantities?—Witness: Yes.—How much morphia do you think that bottle (referring to the phial Dr. McLeod had taken to the druggist's) contains at the present moment?—About 10 or 12 grains.—That is when the bottle is well shaken. Did you shake it when you sold the 20 grains to Dr. McLeod?—Yes, and the bottle was quite full.—That bottle was full up to the brim?—Yes, it was.

Dr. Robert Walker deposed that about 7 o'clock on the previous evening Dr. McLeod had requested him to call and see his wife. He found her lying upon the hearth-rug in the drawing room quite insensible. She had the appearance of morphia poisoning, and Dr. McLeod told him voluntarily she had been taking morphia. He used the stomach pump, and tried various methods of rousing her, but without success, and she died about a quarter before ten. When Dr. McLaren came they tried an injection of atropine into the veins, but he thought she was dead then. Dr. McLeod told him that the morphia was taken to get her to sleep, as she had had none for some nights.—A Juryman: Did Dr. McLeod tell you how much she took?—He said all in the bottle, except what was left in it, and he thought the bottle contained ten grains.—A Juryman: That was tantamount to saying she had taken seven grains.—Dr. Walker: But he said she did not get it altogether. He said he

first gave her a grain, and then as it seemed to take no effect another grain, and so on every half-hour.—When did Dr. McLeod say he gave the first grain?—About four o'clock, and he continued with half-hourly doses up to seven o'clock.—A Juryman: Then according to the chemist's evidence, who said the bottle contained 20 grains, he had given her 17 grains of morphia in three hours.—A Juryman: You are not at present prepared to say the cause of death?—Poisoning from morphia, I think there is little doubt.—Dr. McLeod: Did deceased ever change colour when you were there?—Occasionally. Had you any hope of restoring her?—Yes. I thought when the colour came back she might possibly recover.—Supposing a person were to take 8 grains of morphia, after a dose of that sort would colour return?—I should think it might under artificial breathing.—Is it not a rule in practice that the extent of doses is to be measured by the effect produced; that you are justified in repeating the dose until an effect is made?—Dr. Walker: If you have first waited for the effect to be established.—Was half an hour sufficient to produce an effect with morphia?—Sometimes it does not produce an effect for some hours.—What is the shortest time in which it might produce its effects?—In a quarter of an hour.—A Juryman: Was Dr. McLeod perfectly sober all the time?—Yes, I think he was.

Dr. Roderick McLaren, Honorary Surgeon of Carlisle Dispensary, said: At twenty minutes to nine last night I was called to 22, Chiswick Street. I went, and found Mrs. McLeod lying in the lobby. Dr. Walker was keeping up artificial respiration, assisted by Dr. McLeod. Mrs. McLeod was quite insensible, breathing only at intervals. Dr. McLeod showed me this bottle, and said he had given Mrs. McLeod the whole of the 10 grains of morphia, except what was left in the bottle. I went to get an instrument for injecting atropine. When I came back Mrs. McLeod's colour looked a little better; but by the time the instrument was ready she had given over breathing naturally. Dr. Walker opened her vein and injected a little atropine. We kept up artificial respiration a little longer; but Mrs. McLeod never breathed again, and grew gradually cold. Dr. McLeod subsequently stated that he weighed the first grain of morphia; and he said the reason why morphia was given was that Mrs. McLeod had had no sleep for three nights. The other doses, he said, he gave in quantities, judging from the first grain. There were nearly three grains left in the bottle. I weighed it afterwards. Mrs. McLeod died about a quarter to ten.—A Juryman: How much morphia does that bottle that you took to the druggist's now contain?—It contains 20 grains.—Juryman: It is now half full; the chemist said he sold it full; therefore he must have given Dr. McLeod 40 grains.—Another Juryman: Then Mrs. McLeod has got 37 grains of morphia. Have you any doubt as to the cause of her death?—There is no doubt it was poisoning by morphia.—A Juryman: We should require a *post-mortem* examination.—The Coroner: it would be as well.—Juryman: I noticed there was a black eye on the corpse. What s the cause of that?—I did not notice it, but it could be produced by slapping with towels.

Dr. McLeod: May I speak?

The Coroner: There is no necessity for you to speak.

Dr. McLeod: I am unable to say how much morphia I gave her. I cannot say how much I gave, because I did not intend to stop till I had produced an effect.

A Juryman: I would advise you not to make this statement to the jury about giving the poison in that reckless way.

Dr. McLeod: I gave it upon a fixed principle. Not to stop till I made an effect.

The Coroner: I would advise you not to say too much, and so have anything you have said converted at another time into a meaning you did not intend.

Dr. McLeod continued, despite the coroner's expostulations, to say he had no idea how much he gave. He gave it in a wineglass, and some of it might have been lost. He wished to impress upon the jury that although so much was in the bottle originally, and so much remained now, it was not certain that deceased took the whole of the difference.

A Juryman: You must have made a mistake when you told the jury you only bought 10 grains.

Dr. McLeod: Yes, certainly. I asked for 10 grains.

The Coroner said he thought it right to remark that Dr. McLeod had called upon him that morning, and given him the same frank and open account of the transaction he had given to the other doctors.

Dr. McLeod: I have been advised not to speak, but I have nothing to keep back. Everyone says that what I say may be misrepresented; but I think the more I say the more light will be thrown upon the matter. I am anxious to be asked questions as I say there is nothing to be kept back. I suppose I have committed an error. I was too presumptuous, too confident in my own knowledge. I should not have felt so much confidence in the matter. There can be no doubt deceased was poisoned by an overdose of morphia; but whatever the consequence may be I would rather speak out.

It was then resolved to adjourn till Thursday, Oct. 24, it being understood that a *post mortem* examination would be held in the meantime.—*From the Carlisle Patriot.*

Prosecutions under the Adulteration Act.

Alleged presence of iron and sand in tea.

At the Dale Street Police Court, Liverpool, on Wednesday, October 8, before Mr. Raffles, James Pegram, grocer, was summoned under the provisions of the Adulteration Act, for having sold, as unadulterated, a parcel of tea which, on examination by the borough analyst, proved to be adulterated with metallic iron.

Evidence having been given as to the purchase at the defendant's shop of two ounces of caper tea, for which 3*d.* was paid, which tea was afterwards handed to the analyst,

Dr. Campbell Brown, the borough analyst, said he analysed the sample of the tea referred to, and had granted a certificate to the effect that it was adulterated with metallic iron. In his opinion, and speaking from the result of his analysis, he believed that the pellets of iron and particles of sand and stone which were found rolled up in the leaves of the tea would increase the weight of the tea to such an extent that customers would be defrauded of $1\frac{1}{2}d.$ in every sixteen ounces.

Mr. Raffles: Would the particles of iron and stone be injurious to health?

Dr. Brown said the larger pieces would, but, in point of fact, they would not be swallowed, as they would in almost every case remain at the bottom of the teapot. He believed that these particles were rolled up in the leaves by the original manufacturers. They had the appearance of having been done when the tea was made. He burnt the tea and applied a magnet to the ashes, when particles adhered to it. The use of the magnet was known to the trade, and any grocer who took the trouble might ascertain the presence of the particles. [Dr. Brown produced a magnet, and showed that the pellets adhered to it.]

Mr. Baxter submitted, on behalf of the defendant, that the prosecution had failed to make out a case, inasmuch as tea was neither a drug nor an article of food, but tea-leaves. To be food, it must be something of which a man partakes.

Mr. Raffles overruled the objection, and refused to grant a case upon the point.

Mr. Baxter then proposed to put in a report by Professor Murphy upon an analysis of the same tea, in which it was stated that the tea was not adulterated. This, as well as a proposition that Professor Murphy should give personal evidence in contradiction to Dr. Brown, Mr. Raffles refused to allow, on the ground that the same sample of tea was not analysed. Mr. Baxter urged that if an analyst called by a defendant were not

heard, the borough analyst became sole dictator as to what was and what was not adulterated.

Mr. Raffles said it was quite open for the person charged to go with the nuisance officer to the analyst and see whether the article he sold was adulterated or not. It appeared to him beyond all question that the tea produced in court was adulterated.

Mr. Baxter: Mr. Murphy says that what Dr. Brown says is iron is not iron.

Mr. Raffles said he would hear Mr. Murphy on that point.

Professor Murphy said he did find magnetic matter in the tea, but the weight of it did not average one-thousandth part of the tea.

Mr. Raffles said he was satisfied that the tea was adulterated, and imposed a fine of £5 and costs.

Intimation of an appeal against this decision was given.

The following is said to be a copy of the report which Mr. Baxter wished to read :—

"'*Scented Caper*' *Tea.*

"Dear Sir,—This is to certify that I have made as careful and complete a microscopical and chemical examination and analysis of the sample of 'scented caper' tea which you left with me yesterday evening as the time would permit.

"My microscopic examination revealed that this sample is composed of tea leaves, and that there is no admixture of other leaves than those of the tea plant in it; that there is only a very small proportion of dust in the sample, and that this dust is the matter of the tea leaves, and produced by the abrasion of the leaves themselves.

"My chemical analysis gave me the following results:—Extract normally astringent and indicative of this kind of tea. Disintegrated portion or dust contained a few magnetic particles, but quite inappreciable when viewed as an adulterant. Total mineral matters in the tea, 6·404 per cent., composed of

"Micaceous clay and sand . . .	0·574	per cent.
"Phosphate of lime, containing a mere trace of iron.	2·973	"
"Alkaline and earthy salts . . .	2·857	"
	6·404	

"The amount and quality of the preceding minerals are those natural to the leaves of the tea plant.

"From the preceding data I conclude that this sample of tea is pure and free from adulteration. The few particles of magnetic matter detected do not form the one-thousandth part of the weight of the sample, and therefore cannot be justly be viewed as an adulteration, but rather in the light of a mere accidental matter."—*From the Liverpool Daily Post.*

On Wednesday, Oct. 15, at the same court, Frederick Chambers, grocer, 66, Vauxhall Road, Liverpool, was summoned for selling, as unadulterated, a quantity of tea which was adulterated. Mr. Atkinson, deputy borough solicitor, appeared to support the information, and Mr. Bremner defended.

Inspector Fitzpatrick, an officer of the Health Committee, proved having purchased at the defendant's shop, on the 25th of September, two ounces of caper tea (at 2*s.* 8*d.* per lb.), which he submitted to Dr. Brown, the public analyst.

Dr. Brown said he analysed the tea in question, and found it was adulterated to the extent of six per cent. with particles of iron, small stones, and sand, which were rolled up inside the leaves of the tea. He was of opinion that the tea had been adulterated by the Chinese dealer, and not since it had arrived in this country.

Mr. Bremner said he did not intend to dispute the facts, nor was he going to contest for a moment the opinion of the analyst. He relied not only upon the words of the Statute, but the expression of opinion given by Dr. Brown with reference to the tea having been adulterated in China. In the first place, he contended that according to the wording of the Act there must be some knowledge of the adulteration on the part of the defendant.

Mr. Raffles: But you know I am told to construe it differently. That was the question which was before the Court of Queen's Bench.

Mr. Bremner said, that under those circumstances, it would be necessary for every person who sold any article that could possibly be adulterated to employ an analyst to test his goods before he submitted them to the public.

Mr. Raffles: Don't you think it would be desirable for grocers to have some means of testing the articles they sell? I don't see how they can escape the Act unless they do so.

Mr. Bremner said he had seen a letter in the *Times*, which suggested a way of getting out of the difficulty. The writer of this letter thought grocers might place upon their packets of mustard, and other articles which it was necessary to mix with various ingredients, small labels stating that they were so mixed.

Mr. Raffles: But what would you say of this tea?

Mr. Bremner said the label might be to the effect that the grocer did not offer the tea as being perfectly pure and unadulterated.

Mr. Raffles said that was hardly analogous to the case of the mustard, because here was some tea which was mixed with some nasty substance.

Mr. Bremner said that, with the interpretation Mr. Raffles was bound to give to the law, the only protection grocers and others could possibly have would be by putting out placards stating that they did not profess to sell unadulterated tea.

Mr. Raffles: But that won't do.

Mr. Atkinson: Well, if you say "this is a mixture of iron-filings and tea leaves" it might do.

Mr. Bremner said there must be something done; this sort of thing could not last.

Mr. Raffles said it seemed to him that it would be an easy matter to detect the presence of the iron.

The cases of George Rufus Bailey, 148, Vauxhall Road, and Richard Beckett (Messrs. Southward and Beckett), 211, Vauxhall Road, were also taken. In the first of these cases the tea was adulterated to the extent of 10 per cent., or so much as to make a difference of $3\frac{1}{4}d.$ in the pound; and in the second the adulteration was to the extent of from 4 to 6 per cent.

While these cases were before the court,

Mr. Bremner asked Dr. Brown if he had ever anlaysed any caper tea that was not adulterated; and also if iron was not indigenous to the plant.

Dr. Brown replied that he had analysed several samples of caper tea since he came to Liverpool, which were free from adulteration. The tea that came from British India he had found entirely free from adulteration. There was a small quantity of phosphate of iron in the tea plant naturally, but nothing of the description of iron filings, stones, and sand, which had been used to adulterate it.

In each of the three cases, a fine of £5 and costs (including the analyst's fee) was imposed.—*From the Liverpool Daily Albion.*

ALLEGED ADULTERATION OF MILK.

The case against Alexander Russell, charged at the Central Police Court, Glasgow, with selling adulterated milk, which was adjourned on the application of the defendant to allow of an analysis of the reserved portion of the purchased milk being made by Professor Anderson (see *ante*, p. 318), was resumed on the 14th Oct.

James Anderson, Professor of Chemistry in the University of Glasgow, produced the following report, dated 11th October :—"I have carefully examined a sample of milk sent to me by Mr. P. T. Young, contained in a bottle sealed 'K. M'L.' with the seals unbroken. The sample was sour and curdled, and I have therefore thought

it right to make a complete analysis, which showed it to contain—water 89·95, butter 3·13, sugar 3·42, casein 2·88, ash 0·62—total solids, 10·05. From the results, I have no hesitation in saying that the milk has been watered to some extent. As to the exact quantity of water which has been added, it is somewhat difficult to give a precise opinion, because I have of course no information as to the composition which this milk had as it came from the cow, and no fixed standard has been laid down up to which genuine milk must come. If, however, we assume that milk may contain no more than 11·5 per cent. of solids and still be genuine, then the amount of water added in this case must have slightly exceeded 10 per cent. This, of course, proceeds on the view of the case most favourable to the accused, for it assumes that the original milk was of the lowest possible quality. If we supposed it to have contained 12·5 per cent. of solids, which is a moderate average, the quantity of water added must have been at least 22 per cent.; while if the original milk happened to exceed the average in quality the quantity of water may have been considerably larger. There can be no doubt that the minimum quantity of water added in this case must have been 10 per cent., and that it may be, and probably was, considerably more."

In examination he said: The specific gravity of ordinary milk varies from 1030 to 1040; but I could not give the specific gravity of this milk. To do that I must have had it almost direct from the cow. When water is added to milk it mixes uniformly. That 89·95 per cent includes the watery substance as well as the added water. I can make no distinction between the water which has been added and the water naturally present. The 10 per cent. of solid matters which are present in the milk is just as I found it when it came into my hands. I have formed an opinion in regard to the water which is naturally present in milk. Of course, if I had had a specimen of the original milk as it came from the cow I should have made my comparison between the analysis of that and the analysis I got of the other; but in the absence of that I am obliged to consider what in all probability was the composition of the original milk. I think the solids there are much lower than they are in ordinary milk. There ought at least to be 11½ per cent. of solids, while there is only about 10; therefore, I infer from this that the 11½ originally present in the milk must have been reduced by the addition of water to 10. I make my calculation from that. The solid matters vary in different milks. I have myself analysed genuine milk containing as much as 17 per cent. of solids. That was milk of extraordinary high quality, such as we cannot expect to get in general. It was milk from a cow kept by a family for their own private use, and fed altogether irrespective of cost. We cannot get that in ordinary milk. I should say, from my own analysis, the lowest quantity of solid matter in genuine milk was about 12½. I have seen it as low as 12, but I have never seen it under that. My experience is not so extensive a one as that of a city analyst.

On behalf of the defendant, evidence was given that the milk was sold in the state in which it was received from the wholesale dealer. The wholesale dealer, on his part, deposed that no water was added to the milk by him, but that he had had analysed a sample of milk taken from one of the wooden butts in which it was received by railway from the farmer, and the analyst reported that it then contained 15 per cent. of added water.

After consultation between the baillies and the assessors, Mr. Baillie Craig said there was no doubt as to the milk being adulterated, but judgment would be postponed in order to give an opportunity for consideration whether defendant sold it knowing it to be adulterated.

Another case was heard in which skimmed milk had been added to sweet milk, and, notwithstanding it was urged that this did not come within the terms of the Act, which says "mixed with any other substance," the defendant was convicted, and a fine of two guineas was imposed.

The Preliminary Examination.

Sir,—I was very glad to see that Mr. Reynolds had taken up the question of local Preliminary examinations; it was quite time for some one to do so, if we intended to keep our privileges, and no one could have been found better qualified for the task.

The previous attempt to abolish the local examinations and transfer them to London or Edinburgh, on the ground that they were not satisfactorily conducted, having been taken very quietly by the parties most immediately concerned, it seems to have been thought that a renewed effort might be more successful. This time, however, we must make it very clearly understood that we will neither have our sons and apprentices dragged to London or Edinburgh for their Preliminary, nor be compelled to pay the fees of another examining body in addition to our own. If the present mode of conducting this examination in the provinces is not satisfactory, let it be made so or some other be devised. I do not suppose any local secretary is especially anxious for its continuance, seeing that it causes a considerable amount of trouble and inconvenience to a good many of them, for which they receive no acknowledgment whatever, not even thanks, but on the contrary are told at every opportunity that their duties are performed in a very unsatisfactory manner. This has been repeated so often, and by persons in authority, that I should like some proof of it, for I am very sceptical on the point. Some time ago great lamentation was made because there were so many failures, but since then the proportion has rather increased than otherwise; and that supervision can hardly be considered very ineffective which results in about 40 per cent. of failures.

I believe all these complaints have arisen from the fact that there has been a great deal of foolish tattle on the part of some of the candidates as to what has passed in the examination rooms, and that it has been considerably magnified in the repetition. Much has been said about the prompting and assistance the candidates give to each other when the superintendent is out of the room, or engaged with a book, or in writing, and it seems to be supposed in some quarters that one half of the candidates who pass do so by this means. Such a notion is ridiculous. That the candidates do sometimes give each other hints when they get the opportunity I do not doubt in the least, but that it materially assists them I entirely deny, and I do not hesitate to assert that if a candidate is not pretty nearly able to pass without assistance of that nature, all the prompting he could get would not enable him to pull through. Nay, I will go further, and say that if a candidate is not pretty well prepared he might have a translation of Cæsar, a Latin grammar, an English grammar, and an arithmetic to help him, and still not be able to pass. In the first place, if he did not know the first book of Cæsar pretty well by heart, I defy him to pick out the particular sentences given in the questions, and unless he had studied his Latin and English grammar and arithmetic well, he would have the same difficulty with the other questions, and would spend so much time in finding the answers that the greater part of the three hours would be gone before he began to write; and as regards being assisted by his fellow candidates, it takes one who is well prepared nearly all his time to write his own answers, and he has not much time to assist his neighbours.

On referring to the lists for April and July last I find that the percentage of failures was 45½ and 43½ respectively. I submit that fact to the members of the Society as our reply to the charges brought against us.

W. Wilkinson.

263, *Cheetham Hill, Manchester, Oct. 20th*, 1873.

Sir,—It is with feelings of some reluctance that I take up my pen to write down a few ideas upon the subject of the Preliminary examinations, since they materially differ from those expressed by a gentleman for whose opinion I have a great respect generally; but I think Mr. Haselden for once so clearly in the wrong that I cannot forbear from offering a

few remarks in refutation of his arguments published in last week's number of the Journal.

Now I take it that the object of the Preliminary examination is not to secure the payment of a certain fee to the Pharmaceutical Society, but to prevent the admission of a youth into the business (or *quasi*-profession) of a chemist and druggist until he has such ground-work of elementary education as will fit him for his future calling in life. I am astonished to hear Mr. Haselden express the opinion that it is possible to expect too much education. Did he ever know an assistant suffering from such an ailment? My own limited experience has been rather that the industry which will carry a youth through a somewhat severe course of training will, when he goes into business, be expended in the pursuit of his calling; and it is the man who has been lazy as a boy at school that turns out the troublesome and idle assistant.

Such being the object of the Preliminary examination, is it more likely to be better conducted by a body of men deputed to examine in technical subjects, or by a scholastic educational board? I maintain the latter; and let us have the standard sufficiently high. The entrance to most of the professions is through the gates of the matriculation examination of the London University. Perhaps this is too much to expect of the present generation of pharmacists, but I hope I may live to see our profession raised as high as the medical; and in order to gain that end we must start at the foundations. The worst that such a course could produce would be the necessary expense incurred by the parents of a youth who aspires to the honourable calling of pharmacy in keeping him another year or two at school; but surely with the class whom we wish to encourage to enter our ranks this item would be of small moment compared with the ultimate benefit to the student, whose increased worth would soon repay the extra outlay, even in a monetary point of view (if we must be mercantile in our arguments).

For the above reasons I should object to the conducting of the Preliminary examination, even by the London Pharmaceutical Board of Examiners themselves in person; but with how much greater force do they apply to its present mode of conduct. Certainly, it is a shade better than a few years ago, when the amount of questioning a provincial candidate received depended on the conscience of the examiner, who might be either a schoolmaster, a doctor, or a clergyman, and it depended very much on the selection whether the certificate was signed with but little questioning, or a thorough sifting was endured in Cæsar and Latin grammar. But we can hardly expect men like our local secretaries, actively engaged in business, to devote several hours on a particular day, not of their own choosing, to the conscientious supervision of an examination. They may be good men and true, but it is a little too much to expect them all to be so enthusiastic and self-sacrificing as Mr. Haselden and some of his former colleagues.

CHARLES FRYER.

Scarborough, Oct. 20th, 1873.

UNUSUAL DOSES IN PRESCRIPTIONS.

Sir,—In your impression of the 11th inst. appears a letter from Mr. Giles on Unusual Doses in Prescriptions, written in that gentleman's ordinary florid style.

Two of the individuals therein introduced to notice are disposed of by hanging, whilst I am left gasping for breath. Upon recovering myself, I just wish to say to all whom it may concern that I did not put forth the prescription so strongly commented upon as one that I had actually received, but as one containing an *unusual dose*.

Moreover, whilst pointing to a method of writing unusual quantities which seemed to me most likely to meet the requirements of the case, its being dispensed *as a matter of course* was never expected to be implied, as the entire article was written to uphold the right of a dispenser to follow the dictates of his own judgment.

Speaking for myself, I should not hesitate to refuse preparing any prescription that *seemed to me positively dangerous*, without in some way being ensured as to its compatibility with the safety of the patient.

And here, so far as my own defence is concerned, this communication might cease, but the exigencies of the important subject out of which it springs demand my going a little further.

Now, it must be admitted that a prescriber of known experience, in inadvertently writing strychnia for nux vomica, or perchloride of mercury for calomel, would not be likely to *authenticate it by any special mark*. It seems to me that this would never be a real difficulty to any of us.

But supposing a prescription containing ʒiv doses of tinct. digitalis, or gr. x. doses of ext belladonnæ, properly authenticated, from a well-known physician—are we to refuse them or to dispense them?

As to myself, the latter alternative would be adopted without much hesitation. For although it may be true that small doses of both of these powerful drugs have been known to produce very serious symptoms, still on the other hand we know that in peculiar forms of disease very unusnal doses are given with positive benefit.

As to the exhibition of digitalis in *delirium tremens*, sufficient has already been said in this Journal, as well as in the medical publications, but is it also well known that fabulously large doses of ext. belladonnæ have been given in chorea? I have many times made up even larger doses than 10 grains. Dr. Fuller, of St. George's Hospital mentions in one of his works the very large doses he has given with success.

In Royle and Headland's 'Materia Medica,' fourth edition, 1865, the dose is given as gr. ss.—gr. j gradually increased to gr. v, so that although gr. x doses might be justly considered unusual, they could scarcely be considered as alarmingly dangerous *under all circumstances*. And if a prescription properly authenticated were submitted to me to dispense, although it contained such unusual dose, I should suppose it to have been gradually taken up to this quantity, and that there was no real cause for concern. Without some special mark, certainly I should not dispense it.

Whatever amount of freedom in this matter we may allow to ourselves, we must under all events leave the great burden of responsibility upon the prescriber; having ascertained the standing of the medical man, and his authentication of the dose, we shall not run any great risk.

It is much to be desired that this discussion may be productive of good, and that the medical profession may see the necessity for meeting our just demands in this matter. If they will do this and endeavour to make their writing easily legible, and as free from perplexing hieroglyphics as possible, they will be justly entitled to our warmest thanks.

ONE WHO HAS KNOWN THE DRUG TRADE MORE THAN THIRTY YEARS.

"*Pharmacien.*"—(1) *Salvia Verbenaca.* (2) *Centaurea scabiosa*, var. *alba.* (3) *Reseda alba.* We should be glad to hear from what locality this plant was collected. (4) *Reseda lutea.* (5) Probably *Reseda lutea*: send a specimen with leaves and flowers. (6) *Trifolium arvense.* (7) *Sinapis incana.* (8) *Diplotaxis tenuifolia.* (9) *Matricaria inodora.* (10) *Centaurea calcitrapa.*

"*Truth.*"—As we stated in our former answer, the preliminary operation is to be conducted at the ordinary temperature of the atmosphere. The word "infuse" does not necessarily imply the application of heat.

H. W. Harris.—We think the binoxide would be meant. It occurs naturally as a mineral which is sometimes very pure. For its method of preparation artificially we must refer you to some work on chemistry.

"*Ne Sutor ultra Crepidam.*"—We do not think the method adopted by you was what was intended. A plan frequently adopted is to decolorize by adding to tinct. iodi. a sufficiency of liq. ammon. fort. and filter. Squire gives a formula for a liquor ammoniæ iodidi prescribed by Sir J. Y. Simpson, as follows:—"Liq. ammon. fortiss, 2 oz.; iodine, 10 grains; iodide of potassium, 20 grains; rectified spirit, 1 oz.: dissolve."

"*Graham.*"—See preceding answer.

L. X. Y.—The answer to your question would depend upon whether the widow is at present conducting the business as a registered chemist and druggist in her own right, or as a trustee. We should recommend you to communicate, giving full particulars, with the Registrar, 17, Bloomsbury Square.

The Report of the Manchester Chemists' Assistants' Association has been received, but too late for insertion this week.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Shaw, Kinninmont, Abraham, G. Brown, Long, A. Thompson, E. L. H., P. L., N. H., "A Country Firm."

CINCHONA CULTIVATION IN JAVA.

The examination of Java Cinchona barks commenced by K. W. van Gorkom some months since has been continued by him, and the results obtained are in general very satisfactory. It appears from a translation of his report by Dr. C. Hasskarl* that the several varieties of *Cinchona officinalis* contain different amounts of alkaloid, and that the small-leaved varieties are richest in quinine. The sample No. 29 is taken from a tree which is probably identical with the variety now very frequently cultivated in British India and there known by the name of *Cinchona officinalis Bonplandia* var. *angustifolia*. This variety is very rich in quinine. The opinion that *Cinchona officinalis* would require to be grown at a considerable elevation above the sea level, in order that it might furnish the maximum amount of alkaloid in its bark, is in this instance to some extent supported, for the barks of Kawah-Tjiwidai and Randja Bolang, grown at an elevation of 1950 metres, were those containing the smallest amounts of alkaloid. The examination of *Cinchona Calisaya* is also important in its results. There are likewise different varieties of this bark, and the amounts of alkaloid they contain are different. Those of Ledger's, Nos. 40 to 42, were examined because their identity was doubted. The results of analysis show that sample No. 40 belongs to another variety, while Nos. 41 and 42, although very rich barks, are nevertheless inferior to the true (?) *Cinchona Calisaya*, Nos. 43 and 44, which is always characterized by very small white flowers and very small fruit. The plants from which seed is taken are always examined previously. *Cinchona Caloptera* yields a bark very well suited for pharmaceutical purposes. The *Cinchona lancifolia*, No. 49, also furnishes a very excellent bark, and the examination of this kind will be continued subsequently.

The climate of Lembang appears to be favourable for the cultivation of *Cinchona succirubra*. The bark of *Cinchona Pahudiana* was obtained from one of the oldest trees planted by Hasskarl at Tjiboddas. The trees in those plantations have not been under regular inspection since 1866. Their bark is thick and of fine appearance; but the results of analysis entirely confirm the opinion already expressed, although the trees are now nearly twenty years old.

The weather during the second three months of this year was very favourable to the growth of cinchona plantations. There were again as many as 29,935 young trees planted out and there are now 1,800,252 plants. In the operations of stripping and drying the bark the wives of the workmen are employed on day wages. The harvest is commenced about the end of May; and though the showery weather at that time hinders the drying to some extent, as much as 7000 kilos of bark have been prepared for delivery. About 2000 cinchona plants have been distributed in Java among private plantations as well as those cultivated by the Government. Seeds also are in constant demand, and are always supplied. Thirteen samples of Java bark have also been sent to the chemists attached to the cinchona plantations in British India for comparative examination, and samples for the like purpose are expected from thence.

* *Pharmaceutische Zeitung*, 4th October, 1873.

BISMUTH, ITS ALLOYS WITH THE ALKALINE METALS AND ITS PURIFICATION.*

BY C. MÉHU.

Although the Codex recommends the process of purification of bismuth by nitrate of potassium, it is nevertheless true that there is no certainty of thus obtaining, at the first operation, bismuth free from sulphur and arsenic. I have long sought for a more

* 'Annuaire Pharmaceutique,' 1873, p. 23.

advantageous and certain method of purification, and the following is the result of my researches.

When commercial bismuth is heated over a spirit-lamp in a glass test-tube closed at one end, any arsenic that may be present in it forms above the metallic layer a ring of white crystalline arsenious acid composed of well defined octahedric crystals. Sulphur gives no such ring ; but is volatilized in the state of sulphurous acid. This test therefore appears to me to have little to recommend it, except to detect arsenic, for which it is a very delicate one. Commercial bismuth, which I have melted with 5 per cent. of sulphur, has nevertheless given a ring of arsenious acid in microscopic crystals without admixture with sulphur. Pure bismuth gives no similar reaction, and this simple and easy test allows of rapid estimate being made of the quality of a commercial bismuth. But I do not pretend to say that it will satisfy every requirement.

From the foregoing it will appear that in order to purify bismuth contaminated by sulphur and arsenic it is necessary to keep it melted at a sufficiently high temperature, and in the open air, throwing upon the sides of the vessel the oxide of bismuth as quickly as it is formed. Arsenic and sulphur are volatilized as arsenious and sulphurous acid. It is especially for the removal of arsenic that I recommend this roasting, for it is much more easy to remove sulphur. The following experiments form the basis for a more perfect process :—

In an earthern crucible I placed a mixture of 200 grams of powdered commercial bismuth and 100 grams of dried tartrate of potash and soda. The crucible was closed and kept at a red or even a white heat for about an hour, and at the end of that time the metal was run into a mould ; it then weighed 198 grams. It was besides possible to find some metallic granules in the scoriæ. In this operation I have often replaced the tartrate of potash and soda by a tartrate of potash with one or two equivalents of potash, and by a tartrate of soda with two equivalents of soda. In every case I obtained 198 grams of the metal.

At the temperature of red heat the tartrates are transformed into carbon and alkaline carbonates, then into caustic alkalies, and partially into metallic potassium and sodium. These alkaline metals combine with the bismuth. The tartrate of potash and soda gives a mixture of carbonates of potash and soda much more fusible than either of the alkaline carbonates separately.

I would direct attention to the first result. The dross which floated on the top of the metal was black ; not only because it contained carbon in its bulk, but also because it contained sulphide of bismuth. This was proved easily by heating the dross with water acidulated with hydrochloric acid, which caused a disengagement of sulphuretted hydrogen. As the alkaline tartrates used by me in my experiments were perfectly pure, the presence of the sulphides in the scoriæ could only be attributed to the reduction of alkaline sulphates in the melting. It should be observed, therefore, that this operation deprives the bismuth of any sulphur which it may contain.

The employment of the alkalies at a high temperature does not cause a loss of one per cent. It is true, that the bismuth retains some of the alkaline metal which compensates a greater loss. In operating upon previously purified bismuth, I ascertained that there was no loss in weight, because the alkaline metal replaced the volatilized bismuth ; in one case I found a slight augmentation.

An alloy of bismuth and an alkaline metal has a slightly less shiny and rosy appearance than pure bismuth. The iridescence of bismuth not only charms the eye, but is an evidence of the good quality of the metal, in which it indicates the commencement of oxidation. When much potassium has been present the bismuth has appeared to me more brittle, and its fracture greyish.

Although the surface of such an alloy may have been washed with water acidulated with hydrochloric acid, then briskly rubbed with sand, so as to remove every trace of scoriæ, and again washed and well-dried, the surface exposed to the air gradually becomes moist and tarnished. The moisture has an alkaline taste, insupportable by its causticity. An ingot broken and placed immediately upon the tongue produces a sensation of burning, and the metallic surface becomes covered with a lather, due to the disengagement of hydrogen produced by the decomposition of the water of the saliva.

Placed in water this alloy disengages hydrogen and combines with the oxygen ; the reaction continues for some time, gradually becoming feebler. The alloy is a slightly porous body.

When kaliferous bismuth is thrown into boiling water, there occurs immediately a tumultuous disengagement of hydrogen in great quantity. I have in this manner collected hundreds of cubic centimetres of inflammable hydrogen. When powdered the metal does not so easily produce the effect ; the powdered metal blackens rapidly, becomes strongly heated, and aggregated, and decomposes the humidity of the atmosphere. When the alloy has been obtained with tartrate of potash alone, it contains potassium : in the air its surface becomes covered with a layer of caustic potash ; gradually this absorbs carbonic acid from the air, and is converted into deliquescent carbonate of potash. If the alloy has been obtained with tartrate of soda it contains sodium : in the air it becomes covered with caustic soda, which is gradually converted into carbonate of soda, an efflorescent salt which covers the metal with a thick white layer. This finally becomes dry and powdery, and is easily removed by rubbing. With tartrate of potash and soda the alloy becomes eventually covered with a mixture of carbonate of potash and soda.

To obtain a bismuth as fully charged with an alkaline metal as possible, I recommend the employment of a crucible lined with charcoal, to operate at a high temperature, not to run the metal into an ingot, but collect it at the bottom of the crucible. The scoriæ solidify quickly when soda is employed ; but I have preferred potash or a mixture of the two as being more fusible. The addition of charcoal diminishes the action of the melted alkali upon the crucible. A crucible can scarcely serve for more than one operation.

Nothing is more easy than to free such an alloy from potassium or sodium. For this it should be melted in a porcelain capsule or iron vase exposing a large surface. Gradually the alkaline matter oxidizes, and if it be an alloy of bismuth and potassium a liquid layer of caustic potash is formed on the surface of the bismuth (which has the appearance of mercury under a layer of oil). When the bismuth contains no more potassium it commences to oxidize in its turn, its surface being then covered with a layer of yellow-brown oxide. At this point the metal should

be run off. During the oxidation of the alkaline metal, the caustic potash has formed a protecting varnish on the surface of the bismuth, and preserved it from oxidation. It is necessary to throw the layer of melted potash on to the sides of the crucible, and this may be done more readily if from time to time fragments of wood, paper, starch, etc., be thrown in; these convert it into the less fusible carbonate. The alkali dissolves a small quantity of oxide of bismuth.

It may happen that the bismuth retains a trace of potassium, which will cause no inconvenience when it is to be used in the preparation of the subnitrate. In such a case the metal tarnishes after a time, and the surface becomes alkaline.

The alkaline metal may be completely removed by melting with a small quantity of nitrate of potash, or, more simply, by stirring the fused mass with a wooden rod.

In this operation the alkaline metal carries with it, in oxidizing, such sulphur and arsenic as may not have been already converted into alkaline sulphide and arsenide. But although it is easy to remove the sulphur it is difficult to remove the last traces of arsenic.

The estimation of the quantity of alkaline metal contained in the bismuth yielded by the foregoing experiments appeared at first to be a difficult operation, but consideration has led me to the following method, which I believe to be satisfactory. I melt in a porcelain capsule 50 grams of the alloy, keeping the capsule over the flame of a spirit-lamp, and throwing on the side the layer of alkali as fast as it is formed, until the bismuth commences to oxidize. The alkaline oxide is then dissolved in water, the small quantity of metallic oxide that it contains removed by a current of sulphuretted hydrogen, the solution filtered, partly evaporated, saturated with dilute hydrochloric acid, finally evaporated to dryness, and heated to a dull red heat. The weight of chloride of potassium or sodium obtained serves to calculate that of the alkaline metal. In a button I have found 4·65 per cent. of potassium. In an ingot, washed for a long time, only 2·8 per cent. In another ingot, 3·22 per cent.

Purified bismuth is notably more malleable when hot than when cold. About 100° C. it may be bent, but I have never succeeded in bending it completely into a ring. It crackles when bent, like tin. When cold it is too brittle for this phenomenon to be appreciable.

It is entirely soluble in *pure* nitric acid. The solution is colourless; when concentrated it deposits fine crystals of nitrate of bismuth. Thrown into water it gives a glittering white subnitrate. The use of impure nitric acid in the preparation of subnitrate of bismuth is more frequently than is thought the source of many impurities.

In reducing to a metallic state the residues of bismuth, particularly the tannate, citrate, and sulphide, I have always preferred to roast them upon an iron plate heated to redness, which leaves an oxide of bismuth. This, thoroughly mixed with carbonates of potash and soda, and charcoal, gives easily a metallic button when heated to a red heat in a closed crucible. I have often replaced a portion of the charcoal by colophane or dried soap. The mixed carbonates of potash and soda fuse more readily than either carbonate separately, and considerably facilitate the aggregation of the metallic globules of the reduced bismuth. On the contrary, a considerable loss results by operating directly upon the bismuth salt, whether organic or not, and sometimes no result is obtained.

When impure commercial bismuth is dissolved in nitric acid, "it is observed," says Fourcroy, "that a black insoluble powder is detached from the metal, which Pott has regarded as an oxide of bismuth, and which other chemists have taken for sulphur. It is not yet known whether it is not carbon." This substance is at first sulphide of bismuth, which the nitric acid rapidly decomposes; the metal oxidizes at the expense of the acid, and the sulphur becomes free. This impure sulphur, at first greyish, eventually becomes a clear yellow when treated with dilute nitric acid. If the solution be sufficiently heated, the sulphur melts and collects into a soft paste, formed of amorphous sulphur. This black powder is especially abundant if the metal has been artificially impregnated with one to five per cent. of sulphur.

In order to clear up this point I have precipitated citrate of bismuth dissolved in ammonia by monosulphide of sodium. I have collected the brown-black sulphide of bismuth, and washed it for a long time in recently-boiled lukewarm water, and while moist treated it with pure nitric acid. Even in the presence of a dilute acid the sulphide immediately yielded its metal to the acid with disengagement of nitrous vapours, and the boiling liquor was covered with sulphur in a grey paste, becoming more and more yellow. A large quantity of yellow sulphur floated in the capsule. This sulphur is in great part insoluble in bisulphide of carbon; but upon heat being applied, it becomes soluble in that solvent.

In continuing the action of pure nitric acid upon sulphuretted bismuth the sulphur passes slowly to the state of sulphuric acid, which gives sulphate of bismuth. In concentrating the liquor it takes more and more the yellow colour of sulphur, and deposits sulphate of bismuth mixed with sulphur; the deposit is yellowish white. By adding distilled water freely a deposit is produced of subnitrate containing subsulphate of bismuth, whilst the acid mother liquor, added to a solution of nitrate of baryta acidified by pure nitric acid, yields a deposit of sulphate of baryta, insoluble in strong nitric acid, and reducible to sulphide of barium when heated with carbon to a high temperature.

The subnitrate of bismuth mixed with subsulphate, treated with a boiling solution of pure bicarbonate of potash, gives an alkaline solution in which sulphate of potash may easily be detected.

It appears therefore that the action of nitric acid upon sulphuretted bismuth introduces free sulphur into the subnitrate of bismuth, and if the acid reacts sufficiently long, and with a high degree of concentration, all the sulphur is converted into sulphuric acid; hence the presence of subsulphate in subnitrate of bismuth. The use of nitric acid containing sulphuric acid leads to the same result.

To sum up, the preceding experiments demonstrate —(1) The ready formation of alloys of bismuth with the alkaline metals. (2) The necessity of preparing the subnitrate of bismuth with ingredients of irreproachable purity. (3) The influence of the alkaline metals in removing from bismuth the last traces of sulphur and arsenic left by the roasting.

For the purification of bismuth I propose the following process. Melt the metal in a vessel presenting a large surface, at a temperature considerably above its fusing point. The result is an oxidation of

one-fourth of the metallic mass and a disengagement of sulphurous and arsenious acids. Let the metal cool and then reduce the mass to powder, mixing with it the oxide of bismuth. Then add carbonate of potash (one-fourth the weight of the original metal) quite free from sulphates, charcoal and dried soap. Place this mixture into a crucible which will be about five-sixths filled by it, and then complete the filling with well-washed vegetable carbon. Cover the crucible and keep it for about one hour at a red heat. At the end of that time run the metal into a mould, or, better still, let the crucible cool, when at the bottom will be formed the button of bismuth charged with potassium. I have already described the process for removing the alkaline metal.

Although in my experiments in order to be more precise I used the alkaline tartrates, I am convinced that in ordinary practice they may be replaced by the alkaline carbonate, combined with charcoal. I would also repeat that vegetable charcoal, and especially the use of a lined crucible, prevents the perforation of the crucible and facilitates the production of the purifying alkaline metal. But nevertheless, with bismuth much impregnated with arsenic, a single operation is not always sufficient.

This method would not apply to the elimination of copper or lead which might occur accidentally alloyed with the bismuth. Fortunately in the preparation of the subnitrate, copper and lead would remain in the mother liquor. Moreover I have never met with them in the specimens of bismuth that I have examined.

TEA.*

BY J. ALFRED WANKLYN.

There is no doubt that tea is sometimes adulterated with iron-filings and other preparations of iron, and when public analysts have found that iron had been put into tea leaves they have doubtless, in some instances, found that which really had taken place.

The ash of genuine tea leaves, however, contains iron, and by no means a small proportion of it. In a paper by Zöller (Liebig's *Annalen*, May, 1871), the percentage of oxide of iron in the ash of tea leaves is given as 4·38 per cent. The importance of this determination depends upon the circumstance of the tea having been received direct from the growers, who were personal friends of Liebig; in that instance, therefore, there could be no question of adulteration. It may be interesting to reproduce Zöller's analysis, which is as follows :—

Potash	39·22
Soda	0·65
Magnesia	6·47
Lime	4·24
Oxide of Iron	4·38
Protoxide of Manganese	1·03
Phosphoric Acid	14·55
Sulphuric Acid	trace
Chlorine	0·81
Silica	4·35
Carbonic acid	24·30
	100·00

From this it is abundantly manifest that the mere qualitative detection of oxide of iron in the ash of tea is no valid proof of adulteration; and that in order to make out a case it is necessary to show sensibly more than 4 per cent. of oxide of iron in the ash.

On the present occasion I wish to call the attention of public analysts to the importance of investigating the ash of samples of tea. Zöller found the ash of tea leaves to be 5·63 per cent., using in his investigation tea leaves of guaranteed purity. I find that commercial tea yields a very similar result, as is seen from the following analysis made in my own laboratory :—

	Percentage of Ash.
Specimen of Tea used by myself	5·63
Civil Service Tea	5·56
Horniman's Tea	5·99
Mandarin's Tea, 8*s.* per lb.	5·30
Orange Pekoe, 5*s.* per lb.	5·84
Do. do.	6·60
Green Tea, 4*s.* 6*d.* per lb.	5·86
Average	5·75

These determinations were made on tea in its ordinary air-dried condition, and agree sufficiently with Zöller's. The proportion of ash in absolutely dry tea is 5·92 per cent.

Zöller further calls attention to the composition of the ash of spent tea leaves. This, as might be expected, is far less rich in alkalies, being far less soluble. Zöller's analysis is as follows :—

Potash	7·34
Soda	0·69
Magnesia	11·45
Lime	10·76
Oxide of Iron	9·53
Protoxide of Manganese	1·97
Chlorine	trace
Phosphoric Acid	25·41
Sulphuric Acid	trace
Silica	7·57
Carbonic Acid	25·28
	100·00

This ash, as a matter almost of course, must be composed mainly of material insoluble in water.

For practical purposes, that is to say for use by the public analysts, a complete analysis of the ash would be too cumbrous and troublesome. A great deal of information may, however, be gathered from a tolerably simple operation, viz., from a determination of the relative quantities of soluble and insoluble ash in tea leaves. With the object of rendering a determination of this sort available, I have made such determinations on dried leaves of various kinds. The leaves, with the exception of the tea and Paraguay tea leaves, were gathered by my assistant on the 24th of August this year. The following are the results :—

	Percentages on the Dried Leaves. The Ash.		
	Total.	Soluble in Water.	Insoluble in Water.
1. Common Tea	5·92	3·55	2·37
2. Paraguay Tea	6·28	4·22	2·06
3. Beech	4·52	2·00	2·52
4. Bramble	4·53	1·84	2·69
5. Raspberry	7·84	1·72	6·12
6. Hawthorn	8·05	3·78	4·27
7. Willow	9·34	4·16	5·18
8. Plum	9·90	5·66	4·24
9. Elder	10·67	3·19	7·48
10. Gooseberry	13·50	7·83	5·67

From this table it will be apparent that the ash of Paraguay tea is the only ash capable of being mistaken for the ash of tea; the total percentage would of itself exclude all the others. The ash of Paraguay tea is, however, distinguished from the ash of common tea by containing a higher proportion of soluble matter.

The ash of beech and of bramble is distinguished from that of tea by being too small in amount, and by containing too little soluble matter. All the rest are exceedingly unlike tea ash.

The determinations of the total, the soluble, and the insoluble ash in leaves are made with great facility. Dried leaves burn up with great ease; and, for the pur-

* Reprinted from the *Chemical News*.

pose of getting a complete combustion there is no occasion for the employment of nitric acid. I am in the habit of employing about 2 grms. of the dried leaves for the experiment. These I burn in a small platinum dish, and when the resulting ash has become grey, I allow the dish to cool and weigh it together with its contents. The ash is then heated to boiling with a little water, and the solution filtered, and the filtrate evaporated to dryness in a small platinum dish ; the resulting residue is then ignited, cooled, and weighed. Thus I get determinations of "total ash" and "soluble ash ;" the "insoluble ash" is found by difference.

Sand is sometimes found in tea-leaves ; this is very easy of detection. It will, of course, remain in the insoluble portion of the ash, and refuse to dissolve when that is treated with hydrochloric acid. The portion of real tea-ash which is insoluble in water is almost entirely soluble in hydrochloric acid.

Very many uses may be made of a determination of the ash in a sample of tea. As an example of what may be learnt from such determinations, I will cite an imaginary case, which, however, finds its parallel in practice. Let us suppose that the tea yielded the normal proportion of ash, viz., 5·75 per cent. on the air-dried leaves, and let us suppose that one-third of this consisted of sand. With these data before him the analyst would be justified in finding, not only that there was a little sand in the tea, but that at least one-third of the sample did not consist of genuine tea, but either of some other kind of leaf or of spent tea (which is not so rich in ash as genuine tea).

On a future occasion I hope to publish further researches on tea. I will conclude now with an expression of my conviction that a little careful chemical work bestowed on the subject of tea would render the examination of it highly certain and satisfactory.

THE VEGETABLE COLOURING MATTER FOUND IN MADDER.*

BY W. J. RUSSELL, PH.D., F.R.S.

Of late years it has been the custom of my predecessors in this chair to open the business of the Section with an address, and the subject of this address has almost invariably been a review of the progress of Chemistry during the past year; I purpose, with your leave, to-day to deviate somewhat from this precedent, and to limit my remarks, as far as the progress of Chemistry is concerned, to the history of one chemical substance. The interest and the use of an annual survey at these meetings of the progress of Chemistry has to a certain extent passed away; for the admirable abstracts of all important chemical papers now published by the Chemical Society has in a great measure taken its place, and offers to the chemical student a much more thorough means of learning what progress his science is making than could possibly be done by the study of a presidential address. Doubtless these abstracts of chemical papers are known to others than professional chemists; but I cannot pass them over without recording the great use they have proved to be, how much they have done already in extending in this country an exact knowledge of the progress of science on the Continent, and in helping and in stimulating those who are engaged in scientific pursuits in this country. I believe few grants made by this Association have done more real good than those which have enabled the Chemical Society to publish these abstracts.

I dwell for a moment on the doings of the Chemical Society, for I believe in the progress of this Society we have a most important indication of the progress of chemical science in this country. The number of original papers communicated to the Society during the last year has far exceeded that of previous years; during last year fifty-eight papers were read to the Society, whereas the average number for the last three years is only twenty-nine. Further, I may say there is every appearance of this increased activity not only continuing but even increasing. Another matter connected with the Society deserves a passing word: I mean its removal from its old rooms at Burlington House, which afforded it very insufficient accomodation, to its new ones in the same building. This transference, which is now taking place, will give to the Society a great increase of accommodation, and thus admit of larger audiences attending the lectures, of the proper development of the library, and of the full illustration, by experiment, of the communications made to it. These improvements must act most beneficially on the Society, and stimulate its future development; even now it numbers some 700 members, and certainly is not one of the least active or least useful of the many scientific societies in London.

Since our last meeting at Brighton we have lost the most renowned of modern chemists, Liebig. His influence on chemistry through a long and most active life has yet to be written. Publishing his first paper fifty years ago, it is difficult for chemists of the present day to realize the changes in chemical thought, in chemical knowledge, and in chemical experiment which he lived through, and was, more than any other chemist, active in promoting. His activity was unwearied; he communicated no less than 317 papers to different scientific journals, and almost every branch of chemistry received some impetus from his hand.

Liebig took an active interest in this Association, and I believe the last paper he wrote was one in answer to a communication made at the last Meeting of this Association. On two occasions he attended Meetings of the British Association, and has communicated many papers to this Section. The Meeting at Liverpool in 1837 was the first at which he was present; he then communicated to this Section a paper on the products of the decomposition of Uric Acid, and further, gave an account of his most important discovery, made in conjunction with Wöhler, of the artificial formation of Urea. At this Meeting Liebig was requested to prepare a report on the state of our knowledge of isomeric bodies. This request, although often repeated, was never complied with. He was also requested to report on the state of Organic Chemistry and Organic Analysis; thus our Section was evidently desirous of giving him full occupation. At the Meeting in 1840, at Glasgow, a paper on Poisons, Contagions, and Miasms, by Liebig, was read; it was, in fact, an abstract of the last chapter in his book on Chemistry in its applications to Agriculture and Physiology; and the work itself appeared about the same time, dedicated to this Association. In his dedication Liebig says:—"At one of the meetings of the Chemical Section of the British Association for the Advancement of Science, the honourable task of preparing a Report upon the State of Organic Chemistry was imposed upon me. In this present work I present the Association with a part of this Report."

At the next Meeting, which was at Plymouth in 1841, there was an interesting letter from Liebig to Dr. Playfair read to our Section; in it, among other matters, Liebig describes an "excellent method," devised by Drs. Will and Varrentrapp, for determining the amount of nitrogen in organic bodies: he also says we have repeated all the experiments of Dr. Brown on the production of silicon from paracyanogen, but we have not been able to confirm one of his results; what our experiments prove is, that paracyanogen is decomposed by a strong heat into nitrogen gas and a residue of carbon, which is exceedingly difficult of combustion.

To the next Meeting (which was at Manchester, and Dalton was the President of this Section) Dr. Playfair communicated an abstract of Prof. Liebig's report on Organic Chemistry applied to Physiology and Pathology: this abstract is printed in our 'Proceedings,' and the complete work is looked upon as the second part of the report on Organic Chemistry. This Association may therefore fairly consider that it exercised some influence

* Presidential Address to the Chemical Section of the British Association, delivered at Bradford, Sept. 18, 1873.

on Liebig in the production of the most important works that he wrote. Playfair's abstract must have been listened to with the greatest interest, and I doubt not the statements made were sharply criticized, especially by the physiologists then at Manchester. Playfair concludes his abstract in these words, thus summing up the special objects of these reports:—"In the opinion of all, Liebig may be considered a benefactor to his species for the interesting discoveries in agriculture published by him in the first part of this report. And having in that pointed out means by which the food of the human race may be increased, in the work now before us he follows up the chain in its continuation, and shows how that food may best be adapted to the nutrition of man. Surely there are no two subjects more fitted than these for the contemplation of the philosopher; and by the consummate sagacity with which Liebig has applied to their elucidation the powers of his mind, we are compelled to admit that there is no living philosopher to whom the Chemical Section could have more appropriately entrusted their investigation."

At the Meeting at Glasgow in 1855 Liebig was also present, but he then only communicated to this Section a short paper on fulminuric acid, and some remarks on the use of lime-water in the manufacture of bread.

Such, I believe, is the history of the direct relationship which has existed between Liebig and this Association. Indirectly we can hardly recognize how much we owe to him. Interested as he ever was in the work of this Association, I could not but to-day record the instances of direct aid and support which this Section has received from him.

I pass on now to the special subject to which I wish to ask your attention. It is the history of the vegetable colouring-matter found in madder: it has been in use from time immemorial, and is still one of the commonest and most important of dyes; it is obtained from a plant largely cultivated in many parts of the world for the sake of the colour it yields; and the special interest which now attaches to it is that the chemist has lately shown how this natural colouring-matter can be made in the laboratory as well as in the fields—how by using a by-product which formerly was without value, thousands of acres can be liberated for the cultivation of other crops, and the colouring-matter which they formerly produced be cheaper and better prepared in the laboratory or in the manufactory. That a certain colouring-matter could be obtained from the roots of the *Rubia tinctorum* and other species of the same plant has been so long known that apparently no record of its discovery remains. Pliny and Dioscorides evidently allude to it. The former, referring to its value as a dyeing material, says:—"It is a plant little known, except to the sordid and avaricious; and this because of the large profits obtained from it, owing to its employment in dyeing wool and leather." He further says:—"The madder of Italy is the most esteemed, and especially that grown in the neighbourhood of Rome, where and in other places it is produced in great abundance." He further describes it as being grown among the olive-trees, or in fields devoted especially to its growth. The madder of Ravenna, according to Dioscorides, was the most esteemed. Its cultivation in Italy has been continued till the present time, and in 1863 the Neapolitan provinces alone exported it to the value of more than a quarter of a million sterling. At the present day we are all very familiar with this colouring-matter as the commonest that is applied to calicoes: it is capable of yielding many colours, such as red, pink, purple, chocolate, and black. The plant which is the source of this colouring-matter is nearly allied, botanically and in appearance, to the ordinary Galiums or Bedstraws. It is a native probably of Southern Europe as well as Asia. It is a perennial, with herbaceous stem which dies down every year; its square-jointed stalk creeps along the ground to a considerable distance, and the stem and leaves are rough, with sharp prickles. The root, which is cylindrical, fleshy, and of a pale yellow colour, extends downwards to a considerable depth; it is from this root (which, when dried, is known as madder) that the colouring-matter is obtained. The plant is propagated from suckers or shoots; these require some two or three years to come to full maturity and yield the finest colours, although in France the crop is often gathered after only eighteen months' growth. From its taking so long to develop, it is evidently a crop not adapted to any ordinary series of rotation of crops. The plant thrives best in a warm climate, but has been grown in this country and in the north of Europe.

In India it has been grown from the earliest times, and, as before stated, has been abundantly cultivated in Italy certainly since the time of Pliny; he also mentions its cultivation in Galilee. In this country its culture has often been attempted, and has been carried on for a short time, but never with permanent success. The madder now used in England is imported from France, Italy, Holland, South Germany, Turkey, and India. In 1857 the total amount imported into this country was 434,056 cwt., having an estimated value of £1,284,989; and the average annual amount imported during the last seventeen years is 310,042 cwt., while the amount imported last year (1872) was 283,274 cwt., valued at £922,244. In 1861 it was estimated that in the South Lancashire district alone 150 tons of madder were used weekly, exclusive of that required for preparing garancine. I quote these figures as showing the magnitude of the industry that we are dealing with. Another point of much interest is the amount of land required for the cultivation of this plant; in England it was found that an acre yielded only from 10 to 20 cwt. of the dried roots, but in South Germany and in France the same amount of land yields about twice that quantity. The madder cultivator digs up the roots in autumn, dries them, in some cases peels them by beating them with a flail, and exports them in the form of powder, whole root, or after treatment with sulphuric acid, when it is known as garancine.

The quality of the root varies much; that from the Levant, and known as Turkey-root, is most valued. According, however, to the colour to be produced is the madder from one source or another preferred. To obtain the colouring-matter, which is but very slightly soluble in water, from these roots, they are mixed, after being ground, with water in the dye-vessel, and sometimes a little chalk is added. The fabric to be dyed is introduced, and the whole slowly heated; the colouring-matter gradually passes from the root to the water, and from the water to the mordanted fabric, giving to it a colour dependent of course on the nature of the mordant.

To trace the chemical history of this colouring-matter we have to go back to the year 1790, when a chemist of the name of Watt precipitated the colouring-matter of madder by alum from neutral, alkaline, and acid solutions; he obtained two different colouring-matters, but could not isolate them, and many different shades of colour. Charles Batholdi asserted that madder contained much magnesic sulphate, and Hausmann observed the good effect produced on madder by the addition of calcic carbonate. In 1823 F. Kuhlmann made evidently a careful analysis of the madder-root, and describes a red and a fawn colouring-matter: but the first really important advance made in our knowledge of the chemical constitution of this colouring-matter was by Colin and Robiquet in 1827; they obtained what they believed to be, and what has since really proved to be, the true colouring principle of madder, and obtained it in a state of tolerable purity. Their process for preparing it was very simple: they took Alsace madder in powder, digested it with water, obtained thus a gelatinous mass, which they treated with boiling alcohol, then evaporated off four-fifths of the alcohol, and treated the residue with a little sulphuric acid to diminish its solubility; then, after washing it with several litres of water, they got a yellowish substance remaining. Lastly, they found that, on moderately

heating this product in a glass tube, they obtained a yellowish vapour formed of brilliant particles, which condensed, giving a distinct zone of brilliant needles, reflecting a colour similiar to that from the native lead chromate. They named this substance alizarin, from the Levant name for madder, *alizari*, the name by which it is still known there.

A few years later we find other chemists attacking this same subject. In 1831 Gaultier de Claubry and J. Persoz published the account of a long research on the subject; they describe two colouring-matters, a red and a rose one: the red one was alizarin, and the rose one was another body nearly allied to it, and now well known as purpurin. Runge also made an elaborate examination of the madder-root; he found no less than five different colouring-matters in it—madder-red, madder-purple, madder-orange, madder-yellow, and madder-brown. The first three he considers to be suited for dyeing purposes, but not so the last two. Runge's madder-red is essentially impure alizarin, and his madder-purple impure purpurin. He does not give any analysis of these substances.

During the next ten years this subject seems to have attracted but little attention from chemists; but in 1846 Shiel prepared the madder-red and madder-purple of Runge by processes very similar to those employed by Runge, and analysed these substances: for madder-red he gives the formula $C_{28}H_{18}O_9$, which differs only by H_2O from the formula now adopted; for the madder-purple he gives the formula $C_{28}H_{20}O_{15}$, and for the same substance after being sublimed $C_2H_8O_4$. The chemist who has worked most on this subject, and to whom we are principally indebted for what we know with regard to the different constituents contained in the madder-root, is Dr. Schunck, of Manchester. In Liebig's 'Annalen' for 1848 he gives a long and interesting account of his examination of madder; he isolates and identifies several new substances, which are most important constituents of the root, and has since that time added much to our knowledge of the chemical constitution of madder. In the paper above alluded to he confirms the presence of the alizarin, and gives to it the formula $C_{14}H_{10}O_4$. The principal properties of this body may best be sketched in here. Its volatility and brilliant crystalline appearance have already been mentioned; it is but slightly soluble in cold water, but much more so in alcohol, in ether, and in boiling water. The colour of its solution is yellow; and when it separates out from a liquid it has a yellow flocculent appearance, differing thus greatly from the red brilliant, crystalline substance before described. In order to obtain this latter body, heat had always been used; so, until the elaborate experiments of Schunck, it was a question whether the heat did not produce a radical change in the substance, whether, in a word, these two bodies were really identical. Schunck's experiments proved that they were, and consequently that this beautiful colouring-matter, alizarin, existed as such in madder. If, however, we go one step further back and examine the fresh root of the *Rubia tinctorum* (that is as soon as it is drawn from the ground), we shall shall find no trace of alizarin there. On slicing the root it is seen to be of a light carroty colour, and an almost colourless liquid can be squeezed out of it; but this is entirely free from the colouring-matters of madder. Let the roots, however, be kept if only for a short time, and then they will give abundant evidence of the presence of alizarin; if simply heated, alizarin may be volatilized from them. It appears, then, that the whole of the tinctorial power of this root is developed after the death of the plant. Schunck explains this curious phenomenon as follows:—In the cells of the living plant there is a substance which he has isolated and has named rubian; it is easily soluble in water and in alcohol; the solution is of a yellow colour, and has an intensely bitter taste; when dry it is a hard brown gum-like body. It has none of the properties of a dye-stuff; but if we take a solution of it, add some sulphuric or hydrochloric acid to it, and boil, a yellow flocculent substance will slowly separate out, and on filtering it off and washing it, it will be found to have the tinctorial properties of madder, and to contain alizarin. In the liquid filtered from it there is, with the acid added, an uncrystallizable sugar; so that in this way the original product in the root, the rubian, has apparently been split up into alizarin and into sugar. To apply this reaction to what goes on in the root after its removal from the ground, we have to find if any other substances can take the place of the boiling dilute acid; and Schunck has shown there exists in the root itself a substance which is eminently fitted to produce this splitting-up of the rubian. He obtained this decomposing agent from madder simply by digesting it in cold water and adding alcohol to the liquid; this threw down a reddish flocculent substance; and if only a small portion of this was added to an aqueous solution of the rubian and allowed to stand for a few hours in a warm place, it was found that the rubian was gone, and in place of it there was a thick tenacious jelly; this treated with cold water, gave to it no colour, no bitter taste, but much sugar. From the jelly remaining insoluble, alizarin could be extracted; in fact, of all known substances this very one found in the madder itself is best suited for effecting this decomposition of the rubian.

It has long been known to dyers that the amount of colouring-matter in madder will increase on keeping it; even for years it will go on improving in quality; and an experiment of Schunck's shows that the ordinary madder, as used by the dyer, has not all the rubian converted into colouring-matter; for on taking a sample of it and extracting with cold water, he got an acid solution devoid of dyeing properties; but on allowing this solution to stand some time it gelatinized, and then possessed dyeing properties.

It appears, then, that there must exist in the root two substances kept apart during the life of the plant in some way of which we know nothing; but as soon as it dies they begin slowly to act on one another, developing thus the colouring-matters in madder.

Coincident with the appearance of Schunck's first paper was one by Debus on the same subject: he looked upon alizarin as a true acid, and gave it the name of lizaric acid; but, as far as the composition of it was concerned, the percentage numbers he obtained agreed closely with those given by Schunck. One other investigation concludes all that is important in the history of alizarin as obtained from madder. This last investigation is of great interest; it was by Julius Wolff and Adolphe Strecker, and published in 1850; they confirm the results of others so far that there are in the madder-root two distinct colouring-substances, this important one alizarin, and the other one purpurin. They prepare these colouring-matters much in the same way that Schunck did, and very carefully purify and analyse them: the formulæ which they give for them differ, however, from Schunck's; for alizarin they give the formula $C_{20}H_{12}O_6$, and for purpurin $C_{18}H_{12}O_6$; further, they suggest that, by the process of fermentation, the former is converted into the latter, and they show that by oxidation they both yielded phthalic acid. Since the publication of this research, until the last year or two, this formula for alizarin has been generally adopted by chemists, and in most modern books we find it given as expressing the true composition of that body. It was not only the careful and elaborate work which they devoted to the subject, but also the ingenious and apparently well-founded theory on the subject which carried conviction with it. Laurent had shown, not many years before, that when naphthalin, that beautiful and white crystalline substance, obtained from coal-tar, was acted on by chlorine and then treated with nitric acid, a body known as chlornaphthalic acid, and having the composition $C_{20}H_{10}Cl_2O_6$, was obtained; and on comparing this formula with the one they had obtained for alizarin, Wolff and Strecker at once concluded that it really was alizarin, only containing two atoms of chlorine in place of two of hydrogen; make this replace-

ment, an operation generally easily performed, and from naphthalin, they had prepared alizarin. Further, this relationship between chlornaphthalic acid and alizarin is borne out in many ways; it, like alizarin, has the power of combining with different basic substances, has a yellow colour, is insoluble in water, melts at about the same temperature, is volatile, and when acted on by alkalies gives a strongly coloured solution. Taking, then, all these facts into consideration, can we wonder that these chemists feel convinced that they have established the composition of alizarin, and have shown the source from which it is to be obtained artificially? Apparently but one very simple step remains to crown their work with success, that of replacing the chlorine by hydrogen. Melsens had only shortly before shown how this substitution could easily be made in the case of chloracetic acid, by acting on it with potassium amalgam; and Kolbe had used the battery for the same purpose: both these processes, and doubtless all others that the authors can think of, are tried upon the chlornaphthalic acid; but chlornaphthalic acid it remains, and they are obliged to confess they are unable to make this substitution. Still they are strong in the belief that it is to be done and will be done, and conclude the account of their researches by pointing out the great technical advantage it will be getting alizarin from a worthless substance such as naphthalin. One cannot help even now sympathizing with these chemists in their not being able to confirm what they had really the strongest evidence for believing must prove to be a great discovery. We now know, however, that had they succeeded in effecting this substitution, or had they in any other way obtained this chlornaphthalic acid without the chlorine, if I may so speak of it, which since their time has been done by Martius and Griess, alizarin would not have been obtained, but a body having a remarkable parallelism in properties to it would have been. This body, like alizarin, is of a yellowish colour, but slightly soluble in water, easily in alcohol and in ether, is volatile, and on oxidation yields the same products; it is, in fact, an analogous body but belonging to another group. We also now know that the formula proposed by Wolff and Strecker, and so long in use, is not the correct one. But little more remains to be added with regard to the history of alizarin, as gathered from the study of the natural substance. Schützenberger and Paraf suggested doubling Wolff and Strecker's formula for alizarin; and Bolley suggested the formula $C_{20}H_{12}O_6$, which, owing to the uneven number of hydrogen atoms, was soon rejected. If we compare our present knowledge of alizarin with what it was when these researches on the natural product were completed, it is as light compared to darkness; and we may well ask, whence has come this influx of knowledge? The answer, I hope to show you, is undoubtedly that it has come from the careful and accurate study of abstract chemistry. I know of no history in the whole of chemistry which more strikingly illustrates how the prosecution of abstract science lays the foundation for great practical improvements than the history of alizarin does.

My object now is, then, to show you, as shortly as I can, how by indirect means the composition of alizarin was discovered, how it has been built up artificially, and how it is superseding for manufacturing purposes the long-used natural product.

To trace this history from its source we must go back to 1785, when an apothecary of the name of Hofmann obtained the calcium salt of an acid called quinic acid from cinchona bark. This acid is now known to be of common occurrence in plants; it exists in the bilberry and in coffee, in holly, ivy, oak, elm, and ash-leaves, and probably many other leaves. Liebig also prepared the calcium salt, and was the first to give a complete analysis of it; the formula he gave for it was $C_{15}H_{24}O_{12}$. Baup, on repeating Liebig's experiments, arrived at a somewhat different conclusion, and gave the formula $C_{15}H_{20}O_{10}$. In 1835, at Liebig's suggestion to determine which formula was correct, Alexander Woskressky, from St. Petersburg, then a student at Giessen, undertook the further investigation of this subject, and established the formula $C_{14}H_{24}O_{12}$, the one in fact now in use. In the course of this investigation, which he carried further than merely settling the percentage composition of this acid, he describes what to us now is of most interest, a new substance having peculiar and very marked properties. He says that when a salt of quinic acid is burnt at a gentle heat he gets aqueous vapour, the vapour of formic acid, and a deposit of golden needles, which are easily sublimed; afterwards he describes how this same golden substance may be obtained from any salt of quinic acid by heating it with manganic dioxide and dilute sulphuric acid; it then distils over, condensing in golden-yellow needles on the sides of the receiver, and may be rendered pure by resublimation. The composition of this body he finds to be C_3H_2O, and names it quinoyl, a name strongly objected to by Berzelius, as conveying a wrong impression of the nature of the body; he proposed in place of it the name of quinone, by which it is still known. Far as this body would seem to be removed from alizarin, yet it is the study of its properties which led to the artificial production of alizarin.

(To be continued.)

THE SEWAGE FUNGUS.

In the *Gardeners' Chronicle* (Oct. 25th, p. 1434) there appears under the signature, J. B., an interesting account of the detection of a microscopic fungus, in various waters suspected of being concerned in the development of cases of typhoid fever, and found to be contaminated with sewage matter. The first case was the water of a well at Cirencester, which the writer was requested to examine some years ago. The result of the examination and the inferences drawn from it we give in the writer's own words:—

"On examining the spout of the pump to the well in question, I found that it was lined with what seemed a thick mass of gelatinous matter. This, of course, I submitted to examination under the microscope, and found it to consist of some elegant transparent branched confervoid or fungoid threads, intermixed with which were minute ovoid or rounded cells, which I took to be scattered spores of these plants, and in my report upon the subject I made the following remark:—'The water contains an abundance of fungoid growths, and from the fact of their requiring nitrogen for their nourishment, I am of opinion that they must obtain their supply from some communication from a neighbouring cesspool.'

"At that time I named this plant provisionally the 'sewage fungus,' and subsequent inquiries have only confirmed my views that this fungus is more or less present in water which has been said, rightly or wrongly—I incline to the former—to be concerned in the production of typhoid fever, and I now offer some cases in proof. After examining this well I went to the exit drain of the sewerage of the town, where it is conveyed to some water meadows about a mile from Cirencester, and there I found that bits of sticks, leaves of water plants, and the like, were more or less covered with the same kind of gelatinous matter that I had met with at the mouth of the aforesaid pump, and which I should say the microscope showed to be floating filamentous threads in the water as pumped up from the well. Here, then, I felt sure that these plants were developed through the medium of sewage; and my drawings and report upon them found their way to Dr. Lankester, and in a paper descriptive of some suspected water at St. James', Westminster, he figures the same cryptogamic plant with some of my own figures, and adds the following remark:—'Professor Buckman's microscopic observations exactly coincide with our own, except that he has not found animalcules. His drawings are similar.'

"Having been requested to report upon the sewage works at Croydon, I there found the sewage conduits full

of the same cryptogam, which adhered to bits of sticks, leaves, etc., in the same manner as that previously observed in the Cirencester sewage, whilst the delicate threads before mentioned were found floating in the dirty water.

"Now, it is a very important point to observe that after these waters had been conducted through the soil—that is, had done their irrigating work—they became free from this fungoid matter, and water plants grew in the exit drains healthily, and fish were seen in abundance—all of which was just the reverse in dirty water.

"The next cases of the detection of this fungus in suspected water occurred in Dorset. Some members of my own family were severely attacked with typhoid fever, and, as usual, the medical man suspected the drains or the water to be the cause, and on making a microscopic examination of the water from the well, which was 120 feet deep, there, sure enough, was the same growth, and it was soon discovered that impurities got into the well from a defective drain, which was soon put to rights, and the whole of the water pumped out: since then the water has been of excellent quality.

"Another case occurred at Sherbourne Union Workhouse. As there were some cases of typhoid fever in the house the water was examined when it was found to be foul with fungoid matter, caused by a drain finding its way into the well; this cause was at once remedied, and no attack of typhoid fever has taken place in the house since.

"These facts seem to me to point to the conclusion that sewage-water favours the growth of a peculiar form of fungoid or confervoid growth, the presence of which in water renders it dangerous to health. How it acts it would be difficult to determine, but it is at least conceivable that the spores of the fungus may get into the circulation and bring about changes in the fluids after the manner of yeast in beer, and, if so, the seeds of the fungus would be likely to develop rapidly if they came in contact with milk, or water containing nitrogenous matter. 'A little leaven would leaven the whole lump,' and, as it appears to me, in this way much disease may be accounted for.

"The microscope, then, will enable us to make out the presence or absence of this fungoid or confervoid matter in foul water, and my own observations confirm me in the view that being present it is highly dangerous, and if its cause can be removed, and the water made pure, all danger from this cause at once ceases, whilst if it cannot it should be at once disused, and pure water be sought for elsewhere."

PROGRESS OF MATERIA MEDICA AND THERAPEUTICS DURING THE LAST TWENTY YEARS.

During his introductory lecture, delivered at the Medical College of the London Hospital, Dr. Prosser James alluded to the advance in the medical art which had taken place in the last twenty years, the term of his experience. Referring more particularly to materia medica and therapeutics, he said:—

"Fresh air, change of climate, bathing, exercise, gymnastics, rest, regulation of diet, whatever conduces to the restoration of health or the comfort of the patient, are properly embraced in materia medica, and the mode of availing ourselves of these or any other agencies comprises therapeutics. How erroneous, then, is the popular notion that medicine consists in prescribing drugs. Useful as these are, other things are more important, and therefore the sarcasm that 'the doctor is a man who puts drugs of which he knows little into a body of which he knows less' falls powerless on the scientific follower of medicine. We have, indeed, discovered new drugs, but more than that, we have advanced in our knowledge of the effects of old ones. We have made progress, too, in our methods of employing other remedies, and have devised or discovered no small number of new ones."

After speaking of the development of conservative surgery, antiseptic surgery, skin-grafting, the subcutaneous syringe and the aspirator, he continued:—

"Nitrous oxide has been revived, and other agents have been introduced with the view of finding a safe anæsthetic; while the application of the ether spray has furnished us with a mode of producing local anæsthesia. Allied to these in some respects is another new drug—chloral hydrate—which has already proved a blessing to thousands of sufferers, and from which much is to be hoped as its properties become more completely understood. We have all often longed for a remedy that should be applicable when we dare not administer opium, and the new anodyne is just the thing. It seems to be as great an acquisition to the physician as chloroform was to the surgeon. It has been used in almost all conceivable cases. Just as Liebreich's discovery was announced, I was on the point of crossing the English channel, and provided myself with some of it to test it in sea-sickness. I tried it on myself and others who accompanied me with sufficient success to lead to further trials, and it was mentioned at the Medical Society of London. Long afterwards I found in Germany that two professors had a warm dispute as to the priority in the use of the drug for the same purpose.

"The bromides also have come into use in this time. I remember well Sir C. Locock introducing the use of bromide of potassium as a sedative in certain special cases, and I watched its effect with considerable interest. Soon after it received a much wider application, and is at this moment one of the most interesting remedies to study. In my lectures I have related a series of experiments made with a view of determining its effect on the brain, so far as ophthalmoscopic exploration may be accepted as an index, and this appears to me a proper method of studying the effects. At the Medical Society of London, when speaking of iodides, I took occasion to show how other salts might be substituted with advantage for those formed by potassium with both bromine and iodine, and those observations seem to me still to be of value, inasmuch as they have since been put forward by foreign writers as original.

"The salts of lithia have taken a high position among remedies, and will, I have reason to anticipate, be still more largely used.

"Our knowledge of the alkaloids which form the active principles of certain plants is becoming constantly enlarged, and this ability to concentrate our remedies seems one of the greatest indications of progress.

"In the management of fever the use of the thermometer has enabled us to act with precision, and to measure the effect of treatment. No greater shock to ancient prejudices could well have been given than the proposal to keep fever patients in cold baths for hours; but it has been done, and the improvement has been measured by the thermometer. By cold baths it is to be understood that the water is a little cooler than the body of the patient—not that the contrast is too violent or the shock great. Here it is singular to note that the system called hydropathy has, after all, a rational foundation, though the excess to which it has been carried by ignorant charlatans has been as injurious as it was unscientific. The rational use of cool water in febrile diseases has been fairly tried in the London Hospital, and it is to be hoped that the profession will not abandon it to pretenders. I may add that where, as too often happens in private practice, there are many obstacles to the employment of prolonged baths, similar results may be obtained by assiduously sponging the surface.

"Recent observations go to prove that quinine possesses a considerable power of reducing the temperature in pyrexia, and the discovery enables us to see why it is sometimes so useful a remedy, and to measure its effect.

"Another agent which recent research tends to prove possesses like properties is alcohol. In all its forms this has long been employed as a stimulant, and it

will, perhaps, require further investigation to convince many that their sensations mislead them when they fancy it warms them. As to the medicinal use of alcohol, we have seen it go through a complete cycle of change—a circumstance that might well persuade us that it has not always been rationally employed, and that may also suggest doubts whether we even yet understand and appreciate its properties. Physiological experiment is probably leading us to the true method of employing it, and its power of reducing the temperature is an objective fact that may shortly receive its true interpretation.

"The next remedy I cite is electricity. Assuredly we have lately made great strides in applying electrical influences to the cure of disease. The galvano-cautery is in many cases taking the place of the knife or of the hot iron. The silent, painless, continuous current is made to effect what was vainly hoped for from the more obvious and painful shocks. We remove pain, get rid of effusions —nay, disperse solids by the galvanic current. No greater triumph of treatment can be mentioned than that involved in the removal of tumours by electrolysis."

SHEFFIELD PHARMACEUTICAL AND CHEMICAL ASSOCIATION.

A conversazione of the members of the above Society and their friends was held in the Music Hall, Sheffield, on Friday, October 24th. To add to the enjoyment of the company, many valuable and interesting objects were lent for exhibition by various sympathizers with the object of the Association. Amongst the most remarkable was a splendid case, contributed by Messrs. Southall, Son and Dymond (Birmingham), which justly gained much approbation, the samples of many pharmaco-chemical objects being especially worthy of notice, those of ferri cit. et quinæ, cit. ferri ammon., ammon. iod., with a splendid bottle of potass. iodid., being the more remarkable. Altogether the complete collection forwarded by these gentlemen, consisting of over fifty objects, was greatly admired.

Along with a quantity of novelties kindly lent by Messrs. Maw, Son and Thompson, a "Pindar's" pill-machine caused much amusement to the ladies.

Messrs. Hearon, Squire, and Francis also sent many fine materia medica specimens, noticeable among which were varieties of the cinchona family, a splendid sample of scammon. radix, with guarana, and other obiects too numerous to mention. We must not forget a wonderful piece of gum myrrh, also lent by this firm.

Messrs. Hodgkinson, Stead, and Treacher contributed rad. pareiræ vera, several varieties of gum benzoin, belæ fructus, etc., also a parcel of *hyraceum*, a substance not generally known.

There were also several contributions from the Pharmaceutical Society, comprising many objects perfectly irresistible to a lover of chemistry and its allied sciences. Numberless were the specimens which in display were productive of much instructive and pleasant discussion, many samples being of a character rarely presented for exhibition in the provinces. There were also numerous living botanical specimens of a highly interesting character, which by the permission of the Council of the Pharmaceutical Society had been collected and arranged at much pains by the Curator (Mr. Holmes), and which, duly labelled with their common and botanical names, deservedly excited universal admiration.

For want of space we are compelled to abridge our report, and merely in passing, mention some of the local contributions.

Messrs. Cubley and Preston (Sheffield) :—A collection of chemical apparatus, together with numerous scientific instruments, amongst which were a series of lactometers for the detection of adulterations in milk, etc.

Mr. Ewing, Curator, Botanical Society's Gardens (Sheffield) :—A large collection of cuttings of medicinal plants.

Mr. W. V. Radley (Sheffield) :—A series of rare chemicals, etc.

Mr. T. W. Hime, M.B., L.R.C.S., etc., etc.:—Leclarche's peroxide of manganese cell; also a beautiful instrument for the correct administration of chloroform, invented by himself, etc., etc.

Mr. W. Ward, F.C.S. (President, Sheffield Association): Indian curiosities, etc., etc.

Mr. E. Birks, F.L.S., etc.:—A fine collection of dried plants, arranged in Pharmacopœia order.

Mr. Ellinor (Sheffield) :—A large number of materia medica specimens, etc.

Mr. W. Jervis (Sheffield) :—Contributions of African curiosities, war instruments, etc., etc.

Mr. J. H. D. Jenkinson (Sheffield) :—Not the least attractive was this gentleman's contribution, consisting of a fountain of perfume beautifully embedded in flowers.

Mr. E. Wilson (Local Secretary, Pharmaceutical Society :—Old engravings.

H. Merryweather, Esq., M.D., M.R.C.S., etc. :—A set of specimens illustrating comparative anatomy, etc., etc.

During the evening the proceedings were enlivened from time to time by music, and also an opportunity was found for the delivery of a brief address by the President, Mr. W. Ward, F.C.S.

In the course of his remarks the President alluded to the various schemes put forth by the Council in order to make the Association a success; hitherto he regretted their efforts had not been productive of those salutary results they had hoped for and confidently anticipated. He believed, however, as he looked around him that evening and saw such a brilliant assembly of ladies and brother pharmacists, such as had never been seen before in their town, that a new era had dawned upon them, and that pharmacy would from that time receive such an impetus amongst them that all would feel impelled to aid and support an association which had for its object the advancement of pharmaceutical knowledge and the cultivation of mutual good-will and fellowship. After calling the attention of the visitors to the many and varied objects which were being exhibited, objects not only relating to pharmacy and the collateral sciences, but also of a literary and philosophical character, he said of all the sciences of which they were reminded that evening chemistry was the most sublime and delightful, and such was its general utility that there was scarcely an avocation which was not benefited by it, and even the enjoyments of life were multiplied and enhanced by it. He then showed how useful and important this science was, not only to the practitioner of medicine as a means of inspiring him with professional confidence, but to the manufacturer. He explained that in the manufacture of iron, for which their town had become so famous, from the smelting of the ore down to the conversion of it into steel, every operation was based upon the effect of *chemical* affinities. After congratulating the members and their friends, and giving them a hearty welcome, he concluded by hoping that this their first conversazione would prove the precursor to many others.

At the conclusion of the President's address, Dr. J. C. Hall expressed the great pleasure it had afforded himself and others to be present and take part on the occasion.

A short but highly interesting lecture was delivered during an interval by Mr. A. H. Allen, F.C.S. (borough analyst) on "Spiritualism," which was profusely illustrated by experiments, causing much amusement.

As may well be imagined, amid such numerous attractions the evening sped rapidly away, and at the conclusion of an entertainment which had been promoted by every means at the disposal of the Council, and which was evidently much enjoyed, dancing commenced, which, meeting with hearty appreciation, was sustained till a late hour.

The Pharmaceutical Journal.

SATURDAY, NOVEMBER 1, 1873.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE RESULTS OF THE RECENT EXAMINATIONS.

IF we may judge from the results of the more recent examinations, both in London and in Edinburgh, it would seem that there is still prevailing an extremely low estimate of the general qualifications and technical knowledge requisite for those who contemplate carrying on the business of a chemist and druggist.

To take, for instance, the examinations last held: we find that in London, out of ninety-nine candidates for the Minor, as many as fifty-six failed to pass; while at Edinburgh, out of thirty-one candidates, ten failed to pass. In an examination dealing almost entirely with matters which may be fairly regarded as coming within the daily cognizance of everyone engaged in the ordinary routine of a pharmacist's business, such high proportions of failures to satisfy the requirements of the examiners tend to show that much still remains to be done in the way of impressing the younger members of the trade with a due sense of the qualifications necessary for the creditable pursuit of their calling.

In the Preliminary examinations the case is similar; there being no less than 164 candidates who failed, out of a total of 311 who presented themselves for examination in England, Wales, and Scotland. Here, however, there is less cause for regret than in the case of the Minor examination, for the candidates who failed to pass the Preliminary would be mostly at the outset of their pharmaceutical career, and being made to feel their deficiency at an earlier period would have so much the better chance of remedying it.

But it is not only in reference to the Minor and Preliminary examinations that these remarks are applicable, for we find also a large amount of failure among candidates for the Major examination. This fact is perhaps the more striking, since the Major is still a voluntary examination, and we might reasonably expect that the candidates presenting themselves for it would have formed a more just appreciation of the acquirements that would enable them to pass.

Concurrently with the indications furnished by the examination returns as to the state of opinion prevailing among the junior members of the trade on the subject of pharmaceutical qualification, we may point to the reports of provincial associations as supporting the conclusion we have drawn. In those reports there are almost invariably expressions of regret and disappointment at the comparatively small attendance at the meetings and lectures. The opportunities of this kind now afforded throughout the kingdom are sufficiently adequate and numerous to justify the belief that if proper advantage were taken of them they would prove the means of effecting a vast alteration in the returns of the examining boards. But in order that this desirable result should be attained, there is great reason to believe that the state of opinion on the subject of qualification must be advanced even among the older, and as we may say, independent members of the trade. It is only by such advance that we can hope for that general improvement in the status of the trade which is so requisite. It is, we think, a mistake to argue, as a correspondent does this week, that scholastic training and technical knowledge should not be required of the young pharmacist because the business he contemplates following is a poor one. That would be a sure way to maintain its poverty. Equally mistaken is it to encourage the idea that the pharmacist, by reason of his occupation being trade, cannot hope to rank side by side in the social scale with members of the medical profession, or others in a similar position. It is a mischievous illusion to urge such an opinion as a reason for not insisting upon the education of rising pharmacists.

As a matter of fact, it is well known that even now many members of the trade do take a high social position in this country. They do so, however, as men of education, and we see no reason, if pharmacists be true to themselves, why that should not be very much more generally the case, as it has long been in Germany and France.

CONVERSAZIONE AT SHEFFIELD.

AT a conversazione held last week in the Music Hall, Sheffield, in connection with the Sheffield Pharmaceutical and Chemical Association, there was provided for the first time in the history of that Society an opportunity for the attendance of the fair sex and the immediate friends generally of the members, and from the numerous company assembled we may augur well for the success, should it be attempted, of such an entertainment another year.

The Council had exerted every effort to make the meeting successful, and the result, it is pleasurable to notice, quite accorded with their most sanguine expectations. On such an occasion, the objects sent for exhibition were of course the principal attraction, and the liberality and number of the loans, as enumerated on the preceding page, must have conduced to much of the success of the gathering.

THE next Evening Meeting of the Pharmaceutical Society will be held on Wednesday evening next, November 5th. The Chair will be taken at half-past Eight o'clock. Communications will be made on the Acetic Preparations of Ipecacuanha, and on the Adulteration of Drugs.

IN our remarks last week on Cinchona cultivation in Java we omitted to state that the analyses were made by Mr. MOENS, and that the author of the report was Mr. VAN GORKOM, the resident superintendent of the plantations. The report was only translated from the Dutch into German by Dr. HASSKARL.

Provincial Transactions.

MANCHESTER CHEMISTS' ASSISTANTS' ASSOCIATION.

The Third Annual Meeting of the above Association was held in the class-room of the Manchester Chemists and Druggists' Association on Wednesday evening, the 15th inst., the President, Mr. William Lane, in the chair. The Secretary, Mr. A. J. Pidd, read the report of the last session :—

"*Report.*

"Your Committee have much pleasure in congratulating you upon the success of the past session, at the same time they think that the attendance was not what it should have been in an important city like Manchester, although there was a decided improvement. They make an earnest appeal to all assistants and apprentices, not only to join the Association, but to show by their regular attendance at the fortnightly meetings, and entering into the various discussions, that they wish to strengthen the means already afforded for mutual improvement. The number of enrolled members was forty-eight, showing an increase on preceding sessions.

"The thanks of the members are due to Mr. Siebold for the great interest he takes in the success of the Association, and for his kindness in delivering a very instructive and interesting lecture on 'Volumetric Analysis.'

"Papers were read as follows :—

"On 'Chemical Combination, Atomic Theory, and Quantivalence,' by Mr. J. T. Clarke. On 'Arsenic and Antimony,' by Mr. F. Sanders. On 'Opium,' by Mr. R. de Burton. On 'Sulphur,' by Mr. W. Lane. On 'The Ferrous and Ferric Salts,' by Mr. Cooper. On 'The Alkalies and their Tests,' by Mr. A. J. Pidd. On 'Spectrum Analysis,' by Mr. T. Broughton. On 'The Formation of Cells,' by Mr. W. G. Booth."

The Treasurer's statement showed a balance in hand of £1 5*s.* 8½*d.*

The Chairman moved the adoption of the report, in doing which he urged upon all those present the necessity for united effort, both by their regular attendance at the meetings and by inducing as many of their friends as possible to join the Association, thereby raising its standard beyond that already attained. He also said that the kindness shown by the Chemists and Druggists' Association in placing their rooms at the disposal of this Association demanded the warmest thanks of the members. In concluding, he drew attention to the courses of lectures arranged for the benefit of pharmaceutical students of Manchester and neighbourhood, which he felt sure would prove in the future as it had done in the past, of the greatest use to those students preparing for examination.

Mr. Hedley expressed much pleasure in seconding the adoption of the report, which was carried unanimously.

The election of officers for the ensuing session took place with the following result :—President, Mr. William Lane, re-elected ; Vice-President, Mr. W. G. Booth ; Secretary and Treasurer, Mr. A. J. Pidd, re-elected ; Committee—Messrs. Bathe, Dodge, Hedley, Hodgson, Hughes, and Sanders.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

(*Concluded from page* 336.)

Some Starches Microscopically and Polariscopically Considered.

BY HENRY POCKLINGTON, LEEDS.

Some excuse is due from me for the choice of a subject rather out of the normal sphere of pharmacy. The only one I have to offer is this, that circumstances quite out of my control have prevented the completion of an investigation I have long had in hand, and almost at the eleventh hour I have had to choose between the selection of the present subject and the breach of my engagement with our worthy Secretary. The subject is however not without interest to pharmacists—in truth it has importance to those engaged in analysis of drugs and foods ; for no one engaged in food analysis can afford to neglect the microscopical appearances of any of the economic starches. With a view to making my paper of as much technical interest as possible I propose to pass by the vexed and still unsettled questions as to the life history of the starch granules, their mode of development and structure, and to confine myself pretty closely to the consideration of their morphological and physical characteristics as shown to us by the microscope and polariscope.

Anything like a morphological classification of starch granules lies almost within the impossible if reference be had at the same time to the botanical classification of the plants from which they are derived. An elastic geometry might comprise the granules, but to interweave these with the botanist's diagnoses is quite another matter. In other words the morphology of the starch granules can only with difficulty be made to take its place with other plant diagnostics. At the same time certain starches are characteristic of certain plants, and the mean of the morphological peculiarities of any given starch will be a tolerably definite quantity for that plant. The starch granules of the potato for example may be described as ovate although a large number of individual granules may be round, or mussel shape, so that whilst he would be a very rash man who should pronounce any given granule to be that of the potato, he would be quite justified who should pronounce any given sample of starch to be potato starch. Starch diagnosis is further complicated by the morphological changes that are so easily induced by the application of heat, of water or denser fluids. The so-called amorphous starch that occurs in certain economic roots is, for instance, doubtless due to the drying of the root under a high temperature, and the sensitiveness of wheat starch to the action of heat and fluid is too well known to all who have studied its optical peculiarities. Whence in comparing starches it is needful to secure that they are under the same conditions, or at least, that the effects induced by any other condition be known.

Starches may be classified pretty much as follows, taking simple granules first, the basis of the classification being that of Schleiden.

Round-bodies. These are found everywhere in the form of excessively minute particles and are the commonest of all cell contents. In chlorophyll granules one or more are always to be found, and we may perhaps safely regard this as the primal form, and other shapes to be due to a more or less eccentric deposition of the amylaceous matter, and also look to chlorophyll, as the half way stage from protoplasm to starch. In which case the cause of compound granules becomes explicable. These small round starch granules are therefore of no diagnostic value. Larger granules, irregularly roundish, often truncated and multangular occur rarely. Very large and rough granules with small, more or less central hilum and a laminated formation, occur in certain cycads, and are morphologically transitional into the ovate form as seen in the potato. Common sago affords an example of this type. A still more modified form is the mussel-shaped granule, associated with round and ovate in the potato, and common also in the bulbs of many lilies, and nearly triangular in tulips. The starch of Indian corn affords a further and characteristic modification of the globular type of granule. Here the lamination is indistinct, hilum very distinct, multiradiate and central, and the granule polyhedric in shape, the spaces between the angles being rounded off. It is only by the aid of a high power and the careful use of a dilute magenta solution that lamination can be detected in these and several other starch granules. The starches of the pea family are roundish or oval, the hilum is central but elongated, and suffers much change if the granule be dried

or exposed to a high temperature. The starch of the official orris-root is a marked instance of a modification of this and a departure from the type of the natural order to which it belongs, being an approximation to the type we find in the leguminosæ. Here the granule is irregularly oval and the hilum presents the appearance of a hollow cavity.

Round starches, more or less compressed into lenticular granules, sometimes evidently laminated, more frequently not, with a very variable hilum, are found in our common cereals and are very difficult of accurate observation on account of their convergent refraction upon the illuminating pencil, and the modifications this refractive influence undergoes when different media are used in which to immerse them for microscopical observation. Very much more flattened discs, or granules ovate in contour, are found in the zingiberaceæ and are well known to those who have examined East Indian arrowroot.

The stick-like euphorbian starches defy classification, as also to a great extent do the compound granules found in very many official plants. The most satisfactory classification probably will be one based upon the morphological character of the compound granule, the number, on the average, of granules of which it is composed, their lamination, and the position and character of the hilum. The number of the constituent granules is the most constant diagnostic, after this the position and shape of the hilum, and lastly the shape of the resulting granule.

Of the starches occurring in pharmaceutical plants I have noticed from time to time, during the publication of my articles in the PHARMACEUTICAL JOURNAL, the following ones of interest :—

In Jalap the starch granules are large, vary much in size and shape, are aggregated or isolated. The compound granules consist of three triangular granules, the bases of the triangles being curved ; the resulting granule is muller-shaped, approaching the circular. Many of the single granules are nearly circular, flattened with a triradiate indistinct hilum. In calumba root the granules are also large and very variable, sometimes simple, generally compound. The simple granules vary from nearly circular to mussel-shaped ; the compound are usually muller-shaped. The normal form of hilum is a longitudinal furrow, but a simple point or a three or four radiate slit or furrow are *collectively* as frequent. This starch is exceedingly sensitive to the action of any medium in which it may be immersed, and disrupts under slight elevation of temperature. In Senega root the granules vary from a very small sharp-edged polyhedric granule to one of considerable size, more round and flattened. In rhubarb the compound granule is oval and composed of four well-formed granules, each with a distinct hilum. However, to describe all the starches of materia medica plants would be a longer task than I could well undertake, and detain you longer than you would care to stay.

The size of starch granules is a characteristic of importance, but not if taken alone. In connection with shape it is of the first importance, because although both size and shape vary exceedingly in starch of the same plant, yet a certain shape and a certain size go together pretty closely, and very much simplify the process of getting out a mean. Their measurement is a process of the simplest if an eye-piece micrometer be used, but it is needful to bear in mind that in the case of lenticular granules and discs, the medium in which they are immersed seriously affects their sharpness of outline, and therefore the accuracy of their measurement. It is perhaps hardly needful to mention in addition that if we use a lens of high angle of aperture, and therefore have to make occasional adjustments for difference of thickness of cover, it is necessary to correct the reading of our micrometer. It is in fact always best to use one uniform thickness of cover—and that the thinnest our lens works well with,—and also to mount our starches in some one medium, and to measure them immediately they are mounted. Mr. Rimmington's glycerine jelly is about the most convenient medium for the purpose. Variation in size in starch of the same plant is well seen in the potato, where the granules will range from the $\frac{1}{400}''$ in length and $\frac{1}{800}$ in width down to much less than the $\frac{1}{6000}''$. In maize, on the other hand, the mean is about half the extremes. These measurements of potato starch are taken just before the tuber comes to maturity. Earlier, the larger granules are not numerous ; later, small granules are comparatively infrequent. In wheat starch the granules rarely exceed $\frac{1}{1000}''$, but the smallest are exceedingly minute. The maximum in rice does not often exceed $\frac{1}{3000}''$, the smallest are not measurable by ordinary appliances. It was my hope when I set about this paper to give a somewhat extended series of measurements of the more common starches, showing their variation, their mean, and the change this undergoes, or the range of the mean at different periods of the plants' growth, but I must let it stand over for a more convenient season and ask your attention to a few notes on the polarization of starches.

Here we meet with very varied statements in the text-books, and must feel our way very cautiously lest we copy the inaccuracies of observers who, writing in the infancy of microscopy, used appliances far less perfect than are in the laboratories of the most ordinary observer of the present day. Wheat starch, for instance, is said not to give the black cross by nearly all writers on the subject, from Pereira to the Cantor Lecturer of the present year—Dr. Hassall being almost the only exception. All say rice starch does not polarize, and I think all say the same of oat starch. How far this is true we shall see.

We may conveniently begin with potato starch. This, when viewed by polarized light, shows, as every one knows, a beautiful black cross when the axes of the prisms are at right angles, the starches being white on a black ground, and this cross shifts a quadrant when the axes are parallel, the starches being then (dusky) black, with a white cross on a black ground. The white of the first case and of the second are different, and neither are quite the same white light as enters them from the mirror, as may be easily learned on micro-spectroscopic observation, and indeed follows from the nature of the phenomena. The position of the cross and the whiteness of the granules vary widely in different granules of the same, and still more in other starches, both being determined by the bi-refractive energy of the starch, the eccentricity of its lamination, and, to a great extent, by the medium in which it is immersed. Potato starch is not much affected by the latter condition ; wheat-starch, on the other hand, is, and this explains the varied statements respecting its polarization. The estimation of the bi-refractive energy of any particular starch is not difficult, and its comparison with the refractive energies of other starches is easy, and may be of importance. In the case of potato starch I find it is exactly equal to the bi-refractive energy of a film of selenite sufficiently thin to give the white and black immediately within the first of Newton's orders, the film itself being, as near as I can estimate, half the thickness of the starch granule. In wheat starch the bi-refractive energy is less, but the granule is rather thinner, so that the actual or specific energy will only be slightly less. It *is* less, probably by one-third, but the exact measurement of these energies is beyond the instrumental appliances at my present command. Their estimation may be made in several ways. The easiest is to place the granules over a wedge of selenite, and note where the one energy exactly overcomes the other, the axes of the selenite and starches being oppositely arranged, or we may ascertain by how much the tint of any selenite is raised or depressed by the starch. The former is the more accurate plan.

In the course of observations upon the polarization of starches, particularly of the potato, the black cross naturally comes prominently under attention. The first thing we ascertain is that it does not lie along fixed lines in the starch, but along fixed lines of direction as regards the plane of polarization. In a round granule one arm will be parallel with that plane, the other at right angles to it,

and if we rotate the granule the arms will remain fixed with regard to this plane. In an ovate granule the same holds good, and the hilum being eccentric, long arms of the cross are exchanged for short ones, and *vice versâ*, twice in the complete revolution of the stage. The arms are rarely, however, straight, but nearly always curved, and therefore of varying depth of blackness. If we arrange the plane of primitive polarization so that it is parallel with the front of the stage, and therefore right to left or the reverse, one arm of the cross will be from the stage towards the face of the observer, the other from his right to his left hand. This we will call the normal position of the cross in the following experiment. If we place a film of mica, known as a quarter wave film, between the starch and the polarizer, with its neutral axis parallel therewith, no change is produced in the position of the arms of the cross, but if we revolve the film until its neutral axis is at right angles with the plane of polarization, the prisms remaining crossed, the arms disappear and are replaced by two brush-like arms parallel with the axes of the film and at 45° to the plane of polarization, these arms covering two separate quadrants of the round granules with their brush-like expansions. If we revolve the analyser these arms revolve with it. If we rotate the film the arms are reversed. The explanation of this is that the bi-refractive energy of the granule is sufficient to restore the circular polarization of the mica film to plane polarization. This energy in two quadrants reduces it to vertical polarization, in the other two to horizontal; one is transmitted, the other absorbed, producing a brush. That the energy is in opposite directions, in other words that in one case the ordinary pencil is most retarded and in the other the extraordinary (with plane polarized light) in the two opposite quadrants, may be easily proved by placing any sensitive selenite giving colour beneath the granules, or more exactly by rotating a thin film behind them. In the case of the potato the one bi-quadrant raises the "sensible tint" to red, the other bi-quadrant depresses it to blue. Wheat starch is only competent to raise and depress it one half tint, and this only when immersed in some highly refractive medium. When immersed in water the change only amounts to about one quarter tint. Maize starch is slightly more energetically bi-refractive than potato, raising the violet one half tint beyond red; and Calabar bean is capable of raising the yellow into blue and is perhaps the most powerfully refractive of all the starches. The starch of *Curcuma leucorrhiza* will take rank close with that of wheat.

A few words about the starches that are said to give no cross and I have done.

Oat starch consists of compound granules each of which gives its own individual cross. The resultant when a sufficiently high power is used is weird looking in the extreme. The bi-refractive energy of this starch is a little more than that of wheat, but is difficult of measurement in the compound granule, as super-imposed granules frequently have their lines of force arranged oppositely. Rice starch is too small for observation without the use of a higher power than most persons use with the polariscope. Mounted in balsam each granule gives a decided cross, the point of intersection being central; its bi-refractive energy is twice that of wheat.

In some starches, as in curcuma, one line of no force lies along the side of the granule and the cross is thus not evident without special arrangements. The circularly polarizing film at once brings it into view.

The effect of media of various refractive power is as yet incompletely worked out by me. The general result so far is that a highly refractive medium increases the bi-refractive energy of the granule.

I conclude with an apology for the hasty and incomplete manner in which I am compelled to present this paper, and a promise to lay any further researches I may be enabled to make before the Conference at its next meeting, or otherwise as may be found most suitable.

Mr. Pocklington was thanked for his paper and his promise.

Adulteration Notes Respecting Turmeric in Rhubarb, Aromatic Chalk Powder, and Mustard.

BY W. L. HOWIE.

Turmeric in Powdered Rhubarb.—The experiments of which the following notes are the result were suggested by the expression of an opinion by many pharmacists of my acquaintance that turmeric was responsible for the brilliant yellow colour of certain samples of very fine powdered rhubarb.

The test for turmeric given by Pereira, Christison, and other authorities, and lately elaborated by Professor Maisch, U.S. (*vide* Pharm. Journ., vol. i., 3rd series, p. 1027), requires the preparation of a tincture or decoction of the rhubarb, and is far from delicate owing to the difficulty of detecting the brown-red tinge in presence of the deep yellow colour of the rhubarb. My aim has been to supplant this preliminary exhaustion of the suspected rhubarb by a process which should more completely eliminate the curcumine, and while rendering the test strictly practical for counter use, improve its efficiency.

An effort to discover a menstruum in common use which would dissolve the colouring principle of one only of the drugs under notice proved not altogether successful, in a measure owing to a variation in the peculiar constituents of different varieties of rhubarb, which will be further referred to.

Of turpentine, carbon bisulphide, benzole, ether, and chloroform, I have been induced to prefer the last-named, though the test can be applied with either of the others, should convenience suggest such a course; but, with the exception of ether, none seems so efficient as chloroform, on account of the readiness with which it dissolves curcumine, and its volatility, rendering the manipulation of a number of samples exceedingly rapid.

I discard ether, because crysophanic acid is much more soluble in it than in chloroform.

The application of the test is as follows:—

Let the required number of pieces of white blotting-paper, about three inches square, be numbered and placed on a pill tile or glass slip; in one corner of each of these papers place about five grains of the several rhubarb samples to be tested, keeping the powder as much together in one heap as possible; press it flat and smooth with the aid of a piece of paper, and drop cautiously on the centre of the powder, chloroform, so that it may slowly percolate to the circumference, carrying with it any soluble matters, and extend nearly one inch from the powder, taking care not to float any particles over or under the paper, which would interfere to some extent with the succeeding tests. Having allowed the papers to dry, it will be found that a yellow stain of varying intensity has been left around the powder. With really fine, bright-coloured East Indian rhubarb, this stain is scarcely perceptible, but cheaper and darker samples may yield a brilliant yellow, while even the finest bright-coloured English powder will give a yellow stain as deep, and in most cases, deeper, than the darkest East Indian. Should turmeric be present in quantity in any sample it will at once give a brilliant yellow stain, in tint undistinguishable from that of the rhubarb, but which may readily be identified by the following tests.

Place a minute pinch of biborate of soda in powder on that portion of the paper over which the chloroform had extended, and which probably has a yellow tint, choosing the deepest coloured part. With a glass rod deposit a a single drop of hydrochloric acid over the borax. In a few seconds, should turmeric be present, a distinct red will be produced, which is changed to black or greenish black with solution of potash, but no change, except a slight bleaching, takes place if the yellow is caused by rhubarb colours only. A drop of solution of potash instantly changes the yellow stain of turmeric to a more

or less brown tint, while a pure rhubarb gives a bright reddish-purple colour.

For delicate operations, a saturated solution of boracic acid is preferable to the powder borax, so that any obstruction of view by the white powder may be obviated ; but it is necessary in either case to use hydrochloric acid, which quickens and intensifies the action of the boracic acid.

By this means turmeric can readily be detected in rhubarb containing only 0·05 per cent. While 0·1 per cent., or seven grains in one pound of rhubarb, gives at once distinct and unmistakeable evidence of its presence.

As turmeric often carries in its train wheaten flour or farina, which can be best identified under the microscope (*vide* PHARM. JOURNAL, vol. ii., 3rd series, p. 841), rhubarb in which it is found should always be looked upon with suspicion.

It is gratifying to be able to state that of some thirty-six samples procured in different parts of the United Kingdom, only in one have I found turmeric ; and strangely it was in a specimen of the old time Turkey, which a friend had carefully stored as a curiosity. The quantity present however was so small, about 0·07 per cent., that it could hardly be called a wilful adulteration, and may be accounted for when we remember that it is, or was, the practice of some dealers to rub the roots with turmeric to improve the colour. Some such roots had no doubt been used in this instance for powdering.

That no one may be deterred from testing every parcel of rhubarb before taking into stock, I have only used chemicals found on the shelves of every pharmacy, and may just add that five samples may be tested in as many minutes, leaving no apparatus soiled but a glass rod and pill tile, and at the cost of a fluid-drachm of methylated chloroform.

European in East Indian Rhubarb.—The observation of the regularly varying depth of tint of the yellow stain on paper, given by different rhubarbs with chloroform, suggested this test as a useful and ready means of determining not only the absence of turmeric, but also the quality of the drug.

East Indian rhubarb, sound, pale in colour, dense, and freed from the cortical layer, when reduced to powder gives up almost no colour to chloroform. A dark-coloured but otherwise sound piece gives but a slight tint, while the cortical layer gives a more distinct yellow, as does in a yet more marked degree the interior of such pieces as are worm-eaten and rotten.

English indigenous rhubarb even when carefully selected gives a deep yellow tint, which is yet more intense from cortical and faulty pieces.

French indigenous rhubarb which sometimes appears in commerce in this country (*Vide* PHARM. JOURNAL, vol. ii., 3rd series, p. 1009), though in external appearance and density greatly superior, is in therapeutic value and chemical characteristics much like our own native root, and gives up about as much colour to chloroform.

Of the character of the stain given by inferior or false rhubarbs, excepting its intensity, as compared with that produced by fine East Indian root, I have unfortunately been unable to distinguish any peculiarity such as would lead to its unfailing detection : still the constancy of the variation, according to the kind of rhubarb used, is such, I think, as ought to give a reliable index of quality.

A powder offered as East Indian rhubarb, of pale brilliant colour, having the usual characteristics of that variety, should give but an exceedingly pale yellow tint. Should a deep yellow be given I would suspect English or French contamination. An East Indian powder of a dark hue however may give almost as deep a colour as English, and still be genuine ; though by this colour I would judge it was the product of unpicked roots, trimmings, or even worm-eaten pieces, according to the depth of tint.

The few specimens of Turkey rhubarb I have been enabled to experiment upon, through the kindness of several friends, yield results like East Indian.

The cause of this varying colour yielded by different rhubarbs is somewhat obscure, the chemistry of the drug being as yet far from satisfactorily elucidated. Chloroform seems to dissolve out chiefly the resinous principles erythroretine, phæoretine, (and aporetine ?) which exist in varying quantity in different parts and varieties of root, while the crystalline principles chrysophanic acid and emodine are left behind.

Beautiful aggregates of granular crystals of chrysophanic acid may be easily obtained by percolating ether after chloroform through East Indian rhubarb, and allowing the ether to evaporate spontaneously. It is noteworthy that English and French rhubarbs treated thus yield no such crystals, the residue being a minute quantity of pale brown gummy extractive ; though from all varieties distinct brownish acicular crystals, probably emodine, will be observed on the sides of the evaporating basin.

It may be suggested that chrysophanic acid which is recognized as the chief principle of rhubarb, by continued exposure to atmospheric influences, absorbs oxygen and is converted into what is at present known as the resins erythroretine and phæoretine, which some have not accepted as distinct principles, but assert to be "nothing but impure chrysophanic acid" (Batka). Being thus changed in the exterior insect-perforated and spongy portions of the root into amorphous resins soluble in chloroform, we may trace in imagination the cause of the deep yellow stain given by deteriorated roots.

The formulæ slightly bear out this theory, that of chrysophanic acid given by Rochleder and Heldts, who seem to have obtained it from the lichen *Parmelia parietina*, is $C_{10}H_8O_3$, and that given by Thann, who procured it from rhubarb, is $C_{17}H_{10}O_2$, while that of phæoretine is stated as $C_{16}H_{10}O_7$, and erythroretine $C_{19}H_{18}O_7$ by Gmelin, whose formula for chrysophanic acid is $C_{14}H_{10}O_3$ (altered to new notation).

Chrysophanic acid gives with caustic alkalies a red colour, and erythroretine a bright purple, as may be observed on touching the yellow rhubarb stain with solution of potash.

With a substance such as rhubarb, varying in chemical as well as physical characteristics, great care must be exercised before pronouncing definitely upon any test for distinguishing between the varieties, depending upon such a minute difference as depth of tint. While putting forward this method of identifying European in presence of fine Eastern grown rhubarb with some degree of confidence, having found unvarying results from the examination of well-nigh one hundred specimens, it is much to be desired that others would take up the subject and confirm or discredit the results I have obtained.

It is necessary that day-light be used in following these tests, as gas, or other common artificial light being yellow, the delicate tints are thereby rendered invisible.

Turmeric in Aromatic Chalk Powder.—As with bright-coloured rhubarb, so it is not uncommon to hear turmeric suggested as the cause of the fine yellow colour of some makes of aromatic chalk powder.

This and other powders containing saffron may be tested in exactly the same manner as above directed for rhubarb. Polychroite, or crocine, the colouring principle existing to the extent of 50 to 60 per cent. (Pereira) in hay saffron is quite insoluble in chloroform, which only dissolves out a small quantity of yellowish oil. Aromatic chalk powder should therefore give no yellow stain with chloroform, a very small proportion of turmeric will thus be at once detected.

The saffron yellow, which may be obtained by using alcohol instead of chloroform, unlike that of turmeric, is changed to green by concentrated nitric acid, and to indigo blue, fading to dirty-red and brown, by sulphuric acid.

Turmeric in Mustard.—In "mustard condiment" turmeric will be found by the same process, though like the gilding on otto bottles, it is generally expected, and not so

likely to disturb a proper estimation of the quality; besides, it seems to serve an important purpose in keeping the article presentable for a week or more after being made, while a pure flour soon becomes unsightly, and has to be renewed for table use almost daily.

Mustard branded "genuine" should contain no turmeric.

Other applications of the principle involved in this test will no doubt suggest themselves to many pharmacists.

The author was thanked for his paper, but want of time precluded its discussion.

THE PLACE OF MEETING NEXT YEAR.

The PRESIDENT: You are doubtless aware of the circumstances that have rendered it undesirable that the next meeting of the Conference should be held at the same place as that of the British Association, and the question has arisen, what place shall we select instead of Belfast. Connected with this subject, I have received the following letter from the President of the Pharmaceutical Society:—

"*Pharmaceutical Society of Great Britain,*
"17, *Bloomsbury Square, W.C.*
"*August 7th*, 1873.

"The President of the
British Pharmaceutical Conference:

"My dear President,—I have been requested by the Council of the Pharmaceutical Society of Great Britain to convey to you the following resolution, passed at their meeting yesterday, August the 6th:—

"'That in the event of the members of the British Pharmaceutical Conference deciding to hold their meeting next year in London, the Council authorize the President of the Pharmaceutical Society to write to the President of the Conference, offering the use of the Society's rooms for the purposes of the meeting, and the Council further desire to add that they will be happy to afford every facility for promoting the success of the meeting.'

The VICE-PRESIDENT seconded the resolution, which was carried unanimously.

"And I assure you, Mr. President, that not only will the Council of the Pharmaceutical Society be glad to welcome the Members of the British Pharmaceutical Conference should they determine to meet in London next year (1874), but also that every member of the Pharmaceutical Society, and every pharmacist in London and the Metropolitan Districts, will be glad to welcome and entertain their brethren of the Conference.

"I remain, my dear President,
"Yours sincerely,
"THOMAS HYDE HILLS,
"*President of the Pharmaceutical Society of Great Britain.*"

The Executive Committee have considered the question fully, and they recommend that the Conference should meet next year in London, the exact time being left to the Committee to fix, in such a manner as may least interfere with the arrangements of the Pharmaceutical Society and those of the British Association.

The recommendation was agreed to.

The following letter was read:—

"*Glasgow Chemists and Druggists' Association,*
"*Andersonian University.*
"132, *London Street, Glasgow,*
"*September 9th*, 1873.

"Prof. Attfield,
"Hon. Sec., British Pharm. Conference,

"Sir,—I am instructed by the Council of the above association to express the hope that Glasgow may be honoured in the year 1875 by the presence of the British Pharmaceutical Conference, and to promise the members of the Conference a most hearty welcome.

"I have the honour to be, Sir,
"Yours most respectfully,
"JOS. A. CLARKE,
"*Hon. Sec.*"

THE ELECTION OF OFFICERS.

The PRESIDENT: The next business is the election of officers for the ensuing year.

Professor ATTFIELD: The Committee suggest the following list of officers:—

President.

THOMAS B. GROVES, F.C.S., Weymouth.

Vice-Presidents who have filled the office of President.

H. DEANE, F.L.S., Clapham, London, S.W.
Professor BENTLEY, F.L.S., M.R.C.S., London.
D. HANBURY, F.R.S., F.L.S., Clapham, London, S.W.
W. W. STODDART, F.C.S., F.G.S., Bristol.
H. B. BRADY, F.L.S., F.C.S., Newcastle-on-Tyne.

Vice-Presidents.

T. H. HILLS, F.C.S., London.
J. WILLIAMS, F.C.S., London.
R. REYNOLDS, F.C.S., Leeds.
CHAS. H. SAVORY, London.

Treasurer.

G. F. SCHACHT, F.C.S., Clifton, Bristol.

General Secretaries.

Professor ATTFIELD, Ph.D., F.C.S., 17, Bloomsbury Square, London, W.C.
F. BADEN BENGER, 1, Market Place, Manchester.

Local Secretary.

M. CARTEIGHE, F.C.S., London.

Editor of the Year-book.

(The Editorship is at present vacant.)

Editor of the Transactions.

Professor ATTFIELD.

Other Members of the Executive Committee, 1873-4.

F. C. CLAYTON, Birmingham.
C. EKIN, F.C.S., Bath.
T. GREENISH, F.C.S., London.
W. MARTINDALE, F.C.S., London.
R. PARKINSON, Ph.D., Bradford.
F. M. RIMMINGTON, Bradford.
L. SIEBOLD, Manchester.
F. SUTTON, F.C.S., Norwich.
C. UMNEY, F.C.S., London.

Auditors.

M. ROGERSON, Bradford.
A. ALLCHIN, London.

A ballot having been taken the officers were declared to be duly elected.

ELECTION OF MEMBERS.

During the day the following gentlemen were elected Members of the Conference:—Mr. J. M. Cuthbert (Bedford); Mr. W. Tucker (Bridport); Mr. R. Watkinson (Bamford).

VOTE OF THANKS TO THE LOCAL COMMITTEE.

Mr. SCHACHT: It has been more than once my pleasant duty to propose a resolution thanking the Local Committees of the different towns in which we have met for their successful efforts in organizing the annual meetings. It is evident to those who come from a distance that the success of these meetings depends largely upon the energy and cordiality with which the Local Committees act. On this occasion we can all testify to the brilliant success which has resulted from the efforts

of the Local Committee of Bradford. I beg to move "That the cordial thanks of this assembly and the non-resident members be given to Mr. Rimmington, Dr. Parkinson, Mr. Rogerson, and the other members of the Local Committee for their most successful efforts in organizing the present meeting."

Professor ATTFIELD: It is with the greatest pleasure that I second the resolution. As Secretary of the Conference I have of necessity been thrown into constant communication with the gentlemen named in the resolution, and I have been much struck by the care and forethought with which the arrangements for the meeting have been made by the Local Committee. The Local Committee had considerable trouble in providing rooms for the Conference, and at length succeeded in obtaining those in which we have assembled. Let me add that none of us from a distance can ever forget the hospitality we have received in Bradford on all sides.

The PRESIDENT: Before putting the resolution I should wish to add my personal testimony to what has fallen from Mr. Schacht and Professor Attfield. The task of the Local Committee on this occasion has been unusually difficult, and I can only express my personal thanks to them for the kindness with which the wants of the visitors have been provided for.

The resolution having been put, was declared carried, amid loud applause.

Dr. PARKINSON: I can only express my obligation for the vote of thanks which you have passed for the little the Local Committee have done in the matter, although I may say that that little has been done with hearty good will. I was one of those who were present at Newcastle when the Conference was originated, and I have attended it as often as I could since then. Hence my interest in it and the interest of my colleagues was and is great and what we have done has been done *con amore*.

Mr. GROVES (the President-Elect): I may say that the nomination of the officers for the ensuing year took place in my absence, and that I was never more surprised than when I entered the room this morning to find that I had been nominated as President for the ensuing year. I should not have felt astonished at receiving a step in promotion, but this highest honour is one altogether unmerited. I do not know what to say on the occasion except that I will not show the white feather, and that I will endeavour to discharge the duties you have imposed on me to the best of my power.

I have to propose a vote of thanks to the president and committee of the Church Institute, of Bradford, for their kindness in lending us this handsome room in which to hold the Conference.

Mr. BENGER: I beg to second the vote, and I only regret that we were not sufficiently numerous to quite fill the room.

The vote was agreed to.

THE RETIRING PRESIDENT.

Dr. EDWARDS: I beg to propose that the thanks of the Conference be given to Mr. Brady for the excellent manner in which he has conducted this meeting. To a large extent Mr. Brady has been the backbone of the Conference since its establishment, notwithstanding his numerous other scientific researches and business engagements.

Mr. BELL (Bradford) seconded the vote.

Mr. SCHACHT: I shall not offend your taste by putting this vote to the meeting, because I am sure that it will be carried by acclamation.

The vote was declared carried amid loud applause.

The PRESIDENT briefly expressed his thanks for the cordial manner in which the vote had been agreed to.

THE SECRETARIES.

The PRESIDENT: I beg, gentlemen, that you will not separate without allowing me to propose a vote of thanks to the Secretaries who have so ably discharged their multitudinous and laborious duties.

The vote was also heartily agreed to.

Professor ATTFIELD: I thank you for the manner in which you have recognized my services. So long as there is good work to be done, and I can do it, I shall gladly continue to occupy my present position.

Mr. BENGER also replied.

The Conference then terminated.

Parliamentary and Law Proceedings.

THE COLLECTION OF DEBTS.

On Friday, September 5, Mr. Charles Foottit, of Great Marlow, chemist and druggist, was sued in the Guildhall County Court, London, by Messrs. Stubbs and Co., for the sum of 20*s*. The plaintiffs had been employed by the defendant to collect debts, and the sum in dispute was for a subscription in advance. Mr. Footit pleaded that being dissatisfied with the manner in which the terms of the contract were fulfilled, he had determined not to continue his subscription. He contended that his order had been given in the country, and therefore he had not troubled to send back the circulars. The registrar held that no cause for action could lie at that court, and allowed Mr. Foottit 20*s*. expenses for coming to London to defend the action.—*From the South Bucks Free Press.*

POISONING BY MORPHIA.

The coroner's inquest upon the body of Mrs. McLeod, the earlier proceedings of which were reported last week (p. 336), was resumed on Thursday and concluded at a late hour on Saturday night, Oct. 25. The report of the medical gentlemen who conducted the *post mortem* examination was to the effect that there existed no disease of any vital organ such as would have caused death, and that the appearances were such as would be produced by a fatal dose of morphia. The report of Professor Maclagan, of Edinburgh, upon an analysis of the contents of the stomach and intestines of deceased, stated that he had failed to detect morphia, which he suggested had been decomposed. Traces of the atropine which was injected were detected.

After further evidence as to the affectionate terms upon which Dr. and Mrs. McLeod lived together, the Coroner, in summing up the evidence, said the statement of Mrs. Golland, mother of the deceased, and Miss Golland, as to the affectionate terms upon which Dr. McLeod lived with his wife, rendered a charge of murder untenable. The next question was—was it manslaughter — the unlawful killing of another without malice, either expressed or implied, either by the commission of some unlawful act, or in the pursuit of some lawful act criminally or improperly performed? Again, if a surgeon or physician gave a patient a potion to cure him, and, contrary to his expectation, he killed him, that was neither murder nor manslaughter, but misadventure. The coroner warned the jury against attaching weight to the evidence of a girl as to Dr. McLeod having taken liberties with her. That evidence was open to grave suspicion. It was in evidence that Mrs. McLeod had lost her rest in nursing her sick son, and that was Dr. McLeod's assigned reason for exhibiting an opiate, which he went to the druggists' to purchase. At this time a bottle of hydrate of chloral was standing on the mantel piece capable of destroying two lives. Dr. McLeod obtained 20 grains of morphia and continued to administer it in repeated large doses in a manner quite contrary to accepted theories. That Dr. McLeod should hold such opinions was extraordinary; but they had it in the evidence of Dr. Walker that Dr. McLeod's brain had been degenerated—probably by his twenty years' residence in India. His conduct was utterly irreconcilable with the healthy action of the brain.

The jury retired at nine o'clock. At five minutes to eleven the foreman returned and told the coroner that the

jury could not agree upon their verdict. They were divided into three parts. One part was for a verdict of wilful murder against Dr. McLeod, one was for manslaughter, and one for acquittal. The law upon the subject was referred to, and it was found that if the jury could not agree they must be locked up ; but if that was ineffectual, the coroner should adjourn until the Assizes for the opinion of the Judge. The jury being still unable to agree at a few minutes before midnight, the Coroner adjourned until the next Assizes. Immediately afterwards the chief constable of the city said it was his duty to take Dr. McLeod into custody on the charge of causing the death of his wife. Dr. McLeod, who made no remark, was immediately admitted to bail.

Reviews.

Local Botany. By C. B. Allen. Reprinted from the Cornwall Polytechnic Society's Report, 1872. Falmouth.

This little contribution to the history of the flora of a western county is the work of a pharmaceutist who has recently passed his examination. We gladly welcome efforts in this direction. Though "culling of simples" be not now the recognized occupation of our craft, botany is still in close alliance with pharmacy, and whether we see further developments or not of the uses to which the medicinal virtues of our native plants may be applied, it is obviously of importance as well as of interest to the pharmaceutist to be acquainted with them. The therapeutical properties of conium, for instance, are clearly not availed of to their fullest extent. We were recently told by a surgeon that a woman applied to him respecting a rodent cancerous ulcer of the lip ; he proposed to operate, but deferred doing so on account of her weak state. When she came again, in a few days, it was almost well ; and he found she had treated it with the juice of hemlock, chamomile and a species of ragweed. He attributed the cure to the conium, which, though not unfrequently used in such cases, has fallen into disrepute, mainly because it is with difficulty procured in a perfectly fresh state, and it speedily becomes inefficacious. He spoke of this as but one of the instances within his own knowledge. Then again, accidents occur from eating aconite roots, belladonna berries, etc. Quite recently, one occurred to a serious extent from the roots of *Œnanthe crocata*, which gave rise to quite a controversy in the papers as to what the plant was. Ought a druggist to be absolutely ignorant of these and other poisonous plants if applied to in an emergency ? Surely not ; and although an examination in botany has been decried by some, it is clearly necessary that a decent pharmaceutical education should embrace some practical acquaintance with the science. We believe that it should be an adjunct to all education. Whilst many amongst pharmaceutists have been and are honourably distinguished for their knowledge of botany as connected with materia medica, there are doubtless many others who are known in their respective districts as ardent local botanists. As we write, looking from the side of the Malvern Hills over the beautiful valley of the Severn, the name of one occurs to us who has left an honourable name in its botanical records, the late Mr. T. W. Gissing, afterwards of Wakefield. Our present author is emulous to walk in the same path. The pharmacist of this country is, alas ! a man too often chained by stern necessity behind his counter, but he is also a man who in contradistinction to an ordinary tradesman is expected to know something beyond the mere routine of his business ; he is expected to be a man of general information, and the more he can show that he is not a mere *épicier*, the better will be his position, and correspondingly, if he take care of it, his business.

The west of Cornwall, the district to which this pamphlet refers, differs in its climatic influences from the other English counties. The comparative absence of frost enables many representatives of a vegetation that requires a greenhouse in other parts of England to flourish here in the open air. Orange trees and camellias bear the winter out of doors. We have seen the *Agave americana*, so well known as the "aloe," throwing up a magnificent flowering scape fifteen to twenty feet in height. Numerous other plants might be cited, and it would be an interesting experiment to establish a "physic garden" here, confined to sub-tropical plants. The present list bears evidence of variation from the species to be met with in most midland and southern counties. *Echium violaceum*, and *Illicebrum verticillatum*, Cornish plants, and the beautiful *Erica vagans* are noted, but the pretty *Sibthorpia europea* and *Physospermum cornubiense* do not appear to occur in this district of Cornwall. It would be foreign to our purpose to dwell upon the purely botanical aspect of the distribution of species, but we observe that plants common to the Mediterranean strike the Channel Islands, the coasts of Devon and Cornwall, and the south of Ireland, working their way northwards with more or less vigour, mostly coastwise, many getting as far as, but not beyond, the midland counties. Quite recently *Plantago arenaria*, a native of eastern Europe, was found to have established itself at a point on the Carmarthenshire coast, but it is doubtful how long it may remain, though it may have more chance than if recognized as a British plant, the rarities amongst which are rapidly disappearing under cultivation and the ruthless hands of collectors. The list given of medicinal plants is pretty comprehensive, whence it would appear that a pharmaceutist may obtain his requirements in good condition without much difficulty. In a revised edition which we think might still yield further information, a few printer's errors, probably the result of a country press, might be avoided.

Scientific Handicraft : a Descriptive, Illustrated, and Priced Catalogue of Apparatus suitable for the Performance of Elementary Experiments in Physics. By John Joseph Griffin, F.C.S. Volume I : Mechanics, Hydrostatics, Hydrodynamics, and Pneumatics. 1873.

Every one engaged in experimental chemistry must be familiar with the excellent catalogue of apparatus, published by Mr. Griffin under the title 'Chemical Handicraft,' and, moreover, must have had frequent occasion to acknowledge its usefulness in supplying information as to the construction and use of such apparatus as must necessarily be obtained from the maker, as well as in giving practical hints for numberless little contrivances that can very well be put together at home. In bringing out the 'Chemical Handicraft,' the editor announced his intention of publishing a series of works on the same plan, but relating to apparatus for the illustration of other branches of science. After some considerable delay he now partly redeems this promise by presenting the first volume of the proposed series.

These books, as most of our readers are aware, are illustrated and priced catalogues of the apparatus made and sold by the firm of J. J. Griffin and Sons, but those who have used them will admit that they are in reality something more than that ; and that they deservedly rank far above ordinary specimens of business literature. The 'Chemical Handicraft' contained an account not only of common forms of apparatus, but was characterized by the introduction of many ingenious contrivances.

In the new volume we find all the ordinary experiments and apparatus intelligibly described with the aid of a sufficient number of very fair illustrations, but being restricted to elementary matters, few attempts seem to have been made to improve or modify long familiar forms of instruments. The illustrations consequently exhibit nothing remarkable for novelty. The directions for manipulation seem in some instances—for example, "barometer"—to be less complete than, from experience

of the 'Chemical Handicraft,' we should have expected. Nevertheless, we ought to add that there are here and there very timely hints as to the preservation of apparatus, which will be acceptable to many amateurs, and probably, in these days of science in schools, to many teachers unfamiliar with the practical employment of apparatus.

We have said nothing about the prices, but we fear with the present cost of coal, metals, and glass, the prosecution of experimental science is not likely to become less expensive than it always has been.

THE HALF-YEARLY ABSTRACT OF THE MEDICAL SCIENCES: being a Digest of English and Continental Medicine. By WILLIAM DOMETT STONE, M.D., F.R.C.S. January to June, 1873. London: J. and A. Churchill.

Dr. Stone continues to attempt single-handed an undertaking which can be satisfactorily performed only by division of labour. His volume retains most of the features of its predecessors, while we observe no improvement in the spelling of German words, or, indeed, in the requisite knowledge of German science. A compiler who can pass such things as "Langënbeck's Archiv" (p. 164); "Archiv für Gynäkologi" (p. 294), and so forth, is not likely to have much acquaintance, at first hand, with treatises in the German language. The 'Abstract,' moreover, teems with matter which, except for its filling up space, has no right to be republished. What good can possibly accrue to any reader from this sentence of Dr. Ch. Kidd on chloroform (p. 138):—"The beautiful discovery of anæsthetics, that we owe to Morton, coming in, as Lord Bacon says, aura leni with its 'still small voice,' is ill-adapted to all the contentions, exparte advocacy, and twenty years' continuous doubt which have beset it; scribendi recte, etc., clearness, good sense, and practical experience, the first principles of authorship, too often lost in hasty generalization." The next time Dr. Kidd talks of the "first principles of authorship," let him express himself in grammatical English.

"Turpe est doctori cum culpa redarguit ipsum."

In the "Appendix" Dr. Stone inserts a rather gratuitous puff of "chlorozone" as a disinfectant. His admiration of the commodity is not shared by competent chemists.

BOOK RECEIVED.

PRACTICAL EXAMPLES IN QUANTITATIVE ANALYSIS, forming a Concise Guide to the Analysis of Water, etc. By ERNEST FRANCIS, F.C.S. London: H. K. Lewis. 1873. From the Publisher.

Obituary.

Notice has been received of the death of the following:—

On the 4th October, 1873, Mr. James Brocklehurst, Pharmaceutical Chemist, of Hyde, Cheshire. Mr. Brocklehurst had been a Member of the Pharmaceutical Society since 1842, and for many years had acted as Local Secretary for Hyde.

On the 1st October, Mr. John Dickinson, Chemist and Druggist, of 118, Great College Street, Camden Town.

The following journals have been received:—The 'British Medical Journal,' Oct. 25; the 'Medical Times and Gazette,' Oct. 25; the 'Lancet,' Oct. 25; the 'London Medical Record,' Oct. 25; 'Medical Press and Circular,' Oct. 25; 'Nature,' Oct. 25; 'Chemical News,' Oct. 25; 'Gardeners' Chronicle,' Oct. 25; the 'Grocer,' Oct. 25; 'Journal of the Society of Arts,' Oct. 25; 'Grocery News,' Oct. 25; 'Produce Markets Review,' Oct. 25; 'Carlisle Patriot,' Oct. 23 and 24; 'Leicester Journal,' Oct. 17; 'Practical Magazine,' for November.

Notes and Queries.

[362.] COCHINEAL COLOURING.—*E. Nicholson* will find—

Carmine . . .	60 grs.
Liq. Potas. . .	qs. to deepen colour.
Spt. Vin. Rect. .	℥ x.
Aquæ . . .	ad ℥ x.

a good form for pink colouring.—L.

[363.] MARKING INK WITHOUT NITRATE OF SILVER.—One dram of aniline black is rubbed up with sixty drops of strong hydrochloric acid and 1½ oz. of alcohol. The resulting liquid is then to be diluted with a hot solution of 1½ drachm of gum arabic in six ounces of water. This ink does not corrode metallic pens; is affected neither by concentrated mineral acids nor by strong lye. If the aniline black solution be diluted with a solution of 1½ oz. of shellac in 6 oz. of alcohol, instead of with gum water, an ink is obtained which when applied to wood, brass, or leather, is remarkable for its extraordinary black colour.—*Year Book of Pharmacy*, 1870.—J. B

[365.] POISONOUS KIPPERED MACKEREL.—*C. S.* writes that four persons after eating kippered mackerel have suffered from an effusion of blood into the brain. In each case, the face became almost purple, a burning heat pervading the whole of it, and there was a heavy pain in the temple that lasted some time. *C. S.* asks whether these fish are ordinarily unwholesome when cured.

CHLORODYNE.—*B. G.* and *P. C.* write, in reference to a form given for Chlorodyne in vol. i. of the present series of the PHARMACEUTICAL JOURNAL, p. 496, that they have attempted to make the preparation as there directed, but have not succeeded, because the ether separates. We have therefore communicated with the correspondent who furnished the formula, who says:—"I must confess I have at times subsequently been somewhat puzzled at the different results from the same process. I have come to the conclusion that some treacle will make very good chlorodyne alone, and some will not make it all. For some time I have used equal parts of treacle and muc. tragac. cold, in place of the hot treacle, from which I get more uniform—I think I may say quite uniform—results."

PHOSPHORUS PILLS.—The following extract from a letter on the subject of phosphorus pills, by Mr. B. S. Proctor, of Newcastle-upon-Tyne, has been placed at our disposal by a correspondent:—

"My book does not treat of phosphorus pills. I have had no experience of them, consequently delayed answering yours received till I had time to try the formula. I take bread-crumbs to mean any excipient which I think best.

"A general consideration of the question suggested the following mode of procedure, which I have found work without difficulty. It is my first attempt at phosphorus pills. I have made twenty-four and send you twelve of them:—

"℞.	Phosphorus	gr. vj.
	Bisulph. Carbon	gtt. vj.
	P. Tragacanth	gr. xij
	Sapo Mollis	gr. xxiv.
	Pulv. Glycyrrh., Conf. Rosa.	āā ℥ss.

"In pil. xxiv.

"Put the P into a test tube, with half the CS_2; whilst it is dissolving weigh the tragacanth and put it into the mortar. Have the soap, etc., weighed upon paper, ready to be added at the right moment. Then pour the solution of P on the gum tragacanth, rinse the test-tube with the other half of the CS_2, adding this to the other, rub them together. The CS_2 is almost immediately volatilized, and the P would take fire if the soap were not quickly combined with it. As soon as these are rubbed to a smooth paste, add the liquorice and conserve, work into a mass, divide into pills, and coat with varnish."

Correspondence.

The Preliminary Examination.

Sir,—I observe a letter in this week's Journal, signed by Mr. Fryer, on the subject of the Preliminary examinations. Doubtless he has had more schooling than some who call themselves by the dignified name of "pharmacist," but it is a question if he be not one of those very men to whom Mr. Haselden refers, and whose existence he denies—the over-educated; and whether a little more experience will not dissipate some of his utopian ideas.

Surely there is sufficient demand already upon the pockets of the rising generation of pharmacists without imposing a stringent scholastic examination and its consequent expense, as Mr. Fryer advocates. Is the pharmacist now so much overpaid for the knowledge already dearly purchased by the expenditure of time and labour that he can afford still further to increase the outlay at starting? I think not.

There can be no doubt that the pharmacist is called upon frequently to perform duties of a professional character, but it is an unmistakable fact that his calling is principally mercantile, hence he does not and never can expect to rank side by side in the social scale with his friends of the medical profession. What folly then to insist on a standard of education utterly beyond his requirements—such as a university matriculation.

I endorse Mr. Haselden's opinion that the Pharmaceutical Society is and ever should be the proper examining body for those who desire to wield the pestle, as well as for those who are further advanced in the art of compounding; and although a system can never be made so perfect but that a flaw may somewhere occur, yet the practice of having one standard examination, superintended by qualified men of our own body, is as perfect as could be devised. The possibility of irregularities such as have been asserted to occur under the present *régime* might be reduced to a minimum if, instead of the examinations being conducted in every town that boasts a local secretary, they were only held in certain towns, each commanding a surrounding district. In conclusion, let us rather trust to the dictates of common sense and experience than to high-flown theories.

Charles W. Taylor.

Darlington.

Sir,—Though like my friend Mr. Fryer I have my doubt as to whether the Preliminary examinations would not be better conducted by some distinct examining body, still I think we seem compelled by the wording of the 6th Section of the Act of 1868, to provide them for the convenience of such candidates as may prefer to present themselves to our Society in preference to any other. Such being the case, I would suggest that the number of centres at which they are held be considerably reduced; say to about twelve for England and four or five for Scotland; as it must be evident to all that it is quite unnecessary to hold examinations at many of the places named in last week's Journal. Witness the absurdity of holding examinations at four towns in Norfolk, a county whose extreme breadth is only about seventy miles.

At each of these sixteen or seventeen centres there might be a paid superintendent, who should devote his whole attention to the candidates during the examination, and on its termination hand the papers to the local secretary. By this means all chance of copying would be prevented and the local secretaries relieved of that present call upon their time, which some do not seem able to afford, whilst the extra expense to the examinee would be so slight that I should not fear any complaints on that score.

Whilst writing on the subject of examinations I may perhaps be permitted to express my regret at finding so few of the Minor candidates have any intention of even trying to pass the Major; a circumstance I principally attribute to the apparent impossibility of getting the public to recognize the difference between pharmaceutical chemists and members and associates of the Society, and also to the great mistake of granting to associates in business privileges almost identical with those enjoyed by pharmaceutical chemists. The only remedy for this state of things seems to be either the granting of a new title (such as Fellow of the Society) to such members as are also pharmaceutical chemists, or compelling the attendance of all students for a certain period at such schools of pharmacy as the Council may agree to recognize.

By the former method students would receive an extra inducement to pass the Major, and the latter rule would prevent the excuse so often made of not having had sufficient time to study for it.

Edward H. Storey.

Removal of Nicotine from Tobacco Smoke.

Sir,—In the Pharmaceutical Journal for August 30, under the head of "Notes and Queries," I find a quotation from the *Canadian Pharmaceutical Journal* relative to the above subject.

I find it stated that "a patent has been taken out for a process for the removal of nicotine from tobacco. The smoke is drawn through a sponge saturated with a solution of tannic acid, tartaric or citric acids, glycerine, and a flavouring ingredient, such as Florida or clove water."

I beg to direct the attention of your readers to a note in the *Lancet* of April 7th, 1866, in which M. Melsens' method of preventing the baneful effects of nicotine is indicated. It will be seen on reference to this note that the method devised by M. Melsens is essentially the same as that for which the patent has been obtained.

In a letter of mine in *Scientific Opinion*, April 18th, 1866, I thus comment on M. Melsens' method. "The chemical theory on which his method is based is strictly correct, but I cannot say as much for the method itself. I have tried many experiments with the ball of cotton impregnated with the tannic and citric acids, and in every case I was able to detect nicotine in the smoke, and that too in considerable quantity. I am bound to say, however, that the quantity was by no means so great as when the cotton ball was not used. In a manuscript work which I communicated to the Royal Academy of Medicine of Belgium on the 'Effects of Tobacco' I describe an apparatus for bringing the tobacco smoke through *water* before allowing it to enter the mouth. After I read of M. Melsens' method I substituted a solution of tartaric and citric acids for the water, and in no instance could I then detect the slightest trace of nicotine in the tobacco smoke." I would ask whether it is strictly fair of our Canadian friends to take out a patent for a process which has been invented seven years ago, without tendering some acknowledgment to those who have been, so long ago, working at the subject.

PHARMACEUTICAL NOTES.*

BY J. B. BARNES.

Guaiacum resin, as it is imported, is exceedingly impure, which will be seen by the following experiments:—Sixteen ounces of guaiacum resin supplied by the wholesale druggist, a sample of which I place before you, was exhausted by boiling in rectified spirit, the quantity of purified resin obtained was 13 ounces and 288 grains; the insoluble woody particles weighed 2 ounces and 139 grains, or 14·4 per cent. of impurity.

Another experiment was made by operating in a similar manner upon 8 ounces of powdered guaiacum resin obtained of a wholesale house, which yielded about 7 ounces of pure resin, and 412 grains or 11·7 per cent. of impurity, consisting of a brown bulky powder.

These results show that pure guaiacum resin should be used for all pharmaceutical purposes, in preference to the guaiacum resin as imported and, I believe, universally used.

Simple extract of colocynth, prepared by two macerations of the pulp in cold distilled water, pressing, boiling the liquor, separating the coagulated matter, evaporating to dryness, and exhausting with rectified spirit, yielded the same amount of extract as was obtained from the same quantity and sample of colocynth pulp which had been exhausted with proof spirit and evaporated to dryness until the weight was constant. By this means the use of a large quantity of spirit and subsequent distillation was avoided.

The infusion of roses of the Pharmacopœia, as is well known to all pharmaceutists, loses its transparency when cold. I find that when one part of glycerine is added to eight or nine parts of infusion of roses it at once becomes bright and continues so as long as it keeps good. Also that when three fluid-drachms of glycerine are added to a mixture composed of one grain sulphate of quinia, one minim of dilute sulphuric acid, and nine fluid-drachms of infusion of roses, the precipitate of tannate of quinia which forms is dissolved, and the result is a beautifully bright solution. The precipitate which occurs in gargles containing tannic acid and infusion of roses can also be dissolved by the addition of two fluid-ounces of glycerine to the pint.

[*The discussion upon this paper is printed at p.* 369]

THE PREPARATION OF LIQUOR BISMUTHI.†

BY C. MÉHU.

In the formula given by Mr. C. H. Wood for the preparation of Liquor Bismuthi‡ there are two equivalents of citric acid ordered to one equivalent of bismuth. I have satisfied myself many times that a single equivalent of citric acid is sufficient to obtain a perfectly stable solution of bismuth. In this manner an excess of citrate of ammonia in the liquor is avoided. The method which I adopt is as follows:—

I dissolve an ascertained weight of pure bismuth in three times its weight of pure nitric acid, then concentrate the solution and leave it to crystallize. After one or two days the mother liquor which surrounds the crystals is decanted and evaporated in a porcelain capsule at a moderate temperature, so as to completely drive off the excess of acid: in cooling the liquor forms a crystalline mass. All the crystals being put together, I then pour upon them a concentrated solution of citric acid, made with heat. For each equivalent of bismuth I employ an equivalent of crystallized citric acid, being very nearly equal weights of each. The solution of citric acid dissolves completely the crystals of nitrate of bismuth.

In order to obtain citrate of bismuth I divide this solution of nitrate of bismuth in citric acid into two equal parts, and pour into one of them a sufficient quantity of ammonia to dissolve the precipitate that is formed at first, leaving only a slight excess of ammonia, and then add the other portion of the solution. From this mixture there results a very white precipitate of citrate of bismuth, which I wash with warm water as long as it gives any traces of acidity, and then dry in a stove. The washings are acid and contain a large proportion of nitrate of ammonia, with scarcely any traces of bismuth. This can be isolated in a state of sulphide by means of sulphite of sodium.

The citrate of bismuth so prepared dissolves in ammonia; the solution can be diluted at will with water without becoming turbid, and may be preserved for years. I have examined during two years several solutions of bismuth containing from 20 to 50 grams of metallic bismuth per litre without recognizing the least alteration. The solubility of the citrate of bismuth is very rapid and easy; it is only necessary to wash solid citrate of bismuth with a strong solution of ammonia to obtain a perfect solution too strong for ordinary use.

When the solution of citrate of bismuth in ammonia is evaporated upon plates there is left a white residue insoluble in water, but completely soluble, although rather slowly, in ordinary solution of ammonia.

The citrate obtained by the evaporation of the ammoniacal solution yields nothing perceptible to alcohol, unless it contain nitrate of ammonia in excess or some other impurity soluble in that menstruum. The solution of citrate of bismuth in ammonia is not rendered turbid by acetic acid, chloride of sodium, chloride of ammonium, iodide of potassium, ferrocyanide of potassium, or bichromate of potash. It is precipitated by oxalate of ammonia, nitric acid, phosphoric acid, sulphuric acid, and nitrate of urea.

THE PERMANENCE AND PRESERVATION OF PEROXIDE OF HYDROGEN.*

Hitherto it has been accepted as a fact that peroxide of hydrogen is a very easily decomposable compound of hydrogen and oxygen, which, especially in a non-acid state, cannot be kept without decomposition. Böttger however has found that a peroxide perfectly neutral, and particularly well adapted for medicinal use, may be kept for a month together without any change, in an ordinary corked bottle,—indeed that it might be exposed for some time to a boiling heat, without being impaired in the least; then, if the same liquid, cooled, be mixed with a strong solution of cadmium iodide, and a few small crystals of ferrous sulphate be added to the mixture, the

* *N. Jahr. f. Pharm.*

peroxide of hydrogen immediately becomes coloured deep sky blue, just as if it had not been previously heated; proving that it had not suffered decomposition by the heat.

PATCHOULI.*

Patchouli, or Pucha-pat, is the Hindostanee name of the plant from which the perfume is obtained, which is known to botanists as *Pogostemon Patchouli*. It belongs to the order *Labiatæ*, which furnishes us with so many of our aromatic plants, such as sage, thyme, marjoram, rosemary, lavender, mint, pennyroyal, etc. The patchouli is tall and shrubby, not unlike the garden mint in habit, with broad, egg-shaped, opposite leaves, about three inches long, and thick spikes of small purplish-white flowers. It is a native of Penang, Silhet, and the Malay Peninsula, and is imported into Engand from Hindostan and Bengal. In India it is a very popular perfume, being generally sold in the bazaars, besides being used in tobacco for smoking, and for scenting the hair of women. It was not imported into England until 1844, when forty-six cases, some containing fifty pounds, others one hundred and ten pounds, were put up for sale at Garraway's Coffee House. The price asked was only six shillings a pound; but there were no biddings, which proves that its popularity is of but recent date. This lot was brought from New York, to which place it is said to have been taken from China. The plant flowered in Europe for the first time in the winter of 1844, in the greenhouse of a gentleman at Orleans; since then it has been in cultivation in many botanical gardens, and may usually be seen in the Economic House at Kew. Some years ago genuine Indian shawls could always be distinguished by the peculiar odour which they bore, the cause of which was long unknown. It was, however, at length discovered by the French manufacturers that this odour was due to patchouli, and they imported the plant in order to give articles of home manufacture the same perfume. The smell of patchouli may also be detected in Indian ink, in the manufacture of which it is an ingredient. The dried leaves and tops are the parts imported, and these may be bought in the markets in bundles of half a pound each. Dr. Wallich states that a native friend of his told him that the leaf is largely imported by Mogul merchants, that it is used as an ingredient in tobacco for smoking and for scenting the hair of women, and that the essential oil is in common use among the poorer classes of the natives for imparting the peculiar fragrance of the leaf to their clothes. The sachets of patchouli which are sold in European shops consist of the herb coarsely powdered, mixed with cotton wool, and folded in papers. These are simply placed in drawers and wardrobes to drive away moths and insects. The patchouli plant is in great favour with the Arabs, who use and export it more than any other nation. They take up great quantities on their annual pilgrimage, and use it chiefly in stuffing mattresses and pillows. They believe it to be very efficacious in preventing contagion and prolonging life. It is also said to protect clothing from moths. The preparation of the herb is very simple, the tops—about a foot in length—being merely gathered and dried in the sun. It must not, however, be allowed to get too dry, or the leaves will become brittle and crumble in packing. It is recorded that ill effects, such as loss of appetite and sleep, have arisen from the excessive employment of patchouli as a perfume; and it is very probable that such effects would be produced by it upon certain constitutions. The scent is more powerful in dry than in damp places. The odour is due to a volatile oil, which is contained in the leaves and stems. When distilled, it is yellowish-green, with the same smell as the herb, but neither a burning nor an astringent taste. It is almost as heavy as water. A hundredweight of the plant yields about twenty-eight ounces of oil, or, according to a specimen of the latter in the Kew Museum (where may also be seen the plant in its dried state as imported), one ounce of oil may be obtained from two hundred ounces of the herb. It is from this oil that the essence of patchouli is prepared. In the sachets of patchouli, however, the coarsely-powdered leaves are used.

* From the *Journal of Applied Science*.

SOAP-MAKING AND TALLOW-MELTING.

During the past session of Parliament an interesting inquiry was held by a Special Committee of the House of Commons with regard to certain provisions of the Metropolitan Building Act of 1844, which enacts that it shall be illegal after the expiration of thirty years from the passing of the Act—that is, in 1874—to carry on what are termed noxious businesses nearer than fifty feet to a dwelling-house, or forty feet from a public way. Amongst the trades affected by this legislation are soap-makers, tallow-melters, etc., and a good deal of chemical evidence was given in the course of the inquiry as to the processes used in these manufactures. Mr. Cattley, a large soap-maker, testified as to there being nothing noxious in soap manufacture as at present carried on. The principal ingredients used were tallow, palm oil, and resin. All sorts of grease could be used, and they also used alkalies. The greases are boiled with ley, which is formed from boiling alkali, lime, and salt together, a solution thereof being designated "ley." They had never had any complaints as to their works being injurious to the health of the inhabitants of the neighbourhood. Thirty years ago, when this Act was passed, the manufacture of soap was carried on in a very different way from what it is at the present time. The use of steam has effected quite a revolution in the business. In former days the coppers were boiled by open fires; now they are all boiled by steam. The melting of the material also is done in a much more cleanly way. In 1853 the duty was taken off soap. This set the trade free, and allowed chemistry to do a great deal for soap which was scarcely possible before. Prior to 1853 the "ley" was made from barilla and kelp, and in the process of manufacture the residue contained a certain quantity of sulphuretted hydrogen, which was offensive. From this process, too, the "waste ley," after the soap was made, was boiled down again to recover the "neutral salts" in the form of black-ash. This, however, is now all done away with, the "ley" being made from pure British alkali. The smell of the ley, when deprived of soda, is not offensive, though heretofore it possibly was so. At the present time the manufacture of British alkali is different from what it used to be before the salt duties were repealed.

With regard to the tallow used in soap-making, it is described as being particularly pure, especially that which comes from Australia. This description of tallow, it appears, is very largely superseding the Russian, "as the Russians use their own tallow as civilization increases." Soap-boiling and tallow-melting must not be confounded as similar business; they are quite distinct. Soap-makers do not necessarily melt their own tallow. The business of tallow-melting is described as rendering fat to make yellow soap, kitchen-stuff to make mottled soap. One large manufacturer who gave evidence before the committee, described tallow-melting as simply cooking on a very large scale. If the fat be supplied to the tallow-melter fresh, there is no more harm (quoting the same authority) arising from tallow-melting than there is from cooking a sirloin of beef; it is precisely the some thing. Fresh fat is taken from the inside of the animal, is cooked just the same as a large piece of beef for the table; and supposing the fat to be fresh the process is quite innocuous. It is stated that the fat is usually fresh.

Generally the evidence taken by the committee frees both soap-making and tallow-melting from the imputation of being noxious businesses; and it is difficult to see why they should have been included in the Act of Parliament. There is no doubt that many other trades are infinitely more injurious, and of which the Act takes no cognizance.

The Pharmaceutical Journal.

SATURDAY, NOVEMBER 8, 1873.

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE OPERATION OF THE ADULTERATION ACT IN THE DRUG TRADE.

THE recent case in which a fine of ten pounds was inflicted under the Adulteration Act for the sale of effervescent citro-tartrate of soda under the name of "citrate of magnesia" is one in which so many members of the trade might be involved that it has naturally excited considerable interest. We have received a number of letters on the subject, most of which are published in deference to the principle that this Journal should offer facilities for the free expression of opinion. But we cannot concur with some of the views put forward by our correspondents, and in the first place we dissent from the suggestion that it is the province of the Pharmaceutical Society to prescribe names by which such preparations as the one in question should be designated. To say nothing of the possibility that such a proceeding might be regarded with great disfavour by those who object to centralized action by the Society in regard to trade matters, it must be borne in mind that the case in point is so very simple that every one may protect himself by the use of a label which will correctly represent the nature of the article sold. We are glad to see that steps are already being taken in this direction by individuals, and in the interest of the trade we trust their example will be generally followed.

So long as the Adulteration Act remains in force in its present form there will be a possibility of its being applied as an engine of persecution, as in the case now referred to, where there is not really any ground for the charge of adulteration. It is of course intelligible that when a man is charged with selling as a preparation of magnesia an article that does not contain a particle of magnesia, persons ignorant of the essential facts of the case—as magistrates, lawyers, and public writers too frequently are—may well be impressed with the belief that some serious enormity has been practised. Hence we find sensation paragraphs making fun of the trustworthiness of druggists, and on such an erroneous though plausible basis exciting in the public mind prejudices detrimental to the whole pharmaceutical body.

The only blame, however, that can be imputed to sellers of "citrate of magnesia" is that of lending themselves to the practice of calling things by names that do not belong to them. This practice was long since denounced by Mr. SANDFORD in one of his presidential addresses; it has also been formally condemned by the Pharmaceutical Conference, and, if its continuance be fraught with liability to legal prosecution, it seems idle to attempt to excuse it by saying that the public insist upon its use. It is not the public who introduce these articles or name them.

It seems at least equally unreasonable to attempt to shift the responsibility in such cases upon the wholesale dealers or manufacturers, and we think that Mr. MCDERMOTT was specially ill advised in adopting that course in his defence. We would be loth to lend any support to the plea of ignorance as an excuse for the sale of adulterated or inferior articles, and since we think members of our trade should in this respect take higher ground than the grocer or the oilman, we cannot dissent from the magistrate's proposition that a chemist ought to know whether the drugs he sold were genuine. As to this point, too, we must remind our readers that the decisions of the courts have all tended in this direction; so much so, indeed, as to neutralize the intention of the framers of the Act that liability to its penalties should depend upon guilty knowledge of adulteration on the part of the vendor.*

There is another feature in Mr. MCDERMOTT's case which seems worth notice in connection with our recent remarks on alleged substitution of one article for another in dispensing prescriptions.† Consistently with those remarks we will not attempt to raise any objection to the magistrate's declaration that this was a very serious offence, though we still hold the opinion that it is an ideal offence. So far as we can judge from the newspaper reports, there does not seem to have been any ground for introducing a reference to a prescription in this case, though it was in this way the magistrate was induced to inflict such a heavy fine. We should be sorry to impute improper motives to public officers who in the exercise of their duty may be called upon to take steps which seem harsh; but, all things considered, we cannot avoid the conclusion that in the prosecution of Mr. MCDERMOTT there was at least an excess of zeal.

BOTANICAL students will be glad to hear that the new (third) edition of BENTLEY'S 'Manual of Botany,' is now ready. Messrs. CHURCHILL also announce that another work on a kindred subject will shortly be issued in monthly parts. It will be a book on 'Medicinal Plants,' and will be written by Professor BENTLEY and Dr. HENRY TRIMEN. The work will include full botanical descriptions, and an account of the properties and uses of the principal plants employed in medicine, especial attention being paid to those which are officinal in the British and United States' Pharmacopœias. The plants which supply food and substances required by the sick and convalescent will also be included. Each species will be illustrated by a coloured plate drawn from nature.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL,

Wednesday, November 5th, 1873.

MR. THOMAS HYDE HILLS, PRESIDENT.

MR. ALEXANDER BOTTLE, VICE-PRESIDENT.

Present—Messrs. Atherton, Baynes, Betty, Frazer, Greenish, Hampson, Owen, Radley, Robbins, Sandford, Savage, Schacht, Shaw, Stoddart, Sutton, Urwick, and Williams.

The minutes of the previous meetings of Oct. 1st and 22nd were read and confirmed.

The New Bye-Law.

The Secretary read a copy of the letter which had been sent to the Privy Council with the new Bye-Law in pursuance of instructions given by the Council at their last meeting. The letter was ordered to be entered on the minutes.

A Member and an Apprentice who had neglected to pay their subscriptions within the proper time were ordered to be restored to their former status on payment of the subscription and a fine of one shilling.

Elections.

MEMBERS.

Chemists and Druggists.

Akhurst, William Edward .....London.
Dawson, Alfred.....Woking.

ASSOCIATES.

The following having passed their respective examinations, and being in business, were elected "Associates in Business" of the Society:—

Minor.

Matthews, Thomas Averill .....Gloucester.
Moore, John .....Greenwich.
Morgan, George Henry..... .....Wem.

Modified.

Webster, John Henry.....Scarborough.

The following having passed the Minor examination were elected "Associates" of the Society:—

Appleton, Thomas Alfred .....West Brompton.
Baxter, John Newsome .....Rotherham.
Bibbings, John Henry .....Exeter.
Booth, George Samuel.... .....Heckmondwike.
Campbell, Colin.....Glasgow.
Carson, Robert .....Manchester.
Chapman, Joseph John.....Chertsey.
Clark, William Coltart..... .....Dalbeattie.
Clark, William Inglis .....Edinburgh.
Grant, Donald .....Elgin.
Harding, William.....Bristol.
Holt, George Alfred.....Douglas.
Holyoake, Francis..... ...Wandsworth Road.
Huggett, Sydney .....Lancaster.
Ingham, Thomas Whittaker ...Rawtenstall.
Kirkby, Robert .....Ulverston.
Lathbury, Charles John .....Worcester.
Leslie, John Morison .....Port Elizabeth.
Lewis, Edward Prosser .....Tenby.
Moore, John Ernest .....Southampton.
Normand, Claude .....Hammersmith.
Peacock, Percy.....Chelsea.
Righton, James.....Southport.
Rogers, William Sexton .....Southsea.
Savage, John Welch.....Wells.
Somers, Robert Walter .....Guildford.
Southwell, John William.....Scarborough.
Twist, Edward Herbert .....Prescot.
White, Thomas Lee .....Edinburgh.
Wills, George Sampson Valentine...Hay.

APPRENTICES OR STUDENTS.

The following having passed the Preliminary examination were elected "Apprentices or Students" of the Society:—

Crompton, John Clayton .....Manchester.
Dashwood, James.....Portsmouth.

Finance.

The report of this Committee, recommending sundry accounts for payment, was received and adopted.

House.

The report of this Committee was read. It stated that steps had been taken for the furnishing and lighting of the library, etc.

Mr. Greenish stated that he and another member of the Council had accompanied the surveyor to choose a gasalier for the library, but they had not definitely fixed upon one which they could recommend.

Mr. Williams said it was very important that no time should be lost in providing gas fittings for the new Council room.

Mr. Betty suggested that the discussion of the details of these matters should be left in the hands of the Committee.

The President said it was important that the floor covering of the library should be immediately decided upon, in order that the room might be opened for use.

Mr. Sutton said he had found linoleum exceedingly durable.

The report and recommendations of the Committee were received and adopted. A resolution was also passed for the laying down of the linoleum, according to estimate.

A payment of £400 to the builder on account of the alterations was also ordered.

Mr. Hampson moved that the House Committee be instructed to take steps to fit up and furnish the new Council room in a proper manner. It would be a great pity after the expense which had been gone to of fitting ventilators in the Secretary's room that it should not be occupied as proposed.

Mr. Sutton said the present Council room was often required for the purpose of examinations.

The President was not aware that it had ever been definitely settled that the Council meetings should be held in the Secretary's room in future; in some respects he preferred the present room, and thought that if a ventilator were added it would be all that could be desired. He suggested that at any rate the new room should be tried for one month before the change was finally made.

Mr. Betty also thought it had been understood that the new room should be tried before removing definitely into it.

The Vice-President drew attention to the resolution passed at the July meeting:—

"That the room now used as the Secretary's office be taken for Council meetings."

After some further conversation,

Mr. Hampson said he would not press the motion for a month, on the understanding that the new room should be tried for the next meeting.

Benevolent Fund.

The report of the Committee was read, stating the result of the recent election, which was as follows:—

Potts	2503
Kennett	1416
Moss	1351
Beaton	895
Linging	129

A resolution was passed authorizing the Secretary to pay Mr. Potts and Mr. Kennett, the two successful candidates, the proportionate amount of the pension up to Christmas next.

The Committee also recommended two grants of £10 each, one to a registered chemist and druggist, the other to the widow of a registered chemist and druggist. It appeared, however, that the former had died since making the application, and although it was suggested that the money might be paid over to the widow of the applicant, the Council decided, after full consideration, that such a course could not be taken, but that an application in due form from her would doubtless meet with every consideration. The other grant recommended by the Committee was duly made.

Mr. WILLIAMS wished to draw attention to the small amount of subscriptions to the Benevolent Fund, for it certainly was not supported as it ought to be. The casual grants swallowed up a great deal of money which in his opinion ought to be reserved for annuities, for he believed the Fund was most useful when applied in the form of annuities. He should be sorry to see these grants reduced, because he knew they often did great good, but at the same time, he would remind the Benevolent Fund Committee that so long as the subscriptions were so small as to amount to only £3 18*s.* in a month, they should be cautious not to make too many of these grants.

Mr. URWICK thought it must be satisfactory to the Council and members to know that the applications for relief were principally from registered chemists and druggists, and not from pharmaceutical chemists. He hoped that when this was known chemists and druggists would be induced to support the fund to a greater extent than they did at present.

Mr. BETTY hoped there would be no distinction drawn between pharmaceutical chemists and chemists and druggists.

Mr. OWEN said they ought to know what was the average monthly receipt, as Mr. Williams had given one month's receipt as £3 18*s.* He hoped every reader of the Journal would take this matter to heart, and see what could be done. They were continually charged with not making a right use of the Benevolent Fund, but it now appeared that they had hardly any money to apply. He agreed with Mr. Robbins that they should be liberal at all times, if possible, and he trusted chemists and druggists would become subscribers.

Mr. RADLEY said he had for some time past bestowed some thought upon this subject, and was of opinion that any general appeals were not of much avail. He should be glad if a committee of subscribers could be formed to take the subject in hand and make a direct appeal to every person on the register. He was quite sure any trouble taken in the matter would be well repaid.

The PRESIDENT said the Secretary made a direct appeal a short time ago, the result of which perhaps he would state.

The SECRETARY said the last time he issued a general circular to the whole trade the result was, not money, but applications for relief; he did not, in fact, get anything like enough to cover the cost.

Mr. WILLIAMS hoped those who read the Journal would see that they were really doing good with the money, and that it was being expended for the relief of distress, that more money was wanted for that purpose, and that they were not hoarding the funds. The Council wished to expend the money, and had plenty of objects and means of expending it if it were only liberally supplied; unfortunately it was not, as the subscription list showed.

Mr. ROBBINS said this question ought to be taken into serious consideration, and he should be glad to see a committee formed for considering the whole question of the management of the Benevolent Fund. His opinion was they did not do as much with the money as they might. He thought that with such a number of chemists and druggists in the country the fund ought to be better supported, but still, the first duty of the Council was to distribute the funds which they received from time to time. He did not think it was at all proper to have only about fourteen annuitants in so large a body. Whilst there are deserving cases, they ought to continue to elect until the number reaches at least twenty. There were plenty of funds.

Mr. WILLIAMS: No.

Mr. ROBBINS said he maintained they would have plenty of funds for thirty annuitants, which would only take £900 a year. There would be no difficulty in getting subscriptions to double the amount if they really did good with the money, but if the subscriptions should fall off they would simply have to say that they would not elect another annuitant, until subscriptions came in more freely. They need never touch the original capital. There would still be enough to relieve urgent cases, because the income on account of the Benevolent Fund was between £1100 and £1200 a year, and thirty annuitants would only take £900. In his opinion they went to work the wrong way, making it the first object to save money for future generations, and the second to relieve present necessities, whereas he contended they ought to reverse that principle. Whatever money was wanted he believed would be provided.

Mr. WILLIAMS said he was glad to hear there was a likelihood of so large an amount coming in.

Mr. ATHERTON remarked that his experience of country chemists would show that they were very good hearted, but rather apathetic where money was concerned. On several occasions it had been his duty to go round collecting money, and as a rule he must say they did not subscribe as readily as ought to be expected. Still he thought by organized local effort the Benevolent Fund might be made more effective. He suggested that special meetings should be held in various localities, and an appeal made to increase the funds.

Mr. STODDART said he was very often met with the objection when asking for subscriptions that the Pharmaceutical Society did not help the non-pharmaceutical chemists, and therefore he was very glad that Mr. Urwick had drawn attention to the fact that the "outsiders," as they were called, really got the greatest advantage from the fund. No doubt people would subscribe readily if they could only be got into the humour, but unfortunately that was rather a difficult thing to do. A great deal of money was subscribed in his locality for various objects, but it was always done by means of a dinner.

Mr. GREENISH reminded the Council that the Chemists' Ball would take place on January 21st, and as there was always a contribution from that source to the Benevolent Fund he would suggest that members of the Council should send in their names as stewards.

Mr. SUTTON thought a good deal might be done by looking after little subscriptions which now did not come in at all, and suggested that a personal appeal be made to all chemists and druggists throughout the kingdom to subscribe a trifle, if it were only one shilling per annum. If that were done generally the amount obtained would come to something considerable.

Mr. OWEN observed that the "outsiders" were by far the most numerous, and therefore it was only to be expected that applications for relief should be more numerous in their case also.

Mr. BAYNES was surprised to hear there was so much difficulty in getting subscriptions. In his own town some six years ago an effort was made, and something like twenty-five subscribers were enrolled. But this was only done by personal canvassing. If the local secretaries would make an effort in this direction he thought a good deal might be done, for when they got the first half-a-dozen names to start with the rest would come in tolerably easy.

Mr. SCHACHT said the local associations had other things to do besides attending to the Benevolent Fund. They had to look after educational appliances in their own locality, and that was a great tax upon them, quite independent of their contributions to the Society or to the

Benevolent Fund in connection with it. If attempts were made to draw more and more money out of the pockets of local chemists for imperial objects, the question would be put, What did the imperial society do for them? In fact, that question was frequently raised now. If the Society were a little more liberal in its distribution of funds for the first and most important matter in his opinion, viz., education, possibly they would have a better argument with which to go and ask people to contribute to the Benevolent Fund. Very often persons in a particular locality would say—Come to me for any local case, and I shall be happy to assist you; and he must say that was the manner in which he himself dispensed what charity he was able. He had never subscribed to the Benevolent Fund, although possibly he gave as much in the way of charity as other persons of equal means. He did not think this was the direction in which the chief energies of the Society should be directed, but they should rather aim first to spend their money and efforts in improving the status and education of the whole body, and afterwards, perhaps, assist the unfortunate ones.

Mr. SHAW said that the chemists in Liverpool had supported a local association for many years. They had found considerable difficulty in getting subscriptions from parties who originally had contributed to the support of the institution, and under these circumstances, if they made a direct application, the reply would be, they received no kind of assistance from it, and generally speaking, they declined to give anything. He might also state however that some three years ago they had sent up twenty guineas to the Benevolent Fund from Liverpool, being part of an amount of £150 which had been raised for the purposes of the Conference which had not wholly been expended; and having given so much, of course parties naturally did not feel inclined to subscribe further. He should be happy, for his own part, to make another attempt in Liverpool, and see if anything could be done.

Mr. OWEN said circulars were very often not successful, where a personal appeal would have a better effect.

Mr. FRAZER suggested that a special appeal should be made to all persons whose names were on the register, not at present subscribing, to contribute a shilling or upwards, and that this be recorded in the Journal, and otherwise made known.

Mr. RADLEY said he should much prefer a committee of subscribers being appointed to look into the whole matter.

Mr. ROBBINS said the advantage of having a committee would be that it would take other matters into consideration besides the raising of more funds. For his part he thought those who did not subscribe anything to the Fund ought not to have votes.

Mr. SUTTON said that would involve altering the bye-laws and regulations.

Mr. SCHACHT observed as the Society gave large amounts to the Benevolent Fund such a measure would be out of the question.

Mr. BETTY was rather inclined to favour a proposition for a committee, especially as there appeared to be a feeling in some parts that the Benevolent Fund was not administered to the best effect. If they went immediately and asked for contributions whilst these criticisms remained unanswered, particularly at that time of the year, they would very probably not get very satisfactory replies. Mr. Robbins thought the funds might be available for thirty annuitants, and although that involved a problem which he had not yet mastered, still if the matter were referred to a committee he should be very pleased to be convinced, if possible, that it could be done.

Mr. SCHACHT thought there was no necessity for having a special committee for this purpose, inasmuch as the Benevolent Fund Committee might very well deal with it.

After some further conversation, it was moved by Mr. RADLEY, seconded by Mr. ROBBINS, and carried unanimously:

> "That the subscriptions to the Benevolent Fund falling short of the amount which in the opinion of this Council they should reach, a Special Committee, consisting of the Benevolent Fund Committee, and Messrs. Atherton, Betty, Radley, Sandford, Shaw, and Williams be appointed to consider what steps it is desirable to take to increase both the amount of subscriptions and the usefulness of the fund."

LIBRARY, MUSEUM, AND LABORATORY.

The minutes of this Committee were read. Amongst other things, they recommended the purchase of two additional book-cases for the library, and also certain modifications in the regulations recently laid down by the Council as to the manner in which the professors should use the apparatus and specimens belonging to the Society for the purpose of their lectures. Upon this latter point they suggested that the matter should be again remitted to them before a final decision was come to. The report also stated the number of students now attending the lectures—viz., in the pharmacy class 33, as against 60 last year; in the botany and materia medica class 21, as against 69 last year; and in the laboratory 30, as against 40 last year.

Mr. SCHACHT said it was rather interesting to notice the number of students now attending the establishment after the great change that was made a few months ago. As many of these students probably attended each of the classes, there would be probably from 30 to 45 students in all receiving education or advantages in that institution.

The PRESIDENT said that Professor Redwood was in hopes that his class would very much increase, and believed that the present plan would be ultimately successful.

Mr. SUTTON said it was not at all astonishing they should have this falling off, because they had been doing all they could to stir up educational matters in the country, and great progress had been made in that way. The Chemists' Association at Norwich was associated with the South Kensington Museum, and one of his own apprentices was a certificated teacher, having taken the first prize in botany at South Kensington, and two other of his assistants, having passed the Major examination in honours, were teaching chemistry and materia medica. Under these circumstances, therefore, there was not that necessity for coming up to London there formerly was.

Mr. WILLIAMS said it was only fair to remind the Council that the session being now divided into two parts, they could hardly compare the present numbers with the state of things a year ago. His opinion was that most of the young men would come into the second course, because they would have certain advantages in joining at that time, and he, therefore looked forward to the second half of the session showing a more than usually numerous attendance. He must say he could not account for the falling off in the laboratory.

Mr. SCHACHT thought it was the most natural result possible, seeing that under the new arrangements there was a diminished quantity of instruction given for double the price.

The Report and recommendations of the Committee were received and adopted; the arrangements as to the use of specimens, etc., being left in the hands of the Committee.

GENERAL PURPOSES.

The minutes of this Committee held the previous evening were read, stating that a deputation from the Board of Examiners had been present, who recommended that the Preliminary examinations should be held at thirty or forty centres instead of in every town where there was a local secretary; that the persons to superintend or supervise these examinations should be appointed by the Board of Examiners, and be paid for their superintendence on each occasion; that the examinations be conducted in

a public room, and that the examinations for the Jacob Bell Memorial Scholarships, the Pereira Medal, and the Prize of Books be held in London and Edinburgh only.

The PRESIDENT said they had had a rather lengthened meeting of the Committee, when several irregularities in the mode of conducting the Preliminary examination had been mentioned, and the suggestions above mentioned had been made. For his own part, he should prefer the superintendence being still left in the hands of the local secretaries rather than leave it to the Board of Examiners to appoint superintendents. The Committee had arrived at no conclusion on the subject.

Mr. SCHACHT asked what course was intended to be taken on the present occasion, whether to endeavour to decide on something like general principles and then refer the matter in detail to a sub-committee, or whether to discuss each detail on its merits, and come to a final conclusion at once.

The PRESIDENT thought they might discuss the whole of the recommendations now brought forward.

Mr. BETTY, in the absence of Mr. Hampson, and on his behalf, moved :

"That this Council, having heard the suggestions of the Board of Examiners with reference to the Preliminary examinations, thinks it desirable that the local secretaries, or other properly appointed persons shall continue to supervise the examinations, and that they shall receive fees for holding the same.

"That the examinations be held only in rooms connected with public institutions ; that there be adopted local centres, conveniently placed, and that a committee, including Messrs. Schacht, Greenish, Urwick, Williams, and Hampson, with two members of the Board of Examiners, be appointed to arrange the details for carrying out the new arrangement and framing regulations for guiding the supervisors."

He thought probably it would be more convenient to discuss the first paragraph first.

Mr. SAVAGE begged to second the motion. He could not see why these examinations should be conducted differently to university local examinations, which were carried out by appointing a local committee.

Mr. SCHACHT thought they were proceeding rather too hastily, and not very wisely. He had listened at the committee meeting to the exposition of the view taken by the Board of Examiners with regard to these examinations, and found that their charge amounted to this, that there had been improprieties and irregularities in the carrying out of the regulations, and on the strength of that fact they made a few suggestions, one at least of which appeared to him quite revolutionary, touching a very important principle at present existing and sanctioned by the Society. The bulk of the other suggestions were simply improvements in matters of detail. It appeared to him that the first thing they should do would be to discuss whether they admitted that the case made out was sufficient to involve such a radical change as was proposed, and in the next place to determine whether those irregularities might not be met simply by improvements in details, or whether it was necessary they should go to the extreme length of that important change which was suggested with reference to the Bell Scholarships and the Pereira Medal. His own experience was, that the whole objections to the process already in existence were objections which might be remedied by more resolute attention to details. From all he gathered, no one could say the present regulations had failed, simply, because as yet they had not been carried out. He wished to make no reflections whatever on the Board of Examiners, who, no doubt, had difficult duties to perform, and who exercised their abilities with the very best intentions, but his opinion was, that if they had been resolute in their action a little earlier these irregularities would never have continued to exist. At any rate, it was an argument to show that when the evil was pointed out, they should not immediately jump to extreme measures of reform until they had well tried what milder, more simple, and less revolutionary modifications would accomplish. These gentlemen themselves proposed a number of alterations in the regulations, many of which were very sensible and useful, and many of which were in accordance with those laid down by the Science and Art Department in carrying out their very much more extensive though somewhat similar system of examination. Those regulations were applicable to the entire ground covered by the Society, as might easily be shown. Some gentlemen attempted to draw a distinction between conducting preliminary examinations and those which led to rewards, but the South Kensington authorities gave away large sums of money as rewards, both in a great number of small prizes and also in a few great prizes, such as scholarships of £50 a year, gold medals, etc., and he had never heard of any complaint being made of injustice or irregularity in those examinations. Therefore that the thing could be done was a matter of proved fact, if only rigid attention were paid to the regulations laid down. Feeling, therefore, that the Pereira Medal and Bell Scholarships were rewards which would stimulate their members throughout the country, and bind the provincial members to the Association, he should feel that it would be a grievous mistake if the examiners were taken from the provinces and again centralized in London. He was quite sure that such a measure would do great damage to the cause of general pharmaceutical progress, and therefore, before any question of details was discussed, he hoped they would come to a conclusion on this first point of general principle. He would therefore move—

"That this Council having heard the report of the General Purposes Committee are of opinion that the change in the method of conducting the examination for the Bell Scholarship and Pereira Medal and Prize of Books suggested by the Board of Examiners ought not to be adopted until it be shown that the regulations for the same cannot be so amended and enforced as to meet the necessities of the case."

After this question had been determined, he should be happy to go into any matter of details, or to refer it to the same or a fresh committee, to form new regulations, if it were desired.

Mr. STODDART seconded Mr. Schacht's proposition, and desired to endorse everything which he had said. From what he had been told, he had expected to hear on the previous evening of some great crime having been committed, and he was much relieved when he left at ten o'clock to find that nothing at all had been proved against the Preliminary examination being conducted properly, except the non-compliance with the regulations by persons who supervised the examinations. He held that the present system was perfectly satisfactory; and that it was so, was abundantly proved, because there were other examinations far more extensive conducted on the same plan—viz., those in connection with the South Kensington Museum, and there had never been any complaint made in connection with them. If anything could be said against the present mode of conducting the Preliminary examination, it was with regard to the few persons who literally did not attempt to carry out the regulations. For his own part, if he had held an examination on a wrong day, or at a wrong hour, he should have expected that the examiners would have sent the papers back cancelled. If three or four young men presented themselves at the wrong hour, he should not consider himself authorized to conduct the examination. He might also say that if he had known some time beforehand that he should not be able to conduct the examination on the day appointed, he should have written to the Secretary to apprise him of it, when no doubt his friend, Mr. Schacht, would have been appointed in his place, and no harm would have been done. It appeared to him that the fault lay with the examiners for not cancelling those papers which were irregular ; and he strongly urged the Council not to make any alteration at present in a system which was really working very well

If they would only conduct their examinations for the scholarships and Pereira Medal in the same manner as those of the Science and Art Department, it would be impossible to have anything more perfect, if only the regulations were strictly carried out. He must say to those who had not certificates from authorized bodies, it was a great boon to be able to go to the next town to pass their Preliminary examination, instead of having to come to London at a great expense.

Mr. ATHERTON said he must confess to not having carried out the examinations properly on some occasions, inasmuch as he had not always put his initials in the corner of each paper, but that was no reason why the examination should be taken from the country. He thought other objections ought to be got over in a similar way. As a matter of principle, he believed the Council had agreed that these examinations should not be taken from the country, though whether they should be confined to a certain number of centres was a matter of detail to be settled afterwards. For his own part, he knew several cases where the local secretaries would be very glad to escape the duty of superintending these examinations, and perhaps if a centre were appointed where eight or ten candidates could be examined at once, it would be an improvement. At all events, they should insist upon the examinations being permitted in the country, and not taken away from it.

Mr. SAVAGE said he agreed so thoroughly with Mr. Schacht's views that he should be inclined to withdraw in favour of them the motion he had seconded. He wished to know if he had properly understood Mr. Stoddart to say that if he could not conduct the examination himself he could ask a friend to do it ?

Mr. STODDART said that was not his meaning, he should write to the Secretary and ask that some one else should be appointed.

Mr. FRAZER agreed that there was not a case made out against the local secretaries at present, and it was evident from the numbers rejected from time to time, that these examinations, even as now conducted, were not so inefficient as some gentlemen appeared to suppose. It should also be remembered that from the recent change in the examinations, leading to increased strictness in the Minor, it was really of less importance if one or two men, not thoroughly prepared, did slip through the Preliminary examination. He held that the Minor examination was now quite sufficient without any Preliminary at all. They must take care not to defeat their own object by making regulations so strict that the difficulty already existing of getting assistants would be much increased. He believed they would have to conduct their businesses in many instances with the assistance of men who had not passed any examination at all. The Council ought to protect the interests of the existing trade, and not make the restrictions too onerous.

Mr. WILLIAMS said he was inclined to move an amendment to this effect :—

> "That the proposal of the deputation of the Board of Examiners, laid before the General Purposes Committee, be received and referred to a special committee for consideration."

Mr. SCHACHT thought it would be desirable that the Council should express an opinion upon the general principle in the first place.

Mr. BETTY said that having charge of Mr. Hampson's motion, he should be willing for the whole matter to be referred to a committee.

Mr. SANDFORD said the amendment of Mr. Schacht really went to this extent. that the Council did not agree with the Board of Examiners in their proposition at all, and it stated that the regulations could not be said to have failed, because they had not been fairly tried. But how could they have been tried in any fairer or more perfect way? A perfect code of regulations was sent to the local secretaries, and in return informal certificates, and letters describing irregularities, were constantly received. He had in his hand a bundle of papers stating the irregularities for the last month only. It had been constantly the practice for local secretaries to appoint other parties to superintend the examination ; for certificates were often sent up signed by so-and-so for so-and-so. Now how could they compel local secretaries to abide by the regulations ?

Mr. SCHACHT said the examiners should not pass the candidates. He contended that the Board of Examiners had not carried out the regulations. They should have returned every one of the irregular papers.

Mr. SANDFORD said if the Board of Examiners had returned these informal certificates they would have thrown back the young men for three months, which would have been considered a great hardship ; therefore they felt great difficulty in doing so. He had given proof of the irregularities which occurred, and they seemed to him a great argument in favour of conducting the examinations in some better way. He need not give the instances in detail, but there were abundant proofs of the regulations not having been carried out. If certain centres were fixed upon, so that the young men would not have to go more than twenty or thirty miles, he did not see that it would be any great hardship ; and if one gentleman were appointed to conduct the examination, and paid for it, and it took place in a public room, with proper appliances, so that candidates could not see each other's papers, there would be much greater security for the examinations being properly conducted. As to the Pereira Medal, he considered that of much more importance, because it was the highest honour the Society could bestow, and therefore it was essential that all who competed for it should do so under exactly similar circumstances. Now, when candidates were gathered round the table in that room, under the superintendence of one of the Board of Examiners, it would be a great honour for any young man who gained for himself such a distinction ; but he was always of opinion that if a man in the country, either in Liverpool or Manchester, or any other provincial town, writing his paper under the eye of a local secretary, were successful, it would throw a doubt on the value of the prize altogether. He was not speaking of any particular local secretary, and he had the greatest respect for those gentlemen generally ; but the appointment of them was very loose and vague, there being more than two hundred of them, many of whom were totally unknown to the Council. He hoped, therefore, that the Council would agree in principle to the recommendations of the examiners, or at any rate let it be referred to a committee, for he should be very sorry indeed if they agreed at once to Mr. Schacht's motion, which amounted to a direct repudiation of the view taken by the Board of Examiners.

After some further discussion,

The PRESIDENT appealing to Mr. Schacht to withdraw his amendment in favour of Mr. Williams,

Mr. SCHACHT said, he could not resist the general intimation of opinion, if it were understood that the whole matter was to be referred to a committee for further consideration.

Mr. SHAW said, as far as he could gather the opinion of the committee on the previous evening, it appeared to be against the desirability of an examination being transferred to Edinburgh and London. It appeared that certain irregularities had been committed, and that the system of examination required revision. He was quite certain, however, that the Council would not accede to the removal of these examinations from the country.

The motion of Mr. Williams, seconded by Mr. Greenish, was then carried unanimously :—

> "That the proposal of the Board of Examiners laid before the General Purposes Committee be received and referred to a Special Committee for further consideration, the committee to consist of Messrs. Schacht, Stoddart, Sandford, Betty, Hampson, Williams, Shaw, and Atherton."

It was also decided that the Committee should meet on Tuesday, December 2nd, at 4 o'clock p.m.

Report of Board of Examiners.

The following Reports of the Boards of Examiners were presented :—

Reports of Examinations.

October, 1873.

ENGLAND AND WALES.

Examinations.	Candidates. Examined.	Passed.	Failed.
Major	6	2	4
Minor	99	43	56
Modified	23	7	16
Preliminary	286	129	157
	414	181	233

Certificates received in lieu of the Preliminary Examination :—

University of London	1
University of Cambridge	2
University of Oxford	1
University of Edinburgh	1
College of Preceptors	3
Royal College of Surgeons	2
Faculty of Physicians and Surgeons in Glasgow	1
	11

SCOTLAND.

Examinations.	Candidates. Examined.	Passed.	Failed.
Major	2	1	1
Minor	31	21	10
Modified	6	4	2
Preliminary	25	18	7
	64	44	20

Certificates received in lieu of the Preliminary Examination :—

Royal College of Physicians and Surgeons in Edinburgh	1
University of Edinburgh	1
	2

Mr. Williams said it was rather remarkable that the candidates in Edinburgh were much more successful in passing than in London.

Sheffield Chemists' Association.

A letter was read from the association at Sheffield asking for a grant of £10 for apparatus and £5 for books for the library.

The Secretary stated that the application was made in due form, stating the number of members and associates and the arrangements made for classes during the ensuing session. The application was referred to the Provincial Education Committee.

PHARMACEUTICAL MEETING,

Wednesday, November 5th, 1873.

MR. THOMAS HYDE HILLS, PRESIDENT, IN THE CHAIR.

The minutes of the previous meeting having been read and confirmed,

The following donations to the Library and Museum were announced, and thanks were awarded to the donors :—

'Chemistry, General, Medical, and Pharmaceutical,' Fifth (American) Edition, from Professor Attfield; 'Manual of Botany,' Third Edition, from Professor Bentley; 'University College Calendar for 1873-4,' and 'Professional Dissertations, 1872-3,' from the College; 'Qualitative Chemical Analysis,' by Douglas and Prescott; 'Todd's Student's Manual,' from Mr. T. H. Hills; 'Smee on Sewage, Sewage Produce, and Disease;' 'Canadian Illustrated News Portfolio and Dominion Guide,' from Dr. J. B. Edwards; 'Statistical Tables of Patients in St. Bartholomew's Hospital during 1872,' from the Hospital; a specimen of Rye with the Ergot upon it, from Mr. D. Hanbury.

Mr. Barnes read a paper entitled "Pharmaceutical Notes."

[This paper is printed at p. 361, and gave rise to the following discussion :—]

The Adulteration Act.—The Sale of so-called "Citrate of Magnesia."

The President thanked Mr. Barnes for his communication, and remarked that such papers were always very interesting to practical pharmacists. It was new to him that glycerine would dissolve tannate of quinine, but he had found it useful to dissolve tannin to mix with infusion of roses for gargles.

Professor Redwood said that guaiacum resin was not perhaps a very important medicinal agent, but there was reason to believe that other articles in which impurities were more serious were also frequently impure, and therefore the whole question deserved very careful attention. Scammony, for instance, was often impure, and at the present time, particularly, as it appeared to him, it behoved pharmacists to consider the question of impurity in drugs far more seriously than they had hitherto done. Many impurities had become conventional, and were consequently overlooked, but he was by no means sure that this could be done in future; at any rate it was very undesirable to do so, and he believed it would become an absolute necessity to scrutinize more minutely than had hitherto been the practice the composition of the drugs used. In some cases such impurities were of great importance and really affected the foundation of medical practice, and if permitted would naturally affect the character and position of pharmacists throughout the country. They, as a body, would be looked to to make some greater progress in the way of resisting all attempts at the introduction of impurities in drugs, and also of the sale of substances under incorrect names which did not strictly represent them. There were numerous substances for the sale of which druggists were liable to be punished, although they sold them under the names by which they were commonly known, and thus even imprisonment with hard labour might be their lot, as well as heavy fines, for doing things which really had become conventional acts.

Mr. Bland said imprisonment with hard labour would be no fresh punishment to the majority of chemists and druggists, as they were pretty well accustomed to it already.

The President asked if Mr. Barnes had examined tears of guaiacum, which he believed were generally pure.

Mr. Barnes said he had not. He believed they were generally pure, but they were not often used by druggists.

The President said he was not quite prepared to accede to that.

Mr. Williams thought that the sale of a drug as it came into the market, although it might contain some small per-centage of woody or inactive matter, could not be treated as that of an adulterated article, and he did not believe the Act of Parliament would extend to such a matter as the sale of guaiacum as imported.

Professor Redwood thought it would be very difficult to define exactly what the Act did comprehend in cases of that description. The meaning of the Act had to be interpreted by magistrates when charges were made before them, and different interpretations had been put upon it by different parties. For his own part, he considered that even in the case of a drug sold in the same state in which it was imported, if it could be clearly shown that it was adulterated, it was no exoneration to the dealer that he sold it in the same state in which he received it. It would be considered that a chemist and druggist in the present day ought to be able to distinguish between what was pure and impure, genuine,

and adulterated, and it would be no excuse in a legal point of view to say he did not adulterate it himself. If it came into the market in such a state that it was not fit for use, no druggist would be justified in using it.

Mr. HODGKINSON said the specimen of guaiacum produced was a very poor sample, and any druggist who would go to the expense would find no difficulty in getting a much better article.

Mr. WAUGH said it was very important to know how far their responsibility extended, and whether in such cases as were now referred to the responsibility was with the retail druggist or with the wholesale dealer.

The PRESIDENT was not quite prepared to say that that was the time and place in which to decide so important a question of law. He believed there was a clause in the Adulteration Act providing that a man not knowingly or willingly selling an adulterated substance was not liable. In fact, Mr. Sandford, Mr. Haselden, and himself got those words inserted. No doubt chemists ought not to buy any but good articles, and if this rule were observed a good effect would be produced. For instance, he remembered some twenty-five or thirty years ago, one of the first matters brought before the Society was the adulteration of senna, and by the combined action of the chemists and druggists of that time senna came into the market in a much better state. Professor Redwood had spoken very strongly on the subject of impurities, but he had heard him say himself on a former occasion that it was impossible to find strict purity anywhere. His own impression was that a man was not liable to imprisonment or fine if he sold an article not knowing it to be adulterated.

Professor REDWOOD said a person was only liable to imprisonment with hard labour when he had adulterated an article himself or given instructions to that effect; at the same time, if he sold an adulterated article, and, being an educated man, were deemed to be capable of judging of its quality, and had not exercised that knowledge in detecting that adulteration, he would be liable to a penalty.

A MEMBER thought that the sale of guaiacum did not involve the question of adulteration, since it and similar substances only came into the market with the natural impurities resulting from the rough method of collecting. It was really a question of the purification of drugs rather than their adulteration, which implied the artificial admixture of some impurity.

Mr. HUCKLEBRIDGE asked the President if the question of citrate of magnesia had come before the Council that morning, and, if so, what decision had been arrived at?

The PRESIDENT said the matter had been considered, but it was in committee, and therefore the discussion would not be published. He might say, however, that the decision come to was to sell that which they knew to be pure and genuine and label it accordingly; and that they ought, if possible, to name every article according to its composition. However, the Council were fully agreed as to the injustice of the magistrate's decision in fining Mr. McDermott £10 for selling the article in question, which had been universally known and sold to the public for many years under the name of "granular effervescent citrate of magnesia."

Mr. HASELDEN said, with regard to the Adulteration Act, he was one of those who waited on the Marquis of Salisbury when the Bill was passing through the House of Lords. His impression from what passed then was that if an article were sold, the seller being ignorant of its being adulterated, he was not liable to any penalty. They now found that magistrates had convicted over and over again, entirely refusing to acknowledge that clause. The matter was especially pointed out by Mr. Sandford to Lord Salisbury, and scammony and otto of rose were specially mentioned. It would be a very hard case if a man were summoned for selling virgin scammony if it had 15 per cent. of matter in it which was not scammony resin, and therefore might be said not to be pure, especially if it contained chalk or gum, which it generally did. It was impossible for a man to carry on business and examine everything that came into his establishment, he would have to keep an assistant constantly employed for the purpose, and of course increase his charges accordingly, which would not be to the satisfaction of the public. He should like to ask Professor Redwood his opinion of isinglass, which was, no doubt, sold to them as pure Russian isinglass, while at the same time it was frequently adulterated with gelatine. The Adulteration Act seemed to him one of the most absurd Acts ever placed before the public, and he thought it ought to be repealed.

Professor REDWOOD said that many years ago he had taken up the subject of adulteration of isinglass, and he was not aware that for some time past it had been practised. If it were so, he should certainly bring it again before the public. He should not hesitate to say that anyone selling adulterated isinglass would be liable to the penalties imposed by the Act. Where a man sold an article which had been adulterated by another, he would be liable if he were in a position such as was assumed to give him the knowledge which would enable him to judge of the quality of the article sold. In all such cases he believed that the seller would have his remedy against the man who sold him the article.

Mr. HASELDEN said he could not say positively that isinglass was adulterated at the present moment, though he suspected it was from the various prices at which it was offered. The remedy suggested by Professor Redwood against the original seller of an article at a loss of four or five days' time, and a considerable expense and uncertainty, would be a very poor consolation.

Professor REDWOOD said it might be as well to state how the adulteration of isinglass could be detected. The practice was to roll out a sheet of gelatine between two sheets of isinglass before it was cut, and it might be easily detected by soaking it in water and then putting it under the microscope, when the gelatine would become transparent, whilst the isinglass remained opaque, so that the three strata would be at once apparent.

The ASSISTANT SECRETARY read the first two clauses of the Adulteration Act as follows:—

"1. Every person who shall wilfully admix, and every person who shall order any other person or persons to admix, with any article of food or drink, any injurious or poisonous ingredient or material to adulterate the same for sale, and every person who shall wilfully admix, and every person who shall order any other person or persons to admix, any ingredient or material with any drug to adulterate the same for sale, shall for the first offence forfeit and pay a penalty not exceeding fifty pounds, together with the costs attending such conviction, and for the second offence shall be guilty of a misdemeanour, and be imprisoned for a period not exceeding six calendar months, with hard labour.

"2. Every person who shall sell any article of food or drink with which to the knowledge of such person any ingredient or material injurious to the health of persons eating or drinking such article has been mixed, and every person who shall sell as unadulterated any article of food or drink, or any drug which is adulterated, shall for every such offence, on a summary conviction of the same before two justices of the peace at petty sessions in England, or before two justices of the peace in the justices of the peace court, or before the sheriff substitute of the county, or before any magistrate acting under any general or local Police Act in Scotland, or before justices at petty sessions or a divisional justice in Ireland, forfeit and pay a penalty not exceeding twenty pounds, together with such costs attending such conviction as to the said justices, sheriff-substitute, magistrate, or divisional justice shall seem reasonable; and if any person so convicted shall afterwards commit the like offence, such justices,

sheriff substitute, magistrate, or divisional justice shall cause such offender's name, place of abode, and offence to be published, at the expense of such offender, in such newspaper, or in such other manner as to the said justices shall seem desirable."

Mr. BLAND said he was rather inclined to agree with the President that that was not the time or place in which to enter into a full discussion of this question. It was well-known to many present that before the Adulteration Act came into operation he had expressed a strong opinion as to some of the results which it was likely to produce. Looking to the necessary qualifications of a man who might be able conscientiously to undertake the duties of an analyst, they could not expect to find many such men in the country, and for this reason, that it was necessary not simply to have a theoretical knowledge of chemistry, but a very extensive acquaintance with technical chemistry was also necessary, or else the analyst might fall into most serious blunders, and be the instrument of perpetrating the most grievous injustice. Looking at the different views taken by different magistrates before whom questions had been brought, and the vindictive penalties which in some cases had been inflicted, the severe remarks made by some of the magistrates, and the serious consequences, independently of the mere pecuniary result of the fine, to any person brought up on such a charge. Even if it were competent to any person who had been fined to bring an action against the person who had supplied him with an adulterated article, that would afford no compensation whatever for the very serious loss of reputation in business which might ensue. He was strongly of opinion, looking at the manner in which the Act had been carried out in many places, that the only real remedy would be to get it repealed altogether.

Mr. SANDFORD said he was one of the deputation who waited on Lord Salisbury to represent to him the hardship which the Bill as originally drawn would inflict. They did not go to him with the idea that chemists would wish to connive at the adulteration of drugs by anybody, but they told him there were certain articles brought into the market, scammony, otto of rose, and musk being particularly mentioned, which it was only possible to obtain in a state of comparative purity. The druggist had no power to do more than buy the best samples he could obtain. The Bill as it passed through the House of Commons would have rendered a druggist who sold guaiacum, the article brought under the notice of the meeting by Mr. Barnes, in its ordinary state, liable to penalties, and Lord Salisbury was informed that it was absolutely necessary there should be a guilty knowledge in order to constitute an offence. Lord Salisbury therefore introduced into the Bill certain words making a guilty knowledge necessary, but unfortunately the magistrates had construed the Bill differently; and not only so, but he found that the Court of Queen's Bench had been appealed to, and had decided that a dealer was bound to know and to be a judge of the article in which he dealt. Thus, if a grocer sold mustard, he ought to know whether it was pure or impure. That was not the intention of Lord Salisbury when the Act was passed, though perhaps the wording was not as clear as it might have been. The Bill as amended came into his hands about two o'clock in the day, and having no time to consult any of his friends, he went to the House of Lords, and, meeting Lord Salisbury, pointed out to him its defects, and his lordship then introduced other words, to make it more clear that a guilty knowledge should be required. A few minutes afterwards he met Lord Granville, who agreed to the same course, and considered Lord Salisbury's proposed alteration sufficient for the purpose. The Bill was then produced as it now stood, and though there was a little difficulty as to the punctuation which rendered it somewhat obscure, as almost all Acts of Parliament were, he could not help thinking that those who were interpreting it were running rather wild. The decision of the Queen's Bench, in June last, was to the effect that it was not necessary to prove a guilty knowledge on the part of the seller, and whether or not that was in strict accordance with the wording of the Act, he was quite sure that it was not the intention of Lord Salisbury, Lord Eustace Cecil, or Lord Granville, when the Bill passed through Parliament. He was glad the citrate of magnesia case had been mentioned, because he knew it was in everybody's mind. Everybody knew that what was sold under that name was not citrate of magnesia, and he remembered seven years ago, when occupying the president's chair in that room, saying how much he regretted the tendency of chemists to send out articles under false names, and he then mentioned this very article as one. He then said that citrate of magnesia was a definite chemical term, and the article sold under that name had no relation whatever to it, and it was therefore their duty to discourage it. He was glad to see that the matter had been taken up since at Dundee, at Liverpool, and again at Bradford, and it had even been proposed to enter into a combination to discourage such a thing. It was not right to sell an article as citrate of magnesia which was not that substance at all, but a mere mixture of another alkali and acid. It had been called citro-tartrate of soda, but he had heard it said that it was not even that until mixed in water, and therefore it could not properly be sold even under that name. He could not help thinking that the man who had been fined the other day was most unjustly treated for selling an article under a conventional term by which it was always known. He did not think, however, they could take any action in the matter, because he believed there was no appeal.

Professor REDWOOD said a case could be carried to a higher court.

Mr. URWICK said he had been informed that a fresh hearing could be had before the magistrate. The opinion of some who read the case was that the decision was not in accordance with the facts, and that it would not be fair to the magistrate to appeal in this case until he had had an opportunity of reconsidering his decision.

Professor REDWOOD said an appeal could only be had on a question of law.

Mr. SANDFORD remarked that the question in the case before the Queen's Bench was that of knowledge or no knowledge on the part of the seller. Now the citrate of magnesia case involved simply a question of selling an article by a popular name which did not properly describe it. For his own part he never lost an opportunity of telling a customer that citrate of magnesia was not the correct term. He had always felt ashamed that chemists should condescend to such a misnomer, and on that ground he did not regret the decision, because he thought it would stir them all up to do that which was right. He had heard one gentleman say that he did not care whether he sold any more citrate of magnesia or not, but he would not sell it under a false name; he (Mr. Sandford) thought there would be no fear of any falling off in the sale. Another gentleman had adopted a label saying that it was the preparation generally called citrate of magnesia, and the consequence was that he sold more even than he did formerly. Although he felt that Mr. McDermott had been badly treated, partly he thought owing to his own foolishness, he hoped that the occurrence would do good by opening the eyes of magistrates to the absurdities brought before them as adulterations. They did not want any privilege of adulteration, but simply to be protected in the ordinary exercise of their business.

Mr. URWICK said what had happened to Mr. McDermott might have happened to any one of themselves. He abominated all incorrect names, but many of them had been deprived of the sale of their own preparation of magnesia bearing genuine names by this citrate, and they had simply acted between the maker and the public. Many persons would be looking to see what was suggested at that meeting, and he hoped some decision would be arrived at. There was another question also requiring consideration. Prescriptions very often came in for

a couple of pills to be taken at night with two or three drachms of citrate of magnesia, to be taken in the morning. Now, what were they to do in such a case? He had always, without hesitation, put up what was ordinarily known as citrate of magnesia, feeling sure that that was intended, because if he sent the neutralized citrate of magnesia there would be a very nearly insoluble powder to be taken, which was hardly intended; but since the recent decision he hardly knew what to do. Probably the best way would be to consult the medical man or the customer. Another article of a similar character was lemon and kali, which was really lemon and natron, and not kali at all.

Mr. WILLIAMS said this was a question of names and titles. What authority were they to take as to the name,—the Pharmacopœia or Mr. Bishop's label? A new label was now proposed for Mr. Bishop's citrate—"citro-tartrate of soda with magnesia, commonly called citrate of magnesia." Certainly if they called it citro-tartrate of soda they would be as incorrect as ever, and even the Pharmacopœia preparation was not correctly named, because that was really citro-tartrate of carbonate of soda, there being no citro-tartrate of soda existing as such in the preparation. It was not until it was dissolved or taken into the stomach that it could be so called. He thought the label such as he had mentioned might be adopted without difficulty.

Professor ATTFIELD said it was important that the public should know that chemists had always discountenanced the adoption of misleading names. So far back as 1862 the pharmacy section of the juries of the International Exhibition discouraged this practice; at Dundee in 1866 the subject was again discussed at the annual meeting of the British Pharmaceutical Conference, and it was considered that such names as citrate of magnesia were improper, and should be avoided as much as possible. The next year it again came up at the conference at Norwich, and there again the opinion was tolerably unanimous that such names should not be used. Still more enthusiasm was thrown into the matter at the meeting of the British Pharmaceutical Conference in Liverpool in 1870, when a resolution was passed unanimously to the effect: "That this Conference is of opinion that the term citrate of magnesia, as applied to the ordinary granulated preparation of commerce is a misnomer and ought to be discouraged as inconsistent with the true interests of pharmacy." But this matter of inexplicit and inappropriate names was not so much in the hands of the chemists and druggists as the public seemed to imagine. A medical demand arose from time to time for such compounds as "effervescing iodide of potassium," "effervescing bromides," "effervescing nitrates," and such things. Such names were no doubt absurd and wrong, but the chemist supplied the desired articles according to the prescription, and was he afterwards to be fined for selling that which largely consisted of other ingredients than those mentioned on the label? The history of these things showed that generally a preparation was produced and a name given to it merely describing its leading character at the time it was discovered or introduced. Then improvements were made and other improvements followed, until it became considerably altered from its original composition. Still the public practically would not allow any alteration of the name, for the sale of an article was generally lost if its name was changed. Was the public demand for a good and perfectly definite article not to be supplied, because a few people clamoured for exact names for substances of inexact composition. The name "Citrate of Magnesia" for the ordinary article was wrong, and chemists had long been anxious it should be altered; at the same time interpreters and administrators of the law should be given to understand that they must not condemn as adulterated a medicinal article containing other things than that by which it was named.

Mr. BISHOP said when this article was originally introduced he had no idea it would become such a household institution as it had been, and at that time people were not quite such sticklers for the exact composition of substances as had been hinted at by Professor Attfield. Still he was very sorry that he ever made the mistake of calling this article citrate of magnesia, although it really did contain magnesia, and from that it took its name. He had never practised any deception, and always abhorred anything of the sort. He had now drawn up a new label, which he should be glad to have the opinion of the President and the meeting upon, and if it were approved he would introduce it, though retaining the old label which he had now placed upon something like a million and a-half of bottles. He was very sorry that Mr. McDermott had got into trouble through selling this article, and should take care to see, with the aid of a few friends, that he was not out of pocket by it. He thought it was a very great pity that the learned magistrate should have made such an observation as he was reported to have made as to the composition of an article as analysed by Dr. Muter, which contained citric acid, tartaric acid, carbonate of soda and sugar, as being injurious to the public health. This objectionable phrase had been copied into several of the newspapers, and he hoped to hear an expression of opinion that evening that it was not justified. He was not aware that law courts were the places where lawyers acquired a knowledge of medicine, and he thought if the learned magistrate would turn to his "Phædrus" and read the line in which occurred the words "*Ne sutor ultra crepidam*," it would do him good.

The PRESIDENT said he was unable in his official capacity to answer the question put to him by Mr. Bishop; it was not in his province to give a name to an article belonging to any gentleman, and he would remind Mr. Bishop that fourteen years ago when the preparation was first introduced by him he (the President) thought it a very elegant preparation. On having it examined and finding it contained so very little magnesia, he hesitated about using it, and preferred using an article of his own preparation, which he called citro-tartrate of soda, that being the nearest name by which he could describe it. He had been looking over all his own labels, and he recommended every one to do the same, and to label everything as correctly as possible. Though he could not give an official sanction to Mr. Bishop's new label, he certainly thought it a great improvement on the old one, and saw no objection to it.

Mr. BISHOP said, that as it had been stated by some persons that his preparation did not contain any citric acid, he might be allowed to remark that that article figured as an item in his business last year to the amount of very nearly £4600, and probably he was the largest consumer of it in the country.

Mr. HUCKLEBRIDGE wished some action could be taken by the Council in this matter, and that some rule should be laid down what this article should be called. They hardly knew what to call it. It could not be called citro-tartrate of soda. Saccharated citro-tartrate of soda with magnesia, known as effervescing citrate of magnesia had been suggested, but that was rather a long name. Supposing persons came and asked for citrate of magnesia, and some was put up in a paper and given them, and they went away and then found they had something with another name to it, what would be the result? It had been ruled that if a person asked for coffee, and you gave him a preparation of coffee with chicory, merely putting a label on, it was no defence.

The PRESIDENT said perhaps Professor Redwood could suggest a label.

Professor REDWOOD said what he wished to impress upon the meeting was this, that whoever the article might be made by there was in the first place a certain essential character about it, and, in the second place, there were certain non-essential characters. The essential character was that part of it resembled in composition and properties a preparation ordered in the Pharmacopœia

under the name of citro tartrate of soda, though he would admit there might be a question whether that name was critically correct. Nevertheless, it conveyed all that was required to be conveyed with reference to an article of that description, and did not at any rate give a false impression with regard to it. This effervescing preparation was essentially a compound of bicarbonate of soda with citric and tartaric acids, and when it was administered it formed what might be called citro-tartrate of soda, which was its essential character. Therefore, the name citro-tartrate of soda being given in the Pharmacopœia, he thought, as members of the Pharmaceutical Society, they would do right in following that example and adhering as nearly as possible to that name. It would not be right, however, to adopt it without qualification, which would be as wrong as to continue the old name. He thought the name proposed by Mr. Bishop was quite unobjectionable, namely, citro-tartrate of soda with magnesia or with magnesia and sugar. Although this might be critically objected to, still it gave a generally correct impression, and there was no deception if the article were sold under that name. He thought Mr. Bishop would take both a wise and politic step in endeavouring to bring the name as nearly as possible to represent the real nature of the preparation. He hoped the meeting would be unanimous in recommending one name, so that there might not be a variety in use all different from one another.

The PRESIDENT asked if the use of the word magnesia could not be dispensed with in reference to this preparation.

Mr. WILLIAMS said the public would have it.

The PRESIDENT said there was very little magnesia in the preparation.

Mr. BISHOP said there was more than the President imagined, and it was a most useful adjunct; in fact, the Pharmacopœia preparation was not nearly so useful; the magnesia was required as a slight laxative.

Mr. BARNES suggested "effervescing magnesia" as the name.

Mr. URWICK said he had examined Mr. Bishop's preparation and found it to contain magnesia.

Mr. UMNEY suggested the name granular effervescing citrate, known to the public as effervescing magnesia.

Mr. WILLIAMS suggested "granular effervescing saline compound."

Mr. UMNEY said in parcels in bulk they might call it "sodæ citro-tart. effervescens, B.P., with sugar, magnesia and lemon flavour." That would correctly indicate the composition of the salt, while the simpler label could be put on for the public.

Mr. SANDFORD asked what would then be done with respect to other citrates—citrate of lithia, citrate of iron, and so on. It seemed to him they were discussing a name for Mr. Bishop's preparation, not for that of the Pharmacopœia. Mr. Bishop's composition was citro-tartrate of soda with magnesia and sugar, but in the Pharmacopœia there was no magnesia at all, and no sugar. He knew many persons sold Mr. Bishop's preparation, as he did himself, thinking it the best, but they must adopt some name which would correctly describe the Pharmacopœia preparation.

Mr. HASELDEN remarked that in his opinion the gentleman who undertook the prosecution in Mr. McDermott's case did a very nasty and unfair thing in attacking an article which had always been known under a certain name, a popular article, and only known by its popular name. He thought that if they altered the name, the public would not know what they were going to have in future. He was as much opposed to wrong names as any one, and, fifteen years ago, writing an article in the PHARMACEUTICAL JOURNAL on names in general, and pharmaceutical names in particular, he drew attention to the false names given to preparations which did not represent what they consisted of. He should advise them to stick to their present name, and add a little magnesia, if necessary, in the shape of sulphate. Paregoric was another name which did not represent what was sold under that name, but the public knew what was meant and approved of it. If they did not take care, they would be interfering with the names of half the patent medicines in use. He believed if the Council represented the matter fairly, they would be allowed to retain the name without being considered as infringing the Act of Parliament, and he should like that step to be taken. Mr. McDermott had evidently been made a scapegoat of.

Mr. URWICK said he had taken a legal opinion on the matter, and was assured that if proper representations were made the name could stand as it was. It was the name given by the proprietor to an article which he had introduced, and he had a right to give it any name he liked.

Mr. SAVORY remarked that according to the report of the case which he had read, the article analysed was merely citro-tartrate of soda, without a particle of magnesia in it. Probably if it had contained magnesia, as Mr. Bishop said his preparation did, that might have made a considerable difference in the magistrate's decision.

Mr. GERRARD suggested that a definite formula should be given for this preparation, and let it be inserted in the Appendix. There would then be something tangible to go upon.

The PRESIDENT said this preparation was a child of Mr. Bishop's, and perhaps it would be the best way for that gentleman to take a ease upon it. He hoped the Council would do all they could to assist him, but he did not see how they could take the initiative in the matter.

Mr. BISHOP said his difficulty was that he was constantly receiving applications from chemists in all parts of the country, asking what they were to do.

The PRESIDENT agreed that everybody must have felt the difficulty, but Professor Redwood had given his approval to the new label suggested by Mr. Bishop, and probably that would meet the case.

Mr. BLAND suggested as a label "effervescing citrate, formerly called citrate of magnesia."

Professor REDWOOD said the objection to that would be that it did not sufficiently indicate the nature of the composition.

Mr. BLAND thought one of the principal reasons for giving a particular name to a new preparation was to conceal its composition. The maker of any proprietary article was entitled to keep the nature of the composition secret.

The PRESIDENT observed that the only person entitled to take action in the present case was the party aggrieved, Mr. McDermott.

Mr. BISHOP said unfortunately he had a bad case to start with, because the article sold did not contain a trace of magnesia. If he had sold his preparation he did not believe the difficulty would have arisen.

Mr. SANDFORD, in reply to a question, said he considered that Mr. McDermott had acted foolishly in that instead of putting forward as a defence the popular name of the article, he simply relied on the fact that being out of it himself he had got it from a neighbour, and sold it in the same state as he had received it. There were special difficulties in the way of the Council taking action in the matter, Mr. McDermott not being a chemist and druggist at all.

After some further conversation,

The PRESIDENT suggested that Mr. Bishop should consult his legal adviser and afterwards communicate with the Council.

Mr. BISHOP said that he would adopt this suggestion and the discussion terminated.

It was announced that the next Evening Meeting would be held on Wednesday, December 3rd.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The second general meeting of the Association was held on October 23rd. The President, Dr. Charles Symes, in the chair.

The following gentlemen were elected members :—Messrs. Fred Ellis, James Marson, and Joseph Brown.

The following donations were announced :—The American Chemist, The Pharmaceutical Journal, and the New York Druggists' Circular.

Mr. J. Hallawell, in opening the discussion on the President's address* said that a resolution which had just been passed by the Council rendered, for the present, further discussion unnecessary. He would, however, say that he concurred in all that Dr. Symes had said. No one who had attended the meetings of the Association during the past session would deny that there had been very little interest shown in its proceedings, and that the attendance had been very poor indeed. It was stated at the last meeting that other similar associations were no better off in this respect than themselves. He doubted this, and even if it were so it was no excuse for their apathy. In one comparison that was made the circumstances were very different. There were in the town mentioned two associations, one for the masters, and another for assistants. This division was objectionable, and in itself a considerable element of weakness. If there were not sufficient members and business for one society, there were still fewer and less to do for two ; he hoped that this Association would always remain united, as both masters and assistants ought to have the same aim and end in view, and would work better together than divided. In the instance mentioned also, although the meetings were not so well attended as they ought to be, the classes for the students had this year proved a success, more than fifty pupils having joined the chemistry, pharmacy, and materia medica classes which had been formed. But the question was, not what others were doing, but what they were doing themselves. If they felt they were falling behind, they should acknowledge the fact and try to remedy the evil. Complaints had been made that the papers read were devoid of interest for the members ; but that is merely an excuse for non-attendance. It was absurd to expect that those who could read papers of interest at the meetings would expend time and labour in producing them, and then find they had to address almost empty benches. Let the members by their regular attendance at the meetings prove that they felt the want of the help this Association was intended to afford, and there would very soon be an adequate supply of valuable and instructive papers, and the Council would be glad to add to these any other means of help and instruction that might be found desirable, either by forming classes or assisting the younger members in forming classes amongst themselves.

Dr. Symes then gave an invitation to apprentices and assistants engaged in the study of pharmacy to meet the vice-president, Mr. Alfred Mason, F.C.S., at the Royal Institution, Colquitt Street, on Thursday evening, November 6th, at 7 p.m., to take into consideration the best means by which this Association could assist students in prosecuting their studies.

Dr. Cook then read the following paper on

Some Practices of the Trade which it would Benefit the Profession to Abandon.

BY EDMUND ALLEYNE COOK, PH.D., F.C.S.

Many times and oft I have heard the question discussed and read discussions on the way in which the pharmaceutical career may be made to take rank as a profession, may be enabled to regain the position of dignity it once held when apothecaries were few and honoured. As you all know, the method most esteemed to attain this end has been to petition Parliament to grant exclusive privileges to such as hold the certificate of the Pharmaceutical Society—which certificate is only granted to those who pass its examinations. This may not be the place to discuss the absolute wisdom of this proceeding. The method is on its trial, and, although it is a return to the monopolising system of ancient days, we can only say it has not yet brought in its train the ancient honours. So far as *I* know the pharmaceutical world, there is not now less dissatisfaction with its position than before the inauguration of the new system. The method is on its trial—results alone can decide its efficacy—and perhaps the time of trial has not yet been sufficiently prolonged to enable us either to discuss or pronounce an opinion on it.

But we can at any rate say this—Whatever means are the right ones to employ to raise the pharmaceutical faculty in the estimation of the public to such a degree that they shall esteem it a profession, they *must* go hand-in-hand with honesty and fair-dealing. So far as I can gather, the plea for its being considered a profession is principally that the practice of pharmacy requires an amount of skill which no person can be expected to possess without having passed through a curriculum of study sufficient to make him more than a generally well-educated man. But we must not ignore the half of what this plea carries with it, viz., that if so much skill be required to practise pharmacy rightly, an equal amount of skill must be necessary to detect imposition and fraud on the part of the skilled pharmacien if he be disposed to practise it. The very qualities on the ground of which he asked to be ranked as a professional man place in his hands a power of imposition against which he offers no guarantee whatever, and to which the public are fully aware they are often subjected.

With the medical men the inducements to fraud and imposition are so few and paltry compared with the interests at stake that the public willingly accord confidence and consideration. No medical man would for his own sake (to take the lowest ground) delay the recovery of his patient for the purpose of increasing his fees. But on the other hand, how often is it the complaint of medical men that medicines they prescribe of ascertained virtue do no good unless obtained from thoroughly reliable sources ; and a "thoroughly reliable source" is by no means necessarily every pharmaceutical chemist's shop.

There are two opposite ropes pulling the pharmaceutical chemist ; on the one hand, he wishes to raise his calling, and on the other he has his living to get, and he naturally wants to get it as well as he possibly can. When, then, these influences do not happen to be in conjunction, the temptation is, in too many cases, to let the profession slide.

I happen to have some considerable knowledge of the wholesale drug trade, and can point my meaning more emphatically. Anyone dealing in drugs knows quite well the variable quantity of active principle contained in many of them. The jalapine in jalap root, the cantharidine in flies, the morphia in opium, the quinine in scale preparations, are excellent instances in point. I can attest that the jalapine in jalap root may and does vary from 2 to 12 per cent. ; the cantharidine in flies from 1 per cent. to none at all ; the morphia in opium from 10 per cent. to none ; the quinine in citrate of iron and quinine from 25 per cent. of sulphate to none. And all the qualities of these different drugs are offered for sale to the pharmaceutical chemist at, of course, varying prices. As matters stand at present, he offers to the public no guarantee which he will buy and sell—and certainly the inferior drugs are bought and sold—and yet it is in the present position of matters that he asks for professional consideration at the hands of the public. Gentlemen, it is an axiom that "the public are gullable," but in hitherto refusing your calling the consideration you have asked, they have shown that they not "gullable" to an unlimited extent.

In these days of competition it is natural for every man to wish to buy as cheaply as he can, for he knows he must sell as cheaply as his neighbours, but there is a point broadly indicated by the common sense of every pharmacien, beyond which cheapness simply means fraud ; and inasmuch as he cannot lay the soothing unction to his soul that he has been deceived, cheapness beyond a certain point means fraud on the public. If the market

* See *ante*, p. 327.

price of sulphate of quinine is 9*s.* per oz., and a druggist is offered and buys citrate of iron and quinine purporting to contain quinine equal to 25 per cent. sulphate, at 2*s.* per oz , or, in other words, purporting to contain 2*s.* 3*d.* worth of quinine alone he must be a very stupid man to suppose it genuine, and it would take a very "gullable" public, acquainted with the facts, to acquit him of *unprofessional intentions.* And even if he is informed that the reason why the preparation is sold at so low a price is because it is indefinitely poorer in quinine than the orthodox preparation, the character of the transaction can bear but one opinion, for the object of its purchase is to retail to the public who know of one quality only.

Yet it is well known to every wholesale druggist that by far the largest quantity of citrate of iron and quinine sold is the cheap variety, the variety sold so low that it is impossible it could contain the official quantity of quinine. I have heard of instances where houses offering the good variety and being undersold have represented to the druggist the impossibility of making the genuine thing for the amount he had paid, and the reply was—"We obtain it from a highly respectable house, in which we have every confidence."

I ask you, gentlemen, Is it likely when such things as these can be, that your calling will be raised in standpoint? Is it likely that any number of Acts of Parliament granting monopolies will effect that object? There is something left undone without which the public will not regard you in a higher light with more respect. In the first place, if it is desirable or essential for a candidate to know all about the source of oil of rhodium, for instance, it is still more essential that he should be able to test the purity and strength of every drug he deals in. By this I do not mean that he should be able to *say* how it is done but to satisfactorily *do* it. In the next place, if pharmaceutists voluntarily offer the public a guarantee of the purity and strength of their articles, transgression of which will entail loss to themselves, they will add a very large claim to consideration and esteem. And if they do not offer it the time, I firmly believe, is not far distant when the public will demand and enforce it, and it will be as dangerous to sell drugs below the official strength as it is to sell adulterated tea or butter.

A guarantee of this kind can easily be offered, and so far as this city is concerned, it is within the power of the Chemists' Association to initiate the reform. If each pharmaceutical member of this Association binds himself to buy and sell only drugs of known and recognized strength, and in cases of doubt to submit them to analysis, either by himself or some appointed chemist, the influence of the Association would take a great leap onwards, the confidence of medical men would be gained, and through these means the respect and consideration of the public, for which you seek. It would be futile to assert that drugs of equal and recognized strength are difficult to obtain and must be purchased at more than a proportionate increase of price. You cannot expect to get a gold ring for a brass price.

For many years it has been the rule in the United States that no opium shall be admitted containing less than 10 per cent. morphia. Whether or not this kind of regulation is applied to the importation of other drugs I cannot say, but of its beneficial effect there can be no two opinions. In the London and Liverpool markets can be purchased all kinds of drugs of all strengths. The manufacturers of extracts and active principles know too well what they are about to purchase the qualities of real inferiority. What, then, becomes of them? They must be taken by the trade to retail, and they *are* retailed to and swallowed by the British public.

What can be more annoying to a medical man prescribing a medicine for a patient than to find a thing supplied destitute of therapeutical properties, or prescribing a blister for some urgent case and finding his efforts rendered perfectly nugatory. It is a grim and trite kind of joke to say men often die by the doctor, but let me ask you to whom the joke should apply—to the doctor who prescribes the right thing, or the man who supplies the wrong?

Can I place before you any more cogent reason why the practice of dealing in drugs of uncertain quality should be abandoned? Can I mention any weightier inducement which can sway honest men to voluntarily band together to offer to the public a reasonable guarantee of their integrity, and so separate them from the fraudulent members of the craft? I trust not; and if you will fully consider the advantages such a proceeding will bring you, in all ways, if properly organized and carried out, I am sure it will not be long before you act together and establish an association as necessary as it will be useful, as highly entitled to consideration and esteem as any recognized profession. In fine, let me sketch roughly a plan in which all earnest pharmaciens might join, by which benefit of the public and of the trade might be secured in the matter of drugs.

I would suggest that the Council of this Association should frame a few rules and lay them before a general meeting; that they announce their willingness to form a branch association, consisting of pharmaceutists only, a chief condition of membership being that the member subscribing to the rules and paying the yearly fee shall thereby undertake to sell drugs of genuine and standard quality only, and agree that if he be proved to have sold any of inferior quality after joining the association that he can on judgment of the Council, confirmed by vote of general meeting, be expelled the association, and that such expulsion be advertised in the public papers. That a chemist to the association be appointed who shall be authorized to report upon any drugs which may be purchased in a recognized way in the shops of members, which on analysis may not come up to the official standard of the association, which shall in some degree be regulated by the pharmacopœia. That the association publish a monthly minimum price-list showing the lowest possible prices at which drugs may be purchased of guaranteed purity. That this price list be for the guidance of members only, and for private circulation among members only. That a private list be kept by the Association of the names of firms known to manufacture or offer for sale drugs of inferior quality, or utterly destitute of therapeutical virtue.

I have no doubt many objections may be stated, and pungently stated, to the above rules, that many additions might be made. One very possible objection which I might perhaps be permitted to notice beforehand is the restriction on free trading which such rules and such an association would exercise.

I am ready to maintain that free trade in drugs for the use of the public is not permissible in the way in which free trade in other articles of commerce is desirable. That this fact is generally recognized to a certain extent is patent by the monopoly granted to pharmaceutists. But that the limit of the restriction should be the dealer himself is manifestly absurd. What earthly cause is there to prevent a man selling jalap containing 2 per cent. active principle in place of 12 per cent.? It may be a fact that the less medicine the consumer takes the better, but this has nothing to do with the question as between buyer and seller; there is every reason that what is deemed desirable as a dose should be honestly supplied. A restriction such as the association and the rules for similar ones to those I have had the honour to propose to you is not too severe a one under the circumstances. Drugs whose quality cannot be judged by appearance should in no case be sold but by analysis.

No one rising to speak,

Mr. Abraham remarked on the silence with which the paper was received. Dr. Cook said he had derived his information from his opportunities in connection with the business of a wholesale house, and he (Mr. A.) hoped some of their wholesale friends would throw further light on the subject. For himself he could neither contradict

nor corroborate what had been said in respect to many of the statements of Dr. Cook, but it was important that retailers should know the facts and be put on their guard. He could not but think that there had been an improvement since the establishment of the Pharmaceutical Society, and the more general diffusion of pharmaceutical and chemical knowledge. But he thought that some of the articles said to be sold would bring the sellers within the provisions of the Adulteration Act—for instance, the sale of citrate of iron and quinine with half or less than half the proper quantity of quinine. He did not see how it could be expected that chemists could wish to join an association which exposed them to penalties which they would avoid by simply ignoring it.

Mr. A. H. Mason : Had not Mr. Abraham broken the silence I am afraid our friends would say, "Silence gives consent," but I am not content to let the matter rest with the onus upon the shoulders of the wholesale dealers. I can fully endorse Dr. Cook's observations about citrate of iron and quinine. It is a fact that three qualities are easily obtainable and are largely bought by chemists—one of B. P. strength ; another with about half the quantity of quinine, and the other of indefinite weakness in quinine. If Dr. Cook's paper will do anything to remove this evil so much the better. Without Dr. Cook from his considerable experience can find us some very much more simple tests for the presence of alkaloid in a given specimen of a drug, I am afraid his suggestion to have only analysed drugs sold would meet with very many difficulties, and if all the evils which he refers to *do* occur the only remedy is for physicians to prescribe alkaloids or active principles only, but this again is not practicable.

Mr. Hallawell said he thought the Association was doing more good in its efforts to thoroughly educate the pharmacist than it could ever do in initiating a movement of the kind suggested by Dr. Cook. If every pharmacist could himself with ease and certainty examine the purity of the preparations he employs, and if he were taught the importance of doing so, very few adulterations would creep into use : the interest that each would feel in his business would prompt him to exercise his knowledge for the protection of his customers. But for this there must be better training and less cramming ; and it was one of the objects of this Association to so direct the studies of its younger members, as to render each of them familiar with the highest branches of pharmaceutical science.

Mr. T. F. Abraham said he thought the Adulteration Act would meet most of the cases described by Dr. Cook. That Act required that when the name used in the British Pharmacopœia was employed the article sold should be of the nature and strength therein specified, and that if the contrary were the case the seller should be deemed guilty of an offence against the Act. With reference to the association suggested by Dr. Cook he apprehended that *were it ever formed* the number of analysts required would be almost as great as the number of members, seeing that most chemists received into stock several samples of fresh drugs daily.

Mr. Redford said he thought that some wholesale houses were now offering to the retail trade drugs which had been analysed by themselves, and he supposed with these a written warranty would be given, such as a dealer gave in selling a horse.

Mr. Shaw said that he had listened to the paper with much interest, and considered that it was one which ought to command the serious attention of every chemist and druggist throughout the country, but he was not prepared to endorse all the representations contained in it. Some of the suggestions, he thought, were quite Utopian. He quite agreed upon the necessity of all chemical preparations being definite in their character, and that when citrate of iron and quinine contained less than 25 per cent. of citrate of quinine it should be labelled accordingly. He then alluded to the difference in price and quality between the foreign and English aconitine, and the temptation to substitute one for the other; the so-called cake-saffron, composed exclusively of the florets of *Carthamus tinctorius*, *refined* bees-wax, etc. In reference to the quality of opium, he remarked that the B. P. required that each sample should contain not less than 6 per cent. of morphia, and qualities were often used containing 10 per cent., being nearly double the strength. He thought it very desirable that the Pharmacopœia should indicate a definite quality, say 8 per cent., so that the opium preparations would be more definitely uniform in their character. Some of the evils alluded to by Dr. Cook time alone would remedy. With respect to the analysis of jalap, rhubarb, etc., the trade must in a great measure depend upon the physical character of the drug and the respectability of the wholesale dealer, at the same time paying a fair price. He agreed with Professor Murphy as to the difficulties of a satisfactory analysis, especially after recent experiences of professional analysts.

After Dr. Cooke had replied to criticisms and answered several questions, a vote of thanks to him was proposed by Mr. J. T. Armstrong, seconded by Mr. Mason, and carried by acclamation.

Parliamentary and Law Proceedings.

Sale of the So-called Citrate of Magnesia. Important Decision.

At the Southwark Police Court on Friday, Oct. 31, Mr. Philip McDermott, chemist, 155, Abbey Street, Bermondsey, was summoned before Mr. Partridge, by Mr. Doman, the sanitary inspector of Bermondsey under the Adulteration Act, for selling as citrate of magnesia a compound not containing any magnesia, thereby liable to cause injury to health, etc.—Mr. Harrison, assistant vestry clerk, attended to prosecute.

Mr. Doman said that on the 26th ultimo he left at defendant's shop a prescription to be made up, and on his return for it he saw defendant, and purchased a quarter of a pound of citrate of magnesia, for which he paid one shilling. He distinctly asked for citrate of magnesia, and when he received it he told defendant he was going to take it to the analyst. The defendant said it was the same as he received it. Witness took it to Dr. Muter, who analysed it, and gave him the certificate produced.

The defendant objected to the certificate being received as evidence, as he wished to ask Dr. Muter a few questions.

Dr. Muter was accordingly sent for, and on being sworn said he was analyst to the vestry of Bermondsey. On the 26th of last month he received a parcel from last witness marked "Citrate of magnesia." He analysed it, but there was not a particle of magnesia in it.

Mr. Partridge asked what it was composed of.

Dr. Muter replied that he found citric acid, tartaric acid, carbonate of soda, and a little sugar. It might be injurious to health if mixed in other medicines where citrate of magnesia was prescribed.

Mr. Partridge asked defendant what he had to say in answer to the charge.

The defendant said that when the inspector left the prescription to be made up he was out of citrate of magnesia, consequently he sent to Mr. Farmer, a neighbour, and purchased 2 lbs. weight of him, and he sold it to the inspector just as he received it.

Mr. Partridge told him that as a chemist he ought to know whether the drugs he sold were genuine.

Defendant replied that such was the case, but it would be impossible for him to have all his drugs analysed.

Mr. Partridge told him it was a very serious offence for chemists to mix articles with drugs which were not mentioned in the prescription. In fact, the consequences might be very serious, and the public must be guarded against such conduct. He must pay a penalty of £10 and the costs of the analysis.—*Standard*.

Is "Rowland's Odonto" a Patent Medicine?

At the Wandsworth Police Court, before Mr. Bridge, Mr. Joseph Delayen, hairdresser, Wimbledon, was summoned by the Excise authorities for selling patent medicines and drugs without a licence.

The son of the defendant said his father was not aware that a licence was required, and the defendant a Frenchman, who spoke very little English, said "Rowland's Odonto," which was the article he sold, was not a drug.

Mr. Harris, the supervisor of Excise, said he called upon the defendant, after the article was sold, for an explanation. He said he was not aware that it was subject to duty. He asked him if he would take out a licence, which would cost him £2, but he said he would not. The son said they did not sell enough in the year to cover the £2.

David Collins, an officer of Excise, said that on the 27th of August last he was passing the defendant's shop when he saw "Rowland's Odonto" in the window exposed for sale. He went in and asked the defendant if he sold it. He said he did, and he gave him 2*s.* 9*d.* for a box.

Mr. Bridge looked at the Act which applied to all things for the prevention and cure of any disease or complaint affecting the human body. He said "Rowland's Odonto" was merely a powder for cleansing the teeth. Every hairdresser in London sold it, but they did not take out a licence.

Mr. Harris said they did.

Mr. Bridge then expressed an opinion that it was not a medicament.

Mr. Harris said it preserved the gums. He submitted that by the advertisement set forth that it would cure disease it came within the meaning of the Act.

Mr. Bridge said "Rowland's Odonto" was no more a medicament than a piece of soap was.

Mr. Harris then referred to the fact that the box of "Rowland's Odonto" bore a stamp.

Mr. Bridge said persons might like to get their articles patented for the purpose of giving them additional character in the eyes of the public. It may be that Rowland was not bound to patent it. He should not convict, but he should be happy to give them a case on the point.

On the suggestion of Mr Harris, the case was adjourned for a month to enable him to lay the case before the Board.

Obituary.

GEORGE DYMOND.

We regret to have this week to record the death of a well-known member of the pharmaceutical profession, Mr. George Dymond of Birmingham. Mr. Dymond was a native Exeter, and after being apprenticed to the trade became a pupil at Bloomsbury Square in the early days of the Society, his certificate on passing the Major examination bearing the early number of 64. He commenced business in Manchester, but in 1856 he married the daughter of Thomas Southall and joined the firm of Southall Brothers and Co., of Birmingham.

Mr. Dymond took a lively interest in both the politics and the progress of pharmacy. His services in the former direction culminated in 1870, when he was elected a member of the Council. This was the session in which the celebrated poison regulations were discussed, and Mr. Dymond moved the resolution which removed those regulations from the realm of law to that of ethics, in which they have since quietly slumbered. The adoption of Mr. Dymond's resolution, though it caused the resignation of the president, Mr. Sandford, did not soothe the feelings of the country, and Mr. Dymond with others lost his seat at the Council at the election of 1871, and did not attempt to regain it.

Mr. Dymond was warmly interested in the progress of pharmacy and in affording facilities for pharmaceutical education in the provinces. He was an active supporter and for two years president of the Midland Counties Chemists' Association; and it was mainly through his efforts that the Association found a local habitation, which, though it has not answered all expectations, has proved of considerable service to assistants in Birmingham in providing them with a reading room and a place of meeting.

For the past year or two Mr. Dymond had partially retired from business, but he was at his office on Tuesday, the 28th ultimo. He had visited Atherstone the previous day on a religious mission, and whilst there he supposed that he had slept in a damp bed, as he felt a chill during the night. That evening he was taken seriously ill with what proved to be an attack of inflammation of the lungs. This increased in severity, and he succumbed to it during the following Monday night. He leaves a widow and several children to deplore his loss.

FREDERICK CRACE-CALVERT.

After a long-continued and severe illness Dr. Frederick Crace-Calvert, F.R.S., died on Friday, October 24th, at his residence, Clayton Vale, Newton Heath. While on a visit to Vienna last July, in order to perform the duty of a juror in the chemical department of the exhibition in that city, he was seized with typhoid fever, from the effects of which he never rallied. His condition was aggravated by ulceration of the lungs, which was the cause of death.

Dr. Crace-Calvert was born in London, he being the son of Colonel Crace, a gentleman of fortune, who took his wife's name on marriage. Dr. Crace-Calvert, however, was educated in France, and it is stated such was the success with which he pursued his studies that the value of the numerous honours awarded to him in the schools was sufficient to defray the cost of his education. He studied chemistry at Rouen, under Girardin, and afterwards at Paris, under Chevreul, of whom he was one of the favourite pupils. Under the latter master he was appointed assistant-chemist at the Gobelin works. Upon his return to England, in 1846, he received the appointment of Honorary Professor of Chemistry in the Manchester Royal Institution. He was also for some time a lecturer at the Manchester School of Medicine. As an active member of the Manchester Sanitary Association his attention was particularly attracted to hygienic subjects, and this, it is said, led him to take out a patent for the preparation of carbolic acid, which was a successful application of the results of the Prussian chemist Runge. Another of his patents which led to a considerable business was for the desulphurizing of coke by means of chloride of sodium. Other patents for the sizing of cloth and the preparation of aniline colours from coal tar were not so successful.

Dr. Calvert's experiments on protoplasmic life and the origin of putrefaction, so far as they are published (see Pharm. Journ., vol. ii., pp. 184 and 1013), have been of great interest, and were the cause of the invention of an ingenious apparatus for the distillation of absolutely pure water free from germs (Pharm. Journ., ii., p. 263). In connection with the Society of Arts, Dr. Calvert delivered courses of Cantor Lectures on "Chemistry Applied to the Arts," "Synthesis, and the Production of Organic Substances," "Aniline and Coal Tar Colours," and on "Dyes and Dye-stuffs other than Aniline," the latter printed in the second volume of this Journal.

Dr. Crace-Calvert was a Fellow of the Royal Society of England, Fellow of the Chemical Society, Honorary Fellow of the Chemical Society of Paris, a Member of the Royal Academy of Turin and of the Imperial Academy of St. Petersburg. His doctor's degree was forwarded to him by the late Baron Liebig.

Notice has also been received of the death of the following:—

On the 6th October, 1873, Mr. Benjamin Jones, Chemist and Druggist, of London Road, Twickenham. Mr. Jones was a Member of the Pharmaceutical Society.

On the 23rd October, 1873, Mr. William Horsley, Chemist and Druggist, of Malton, Yorkshire.

On the 3rd November, 1873, Mr. Joseph Bateman Dodd, Chemist and Druggist, of Manning Street, Bermondsey.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

THE ADULTERATION OF FOOD AND DRUGS ACT AND THE SO-CALLED "GRANULAR EFFERVESCENT CITRATE OF MAGNESIA."

Sir,—The decision of the magistrate in the McDermott case, fining him £10 for selling a preparation labelled "Citrate of Magnesia," which, according to the analysis of Dr. Muter, did not contain a particle of magnesia, has caused much anxiety among chemists, dealers in the so-called citrate of magnesia. The subject was brought before the Council of the Pharmaceutical Society in committee, on Wednesday afternoon, and again at the evening meeting of the Society of the same day. The Council appeared to be fully agreed as to the injustice of the magistrate's decision in fining Mr. McDermott £10 for selling a popular, useful, and harmless preparation, under the name it was called when first introduced about fifteen years ago, and by which name it has been universally known and sold to the public ever since, and I leave to the report in to-morrow's Journal that which took place at the evening meeting, when there was great discussion and much interest felt in giving this useful and harmless preparation a new designation; and, in reply to many private correspondents, I beg to say that I intend to attach the following label to all sold by us—John Bell and Co.—until I hear of a better one, and which I trust will be sufficient to prevent us chemists from being placed in the position of the unfortunate defendant, Mr. McDermott, to whom I yet hope that justice will be done by getting the decision reversed:—

This preparation, generally known as "Granular Effervescent Citrate of Magnesia," is the "Effervescent Citro-tartrate of Soda" of the British Pharmacopœia, with Magnesia, Sugar, and Essence of Lemon.

THOMAS HYDE HILLS.

338, *Oxford Street, W.*

Sir,—On account of the recent prosecution of a retail chemist for the sale of so-called "citrate of magnesia" we have determined as manufacturers to label all such effervescent salt when sent out in bulk as

SODÆ CITRO-TART. EFFERVES.
(*Brit. Pharm.* 1867).
WITH MAGNESIA, SUGAR, AND LEMON FLAVOUR,
KNOWN BY THE PUBLIC AS
CITRATE OF MAGNESIA.

As it is undoubtedly advisable that the label to which the public has for so many years been accustomed, upon the usual retail bottle, be altered as little as possible, we would suggest that the name (for retail) be modified as follows:—

GRANULAR
EFFERVESCENT CITRATE,
KNOWN BY THE PUBLIC AS
CITRATE OF MAGNESIA.

and possibly in addition, in order more strictly to comply with the requirements of the Act, and that the public may be educated as to its true composition, it would be expedient to affix a small label to the bottle indicating that citro-tartrate of soda, sugar and magnesia are the component parts of the salt.

Although we have during the past week communicated our views by circular to our friends, still we thought, that through the medium of your valuable Journal, greater publicity would be given to a matter which at the present time is of interest to the trade.

HERRINGS AND CO.

40, *Aldersgate Street, London, Nov.* 7, 1873.

Sir,—I wish to call your attention to the prosecution of a chemist which appeared in Saturday's papers, the result of which will, I am sure, astonish and rouse the pharmaceutical brotherhood.

It is doubtless a desirable thing to have the watchful eyes of inspectors and the scientific skill of analysts brought to bear upon all frauds and adulterations, so that the public may enjoy the necessaries of life without fear and suspicion, but there is a possibility of over-officiousness, which, combined with the ignorance of the presiding authorities, may render its working vexatious and unjust. Now, I venture to say that no chemist will concur in the justice of the fine imposed last week upon Mr. McDermott of Bermondsey for supplying the well known granular preparation, popularly as citrate of magnesia, but in reality being nothing more than the Pharmacopœia preparation of citro-tartrate of soda with sugar.

The offence consisted in supplying the above-mentioned compound under the name of citrate of magnesia, backed up by the opinion of the analyst (Dr. Muter) that it might be injurious when taken with other medicine. Mr. McDermott, in defence, said he supplied his customer with the article as he obtained it from another chemist, being himself out of it at the time. But a second "Daniel had evidently come to judgment," and decided that as a chemist he was responsible for, and should know whether his drugs were pure or not.

Such a decision is evidently a matter of congratulation for the wholesale trade, for it relieves them in future from all responsibility, and the retail chemist must henceforth submit his goods to the strictest analysis, and, in the event of having to send out for anything in haste, must keep his customer waiting till the analysis is performed. It is very unfortunate that names should be given to compounds, which in no way express their composition until the public identify the article with a certain name, and will receive it under no other; and it is rather hard that the penalty—a public fault—should fall upon the shoulders of an individual. I am sure the trade will watch with anxiety the steps which the Pharmaceutical Society may think fit to take in the matter, and will feel much relieved for such information as shall enable it to be secure from traps such as that in which Mr. McDermott has been caught.

WM. WARREN.

1, *Ormond Villas, Cheltenham.*

Sir,—I enclose paper extracted from the *Daily Telegraph* of Saturday, November 1st. If such convictions are to take place very few chemists are, I think, free from danger.

In my opinion the article sold as mag. cit. should have its official christening by the Society, who should look after chemists' interests.

T. BIFFIN.

Herne Hill, Nov. 3rd.

Sir,—The recent decision of the Southwark magistrate with reference to citrate of magnesia must have caused an anxious thought to many chemists, as it may safely be asserted that all, from the proprietor of the select West-end dispensing establishment to the remote country sundryman, are equally liable to be placed in the same unpleasant position as Mr. McDermott.

As a temporary bridge over the present difficulty, I would suggest to others of the brethren favoured with a similar prescription for effervescing citrate of magnesia the following form, while in selling the article now known by the name of citrate of magnesia the labels might be printed to read "Granular Effervescing Salt, usually called Citrate of Magnesia," etc., etc.

℞

Mag. Carb.	6½ drachms.
Sodæ Bicarb.	12 ,,
Acid. Citric.	20 ,,

Mix.

H. BUTTERWORTH.

70, *Tottenham Court Road, London, Nov. 3rd,* 1873.

Sir,—Prominent members of our Society have been very fond of advocating and agitating for legislative enactments calculated to render more select and "respectable" the pharmaceutical body in which they themselves have won, *or inherited*, so much credit.

The 5th of November of this year will be memorable in the annals of *our* Parliament for the spectacle it afforded of the consternation and indignation of these our representatives at the turn events have recently taken; our worthy leaders are afraid of being "hoist by their own petard"! I do not mean by this to insinuate that the indignation of the trade at large (of which the Society has now become the recognized embodiment) will lead them to do anything so revolutionary as to sweep away the old regime *in toto* and substitute a less oligarchical form of government—one less aristocratic and more representative of the average shopkeeper. Without presuming to prophesy this I do urge that if the Council wish to remain popular they should not ask individuals to bear the brunt of such a contest as now threatens, so evidently felt by everybody as affecting themthemselves. Subscriptions have accumulated to an inconvenient amount, yet when the subscribers are threatened with heavy penalties by Acts which Council-men have promoted, the said Council backs out from the onus of settling the question, though that solution would be a relief to every member of the trade. We are not *all* getting our living by the leading dispensing establishments of Britain, and cannot therefore wash our hands of the matter by saying we do not care if we never sell another ounce of mag. cit.

As far as I am personally concerned I do not suppose I shall sell any more, but if I run foul of the Act it will be in the capacity of manufacturer (at others' dictation) and therefore incur the "imprisonment with hard labour" which amused the meeting so on Wednesday.

JOHN P. CATFORD.

36, *Prince's Square, Kennington Park Road,*
Nov. 6, 1873.

Sir,—Now that the Adulteration Act passed in August last year is being enforced in a manner by which many vendors of food, drink, and drugs are fined, as they think not altogether in accordance with either the letter or the spirit of the Act so far as the meaning of the word adulteration is held to be there laid down, I think the time has arrived when it has become necessary for the drug trade, or the Council of the Pharmaceutical Society as having the initiative in the enforcement of the Pharmacy Act, 1868, which it will be recollected is incorporated in the Adulteration Act, to take some steps of united action to prevent and protect themselves from factious and, if not ignorant, hastily considered litigation upon the purity of drugs. Some vendors of the first and second divisions—food and drink, and notably milk in the latter—admit their adulterations, are fined, and may be dismissed accordingly, hoping they will "go and sin no more;" but I am induced to write to you to bring under consideration cases of the third division—drugs—where there is not the slightest intention of adulteration or fraud upon the public, and these cases, as I think, will apply with the same force to the wholesale as to the retail trade. By the Medical Act, 1858, and a subsequent Act, 25 and 26 Vic., the British Pharmacopœia, 1867, is the unquestionable standard and guide whereby the definition, nature, strength, and composition of the *medicines the physician prescribes* is to be ascertained and determined, and in the Pharmacopœia, so far as I can find, though the word drugs is not mentioned, yet I presume no one will cavil at the idea of the words being considered synonymous, and, therefore, chemical compounds used in medicine would be classed in the division of drugs. Those engaged in the preparation of medicines, that is drugs as intended in the Adulteration Act, sell them to the public in two ways, either by prescription of some medical practitioner, which method is under particular restrictions, as laid down in the Pharmacy Act, or directly to the vendee on demand. This being the case prescriptions can only be prepared with strictly pharmacopœial articles, and any departure in such articles in nature, strength and composition must be looked upon as an adulteration and ought to be rigorously treated as such; but when selling direct I apprehend the argument does not hold, at any rate, the Pharmacopœia nowhere notices it. Drugs that are simple natural products at once and clearly speak for themselves. Compound medicinal substances if according to some Pharmacopœia, though differing from that of 1867, surely ought not to be considered as adulterations of the said 1867 pharmacopœial articles, when they happen to have the same or a similar name, and when sold ought not to require the double declaration, printed and verbal, that they are compounds not injurious to health. I have purposely put this in its widest or most general sense, but as an illustration will take the (in England) familiar instance of the every day sold sweet spirit of nitre formerly spt. etheris nitrici, sp. gr. ·850. The ultimate replacement of this as in the present Pharmacopœia is the spirit of nitrous ether, sp. gr. ·845., and which is, as every one in the trade knows, the dearer of the two, arising both from spirit, strength and process of manufacture. Now if I sell the former under the ordinary popular name, have I committed an offence, as defined in the Adulteration Act? I think not, and should like to see some authoritative opinion, say that of the public analysts themselves and the trade, on the subject in all its bearings.

With regard to the citrate of magnesia prosecution of Mr. McDermott, of Bermondsey, reported in the London papers of Saturday last, you will doubtless have numerous communications, so I will not trouble you about it at present, as I fear I have trespassed already too much on your space.

Will you allow me to suggest that if you were to publish the full text of the Act it would be a great aid to the discussion of the legality of a certain course of action contemplated by the sanitary authority in one of the metropolitan districts?* I refer to the reported recommendation to the public analyst in that district that he should obtain *privately* samples of drugs for analysis. That this phase of the Act, if legal, is a very undesirable one, is the opinion of

A DRUG TRAVELLER.

THE ADULTERATION ACT.

Sir,—Seeing in the *Standard* of the 1st inst. an account of a chemist and druggist in London being fined £10 for selling citrate of magnesia, which same was proved to contain no magnesia whatever, I beg to make a few remarks on the subject.

It is well known that the substance commonly called citrate of magnesia is used chiefly, throughout England, simply as a cooling effervescent drink.

When prescribed by physicians it is usually called by its correct name—sodæ citro-tartras effervescens.

With regard to this case, the defendant pleads that he cannot have *all* his drugs analysed, and with great truth too. Surely our profits are not so large that we must fling them away on analysis.

As to the fine, I must say, and I know that others will think with me, that it is excessive for so slight an adulteration, if one it can be called. As the article in question does not appear in the Pharmacopœia (under its present name), why does Mr. Partridge comment so strongly on the danger the public are placed in by taking citrate of magnesia, which same contains no magnesia. Surely it is a voluntary act on their part, and I doubt very much whether, were the magnesia added in such proportion as to make it effective, one half of the people would patronize it who do so now. Are there no other things called by wrong names? In a seidlitz powder how much is there of the *real* salt? How much oftener is seltzer water made from water and carbonic acid? and of the chief part of the soda and potash water sold how seldom do we find either one or the other alkali in them on analysis?

The man who sells adulterated tea is not tho more leniently dealt with because he pleads that he is not responsible for the failings in honesty of his wholesale house. But who is it that ought to be dealt with on *this* and on other similar occasions? Surely the manufacturer. The chemist orders citrate of magnesia, never expecting for an instant that the respectability and high principle of the manufacturing establishment carried on for so many years back would stoop to send him anything but the *genuine* article; and he receives a compound in which the most prominent ingredient (in the name of the substance) is entirely left out. He takes it in perfect good faith and retails it to his customers, fully believing that it is all right, until he is awakened from his lethargy by finding, from the sudden demand on his pocket, that it is not all right—in fact, it is anything but right. No wonder he exclaims, "Is this justice!"

In conclusion, let me advise the members of the profession

---

* It has already been printed in vol. iii. p. 252.

to endeavour to rectify the error into which they have fallen as regards this compound by appending a new label to the following effect:—"Effervescing Citro-Tartrate of Soda, commonly called Citrate of Magnesia."

Some Practices of the Trade which ought to be Abandoned by the Profession.

Such is the title of a very suggestive paper read at a recent meeting of the Liverpool Chemists' Association by Dr. Cook.

It is generally admitted that one of the greatest difficulties in preparing a paper is the selection of a proper title, one which will convey to the mind what is really intended by the author, and I might venture to suggest that a title somewhat shorter and to the purpose would have read thus—"Some Unprofessional Practices of the Trade"; for wherever the trade merges into the profession the practices which Dr. Cook charges on the former must of necessity have disappeared. It is a case in which Darwin shines resplendent; an instance of development and natural selection. In our primitive condition we are *tradesmen*, (and it would appear not always of the most satisfactory character); as our educational position improves—in fact, as we rise in a higher state of development—the tone of our business improves, our drugs become purer, and these facts influencing the medical profession and the public, selection is made for confiding the higher duties of our calling.

If this be correct, it will be evident that there is still much, very much, of the trade character existing amongst us. Dr. Cook makes his statements from his past experience in the wholesale, and it could have been hoped that the "practices" were of the past also, but that in the subsequent discussion they were substantiated as of the present by two representatives of wholesale firms.

Citrate of iron and quinine is taken as a familiar example, and we are told that about three-fourths of the quantity sold in this country does not contain more than 12½ per cent. (much of it an indefinite quantity) of citrate of quinine instead of 25 per cent. as required by the British Pharmacopœia. It seems almost impossible to realize such a fact, such an open violation of all law and conscience. Before its introduction into the B. P., manufacturers had a right to prepare this article of any strength they chose, and allow it to stand on its merits, but immediately it became thus recognized, citrate of iron and quinine meant simply a preparation containing one-fourth citrate quinine and three-fourths ammonio-citrate of iron, and *the manufacturer who uses a less proportion of the former is just as much a sophisticator and adulterater as he who waters our milk, tampers with our food, grinds sawdust with medicinal powders, or mixes cinchonine with quinine, and is equally amenable to the law.* It would be well if the wholesale people would expunge such compounds from their lists, and cease to offer them for sale. The questions, too, of opium with only 4 per cent. of morphia, jalap containing but 2 per cent. of jalapin, and yellow bark minus quinine, are such as merit attention. If there were no demand for these the supply would soon cease, and here the sin comes home to the retailer, who has many plausible excuses for his malpractices. If in a poor neighbourhood, he says, his customers will not pay the price for best drugs. This I believe to be a mere subterfuge; I have had some experience amongst poor as well as rich customers, and never found the former more unwilling than the latter to pay a fair price for a good drug.

Pharmacy is indebted to Dr. Cook for the initiative step he has taken, but I trust the matter will not rest here. There are many as desirous as himself of seeing the English market cleared of such vile compounds and such unsatisfactory drugs. Let us hope it will not be long ere it is so.

A Practical Pharmacist.

The Remuneration of Assistants.

Sir,—In the Journal of Nov. 1, I observe a leading article upon the result of the recent examinations held in London, and an expression of surprise at the reluctancy with which assistants avail themselves of the great advantages and opportunities offered to them.

Now it is my opinion as an assistant, studying at the present time for the Minor, that before the assistants will grasp the opportunities offered to them, with readiness and pleasure, a better future must be offered, with better situations and larger salaries, and with sufficient time for study.

Now, to you as a man of practice, and one with an interest in the trade, it must be evident that after being in business from 7.30 a.m. until 9 or 10 p.m., any time between that and bedtime is required for bodily exercise, not *mental labour*. I have myself filled several situations, but at neither of them have I had time given me for attending lectures, or for study. The time an assistant gets to himself as a rule is that part of the day or night which is of little use to his employer or himself; and before the body of assistants are condemned for want of knowledge it would be more in place to show to them some leniency and pity, and consult those under whom they labour, as I think the matter lies more in the hands of employers than with the employed. I, during my career in the trade, have not met with a single man who did not wish to shine and progress in the scientific part of his trade, if money and time would but allow him.

It is well for those living in London, where lectures, museums, botanical gardens, etc., are available; but assistants must be had in country as well as town, and to country assistants these examinations are a great hardship, and a great labour, and it is not in the power of all to go up to London for three or six months' scientific training; salaries will not allow that. For my part, I do not quite see what amount of science is required to qualify one to retail horse powders, face powders, paraffin oil, and lamp candles, which constitute a part of a country chemist's stock in trade. In conclusion, I should like to relate an instance respecting salary that was brought under my own notice. A chemist, who had passed the Minor with honours, being in London, applied at a pharmacy not far from South Kensington, for a situation there vacant. His qualifications were stated, and he was offered the magnificent sum of *twenty-five* pounds per annum, more being decidedly refused; of course the offer was declined. With such encouragment who would strive to become a Minor man, with honours, by severe application to hard study, and spend in the attempt money which it would take two years of hard work to return.

W. H. Heynes.

Remuneration of Chemists.

Sir,—I find in the Journal of Oct. 18th a letter from "Sensitive," 520, Oxford Street, having reference to the remuneration of chemists, and complaining of the low charge made by a "House of position" for dispensing a prescription. I would wish to point out to "Sensitive" that statements made by customers are not always to be depended upon, and that a chemist charging 1*s.* 3*d* for dispensing the prescription in question does not himself occupy such a position as would warrant him in finding fault with prices charged by any other House, however low they may be.

E. L. H.

Chelsea.

R. Y.—The genitive should be used, some such phrase as "a sufficient quantity of" being understood.

"*Colchicum Autumnale.*"—A thorough acquaintance with the contents of Attfield's Chemistry would enable you to pass the chemical portion of the Minor examination. The other subjects are pharmacy (including practical dispensing and the reading of prescriptions), botany, and materia medica.

"*Subscriber.*"—Forms for pot-pourri and sachet perfume will be found in the first volume of the present series of this Journal, pp. 377, 496, and 515.

A. D.—'Proctor's Practical Pharmacy' is published by Messrs. Churchill. Price 12*s.*

"*A Pharmaceutical Chemist*" is thanked for his communication. The case was not heard by the magistrate until after the last number of the Journal had been printed.

E. L.—The colouration is probably due to the presence of a little free acid.

C. B. A.—(1) We have not found that anything of the kind that you describe takes place. (2) The specimen you have forwarded is ordinary soluble glass.

Communications, Letters, etc., have been received from Messrs. W. J. Pridgeon, G. L. Napier, Whitrod, Bilney, E. T. H., R. T., J. H., W. J. S., Secretary of Glasgow Chemists' Association, Secretary of Norwich Chemists' Assistants' Association.

MUSTARD.

BY THOMAS GREENISH, F.C.S.

Since the passing of the Act "for the Prevention of the Adulteration of Food," no article has created more discussion or been more severely handled than mustard. The public press has teemed with letters on the subject of its adulteration, some from writers who evidently know little or nothing about it, and others from those who should know all about it. In some of them it is not difficult to detect the promptings of the manufacturer; as a consequence, a cloud of "commercial dust" has blinded many persons to the real question at issue, Does the admixture of flour with mustard fulfil any beneficial or necessary purpose, or must its presence be regarded as a substance to "increase weight or bulk, in fraud of her Majesty's subjects"—in fact, as an adulterant?

A glance at the early history of the mustard manufacture may not be out of place here, Mustard seed was used medicinally by the Greeks, and held by them in such estimation that the discovery of its medicinal value was attributed to Æsculapius. It would be difficult to determine satisfactorily when it was first used as a condiment in this country, but it seems probable that its employment dates from about the time of the Saxons. It does not appear generally to have been ground up, as it is at the present time, but was usually eaten whole, a practice that at least protected the consumer from adulteration. Gerarde says, "The seede of mustard, pounded with vinegar, is an excellent sauce, good to be eaten with any grosse meates, either fish or flesh, because it doth help digestion, warmeth the stomacke, and provoketh appetite." At the present time vinegar and spices enter into the composition of the French mustard, and contribute to its keeping qualities. Mustard is not a fancy condiment, it has a distinct hygienic value. A French writer* thus speaks of it:—

"Of all the condiments used at table for giving flavour to meat, for stimulating the appetite, and disguising the faults of cooks, mustard is without doubt that which occupies the first rank, not only from its antiquity, which dates back to the time of the Hebrews, but also from its beneficial qualities. According to medical authority this condiment, the dietetic use of which is so general, greatly assists the organs of digestion. It augments, by the slight irritation it causes, the strength and elasticity of the fibres, it excites in the stomach and intestines the digestive juices, and promotes the passage of the residues of food by accelerating the peristaltic movement.

"Mustard agrees, therefore, with indolent, lymphatic, and weak stomachs. It is wholesome to those whose stomachs and intestines are torpid, and hence it is especially useful to aged persons."

Previous to the year 1720, mustard was prepared for use by pounding the seeds in a mortar, and roughly separating the integuments, but it is said to have occurred to a woman named Clements, of Durham, to grind the seed, and then dress the flour. The mustard so prepared was superior to any other, received royal patronage, and enjoyed an extensive sale; the process was kept a secret, and a fortune realized. Hence Durham mustard became celebrated, and the name was long retained by makers to indicate mustard of a superior quality. Thus far efforts were directed to the manufacture of a pure mustard; but all this has long since undergone a great change, and now looking over a manufacturer's list of qualities we see a great variety, from a mustard flavoured with flour to a flour flavoured with mustard.

Attempts have been made to justify the addition of flour to mustard on two grounds only worth consideration. The first is, that a pure mustard when made for table use is more liable to fermentation than one made with an admixture of flour. Theoretically, I should doubt this statement; at this cold season of the year any experiments to determine the point would not be conclusive, but my own experience is opposed to it, and I have frequently examined samples which had been mixed and kept in a mustard pot more than a week, without showing any sign of decomposition. If mustard for table use will keep good a week or more, I do not think there is much ground for complaint. Pure mustard becomes darker after being prepared for use, but the same remark would apply to the mixed article did not the turmeric present in it keep up the colour. I do not, therefore, consider the statement as regards the relative keeping qualities of a pure mustard and one having the addition of flour of much value.

The second ground of justification is, that the public taste prefers the mixture of flour and mustard to pure mustard, on the same principle, I presume, that a donkey prefers thistles when unable to get hay. I have long kept nothing but a pure mustard flour, and have used nothing but a pure mustard flour, but I am ignorant of any difficulty as regards its introduction or use. I would here refer to a letter bearing on this part of the subject, written by Mr. Frazer, and to which I would direct attention.* He states that his difficulty in introducing the genuine mustard was mainly due to its differing from the commercial mustard in colour; the public had been accustomed to a bright yellow, whereas a genuine flour of mustard is rather of an olive green colour. The demand is daily increasing for a pure flour of mustard, and manufacturers may rest assured that the time is not far distant when the public will have no other. I cannot conceive any special difficulty in its more general introduction and use, neither can I accept the apologies for the admixture of flour, and those other things which follow in its train. If flour possesses a value in itself, why add turmeric to make it resemble mustard? I have not yet heard an argument capable of being maintained in justification of this dilution of mustard by the addition of flour, and I must adhere to my former statement that a mixture of the flour of black mustard seed with a fair proportion, not more than 20 per cent. of that of the white seed, will make a mustard acceptable for table use; strong it must necessarily be, but that surely cannot be considered an objection.

It is curious to observe the different reasons given for the addition of flour to mustard: one says that a little flour gives a flavour to mustard; another that it adds to its keeping properties; and a third that mustard without flour is too pungent for use at the table. It is much to be desired that the advocates of these several theories would institute some experiments, and publish the exact quantity of flour necessary for each and all of these purposes.

It is a significant fact that in the International Exhibition just closed, a large and celebrated manufacturer of mustard had a model manufactory, showing every stage of the process, and nothing but the

* *Journal des Travaux de l'Académie Nationale.*

* PHARM. JOURNAL [3], vol. iii., p. 783.

pure flour of the black and white mustard seed was manufactured, packed, recommended, and sold there. No allusion was ever made to such a "valuable" addition as flour, and no apology made for its absence.

The mixture of flour in different proportions with mustard enables the manufacturer to suit the article to the price of the retailer, but the ultimate purchaser is the sufferer; he pays for the mixed article more than the intrinsic value of the mustard and flour. Its sale to the public as mustard is not justifiable.

In a former paper I have shown that the flour of the black seed is the essential constituent of mustard, and to the production of its volatile oil the pungency is due; that white mustard yields the milder flour; and also the theory of its addition to the black in definite proportions. I have likewise alluded to the process for detecting by the microscope the presence of flour and turmeric in commercial samples; but this is not all that a thorough examination of mustard, even when pure and free from flour, involves; care must be taken to determine the relative quantity of black and white, as the latter in too great a quantity is also a diluent, though not an adulterant.

In mustard the distinction should always be borne in mind between genuineness and quality. A genuine mustard may be made of any quality and to suit any price, dependent mainly on the relative proportions of white flour to the black. The large white seed costs less as seed and gives more flour than the black; and on reference to trade circulars it will be seen that genuine mustards range from 9*d.* to 1*s.* 6*d.* per lb. In some cases the mustard sold at a low price as genuine is composed of the white flour alone.

I cannot avoid the conclusion that if the retailer, when asked for mustard, sells a compound of mustard and flour, without at the same time declaring it as such, he renders himself liable to the second part of the 2nd section of the Adulteration Act,—"and every person who shall sell as unadulterated any article of food which is adulterated, etc.,"—in selling an article adulterated or "debased by foreign mixture."

BOTANICAL ORIGIN OF THE BALSAMS OF TOLU AND PERU.*

BY PROFESSOR BAILLON.

The plant which yields the balsam of tolu, and which, during the present century, has been described under the name of *Myroxylon toluiferum*, was named by Linnæus, in his 'Materia Medica,' *Toluifera balsamum*, and that name should still be retained for it. The younger Linnæus thought that the balsam of Peru was the product of another leguminous plant of the same genus, which he had received from Mutis, and which he named *M. peruiferum*. This was an error, since the pretended balsam of Peru did not even come from South America, but from the *Costa del Balsamo*, or Balsam Coast, in San Salvador. The tree which produces the greater part of this San Salvador balsam is that which Klotzsch, multiplying beyond measure the species of the genus, designated under the name of *M. Pereiræ*, but which cannot be separated specifically from *Toluifera balsamum* (*M. toluiferum*). Here, as in the entire genus, characters taken from the form, size, and proportions of parts of the fruit,—especially of the wing at its base, which varies infinitely in size and direction in one and the same plant,—cannot be held sufficient for the separation of species. The elongated, or more or less punctiform pellucid spots of the leaflets, do not appear as though they ought to be considered to have specific value; hence the slight value of *M. punctatum*.

The different qualities and characters of the balsams seem to depend entirely upon the method of extraction. But all the forms of *T. balsamum* have one constant character in the smooth surface of the seeds, which arises from the fact that the cotyledons are not ruminated. On the contrary, in *M. peruiferum*, which should take the name of *Toluifera peruifera*, they are ruminated. This latter tree yields scarcely any useful products, or at least any sent as such to Europe. The balsamic substance is present, however, on the surface of the seed, as in *T. balsamum*, but in less quantity, and it is sunk into the crevices of the seminal envelope, instead of being deposited in a smooth layer. This is the sole difference between the two species of the genus *Toluifera*.

* Note read before the Congress at Lyons (*Répertoire de Pharmacie* [N.S., i., 566], from the *Revue Scientifique*).

THE VEGETABLE COLOURING MATTER FOUND IN MADDER.*

BY W. J. RUSSELL, PH.D., F.R.S.

(*Concluded from page* 348.)

Some years afterwards Wöhler also examined the decomposition of quinic acid; he prepares again this quinone, and follows exactly the process described by Woskrensky: he states that, with regard to the properties of this remarkable body, he has nothing particular to add; however, he proposes a different formula for it, and discovers and describes other bodies allied to it; among these is hydroquinone, $C_6H_6O_2$. Laurent afterwards shows that the formula proposed by Wöhler is inconsistent with his and Gerhardt's views, and by experiment confirms the former formula for this body. Although many other chemists devoted much attention to this substance, still its real constitution and relation to other compounds remained long unknown. Thus Wöhler, Laurent, Hofmann, Städeler, and Hesse all had worked at it, and much experimental knowledge with regard to it had been acquired. One important point in its history was, first, the discovery of chloranil by Erdmann in 1841, and then Hofmann showing that by heating quinone with potassic chlorate and hydrochloric acid, chloranil could be obtained from it—that, in fact, chloranil was quinone in which all the hydrogen had been replaced by chlorine. Perhaps the most general impression among chemists was, that in constitution it was a kind of aldehyde; certainly its definite place among chemical compounds was not known. Kekulé suggests a rational formula for it; but it is to Carl Graebe that we owe our knowledge of its true constitution. In 1868 he published a remarkable and very able paper on the quinone group of compounds, and then first brought forward the view that quinone was a substitution-derivative of the hydrocarbon benzol (C_6H_6). On comparing the composition of these two bodies, it is seen that the quinone contains two atoms of oxygen more and two atoms of hydrogen less than benzol; and Graebe, from the study of the decomposition of quinone and from the compounds it forms, suggested that the two atoms of oxygen form in themselves a group which is divalent, and thus replace the two atoms of hydrogen; this supposition he very forcibly advocates, and shows its simple and

* Presidential Address to the Chemical Section of the British Association, delivered at Bradford, Sept. 18, 1873.

satisfactory application to all the then known reactions of this body. This suggestion really proved to be the key, not only to the explanation of the natural constitution of quinone and its derivatives, but to much important discovery besides.

At this time quinone seemed to stand alone, no other similarly constituted body was known to exist; but what strikingly confirms the correctness of Graebe's views, and indicates their great value, is that immediately he is able to apply his lately gained knowledge, and to show how really other analogous bodies, other quinones in fact, already exist. He studied with great care this quinone series of compounds and the relation they bore to one another—the relation the hydrocarbon benzol bore to its oxidized derivative quinone, and its relation to the chlorine substitution-products derivable from it. At once this seems to have led Graebe to the conclusion that another such series already existed ready formed, and that its members were well known to chemists—that, in fact, naphthalin ($C_{10}H_8$) was the parent hydrocarbon, and that the chloroxynapthalin chloride ($C_{10}H_4Cl_2O_2$) and the perchloroxynaphthalin chloride ($C_{10}Cl_6O_2$) were really chlorine substitution-compounds of the quinone of this series, corresponding to the bichloroquinone and to chloranil; that the chloroxynaphthalic acid, $C_{10}H_4Cl(HO)O_2$, and the perchloroxynaphthalic acid, $C_{10}Cl_5(HO)O_2$, all compounds previously discovered by Laurent, were really bodies belonging to this series; and, further, that the supposed isomer of alizarin discovered by Martius and Griess was really related to this last compound, having the composition $C_{10}H_5(HO)O_2$. Further, he was able to confirm this by obtaining the quinone itself of this series, the body having the formula $C_{10}H_6(O)_2''$, containing also two atoms less of hydrogen and two atoms more of oxygen than the hydrocarbon naphthalin; and to this body he gave the characteristic name of naphthoquinone. The chlorine compounds just named are, then, chlornaphthoquinones or chloroxynaphthoquinones, and correspond to the former chloroquinones; and Martius and Griess's compound will be an oxynaphthoquinone: many other compounds of this series are also known. Another step confirmatory of this existence of a series of quinones was made known by Graebe and Bergmann: as the choranil could be found by treating phenol with potassic chlorate and hydrochloric acid, and quinone derived from it, they showed that in the next highest series to the phenol series, viz. with cressol, the same reaction held good; and by treating it in the same way, they obtained a di- and a trichlorotoluquinone, $C_6\begin{cases}CH_3\\(O_2)''\\Cl_2\\H\end{cases}$, $C_6\begin{cases}CH_3\\(O_2)''\\Cl_3\end{cases}$, which in physical properties very closely resembled the corresponding compounds in the lower series: other compounds have also been prepared.

In the next step we have the application which connects these series of discoveries with alizarin. Following the clue of a certain analogy which they believed to exist between chloranilic acid $\left(C_6Cl_2\,\frac{(O_2)''}{(HO)_2}\right)$ and the chloroxynaphthalic acid $\left(C_{10}H_4Cl\,\frac{(O_2)''}{HO}\right)$, which they had proved to be quinone compounds and alizarin, believing that a certain similarity of properties indicated a certain similarity of constitution, Graebe and Liebermann were led to suppose that alizarin must also be a derivative from a quinone, and have the formula $\left(C_{14}H_6\frac{(O)_2}{(HO)_2}\right)$.

This theory they were able afterwards to prove. The first thing was to find the hydrocarbon from which the quinone might be derived. This was done by taking alizarin itself and heating it with a very large excess of zinc powder in a long tube, closed at one end. A product distilled over, and condensed in the cool part of the tube. On collecting it and purifying it by recrystallization, they found they had not a new substance, but a hydrocarbon discovered as long ago as 1832 by Dumas and Laurent, and obtained by them from tar. They had given it the formula $C_{15}H_{12}$; and as apparently it thus contained once and a half as many atoms of carbon and hydrogen as naphthalin did, they named it Paranaphthalin. Afterwards Laurent changed its name to Anthracene, by which it is still known. Fritzsche, in 1857, probably obtained the same body, but gave it the formula $C_{14}H_{10}$. Anderson also met with it in his researches, established its composition, and formed some derivatives from it. Limprich in 1866 showed it could be formed synthetically by heating benzyl chloride (C_7H_7Cl) with water; and Berthelot has since proved that it is formed by the action of heat on many hydrocarbons. This first step was then complete and most satisfactory; from alizarin they had obtained its hydrocarbon, and this hydrocarbon was a body already known, and with such marked properties that it was easy to identify it. But would the next requirement be fulfilled? would it, like benzol and naphthalin, yield a quinone? The experiment had not to be tried; for when they found that anthracene was the hydrocarbon formed, they recognized in a body already known the quinone derivable from it. It had been prepared by Laurent by the action of nitric acid on anthracene, and called by him anthracenuse; and the same substance was also discovered by Anderson, and called by him oxanthracene. The composition of this body was proved by Anderson and Laurent to be $C_{14}H_8O_2$, and thus bears the same relation to its hydrocarbon anthracene that quinone and naphthaquinone do to their hydrocarbons. Graebe gave to it the systematic name of Anthraquinone.

We have then now three hydrocarbons—C_6H_6, $C_{10}H_8$, and $C_{14}H_{10}$—differing by C_4H_2, and all forming starting-points for these different quinone series. Anthraquinone, acted upon by chlorine, gave substitution-products such as might have been foretold. It is an exceedingly stable compound, not acted upon even by fusion with potassic hydrate. Bromine does not act upon it in the cold, but at 100° it forms a bibromanthraquinone. Other bromine compounds have also been formed.

Now, if the analogies which have guided them so far still hold good, they would seem to have the means of forming alizarin artificially. Their theory is that it is dioxyanthraquinone $\left(C_{14}H_6\frac{(O_2)''}{(HO)_2}\right)$, and if so, judging from what is known to take place with other quinone derivatives, should be formed from this dibromanthraquinone on boiling it with potash or soda and then acidulating the solution. They try the experiment, and describe how, contrary at first to their expectation, on boiling dibromanthraquinone with potash no change occurred; but afterwards, on using stronger potash and a higher temperature, they had the satisfaction of seeing the liquid little by little become of a violet colour. This shows the formation of alizarin. Afterwards, on acidifying this solution, the alizarin separated out in yellowish flocks. On volatilizing it they get it in crystals like those obtained from madder; on oxidizing it with nitric acid, they get phthalic acid; and on precipitating it with the ordinary mordants or other metallic solutions, they get compounds exactly comparable to those from the natural product. Every trial confirms their success; so, by following purely theoretical considerations, they have been led to the discovery of the means of artificially forming this important organic colouring-matter. A special interest must always attach itself to this discovery, for it is the first instance in which a natural organic colouring-matter has been built up by artificial means. Now the chemist can compete with nature in its production. Although the first, it is a safe prediction that it will not long be the only one. Which colouring-matter will follow next it is impossible to say; but, sooner or later, that most interesting one,

scientifically and practically, indigo, will have to yield to the scientific chemist the history of its production.

Returning for a moment to the percentage composition of alizarin, now that we know its constitution, its formula is established; and on comparing it ($C_{14}H_8O_4$) with all the different formulæ which have been proposed, we see that the one advocated by Schunck was most nearly correct—in fact that it differs from it only by two atoms of hydrogen. It is not without interest to note that the next most important colouring-matter in madder, purpurin, which so pertinaciously follows alizarin, is in constitution very nearly allied to it, and is also an anthracene derivative.

Scientifically, then, the artificial production of this natural product was complete; but the practical question, Can it be made in the laboratory cheaper than it can be obtained from the root? had yet to be dealt with. The raw material, the anthracene, a by-product in the manufacture of coal-gas, had as yet only been obtained as a chemical curiosity; it had no market value; its cost would depend on the labour of separating it from the tar and the amount obtainable. But with regard to the bromine necessary to form the bibromanthraquinone it was different; the use of such an expensive reagent would preclude the process becoming a manufacturing one. But could no cheaper reagent be used in place of the bromine, and thus crown this discovery by utilizing it as a manufacturing process? It was our countryman Mr. Perkin who first showed how this could be done, and has since proved the very practical and important nature of his discovery by carrying it out on the manufacturing scale. The nature of Perkin's discovery was the forming, in place of a bibromanthraquinone, a disulphoanthraquinone; in a word, he used sulphuric acid in place of bromine, obtaining thus a sulpho-acid in place of a bromine substitution-compound. The properties of these sulpho-acids, containing the monovalent group HSO_3, which is the equivalent to the atom of bromine, is that on being boiled with an alkali they are decomposed and a corresponding alkaline salt formed. Thus the change from the anthraquinone to the alizarin was effected by boiling it with sulphuric acid. At a high temperature it dissolves, becoming a sulpho-acid, $C_{14}H_6\begin{cases}(O_2)''\\HSO_3\\HSO_3\end{cases}$; and then the further changes follow, as they did with the bromine compound. The sulpho-acid boiled with potash is decomposed, and a potash salt of alizarin and potassic sulphite is formed; acid then precipitates the alizarin as a bright yellow substance.

While Perkin was carying on these researches in this country, Caro, Graebe, and Liebermann were carrying on somewhat similar ones in Germany; and in both countries have the scientific experiments developed into manufacturing industries. My knowledge extends only to the English manufactory; and if any excuse be necessary for having asked your attention to-day to this long history of a single substance, I think I must plead the existence of that manufactory as my excuse; for it is not often that purely scientific research so rapidly culminates in great practical undertakings. Already has the artificial become a most formidable opponent to the natural product; and in this struggle, already begun, there can be no doubt which will come off victorious.

In the manufactory is rigidly carried out the exact process I have already described to you. In tar there is about one per cent. of anthracene; this, in a crude impure state, is obtained from it by the tar-distiller and sent by him to the colour-works. Here it is purified by pressure, by dissolving from it many of its impurities, and lastly, by volatilizing it. Then comes the conversion of it into the anthraquinone by oxidizing agents, nitric or chromic acid being used, then the formation of the sulpho-compound by heating it with sulphuric acid to a temperature of about 260° C. The excess of acid present is then neutralized by the addition of lime, and the insoluble calcic sulphate is filtered off. To the filtered liquid sodic carbonate is added, and thus the calcic salt of the sulpho-acid is changed into the sodic salt, $C_{10}H_6\begin{cases}(O_2)''\\NaSO_3\\NaSO_3\end{cases}$. This is afterwards heated to about 180° C. with caustic soda, thus decomposing the sulpho-acid and forming the soda salt of alizarin and the sodic sulphite. The alizarin salt so formed remains in solution, giving to the liquid a beautiful violet colour. From this solution sulphuric acid precipitates the alizarin as an orange-yellow substance. It is allowed to settle in large tanks, and then is run, in the form of a yellowish mud, which contains either 10 or 15 per cent. of dry alizarin, into barrels, and is in this form sent to the print-works, and used much in the same way as the original ground madder was used.

This alizarin mud, as I have called it, containing but 10 per cent. of dry alizarin, is equal in dyeing-power to about 8 times its weight of the best madder, and is the pure substance required for the dyeing, in place of a complicated mixture containing certain constituents which have a positively injurious effect on the colours produced.

The scientific knowledge and energy which Mr. Perkin has brought to bear on the manufacture of this colouring-matter seem already to have worked wonders. The demand and supply for artificial alizarin are increasing at a most rapid rate, and yet the manufacture of it seems hardly to have commenced. The value of madder has much decreased; and in fact, judging by what occurred in the year of revolution and commercial depression (1848), when the price of madder fell for a time to a point at which it was considered it would no longer remunerate the growers to produce it, that point has now been again reached, but certainly from very different reasons. Last year* artificial alizarin equal in value to about one fourth of the madder imported into England was manufactured in this country. This year the amount will be much larger.

Thus is growing up a great industry, which, far and wide, must exercise most important effects. Old and cumbrous processes must give way to better, cheaper, newer ones; and lastly, thousands of acres of land in many different parts of the world will be relieved from the necessity of growing madder, and be ready to receive some new crop. In this sense may the theoretical chemist be said even to have increased the boundaries of the globe.

THE ADULTERATION OF LINSEED OIL WITH COD OIL.†

BY AUG. MORELL.

Among many other adulterations of linseed oil is one which has been practised only recently, *i.e.*, by means of cod oil almost deprived of smell. This is most frequently to be observed in the oil which is intended for the preparation of printing ink. The proportion used is such that it is impossible, by the smell or by external appearance, to suspect any admixture in the oil mentioned.

In order easily to ascertain the presence of cod oil in the oil to be tested, ten parts by weight of the latter are poured into a small cylinder glass with about three parts by weight of crude nitric acid, well stirred up with a glass rod, and the whole left at rest. The oil and acid soon separate into two distinct strata.

If the linseed oil operated upon contains cod oil, after long standing the oil layer assumes a dark brown to blackish brown colour, whilst the acid at the bottom of the vessel is coloured bright orange to orange or even dark yellow. The depth of colour indicates the extent of

---

* On the 1st of this month (September) the value of madder-roots in France was 24 to 26 francs per 50 kilogrammes. The average price in 1848 was 27, but in June and July of that year it was 22 francs.

† *Pharm. Cent. für Deutsch.*, No. 40, Oct. 2, 1873.

the adulteration. Linseed oil to which not more than three per cent. of cod oil has been added, shows the above reactions unmistakably.

If the oil examined is, on the other hand, pure and unadulterated, during the stirring it becomes first sea green and afterwards dirty greenish yellow; whilst the separated acid shows a light bright yellow colour.

DETECTION OF DIGITALIN AND ATROPINE.*

BY H. BRUNNER.

The detection of digitalin in toxicological researches is very difficult. By employing the method of Stas-Otto, the greater part of this glucoside is obtained from the acid ethereal solution as a resinous body, which in most cases does not give the characteristic red colour with sulphuric acid and bromine-water. The smaller portion which is found in the alkaline-ethereal solution, cannot be distinguished from delphinine and aconitine, because delphinine gives the same reaction with sulphuric acid and bromine, and both alkaloids yield the same results with the phosphoric acid test as digitalin. The latter compound can, however, easily be detected by Pettenkofer's test.

On adding sulphuric acid to a dilute solution of dried bile containing a trace of digitalin, a splendid red colour is produced as soon as the temperature rises to 70°. One c.c. of a decoction of 0·3 gram of foxglove-leaves in 180 grams of water gave the reaction quite distinctly. 0·03 and 0·05 gram of digitalin were dissolved, each in half a litre of Bavarian beer, and the solutions treated by the method of Stas-Otto; no digitalin could be detected in the residue by means of bromine and sulphuric acid, whilst the least trace of it, after being washed with water, gave an intense colour with Pettenkofer's test. Other glucosides give the same reaction, but this does not prevent its application in a toxicological research, if the physiological effects are also taken into consideration. A similar case is the detection of the picrotoxin by means of Fehling's solution, which is also reduced by many other substances.

The residue obtained from the acid ethereal solution may also contain lactic acid, tartaric acid, colchicine and traces of atropine and picrotoxin, but these bodies are not coloured by Pettenkofer's test, nor are other alkaloids affected by it, with the exception of narcotine and others which give a red colour with sulphuric acid alone.

The most characteristic tests of atropine are the dilatation of the pupil and the aromatic smell which is produced by adding this alkaloid and a little water to a hot mixture of sulphuric acid and potassium dichromate or ammonium molybdate. The latter reaction, although very characteristic, requires great skill; but it takes place without fail on placing the atropine on a few crystals of chromic trioxide contained in a porcelain basin, and applying a gentle heat until the trioxide assumes a green colour.

AUTUMNAL COLOURING OF LEAVES AND FORMATION OF VEGETABLE ACIDS.†

BY C. KRAUS.

The author considers it doubtful if xanthophyll is converted by oxidation into erythrophyll, but regards the red colouring matter of autumnal leaves as due to the presence of pyrocatechin together with organic acids. In red leaves the same xanthophyll grains are seen under the microscope as in yellow leaves, but a red sap is present in addition. Pyrocatechin mixed with citric acid, and exposed to the air, becomes of a beautiful red colour, and after some time ceases to give the reaction with ferric chloride. Watery extracts of all the autumnal leaves observed gave the reactions of pyrocatechin, but ceased to do so on standing with citric acid in the air. That access of air is necessary to the red colour in plants, is seen in leaves of poplar, etc., injured by insects, or otherwise turning red, also in the young shoots of Mahonia, which are only imperfectly protected by the cuticle, whilst in autumn the cuticle of leaves is so altered that air obtains access to the cells containing the pyrocatechin. It is probable that pyrocatechin is a very generally distributed ingredient of plants. Gorup-Besancz (*Chem. Soc. J.* [2], x, 171) found it in the leaves of *Ampelopsis hederacea*, and it is not unlikely that it has been confounded with, or at all events occurs along with, quercitrin, which it resembles closely in many reactions, and which has been found by various observers in the leaves of the tea-plant, horse-chestnut, and vine. Again, leaves and berries containing much organic acid are generally coloured red. This view is in accordance with the observation of Hoppe-Seyler (*Chem. Soc. J.* [2], ix, 226), that carbo-hydrates heated in sealed tubes with water, yield pyrocatechin together with formic acid.

The author suggests that chlorophyll decomposes carbonic anhydride into oxygen and carbonic oxide, this latter combining with hydrogen from water to form formic aldehyde, which with water $= CH_2(OH)_2$; this, by polymerization and abstraction of water, would form a carbo-hydrate, $C_6H_{12}O_6$, probably on the type of Carius's phenose. This carbo-hydrate (grape sugar) by elimination of water and oxygen, would form pyrocatechin, the oxygen so set free oxidizing other molecules of carbohydrate, to form vegetable acids.

The following formulæ represent the possible simultaneous formation of pyrocatechin and organic acids from grape sugar:—

$$10C_6H_{12}O_6 = 9C_6H_6O_2 + \underset{\text{Oxalic acid.}}{3C_2H_2O_4} + 30H_2O.$$

$$8C_6H_{12}O_6 = 6C_6H_6O_2 + \underset{\text{Malic acid.}}{3C_4H_6O_5} + 21H_2O.$$

$$11C_6H_{12}O_6 = 9C_6H_6O_2 + \underset{\text{Tartaric acid.}}{3C_4H_6O_6} + 30H_2O.$$

$$4C_6H_{12}O_6 = 3C_6H_6O_2 + \underset{\text{Citric acid.}}{C_6H_8O_7} + 11H_2O.$$

OLIVE OIL FROM CRETE.

The export trade of Crete to Great Britain is confined entirely to olive oil, the other products of the island not being of sufficiently good quality to compete with those grown in Sicily, Cyprus, etc. The export of oil for the home market is influenced by two circumstances—the quantity of the crop in any given year, and the prices of oil in England. After a redundant harvest, it is stated that the export to foreign countries from Crete has sometimes amounted to as much as 6000 tuns, while on the other hand the quantity available for export after a poor crop has occasionally only reached 2000 tuns. A great deal, however, depends on the prices the article will realize for exportation, as in the event of rates being low a large portion of the oil is converted into soap for the Turkish market. The quotations for the oil during the past twenty years have ranged from £33 to £57 per tun. With regard to the latter sum once only, in 1855, was it realized, while during more recent years prices have oscillated between £40 and £45. The greater part of the Cretan olive oil used formerly to find its way to Marseilles: but of late years, excepting 1871, the Egyptian and Russian markets have taken by far the largest quantities, as the crushing mills at Marseilles have had their machinery adapted for extracting oil from various oleaginous seeds. In the Consular Report from Crete for the year 1855 it is noted as an unusual circumstance that as much as 772 tuns of olive oil were shipped for England: and it may be worthy of notice that in no subsequent year, until 1870 and 1871, has so great an exportation of

* Deut. Chem. Ges. Ber., vi. 96—98. From the *Journal of the Chemical Society.*

† N. Rep. Pharm., xxii. 273—296. From the *Journal of the Chemical Society.*

the oil been sent to this country. In 1871 the amount shipped to England was 2573 tuns, valued at £103,267. In 1871 the price was as low as £40. As an instance of the fluctuation of the trade it is mentioned that last year the export of the oil to England was very inconsiderable, the falling off being attributed principally to the deficiency of the crop, which left but a small surplus for the purposes of exportation. The oil trade of Crete with the English markets is carried on by commission merchants, who receive orders from their principals in Smyrna and Constantinople to make purchases, and the necessary funds are remitted in specie. No English firm, it is stated, could carry on this business which had not commercial relations with a house in one of the above cities or in Syra, on account of the impossibility of remitting bullion for purchases in consequence of the absence of a bank in the island. Another difficulty which would be experienced in carrying on the trade is the necessity for the vessels which ship the oil bringing with them a supply of barrels, for which they have to call previously at Gallipoli, Messina, or Naples. One great obstacle thrown in the way of British trade with Crete has been a long standing grievance with the merchants of the town of Candia, consisting in the custom prevalent there of weighing olive oil destined for exportation instead of measuring it. The latter method is usually practised and entails the least possible trouble and expense to the merchant, the operation simply being that the oil is poured from the measuring vessels into skins at the merchant's store, in the presence of a custom-house officer, who verifies the quantity. After this the skins are allowed to be sent direct to the ship, and emptied into casks in the hold. By the weighing process, however, the casks, filled with the oil, must be weighed before being sent on board, and as each weighs from half a ton to nearly a ton, considerable additional expense is incurred. The casks, moreover, have first to be weighed and their weight deducted before receiving the oil; and generally this process is described as a loss of time and an increase of trouble. No good reason seems to exist why a uniform system of measuring should not prevail throughout Crete, and doubtless this might be obtained by a little judicious pressure upon the authorities.

THE MODERN PROGRESS OF CHEMICAL INDUSTRIES.*

BY AIMÉ GIRARD.

Among the chemical products which are used in manufactures there is one which science has designated under the name of sulphuric acid, but to which an old custom still preserves the name of oil of vitriol. Its importance is very great, so great indeed that it has been thought that in the amount of its consumption might be found a measure of the degree of civilization of modern times. This is an error. Without doubt the civilization of a people is a function of its industry; but other elements also concur in assuring it, and moral and intellectual influences do not yield the palm to those which are purely practical. But if it be an error to estimate so highly the value of this substance, still it must not be forgotten that it is the common pivot around which revolve all the industries that call chemical reactions to their aid.

Heated with rock salt, or marine salt, sulphuric acid gives us on the one hand sulphate of soda, and on the other hydrochloric acid; that is to say, the primordial agents in the manufacture of soaps, glass, and paper, and in bleaching, dyeing, etc. Heated with saltpetre it engenders aquafortis, or to use the language of science, nitric acid, the oxidizing agent *par excellence*, the creative agent of those splendid colouring matters which are now used so magnificently in Lyons for the dyeing of silks. It is by the aid of sulphuric acid also that metals are cleaned, oils are purified, and candles made; thanks to it, it has been possible to popularize the galvanized silver and gold ware; it is from the reactions to which it gives birth that the greater part of the chemical products employed in the arts and sciences, the greater part of the medicaments used in the art of healing, result. In one word, it is the principal reagent in the whole range of chemical industry.

To manufacture this sulphuric acid on the colossal scale required for modern consumption would cause serious embarrassment if we had now to look for it to the only source that furnished it forty years since, namely, to the burning in leaden chambers of the native sulphur got from the volcanic soil of Sicily. At that time not much of this sulphur was required; chemical industry was in its early stage, and about 20,000 tons sufficed for the manufacture of all the sulphuric acid then used in Europe. At the present time this manufacture has increased more than tenfold, and 250,000 tons of sulphur would scarcely yield sufficient sulphuric acid for the European demand.

Where, then, is this sulphur found? Sicily is powerless to furnish it in such large quantities, and moreover, the vine disease,—the oïdium,—by causing the vine growers to become large consumers of sulphur, has during the last twelve or fifteen years created an industry of considerable importance. It has therefore become necessary to resort to another source. In 1793, when France, separated by war from the rest of Europe, was compelled to find upon her own soil the resources necessary for her industrial existence, a scientific man, D'Artigues, attempted to substitute pyrites, those compounds of iron and sulphur, of which France possesses such rich beds, for the sulphur of Sicily. But he failed. Later, in 1818, the same substitution was tried in England, but with the same want of success, and it was reserved for Lyons to resolve the problem. At that time there existed, very modestly then, the manufactory of chemical products which its skilful directors, MM. Perret, have since rendered celebrated. It was there that, in 1830, a fresh attempt was made to manufacture sulphuric acid by means of pyrites; it was there too that the manufacture succeeded for the first time, and from thence it spread through the world. The mines of Chessy, near Villefranche, had been already worked to extract the copper. Afterwards MM. Perret worked them in order to utilize the sulphur, and now the manufacture of sulphuric acid has nearly exhausted them. The mines of San-Bel, and of Sourcieux, near Arbresle, have succeeded them; minerals of the same nature have been discovered and worked in Gard and in Ardeche, and gradually the sulphur of Sicily has had to recoil before the French pyrites. Nor is this progress limited to France: it is general. Throughout England and Germany there is a consumption of pyrites analogous to that in France.*

I have made approximate calculations, and do not think that I am far wrong in estimating the annual production in Europe of concentrated sulphuric acid at 800,000 tons. I know not whether these figures, speak with sufficient plainness to the mind, but in order to assist in appreciating their grandeur I will put them into a more popular and, perhaps, more telling form. Imagine that all the sulphuric acid made in Europe were carried to Lyons, and that it was intended to store it in a lead-lined canal dug parallel to the Rhone, what dimensions would it be necessary to give to such a canal? Supposing that it had been dug two metres in depth, and were ten metres wide, it would be necessary, in order to contain all the sulphuric acid manufactured in Europe in one year, that it should be carried past Givors to Vienne in the department of Isère, or a distance of from twenty-five to thirty kilo-metres; and to produce all this sulphuric acid pyrites would be required to the extent of 660,000 tons—a quantity that would fill an ideal train of 60,000 to 80,000 railway waggons.

* Abstract of a lecture delivered at Lyons upon the occasion of the visit of the French Association for the Advancement of Science. (*Moniteur Scientifique*, vol. iii., p. 851.)

* Probably the restrictions attempted by the Sicilian Government on the export of sulphur were the most decided influence in determining the general use of pyrites as a source of sulphur. The chief sources of sulphur pyrites now are Spain and Sweden.—Ed. Parm. Journ.

And now to indicate rapidly some of the directions in which modern chemical industries have made very great progress. You are near to Marseilles, and know how its industrial growth keeps pace with its commercial power. The manufactories of chemical products there are numerous. It is there that the Marseillais *soudier* decomposes the salt of the salt marshes, and manufactures by millions of tons the alkali required by the soap makers; it is there also that, arising from the same decomposition, is produced the hydrochloric acid gas, or "spirit of salt." Formerly this was all lost; the immense streaks of smoke which escaped from the high chimneys of the works and covered the horizon with white and picturesque clouds will not readily be forgotten. But those clouds, which at a distance may have looked so charming, contained in their womb a cruel enemy, which the improvident manufactories spread daily in surges over the culture and harvests of the neighbourhood. This was the hydrochloric acid originated in the reaction of the sulphuric acid upon the marine salt; the acid which offends our lungs, burns the vegetation, rusts the iron, and carries everywhere that it goes disorder and perhaps ruin. Examine now the manufacturing centres where formerly those vapours were seen, and they will no longer be found. If the chimney still shows a discharge, that consists only of smoke and the vapour of water; the hydrochloric acid has completely disappeared. Skilfully condensed, it has now become the primary material of new manufactures; at the same time, cultivation freed from its pernicious influence can be carried on down to the very doors of the works.

It was from England that this progress came. True, there it was not spontaneous, and the English parliament perhaps has the best title to claim the honour of its initiation. In 1864, induced by the incessant complaints of agriculturists, it had the boldness to impose upon manufacturers of chemical products the condensation of 95 per cent. of the hydrochloric gas yielded by the decomposition of the salt. Whether such condensation were possible, especially economically, was not yet certain; that was not the question for the legislators. The public health required that the gas should be condensed, and the law ordered that it should be done. The manufacturers, complaining a little at first, but obedient to the law, set themselves promptly to the task, and four years had not passed before, throughout Great Britain, the problem was resolved. From England the progress spread to the continent, and to-day it is general.

But it must not be thought that this salutary change has been a source of loss or vexation to the manufacturers; on the contrary, it has been to them a source of wealth, at the same time that it has exercised a considerable influence upon the general welfare. The reason of this is simple. The hydrochloric acid once condensed, the gas once transformed into the yellow fuming corrosive liquid, it was necessary to seek some way of utilizing it. It was then that it was used in making the decolorizing chlorides, all those products that are known popularly as chlorine, bleaching powders, javelle water, etc., products which skilfully used render such valuable services in the bleaching, staining, and manufacture of paper, etc.

It is a remarkable fact, of which history offers more than one example, that the importance of these added manufactures increases each day, and the consumption of their products develops with such rapidity that to-day it is the skilful and scientific utilization of hydrochloric acid—the residue of yesterday—which has become the regulator of the profits of general manufactures. At the present time, it is to the perfecting by the aid of chemistry of the processes by which these bleaching agents are manufactured that the attention of investigators is directed. In England, Weldon regenerates the manganese usually employed in the conversion of hydrochloric acid into chlorine; more boldly, Deacon has endeavoured to do away with it altogether, demanding from the air itself the oxygen necessary for the transformation, and has promised the production of chloride of lime at ten to twenty francs the kilogram instead of thirty-five or forty francs as heretofore. These would be immense advances, rich in unexpected consequences; for the day in which we can cheaply obtain from this hydrochloric acid the chlorine which it contains, we shall furnish to the textile industry the means of bleaching economically the tissues of thread and cotton of which our populations make their usual dress, and we shall supply to the paper manufacturer the means of utilizing substances hitherto refractory, and consequently of producing a substantial paper at a low price.

When the salt has been decomposed, when the manufacturer, besides the hydrochloric acid, has obtained sulphate of soda, the era of transformation commences for that compound. Of those transformations the most important is its conversion into carbonate of soda. In order to do this it is heated to a high temperature—1000° C., or thereabouts—in reverberatory furnaces, the sulphate being previously mixed with calculated quantities of chalk and carbon. But to this heat, in order to obtain a good result, must be added a nearly continuous agitation of the mass. Formerly this was a most laborious operation. In front of the furnace stood two, or sometimes three, workmen, naked to the waist. They used enormous iron shovels, with handles at least ten metres long, which sometimes weighed fifty kilograms; armed with these formidable utensils, they stirred the thousand or twelve hundred kilograms of burning and half-melted matter with which the furnace was filled. But this severe labour is gradually disappearing. In some of the large English works the ordinary alkali furnace has given place to a new machine, which imparts to the mass the motion necessary to the formation of the alkali. This, which is called a revolving furnace, is an enormous horizontal cylinder, about five metres long and three in diameter, which, by means of a small steam engine, is caused to rotate upon its axis, that traverses from end to end the flame of a fire. The contents, thus thrown pell-mell together, shaken and stirred without cessation by the rotation of the cylinder itself, react rapidly upon each other, and the soda is converted without the intervention of muscular labour to assist the reaction.

But the products originating in the decomposition of sea-salt and rock-salt ought not alone to occupy our attention; they are not the only chemical agents utilized in the arts and manufactures. The compounds of potash also have their importance, for from them are manufactured crystal glass, soft soaps, manures, saltpetre, etc., so that it would be a grave forgetfulness not to allude to them. Moreover, it is in the production of these potash compounds that perhaps the most remarkable progress in the modern history of chemical industries is to be met with.

It will be remembered how potash was formerly obtained. The ash left in the fire-place or stove where wood has been burned is a mixture of lime compounds which are insoluble, and of potash salts which are soluble in water, and among the latter the carbonate predominates. Thrifty housewives know this well, and it is to utilize the detergent properties of the carbonate of potash that they employ wood ashes in the washing of their linen. This, so often done on a small scale, was for a long time carried on in vast proportions in the woody countries; but gradually, as the demand for wood for the arts and manufactures has increased, and the means of transport have been improved, the barbarous practice of incineration has disappeared. It was formerly very prevalent in France, in the Vosges, where it is now no longer practised; Germany and Austria formerly thus manufactured considerable quantities of potash, but there, also, the practice has been displaced by progress, and one may search Bohemia in vain for the places where it was made. In their stead will be found extensive saw mills, the manufacture of natural potashes having disappeared before a more judicious employment of the wood. It is only in Hungary, America, and Russia that this method of production still continues.

Whence then comes the supply of potash required for various purposes? This question leads us to notice three important modern events in chronological order. It was the sugar industry that first competed with the forestal potash manufacture. The beetroot is a very absorbent plant, carrying off from the soil in which it is grown the potash compounds that are mixed with it. A beetroot of ordinary weight—about two kilograms for example—contains no less than one to two grams of those compounds. Submitted to various operations in the sugar manufactory the root is eventually divided into three parts: a cake of pressed pulp used by the agriculturist for feeding cattle, the sugar, and the molasses. In the latter product are concentrated all the potassic salts which the beetroot originally contained, and from it they are extracted by the method of M. Dubrunfaut. Allowed to ferment, the molasses is converted partly into alcohol, which is collected by distillation, and a solution, which when evaporated and the residue calcined in a reverberatory furnace, yields finally in a saline state the potash which the beetroot had fixed in its tissues during vegetation. It was in 1840 that this process was first applied, its importance rapidly increased, and at the present time it yields in France annually about 6000 tons of potash compounds, representing a value of 3,000,000 francs. But these 6000 tons are not sufficient to supply the demand in France; more than double that quantity is required, and it is necessary to seek elsewhere that which will supply the deficiency.

(*To be continued.*)

THE DOSES RECOMMENDED IN THE PHARMACOPŒIA.

In a recent number of the *Practitioner*, Dr. Anstie writes as follows upon the subject of "Doses," in relation to the recent occurrence at Ramsgate:—

"The chief fault rests, as it appears to us, with the compilers of the posological list of the Pharmacopœia, who, by indicating 30 minims as the extreme dose of tincture of digitalis, have been guilty of an unpardonable blunder which might well mislead the dispensing druggist. * * * The matter is all the more important because this is by no means a solitary instance of extraordinary ignorance or negligence on the part of the officials who have compiled the list of doses of different drugs published in the British Pharmacopœia. In fact, the evil is so serious that we propose to call attention to a number of instances in which it is easily apparent to a careful observer.

"Let us take first the case of hyoscyamus, of which we find that the Pharmacopœia recommends the tincture to be given in doses of 15 to 60 minims. The smaller of these quantities is probably completely without effect upon the human organism; and as to 60 minims being the maximum dose, anyone in the least familiar with asylum practice must be aware that as much as half an ounce is frequently required by, and given with good effect to, maniacal patients. In the case of belladonna, the official scale of doses is deficient in both directions; 5 minims is far too large to be assigned as a minimum, and 20 minims is a long way from being the largest dose that may be given with benefit in certain conditions. The official doses of the extract only range from $\frac{1}{4}$ to $\frac{1}{2}$ grain, a still more obvious absurdity to anyone who is familiar with the varied circumstances under which belladonna may be usefully employed.

"Take next the instance of conium: what sort of value can be attached to the statement that the succus conii may be given in doses of from 30 to 60 minims? It has certainly been known for many years past that 4 or 5 drachms may often be given without the production of any marked physiological phenomena; and it is only to-day that a physician of large experience in the treatment of nervous diseases reported to us that he had been administering *ounce* doses of a succus made by one of our very best manufacturing druggists, without producing any recognizable effect whatever.

"Again, look at the official dose of potassium iodide—2 to 10 grains; what kind of guidance does such a direction afford to the student or the practitioner? Surely it had been discovered long enough before the publication of the last Pharmacopœia that doses three and four times as large as the highest of those just mentioned might be given, not only with impunity, but with the most remarkable benefit, in many cases of tertiary syphilis and of lead-poisoning. Now these are cases in which a timid and feeble style of administration is very far from being a trifling evil, for the affections in question are often most dangerous, and urgently require to be treated with rapidity and efficiency.

"Take next the instance of quinine (we are purposely selecting examples of remedies that are in constant and familiar use): the official dose of the sulphate ranges from 1 to 5 grains. It is unnecessary to remind any well-informed practitioner that in severe intermittent and septicæmic fevers, and also for the specific purpose of reducing pyrexial temperatures, it is idle to talk of a maximum dose of 5 grains; 30 would have been nearer the mark, but even larger quantities than this, in repeated doses, have been recommended by high authorities.

"If the examples above given seem to indicate a lamentable timidity on the part of the compilers of the Pharmacopœia, there are others which show quite a different tendency, in fact an unaccountable rashness in recommending high doses of very powerful poisons. Who could have suggested such a range of doses of tincture of nux vomica as 10 to 30 minims, and of the extract of the same as $\frac{1}{3}$ grain to 1 grain? The person, whoever he was, must have been entirely unfamiliar with the practical use of the drug, or he would have known that much less than 30 minims of the tincture would half tetanise many patients, and that it is very rarely advisable to exceed 10 minims; this is a matter on which we speak with great confidence from a large experience of the use of nux vomica. The official dose of strychnia is not quite so extravagantly wrong; yet $\frac{1}{30}$ grain is at least twice as high as the minimum dose should be fixed, and $\frac{1}{12}$ grain is a quantity far too large to be given in repeated doses (as strychnia usually is given) with advantage or even safety. So again with morphia: the acetate and hydrochlorate are recommended to be given in doses of from $\frac{1}{8}$ to $\frac{1}{2}$ grain; the former of which is excessive as a minimum dose even for adults, much more for children.

"We could go on, for a considerable time, multiplying these examples of an insufficient and often mischievously misleading official posology: and we cannot but remark that the occurrence of such errors in works of official authority are exceedingly to be regretted, for more than one reason. That the result may be highly inconvenient in a practical point of view is shown by such an occurrence as that which led to the recent inquest at Ramsgate; but there is another point of view in which the official neglect of accurate attention to dosage is of even more unfortunate significance. We fear that it does but indicate an ignorance and a carelessness which are very widespread in the profession, and of which we are constantly encountering proofs in prescriptions which come under our notice. It is not too much to say that the majority of practitioners—consulting and general—seem to be almost wholly unaware of the important differences of effect which may be produced by extending the range of variations of doses, and especially by so breaking up one large dose into many small ones as to ensure its passage into the circulation without exciting inconvenient and unnecessary disturbance. We believe that no greater service could be performed by the colleges, or the great medical societies, than the formation of a committee of competent men for the special investigation of this question of dosage: for it is a subject which is as yet only in its infancy, and the best knowledge which exists about it is undoubtedly confined to a very small section of the medical profession."

The Pharmaceutical Journal.

SATURDAY, NOVEMBER 15, 1873.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

POSOLOGICAL DOUBTS.

WE learn that the President of the British Pharmaceutical Conference, in pursuance of the request addressed to him at the Bradford meeting, is about to issue a circular for the purpose of communicating to the leading representatives of the medical profession the suggestions embodied in the resolutions passed after the discussion of the subject of unusual doses. It is hoped that the action taken in this matter will be approved and supported by physicians and medical practitioners generally, and in order to give more general publicity to the proposals made by the Conference, we avail ourselves of the opportunity afforded by the courtesy of the Honorary Secretaries to publish the substance of the circular and resolutions, as follow :—

"Sir,—At the tenth annual meeting of the members of the British Pharmaceutical Conference, held at Bradford during the third week of September, 1873, the important subject of unusual doses in prescriptions, and the position which pharmacists should occupy in relation thereto was carefully and patiently discussed in its pharmaceutical bearings by members from all parts of the country. By an 'unusual dose' was understood a large quantity of potent medicine designedly prescribed in rare cases, but which, as a rule, would not be dispensed by the pharmacist without hesitation. The result of the debate was the unanimous adoption of a series of resolutions embracing what was believed to be the essentials of safe practice in the matter. Further, the President of the Conference was requested to bring the resolutions under the notice of the presidents of the medical colleges and corporations, and other leading medical authorities, and the medical journals, in the hope that the action taken would be approved and supported by physicians and medical practitioners generally. The proposal is that the prescriber should call attention to an unusual dose by adding, on the same line, his bracketed initials, thus, (F. W.) A similar plan is already adopted on the continent, and indeed in some countries is enforced by law.

"On the next page is a copy of the resolutions. I trust that they will meet with your individual approval, and that you will contribute your influence in giving them wide publicity amongst the members of the medical profession.

"I am, Sir, yours faithfully,
"THOMAS B. GROVES, *President.*"

"UNUSUAL DOSES OF MEDICINES.

"The following resolutions were passed at the tenth annual meeting of the members of the British Pharmaceutical Conference, held at Bradford, Yorkshire, during the third week of September, 1873 :—

"'That this Conference having considered various proposals for the use of special signs to mark unusual doses on prescriptions, and the great advantages to be derived from such signs, considers that the bracketed initial letters of the prescriber's signature, written immediately after the unusual dose, is the best suited for the purpose.

"'This Conference also respectfully urges upon medical men the importance of the prescriber's full name and address being written on *all* prescriptions, to facilitate communication between the prescriber and dispenser.

"'This Conference likewise considers it desirable for the dispenser to retain all prescriptions in which initialled unusual doses are prescribed.'"

Together with these we have placed in the previous page an extract from an editorial article in the *Practitioner*, where the subject is treated of from a medical point of view, and thus our readers will be in possession of material to enable them to form correct views.

In the current number of the *Druggists' Circular and Chemical Gazette*, just received from New York, we find the course taken by some of the medical journals in regard to the Ramsgate case is severely commented upon, and described as partaking of the Yankee principle satirized by Mr. LOWELL, that "the side of our country must ollers be took." Our Transatlantic contemporary, perceiving that the affected astonishment as to anybody being unaware of the practice of Mr. JONES of Jersey was inconsistent with the accompanying sneering animadversions on the exercise of judgment by a druggist, asks what would be the use of a druggist studying Mr. JONES of Jersey at all, unless it were for the purpose of using his new information somehow ?

The notion that the dispensing druggist is a mere serf to the physician is also repudiated and dismissed as not worth argument to disprove it, since "physicians themselves do not so regard him, and it is not worth while to vex ourselves over the acrimonious diatribes of writers whose first aim is smartness." And, as regards the duty of the dispenser, we are glad to find it stoutly declared that, with the chance of a verdict of manslaughter hanging over his head, it surely behoves him to be cautious, and gives him a right to decline accepting any risk.

Singularly enough, the correspondence columns of the same journal contain a query respecting a case somewhat similar to that which occurred at Ramsgate. The following prescription was taken to a druggist in Manchester, New Hampshire, to be dispensed :—

℞

Hyd. Chl.	ʒss.
Syr. Ginger	℥iss.
Tr. Card. Co.	ʒj.
Aquæ	ʒss.

Mix.

The druggist on looking at it told his customer that if he put it up as written one dose would be fatal, and the inquiry was made whether he was justified in making such a statement. The editor, in his reply, expresses the opinion that he was not altogether wrong, since "Hyd. Chl." sometimes stands for corrosive sublimate, and he adds that a druggist would be justified in hesitating to dispense such a prescription unless he were satisfied by other evidence that hydrate of chloral were intended, and that the patient

or his attendant knew when and in what doses the medicine was to be administered.

As regards the wider question of unusual doses, our American contemporary expresses approval of the course taken by the Pharmaceutical Conference, and adds the suggestion that if medical journals would only urge this practical point, instead of expending their influence in trying to arouse a bad feeling between medical practitioners and pharmacists, they would be serving their generation more worthily than is sometimes the case. We trust that the suggestions of the Conference will be received by the medical profession in the same spirit that they have been offered, and that by mutual consideration and assistance, a means may be devised of protecting prescribers, patients, and dispensers from possible disappointment, inconvenience, and perplexity.

ALBUM OF AMERICAN PHARMACISTS.

Two years ago Mr. HENRY B. BRADY, on his return from a visit to the United States, collected the card-photographs of leading English pharmacists, arranged the pictures in an album, and presented them through Professors PARRISH, MAISCH, and PROCTER to the American Pharmaceutical Association. An account of the reception of the gift will be found in the 'Proceedings of the American Pharmaceutical Association,' 1872, p. 56. Soon afterwards a Committee of the American Association with Professor F. W. BEDFORD as Secretary, collected the "shadows," as they termed the photographs, of the prominent pharmacists of the United States, mounted the cards in an album, and sent it over a few weeks ago as "A Souvenir of fraternal regard from the American Pharmaceutical Association to the British Pharmaceutical Conference." That album, to which an alphabetical index has been added, will remain in the possession of Professor ATTFIELD, as the Senior Secretary of the Conference, who will gladly show it to pharmacists or others, or will forward it to any provincial pharmaceutical association whose members would like to see it at their meetings. Photographs of the following gentlemen are contained in the album :—

Andrews, G. W.	Chapman, W. B.	Grahame, I. J.
Bache, F.	Close, G. C.	Gordon, W. J. M.
Bakes, W. C.	Coggeshall, G. D.	Green, T. T.
Balluff, P.	Colcord, S. M.	Hancock, J. F.
Bartlett, N. G.	Covell, T. J.	Harrop, J.

Mill, J. W.	Roberts, J.	Squibb, E. R.
Milleman, R. L.	Rother, K.	Taylor, A. B.
Moore, J. B.	Russell, E. W.	Thompson, W. S.
Moore, J. F.	Rust, W.	Tufts, C. A.
Neergaard, W.	Sander, E.	Wayne, E. S.
Newton, L. V.	Sargent, E. H.	Wenzel, W. T.
Nichols, E. P.	Saunders, W.	Whiting, F. T.
Orne, J. S.	Scheffer, E.	Wiegand, T. S.
Osborne, H.	Shedden, J. W.	Wood, G. B.

Drs. Bache and Wood are well known to us as the authors of 'The United States' Dispensatory.'

Among the twenty-one distinguished men who have presided over the meetings of the American Pharmaceutical Association since its formation in 1852, we have the good fortune to possess in this album the likeness of twenty, namely, Messrs. D. B. Smith (1852), Brewer, Chapman, Meakim, Andrews, Ellis (Kidwell, 1858, absent), Colcord, Kiersted, Procter, Moore, Gordon, Lincoln, Stearns, Milhau, Parrish, Sargent, Stabler, Sander, Ebert, Hancock (1873).

Authors of researches, whose works will last even longer than their photographs, are also well represented. P. W. Bedford, who has contributed eight papers to the Association ; G. C. Close, seven papers ; S. M. Colcord, ten or eleven papers on ethical subjects ; C. L. Diehl, six or seven pharmaceutical papers ; T. Doliber, four papers ; A. . Ebert, who was at the Dundee meeting of our Conference, four papers ; H. F. Fish, four ; S. S. Garrigues, six ; W. J. M. Gordon, four ; H. W. Lincoln, four ; Professor Maisch, twenty-five papers, besides annual reports ; Professor Markoe, who was present at our Brighton Conference, nine papers ; J. W. Mill, four ; Professor J. F. Moore, several papers and reports ; the late Professor Parrish, twenty-eight ethical and scientific papers ; W. H. Pile, six papers ; Professor William Procter, Junr., who is personally known to most of us, twenty-nine essays and reports ; J. P. Remington, five papers ; Dr. E. R. Squibb, forty reports, notes, and researches ; Frederick Stearns, nineteen papers ; A. B. Taylor, seven papers ; Professor Wayne, six papers ; and T. S. Wiegand, seven papers.

A leading feature in the organization of the American Pharmaceutical Association is the formation of committees to investigate subjects affecting pharmacy, and the photographs of hard workers on such committees will be found in the album : Chairmen and other Members of Committees on the Progress of Pharmacy, the Drug Market, Papers and Queries, Adulteration and Sophistications, Legislation, the Pharmacopœia, etc.

Photographs of the Treasurers and Secretaries of the Association are included ; also Editors of Journals, Authors of Educational Works, and the Phar-

maceutical Members of the Council or Convention entrusted with the preparation of the Pharmacopœia of the United States. The Schools of Pharmacy distributed throughout the country are represented; We mean, of course, educational schools, for cram-schools such as have recently sprung up in England are unknown in America.

Almost all the photographs are good works of art. They are mostly vignettes of the bust; quarter, half, and full-plate size. The first president has all the appearance of the father of the Association; William Procter, Junr., seems younger than ever; the picture of Professor Parrish, whom everybody loved so much, is particularly clear and vigorous; Albert E. Ebert was evidently still an invalid when he sat to the sun; C. Lewis Diehl, in photograph, is strikingly like the late J. C. Brough, and the features of Dr. Newton still more vividly recall those of Thackeray; Wm. Saunders need not to have written across his *carte* words stamped there already, namely, "very sincerely yours"; Professor Bedford has the face of a kind and shrewd teacher; the pictures of Charles F. Fish and Professor Judge are marvels of sharpness and relief.

The whole album is interesting; it and that which has gone across the Atlantic are the offspring of "fraternal regard," which is mutual. Their interest is lasting, and will increase from year to year.

VOTING FOR THE BENEVOLENT FUND ELECTIONS.

It may not be altogether useless to inform our readers that since the election on the 24th ult. voting-papers have still continued to come in daily up to the early part of this month, and that as many as twenty-five have thus been sent in, of course too late to count. It so happens likewise that most of these votes are for one candidate. We think the mention of these facts may tend in future to render voters more mindful of the conditions to be complied with in sending in papers, and that a knowledge of them may conduce to prevent disappointment on their part as well as on the part of the candidates they support.

LECTURES have been arranged to be delivered in connection with the Bristol Pharmaceutical Association, at the Museum and Library, Queen's Road, Clifton, on Friday, January 16th, by Dr. PORTER SMITH, late of China; on Friday, February 13th, by Dr. WATTS, F.C.S., of Oxford; on Friday, March 13th, by Mr. THOMAS WILLS, F.C.S., Royal Institution; and on Friday, April 10th, by Dr. REDWOOD.

A NOTICE has been issued by the National Chamber of Trade, inviting chemists and druggists to attend a meeting at the offices, Sussex Chambers, 10, Duke Street, St. James's, S.W., to consider the late prosecution under the Adulteration Act, and to take steps, if necessary, to obtain an amendment of that Act. The meeting will be held on Wednesday next, the 19th November, at eight o'clock P.M., under the presidency of Mr. A. F. HASELDEN.

Mr. G. C. Fox (the Secretary) then read the following general report :—

"The Council regret that they are compelled to report a marked falling off in the number of members and students during the past year.

"As the reports of the class teachers and examiners were read at the distribution of prizes, it is unnecessary to refer to them now, further than to notice that while the attendance was in the point of numbers highly discouraging, the attention shown by the few regular members was most satisfactory, and the progress made was good. The practical testing carried on by the practical chemistry class seems especially to have been successful in causing greater diligence among the pupils. The reports of the examiners show that while the pupils are well up in theory they are in many cases deficient in the practical part of the subjects, showing that the class teaching is not supplemented by homework and attention to the general routine of business. The chemistry class, however, forms an exception to the rule—Professor Attfield's report last spring having been most satisfactory.

"The Council believe that the regularity and attention have been to some extent owing to the system of prizes now carried on during two sessions, and last session so much extended by the kind donation of J. D. Smith, Esq.

"The resolution passed at the last annual meeting to the effect that Preliminary classes should be carried on during the then ensuing session has been of no effect, no members having offered themselves as pupils.

"The ill-success of lectures during the session 1871–72 deterred the Council from making arrangements during the past year.

"The library presents the most satisfactory feature of the Association. The Librarian says : 'The library has been opened sixty-eight times during the past year. It now consists of forty-two volumes ; and these have been issued and re-issued 188 times among seventeen members. These numbers show that although comparatively few members have availed themselves of the use of the library, those who have done so have been very regular in their applications.

"During the past year five members have passed the Minor (two in honours) and one the Major. Two pupils have also taken good positions in the Science and Art examinations.

"The most important subject for the consideration of the members is the marked falling off in the number of members and students. During the three years of the Association's existence the numbers of members have been respectively 42, 36, and 25, and the average attendance of students at the classes has been 14, 10, and 8. This falling off the Council regard as a most serious feature, showing as it does that the Association fails to interest many of its members and still more to enlist in its ranks the recent additions to the apprentices of the city. Under these circumstances the Council cannot recommend, even supposing the necessary funds would be forthcoming, in the face of the reduced numbers, that the Association should be carried on under the existing conditions, feeling

that the expenditure of labour is not justified by the results. In consequence, however, of many expressions of regret at the probable dissolution of the Association they are disposed to recommend that an attempt should be made to extend the sphere of labour by engrafting the Association upon the Science and Art Department and admitting upon payment of certain fees to the chemical and botanical classes any of the public who may be desirous of pursuing those studies. By this step the Council imagine larger classes would be attained, and at the same time the funds would be considerably augmented.

"The Council cannot close the report without mentioning the entertainment so kindly given to the candidates at the spring examinations by H Thompson, Esq., and without expressing their sense of the deep obligation which the Association is under to the class teachers, Messrs. Corder, Caley, Butler, and Nuthall; to the examiners, Professor Attfield and Messrs. Corder, Fox, Hill, Nuthall, and Mason; to the librarians, Messrs. Lincoln, King, and Woolnough."

After a desultory conversation it was agreed to adopt this report without discussion, as its more important features would come under notice when the programme for the ensuing session was arranged.

The usual votes of thanks where thereupon passed, and after a resolution reducing the number of the Council had been adopted, the following officers were elected :—President, Mr. E. Nuthall; Vice-President, Mr. A. Hill; Treasurer and Financial Secretary, Mr. W. J. G. Butler; Honorary Secretary, Mr. G. C. Fox; Messrs. G. S. Tooke, H. A. Woolnough, and W. G. Piper; Librarians Messrs. Piper and Decarle.

Mr. Nuthall said he had been entrusted with the task of proposing certain resolutions which would bear out the recommendation of the retiring Council, to the effect that the Science and Art system should be introduced to their Society, but before doing this he wished to state that the Council had not been entirely unanimous in adopting this recommendation, and, in fact, most of the members had only done so after great hesitation. For his own part, also, he regretted extremely that such a step should be necessary, but he certainly could not see how the Association could be satisfactorily carried on in face of the figures of the prceding reports. He said "satisfactorily" because he had no doubt but that by strict economy they might drag on a sluggish existence for another year or so, but this was far from what had at the foundation of this Association been anticipated. Then they all looked forward to an active and useful course, imagining that each year would strengthen their position, but now, after three years, their Council were driven to confess that they considered the results attained far from being equivalent to the amount of money or effort in teaching expended, and were unable to recommend that such an outlay should be continued, or that so much work should be done by the various class-teachers with so little encouragement. The questions, then, for them to decide were "How to increase their funds?" and "How to enlarge the number of their students?" The former was necessary for the convenient carrying on of the Society, and especially if they wished to realize the long-cherished plan of establishing a working laboratory, which would undoubtedly largely increase the popularity of the Association. The latter was necessary to give them sufficient grounds for asking the class-teachers again to undertake their arduous tasks. Both these requirements would be fulfilled if the recommendation of the Council be adopted. After explaining the working of the Science and Art Department, Mr. Nuthall proceeded to say it had been proposed that as several of their number held teachers' certificates under this department, two of them should undertake respectively classes in botany and chemistry, and those gentlemen, Messrs. Piper and Tooke, who had volunteered to do so, had promised that what grants they might obtain as results of their teaching should be handed over for the use of the Association. He therefore begged to propose—

"That the botany and chemistry classes be affiliated to the Science and Art Department, and that the teaching at the same be especially directed to the requirements of the pharmaceutical examinations, and those of the Science and Art Department."

"That the existing rules of this Association be so modified as to admit the general public, upon payment of fixed fees, to the above classes."

Mr. Tooke seconded both these resolutions; but the second one was opposed by Messrs. Woolnough and Lincoln, who brought forward a negative proposition.

After a spirited discussion, in which most of the members present took part, the original resolutions were carried, and the meeting shortly afterwards closed with a vote of thanks to the chairman, Mr. A. Hill.

Since the above meeting, arrangements have been made to cater for the winter session, comprising lectures on the chemistry of the Pharmacopœia, materia medica, and pharmacy, by Messrs. Nuthall, Caley, and Butler; and Science and Art classes in botany and chemistry, by Messrs. Piper and Tooke.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The second general meeting of this Association was held in Anderson's University, on Wednesday, Oct. 29th, at 9 p.m. Mr. John Currie, president, in the chair.

The attendance was remarkably good. Preliminary business being over, Dr. A Wood Smith, Glasgow, delivered an able and very interesting lecture on "The Circulation of the Blood," illustrated both by means of diagrams and microscopes.

Before closing the lecturer gave a short sketch of the life of Harvey, the discoverer of the circulation of the blood.

On resuming his seat, the lecturer was accorded a most hearty vote of thanks; as were also Drs. Gemmill and Oliver, who assisted the lecturer with the microscopes.

The secretary then drew the attention of the junior members to a note which he had received from Professor Thorpe, asking if the hour from 4 to 5 p.m. would suit those intending to join his chemistry class, as it was the desire of the medical students that it should be held at that hour. This being agreed upon, the meeting dissolved.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION.

Inaugural Meeting of the Winter Session, Soirée, and Exhibition.

A meeting of an exceedingly interesting character, well calculated to increase the popularity of this Association, and at the same time to deepen the interest of its members in scientific pursuits, and widen their knowledge of the many practical applications of physical science, was held in the Memorial Hall, Albert Square, on Friday evening, November 7th. The attendance was large and thoroughly representative, including nearly all the members and associates, many medical men, professional chemists, and others interested in the objects of the Association. The exhibition was opened in the large hall at half-past six o'clock, tea was served in an adjoining room at seven, and at half-past eight the chair was taken by the President, Mr. W. Scott Brown. The only formal business was the election of twenty-five associates. The President then delivered the following address :—

"Gentlemen,—

"In conformity with custom, it is my duty as President to open the formal proceedings of this evening, and I have to ask your indulgence for the few remarks I shall offer. This being the fifth year since the formation of the Manchester Chemists and Druggists' Association, it was thought desirable that we should commence the term by an exhibition of pharmaceutical and chemical appliances,

specimens, and other objects of interest, and hold a soirée of a similar character to that held in this hall during our first session, on April 20th, 1869, and which excited considerable interest, and I hope afforded information as well as gratification to the large assembly who on that occasion assisted us by their presence. I trust the meeting this evening and the exhibition now displayed, may lead to a more general interest in the objects of our Association, and be the means of strengthening the bonds of union and inducing a larger number to take an active interest in our periodical meetings. The educational arrangements made through this Association result from, and are largely dependent on, the co-operation of the chemists and druggists of this city and district. To-night our twofold object is to gratify our members and friends, and to promote those social relationships which are fostered by such gatherings as the present. The number of medical friends who, I am gratified to say, have favoured us with their company evidences their interest in the efforts we are making to educate the rising generation of chemists and druggists. We hope also to stimulate to a more lively interest in and appreciation of the labours of our Association, the large body of our own trade in this city, the adjoining borough, and the surrounding towns, who have not yet joined our ranks. Five years have elapsed since the formation of this Association, and it is fitting that I should refer to the period of its formation, the objects then contemplated, and reviewing the work of the past, ask how far we have accomplished the task we then undertook, and what we may hope in the future. When the Pharmacy Act of 1868 became law, we possessed no association ; we had no educational machinery ; we had no means of giving to our assistants or apprentices that scientific knowledge the possession of which had suddenly become legally essential. I recall the efforts of the past and the names of many good and enlightened men, who in their day strove to establish meetings for mutual instruction and improvement, and lectures and classes for the juniors. It is somewhat saddening to me this night to find myself, by the lapse of years, placed in a position which was then filled by abler and better men, whose names we still hold in respect, and to think that all their efforts were in vain, and that for so many years Manchester, with its vast material resources, did not maintain among the large and respectable body engaged in our business, an association for such desirable purposes as mutual intercourse and improved scientific education. All this changed in 1868, and the interest then awakened will I trust continue to have effect and produce results in the future which will well repay the toils and labour of to-day. At the commencement of our Association we declared our objects to be to provide for the better education of assistants and apprentices, the foundation of a library and museum and a school of pharmacy for Manchester and district ; these were our views, and subsidiary, the monthly meetings for promoting mutual improvement and social fellowship. During the past five years how have we succeeded and what is our present position ? I venture to assert that we have to a great extent accomplished what we then commenced ; true, if judged by the number of members, we may seem to have retrograded and I wish that my remarks may induce the whole or a large proportion of the trade to join us. We know that the ordinary routine of our business avocations does not and cannot furnish the accurate and scientific knowledge required to pass the compulsory examination of the Pharmaceutical Society, and though it is gratifying to know that the hours of labour are somewhat diminished, and more opportunities for self culture afforded to young men of the present than were available in the past, the duty still devolves on all the principals in the business to aid in supporting the means by which systematic and special teaching may be given to apprentices and assistants, as it is difficult to attend examinations unless so aided. It is only by large association of members that a school of pharmacy can be supported, and it would indeed be a most deplorable circumstance if for want of sympathy and support the council of this Association should be placed in any difficulty. Indeed, though much has been accomplished, more remains to be done, and I earnestly appeal to all for assistance. We have steadily adhered during our five years' career to the lines laid down at first, and have now a reading-room, a lecture-room, a fair library, a good museum, and most excellent and complete courses of lectures. All these are, of course, on a small scale as compared with the parent institution in London, but being our own unaided work, we feel a justifiable satisfaction in contemplating what we have accomplished. I need not refer to the details of our work, or to the subjects which have engaged attention at our many meetings, all, I am sure, will unite in the feeling that we have, whilst doing good to our young men, been receiving much benefit ourselves. Mutual association has, I feel assured, produced many pleasant results, and as our object is, and ever has been, the public interest, protecting them from ignorance and incompetence by providing an educated and responsible body for their future requirements, we hope to receive from the members of the medical profession a full recognition of our Association. I am pleased to say this has not been wanting, and I gratefully acknowledge it. To the young men who are with us to-night I would address a few words. It has afforded great satisfaction to the Council that a Chemists' Assistants' Association has been formed and has prospered so well ; the advantage of the rooms and the means of instruction provided has been felt to be a boon, and I feel certain that the future will develop many good results which have had their foundation and commencement in Blackfriars Street. I ask only that what has been cheerfully and freely given be extensively and constantly used, remembering that much is expected from those who have advantages placed within their reach. Let this stimulate to thoroughness. The immediate gain may not be apparent, but the public are learning to appreciate the distinction between the title and the qualities that should accompany the name ; and as by them you must be judged, and the requirements are yearly advancing, strive to be ahead, and to anticipate the day when, as (educated and competent) members of the pharmaceutical body, you will be trusted by the physician, his patients, and the public."

Mr. J. T. Slugg, F.R.A.S., then briefly addressed the meeting. He congratulated the members on the variety and interest of the exhibition, alluding especially to the microscopes and the immense importance of those instruments in the study of chemistry, pharmacy, and medicine.

Later in the evening Mr. Louis Siebold delivered a lecture on dialysis and its applications to pharmacy. Mr. Siebold's experiments were of a most striking and convincing nature, showing both the theory and practical application of the process. The latter he demonstrated by separating the meconic acid from a mixture of mucilage, extract of liquorice, and a trace of tincture of opium. The lecturer said dialysis afforded to the pharmaceutical student a wide field for original research, in the isolation of many alkaloids and active principles at present involved in much obscurity and the very existence of which was sometimes doubted.

In connection with Messrs. Howards' contribution of sample bottles of sulphate of cinchonidine, Mr. F. B. Benger gave a short explanatory lecture on that substance, describing its chemical and physical properties, the tests by which its admixture with or substitution for quinine may be detected, and detailing the opinions expressed by members of the Royal Commission appointed by the Indian Government to inquire into the value of it and other cinchona alkaloids. The importance of giving it a fair trial in this country was urged, as, should the results obtained in India be confirmed at home, a most important addition to the materia medica would be gained ; one especially to be appreciated at a time when the great demand for quinine had so enhanced its price, and when

there seemed every probability of an unlimited supply of cinchonidine obtained from barks grown in the Indian plantations.

Votes of thanks were passed to the exhibitors, the medical profession for their presence and support, the lecturers of the evening, and the president for his address.

The following were the most important contributions to the exhibition :—

Messrs. Howards and Sons (London) :—Fine specimens of cinchona barks, grown in India, and 200 sample bottles of sulphate of cinchonidine.

Messrs. Hopkin and Williams (London) :—Rare chemicals.

Messrs. Johnson and Mathey (London) :—A collection of platinum vessels, and a very beautiful series of platino-cyanides, and other chemicals not commonly met with by pharmaceutical students.

Messrs. Southall, Son, and Dymond (Birmingham) :—A fine display of chemicals, pharmaceutical preparations, and materia medica specimens.

Messrs. Poths and Semple (London) :—The contribution of this firm was very varied and interesting, consisting largely of German pharmaceutical appliances, many of them little known, and therefore little used in this country. The many applications of transparent horn in the construction of scale pans, dishes, strainers, spatulas, pill-silverers, etc., were remarkable. The hardness, durability, lightness, beauty, and nonmetallic nature of this substance, admirably adapting it for those purposes. Cardboard boxes of exquisite finish, and almost endless diversity of form, enamelled labelled bottles, delicate balances, and an array of German productions too numerous to describe. Mr. Poths, himself an examined chemist of England and Germany, came from London to be present at this meeting, and was most courteous and obliging to the many inquirers respecting the nature and uses of the appliances exhibited.

Mr. P. Spence (Manchester) :—A large case of specimens illustrating his patent processes for the manufacture of alum.

Messrs. F. C. Calvert and Co. (Manchester) :—Carbolic acid. Preparations of ditto, and apparatus for diffusing its vapour as a disinfectant.

Messrs. C. Lowe and Co. (Manchester) :—Fine specimens of crystal carbolic acid.

Messrs. J. Woolley, Sons, and Co. (Manchester) :—An extensive collection of chemical apparatus, furnaces, drying-closets, microscopes, etc.

Messrs. Mottershead and Co. (Manchester) :—English, French, and German batteries for medical purposes. Electric bells and fire alarms. Revolving stereoscopes, graphoscopes, and microscopes. Slides illustrating Stoddart's micro-chemical test for quinine, etc., etc.

Messrs. Bailey and Co. (Salford) :—Electric bells and patent indicators for use on board ship. A tell-tale clock "to watch the watchman," etc.

The Middleton Botanical Society :—A collection of rare indigenous plants, and two copies of a very valuable old work, 'Flora Londinensis,' by W. Curtis, Demonstrator to the Company of Apothecaries, published in 1777, consisting of large coloured plates of all plants growing in the neighbourhood of London, with descriptive letter-press.

Mr. Cockshott (Manchester) :—A selection from his fine herbarium of British plants.

Mr. Louis Siebold (Manchester) :—Herbarium pharmaceuticum, arranged for medical and pharmaceutical students.

Mr. Johnson (Bury New Road, Manchester) :—A very valuable microscope and a remarkably choice collection of objects to the exhibition of which Mr. Johnson most kindly devoted the whole evening.

Professor Attfield (London) :—A case of beautiful models of gems, showing their crystalline form and colour.

Mr. Leech (Lower Broughton) :—A polariscope, and objects for ditto, constructed by himself.

Mr. Robinson (Pendleton) :—Microscope and objects.

Mr. Goodwin Mumbray (Richmond) :—A very interesting series of diagrams of microscopical subjects.

Mr. W. S. Brown (Manchester) :—A number of valuable illustrated books.

Messrs. Payne and Chapman (Manchester) :—Revolving stereoscopes and graphoscopes.

Messrs. Kay Brothers (Stockport) :—Specimens of their new patent soda-water bottle, percolators, etc.

The British Pharmaceutical Conference :—An album of photographs of members of the American Pharmaceutical Association.

Messrs. Zimmermann (London) :—Wine-testing apparatus, etc.

Mr. Hughes (Manchester) :—An improved pill machine.

The Aniline Company (Manchester) :—Specimens illustrating their manufactures.

Mr. Warrick Brookes :—A series of most effective photographic studies.

Mr. Clark (Mount Pleasant Square, Salford) :—An improved compound screw tincture press, affording a means of exerting enormous pressure, and appearing to offer many advantages over the press commonly used by pharmacists.

Mr. H. G. Mumbray (Higher Broughton) :—Gyroscopes, etc.

Messrs. Allen, Harrison, and Co. (Manchester) :—Stills and models of vacuum apparatus.

Mr. Darling (Manchester) :—Specimens of minerals, etc.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, 6th November, 1873. Dr. Odling, F.R.S., etc., President, in the chair. After the ordinary business of the Society was finished, the President delivered a short address, congratulating the Fellows on taking possession of their new rooms in Burlington House. A paper was then read by Mr. David Howard: "On the Optical Properties of some Modifications of the Cinchona Alkaloids," being an elaborate investigation of the variations in the rotatary powers of this class of bodies when examined by the polarimeter.

The other communications were, "A Preliminary Notice on the Oils of Wormwood and Citronella," by C. R. A. Wright, D.Sc.; "On the Estimation of Nitrates in Potable Waters," by W. F. Donkin, B.A.; and "A Note on the Action of Iodine Trichloride upon Carbon Disulphide," by Mr. J. B. Hannay. The meeting finally adjourned until Thursday, 20th Nov.

Parliamentary and Law Proceedings.

The Case of Poisoning by Morphia at Carlisle.

On Friday afternoon, October 31, Dr. C. F. McLeod, surgeon-major in the Madras army, was charged before the magistrates at the Town Hall, Carlisle, with having caused the death of his wife. After some evidence had been taken, during which Mr. Ruston, the druggist's assistant stated that the amount of hydrochlorate of morphia supplied by him was twenty grains, and that he was quite clear that Dr. McLeod did not ask for ten grains, the magistrates intimated that they had heard enough to justify them in committing the prisoner for trial upon a charge of manslaughter. Dr. McLeod simply said that he should reserve his defence, and immediately after his committal he was admitted to bail.

The Adulteration Act.—Prosecution of a Wholesale Dealer.

At Bow Street, John Tyman, Witherden Farm, Ticehurst Road, was summoned before Mr. Flowers to answer the charge of supplying Mr. George Barham with adulterated milk. Mr. Longstaff, solicitor, who appeared for

the prosecution, stated that Mr. Barham was the managing director of the Express Country Milk Company, and had entered into a contract with the defendant to supply him from time to time with pure unadulterated cow's-milk. Mr. Barham, however, received complaints from numerous customers respecting the weak state of the milk, and in consequence submitted the milk received one day to Dr. Muter, and that received the next day to Dr. Redwood, both district analysts appointed under the Act. Dr. Muter found the milk to contain water to the extent of a fourth part; Dr. Redwood deposed that the second quantity contained 30 per cent. of water and a small quantity of fat. Mr. Barham had no ill-feeling in the matter, although he was liable to be prosecuted by each of his customers. Evidence was called in support of this statement. In reply to the charge, the defendant admitted that the milk was adulterated, but not with his knowledge or consent. His assistant had put the water in. The man was called, and deposed that he put three pints of water to four-and-a-half "barn" gallons of milk without his master's knowledge. Dr. Muter said that such a quantity of water would scarcely be detected. The defendant then insinuated that the milk had been watered after it had left his hands. Mr. Flowers said the assertion that the defendant was not aware his assistant had adulterated the milk did not render him any the less responsible to the law. He felt it was a very serious matter, and should therefore fine the defendant £10 and £5 costs. It was hardly fair to punish sellers in London, since it appeared that the farmers themselves adulterated the milk. The defendant on leaving the court complained of the amount of costs, and said that the doctors and solicitors would no doubt like cases of this sort every day, if they could get them.

Remarkable Results of Bread Analysis.

At a meeting of the Shoreditch Vestry, held on Thursday, November 6, a deputation of master bakers attended to complain of the unsatisfactory character of certain analyses of bread recently carried out by the public analyst of the district, Dr. Stevenson, and to present the following resolution, passed on the 20th ult. at a meeting of master bakers, ratepayers of the parish of Shoreditch :—"That in the opinion of this meeting the present method of analysing bread is far from satisfactory to the respectable portion of the trade. who have a desire to conform to the existing Act of Parliament in regard to the Adulteration of Food Act." Mr. Butler, the spokesman of the deputation, said that a sample of pure bread, made by himself, was recently sent to Dr. Stevenson, who analysed the same and gave a certificate to the effect that it was one of the best that had been analysed, and that it contained no adulteration which would be injurious to health. As this was a somewhat qualified statement in regard to a pure article, he was instructed at a subsequent meeting of master bakers to procure two samples of cheap bread, which there was every reason to believe was not pure. Two such samples were submitted to the analyst, who pronounced them not adulterated, and cast not the slightest suspicion upon them. He (Mr. Butler) was then deputed to make an adulterated loaf of bread, and, in accordance with his instructions, he made a two-pound loaf, containing one drachm of alum—a quantity sufficient to be injurious to health. It was submitted to the analyst, the usual fee of half-a-crown being paid, and the certificate returned was "not adulterated." A portion of this sample was then taken to the Royal Polytechnic Institution for analysis, and handed to Professor Gardner, who charged half-a-guinea, and afterwards returned the following certificate :—"I have examined this piece of bread, left with me; it is perfectly free from alum." On receipt of this astounding information he wrote to Professor Gardner, informing him that one drachm of alum had been purposely put in the loaf, and expressing his surprise that no adulteration had been detected. In reply Professor Gardner wrote that unless a quantitative analysis were performed it was impossible to tell the quantity of alum in bread. For the half-guinea he had only performed a qualitative analysis, and had certainly found indications of alum, but of so slight and feeble a character that he did not think it worth while to mention it in his report lest it should be used as a cause for prosecution. The charge for a quantitative analysis was five guineas. He (Mr. Butler), on behalf of deputation, hoped the vestry would give the matter their serious consideration, for heavy fines were in some parishes being imposed upon those who adulterated bread, and the respectable bakers of this parish were anxious that the law should be put in force against dishonest tradesmen; but, at the same time, if the certificates of public analysts could not be relied upon, the question would arise, of what use were such officers? After a long discussion a select committee was appointed to investigate the matter and report to the vestry.—*Standard.*

Review.

The Febrifuge Properties of the Cinchona Alkaloids, Cinchonine, Quinidine, and Cinchonidine. By Joseph Dougall, M.D.

On Cinchonidine. By Howard and Sons.

Compared with several other remedial agents,—such as rhubarb, jalap, aloes, ipecacuanha, sarsaparilla, etc.,—the cinchona barks have had an unusually large amount of attention paid to their collection and cultivation, and science has been successfully called in to assist nature in the production not only of a regular supply, but a supply of those varieties which yield the particular alkaloids in favour with medical men. And yet how little is known even upon this subject is evidenced by the prevailing impression that compared with quinine,—the only officinal cinchona alkaloid,—the remaining cinchona alkaloids are comparatively worthless. At any rate such would appear to be the case from the fact that cinchonidine can be obtained at less than half the price of quinine, and that it is barely alluded to in the last edition of 'Pereira.' This would be the more remarkable if it be true, as Mr. J. E. Howard thinks, that the early reputation of cinchona bark was gained by a kind in which cinchonidine is the predominant alkaloid, as illustrated in the analyses recently published in Van Gorkom's report on Java bark. An explanation of this neglect is given by Messrs. Howard in the leaflet bearing the title quoted above, which also calls attention to important medical testimony as to the therapeutic value of cinchonidine. Messrs. Howard say that of the less known cinchona alkaloids "Cinchonidine has been most neglected, in great measure owing to the confusion, scientific as well as commercial, which arose between quinidine and cinchonidine—the name quinidin being still applied by German writers to cinchonidin. The sulphate of quinidine of commerce has hitherto consisted of a mixture of the two alkaloids, and in some cases of almost pure sulphate of cinchonidine."

In 1866 medical commissions were appointed in Madras and Bombay for the purpose of testing on a large scale the comparative efficacy of the sulphates of cinchonidine, quinidine, and cinchonine in the treatment of the forms of fever met with in the malarious districts of Southern India. The general results of these experiments were recorded in this Journal (vol. i., p. 325) immediately after the issue of the report, and need not be repeated here. Suffice it to say that the Madras Commissioners stated their opinion that these alkaloids are scarcely inferior, if at all, to quinine, and that any difference is of degree and not of kind. The cases treated appeared to show that "chemically pure and ordinary commercial sulphate of quinine and sulphate of quinidine are equal in value; sulphate of cinchonidine only slightly less efficacious, and sulphate of cinchonine, though considerably inferior to the others, is a valuable remedial agent in fever." The Bombay Commission reported that they

considered all the alkaloids to be febrifuges, antiperiodics, and tonics, and that the doses of each required to produce similar results would be—Quinine, 3 to 20 grains ; quinidine, 5 to 20 grains ; cinchonidine, 7 to 20 grains ; cinchonine, 7 to 20 grains.

In 1866 the author of the pamphlet under our notice, after some years' experience in the usual treatment of malarious fevers in India, China, and the Straits of Malacca, but during which he had never tested the physiological or therapeutic action of cinchonine, quinidine, or cinchonidine, received a suggestion from the Principal Inspector General of the Madras Medical Department, that he should experiment upon the comparative utility of those alkaloids. He entered upon the investigation "entirely free from bias in favour of any one of them being more efficacious than another, or of any or all of them proving either more or less active towards the desired end than the sulphate of quinine."

In order to meet with an adequate number of well-marked cases of malarious fever of the most perfect type, the author visited four of the most noted feverish places,—Russelkondah, Kimedy, Chetterpore, and Jeypore. The cases were taken mostly from the public hospitals, where the patients were under some amount of control, and they were treated indiscriminately in rotation with the three alkaloids. The result is a series of facts which have formed the groundwork of a thesis, for which a gold medal has been awarded by the Medical Faculty of the University of Edinburgh, and an abstract of which has been kindly brought under our notice by Sir Robert Christison.

This would not be the place to enter into the medical details of the various cases instanced by Dr. Dougall. But the importance which attaches to the question whether the at present comparatively unused alkaloids may not be more generally utilized will give the general results a special interest to the pharmaceutist. In all 108 cases of intermittent fever,—92 quotidian, 16 tertian, and 2 quartans,—are reported upon, and these were treated in nearly equal proportions with quinidine, cinchonidine, and cinchonine. The whole of these cases recovered. In 27 cases there was either no paroxysm at all after the first dose, or a very mild one merely, although the alkaloid was given during a single day only ; in 30 the treatment was continued for two days, and in 14 others for three days only, and in three cases only was it necessary to prolong it to twelve or thirteen days. Dr. Dougall states that there was very little difference between the alkaloids in the necessary duration of the treatment, but a difference was observed in the doses required. This agrees with the report of the commission quoted above. The quantity of quinidine given in each case, excluding extreme cases, varied between 31 and 70 grains ; of cinchonine between 54 and 76 grains, and of cinchonidine from 43 to 90 grains. The conclusion drawn is "that quinidine is the most powerful, cinchonidine next to it, and cinchonine the least active ; but that even cinchonine is energetic, and in an adequate dose a sure remedy." The relation of these alkaloids to quinine in point of energy was not made the subject of direct trial, but previous experience leads Dr. Dougall to believe that quinine is equally active and certain in doses between two-thirds and three-fourths those of quinidine.

In closing this notice we thoroughly adopt the opinion of Dr. Dougall, that the conclusions flowing from the preceding inquiries seem of great practical consequence, since it has been established by frequent recent experience that in various circumstances quinidine. cinchonine, and cinchonidine are largely obtained from several valuable cinchona barks used by manufacturers for obtaining quinine, and that they are by no means the feeble much less the inert febrifuge remedies which at one time they were supposed to be.

BOOKS RECEIVED.

A Manual of Botany, including the Structure, Functions, Classification, Properties, and Uses of Plants. By Robert Bentley, F.L.S., M.R.C.S. Eng., etc. Third Edition. London : J. and A. Churchill. 1870. From the Publishers.

Waste Products and Undeveloped Substances : A Synopsis of Progress made in their Economic Utilization during the last Quarter of a Century, at Home and Abroad. By P. L. Simmonds. London : Robert Hardwicke. 1873.

Obituary.

Notice has been received of the death of the following :—

On the 21st October, 1873, Mr. Alfred Rushton, Chemist and Druggist, of 285, Mile End Road.

On the 9th November, Mr. Robert Roper, Chemist and Druggist, of Sheffield.

Notes and Queries.

[363.] MARKING INK WITHOUT NITRATE OF SILVER.—ANILINE MARKING INK.—A good recipe for making this ink is still a desideratum. *W. H.* writes in reference to the recipe given on p. 359 from the *Year Book of Pharmacy*, "Unless my aniline black is at fault, I consider the form a miserable failure. There is not enough gum to make it writeable, it is not permanent, and very calculated to rot the material."

[366]. LAVENDER WATER.—*E. T. H.* would feel obliged by any correspondent supplying a formula for best lavender water.

[The following is given by Piesse ('Art of Perfumery,' 3rd edition, p. 96).—Ed. P. J. :—

"Take—

English Oil of Lavender . . .	4 oz.
Spirit	3 quarts.
Rose Water	1 pint.

Filter, and it is ready for sale."]

[367]. INSECTICIDE.—Would you kindly allow me to ask, through the medium of the Journal, if any reader could tell me how to go about clearing a closet (by my kitchen fireside) which is infested with ants ? I cannot find any nest of them, but any article placed in the closet gets covered with them.—W. Rudd.

[368.] POMADE.—Would you kindly oblige me with a formula for a pomade, with a colour that will stand sunlight ? I find it is difficult to produce an article which will not turn white round the sides of the bottle. – J. W. Y.

[369.] AQUARIUMS.—What is the best grass, etc. to put in a leech aquarium ?—T. P. Clark.

[370]. HOMINY.—A customer of mine asks me for a dietetic preparation called "Hominy." I have tried in vain to get it. Can any reader give me any information respecting such a preparation ?—*J. T. H.*

ADMINISTRATION OF PHOSPHORUS.—Mr. S. M. Bradley of Manchester, in a letter to the *British Medical Journal*, publishes the following formula for the administration of phosphorus, constructed by Mr. Potts, Dispenser to the Manchester Royal Infirmary :—Ten grains of phosphorus are dissolved in two ounces of ether, the solution being agitated from time to time. Of this solution, one minim (containing one-hundredth of a grain) is administered in an ounce of water with half a drachm of glycerine. The glycerine suspends the phosphorus so perfectly that a transparent mixture is the result. It is stated to be tasteless, but the addition of a little bitter infusion would effectually cover any trace of the savour of phosphorus.

Pity the Poor Plucked Preliminarians.

Sir,—I had recently occasion to question the correctness of the circular which plucked preliminarians receive in reply to their inquiry as to what part of their examination paper was so faulty as to cause their rejection. All the unfortunates receive the same reply—that they had failed "in every subject." In reply to my inquiry fuller information was given me in confidence, and an intimation that the circular in question did not fairly convey the meaning intended by the Board of Examiners, and that it would be altered. This was so far quite satisfactory, and I might have let the matter rest had it not been that some hundreds of preliminarians have been plucked, and I do not know how many of them may be suffering from the impression that injustice has been done to them, or are discouraged from trying again, knowing that they had worked honestly, and believing that they had done fairly well in one or more of their subjects, and yet being informed that they had failed in them all. In my very limited acquaintance with plucked candidates I know some, having feelings such as those alluded to, have resolved to quit the trade. Now, my object in writing is to give a word of encouragement to the downhearted, and to advise them if they can induce the Board of Examiners to give them the information as to which was their weak point that they should steadily give two nights a week to that subject, and one night a week to each of the others, through the winter, and when they present themselves again to commence answering the questions in a subject in which they feel some confidence of success; then take the most difficult, the consciousness of having gone through the first satisfactorily will relieve them of the nervousness which a candidate is apt to feel at the commencement, and the knowledge that he has something less formidable to finish with, will encourage him through the difficulty. Some say too much is made of this question of nervousness, but I cannot agree with them so long as I find examined men who do not understand the meaning of five per cent., and cannot convert grams into grains with the aid of the Pharmacopœia, and plucked men who at home appear in all respects better qualified.

And as an ex-member both of Board and Council I would like to give publicity to my opinion that the best thing for plucked students would be to let them know precisely the position they have taken, and the position they will be required to take before they can be passed; and there might advantageously be added a word of caution against their allowing their better subjects to grow rusty while they were polishing up the more defective.

Barnard S. Proctor.

The Benevolent Fund.—A Suggestion.

Sir,—On reading the minutes of the "Council Meeting" held last week, I regret to find the subscriptions to this fund are inadequate to meet its requirements. This I much regret, as it is an institution which has ever had my best sympathies, though I have been unable hitherto out of my stipend as an *assistant* to contribute materially to it.

The discussion following the statement of deficiency has induced me to take a liberty which I trust will not be considered impertinent or out of place, that of making the following suggestion:—

That instead of a circular being posted to every "chemist" throughout the country merely, such "circular," stating in clear and concise terms the objects of the "Fund," having appended to it a list giving the numbers of past recipients, whether pharmaceutical chemists or otherwise, with the amount expended, and further showing the urgent necessity of increased subscriptions to meet the requirements of the Fund, be placed in the hands of a committee in towns where there is a local association, and in smaller places entrusted to the local secretary to be presented "personally" to the members of the trade, and their assistance urgently solicited.

I venture to hope that the short time necessarily employed in calling upon these gentlemen would be devoted ungrudgingly, as large towns might be divided into districts, which would greatly facilitate the work and decrease individual labour, each taking a part.

I think one reason why the Fund is not more generally supported is, that its operations are not brought forward with sufficient prominence.

On the majority of chemists, who do not read the "Journal," a communication sent through the post simply would hardly make sufficient impression; such might, however, be used in cases where personal application is impossible.

I think, sir, if some such plan were to be adopted, and the committees were to work in the spirit of true benevolence a noble result would follow.

Local cases might be cited to show that the Fund was distributing its benefits to many who through misfortune, sickness, or old age, were unfortunately compelled to apply for help.

Could these nonsubscribers but once see for themselves the look of gratitude and thankfulness which is lit up in many a poor wan face by this means they would not readily withhold their hand.

As I write I see before my mind's eye the form of one old gentleman who has been the "recipient" of this bounty, and as I remember his aged and decrepit form—bent with the weight of many years—I see his face before me bright with happiness once again, and hear him say in language simple but *sincere*: "I am very thankful, very; please tell the gentlemen I am *very thankful*. My friends paid more than one hundred pounds premium for me *once*." And I notice as he turns to go, the tear just now glistening in his eye falls upon his rugged hand, and mingles with the modicum just received.

Then can nothing be said about the widows and orphans? Surely compassion *must* be felt for them.

It may be suggested that "Charity begins at home," therefore I beg to enclose my humble contribution to an object which I believe to be alike admirable and humane.

E. R. L.

Sheffield.

[*** We beg to acknowledge the receipt of the stamps enclosed as our correspondent's contribution to the Fund, and have handed the same to Mr. Bremridge.—Ed. Ph. J.]

How to Increase the Revenue of the Benevolent Fund.

Sir,—My time will not permit me to write a long letter in support of the proposition I am about to make; but I trust its practicability will be self-evident. I beg to suggest to the Committee of this Fund, as a means by which to increase its income and of obtaining subscriptions from the general body of chemists and druggists as well as pharmaceutists, that a circular letter be addressed to every local secretary, requesting that a meeting of the trade be called, and that a committee be elected to canvass the town for subscriptions. Some statistics should at the same time be furnished. In this way there is little doubt a large addition to the annual income might be made.

F. M. Rimmington.

Nov. 10*th*, 1873.

Honour to whom Honour is Due.

Sir,—I think it should be more generally known that the firm of wholesale druggists, Southall, Son, and Dymond, of Birmingham, have long publicly condemned the practice of calling effervescing citro-tartrate of soda "citrate of magnesia," having for some years labelled all they sent "so-called," and more latterly attaching a slip certifying what the ingredients really were. I believe I am correct in stating that the late George Dymond, whose sudden death was mentioned in your last Journal, was the first to call public attention to the misnomer, and to urge on chemists the desirability of adopting a correct name. A reference to the report of the Conference Meeting in Dundee will bear out my statements. It is there stated that at the conclusion of Mr. Dymond's paper, "Several Members took part in the discussion, etc., etc. . . . the general feeling, however, did *not* appear to be that the practice of using the conventional name of Granular Citrate of Magnesia was an *abuse demanding protest*." Then again at the Liverpool Meeting, although Mr.

Dymond's resolution was carried, the members were far from being either unanimous or warm on the subject. Compare these two, however, with the Evening Meeting of the 5th instant, where every member appeared only too anxious to clear his conscience. Mr. Bishop's repentance comes too late, himself and his brother manufacturers should have taken the matter into their consideration six years since, and not have left its settlement to a police magistrate.

Mr. Dymond's persistency through dire opposition has at length been fruitful, and it is a curious and sad coincidence that the evening before the meeting to which reference has been made Mr. Dymond breathed his last.

M. J. ELLWOOD.

Leominster, Nov. 10th, 1873.

THE SO-CALLED "CITRATE OF MAGNESIA."

Sir,—The "effervescent citrate of magnesia" seems to have thrown the trade into a panic. How far this is justifiable remains to be seen.

This article, primarily the speciality of one manufacturer, has become such a favourite of the public and physicians that other makers have been called into existence, more or less faithfully imitating the original formula. The original compound did, and still does, contain magnesia as a salt, and many of the preparations of other makers contain it also, and produce the citrate of magnesia when in solution. Whether citrate of magnesia be formed depends entirely on the proportions of bicarbonate of soda, sulphate of magnesia, and citric acid used. If citrate of magnesia be *not* formed carbonate of magnesia can be thrown down by boiling the solution of the granule and volatilizing the excess of carbonic acid. To sell citro-tartrate of soda for the magnesian compound is manifestly wrong, and is open to be characterized by the legal term fraud, as I understand it. This was Mr. McDermott's case.

The magnesian granule is certainly not a citrate until in solution, but then no more is the citro-tartrate of soda, which is an authorized medicine.

Again, "citrate of magnesia" is said to be liable because it contains other articles than citrate of magnesia. Well, so also do sulphate of beberia, (for which, by-the-bye, a chemical formula is given in the B. P.!) soap liniment, the solutions of arsenious acid, and ammonio-citrate of bismuth. The last-named is very similar to the magnesian preparation, inasmuch as it also is a citrate combined with abundant quantities of other unnamed substances. The term applied to it is intended to represent a speciality and a definite solution of a salt, but the preparation contains other and, perhaps, antagonistic substances.

Some of the alterations of name proposed would still leave us within the scope of the Act. Thus Mr. Bishop proposes to designate the compound a citro tartrate of soda with *magnesia* and sugar, but how comes it that free magnesia can exist with carbonic and citric acids in the same solution?

Mr. Umney proposes "effervescing citrate," but this leaves the tartrates unnamed, and seems to be as objectionable as our present name.

I proposed at the meeting to call the preparation effervescent compound citrate of magnesia, and if physicians would so order it we should be able to understand when the granule or when the salt was required.

The Act, as I understand it, was intended to catch wilful adulterators, and not to stop the sale of popular articles by micro-chemical definition. Let the trade therefore demand the immediate repeal of the Act, and substitute in its stead one that will catch the fraudulent without becoming vexatious.

GEO. BROWNEN, F.C.S.

Laboratory, 143, *New Bond Street, London, Nov. 8th*, 1873.

Sir,—The discussion at the last Pharmaceutical Evening Meeting commends itself to the attention of every pharmacist. I feel, therefore, no apology is needed in adding a few further remarks upon the same subject.

The chief point, of course, is the settlement of the name by which the preparation long known to the public as citrate of magnesia is in future to be recognized—*i. e.*, to re-christen an old friend so as to satisfy the demands of our legislators, and at the same time be intelligible to the general public.

Being absent from home through sickness, I am unable to refer to the Adulteration Act, but so far as my memory carries me I do not remember that that Act requires the distinct avowal of the exact composition of every article offered to the public; hence, would it not be far more simple and desirable to all parties (analysts excepted) at once to drop any attempt at a chemically accurate name, and to introduce one in no way committing either manufacturer or retailer? We have already an endless catalogue of such names—*e.g.*, Dover's Powder, Gregory's Powder, Parrish's Chemical Food, Seidlitz Powder, etc., familiar household terms representing definite preparations, the assumed compositions of which, to a great extent, are known by the purchasers, although in no way hinted at by their respective names. Might not the same be adopted in the present case, instead of inflicting upon our customers and their not always over-intelligent messengers, such to them unintelligible terms as "Citro-tartrate of soda, with magnesia, sugar, and lemon flavour?" What might we not expect such a name to be turned and twisted into before being asked for at our counters?

The addition of "known by the public as, etc.," of course being intended to stem over a temporary difficulty, should be dropped as soon as the new name becomes sufficiently familiar to the public.

One difficulty alone presents itself to the absence of any reference to the composition of the article in question, viz., the fact that magnesia being so intimately associated therewith in the public mind its retention seems an absolute necessity, but on the authority of Mr. Bishop we are assured that magnesia not only *is* an ingredient of his preparation, but that its presence is absolutely desirable. May we not therefore fairly assume that in future its addition will be universally adopted by all makers, and the quantity also increased, as far as practicable, so as to render its presence no longer a questionable fact.

The name I would venture to suggest as embracing all these requirements, is—Granular Effervescent Magnesian Saline—with the additional statement (*pro. tem.*)—originally called Citrate of Magnesia. It appears to me this would be a simple and sufficiently clear exponent of the article to which it would be attached. Commending it as such to the consideration of the trade.

EDWIN B. VIZER.

Montpelier Road, Brighton, Nov. 11th, 1873.

Sir,—With regard to the recent discussion on the so-called citrate of magnesia, we must all agree that it is highly desirable to alter the name of the old familiar preparation as *little as possible*, and it has occurred to me that the following designation would meet the requirements of the Act, and protect the trade from more unfair prosecutions:—"Granular Effervescent Citrate, *with* Magnesia." This form presents simply the trifling alteration of one word, without any pretension to a definite chemical composition which it may not possess. And it would be only necessary for practical purposes, that it should contain *some proportion* of magnesia.

The basis of the late prosecution evidently consisted of the fact that the label signified a definite compound which analysis in that particular case proved not to exist.

H. J. BROUGH.

30, *Conduit Street, London, W., Nov.* 11, 1873.

Sir,—Having been somewhat exercised in my mind of late, in common, I suppose, with all other chemists, on the subject of the misnomer, "Citrate of Magnesia," it has occurred to me that since magnesia is as stated by Mr. Bishop, the essential ingredient in the compound, the best name would be, "Effervescent *Granules* of Citrate of Magnesia," which would come under the same category as pills of iodide of iron, or lozenges of bismuth, etc., etc., and would involve less alteration in the words than any name I have seen suggested.

It is of course superfluous to inform the public that the above pills are compounded with the aid of liquorice, etc., as it is that the lozenges are made up with sugar, and it seems to me that it would be equally unnecessary to enlighten that body as to the nature of the excipient used in the formation of "Effervescent Granules of Citrate of Magnesia."

J. GIBBS.

Cheltenham, Nov. 11th 1873.

THE SO-CALLED CITRATE OF MAGNESIA.

Sir,—Having read the discussions which took place at the Pharmaceutical Meeting on the 5th inst., respecting the name of the above article, etc., being difficult to get at a proper one, in consequence of the new Adulteration Act, I propose the following label to be adopted for it, with safety, from any analyst or Act of Parliament :—

For the Profession.
SODÆ CITRO-TARTRAS EFFERVES. CO.

For Retail.
Compound Effervescent Citro-Tartrate of Soda,
Known by the Public as
CITRATE OF MAGNESIA.

This form of label is equally as proper for the above preparation as the term "compound tincture of cardamoms" is for that preparation: if the latter term be legal the *former* is quite as legal. I think a formula for the preparation should be inserted in the Appendix to the British Pharmacopœia.

D. J. T.

Brixton, S.W.

REMUNERATION OF ASSISTANTS.

Sir,—Observing in your last issue a letter from Mr. Heynes respecting "Remuneration of Assistants," allow me to supplement it by a few remarks as to my own experience in the matter, leaving your readers to judge of the pecuniary encouragement held out in some quarters to the rising generation of pharmacists.

Some few years ago, having completed a six years' apprenticeship, I heard of a vacancy for an outdoor assistant in an establishment holding a foremost position in a northern city, and I accordingly made personal application. The principal (who by-the-bye, rejoiced in the title "Pharmaceutical Chemist"), after putting numerous questions as to experience and capability, and requesting me to furnish him with a specimen of my caligraphy, in the form of a label for "two tablespoonfuls to be taken three times a day," offered to conclude an engagement (*outdoor*, remember,) with me, for three years, at the rate of £40 for the first year, £45 for the second, and £50 for the third. Comment is superfluous, I therefore merely add as my opinion that those who are unable, or unwilling, to offer more than such pittances as the above-named should work the harder themselves instead of holding out temptations to dishonesty in the shape of salaries such as would be spurned by the commonest unskilled labourer.

AN ASSOCIATE IN BUSINESS.

Mexborough, Nov. 11th, 1873.

REMUNERATION OF CHEMISTS.

Sir,—In reply to E. L. H., I would beg to inform him that before attempting to point out to "Sensitive" what he already knows, it would, in his opinion, be decidedly better to get a more extended knowledge of the subject. If E. L. H. thinks it worth his while to call upon "Sensitive" he will try to explain matters to him, his predecessor being abroad, and therefore unable to give an account of his miscalculation. As this was not the first, second, or, I might say, the twentieth offence by the house spoken of, "Sensitive" felt justified in penning the letter of the 18th. more especially as the gentleman, who had up to that period been a good book customer, has almost discontinued coming at all, attributable no doubt to the exorbitant price, as he then called it, of the liniment. Perhaps his being a foreigner will partially excuse his young ideas of English prices, still, had "Sensitive" occupied the position he now does, he would not have charged less than 2*s.* 6*d.*—so much for the house in question. Perhaps another would serve to strengthen my statement. The following was left at the same house by a German and charged 1*s.* 6*d.*; afterwards with a first-class chemist in Bayswater, "not at Chelsea," who also was surprised at the extremely low price. The same will vouch for the truth of the above fact:—

℞

Quinæ Disulph. . . . . gr. xxxvi.

SENSITIVE.

520, *Oxford Street, W.*,
Nov. 10th, 1873.

"*An M.P.S. from the Country*" is referred to the rule respecting anonymous contributions.

P. M.—See the British Pharmacopœia, under "Alcohol Amylicum."

"*Alpha*"—The publication referred to is the *British Journal of Dental Science*, published monthly by Messrs. Churchill, price 1*s.*

C. H. L.—See some particulars respecting croton chloral in the present series of this Journal, vol. ii., p. 424, and vol. iv., p. 233. See also *Brit. Med. Journ.*, p. 484.

W. J. S.—A formula for Ol. Morrhuæ c. Ferro was given in vol. ii., p. 858, and see also p. 488 of the same volume.

H. Whitrod.—We should recommend you to study carefully Wanklyn's work on "Water Analysis."

"*Chemist*" (Bourne).—Formulæ for Glycerine Jelly have been given in the present series of this Journal, vol. i., pp. 397 and 497. We are unable to answer your second question.

J. W. Y.—(1) See preceding answer. (2) It would be one of the lower oxides of nitrogen. (3) Although ¼ grain of phosphorus would be a very unusual dose, still larger doses than those you mention are given. For instance, Mr. Thompson reports (*Practitioner*, July, p. 16), that a patient took ¼ grain every four hours for some days without harm. But the object of the formula was the pharmeceutical one of furnishing a method of exhibiting phosphorus in pills rather than of prescribing any fixed dose.

Brighton Association of Pharmacy.—The report of the opening meeting of the session, on Friday, the 7th instant, has reached us just as we were going to press, too late for insertion in the Journal for this week.

C. Crook.—The crystalline deposit referred to was normal carbonate of ammonia. We should imagine that either the distillate was not perfectly mixed, or else the spirit of wine was deficient in strength. Did you determine the specific gravity?

J. H.—We should recommend 'Pereira's Elements of Materia Medica,' by Bentley and Redwood, or 'Garrod's Materia Medica' (latest edition), and 'Attfield's Manual,' or 'Roscoe's Elementary Chemistry.'

"*Spes.*"—Apply to the Secretary, 17, Bloomsbury Square, for a copy of the pamphlet entitled, "Hints to Students."

Dr. Charles Kidd certainly does not fail in the Quixotian desideratum that every knight should have a grievance, but we are constrained to inform him that we cannot undertake to discuss subjects of such purely medical character as the relative anæsthetic merits of chloroform and ether, and in reference to his repeated attempts to make this Journal a medium for the publication of his opinions and arguments on this topic we must again refer him to the medical press as the proper channel for him to have recourse to. As regards our criticism of Dr. Kidd's grammar (see p. 359) we are really sorry he appears to have been unable to smile at it, though we fail to understand the reason he assigns. We may take this opportunity, however, of informing Dr. Kidd that there is no novelty whatever in the ether which he terms "new," nor anything unknown as to the specific gravity he refers to; but his supposition that perhaps not one London chemist is aware of such an ether is a delusion we hope peculiar to himself.

The Half-Yearly Abstract.—Dr. W. Domett Stone writes in reference to our brief notice of this work (p. 359) a letter which we presume he desires us to regard as a reclamation, but as he abstains from pointing out "all the errors" he supposes we have fallen into, we must be equally reticent in our reply as to the objection he raises to the statement in the first line of the notice, which he says "is at variance with fact"; we can only say that in that case there is the less excuse for the blunders we pointed out. The array of names quoted as having borne testimony to the virtues of "chlorozone" in no way alters our opinion that Dr. Domett Stone's admiration of that nostrum is not shared by competent chemists.

Mr. Bourne.—Your advertisement and enclosure have been handed to the publishers, to whom all similar communications should be sent.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Benger, Dr. Burchardt (Berlin), Mr. Baynes, Mr. J. Young, Mr. Hart, Secretary of the Carlisle Chemists' Association, Mr. Horncastle, Mr. Twemlow, Mr. Knapman, F. W. S.

THE TEACHING OF VEGETABLE MATERIA MEDICA.*

BY PROFESSOR PLANCHON.

Among the characters which are useful in determining the identity of a substance, there are some which are very easy to recognize ; which are exterior and appeal immediately to the senses, without previous preparation : these characters may be called *easy*. There are others which require, before they can be put in evidence, a certain amount of preparation, because they are more internal and belong to the disposition and arrangement of the tissues ; they are *more difficult* to establish, and generally, because of this difficulty, they are neglected, and the exterior characters employed by preference. To this there would not be any great objection if these "easy" characters were as sure, as constant, and consequently as important, as the others ; I will say more, if they were sufficient. But it is in this matter as it has been with the various methods of classification of plants. In the last century botanists followed the Linnean system ; but since the time of the Jussieus, De Candolles and others, they have classed plants according to the natural system. And yet it is much more easy to recognize that a plant belongs to a Linnean class,—it being for this frequently only necessary to count the stamens or styles,—than to allot it to one of the natural families since established by botanists. Why then has a convenient system been laid on one side in order to accept a method much more difficult ? The answer is, because the characters of the natural families have an importance and scope very different to those of the artificial groups of Linnæus. And the same course ought to be taken with the materia medica. The *important* and not the *easy* characters ought to be sought ; and it may be shown, not merely by theoretical considerations, but by a series of examples, that the structural characters predominate over all others in value.

In teaching this subject the more natural means would evidently be to place the various preparations required for a demonstration upon the object glass of a microscope, and thus enable the student to seize the salient characters. But this method, excellent for two or three persons, would be absolutely impracticable even for a small assembly ; and it becomes necessary to find some way of placing before all the auditors at the same time the peculiarities to which it is desired to call attention. With this object the following plan was adopted by Professor Planchon, in the course of lectures delivered by him last winter at the Paris School of Pharmacy.

The instrument used, and which was contrived by M. Van Heurck, of Antwerp, was a kind of lantern, with a dark chamber, and containing the necessary arrangements for producing the oxyhydric lime light. Upon the anterior side of the lantern there was a large round opening, to which was adapted, according to circumstances, a large lens, or a Ross's objective, of remarkable clearness. Between the magnifying glass and the light the object to be exhibited was placed, and an image was thus projected upon a white surface, placed at a little distance from the apparatus. In this manner a very exact idea of the general structure of a substance may be rapidly given. It suffices for that purpose to have a skilfully prepared thin section of the substance. Take, for example, a transverse section of turpeth (*Ipomœa turpethum*) : the cortical portion and the large resinous lacunæ that it contains are clearly seen ; then the ligneous tissue, remarkable for the large vessels, the opening of which gives it the appearance of lace work. It will be noticed that this tissue is not all entirely concentrated at the middle of the root, but that isolated fragments appear here and there about the circumference, amongst the cortical tissue.

Such a projection of a microscopic preparation by means of a Ross's objective will give a good idea of the general organic structure ; but the magnifying power is not sufficient to show certain details which sometimes it is necessary should be observed. Potato fecula, for example, is formed of small grains, of which it is impossible, especially at a distance, to appreciate the exact form and peculiar structure. In such a case, in order to supply the deficiency of the magnifier, the microscopic projection can be photographed, by which means an image already magnified is obtained, and this photograph may afterwards be further magnified by means of a large lens. In this manner a considerably developed image of the microscopic preparation can be obtained. Pending the preparation of such photographs, another but much more imperfect method has been adopted at the Paris School of Pharmacy. Upon a sheet of ground glass, which will readily take a crayon mark upon its rough surface, a drawing of the object is made. A coat of varnish over the design renders the ground glass transparent, and allows of the projection of the image on to the screen. By means of these methods combined, it is possible to exhibit a series of preparations showing the utility of the study of the anatomical structure for the determination (1) of the true characters of simple drugs, (2) of their botanical origin, and (3) of the seat of certain principles which they contain.*

1. *The Anatomical Examination of Substances as a Means for the Determination of their True Character.*

Whilst the characters of dimensions, colour, odour, and taste are sometimes not very constant in the same substance, the structural characters are identical in various specimens of the same species. Take a microscopic preparation of Vera Cruz sarsaparilla, a transverse section, for instance, and the following layers will be found ranged from the exterior to the interior :—(1) A very thin primary zone, formed of cells with thick walls, much crowded one against another ; (2) A second and much broader zone, composed of cells containing a quantity of small starch grains ; (3) A third zone, remarkable for the number of orifices that render it porous, which are the openings of the large vessels characterizing the ligneous portion of the roots ; (4) A kind of central pith, of analogous structure to that of the second zone. Between the second and third zone may be remarked also a thin circular line of a darker colour than the rest. Examined under considerable magnifying power, this layer appears to be composed of very special cells. Their form is elongated in the direction of the ray, and their walls are unequally thickened in such a manner that the wall furthest from the centre

* Abstract from a lecture delivered at the General Meeting of the Pharmacie Centrale of France (*L'Union Pharmaceutique*, xiv., 305).

* During the remainder of the lecture each point was illustrated by microscopical sections, magnified and projected upon a screen in the manner previously described.

remains thin, while the lateral walls enlarge in proportion as they approach the internal wall, which becomes very thick. It results that the interior cavity of the cell appears, in transverse section, in the form of a triangle, with the base towards the exterior, and the apex turned towards the centre of the root. At whatever point Vera Cruz sarsaparilla may be cut it presents the same characters, both in general arrangement of the structure and in the details of the layer of cells that has just been described. If this sarsaparilla be compared with other commercial varieties, it will readily be seen that (1) All the commercial species present general structural characters that are quite analogous, they being found equally in transverse sections taken from Brazil, Honduras, and Caracas sarsaparillas ; (2) That each sort presents specific characters which can assist, and indeed suffice, for their determination. Compare, in fact, the relative thickness of the ligneous zone in Vera Cruz sarsaparilla with that in Caracas sarsaparilla, and it will be seen that whilst the one is considerable, the other is very much narrower. Besides, if the cells of the characteristic layer be examined attentively it will be found that the cells of the Caracas sarsaparilla are square and the cell walls equally thick in all directions, whilst the cell walls of the Vera Cruz variety are, as has been said, very unequal in thickness. By combining these two characters—the relative thickness of the different zones and the various forms of the characteristic cells—the differences between the several kinds of sarsaparilla may be sufficiently defined, although it would be very difficult to distinguish them by a simple examination of the exterior.

This very important fact—that the various species of the same natural group of substances present at the same time characters in common which allow of their being united as a genus, and also peculiar characters by which they can be distinguished as species—is not special to the sarsaparillas, but may also be shown in a certain number of very natural groups of products. Take, for example, the cinnamons yielded by the genus *Cinnamomum*—China cinnamon, Ceylon cinnamon, cassia lignea, etc. In all of these will be found—(1) A layer of suberous cellular tissue, with fibrous bundles scattered here and there ; (2) A zone of sclerogenous cells, with thick walls, more or less continuous and regular ; (3) A liber zone, containing large cells of mucilage, and the liber fibres disposed regularly. The common characters are obvious, and distinguish very clearly the barks of the Lauraceæ from those of different families, which have been designated as cinnamons, such as *Canella alba*, Winter's bark, etc. On the other hand, the development and greater or less regularity of certain zones, and particularly that of the sclerogenous cells, present sufficiently marked differences to distinguish between the species.

These same structural characters clearly indicate that the substance frequently found in French pharmacies under the name of Winter's bark, does not answer at all to the characters of the genus *Drimys*, to which the true Winter's bark belongs, but to those of the Canellaceæ, recalling rather those of *Canella alba*. And, in fact, it is now known that this false Winter's bark is the product of a Canellaceous plant, the *Cinnamodendron corticosum*, Miers.

Another example, that of the roots of the genus *Aristolochia*, also shows the constancy of the characters in the various substances of a single group. The root of *Aristolochia cymbifera* presents to the naked eye a very special structure, especially in the disposition of the ligneous bundles, with large vessels, which spread like a fan from the centre of the root towards the cortical portion.

These same characters will be formed in the rhizome of *Aristolochia serpentaria*. They can also be recognized, though reduced and distorted, in *A. Clematitis*, *A. longa*, and *A. rotunda*. There results from this an excellent method for distinguishing Virginian serpentary from substances that resemble it—the Maryland spigelia, for example, which has all the elements of the ligneous zone arranged regularly in concentric layers around a medullary canal.

From what has been said it will be evident that an anatomical study of the roots, barks, etc., which are met with in our pharmacies, would furnish very constant characters for the determination of species as well as of natural groups, which would be much more trustworthy than purely exterior characters.

2. *The Value of the Anatomical Method of Investigation in Recognizing or Confirming the Botanical Origin of a Substance.*

There are some simple drugs which, although widely diffused, are of doubtful origin. In this case the officinal rhubarb was, until recently, to be found. It was well known that it was yielded by a plant of the genus *Rheum*, but to what species could it be referred ? It was there that uncertainty commenced. As soon as a new plant of this genus was discovered, the officinal substance was usually attributed to it. In this manner it has successively been considered to be the product of *Rheum undulatum*, L., *R. compactum*, L., *R. palmatum*, L., *R. Emodi*, W., etc. Lastly, Guibourt thought, from some experiments in cultivation, that the *Rheum palmatum* was certainly the mother plant of rhubarb, an opinion that has passed into many works on materia medica, and was unanimously accepted in France. Nevertheless, there is a considerable difference of structure between the roots of *Rheum palmatum*, which Guibourt had taken for a type, and the rhubarb of the pharmacy. Whilst the first showed medullary rays regularly diverging from the centre to the circumference, the true rhubarb has an extremely complicated tissue, in which it is very difficult to follow the course of those rays ; besides, it is marked by numerous very special stars, which may be projected on to the screen in their natural colours. They are formed of yellow (medullary) rays, starting from a common centre and diverging into the midst of the white ligneous tissue.

Such a difference of structure appeared to indicate a corresponding difference in origin. Already I had expressed a doubt as to the true rhubarb being a product of *Rheum palmatum*, when a new species, obtained from fragments of rhubarb, nearly rotten, but still containing some buds, came to confirm that supposition. This *Rheum*, which M. Baillon has described under the name of *Rheum officinale*, produces, in fact, stems presenting all the structure of rhubarb. Everything proves that we have now to do with the veritable mother plant of the substance of which China has so long monopolized the production. Anatomical study had, therefore, in this case, foreshadowed that which events have shown to be true, namely, that the species of *Rheum* hitherto known might produce the home-grown rhubarb, but were none of them the source of the true officinal product.

Another example will show how anatomical investigation will assist at the same time in distinguishing between neighbouring species and determining their true origin. Under the name of striated ipecacuanha until recently had been confounded two roots rather similiar in their external appearance, but in reality very distinct: these are the ipecacuanhas that I have recently named the "major" and the "minor" striated ipecacuanhas.* Images of transverse sections of these two roots, thrown upon the screen, will show considerable differences of structure between them. In the "major" kind—which, under the name of "violet ipecacuanha," I first met with at the Pharmacie Centrale—the cortical layers contain not a trace of starch, but a substance which strongly reduces the cupro-potassic liquor; the ligneous tissue contains vessels with very small openings, scarcely to be distinguished from the surrounding liber tissue. In the other ipacacuanha the bark is gorged with starch, and the ligneous portion has large vessels with openings that render those layers quite porous. These characters would be sufficient to distinguish clearly between the two roots.

This point ascertained, it remained to determine the origin of these products. Now, the striated ipecacuanha had been attributed by authors to the *Psychotria emetica*, Mutis, and it was presumable that, in fact, that plant did yield one of the forms of the striated ipecacuanha. But which of the two? To resolve this question, there remained but to procure roots of *Psychotria emetica*, and see if their structure agreed with that of either of the two ipecacuanhas. This I have been able to do, thanks to the kindness of M. Triana, who has sent me authentic roots of *Psychotria*. An examination of a transverse section of one of these roots shows that it is easy to recognize in it the structure of the "major" striated ipecacuanha, and it may thence be concluded that it is this commercial variety which is really yielded by the New Granada plant. As to the "minor" striated ipecacuanha, it is impossible, at present, through want of sufficient materials, to determine its origin. These examples will demonstrate sufficiently the method by which, in a great number of cases, we might proceed to discuss or confirm a doubtful or contested botanical origin.

3. *Value of the Study of the Structure in the Determination of the Seat of Certain Active Principles.*

It is easy to understand that when the active principles are contained in special reservoirs, the true method of ascertaining their seat is to seek in what layers those organs are placed. It is thus that even by the naked eye it is possible to see that the most active portion in the rind of an orange is the outer zone of the pericarp, which is filled with large glands containing essential oil.

That which in the preceding case may be recognized without employing any magnifying power, may be easily recognized by means of a glass or a microscope in a great number of substances—roots, bark, etc., which owe their activity either to resins or essential oils. Take, for example, transverse and longitudinal sections of angelica root. The glands containing oleoresin—nearly circular in shape in a transverse section, and fusiform and elongated in the longitudinal section—can be very easily distinguished, and it can be seen that these cavities occur nearly exclusively in the bark. Take, again, a section of elecampane root. Still larger glands are seen, and they occur scattered through both the cortical and ligneous portions. In jalap root the cavities which contain the resin—the active principle of that substance—can be seen very distinctly, and it will be observed that these reservoirs form pretty regular concentric layers around the centre of the root. In a fragment of squill bulb there may be seen the large crystals which resemble veritable barbs arranged one against another, in such a manner as to produce upon the skin, when struck with a piece of fresh bulb, small excoriations which allow the acrid matter to penetrate and exercise its irritating action.

These examples might be multiplied, but I will use only one more, because it is at the same time very clear and very curious; it is a section of a leaf of *Aloë socotrina*, showing that it is the seat of the bitter juice that yields aloes. At first sight there appears a central mass, formed of a loose cellular tissue; this portion is full of a kind of inert mucilage, which it is desirable as far as possible to remove in the preparation of the aloes. On the other hand, there will be seen at the exterior a thin layer of epidermis which also contains no active matter. It is between these two portions, and in the midst of the fibro-vascular bundles, that may be seen the special cells which contain the coloured bitter juice sought for in the leaves.

Here I will stop, in order not to fatigue the attention with too many details. My object will have been attained if by this rapid exposition I have demonstrated not only the interest of these studies from a theoretic point of view, but also, and especially, the necessity of bringing them down from the domain of pure science into that of daily practice. The difficulty is less than it appears, and the results are of the first importance. I should be happy if employers, convinced of this truth, would support these methods of study by the authority of their personal experience, and would encourage their young pupils, over whom they may so legitimately exercise their influence, to enter into so fruitful a field.

* See PHARM. JOURN. [3], vol. iii., pp. 521 and 642.

THE MODERN PROGRESS OF CHEMICAL INDUSTRIES.*

BY AIMÉ GIRARD.

(*Concluded from page* 388.)

Search the coasts of France and there will be found a source of potash of incomparable beauty. This source is the sea, by which on three sides France is surrounded, and which offers in abundance its industrial as well as its alimentary riches. It is an inexhaustible mine. The saline compounds that it holds in solution are numerous. To speak only of the more important, each litre of sea-water, taken either from the ocean or the Mediterranean, contains at least 25 grams of chloride of sodium and one gram of chloride of potassium.

Imagine those vast flat areas known as salt marshes covered with sea-water, which is left to evaporate spontaneously; gradually concentrating, the time arrives when the chloride of sodium, incapable of remaining longer in solution, is deposited in a solid crystalline state. Formerly, this concentration was never carried to extreme limits; at the end of a few weeks, when the deposit had acquired a thickness of ten to twelve centimetres, the salt was

* Abstract of a lecture delivered at Lyons upon the occasion of the visit of the French Association for the Advancement of Science. (*Moniteur Scientifique*, vol. iii., p. 851.)

removed, and the water not yet evaporated—the "caumère" as it is termed,—was rejected, without a thought as to the riches it might contain—riches amongst which naturally figured the potassic compounds. It was thus that from time immemorial affairs passed upon the Mediterranean coast, and each year enormous quantities of potash, lost to industry, were returned to the sea from which they had proceeded a few months previously.

Was it then a difficult matter to collect these salts of potash, and to store up these lost riches? Truly, it was, and it required nothing less than the science of a master, M. Balard, and the tenacious skill of one of those manufacturers who do honour to their country, M. Merle, of Salyndres, to accomplish it. The process of M. Balard for treating the "eaux mères" of the salt marshes consisted in a series of double saline decompositions of extreme delicacy, the accomplishment of which required the assistance, not, as usual of heat, but on the contrary of an energetic cooling, of a true congelation. Refrigeration of this kind was hardly known on the coasts of the Mediterranean, and the method of M. Balard would very probably, in spite of its elegance, have been confined to the region of scientific experiment, if in the first rank of modern discoveries the machines for the artificial production of ice had not appeared. The refrigeration that the climate of the Mediterranean refused was quickly demanded from these machines. At an enormous expense powerful apparatus were constructed and set up in Camargue, at the great salt works of Giraud, and the manufacture was at once commenced. Twenty-five years of study had been necessary to ensure success, but the success was complete. Attempted in 1835, by M. Balard, and followed up with indomitable courage, about 1860, the extraction of potash from sea water was accomplished, and the product was successfully introduced amongst the products of chemical manufacture.

But the success was only to be ephemeral; to the efforts already made it was necessary to add still greater, and at the moment that it was thought the new industry had reached port it came into violent collision with an unknown rock, from the shock of which it is wonderful that it did not founder. A marvellous discovery, one crushing in its effects to all producers of potash, came suddenly to enrich their neighbours across the Rhine. At Stassfurt, enormous mines of rock salt were being explored, and above the thick beds of which those mines were constituted, were found, disposed regularly in successive layers, all the saline compounds yielded by the "eaux mères" of the salt marshes, as though in this bed, hitherto unknown, some immense sea had deposited, first, the marine salt, then the magnesian compounds, and finally the salts of potash which it originally held in solution. How terrible a blow was thus dealt at the new French industry may easily be divined. At Stassfurt, in fact, neither large evaporating surfaces to separate the salt, nor powerful refrigerators to cause the double decomposition, were required; it was only necessary to dig up from the mine the potash ore,—carnallite,—and boil it with a little water in order to obtain the chloride of potassium nearly pure. The appearance of the Stassfurt potash in the European market worked a complete revolution; chloride of potassium worth previously 55 francs the 100 kilograms fell at once to 22 francs, or more than 50 per cent. But the men who had brought the new manufacture to the point of success were not discouraged; they had fought so long that still to fight appeared to them only natural. M. Merle and his colleagues set to work, bravely took up again the economic study of their processes, and modified them in accordance with the necessities of the situation. To the primary action of cold they added the secondary action of well-applied heat; they called to their aid skilful mechanical contrivances, and advancing slowly but surely in the path of reform, they reconstituted their processes, and a second time saw success smile upon their efforts. And thus, after ten years of fresh struggles, the French potash industry is again set on foot; potash is manufactured regularly at Camargue, not far from Lyons, and already not less than ten or twelve hundred tons of potash compounds are delivered annually, which neither in quality or price have anything to fear from foreign competitors. A new source of wealth has been definitely acquired by the country; and this conquest once more teaches that in pacific industrial fights, as well as in others, it is necessary never to despair.

Many other evidences of progress might yet be described in pursuing the study of the manufacture of chemical products. We might note the manufacturer on the watch to collect ammoniacal compounds wherever they present themselves; or point to the working of the enormous beds of calcareous phosphates discovered on all sides in France, in the Lot as well as in the Ardennes, at Bellegarde as at Boulogne-sur-Mer, and which, converted into more easily assimilable phosphates, and mixed with the ammoniacal salts just referred to, become in the hands of agriculturists powerful fertilizing agents. There is also the manufacture of alum—sulphate of alumina—in France by the utilization of the bauxite of Tarascon, in England by the employment of the recently discovered native phosphate of alumina. Finally, there are those innumerable industries which all, as was said at the commencement, revolve around sulphuric acid as around a common centre.

A DISCOURSE ON MOLECULES.*

BY J. CLERK MAXWELL, M.A., F.R.S.,

Professor of Experimental Physics in the University of Cambridge.

An atom is a body which cannot be cut in two. A molecule is the smallest possible portion of a particular substance. No one has ever seen or handled a single molecule. Molecular Science, therefore, is one of those branches of study which deal with things invisible and imperceptible by our senses, and which cannot be subjected to direct experiment.

The mind of man has perplexed itself with many hard questions. Is space infinite, and if so in what sense? Is the material world infinite in extent, and are all places within that extent equally full of matter? Do atoms exist, or is matter infinitely divisible?

The discussion of questions of this kind has been going on ever since men began to reason, and to each of us, as soon as we obtain the use of our faculties, the same old questions arise as fresh as ever. They form as essential a part of the science of the nineteenth century of our era, as of that of the fifth century before it.

We do not know much about the science organization of Thrace twenty-two centuries ago, or of the machinery then employed for diffusing an interest in physical research. There were men, however, in those days, who devoted their lives to the pursuit of knowledge with an ardour worthy of the most distinguished members of the British Association; and the lectures in which Democritus explained the atomic theory to his fellow-citizens of Abdera realized, not in golden opinions only, but in golden talents, a sum hardly equalled even in America.

To another very eminent philospher, Anaxagoras, best known to the world as the teacher of Socrates, we are indebted for the most important service to the atomic theory, which, after its statement by Democritus, remained to be done. Anaxagoras, in fact, stated a theory which so exactly contradicts the atomic theory of Democritus, that the truth or falsehood of the one theory implies the falsehood or truth of the other. The question of the existence or non-existence of atoms cannot be presented to us this evening with greater clearness than in the alternative theories of these two philosophers.

Take any portion of matter, say a drop of water, and observe its properties. Like every other portion of matter we have ever seen, it is divisible. Divide it in two, each portion appears to retain all the properties of the original

* Lecture delivered before the British Association at Bradford, September, 22, 1873.

drop, and among others that of being divisible. The parts are similar to the whole in every respect except in obsolute size.

Now go on repeating the process of division till the separate portions of water are so small that we can no longer perceive or handle them. Still we have no doubt that the sub-division might be carried further, if our senses were more acute and our instruments more delicate. Thus far all are agreed, but now the question arises, Can this sub-division be repeated for ever?

According to Democritus and the atomic school, we must answer in the negative. After a certain number of sub-divisions, the drop would be divided into a number of parts each of which is incapable of further sub-division. We should thus, in imagination, arrive at the atom, which, as its name literally signifies, cannot be cut in two. This is the atomic doctrine of Democritus, Epicurus, and Lucretius, and, I may add, of your lecturer.

According to Anaxagoras, on the other hand, the parts into which the drop is divided are in all respects similar to the whole drop, the mere size of a body counting for nothing as regards the nature of its substance. Hence if the whole drop is divisible, so are its parts down to the minutest sub-divisions, and that without end.

The essence of the doctrine of Anaxagoras is that parts of a body are in all respects similar to the whole. It was, therefore, called the doctrine of Homoiomereia. Anaxagoras did not of course assert this of the parts of organized bodies such as men and animals, but he maintained that those inorganic substances which appears to us homogenous are really so, and that the universal experience of mankind testifies that every material body, without exception, is divisible.

The doctrine of atoms and that of homogeneity are thus in direct contradiction.

But we must now go on to molecules. Molecule is a modern word. It does not occur in *Johnson's Dictionary*. The ideas it embodies are those belonging to modern chemistry.

A drop of water, to return to our former example, may be divided into a certain number, and no more, of portions similar to each other. Each of these modern chemists calls a molecule of water. But it is by no means an atom, for it contains two different substances, oxygen and hydrogen, and by a certain process the molecule may be actually divided into two parts, one consisting of oxygen and the other of hydrogen. According to the received doctrine, in each molecule of water there are two molecules of hydrogen and one of oxygen. Whether these are or are not ultimate atoms I shall not attempt to decide.

We now see what a molecule is, as distinguished from an atom.

A molecule of a substance is a small body such that if, on the one hand, a number of similar molecules were assembled together they would form a mass of that substance; while, on the other hand, if any portion of this molecule were removed, it would no longer be able, along with an assemblage of other molecules similarly treated, to make up a mass of the original substance.

Every substance, simple or compound, has its own molecule. If this molecule be divided, its parts are molecules of a different substance or substances from that of which the whole is a molecule. An atom, if there is such a thing, must be a molecule of an elementary substance. Since, therefore, every molecule is not an atom, but every atom is a molecule, I shall use the word molecule as the more general term.

I have no intention of taking up your time by expounding the doctrines of modern chemistry with respect to the molecules of different substances. It is not the special but the universal interest of molecular sciences which encourages me to address you. It is not because we happen to be chemists or physicists or specialists of any kind that we are attracted towards this centre of all material existence, but because we all belong to a race endowed with faculties which urge us on to search deep and ever deeper into the nature of things.

(To be continued.)

THE ARCHBISHOP OF CANTERBURY ON EXAMINATIONS.

The prizes and certificates won at the recent Oxford Local Examinations for the Margate Centre were distributed to the successful competitors by the Archbishop of Canterbury at Margate on Tuesday afternoon. After congratulating the recipients and their masters and mistresses, he proceeded to deliver an address, in the course of which he said:—

"We live in an age of examinations. He did not know where they were to stop. He did not know that even civic authorities would not, in course of time, be subjected to a kind of competitive examination. Some of them might live to the time when such positions as he had the honour of holding would be advertised as vacant in the public newspapers, and all the world would be invited to come forward at a specified day to compete for the vacant post. Though it was true that a thing might be overdone, yet no man who, like himself, had had practically to do with education could doubt that a really good examination was a necessary part of the preliminary education which fitted youths for manhood. Unless they had these tests, the boy might be going on in a dream during the whole time of his work, fancying he was working when he was making no progress; and the examination was a wholesome stimulus during the work, and a wholesome test at the end. We were, he thought, greatly indebted to the Universities—of Oxford especially, and both Oxford and Cambridge—for having established those strict and real examinations throughout the land. He believed that those who were preparing for competitive examinations were very well acquainted with a system, now too common in the country, which went by the name of "cram," and that a great deal of what appeared as most successful results in many examinations now held throughout the country was of very little value. He had been told, for example, of an eminent tutor who had a vast number of pupils, because his pupils were almost sure to be successful in some of these examinations, who had this mode of enabling his pupils to exhibit before the examiner the writing of essays on any subject of history. The tutor, from long experience and careful study of the questions set in past times, ascertained with almost mathematical precision that one of ten subjects would be set for an essay at the coming examination. He in his study carefully prepared ten essays on ten subjects; one, the history of Queen Elizabeth; another, the influence of the French Revolution on the civilization of the world, and other subjects. Having prepared these day by day, he required his pupils to commit those ten essays to memory. They entered the competition, and, to their delight, they found a familiar subject in the essay proposed, and in a moment a beautifully prepared essay, such as filled the examiner with surprise, was prepared by the youth of fourteen, and he was awarded the required number of marks. Those who were engaged in preparing young men for examinations were acquainted with this system. He was not going into the question of preparing young people for examination. He thought, fairly conducted, it produced a good result. He regretted to hear the remark continually made by our great teachers in public schools—that very often those boys who were most distinguished in their career in these great places, and were carrying on a really good and vigorous system of education under their care, were obliged to leave them, in order to be subjected during a month or two to some system of "cram" before they were produced before the examiners in these competitive examinations; and if that was the case, he thought it showed that they had great reason to be obliged to those who, in the present examination, sent us really good examiners who would be able at once to sift the wheat from the chaff, and to see what was "cram" and what was knowledge really and carefully acquired by hours of labour, such as, he had no doubt, had been bestowed on the subjects of these exa-

minations by the youths who had been fortunate enough to obtain prizes. But they should altogether deceive the young men and young women who had obtained prizes that day if they taught them that their education ended when they were prepared for the business of life. Everyone knew the almost hackneyed expression that the best education was that which a man got himself, and the highest education must be carried on throughout the whole of a man's life. They knew very well that the flowers which bloom early might be the first to fade, and it was quite possible that those who had been most carefully prepared in the previous part of their education might fail altogether in the business of life, and not only in the business of life, but might relax those efforts which every thinking human being was bound as long as life lasts to be making in order to carry on his education when he had attained to manhood. He would advise the young persons who had obtained prizes, as well as those who had failed, to remember that the real second part of their education was that day only beginning, and it might well be that those who had been least successful in the preliminary struggle which had been decided on that day might be the most successful in the struggle of life, and not only in the struggle in the business of life, but in that high education of the human soul which every man desired to give to himself while he was doing his part among his fellow men. They should take care that their education was conducted carefully by their own efforts; that business did not so entirely engross them but that they should find time also for higher pursuits. Above all, he would advise every young man and young woman always to have in reading some really good book, not to be satisfied with the trashy productions which issued continuously from the press, but to see, every one, that he was reading the works of some author whose name was known by the benefits he had conferred on mankind, and to live in whose society was one of the greatest privileges which could be vouchsafed to them. But he had said also that their education must be conducted by great efforts of their own. He had said that no one would succeed in life who considered his education ended when he finished boyhood. He need not speak of those great subjects connected with material science, a knowledge of which was amply rewarded in the present day, which offered so very ready a road to distinction and to wealth; but he would remind them rather of those other subjects with which they could not cease to be familiar without losing a great vantage-ground for the business to which they were called in life. Were some of those who had obtained prizes or had passed through this examination going to be teachers of others? How was it possible for anyone to acquit himself well as a teacher unless he was every day a learner? and how could he teach those great subjects connected with the literature of their country and other countries unless he was adding daily to his own stores in his acquaintance with that literature? How was a man to perform his part well as a citizen unless he was cultivating his mind? How were they, as employers of labour, to learn to influence those over whom God had placed them unless they understood those subtle feelings by which one man was able to guide the will of another man; and how should they ever study with real advantage those subjects unless they were to a degree acquainted with poetry, eloquence, and history, and other kindred arts by which man had been raised in the generations which were passed."

THE CITRATE OF MAGNESIA QUESTION.

Trade Conference of Chemists and Druggists.

A meeting of chemists and druggists, convened by the National Chamber of Trade, for the purpose of considering the late prosecution under the Adulteration of Food and Drugs Act, 1872, and taking such steps as might be found expedient for procuring an amendment of that Act, was held on Wednesday evening, Nov. 15, at the offices of the Association, Duke Street, Piccadilly. The chair was taken by Mr. A. F. Haselden.

The chairman, in opening the proceedings, said that the recent penalty was imposed for the use of a certain name. Its imposition was contrary to the third section of the Adulteration Act, which provides that any person who shall sell any article of food or drink, or any drug, knowing the same to have been mixed with any other substance, with intent fraudulently to increase its weight or bulk, and who shall not declare such admixture to any purchaser thereof before delivering the same, *and no other*, should be deemed to have sold an adulterated article under the Act. Notwithstanding this provision, it had been held in the courts that the seller was bound to know the composition of the article he sold. It seemed to be therefore a matter for consideration whether an effort should be made to amend the Act, or to secure its repeal altogether. The object of the Act was not to harass the tradesman, but to protect the public, and this protection, he considered, was fully provided for in the Pharmacy Act. He thought that the Government would listen to any proper representation of the subject, and Lord Eustace Cecil, who had taken charge of the Bill during its passage through the House of Commons, had stated at a meeting of the Association of Medical Officers of Health that if any amendment of the Act was found necessary after a trial had been given to it, he would use his best efforts to secure it.

Mr. McDermott, who was present, said, in answer to a question that the order for the citrate of magnesia was written in imitation of a prescription, but evidently not by a medical man.

After a very desultory conversation, it was moved by Mr. Breton, seconded by Mr. Bristed, and resolved:—

> "That it is the opinion of this meeting that the late proceedings which were taken under the Adulteration of Food and Drugs Act, 1872, against Mr. Philip McDermott, of 155, Abbey Street, Bermondsey, a chemist and druggist, for selling the citrate of magnesia of commerce were not justifiable, and that the judgment was contrary to equity; and also that, as far as it refers to the analysation of drugs and chemicals, the said Act in its present shape is mischievous and ineffective, and ought to be repealed."

It was moved by Mr. T. Donald Watson, seconded by Mr. Chubb, and resolved:—

> "That Parliament be petitioned to repeal that portion of the aforesaid Act which relates to drugs and chemicals, the clause in the Pharmacy Act being sufficient for the protection of the public."

It was proposed by Mr. Breton, seconded by Mr. Johnson, and resolved:—

> "That a committee of chemists and druggists be appointed to act with the Committees of the National Chamber of Trade to give effect to the foregoing resolutions, and to adopt such measures as shall to them seem desirable; and that the committee be composed of the following persons: Messrs. Carteighe, Haselden, Howden, Lloyd, and Wood, with power to add to their number."

Mr. Mann, of New Hampton, then called the attention of the meeting to the irregularity which existed in the rates at which the licenses for dealing in patent medicines were charged. He said persons residing within the London postal district were charged £2 per annum, those in towns and corporate boroughs, 10*s*., and those in rural districts were charged only 5*s*. It was sometimes very hard for a man in a small way of business to be called upon to pay £2, whilst another a short distance off, but outside the postal district, only paid 10*s*. or 5*s*., although perhaps doing a larger trade. He suggested that the meeting should pass a resolution asking the Council of the Pharmaceutical Society to take the matter up, and endeavour to secure a uniformity of rate, say 10*s*.

The chairman, however, expressed an opinion that it was then too late to discuss the question; and, after a vote of thanks to him for his services, the meeting broke up.

The Pharmaceutical Journal.

SATURDAY, NOVEMBER 22, 1873.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square,*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

"CITRATE OF MAGNESIA."

IT is now five years since the late Mr. DYMOND brought before a meeting of the British Pharmaceutical Conference an illustration of the way in which he conceived the first principles of sound morality were frequently set at defiance by pharmaceutists.* The particular case to which he referred has now been forced on the consideration of the trade by the recent magisterial decision under the Adulteration Act; and though his contention that the welfare of true pharmacy was jeopardized by such practices did not at the time meet with any great concurrence, it is evident, from the correspondence of the last few weeks, that there is now a very general recognition of the necessity of taking some step to prevent the annoyance and damage attendant upon a prosecution under the Adulteration Act.

Though we do not hesitate to express the opinion that, as regards the ostensible objects of the Adulteration Act, the recent prosecution was an utter absurdity, we think there is so little good to be gained by discussing whether or not the sale of "citrate of magnesia" comes within the scope of the Act, that this question may be at once dismissed. In like manner, though the infliction of a fine on Mr. MCDERMOTT may command our sympathy, it would do so only in the same degree that sympathy would be extended, under similar circumstances, to any other tradesman who became the victim of a harsh or strained interpretation of the law. The important question is what to do as regards articles that are commonly sold under names which do not represent them.

Opinions evidently vary much as to this question, and the influence of habit is in some cases evidently strong enough to have established so intimate an association between the term "citrate of magesia" and the preparation sold under that name, as to lead to the idea that the absence of magnesia should prevent a conviction under the Adulteration Act! Some of the modified designations proposed recommend themselves as precautionary measures; but regarding the matter from a pharmaceutical point of view, none of them appear quite to satisfy the requirements of the case. It is thoroughly well known that the preparation referred to is not properly magnesian at all. In some instances it is totally destitute of magnesia, and is at the same time none the worse.* When magnesia is present it is not as citrate; and then again the amount of magnesia is often so small that it can only be regarded as introduced to swear by.

Why then retain the word magnesia at all? The same question might well be asked as regards the term "citrate," for even with those manufacturers who use citric acid at all it is only a subordinate ingredient to the tartaric acid.

But in order effectually to meet the objection raised to applying definite chemical names to substances which bear no resemblance to them, would not the public be as well satisfied with some trivial name, such as "effervescing powder," which is commonly used in Germany for this preparation and for seidlitz powders, of which it is merely a more elegant form?

We believe that the adoption of such a course would be beneficial in many ways, besides fulfilling the obligations of the pharmacist to keep faith with scientific truth.

Before leaving this subject it may be well to recall to our readers the remarks made by Mr. HANBURY when it was discussed at Dundee. While strongly objecting to the use of definite chemical names for things of which it was intended to conceal the composition, he said that it appeared to him medical men were chiefly responsible for this sort of thing, since strange compounds, such as granular effervescent bromides or iodides were introduced by the makers to their notice, and by prescribing them they create the demand for substances of whose real nature they knew very little.

TRADE IN DRUGS, ETC., WITH BRITISH INDIA.

OFFICIAL statistics giving the trade of British India in drugs, medicines, etc., are not without features of interest to the readers of this Journal. Such statistics have just been compiled, and bring to light some facts of importance. The imports of drugs into British India are not large. In 1863 they amounted only to the sum of £113,436, while in 1872 they were £236.424, it being pointed out that this latter amount "includes medicines." It will be perceived that there is a slight increase in recent years. The figures referring to the exports are more interesting than those referring to the imports. Thus we find that in the year 1863 drugs and medicines were exported from British India to the value of £83,314, and in 1865 the amount was £101,043. Latterly, however, this branch of the export trade appears to have languished to a very great extent, the exports of the articles having considerably diminished. Thus in 1867 they only amounted to £31,182, although in 1872 they were £75,328. Opium is honoured with a separate classification of statistics, from which the position of the trade may

* PHARMACEUTICAL JOURNAL, 2nd Series, vol. ix., p. 167.

* The formula authorized by the British Pharmacopœia for this preparation comes under this category.

be clearly perceived. The exports of this article do not appear to fluctuate much, a large aggregate being annually maintained. In 1863 opium was exported from British India to the value of £12,494,128, while in 1872 the largest amount was exported than for many years, the value then being £13,365,228. Opium is one of the principal articles of export from the country, in fact being second only to cotton wool. The exports of saltpetre from British India have decreased of late years. In 1863 they amounted to £897,228, and in 1872 to £397,251, thus indicating that the trade has considerably fallen off. The exports of oils show little fluctuation. In 1863 they amounted to £372,107, and in 1872 to £414,918. So far we have given the exports in sterling value only, but it will be interesting to give shortly the actual quantity. Thus with regard to opium the exports were in 1863 82,216 chests, while in 1872 they were 93,364 chests. In 1863 oils were exported to the quantity of 3,928,191 gallons, and saltpetre to the amount of 684,250 cwts.; in 1872, the exports were—oils, 2,733,162 gals.; saltpetre, 432,210 cwts. From a statement showing the Customs' tariff of British India, we find that the rates of duty on drugs and medicines imported are 7½ per cent., the export being free.

ALLEGED PRESENCE OF IRON FILINGS IN TEA.

In several cases of prosecution under the Adulteration Act which have recently been reported, the analyst has been able to demonstrate that a magnet thrust into a specimen of tea would attract certain particles which were stated to be iron filings; and held to be indisputable proof of a fraudulent admixture. That this inference is necessarily correct has, however, been disputed in more than one quarter. Mr. Treffry, of Exeter, writing to the *Grocer*, asserts that the mineral matter found in tea is not iron filings but a native magnetic oxide of iron, and he states that "it is probably titaniferous iron-sand, which is very abundant in China." Mr. Alfred Bird, F.C.S., of Birmingham, says that he has separated particles of mica and quartz from the magnetic oxide of iron found in tea, his inference being "that as magnetic oxide of iron forms part of the soil of China, it would rise with the dust of the country, and coming in contact with the damp leaves would adhere to them when they are dried, and thus make the dried leaves stick to the magnet as if there were iron filings mixed up amongst them." Speculative, to say the least, as this may seem, it would appear to receive some support from an experiment made by Mr. Bird upon some French bean leaves grown in his own garden. One hundred grains were dried, and upon testing with a magnet were found to be attracted by it in a similar manner to that reported of some specimens of tea leaves. A closer examination of the matter adhering to the leaves showed that it was magnetic oxide of iron, and 0·02 of a grain was obtained from the 100 grains of bean leaves. An investigation of the black mould of the garden in which the plants were grown showed that it contained an abundance of magnetic oxide of iron.

If all that the opponents of the Adulteration Act say against it were true, it would be but little to be able to reply that it is not an unmitigated evil; but still it is a fact that the Act has given a great impulse to the investigation of food substances, the benefit of which must appear in an acquisition to our store of knowledge respecting this important subject. For even should Mr. Bird's speculations prove correct, it would not be the only instance that has recently come under our notice where the presence of a gross adulterant has been alleged upon insufficient grounds.

FLOWERING OF THE JALAP PLANT IN ENGLAND.

Mr. W. Terry, of Peterborough House, Fulham, has written to the *Gardeners' Chronicle* to say that he has had the jalap plant in flower in his garden this season for the first time. There were about thirty flowers and buds on his plant.

We have before alluded to the use of bullocks' blood in France as a remedy for anæmia, pulmonary phthisis, and other diseases. (Vol. iii., p. 67.) We learn now from the *Medical Press and Circular* that Dr. Pascal gives it in the form of powder, the blood being reduced to that condition by drying. It is said that the repugnance which patients might otherwise have to its use is overcome, and the administration of the various constituents of blood—fibrin, albumen, salts of iron, and manganese is thus secured.

The *Répertoire de Pharmacie* states that a natural deposit of sulphate of soda has been discovered recently in the mountains of the Caucasus. The experimental boring showed first marl off the depth of one foot, then two feet and a half of damp clay, next nine inches of bituminous clay impregnated with salts, and finally the Glauber salt, forming a layer five feet thick. It is estimated that the deposit is equal to at least 15,500,000 cubic feet. In certain places the compound is nearly pure, containing only about 9 per cent. of foreign matter.

The discovery has been announced of a deposit of bismuth in the department of Corrèze, France. The bismuth is said to be found in its native state as well as well as in combination as oxide and sulphide the most abundant mineral being the oxide, which contains 70 per cent. of bismuth. The method of extraction consists in exhausting the mineral by means of hydrochloric acid and precipitating the metal from the solution by bars of iron. The bismuth, already fairly pure, is then treated in the ordinary way, to purify it from a little lead and arsenic. The deposit contains also molybdate of lead, tungstate of lime, and mispikel. This is said to be the first bismuth mine that has been worked in France.

Provincial Transactions.

CARLISLE CHEMISTS' ASSOCIATION.

This Association held their first Annual Meeting in the rooms of the Association, Barwise's Court, on Friday evening, Nov. 7th, Councillor Thompson, President, in the chair.

The Secretary read the following Report and Financial Statement :—

"The first year's labour of the Carlisle Chemists' Association having drawn to a close, your Committee present their report, showing what has been done, and how we stand financially.

"The Association was formally opened by an address, delivered by Mr. Hallaway, on the 15th November, 1872, and since then there have been four monthly meetings, at which papers were read, viz. :—'On Water and Water Analysis,' by Mr. Jos. Pattinson; 'On Glycerine as a Means of Preserving Infusions,' by Mr. Robson; 'On the Human Heart,' by Mr. Sawyer; and 'An Evening with the Microscope,' by Mr. Walker; Mr. E. Prewst gave a lecture upon Chemistry, and also treated upon Arsenic and its tests.

"Your Committee are sorry to say that the attendance of members has been very poor, and, as it is really of importance in associations of this kind that there should be an interest taken in them by their members, they earnestly and respectfully press upon you the necessity of attendance, believing that were the members of this Association to attend more numerously and more frequently, it would not only be conducive to the welfare of our Association and harmony amongst ourselves, but would also tend to create and foster an interest for and in it by our apprentices and assistants.

"During the past year we have lost by death one member, our Secretary (the late Mr. Moss), to whom we were always much indebted—he always gave his services cheerfully, being very anxious that the Association should succeed—and whose loss we regret very much, and four associates, from removal and other causes, thus leaving our numbers at the present time to be nineteen members and nine associates.

"The attendance upon the classes,—chemistry and materia medica,—under the care of Mr. Jos. Pattinson and Mr. Little, to whom we all owe much for the time and attention they have given, has not been large, but we have great pleasure in saying that it has been very regular, and the young men attending appear to appreciate very much the advantages the Association affords, and have taken great interest in preserving, labelling, and arranging the specimens of materia medica, and forming the beginning of a museum.

"Several very handsome donations have been presented to the Society during the year, viz. :—Specimens of materia medica, by Messrs. Southall, Son, and Dymond; Barron, Harvey, and Co.; Howard and Sons; and Clarke, Bleasdale, Bell, and Tollington—Bentley and Redwood's 'Materia Medica,' by Mr. W. Martindale of London—Shelving, etc., by Dr. Barnes—Books and bottles by Messrs. Thompson, Sawyer, Hallaway, Robson—and 'The Dispensary.'

"This being as we might say the only real effort that has been made in Carlisle to establish on a sound basis a chemists' association, your Committee think that it is a matter for congratulation that it has succeeded so well, and trust that as years roll on it will improve and become one of the permanent institutions of our city.

"The Committee now hand in the financial statement, and, as the term for which they were elected has expired, their resignation also."

Nov. 7, 1873. To Cash on Hand and Balance in Bank, £17 4s.

It was moved and seconded that the report be approved of and sent to the PHARMACEUTICAL JOURNAL for publication.

The old Committee, Messrs. Thompson, Robson, Walker, and Hallaway, were re-elected, and in addition Messrs. Taylor and Pattinson.

Mr. Jno. Atkinson was admitted as an associate.

A vote of thanks was moved and seconded to Dr. Barnes for his present to the Association, as also to Messrs. Little and Pattinson for their conducting the classes of materia medica and chemistry.

It was resolved that a microscope suitable for students be bought for the use of the classes.

Upon the table were fourteen specimens of rare and new chemicals, kindly lent by Messrs. Hopkin and Williams, which were much admired.

BRIGHTON ASSOCIATION OF PHARMACY.

The opening meeting of the present session in connection with this Association took place on Friday evening, at 150, North Street. Several only of the fifty members were present. Mr. W. D. Savage, the President of the Association, read the following paper :—

"Gentlemen,—

"Last year it was my privilege to address you on the reorganization of our Association, and following the time-honoured custom (as you have been pleased again to place me in the same position), as your President, I will endeavour to take a review of the work done during the past year, and to make such suggestions for the future as circumstances may seem to indicate. As soon as suitable accommodation was obtained, and after some of our friends had favoured us with their papers, we engaged Mr. Pankhurst to give a course of lectures on chemistry. These were, on the whole, well attended, and gave satisfaction, but as the season advanced our numbers attending the meetings diminished, and this seems to be the case in most places, although there are few towns like Brighton that have their season so late in the year; when other towns are comparatively quiet we are in the midst of bustle, and after the physical and mental work of the day, prefer a little repose and quiet. At the same time, our meetings are well calculated, from the friendly interchange of thought in discussion, to dissipate any weariness, and effect a change that cannot be otherwise than beneficial. When the appeal was made to the chemists of the town to sustain the efforts about to be made on behalf of those connected with the Association, it was most satisfactory to find how generally they responded to it, and this favourable beginning augured well for the future. If all the hopes of the committee have not been realized, sufficient success has been accomplished to give confidence for the future. I would here venture to suggest that the young men attending our meetings should take a more active part in the proceedings. Previous intimation is given of what is to be read or discussed, and they should come and be prepared to give their *confrères* the benefit of their views. A degree of diffidence or reticence frequently pre-

vails, so that unless the seniors take more than their share of prominence a silent meeting would be the result. This should not be, and if the presence of the principals is the cause, the sooner they leave matters in the hands of the assistants the better—rather let us all endeavour as far as we can to break through this state of isolation. Allow me to suggest that as the subject for discussion is previously known, that each person present should come prepared, and, if necessary, to take part, so that good results would follow, as each views the subject from his own standpoint. The principals are not quite free from blame. Some of the gentlemen who attend our evening meetings are eminently qualified to confer a benefit on the members of the Association, by giving them papers on subjects with which they are familiar. I am afraid to say more on this topic, lest you should, in the language of Sidney Smith, dub me a lemon juice squeezer, but I could not, in reviewing the past, avoid adverting to these circumstances. However, I look hopefully to the future, as several members have kindly intimated their intention of contributing papers during the ensuing session. The early closing movement in connection with our trade, so far as it applies locally, originated and was promoted by the members of this Association, and although it has not been strictly adhered to by all, yet the result has been beneficial to many, and it is a subject of regret that its adoption was not unanimous, and that *all* did not avail themselves of the opportunity of diminishing the hours of labour, which are unnecessarily long. A further diminution is proposed to take place on the 1st of November, for the winter months. I do hope that all those who have the interest of those in their employ at heart will feel it incumbent on them to act in concert and make the movement as general as possible. In the spring, Mr. W. H. Smith kindly undertook to give a course of instructive lectures on botany, but the lateness of the period was unfavourable for securing a good attendance, and after the seventh lecture they were postponed. I hope however they will soon be resumed. In accordance with the wishes of the donor, and by the kindness of the Pharmaceutical Conference, the Association received the Bell and Hills valuable gift of £10 10*s.* worth of books, selected by the committee of the Association. These added to what they previously had, and additions subsequently made, form the nucleus of a capital library of reference, available for every member of the Association, and no doubt the younger members will take advantage of the opportunity that they may keep pace with the growing necessities of the age and the requirements of the Pharmaceutical Society. Every year must develop more and more a desire among our apprentices to become worthy of the efforts made on their behalf, and we must endeavour to meet their wishes by adding from time to time such books as circumstances may indicate and necessity require. Recent discussions will have shown you that in some quarters a strong desire exists for centralization, that the present method adopted for conducting the local Preliminary examinations should cease, and that for the future the certificate of one or other of our recognized educational institutions should be the door of entry. This may be a very proper suggestion for the distant future, but for the present the project cannot be entertained. The letters of Messrs. Reynolds and Haselden convey my views—they point out many reasons why the present plan should be continued. The proposed alteration seems to me unnecessary and arbitrary, inasmuch as local university centres, as compared with local secretaries engaged in examinations, are very few, and consequently the distance that young men would have to travel would be greatly increased, and instead of occupying as at present three hours, it would, if conducted according to the existing university arrangement, take five or six days, thus adding a serious item to the expense. Has anything occurred to justify so great an innovation? We are told that some isolated cases of irregular practices of local secretaries have occurred; but even if it were so in one or two instances, surely the whole body of our most respectable representatives are not to be so easily set aside, and their valuable services for the past to be ignored because from ignorance, or some other cause, efficient supervision has been wanting. It occurs to me that a much easier method of obviating the difficulty would be to appoint a local committee, the same as the local universities do in all towns sufficiently large, and in smaller ones—as proposed by our ex-President—another gentleman to be associated with the local secretary, so that in case of illness, absence, or other causes, there would be no difficulty in the way of the duty being efficiently performed. The duty of preparing the Preliminary examination papers now devolves upon one or more of the Board of Examiners—a very onerous duty, which occurs to me might be as well or better done by an educational body like the College of Preceptors, or by an individual member selected by them, not only to prepare the questions but report the result of the answers (subject to the approval of the Board of Examiners). This course would not only lighten the duties of the Board, but be on the whole more satisfactory. A subject of considerable interest to chemists is now occupying the public mind, and the adverse decisions given by different magistrates is perplexing and unsatisfactory. I allude to the Adulteration of Foods Act. It seems very important that some distinctive definition should be given as to what is an *adulterant;* for if we take the broad line of demarcation, *injurious to health*, as our guide, it does not apply. For instance, farinaceous preparations mixed with mustard absorb the oil in grinding, and cannot possibly be injurious to health. Farina and sugar, mixed with chocolate, makes cocoa very much more palatable, and by no means injurious. The excessive use of these things, like the 20 or 30 per cent. of water in milk, is not justifiable, and ought not to be allowed. But then comes the difficult question—what are the limits and how are the public to know them? As far as chocolate is concerned the same plan of indication as is adopted with coffee and chicory might do, but to place outside a milk can "This milk contains 20 per cent. of water" would not be satisfactory to any party, and would sanction a practice alike unnecessary and deceptive. For some time the appointment of analysts was a subject of doubt and uncertainty, arising from the difficulty of knowing what was meant by *medical, chemical*, and *microscopical* qualifications. Viewed by some of the local boards of health, the "medical officer" was appointed as the only person possessing the necessary qualification. However, the Pharmaceutical Council thought otherwise, and it was my privilege to move, and Mr. Hampson's to second, a resolution that a deputation wait on Mr. Stansfeld and ascertain from him what were the requirements of the appointment. The gentlemen composing that deputation explained to Mr. Lumley (in the absence of Mr. Stansfeld) the object they had in view, and whilst there was at first some misapprehension and misconception, the result has proved satisfactory, and many of our worthy *confrères* have been appointed analysts to large and important districts. Hitherto the duties have been exercised on the retailers of food. But we know not how soon our own stores may be overhauled, and similar scenes enacted to those of the Apothecaries' Company many years ago in London. We might find varied proportions of quinine in our citrates. Sulphur. precipitatum might not be the pure article of the B.P., neither might conf. sennæ. We all know the large quantity of salt in cayenne pepper, and without it the public would not recognize the article. Other things might be enumerated of a like character, and after all, unless they are articles of home manufacture, you must greatly rely on the antecedents of the firms with whom you deal. One thing seems pretty certain, that we are getting superlatively wise in our generation, and whilst no respectable man would object to healthy criticism on what he sells, there is the same fear of jealous rivalry and the unjust exercise of arbitrary power that existed when the Apothecaries' Company of London exercised supervision over London druggists. I may recall to

your recollection an instance which I mentioned in my paper on the 'History of Chemists and Druggists,' read at Exeter; it was to the effect that the Company having obtained an order to supply the E. I. Co. with drugs, on the condition of being *good and cheap*, and to enable the E. I. Co. to ascertain these facts, two eminent wholesale apothecaries were consulted, and they condemned both the quality and price. The Apothecaries' Company, in retaliation, went to a Mr. Lawrence's shop during his absence (he being one of the examiners), and took samples of his goods to the Hall for examination. Mr. L., foreseeing the result, got some of his friends to go to the shops of the managers of the Company, and purchase similar articles to those which they had taken from him; so that, when summoned, he pleaded that the articles taken were not finished making, but, said he, I have brought some by which I will stand. These they also condemned; when, being prepared by witnesses, he proved them to be their own. This evidence was too strong for them, and they gladly compromised the matter. It is not probable that such circumstances will occur again; at the same time it behoves us to carefully avoid any necessity for supervision. Self-interest, after all, if rightly appreciated, is the best monitor; sooner or later the public become acquainted with those shops that serve them best, and honest dealing gets its reward. Since writing the preceding passage, a case of some importance has occurred bearing on the subject. Probably, most of you have seen a case brought before a London magistrate of a druggist selling citrate of magnesia, which on the chemical evidence of Dr. Muter contained no traces of magnesia. His evidence, contained in a letter to the London *Times*, was: 'That it does not contain a trace of magnesia, but is a mixture of citric acid, tartaric acid, bicarbonate of soda, and a little sugar.' Although the person who sold the so-called citrate was in no way connected with the Pharmaceutical Society, the subject is one of great importance to all of us. The magistrate who inflicted the fine of £10 might as reasonably fine all of us for selling *Epsom* salts that never saw Epsom, soda-water that contains no soda. At the Pharmaceutical Conference, held at Dundee, 1867, Mr. Dymond, of Birmingham, called attention to the fact that the so-called citrate of magnesia was a misnomer, at the same time pointing out that a saccharated effervescing citrate of magnesia might be made by mechanically mixing equivalent quantities of carbonate of magnesia and citric acid, together with 15 per cent. of sugar. To obviate any misconception Mr. Sutton, of Norwich, adopts the following label:—'This preparation, so long known as citrate of magnesia, is in reality a citrocarbonate of soda. Mr. Sutton desires to give this explanation to prevent misconception as to the true chemical nature of the compound.' Although it does not really represent the compound usually sold, Mr. S. added that instead of diminishing it had increased its sale. One gentleman suggested the same label as Bishop's, another that it should be called "Granular Effervescent Aperient." It is obvious that we should adopt some course of protection against unprincipled informers or spiteful enemies, and use so far as we can appropriate names. Another subject of interest to all of us is the recent alterations suggested by our professors—*i.e.*, a course of ten months' lectures should be so condensed as to embrace all that was necessary in five months, or what used to be designated half a session, and that instead of, as previously, the professors being paid so much a year by the Council, they should receive a certain sum, and take all the proceeds of lectures and laboratory fees, which have been raised to meet the altered circumstances. The Council, by a majority, decided to adopt the new regulations, although it was not without opposition, for one distinguished member of the Council said the students got half the material, for which they were required to pay double price. We can only hope that the results will prove the wisdom of the alteration. At present appearances are not encouraging. I am afraid that I have exhausted your patience, but I hope that some of the circumstances named may be suggestive, and lead to discussion mutually advantageous."

A discussion followed the reading of the paper, in which Messrs. Brew, Cornish, Mathews and W. H. Smith took part, the President replying to numerous questions addressed to him. A hearty vote of thanks was accorded to Mr. Savage for his paper, and it was very much regretted that the young members of the Association did not attend the meetings.

HULL CHEMISTS' ASSOCIATION.

The annual meeting of this Society was held on Thursday evening, November 13, at the Cross Keys Hotel, the president (Mr. Anthony Smith) in the chair. The report was read by the Secretary, Mr. C. B. Bell, and the members present seemed especially gratified at the great success which has attended the educational endeavours of the committee. From the reports of Messrs. Pearson and Niven, the lecturers to the Society, both the chemistry and botany classes appear to have given results of a most satisfactory character. Prizes were awarded for chemistry to Mr. Roberts (senior), Mr. Morley (junior); for materia medica to Mr. Roberts (senior), Mr. H. T. G. Wood (junior); for botany to Mr. W. H. Hammond (senior), Mr. H. T. G. Wood (junior). The treasurer announced that the balance in his hands was most satisfactory.

A ballot took place for the election of officers for the ensuing year, when Mr. Anthony Smith was re-elected president; Mr. F. Earle, vice-president; Mr. C. B. Bell, secretary and treasurer. Messrs. Myers and Pickering were also re-elected on the committee, with Messrs. Oldham and Grindall. The officers of the Society received the hearty thanks of the members for their services during the past year.

In reference to the arrangements for pharmaceutical education during the session 1873-4, the committee of the Hull Chemists' Association announce that the fifth winter course of twenty-four lectures, comprising elementary chemistry, materia medica, pharmacy, etc., will be delivered by Mr. H. J. Parson, in the Society's Room, at the Church Institute, Albion Street, commencing on Thursday evening, October 23rd, at 8.15 precisely, and continued weekly at the same place and hour. Fee for the course, £1 1*s.*, due in advance. Intending students are requested to send in their names as early as convenient to the honorary secretary, who will be happy to furnish further information if required.

The course of instruction will have special reference to the requirements of the Minor examination of the Pharmaceutical Society, which it is now incumbent on all chemists and druggists to pass before commencing a business. Each lecture will be fully illustrated by experiments. The committee earnestly request members of the trade living in Hull and its neighbourhood to use every effort to induce those in their employ to attend these lectures. At the close of the session it is intended to offer four prizes for competition, viz., senior and junior materia medica and pharmacy, and senior and junior chemistry.

MANCHESTER CHEMISTS' ASSISTANTS' ASSOCIATION.

The first ordinary meeting of the session was held on Monday evening, Oct. 27th. The President, Mr. William Lane, read an able and interesting paper "On Opium." After an animated discussion, a hearty vote of thanks was awarded to Mr. Lane for his exhaustive treatment of the subject. Fifteen gentlemen were elected new members of the association. The meeting was very well attended.

The second ordinary meeting was held on Wednesday evening, November 12th. The Secretary, Mr. A. J. Pidd, read a paper on "Phosphorus and its Compounds." He explained at great length by equations on the black board the phosphites, hypophosphites, metaphosphates, and pyrophosphates. He also described the method for detecting phosphorus in poisoning cases. A hearty vote of thanks was awarded to Mr. Pidd for his excellent paper. The attendance was very good.

Proceedings of Scientific Societies.

CLINICAL SOCIETY.

Cases of Poisoning by Homœopathic "Concentrated Solution of Camphor."

(*Abstract of a Paper read Nov.* 14, 1873.)

BY GEORGE JOHNSON, M.D., F.R.S.,

Professor of Medicine in King's College, and Physician to King's College Hospital.

Miss T., aged 20, having a cold, took in water twenty-five drops of "Concentrated Solution of Camphor," She went to bed, and in a short time was found foaming at the mouth, black in the face, and violently convulsed. Mr. Drake, of Brixton, was sent for in great haste. For several hours she was unconscious. She vomited blood-tinged fluid, smelling strongly of camphor, and had severe pain in the stomach. For several days she was partially paralysed, and six months afterwards she was still suffering from symptoms of nervous disorder. The preparation which caused these serious results is a saturated solution of camphor in spirit, in the proportion of an ounce of camphor to an ounce and a quarter of spirit. It is therefore stronger than the spiritus camphoræ of the Pharmacopœia in the proportion of 7·2 to 1.

Case 2.—The Rev. W. R. was advised to take for a cold three drops of the same preparation every five minutes for an hour. After taking the eighth dose, he was seized with intense headache, which confined him to bed for forty-eight hours, and he was afterwards so weak and ill that he was unable to enter his pulpit for two months.

Case 3.—A third case was communicated to Dr. Johnson, by Mr. Delamark Freeman. A young lady, aged 19, took for diarrhœa a teaspoonful of the same concentrated solution. The result was, that she was rendered unconscious for several hours, and then she had a variety of nervous symptoms, which did not pass away for several days.

Dr. Johnson remarked upon the notorious fact that many of the disciples of Hahnemann have passed from the irrational and ludicrous extreme of infinitesimal dilutions to the dangerous extreme of the greatest possible concentration of active and poisonous drugs. There is an obvious risk that this concentrated solution of camphor may be mistaken for the much weaker solution of the British Pharmacopœia, or the yet weaker essence of camphor which is often used to make camphor julep, a mistake which, in spite of the printed directions on the bottle, was probably made by both the young ladies who suffered so seriously for their error.

SOCIETY OF ARTS.

On the Energies of the Imponderables, with especial reference to the Measurement and Utilization of them.*

BY THE REV. ARTHUR RIGG, M.A.

Lecture V.

On the Energy of Electricity, with especial reference to the Measurement and Utilization of it.

(*Concluded from* p. 217.)

The promise to let you have proof that there are currents of electricity passing through the atmosphere of this room may now be redeemed. Here is a circular wooden ring, with wire round it as before. You may notice that it can be turned as a looking-glass in its frame. The ends of the wire coiled round it are now connected with the wires of the galvanometer, the mirror of which reflects that speck of light on the screen. The looking-glass mounted ring is placed in reference to the (so called) current of electricity always passing through the atmosphere, that were there a glass in the frame the current would beat upon that glass. If the frame be turned one-fourth round, then the current will pass parallel to the face of the frame. Or thus :—If the frame of the wire-enclosed ring be placed parallel to the direction of this magnetized needle, then the current of electricity through the atmosphere of this room is passing parallel to the ring. To move it, therefore, from this position to one at right angles to it, it is clear that the circumferential wire must, as it were, cut the stream of electricity, if there be one. Now, so cutting it, there will be a disturbance in the electrical condition of the wire, which may be manifested by a motion of that speck of light. Observe, now, that every motion of the frame causes a motion in the needle of that galvanometer, which is placed on a stand far removed from the table on which the motion of the frame takes place.

The two experiments now made may satisfy you :—1st. That there is what, for want of another name, we may call a current of electricity passing through the air ; 2nd. That disturbance of the uniform quiet flow of this current may be caused ; 3rd. That this needle is sensitive to such a disturbance ; and 4th. You will perhaps accept my word for that which time alone prevents being illustrated, viz., that the amount of this disturbance may be measured by the needle ; that is to say, the greater the disturbance the further will the needle be moved from its original position.

It will be obvious to all that the amount of motion in the needle for any given disturbance will depend upon its sensitiveness. Hence, two needles may, or may not move equally from the same cause. A mode of measurement, therefore, which depends upon an artisan's capability to make either unit jars or needles equally sensitive cannot be one to be much relied upon. There is, however, a relationship between the motion of the needle and a totally different mode of absolute measurement of the quantity of electricity that may pass in a unit of time, which solves the difficulty now expressed.

The usual apparatus for the decomposition of water by an electrical current is standing here. It is in consequence of completing the wire circuit from this combination of four cells that decomposition takes place. The bubbles are rising regularly and rapidly. Patient and watchful experimenters have established this—viz., the amount of water thus separated into its constituent elements of oxygen and hydrogen is always in exact proportion to the quantity of electricity that passes. If, then, it were convenient to be thus always decomposing water, a measure might be had. Thanks, however, to the mathematician, we have a much more simple mode of gaining this knowledge.

Suppose one end of the wire from these four cells is connected with the decomposing apparatus—this apparatus connected to the ring already explained—then from the ring to the other end wire of the cells. With such an arrangement, observations can be made both on the decomposing apparatus and the deflections of the needle, when each is under the influence of the same current. If the quantity of electricity in circuit varies, the amount of gas produced and the position of the needle vary also. These have been so frequently observed, that by looking at the needle the mathematician could always tell the amount of gas obtained ; in fact, he could lay down a very simple rule for guidance. The application of this rule enables a person at all times to state what quantity of electricity is passing, even though he look to the needle only.

An arithmetical illustration may make this clear. Suppose that in one minute these gases, which may be seen coursing up the tube, filled a space in the tube marked ten cubic inches—observe where the needle pointed. Let us assume that it is pointing to 45°. Suppose on another and future occasion the needle is observed to point to 60°, now, either from memory or from tables, we find that the tangent of 60° is entered as 1·73.

* Cantor Lecture, delivered March 3, 1873; reprinted from the *Journal of the Society of Arts*.

Then, if 10 be multiplied by 1·73, the result would be that 17·3 cubic inches of gases might be evolved. As there are in chemistry laws connecting the composition of bodies, such a result as this would enable a manufacturer to know how much silver, for example, this current of electricity would cause to be deposited in any fixed space of time. Thus may be measured the *quantity* of electricity passing in a unit of time.

But the deposition of gold and silver or other metals is not the only utilization of electricity, and as other results of a different kind are obtained from this "imponderable," it is time to turn to illustrations of another form.

Telegraphy seems at present to have taken the most important position in the manifestation of the energy of electricity. Telegraphists, therefore, naturally consider how they can measure the energy with which they deal. If there are any connected with telegraphy present, perhaps they will remember that this is not a lecture on the present advanced state of telegraphy nor on modern instruments, it is simply an attempt to make as clear to a general audience as is in the lecturer's power the principles which govern the uses and measurements of electricity in relation to telegraphy. To enter into details in reference to those laws which the electrician and mathematician have been enabled to propound, would be not only very injudicious, but very unsatisfactory. A sketch of the broad principles on which they are founded, and an illustration of the application of them, may prove more useful than an attempt to show how details of measurement have been accomplished.

The first question that presents itself is what may be called the measure of resistance. It was soon observed that electricity passed along certain metal wires more freely than other metal wires of the same size and length. The observation admitted of a very important utilization. For example, suppose the wire now stretched from one end to the other of this room was one mile in length, and that the little apparatus with which electricity is being produced at this end could produce a certain result at the other end. Now, let us take another metallic wire of the same length, and suppose the result produced in this case is much less than in the first. It will be admitted, without any detailed experiment, that by shortening again and again, the second wire may be reduced to a length which permits the phenomenon at the end of the first wire to be repeated at the end of the second. Now measure the second; it is only one quarter of a mile. Try a third and a fourth wire; perhaps they are respectively reduced to one-eighth and one-tenth of a mile. Evidently there is some property in these wires which hinders, retains, or resists the progress of electricity. The property is called "resistance," and is available for very useful purposes. The British Association for the Advancement of Science were so conscious of this that in 1861 and 1862, there were grave considerations as to what steps should be taken in order to assign a value to this resistance. You have seen how the quantity of electricity may be measured, but then that measured quantity had not to convey itself to a distance. It quietly, as it were stayed at home and worked. When telegraphy entered then electricity had to travel to or act at a distance. This state of affairs rendered it very desirable to determine "resistance" from what is called first principles, that is to say, to deal only with the three units of measurement—mass, space, and time. It was needful, by some means or other, to get this resistance into the form of mass, space, and time. It was considered that if we could regard it as velocity we thereby involved both space and time, because velocity is measured by space and time. If one runs a mile in an hour, then it is only needful to divide one mile by sixty minutes, and the space run in one minute is known. That would be the measure, assuming the minute to be the unit of time. The British Association appointed a committee. The chief gentlemen concerned in the committee, and who had the designing of a mode of grappling with one of the most critical tasks of science, were Mr. Clerk Maxwell, now Professor of Physical Science at Cambridge, Mr. Balfour Stewart, of Kew Observatory, now at Manchester, and Mr. Fleeming Jenkin, now Professor of Engineering in the University of Edinburgh. Their experiments were carried on in King's College, and the scheme now to be very briefly described is found in the report of the British Association for 1863.

It may here be remarked that perhaps there have been no lectures ever given in this room of a more important and scientific character than a course of Cantor lectures on electricity by Mr. Fleeming Jenkin. This course commenced in January, 1866, and will be found reported in the Journals published between 2nd February and 2nd March, 1866 (inclusive). It is well to make this further statement, that those lectures have frequently been appealed to by writers on electricity who regarded the phenomena thereof in the light of an accurate science.* The question, then, is, how are we to measure in velocity this resistance? How are we to convert that which is resistance in a wire into an electrical measure of velocity? [The lecturer here, by apparatus and diagrams, illustrated the principle upon which this mode of measurement was based, and in so doing referred to the currents passing through the room, as already described.] At Kew there is a record of these currents kept continuously night and day, and it is found that they are changing every minute. The main object, then, of the committee of the British Association, was to devise a plan by which they could ascertain the resistance that a given wire offers measured by comparison with the velocity of these currents. You may remember that Kater could not measure the law of gravity, owing to the fact that it was rapid in its actions, and he felt that he must have some means of causing that law to repeat itself. Kater adopted the pendulum, and recorded the number of times it oscillated in twenty-four hours, and thereby got at the law. If, instead of having a long wire and three others running along the bar, as in the apparatus before you, we had a ring of this kind, and caused that to revolve rapidly, say at the rate of 100 or 200 or even a thousand revolutions a minute, we still get the laws of the magnetic force in the same way as described, similar to when the bar passed along the rods before you. This causes the magnetic force to act upon the needle, and in reality, in the experiments which determined what is called "the British Association unit of resistance," these currents acted upon a very small needle carefully suspended, so that they were enabled to estimate the resistance of this wire in an absolute measure of space and time. That led to the adoption of what is called the "ohm," or "British Association's unit of electrical resistance." This term "ohm" is a name given in compliment to one who suggested an important relationship among the elements of current, force, and resistance. Indeed, that table of electrical measurements which may some day be placed in books of arithmetic, with corresponding tables of weights, measures, and money, will be found to contain the names of men who have investigated special departments of electrical science, such, for example, as Ohms, Farads, Volts, Webers, etc.

In this little glass cylinder there is a coiled length of German silver wire, German silver being used because it possesses great resistance to electrical currents, and that resistance does not change much with change of temperature. This coil constitutes what is called half a British

* Since the commencement of the publication of this course of Cantor lectures, a volume has been issued, entitled 'Electricity and Magnetism,' by Fleeming Jenkin, published by Longmans and Co., price 3*s.* 6*d.* In this volume the author has treated the subject in a novel and a practical manner, very different indeed from ordinary text-books on electricity. It will be found to contain matter of great value and interest to the thoughtful student of electricity.

Association unit, which becomes the measure of electrical work, just as the standard pound becomes the measure for weight, or the foot is the standard measure for length. Being possessed of this measure, we have all that is needful for the measurement of resistance, and therefore for measuring electrical work connected with telegraphy.*

To show the way in which a knowledge of this measurement can be utilized, rather than to enter upon those investigations by which it was obtained, seemed likely to win so much more attention and interest, that these arrangements before you are for this purpose. The intention is to show how electricians determine the distance at which a deep sea cable is broken, so that they can tell how far the fracture is from the shore. Let it be understood that it is the illustration of a principle, and not the nature and modes of dealing with different kinds of "faults" that are to be our concern.

There is a wire, which may represent a cable, round the room. In this box there is placed a number of "ohms," arranged in three sets of nine each, so that by moving these pegs a current of electricity can be caused to pass through either one or more of them. Assuming each "ohm" in the first set to represent one resistance, each in the second set ten, and each in the third set one hundred, the consequence is that if a current of electricity passes through all it would meet with a resistance of 999. If it passed through one of the first set it would only be one resistance; so that with the moving of these brass pegs there is the power of bringing in any number of "ohms" required. This flat board, about 3 ft. 6 in. long, with a German silver wire and broad bands of copper divided at intervals, but capable of being put into electrical connection by the insertion of pieces of metal, constitutes what may be called the beam of electrical scales. Resistance, however, is to be measured instead of weight. Along a wire at the back electricity can pass, and when connected with the galvanometer the speck of that instrument serves the same purpose as the pointer of a pair of scales. If the galvanometer speck points to nothing, we assume that there is equilibrium between the resistances at each end of the scale beam. If I put 999 "ohms" in what we may call one scale, and other resistances into the other scale, or that which we may consider as such, then if the current of electricity arranged as provided can pass one of these groups of resistances more freely than the other, the speck of light will be moved. This is the same as though one end of a scale beam were "kicked up." Therefore, resistances which in this case act the part of weights on ordinary scales must be taken out or added as may be required.

This wire running partially round the room represents a cable. The two ends of this cable are in my hand. Let us assume that we want to measure the resistance the cable opposes to the energy of electricity, and to ascertain the value of its opposing power. Here is what is usually called a battery, consisting simply of a little salt and water, in a very small tumbler glass. "Battery" is a very misleading name in these days. This, with all its belongings, is really not worth sixpence, and it certainly seems a piece of pedantic magniloquence to call it a "battery."

The wires from this battery are so arranged that the current may divide itself between the cable that is round the room and this box of "ohms."

It may perhaps make the illustration more intelligible to those who have not familiarized themselves with terms of electrical science if for a while this current be regarded as consisting of passengers. Let it be represented by 100 passengers setting out from this battery, and having the choice of two routes, viz., one by the cable, and one by this box of ohms.

If the two routes are equally free, *i.e.*, offer equal resistances, then fifty of these passengers will pass by one way and fifty by the other. Suppose that the resistance of one route (say the cable) is greater than that by the other route. Then that other route, or the way through the box of ohms, will be available for some of those passengers who cannot readily pass by the cable. Here is a wire connecting these two routes; indeed the large letter A may convey a clear idea of the plan. Consider what is likely to happen if fifty of these electrical passengers set off from the top of the A down the thick stroke, and fifty down the thin stroke. We may say that those passing down the thin line cannot pass so freely as those down the thick one. Hence finding the course down the thick line clear, some of these delayed passengers by the thin line may avail themselves of this cross-wire bridge, viz., the stroke in the A, and go to the place appointed for them by passing down the thick stroke. In this homely illustration the thin stroke is the cable—the thick stroke is the box of ohms. Clearly by moving these brass pegs, the resistance in the box of ohms is increased; that is, the thick stroke of the A is made more nearly the same as the thin stroke. Now introduce into this cross-way—this bye-path, as it were—the galvanometer. Then if any electrical passenger avail himself of this bye road, the bright speck of light will tell the tale, and by noticing whether the speck moves to the right or left, the direction in which the passenger travelled is known, and therefore the electrical pathway which offers the greatest resistance is also known. By moving the pegs in the box of ohms, an equality of resistance may be established, and then passengers will not pass along the bye-way through the galvanometer; therefore the speck of light will not move.

Nor is this indication of an electrical traveller the only use which may be made of the galvanometer speck. You are aware that the extent of deviation of this needle is the measure of the quantity of electricity in transit; therefore the extent of deviation tells the number of passengers; in fact, the galvanometer becomes an electrical tell-tale turnstile for counting the number passing through, and so indicating or measuring the difference in resistance between the two courses.

Let us leave this figurative mode of expression. In the experiment before you the pegs in the box of ohms read 505; the speck of light is steady; therefore we know that the entire length of cable, of which the two ends are here, also offers a resistance of 505. Before this cable was laid a comparison with those ohms had been instituted, and it was found (say) that one mile of the cable offered a resistance to the passage of electricity equal to one ohm, therefore there are 505 miles of cable, because there are 505 ohms.

Now let us break the cable by cutting the wire. There! one end has fallen to the bottom of this large pan of salt and water. This pan must, for the present, be looked upon as an Atlantic Ocean; one end of the cable is at the bottom of it, and we wish to know how far from the end in my hand the separation has taken place. To compensate for the portion of the cable hitherto used, but now detached, the earth is available, this sheet of copper, in and on the shore of our Atlantic Ocean, is buried. Soldered to the copper is a wire, of which the end is in my hand.

There are therefore in my hands the ends of two wires; one, that of the broken cable—the other, that connected with the buried sheet of copper. Let us deal with them as we did with the complete cable. [After various trials the pegs in the box of ohms were so arranged that the speck of the galvanometer was steady.] The speck is now steady, and the pegs read 350. This means that there are 350 miles of cable, or its equivalent. Now, the cable and the earth are the only elements on the one side; and since the earth is as a large reservoir of electricity it offers no appreciable resistance; hence the only resistance is that of the broken cable. The length of this is pointed

* Those who are disposed to give the thought and application requisite for a clear comprehension of these principles of electrical measurement may refer to chapters ix. and x., extending from page 147 to page 165 in Jenkin's 'Electricity and Magnetism.'

out as 350 miles; this, therefore, is the distance of the fracture from the shore.

It is perhaps superfluous to state that many circumstances arise differing from those described, and many precautions have to be taken to which no allusion has been made. If, however, the general principles be made clear, that is accomplished which was intended to be done and those who are desirous of further information may consult the higher class of books which treat on practical telegraphy. It may be of some interest to let you see how delicate and perfect a test even this loaded galvanometer speck is. One or two illustrations will show how electrical currents are set in action when we are least aware of them.

Here is a small piece of zinc, like the blade of a penknife, attached to one end of a wire passing round the galvanometer; and here is a piece of copper attached to the other end. The zinc is now pushed into this apple. Observe, the speck moves so soon as the copper enters the apple. Repeat the experiment with a potato; the same phenomenon takes place. The potato forms a very good battery. There is another mode that is really more extraordinary still. If the galvanometer was sensitive, it is no fiction to say you can send a kiss across the Atlantic. Here are two little bits of zinc and copper attached to the ohms and cable combined as one length, and the galvanometer is now in circuit with them. If I kiss these two ends the speck moves. Therefore that mysterious something which is called electricity, and which has its origin at the lips, has exerted an energy sufficient to move the needle; indeed, sufficient to travel by the cable from one side of the Atlantic to the other, and move a needle when it arrives there.

Again, here is a small beef-steak and a knife and fork. These latter are connected by two thin copper wires with the galvanometer. One wire is attached to the blade of the knife and the other to the prong of the silver fork; by watching the speck you see that even one mouthful of meat cannot be cut without causing a current of electricity quite sufficient to manifest itself on the other side of the Atlantic.

Thus, surrounded by ever-active phenomena, which seem to have escaped the notice of men until the present age, he would indeed be more bold than prudent who ventures to speak confidently of what may or may not be done by one or other of the energies of the imponderables. How novel and delicate are the instruments employed, how accurate are the measurements obtained, and how marvellous are the uses to which electricity has been applied; yet these are not consequences of a blind rule-of-thumb following of that which has been long known. Patient research, persevering labour, and much thought have not only "put a girdle round the earth," but they promise fair to enter upon and possess electrical territories of vast extent and luxuriant social fertility. When will the people of England recognize this? Echo answers, "When!"

Parliamentary and Law Proceedings.

Prosecutions under the Adulteration Act. The "Facing" of Green Tea.

At the Central Police Court, Glasgow, on Tuesday, Nov. 11, John M'Kim, grocer, was charged with having sold a quarter of a pound of green tea, which was adulterated with turmeric and other ingredients.

A food inspector deposed that his attention having been drawn to some green tea in Mr. M'Kim's shop window, because of its particularly bright colour, he had purchased some of it, and handed it to the analyst. Dr. Thorpe deposed that he found the sample of tea to be adulterated with a mixture of turmeric, Prussian blue, and some silicate of alumina and magnesia, which he believed to be soap-stone or French chalk. The aggregate amount of these ingredients was about three per cent.

On behalf of the defendant, evidence was given that the tea sold was a genuine green tea, and that the facing was not an adulteration.

Bailie Hamilton (after consultation with the Assessor in private) said that having taken this case into consideration, the Court had come to the conclusion that the practice of selling faced tea as genuine green tea was very apt to deceive the public, and came properly within the meaning of the Act preventing articles from being sold which were different from what they were represented to be. Dealers who wished to sell this dressed green tea were quite at liberty to do so by labelling and selling it as such. The Court held the case to be proven, but considering the universality of the practice, the fine should be reduced to the minimum. The decision was that Mr. M'Kim be fined in 10*s.* 6*d.*

The Fiscal: I move for expenses.

Bailie Hamilton said that this being the first case, he thought it would be improper to give expenses. They did not wish to make Mr. M'Kim the victim for the trade. He had just been doing what the trade had been doing, but the Court trusted that this decision would put an end to the practice.

Mr. Lang, for the defendant, said that as this was a matter of principle which they wished to test to the utmost, he would give notice of appeal.

On the following day, Mr. Henderson, grocer, was charged with selling tea containing the same adulterants as those in the preceding case, with the addition of iron filings. The offence was admitted, but it was urged that the tea had not been adulterated since it came into the defendant's hands.

The Assessor: I look upon this case as a very different one to that which was before us yesterday. In it there were only the usual elements necessary to accomplish what is called "facing," but here we have the presence of a foreign article, which any trader without difficulty could detect if he chose to take the trouble. That is a serious element in this case, which the Court cannot overlook. The simple insertion of a magnet among the tea would have disclosed the presence of these iron filings at once.

The Bailie: The penalty must be in proportion to the amount of adulteration. I should have liked if this case had gone on, that we might have seen exactly the amount of adulteration. Seeing that you have pleaded guilty, we must assume that there is a considerable amount of adulteration, and, as the Assessor has remarked, it is quite a different case from that we had yesterday. The penalty must be very different. The decision of the Court is that Mr. Henderson be fined £5, with £2 3*s.* 6*d.* of expenses.

Review.

Reports on Forest Management in Germany, Austria, and Great Britain. By Capt. Campbell Walker, F.R.G.S., Staff Corps, Deputy Conservator. With Extracts from Reports by Mr. Gustav Mann, Mr. Ross, and Mr. T. W. Webber, and a Memorandum by D. Brandis, Ph.D., Inspector-General of Forests to the Government of India. London: Eyre and Spottiswoode, for Her Majesty's Stationery Office. 1873. 8vo. pp. x, 200. With cuts.

The subject of the preservation and improvement of forests is one of great and increasing interest and necessity. In all civilized countries the great demand for wood for fuel and for building, and also the requirements of space for building and agriculture, have much reduced and in some cases almost extirpated forests. In newly colonized countries this indiscriminate destruction of forests has been very rapid, and has not only created a difficulty in obtaining a sufficiency of supply of forest products, but has in some instances had a marked effect on the climate of the country, and turned fine pastures

into wildernesses. To guard against the repetition of such acts, and to repair the injury already done, recourse must be had by Governments to conservation and cultivation of forests, and the protection of collective rights against individual aggression.

"The main object," says Capt. Walker, "aimed at in any system of scientific forestry is, in the first instance, the conversion of any tract or tracts of natural forest, which generally contain trees of all ages and descriptions, young and old, good and bad, growing too thickly in one place and too thinly in another, into a closed or compact forest, consisting of trees of the better descriptions, and of the same age or period, divided into blocks, and capable of being worked—*i.e.*, thinned out, felled, and reproduced or replanted—in rotation, a block or part of a block being taken in hand each year. In settling and carrying out such a system, important considerations and complications present themselves, such as the relation of the particular block, district, or division, to the whole forest system of the province; the requirements of the people, not only as regards timber and firewood, but straw, litter, and leaves for manure and pasturage; the geological and chemical formations and properties of the soil; and the situation as regards the prevailing winds, on which the felling must always depend, in order to decrease the chances of damage to a minimum; measures of precaution against fires, the ravages of destructive insects, trespass, damage, or theft, by men or cattle; all these must be taken into consideration, and borne in mind at each successive stage."

The German forests, particulars of which are given as to the extent and kinds of trees grown, are divided into three classes, viz. (*a*) Those which are entirely the property of the State, but which in some instances are burdened with communal or individual rights; (*b*) Forests which were formerly church property, but which by particular Acts of Parliament are placed under a special department, which applies the profits arising from their working to educational and charitable purposes, and (*c*) Communal forests, which, like the preceding, are managed by Government forest officers; their annual yield, after deducting working expenses, being the entire property of the commune to use or sell as they please. The Government also takes up all extensive waste tracts and brings them under cultivation. The general way in which the forests are managed is as follows. The forest is first carefully surveyed and valued, and a plan prepared as to what trees are to be planted and what trees to be cut down annually, and detailing other items of management. These working plans are so well drawn out that they last with little or no revision for from twenty to even a hundred years. A register is also made of all rights of firewood, pasturage, etc., claimed by the inhabitants, and these rights in many cases are bought up by the State. It is found that when sums of money are given in commutation of such rights the successful working of the forest is much less hampered. In the case of communal forests the head inhabitants are always consulted as to their wishes, and they have the power of appeal against any working plan of which they do not approve. Such appeals are, we are told, very rare, as the people have learned that it is to their advantage in every way that the forests should be well managed, and such pains are taken to educate forest officers in their duties that their skill and knowledge create confidence.

In England much is done by private enterprise, and people do not look, as on the Continent they do, for Governments to do everything. Still we think that it is high time that our own Government should take the management of all communal forests in this country into their own hands, and thus guard the community against suffering from individual caprice. If this had been done with regard to the Epping Forest one would not have been scared by the unhappy ghosts of decapitated or "lopped and topped" trees one now sees.

The whole of the reports are full of interesting matter, but are of too technical a character to quote here. The suggestions of Dr. Brandis on the professional studies of forest officers on leave are exceedingly good. He warns any one from supposing that professional skill in the management of forests can be obtained in any other way than by hard work, and that "to work in a *dilettanti* sort of fashion" is of no good whatever. The suggestions are on the peculiarities of various European forests—what forests they should visit, and the best methods of study, and the literature of the subject.

These reports are the result of certain arrangements made in 1866 by which Indian forest officers who came to Europe during their furlough might have it in their power to increase their professional knowledge by studying forest management, and other subjects connected with forestry, in this country or on the Continent of Europe, and we trust they will not be the last of such reports. The Forest Department is now a very important one, as in India there is an increasing demand for building and firewood, and to provide the railways with sleepers and fuel, not only for the present time, but also to provide for the future. From India, too, we obtain many of our most valued medicinal and other vegetable products, and it devolves on the Forest Department to guard against any failure in such indigenous supplies, and to supplement supplies obtained from other countries. For the latter purpose careful meteorological observations are highly necessary.

The various points connected with the collection of forest products form also an important branch of forest study—such as the best time of the year for collection, the best kind of tools to use, and, where any preparation is necessary, the best method should be ascertained. Native collection is at the best of times wasteful, and such waste ought to be guarded against. Even where the tree has to be cut down, the bye-products should be utilized. The number of instances too in which the life of a tree has to be sacrificed might be considerably lessened, as, for instance, in the case of cinchona, where the coppicing system or lopping answers well. We are glad to find such an authority as Dr. Brandis speaking of this as probably the mode of cultivation to be followed in the future, for it is too often forgotten that a large timber tree is not grown as quickly as rice or corn.

The subject altogether is a highly important one, and we trust that the Government will not, from any false ideas of economy, prevent Dr. Brandis from making the Forest Department of India a highly organized and model establishment.

[372.] FLEXIBLE VARNISH.—*R.* asks for a recipe for making a pliable varnish for fly-fishing lines.

[373.] BROWN BOOT-TOP LIQUID.—Can any reader inform me of a good recipe for *Brown* Boot-top Liquid (without anatto colouring) ?—A SUBSCRIBER.

[374.] BOOT VARNISH.—Can any one give a recipe for varnish for dress boots, which will stand moisture ?—T. P. C.

RESEDA ALBA.—Your reply to "*Pharmacist*" on p. 340 of the Journal induced me to think that another locality for *Reseda alba* might not be altogether unwelcome. I found two specimens growing in a turnip field about two miles from Northampton, near a village called Upton, only a short distance from the Ironstone Quarries, where *Reseda luteola* grows in great profusion. *Reseda lutea* I have not as yet found in Northamptonshire, though my collection of flowering plants this year reaches 500 species.—G. C. DRUCE.

[*** The specimen of *Reseda alba* referred to was interesting, on account of its having six sepals and petals, and being therefore the *Reseda alba*, L. of continental botanists. The white flowered *Reseda*, with five petals and sepals, is usually regarded as a variety of *R. suffruticulosa*, L. Watson, in his 'Cybele Britannica,' states that the number of petals and sepals varies on the same specimen.—ED. PHARM. JOURN.]

ESTIMATION OF ALCOHOL IN COMMERCIAL CHLOROFORM.—A. C. Oudemans recommends (*Zeitschr. anal. Chem.*, xi., 409) that for the purpose of detecting and estimating the quantity of alcohol present in a specimen of chloroform, ten to fifteen grains of it should be placed in a glass flask with excess of dry pure cinchonine and kept for an hour at 15° C. by means of a water-bath and constantly shaken. The liquor is then filtered, 5 c.c. of the filtrate evaporated on the water-bath, and the residue weighed.

The following amounts of residue have been obtained with chloroform containing varying proportions of alcohol :—

Per cent. of Alcohol in Chloroform.	Milligrams residue left by 5 c.c.
0	21
1	67
2	111
3	152
4	190
5	226
6	260
7	290
8	318
9	343
10	346

GLYCERITE OF LIME.—The New York *Druggists' Circular* states that a glycerite of lime is recommended by Mr. De Bregne to be used in burns to soothe the pain and to prevent inflammation or diminish its intensity. It is prepared from—

Recently Slaked Lime	1 part.
Glycerine	50 „
Chlorinated Hydrochloric Ether	1 „

SOLUBILITY OF ARSENIOUS ACID IN WATER.—Buchner reports (*Neues Rep. f. Pharm.*, xxii., 265) that amorphous arsenious acid is more soluble than crystalline. The experiments were made by shaking with cold water, and allowing to stand for twenty-four hours, when it was found that the solubility of the amorphous variety was 1 in 108, and of the crystalline 1 in 355. Treated with boiling water and allowed to stand for twenty-four hours at 15° C., their respective solubilities were,—Amorphous acid, 1 in 30 parts of water; crystalline acid, 1 in 46 parts.

ACTION OF AMYLIC ALCOHOL ON POLARIZED LIGHT.—MM. Pierre and Puchot, in a paper read before the French Academy (*Comptes Rendus*, lxxvi., 1332), amongst other details as to the rotatory power exercised by amylic alcohol and its derivatives upon polarized light, state that the action of amylic alcohol is equal, though in an opposite direction, to that of a solution containing 1·4 per cent. of cane sugar, and that this rotatory power is increased one-third by the addition of about six per cent. of water. O. Popoff has found (*Deut. chem. Ges. Ber.*, vi., 560) that amylic alcohol which has been treated with an alkali or a solution of a calcium chloride does not yield the powerfully polarizing alcohol upon fractional distillation.

ANALYSIS OF JUNIPER BERRIES.—E. Donath gives the following (*Ding. Polyt. Journ.*, ccviii., 300) as the result of an investigation of the constituents of the berries of *Juniperus communis* :—

Water	29·44
Essential Oil (obtained by distilling the berries with steam)	0·91
Formic Acid	1·86
Acetic Acid	0·94
Malic Acid (combined with a base)	0·21
Fat resembling wax	0·64
Green Resin	8·46
Hard Brown Resin	1·29
Juniperin (found not to contain nitrogen)	0·37
Pectin (extracted from dried berries by water, and precipitated with alcohol)	0·73
Protein Substances	4·45
Sugar	29·65
Cellulose	15·83
Mineral Constituents	2·33

The wax was extracted with ether, and purified by successive treatments with water and boiling alcohol. From this alcohol, after the wax had deposited, was obtained, upon evaporation, the "green" resin, which had acid properties and resembled fir resin. The "brown" resin was obtained from the berries after being treated with ether by means of alcohol, and was soluble in alkalies.

CORKS SATURATED WITH PARAFFIN are, according to the *Apotheker Zeitung*, sometimes used for corking bottles containing alcoholic or caustic liquids. They are prepared by fusing paraffin in a suitable vessel, and immersing the dry corks in the paraffin by means of a perforated cover or dish. After about five minutes the corks are removed and cooled. Thus prepared, they may be cut and bored like wax, are easily driven into the necks of bottles and readily removed, retain their smoothness, and are air-tight throughout.

Correspondence.

"Citrate of Magnesia."

Sir,—During the past summer I required a new supply of "citrate of magnesia" labels, and bearing in mind a discussion, at which I was present, as to the propriety of calling any article by a name not strictly correct, I adopted the following addition to the ordinary label—"Granular Effervescing Aperient, usually known as," etc. This may interest some of your readers during the present discussion on the subject.

Chester, Nov. 11th, 1873. John Mills.

Sir,—The recent decision in the "magnes. citras" case has not only taken myself by surprise, but, I am sure, the whole trade in general; it is really something marvellously astounding (even though the case may have been proved to be an infringement of the Adulteration Act) to find the magistrate should not only fine in the case, but fine so excessively, which to my way of thinking is most outrageous. I certainly think an appeal should be taken, and if perchance the decision cannot be reversed, it will the more satisfy us that the case in point really does come under the Adulteration Act, and that it is illegal to sell that preparation by its present name. Under any circumstances, I think we ought not, as a body, to allow Mr. McDermott to be under the expense of the fine and costs himself. I for one shall be most happy to give my mite, and I am quite certain many others will join me in paying off any expenses that are already incurred and which may be incurred, providing an appeal be taken, seeing that we, each one individually, are equally guilty—if guilty we may term it—in selling "sodæ citro-tartrate effervescens," B. P., with the addition of sugar and lemon, under the title of "granular effervescent citrate of magnesia." Your kindness in inserting the above brief remarks will greatly oblige,

Manchester, Nov. 13th, 1873. Richard Twemlow.

[*** If Mr. Twemlow will refer to the report of the discussion at the Evening Meeting of the Pharmaceutical Society (*ante*, p. 372), he will find that Mr. Bishop said he would take care, with the aid of a few friends, to see that Mr. McDermott was not out of pocket. To this promise we would also direct the attention of another correspondent—Mr. Nottingham, of Shadwell,—who has kindly offered to subscribe 10*s*. towards the same object.—Ed. Pharm. Journ.]

Sir,—It seems to me that the absence of magnesia in the effervescing compound sold as citrate of magnesia should have prevented a conviction under the Adulteration Act. Could a grocer who sells a pound of salt when asked for a pound of sugar be fined for selling adulterated sugar? He might be sued for damages if any arose from the substitution, but certainly not for adulterating it.

Ipswich, Nov. 11th, 1873. H. C. Chapman.

Sir,—I have adopted the simple plan of putting a pen through the words "of Magnesia," when supplying the so-called "Citrate of Magnesia."

It seems to me that "Granular Effervescent Citrate" is not a bad name for the preparation. It is sufficiently definite, and sufficiently indefinite, to protect chemists and the public from the misapplication of the Adulteration Act.

Glastonbury, Nov. 17th, 1873. T. Mayhew.

Sir,—I see in to-day's Journal many suggestions relative to "citrate of magnesia."

I think a good and simple plan to adopt will be to have two additional lines printed to our accustomed style of label, but in smaller type, as under:—

Effervescing Saline,
usually called
Effervescing Citrate of Magnesia.
Etc., etc.

T. F. Hudson.

Holt Place, Birkenhead, Nov. 15th.

Sir,—Without adding much to the already voluminous correspondence upon the subject, I would remark that there is no longer need for a full definition of the nature and composition of the material upon the labels of the so-called citrate of magnesia. I would suggest that it be henceforth called simply:—

"Magnesian Citrate"
instead of
"Granular Effervescing
Citrate of Magnesia."

The public, when once told, will soon learn that it is simply a new and more comprehensive way of expressing the nature of the article, presuming, of course, that there will be in future some magnesian salt with citric acid in all that is sold.

I think the name will answer all practical purposes, and not involve the risk of a penalty.

Should any of your readers think otherwise, I shall be glad to hear their objection.

John C. Pooley.

8, *George Street, Bath, Nov. 18th.*

Sir,—Upon seeing the notice regarding the sale of "Granular Citrate of Magnesia," as being under the Act illicit, we sent a sample of our manufacture to Professor Stevenson Macadam for analysis, and beg to enclose his report.

Sang and Barker.

Edinburgh.

"Analytical Laboratory,
"Surgeons' Hall,
"Edinburgh, November 12th, 1873.

"I hereby certify that I have made a careful chemical analysis of a sample of 'Granular Effervescent Citrate of Magnesia,' manufactured by Messrs. Sang and Barker, Pharmaceutical Chemists, Edinburgh, and find such to contain 1·52 per cent. of magnesia, which is equivalent to 8·81 per cent. of the acid citrate of magnesia.

"I am therefore of opinion that this sample is of excellent quality, and is entitled to be regarded as 'Granular Effervescent Citrate of Magnesia.'

"Stevenson Macadam, Ph.D.,
"F.R.S.E., F.C.S.
"Lecturer on Chemistry."

Sir,—The delay in my communicating with you after the discussion at the Society's house, has arisen from my desire to secure the advice of the Attorney-General and Mr. Poland, and the difficulty which I have had to get their opinion. Consequent on the opinion which I have at last received, it is plain that the proper course is for the name to remain as it is; and to explain my course I have made a statutory declaration, and prepared a circular, with a view to sending a print of each to every gentleman on the register of chemists and druggists, and others who buy of me. One will of course reach you. It would have been a pleasure to me to have carried out what I know would have been, from a pharmaceutical point of view, a desirable object, viz., a change of name, but I feel that by long usage the name which has been used has become the only name of my article, and that whilst a change would have been understood by the educated body of chemists and druggists, it would not have been understood by consumers generally either at home or abroad.

Alfred Bishop.

17 *and* 18, *Speck's Fields, Mile End New Town, Nov. 20th.*

Sir,—In order to avert further proceedings in connection with the so-called "citrate of magnesia," and to protect its extensive sale, I would suggest that all manufacturers of it should hereafter adopt Mr. Bishop's system of preparation—that of the addition of magnesia—when the seller could with all safety designate it as "Compound Granular Effervescent Magnesia," thus avoiding as much as possible an apparent difference in the label. Allow me at the same time to draw attention to another misnomer, extensively used, and by which it appears to me we are equally as much exposed to danger—viz., the so-called "soda water." It is well known that the larger quantity of this preparation sent out does not contain a particle of bicarbonate of soda, I believe on account of the addition of that salt rendering the water less agreeable as a beverage. The remedy I would suggest for this is

to see that soda is present, and if the water be preferred without the alkali, to have it labelled "Aerated Water," which I think the public would not much object to. Hoping these suggestions may be of some little service, I am, etc.,

AN ASSOCIATE.

Edinburgh, Nov., 1873.

THE ADULTERATION ACT.

Sir,—Citrate of magnesia is a subterfuge, and it has always been so considered by the trade, and some, if not all, of the public. How is it that it comes under the provisions of the Adulteration Act?

How can a preparation sold as a certain article be an adulteration if the article is not contained in it at all?

I hope this subject will now be thoroughly discussed, in order that something definite may be arrived at.

F. W. S.

Walworth, Nov. 12th, 1873.

WHO'S PHILIP?

During the discussion which took place on the citrate of magnesia question, when it was stated that the Adulteration Act prescribed for the second offence imprisonment with hard labour, one of the speakers remarked that the sentence would involve a change of residence, but not of occupation.

This observation indicates the prevalent feeling that the daily routine of a dispenser of medicine is considered to be one of continuous labour as well as responsibility. Dog Latin and bad Latin, errors and excessive doses, equally demand the most careful attention to every prescription. His mental faculties are in a state of tension from the time that he takes his stand behind the counter until he retires to rest; but when to this is added the occasional appearance of such a prescription as the one now before me, it is the last straw that breaks the camel's back.

℞

Pil. Philip. vj.
St. j hora somni semel hebdom.
Sig. Specific Liver Pills.

Rufus we know, and Plummer we know, but who is Philip? A little alteration in the heading of the paper read before the Liverpool Chemists' Association by Dr. Edmund Alleyne Cook would supply an equally good subject for another occasion. I would suggest that the reading be "Some practices of the profession, the abandonment of which would benefit the trade."

The practice of prescribing a preparation, the formula for which has not been published, and the composition of which is not indicated by its name, and the only merit of which is its novelty, is bad enough—and in all conscience troublesome enough—but when to this is added the practice of supplying a chemist with private formulæ, obliging patients to go to one particular shop, and that only, to get the prescription dispensed, it is beyond quiet endurance. To take the usual professional fee from a patient, and then to give that patient a prescription which can be dispensed only at the particular establishment which is in possession of the formula is unprofessional and indefensible. It implies a compact and cannot be too sharply condemned. Perhaps in some future opening address at one of the medical schools, when discoursing on the ethics of the profession, this subject may receive some attention. It is my intention on all future occasions when a prescription of this kind comes under my notice to ask for information through the medium of the PHARMACEUTICAL JOURNAL, giving the name of the prescriber, and also that of the chemist who has previously dispensed it. The practice of prescribing from secret formulæ is now quite exceptional, but it should have no existence, and then it would be unnecessary to ask the question, Who's Philip?

THOMAS GREENISH.

20, *New Street, Dorset Square, N.W.*
Nov. 8th, 1873.

MUSTARD.

Sir,—As a lover of what is true and genuine, and a disliker of all "*shoddy*," under whatever pretext or disguise it may be offered, I was extremely glad to observe Mr. Greenish's paper on Mustard in your last week's Journal.

Mr. Greenish's quotation as to the purposes served by mustard as a condiment, if accepted as true, should brush away, as the merest rubbish, all the alleged arguments used in favour of its admixture with other ingredients. I would put it thus: For what purposes is mustard employed by its consumers? That question being answered, I want to know whether even "the finest wheaten flour" (as it was lately termed in a court of justice by a representative of one of the most respectable of our mustard manufacturers) will promote these ends? Does turmeric do it? If not, then comes on the question brought out in recent discussions on the subject, and asserted by advocates of the present "use and wont" system of manufacturing mustard, or, as I lately found one eminent public analyst terming it, "mustard condiment"!!—viz., the keeping powers of the true article. It is broadly asserted that it won't keep when made up for table use as long as the adulterated article does. On this point I can only state that, for more than twenty years, my firm has sold no other mustard than Dewar's (Newcastle) pure brown, and that, during that period, it alone has been in use at my own table, and that no complaint of its not keeping has ever reached me. Besides, supposing such were the fact, does everybody not know that mustard ought to be mixed for use daily, just as our coffee has to be made every morning, and not once a week; the first operation takes a minute or less, the latter at least a dozen times as long.

I further hold that it won't do, at this time of day, for makers or for sellers, wholesale or retail, to cast the blame of their selling adulterated articles on the "*public*." The public are quite helpless in the matter. If the manufacturer won't *manufacture*, and the trader won't *sell*, anything but the genuine article, then the poor, much abused, but really, in such matters, helpless "public" must *buy*, and must pay for the genuine article. They are quite as helpless in this as they are in regard to railway travelling. If the great railway companies say they will run no fast trains, then the public must just be content to travel by slow ones. So with us traders and all our commodities *and* our customers.

DANIEL FRAZER.

Glasgow, 18th Nov., 1873.

P.S.—As an odd coincidence with the writing of this letter, I am tempted to add these two facts that occurred this very day in my own shop: 1st. We were asked to supply one of our public bodies, on the footing that they "knew ours to be pure," with a sample of our mustard, that it might be used as a standard for comparing other so-called mustards by under the microscope. 2nd. We were asked by a druggist in a neighbouring country town for another small sample, to assist him in his illustrations of a lecture on the subject, we understand, of adulterations, he was to deliver last night. These little incidents testify that the public somehow find out where a genuine article is kept, and that they can appreciate it when found.

UNUSUAL DOSES IN PRESCRIPTIONS.

Sir,—The subject of unusual doses has special prominence in your last issue, and also in that of your trade and medical contemporaries, by reason of the publication of the resolutions passed at the Pharmaceutical Conference at the Bradford meeting, and of the resulting circular to the heads of the medical profession. This, with your expressions of the opinions taken from the *Practitioner* and the *Druggists' Circular and Chemical Gazette*, coupled with your trust that a means may be devised of protecting prescribers, patients, and dispensers from possible disappointment, inconvenience, and perplexity, has prompted me to suggest that the method in use by some of our continental neighbours might be taken as a complete solution of the question, and that such method, or whatever may be adopted, should have the official stamp of a place in the next Pharmacopœia. In the seventh (1871) edition of the Pharmacopœa Suecica there are certain canons laid down for the dispensing of medicines, the seventh of which runs thus:—"7. Si ad internum usum præscripta fuerit major medicamentorum vehementium dosis, quam quæ in Tabula A indicatur, ea ne dispensetur, nisi vel signum exclamationis! vel verbum *sic* a medico adscriptum sit." I may add "Tabula A" is described as "quantitatem maximam medicamentorum vehementium adultis interne prodosi dispensandam exhibens." Then follow the articles and doses. Whether in the above way or by bracketed initials of the prescriber is a matter of detail, but in any way let it be as much on authority as in the Swedish Pharmacopœa, or as the nature and purity of the medicines themselves in our own. When in the Pharmacopœia it will have the force

of law, and from its obvious utility in defining the position of prescribers and dispensers, it will, I feel sure, gain the approval and support of all concerned.

I hope that you and your contemporaries and the interests represented will agree with me.

A Drug Traveller.

London, November 17th, 1873.

Phosphorus Pills.

Sir,—In your "Notes and Queries" for Nov. 1, 1873, you publish a formula for making ¼ grain phosphorus pills which I supplied to a neighbour requiring such. My original letter contained a caution that ¼ grain doses were exceptional.

My attention has just been drawn to the absence of this caution in your note, from the circumstance that a young pharmacist who had been under treatment with phosphorus capsules containing one-thirtieth of a grain each, desirous of preparing his own medicine, substituted pills by the published formula, and suffered disagreeable irritation in consequence.

Phosphorus requires caution, no less in its admistration than in its manipulation, and will not allow of its dose being increased fourfold with impunity.

Barnard S. Proctor.

Grey Street, Newcastle,
Nov. 14th, 1873.

[*** We published the extract from Mr. Proctor's letter just as we received it from our correspondent, in which state it was unaccompanied by any remark as to the dose. We agree with Mr. Proctor that ¼ of a grain of phosphorus is a large dose, though we happen to know that such doses are prescribed, and in publishing the formula we took it that Mr. Proctor's object was to assist pharmacists in manipulating that quantity of phosphorus into a pill rather than to help them in deciding when such a dose should be taken.—Ed. Ph. J.]

Local Secretaries and their Duties.

Sir,—Judging from what is said in the Council and out of it, local secretaries are receiving scant praise for the way in which the duties devolving upon them have in many instances been performed.

The Council has on many occasions given broad hints that there is room for improvement as regards these functionaries, and as a means to bring it about they have pressed the subject on the attention of members at the annual election of the Council. The result, I imagine, has been rather disappointing.

There are two or three phases of the subject deserving notice. In the first place, the office is one that is not coveted by many, and in the second place, few people care to propose any change so long as the present occupier expresses no desire to resign; and thirdly, some persons hold so tenaciously to the honour because it is supposed to distinguish them in particular, and they have no inclination for less distinguished men in the town to hold it. Now this ultra-Conservatism is bad, and acts as a dead weight on the energies of the Society. The remedy I would propose for this would be to pass a bye-law that local secretaries be elected for two years only, and not be eligible for re-election. By this plan an interest in the affairs of the Society is spread over a larger number, and the duties of the office fulfilled for so limited a period with zeal. New brooms sweep clean.

F. M. Rimmington.

Nov. 15th, 1873.

Chemists' Assistants' Association.

Sir,—Some time ago a society for chemists' assistants was hinted at in the pages of this Journal by some well-wisher, but no steps appear to have been taken at present in the matter. It is generally known amongst us assistants that our remuneration is much about the same as that given to those who require very little mind for their business. Most certainly it is very little, if *any*, more, and yet *we* must rack our brains night after night, when (as stated by Mr. Heynes) we should be taking bodily exercise, after the long toilsome hours of business, in order to pass our examinations. Surely the instance of payment that he quoted was low enough in the scale. Out of £25 per annum how much is a young man likely to save towards his Major examination expenses, after deducting no small amounts for clothing, washing, railway travelling, etc.? Such a salary would be fair enough for an improver, or even a junior assistant, but to a Minor man, and in honours, too, the offer was an insult.

At a foreign pharmacy, not a hundred miles away from Soho Square, I was expected to speak French and take entire charge of the business (the proprietor being a surgeon) for the munificent recompense of £30 per annum. The rising pharmacists of the day overlook their assistants. They do not consider them, but were they to do so more I think that they would find that their young men would take much more interest in business, and strive to forward their employers' ends to the utmost. But at present the employer appears only to think to himself: "I was once an assistant, and had to put up with the same hardships that others do now; if it did not hurt me, it cannot injure them." There he stops, but he does not consider that when he was a young man he had not the difficulties to cope with that one has now. Then the examinations were not obligatory, then the law was not so severe as to hunt down every luckless chemist who had commenced business without having first presented himself for examination. Our employers, now-a-days, don't seem to think of any of these things. They think if their assistant is well fed, and comfortably lodged, their duty towards him ends there, and he must do *his* duty by them. If he complains that his salary is insufficient, the answer he receives is that he can go elsewhere and seek for more. But most young men don't like chopping and changing, neither do *many* employers.

Far be it from my thoughts to wish to raise discontent amongst my comrades at their hard lot. My desire, and that of others also, is merely to form an association for chemists' assistants, in which their interests would be forwarded in many ways.

Will no benevolent employer come forward, and with heart and hand take the lead in this scheme? I will warrant that plenty of young men will be found ready to enroll themselves members.

Let assistants all unite together in endeavouring to persuade English employers to copy the liberality of their American brethren in this particular, and to study their assistants a little more, doing unto others as they would men should do unto them.

Minor Associate.

Nov. 10th, 1873.

"*Cleopatra.*"—There is no known acid that will dissolve a diamond, but it may be dissolved by oxygen at a sufficiently high temperature.

E. J. Davies.—We have inserted your query, though we do not think it will be possible to prepare a solution that will keep more than a limited period.

"*Henricus.*"—We have sent on your query to a veterinary friend, and upon receiving his answer will forward it to you.

A. Stringer.—The answer to your first question would depend upon whether you mean what is vulgarly known as a "patent medicine," *i.e.*, a proprietary article. We should recommend you to consult a solicitor respecting your second question.

Dr. Domett Stone is thanked for his information.

Mr. Kinninmont is thanked for his communications.

Catchpenny Advertisements.—A correspondent informs us that observing recently an advertisement in our columns offering a good position to an experienced man, he sent in an application for it. After a few days he received a letter stating that the vacancy in question was filled, but that by sending 5*s.* in stamps to the writer, "to defray little expenses," etc., the applicant could be assisted in getting a first class appointment. We are glad to say that our correspondent was "one who values five dozen stamps" too well to part with them in that way, for the transaction has the appearance of a trick which is neither new nor peculiar to pharmacy, and which we therefore regret to infer is not unprofitable.

Communications, Letters, etc., have been received from Messrs. McNeile, Dittmar, H. J. Davies, Stringer, E. Davis, "Dolomite," "Spero," "Edina," "An Associate," "Gradibus," F. F. H., S. X. N., A. P. S.

AFRICAN TEA PLANTS.

BY JOHN R. JACKSON, A.L.S.,

Curator of the Kew Museums.

It is interesting to note the numerous British plants that are used by the peasantry in rural districts in this country for the purpose of making an infusion which is commonly called tea, and which is often given for the cure of various disorders of the human system. A more extended interest is attached to the numerous plants which are used in different countries for a similar purpose, as well as for a refreshing beverage which is drunk as we drink the Chinese article. Thus we have Labrador tea, the leaves of *Ledum latifolium;* Faham, or Orchid tea of Madagascar (*Angræcum fragrans*), and, above all, Paraguay tea, the leaves of *Ilex paraguayensis*, which occupies as important a position in South America as the leaves of *Thea chinensis* do with us. Its use is said to have been derived from the aborigines, and has been continued for a long period of time. It is estimated that the quantity consumed in the country comes to nearly or quite 8,000,000 lbs. annually. The mode of preparing the leaves for use differs from that adopted by the Chinese, inasmuch as the leaves are not gathered separately, but whole branches or twigs are cut off and placed on hurdles over a fire until properly dried or roasted, when each branch is beaten and the leaves which are thus removed are reduced to a powder. To drink this tea an infusion is made in a small pot formed of a gourd, and the fluid is drawn into the mouth through a small tube.

The names Tea plant and Tea tree are sometimes applied to large timber trees, as in the case of the Australian tea trees, species of *Leptospermum* and *Melaleuca*. It is, however, of some of the African tea plants that we have now more especially to speak. *Cyclopia*, *Borbonia*, *Cliffortia*, and *Catha* are genera whose species are known in certain localities as tea plants. The first two belong to the Leguminosæ. *Cyclopia* consists of nine species, mostly shrubs or bushes, natives of South Africa. The leaves are alternate, sessile and trifoliate, the leaflets linear, smooth or pubescent, their margins frequently revolute. The flowers are yellow, papilionaceous, stalked and bracteate, and are mostly borne in the axils of the upper leaves. Round the pedicel at the base of the calyx is a circular depression, a character by which the species may be recognized from their allies. The fruits are compressed oblong pods, bearing numerous seeds.

C. genistoides, Vent., is known at the Cape as bush tea, the leaflets being used for that purpose. It has a strong aroma resembling Chinese tea, and a sweetish astringent taste. It is used in medicine for assisting expectoration in chronic catarrh, and also in consumption. Though the present species is that generally spoken of as yielding bush tea, the leaflets of other species no doubt are used for a similar purpose, *C. Vogelii*, Harv., undoubtedly being one of them. Another South African leguminous genus, the leaflets of which are used for making a medicinal infusion, known to the colonists as "Stekelthee," is *Borbonia;* the genus consists of thirteen species all natives of South Africa. They are shrubs with compressed, angular, winged branches, and alternate, many-nerved leaves. The flowers are papilionaceous, yellow, and are borne in terminal or axillary racemes. The pods are linear, somewhat flattened, and are mostly covered with long soft hairs. *B. parviflora*, Lam., is the species mostly used, the leaves of which are given as a diuretic in the form of decoction.

Cliffortia is a genus of Rosaceæ, and is composed of about forty species. They are bushes, all natives of South Africa. They have small alternate leaves, composed of two or three leaflets; in the species in which the three leaflets occur, the two side ones are small and united more or less to the centre one, thus giving the leaf the appearance of being a simple, instead of a compound one. The flowers are small, diœcious, and produced in the axils of the leaves. Both the male and female flowers have the calyx tube contracted at the top, the former containing about thirty stamens, and the latter with one or two achenes, each surmounted with a bearded or feathery style. *C. ilicifolia*, L., is the species the leaves of which are used at the Cape under the name of Doorn-thee as an emollient and expectorant in coughs.

The leaves of two or three species of *Helichrysum* —a well-known genus of Compositæ—are used at the Cape under the several names of Caffre tea, Hottentot's tea, and Duinen-thee. The first-named is procured from *Helichrysum nudiflorum*, Less., a common herbaceous plant of the colony, with stalked, amplexicaul, ovato-lanceolate radical leaves, and narrow, lanceolate, sharp-pointed cauline leaves. The flower heads are terminal, corymbose, and the flowers yellow. The plant is demulcent, and an infusion made from it is recommended in phthisis, catarrh, and pulmonary complaints generally. *H. serpyllifolium*, Less., furnishes Hottentot's tea. It has an agreeable smell, and is a favourite amongst the natives. It is said to possess demulcent and emollient properties, and is used for similar purposes as the last-named species. The leaves of *H. imbricatum*, Less., constitute the Duinen-thee—literally tea from the Downs, in reference to the plant being common on the Cape Downs. This is likewise used in coughs and chest diseases, as are also the leaves of *H. auriculatum*, Less.

Methyscophyllum glaucum, E. and Z., an amyridaceous shrub, with opposite, lanceolate glabrous leaves, recurved at the margins, and flowers borne in axillary panicles, furnishes what is known as Boschjesmansthee; from the leaves is made an infusion which has a very pleasant flavour, and besides being used for coughs, asthmatic, and similar diseases, is a favourite drink with the bushmen and others.

Catha edulis, Forsk., a celastrineous shrub, the leaves of which are largely used as tea in Arabia, under the name of Kât, is, so far as its African habitat goes, confined to the eastern part of the continent. In Arabia the twigs, with the young leaves remaining, are very extensively collected, and form an important article of trade among the Arabs, large quantities being annually brought to Aden from the interior. The twigs are made up into bundles, varying in size according to quality. The use of this tea is said to produce effects somewhat similar to those produced by the Peruvian coca (*Erythroxylon Coca*), namely, extreme wakefulness and capability of bearing extra strain with a minimum of fatigue. Taken in decoction, in moderate quantity, its effect is exhilarating, nearly analogous to that of Chinese green tea.

THE ACTION OF THE CINCHONA ALKALOIDS AND OTHER SUBSTANCES UPON BACTERIA AND COLOURLESS BLOOD CORPUSCLES.

In an exhaustive and interesting paper printed in the *Practitioner* for November, Dr. E. Buchanan Baxter gives the results of numerous experiments upon the action of the cinchona alkaloids and their congeners on bacteria and colourless blood corpuscles. Referring the reader to the original article for the details of Dr. Baxter's numerous experiments, it is proposed to give here a short abstract of the general conclusions drawn from them upon points likely to be of interest to the pharmacist.

Cinchona bark and quinine are generally considered to possess antiperiodic, antiseptic, and antiphlogistic properties, terms which the author defines respectively as indicating their specific influence over morbid states caused by the paludal miasm, their curative virtues in septic conditions of the blood, and their power to restrain the migration of the colourless corpuscles of the blood, and thus to control the violence of suppurative inflammation. The author deals mainly only with the latter properties. The antiseptic action of the four principal cinchona alkaloids, and some other substances whose relation to them is not yet understood, are compared with their power to control the migratory movements of the blood corpuscles. The question of their antiperiodic virtues is only indirectly touched upon, in so far as their power to destroy the vitality of bacteria and other microscopic organisms bears upon the doctrines advanced as to the spread of specific fevers, and other forms of disease, by living germs.

The subject cannot be said to be a new one, and the author, in the few paragraphs which are here quoted, rapidly sketches the probable origin and form of the inquiry.

"The singular freedom from decay enjoyed by all the varieties of cinchona bark must have been noticed by pharmaceutists from a very early period. The permanence of decoctions and infusions of bark, as compared *e.g.* with those of quassia, forces itself on the attention of the most careless dispenser. It was not till the middle of the last century, however, that the antiseptic qualities of bark were experimentally investigated. In the *Philosophical Transactions* for 1750, there is a paper by Sir John Pringle, entitled 'Some Experiments on Substances resisting Putrefaction,' giving a series of observations on the comparative antiseptic power of a variety of substances, including 'the Bark.' The author exposed bits of meat, steeped in solutions or decoctions of the antiseptics employed, to a temperature of 94°—104° F. for several days, and noted the kind and degree of putrefactive change which they underwent. His observations are reduced to a common standard, viz., the antiseptic power of a solution of common salt of known strength.

"These experiments laboured under several disadvantages; the true nature of putrefactive decay was still unknown, more especially as regards the part played by bacteria; the substances employed were not chemically pure; and the sense of smell, as a test of decomposition, is neither wholly trustworthy, nor capable of quantitative expression. Notwithstanding these drawbacks, however, the results obtained were, upon the whole, singularly correct, and have been corroborated by the more exact researches of later inquirers. With regard to cinchona bark, Pringle makes the following statement: 'The common neutral salts, however powerful in resisting putrefaction, are inferior to some resinous substances, and even some vegetables, which I have tried. Thus myrrh, in a watery menstruum was found at least twelve times more antiseptic than sea-salt.' After alluding to camphor, Virginian snake-root, and chamomile flowers, he goes on to say: 'the Jesuit's bark has the same extraordinary quality' (*i.e.*, that of hindering putrefaction); 'and if I have not found it so strong as the two substances last-mentioned, I impute that in part to my not being able to extract its embalming parts in plain water.' The experiment is described thus: 'I made a strong decoction of the bark, and infused a piece of flesh in two ounces of it strained; which flesh never corrupted, though it remained two or three days in the furnace after the standard' (flesh steeped in brine) 'was putrid. In this time, the decoction became gradually limpid, whilst the grosser parts subsided; by which it appears that a most minute portion of the bark, intimately mixed with water (perhaps less than of the snake-root or chamomile flowers) is possessed of a very extraordinary antiseptic force.'

"His theory, as may be expected, falls short of his observations; he is inclined to attribute the antiseptic virtue of the bark to its astringent properties. 'By the success of the bark in so many putrid cases, it should appear that astriction had no small share in the cure, and indeed the very nature of putrefaction consists in a separation or disunion of the parts.'

"Pringle's observations lay forgotten for upwards of a century. Even Briquet, in his elaborate and valuable monograph, refers very briefly to Pringle's results, and obviously confounds the antiseptic with the astringent properties of the bark:—'Ces tentatives montrent seulement l'influence de l'action chimique du tannin sur la putréfaction, mais elles ne prouvent rien sur la prétendue propriété antigangréneuse attribuée au quinquina' (p. 40). It was not till the researches of Professor Binz and his pupils that the high place of quinia among antiseptics became generally recognized. And this recognition has already thrown much light on the efficacy of quinia in cases where its use had previously been ascertained by clinical trials, and is likely to extend the sphere of its future application.

"No really adequate conclusions as to the antiseptic power of the cinchona alkaloids were possible so long as the intimate nature of the putrefactive process remained unknown. The circumstance that it depends on the evolution of a multitude of extremely simple organisms, narrows the area of the inquiry very materially. The question as to the antiseptic properties of quinia and other substances resolves itself into the question of their action upon microzymes."

In estimating the effect of drugs on the vitality of microzymes, the author took the power of spontaneous locomotion and of undergoing unlimited multiplication in suitable media as reliable criteria in deciding whether the microzymes were alive or dead. The entire absence of all but passive movement does not afford conclusive evidence of death; it may result from a rigidity or torpor, lasting only as long as the cause to which it is due continues to operate; but not destroying the reproductive power of the microzymes. The fertility of the microzymes was tested by introducing a drop of the liquid into a tube containing 4 c.c. of Pasteur's or Cohn's solution; the solution being previously boiled and the tube and pipette superheated. The tube was then plugged with cotton wool and kept at 65° to 75° F. for two or three days, when, if the microzymes retain their vitality, an examination of a drop of the liquid under the microscope revealed them in swarms.

We may note in passing that the degree of heat required to destroy the vitality of microzymes is variously given by different observers. Bastian concludes that the temperature of 70° C. suffices to completely destroy all germs, whether in saline or organic infusions; Cohn says that 62° C. for one hour is fatal

to bacteria; Lex found 127° C. insufficient to kill them, and Calvert requires 204° C. for their complete destruction. The author found that at from 20° to 40° C. the locomotive activity of microzymes increased with the rise of temperature; above this it gradually decreased, and at 60° C. they became motionless. Experiment showed however that their reproductive power was not impaired by the temperature that rendered them motionless; but Dr. Baxter thinks that a temperature of 100° C., and probably much less, abolishes both the locomotive and reproductive powers; and in no case did he find that microzymes were ever developed when the liquid had been boiled for a few minutes in a superheated tube and guarded from subsequent contamination by keeping the mouth of the tube plugged with cotton wool.

Turn now to the author's experiments with the quinine alkaloids and other substances that have been reputed to have antiseptic properties. One part in 400 of hydrochlorate of quinine was found to considerably reduce the motion of microzymes, and when the proportion of quinine salt was raised to 1 in 250 locomotive particles could no longer be detected. As soon however as the microzymes were liberated from the inhibitory influence of the quinine they resumed their vital powers and multiplied almost as rapidly as usual. Life was however destroyed by the addition of mercuric chloride (1 in 133), liquor sodæ and hydrochloric acid. The sparing solubility, even of the hydrochlorate, prevented the accurate determination whether quinine in larger proportions would produce similar fatal effects.

The hydrochlorates of quinidine, cinchonidine, and cinchonine were next experimented with. They were found very nearly equal in antiseptic power; arranged in the strict order of their efficacy, quinine and quinidine are equal, next comes cinchonidine, and last, though at no great distance, cinchonine. It is remarkable that this is the precise order in which febrifugal powers are attributed to these alkaloids in the reports of the Bombay and Madras Medical Commissions, quoted in a recent number (p. 396.) It is also interesting to note that of these four alkaloids cinchonine is the only one which is not fluorescent, and this suggested to the author whether that physico-chemical property was in any way correlated with antiseptic power. The question was answered by an experiment with æsculin,—the active principle of the horse-chesnut bark,—which, although more fluorescent than quinine, possesses no antiseptic property comparable with that of the cinchona alkaloids.

Besides comparing the cinchona alkaloids with each other, the antiseptic powers of the following substances were compared with those of a standard solution of quinine:—

1. Mercuric chloride, sodic sulphocarbolate, and strychnia—substances to which antiseptic properties are ascribed.

2. Berberin, beberia, picrate of potassium, quinidine, cinchonine, cinchonidine, æsculin—substances credited with antiperiodic virtues.

3. Sodic sulphite, and hyposulphite—to which both antiseptic and antiperiodic properties are attributed.

The following inferences were suggested by the results of these comparisons:—

"1. Quinine is doubtless excelled by other antiseptics, but there is no substance equal to it in antiseptic power which can be introduced into the blood in the same proportions without risk of fatal effects, if we except the other cinchona alkaloids and the sulphate of beberia.

"2. Quinine, in such fractional doses as are capable of being introduced into the circulation, exerts an inhibitory, not a toxic, action upon microzymes. It *may* check septic changes; it cannot destroy the organisms to which such changes are due.

"3. The four cinchona alkaloids are very nearly equal in antiseptic power.

"5. Among reputed antiperiodics, the sulphate of beberia seems to equal quinine in antiseptic power.

"6. Among reputed antiseptics, sodic sulphocarbolate and strychnine have a decided value, though they stand some way below quinine.

"7. Sodic sulphite has a feeble, though decided, antiseptic power; sodic hyposulphite little or none.

"8. Berberin and æsculin are hardly, if at all, antiseptic.

"9. Potassic picrate is a strong antiseptic, almost, if not quite, equal to quinine. It is doubtful, however, whether it can be administered in sufficient doses without danger to life.

"10. The action of inhibitory drugs on the vitality of microzymes affords no clue to their action on *Penicillium*. Substances like mercuric chloride, which are immediately fatal to the former, arrest the growth of the latter when employed in the same minute proportions."

The toxic action of quinine upon the colourless corpuscles of the blood was first noticed by Binz, and this effect of the alkaloid acquires a special significance in view of recent theories concerning inflammation and suppuration. It seemed desirable to the author to ascertain whether the other cinchona alkaloids, and also some other substances, resembling them in antiseptic or antiperiodic properties, were endowed with similar properties, and if so, in what degree. Comparative experiments were therefore made upon the blood corpuscles of the newt, the drugs employed being the hydrochlorates of the four cinchona alkaloids, potassic picrate, æsculin, sulphate of beberia, and nitrate of strychnia. The solutions were all neutral to test paper, and the temperature of the room varied between 65° and 75° F. The four cinchona alkaloids, in the proportion of 1 in 1500, were found to speedily arrest the migratory movement of the colourless corpuscles, quinine appearing to stand first in order of power. Sulphate of beberia, which approached them so closely in antiseptic power, rivalled them also as an antiphlogistic. Strychnine had some influence upon the corpuscles, but very much less than the cinchona alkaloids or beberia. Potassic picrate, almost equalling the cinchona alkaloids as an antiseptic, exerted a comparatively feeble influence over the movements of the colourless corpuscles, indicating that the antiseptic and antiphlogistic properties of a drug are not necessarily connected with each other. Æsculin exerted no very marked influence upon their activity.

EXTRACTUM AURANTII CORTICIS FLUIDUM.*

BY MONROE BOND.

Owing to the highly aromatic and somewhat tonic properties which the rind of sweet orange possesses, it is extensively used in the form of a fluid extract as an ingredient in the multiform tonics and elixirs now so much used

* *American Journal of Pharmacy*, Nov., p. 483.

in the United States. No formula for such a fluid extract is, however, given in the United States' Pharmacopœia, and the author having been called upon frequently to prepare it, and knowing of no published formula, has made numerous experiments to ascertain the most appropriate menstruum. He states that he has found the following formula to furnish a most satisfactory preparation :

Take of—

Sweet Orange Peel, in moderately fine powder	℥ xvj.
Glycerin	fl. oz. iij.
Alcohol,	
Water, each a sufficient quantity.	

Mix fourteen fluidounces of alcohol with two fluidounces of glycerin ; moisten the orange peel thoroughly with twelve fluidounces of the mixture in a large Wedgewood mortar, or any convenient vessel, and having covered it carefully, let it stand for twelve hours ; then pack moderately firm in a suitable percolator, and proceed as directed in the U. S. P. officinal directions for preparing fluid extracts. Finish the percolation with a mixture of two parts of alcohol and one part of water, reserving the first fourteen fluidounces, add one fluidounce of glycerin to the remainder, carefully evaporate to two fluidounces and mix with the reserved portion.

The author states that fluid extract of orange prepared in this manner has a heavy rich appearance, is permanent, and possesses all the aroma of the orange peel, if a fresh and good article of the drug has been employed. One fluidounce, added to fifteen fluidounces of simple syrup makes what he considers a stronger and better "Syrupus Aurantii Corticis" than the officinal. The resulting syrup is entirely destitute of any opaqueness.

Four fluid drachms of the fluid extract and a few drops of solution of citric acid mixed with one pint of syrup, make a syrup unsurpassed in delicacy of flavour and unfermentable for use at the mineral water counter.

THE TESTING OF GLYCERINES.*

BY MM. CHAMPION AND PELLET.

The following methods of testing the purity of glycerines are recommended by the authors as being convenient in application, and yielding exact results :—

Qualitative Test.—The glycerine diluted with twice its weight of water is treated in the cold—

(1) With tribasic acetate of lead. If an abundant precipitate be formed, and rapidly deposited, the presence of a proportion of foreign matters may be assumed which would make it unsuitable for use in various applications, such as the manufacture of nitro-glycerine, etc. The crude glycerine obtained in treating fats with sulphuric acid is frequently thus contaminated. These foreign matters result from the action of sulphuric acid at a high temperature (about 110° C), upon the fatty matter itself, or on the impurities it may contain.

(2) Glycerine obtained by calcareous saponification, also, may contain oleate of lime. This may be detected with oxalate of ammonia, which throws down the lime as a clearly perceptible precipitate.

The colour of glycerine is in no way an index of the purity of the product. In all cases it is useful to be assured of the neutrality of the glycerine. The preceding tests are suited for glycerines more or less impure, but not adulterated. According to the author's experiments, the tribasic acetate of lead separates all the foreign substances due to normal impurity of the product or alteration in the glycerine during its manufacture. Any addition of glucose may be detected by Fehling's solution.

Quantitative Test.—This test should comprehend the determination of the water, the foreign organic matter, the lime, and the glycerine. In France commercial transactions in glycerine are generally based upon the results given by the areometer. This, however, is undesirable, in consequence of the variations in graduation adopted for that instrument. These variations have recently been the subject of investigation, and a report on the verification of the areometer of Baumé has been drawn up by Berthelot, Coulier, and d'Almeida ; but whilst acknowledging the value of their labours the authors prefer trusting to the hydrometer. In the following table the authors have given the densities of various mixtures of water and glycerine, comparatively with the degrees Baumé (as indicated in the above-mentioned report), and also the proportions of water corresponding to the densities. These determinations have been verified by means of pure anhydrous glycerine, prepared by keeping glycerine for several hours at a temperature of 160° C., and terminating the operation *in vacuo*. The density found was in accord with that given by Berthelot, namely 1·264. The hydrometer used was specially constructed, and indicated one-tenth of a degree between 25° and 35°. When water is added to concentrated glycerine, a rise in temperature takes place, but the authors ascertained that the chemical action manifested did not interfere appreciably with the results. The density was calculated according to the formulas $1000 \times \delta + x \times 1 = (1000 + x)\delta'$; where $\delta =$ density of the glycerine, $x =$ volume of the water ; $\delta' =$ density of the mixture determined directly. The densities were taken at 15° C. ; but a range of a few degrees above or below does not notably influence the result.

Hydrometer. Weight of litre.	Areometer Degrees Baumé.	Water. Per cent.	Hydrometer. Weight of litre.	Areometer Degrees Baumé.	Water. Per cent.

1236·2	28·7	10·5	...	...	...

Estimation of Organic Matter.—50 grams of glycerine diluted with water are treated with an excess of tribasic acetate of lead, and the precipitate collected on two tared filters, and the lead compound weighed. The whole is then calcined, the residue treated with nitric acid, and then with sulphuric acid ; and from the sulphate of lead is calculated the quantity of oxide of lead that was in combination with organic matters, and consequently the proportion of the latter, which rarely exceeds 1 to 1·5 per cent.

Lime may be estimated in the usual manner by oxalate of ammonia.

The authors consider that industrially the tribasic acetate of lead might be used for the removal of organic matter from crude glycerine. After separation of the precipitate, excess of the lead salt could be removed by a

* *Moniteur Scientifique-Quesneville*, [3], vol. iii. p. 1033.

current of sulphuretted hydrogen, and during the concentration of the glycerine the acetic acid set free would be volatilized without injury to the product. The lead salt might be regenerated by calcination, and again converted into acetate.

A DYING FAITH.

The following remarks appeared in the last number of the *British Medical Journal* in reference to the paper read at the Clinical Society, of which we published a report last week :—

"We had occasion lately to point out that homœopathy, which had begun as a delusion, is now ending as a fraud, This also appears to be the verdict of the Clinical Society of London, delivered on the occasion of an interesting paper by Dr. George Johnson. Dr. George Johnson has the art of provoking interesting debates ; both the Clinical and the Medical and Chirurgical Societies owe to him some of their "best nights." The clinical lectures and the papers of this accomplished physician have always the quality of novelty and sterling thought. It is always either a new fact or a new thought which Dr. Johnson contributes. His paper on "Homœopathic Poisoning by Camphor" was one of the least elaborate of his contributions to medicine ; but he rightly judged that it had considerable collateral interest, and it made the Society the scene of an interesting debate. It has long been known to practitioners in London that persons practising pseudo-homœopathy, and catching the sunshine of whatever fashionable notoriety attaches to that as to other delusive innovations, have in fact long since abandoned all scientific claim to be considered as the apostles of a theory, and have been in the habit of administering the time-honoured medicines in time-honoured doses, and on the ordinary common-sense principles embodied in the maxims, *Contraria contrariis curantur*, and *sublatâ causâ tollitur effectus*. We have all of us heard of, and most of us have seen, patients who, under "homœopathic treatment," have been leeched, poulticed, fomented, and even blistered ; who have had opiates administered to relieve pain, purgatives to remove constipation, iron to remedy anæmia, strychnia and phosphorus to cure nervous paresis or neuralgia, and so on through the whole pharmacopœia and through the whole range of disease. It is less generally known, but it is still known to a great many, that homœopathic pharmacy has undergone a corresponding transition. No doubt there are staunch homœopaths to be found of the old deluded sugar-plum school ; and there are amateur homœopaths, deluded unprofessional persons, to whom nothing stronger than sugar-plums can be entrusted for their zealous and misguided ministrations. But these are the neophytes. Ministrants behind the veil practise other mysteries. Harmless sugar-plums, of absolutely neutral character, and chemically innocent of anything but starch, sugar, and dextrine, are the pellets with which the public are encouraged to play. The enlightened homœopathist of the present day takes the drugs of rational medicine and concentrates them to the furthest extent to which modern chemical skill can furnish the means, and administers them in single drops, apparently in order to maintain the appearance of practising the old delusion after the old seeming method. Great precautions are taken to prevent neophytes from cutting their fingers with these sharp weapons. Persons now asking for the "strong tinctures" and the mother tinctures of nux vomica and belladonna, are politely told that they cannot be furnished without a doctor's order. Reason enough there is for this precaution. Dr. Stewart mentioned at the Society, in the course of the discussion last Friday, that he had occasion to order "tincture of strychnia" for a lady who mentioned that she had some in the house. He suggested, accordingly, that she should take ten drops at stated hours. She mentioned, however, that it was "homœopathic tincture," and so strong that three drops was a dose. Cases in which severe twitchings have followed the domestic use of one-drop doses of a homœopathic tincture of strychnia, in which belladonna-poisoning, with mania lasting for several days, followed the use of a homœopathic tincture of belladonna, and in which dysentery followed the use of a homœopathic aperient drop (probably croton oil), are within our own knowledge. The epoch of dynamisation, of cure by the imperceptible action of inappreciable doses, has merged into a period of concentration and of return in secret to the ancient paths of medicine, trodden over under the disguise of the old war-paint, and with the old outcry.

"There is no question that the homœopathist is a much more dangerous person under his new than in his old disguise. Alkaloids are more dangerous weapons than sugar pellets. The most strenuous efforts will not very long suffice to keep the amateur homœopathist in the dark, and induce him or her to rely for mild domestic ailments on starch and dextrine in globules, put up in variously labelled bottles. The course of nature will do much for anxious relatives. The study of the natural history of disease, and of the tendency of disease towards spontaneous cure, has been largely aided by the earlier homœopathic efforts ; and for this, as for their earnest though overstrained and delusive protests against anything like polypharmacy, we owe them thanks. But this is a vein which may be worked too freely. It cannot, as they and their patients have found to their cost, be followed with invariable success. Mothers will sigh for the mother tincture ; for the tincture of aconite, of which a drop every hour allayed fever ; for the nux vomica, the belladonna, and the jalapine ; and, confounding the plaything with the poison, accidents will happen and the fraud will appear. Mr. Brudenell Carter told, at the Society, an amusing story of the customary practice of a wholesale homœopathic purveyor of globules and his ways, which were dark. The story not long since appeared in print, without authority, and we are glad to have his authority for a statement which is of great value when so authenticated. We are favoured by Dr. Alfred Swaine Taylor with a further communication to the like effect, and of an extremely decisive and weighty character. He has many times examined homœopathic globules, and, in general, has found them to be composed of sugar and starch only—the sugar, sometimes cane or sucrose, and sometimes sugar of milk or lactose.

"In Dr. Smethurst's case, Drs. Taylor and Odling examined sixty-four small tubes of homœopathic globules, averaging fifty-two globules to a grain, and including, as would appear from the attached labels, every variety of mineral and organic poisons and medicines—arsenic, antimony, charcoal, sulphur, arnica, strychnia, morphia, etc. They satisfied themselves of the absence of any trace in the globules of the substances mentioned ; for all the most delicate tests gave negative results. They then mixed up some thousands of the globules with distilled water, and drank off the mixture between them. No effects followed. They used hundreds of the globules in testing, and could easily have found in them the 1·4000th part of a grain of arsenic or mercury. As their tests gave no indication, it was quite obvious that if labels dropped off, or bottles were jumbled together, or the manufacturer put, by mistake, the arsenic label on the strychnine bottle, or *vice versâ*, no one could find out the mistake. In those days, no homœopathist, unless he himself prepared the globules or powders could be sure of what he really was giving to a patient ; and we have yet to learn that there is greater security for the community at the present time. Perhaps the public analysts will look to the matter. There is here an obvious source of public danger which needs to be guarded against. Homœopathists have, in the words of Dr. George Johnson, "passed from the irrational and ludicrous extreme of infinitesimal dilutions to the dangerous extreme of the greatest possible concentration of active and poisonous drugs." Hampered by their partiality for

infinitesimal doses, they usually prescribe none but powerful medicines. As Dr. Stewart expressed it, "being identified in the mind of the public with their own absurdity of infinitesimal doses, and being unwilling publicly to renounce it, they have recourse to concentrated tinctures, in order to produce an appreciable effect by very minute doses." Evidence was adduced before the Clinical Society, of this concentration of strength in modern homœopathic tinctures, solutions, powders, and globules—but especially in the tinctures. The public are kept ignorant of this change, and are using the potent poisons as though they were the original trillionths, which might be either charcoal or arsenic, and might be taken with equal impunity, in doses varying from a globule to a malt-shovelful. Already serious results, even death itself, have arisen from this ignorance of the changed conditions of the case. It were a charity to warn the deluded disciples of this fraud of the dangers they run. Homœopathic medicines, made according to the old plan, can be of no use; when manufactured after the modern fashion, they are the most dangerous (because the most concentrated) medicines which can be handled. The one is a fool's bauble; and the other is a double-edged sword.

It will, of course, be urged by the advocates of homœopathy, that these charges were advanced at the Clinical Society by practitioners interested in the overthrow of the system. We reply, that they were made by men who have the discovery of truth for their object, and who would practise any mode of cure could they ascertain that its principles are based upon sterling facts, capable of standing the test of experiment. They fulfil their duty now in denouncing the fraud, as they fulfilled their duty before, in contemning the delusion which is known as homœopathy.

THE DETECTION OF SOLANINE AND SOLANIDINE.*

BY PROFESSOR FRANCOIS SALMI.

The author, in a memoir presented to the Institute of Bologna, demonstrates that solanine, in an acid solution, and at a temperature beyond 10° or 11°C. is in twenty-four hours decomposed partially into solanidine and other products. After remarking that this decomposition would nearly always take place in the viscera, he points out that although toxicologists are acquainted with some characteristic reactions of solanine, they are as yet unacquainted with the means for detecting solanidine. This has led Professor Salmi to investigate the subject, and to publish in his memoir what he considers to be the most characteristic tests for the presence of solanine and its derivative. The principal reagents for solanine are—

1. Brominated hydrobromic acid, which gives a violet colouration.
2. Dilute sulphuric acid reduces it by eremacausis, giving a violet red colouration.
3. Nitric acid and an alkali give a pale yellow colour.
4. Sulphuric acid and arsenic or phosphoric acid, added successively, give a red colouration.
5. Traces of chloride of platinum give a purple colouration.
6. Phosphoric acid and traces of molybdic acid give the same purple colour.
7. Brominated hydrobromic acid gives rise to long acicular crystals if the combination be treated with water and evaporated to dryness.

Solanidine may be recognized by—

1. The special form of the crystals of its hydrochlorate.
2. The form of the crystals of its hydrobromate.
3. The bright yellow colour which results from the action of nitric acid, and a caustic alkali.
4. The red colour caused by phosphoric acid, and traces of molybdic acid.
5. By the orange-yellow colour produced by brominated hydrobromic acid when the mixture is evaporated to dryness.

Professor Salmi states, that by operating with the care required in such experiments, small quantities of either of these substances may be indubitably detected that would escape observation with any of the processes indicated in treatises on toxicological chemistry.

THE ROSE HARVEST IN ADRIANOPLE.

The following report on the Rose Harvest for 1873 in the vilayet of Adrianople has been received from Mr. Vice-Consul Dupuis:—

Although the rose harvest in this province does not take place at any precise period, still, it is generally expected to commence early in the month of April; but, owing to wet weather and a cloudy spring, this year harvesting operations did not begin till near the end of May. It is also to be remarked that a high temperature in April will cause the rose-buds to develop early, chilly weather retarding the blossoming of the flowers until milder and softer weather sets in.

In cloudy or wet seasons the rose plants blow gradually, and harvesting lasts about a month, when the gathering of the flowers is rendered easy, and operations of distillation are conducted with care and attention; whereas when the weather is dry, only half that time is occupied, and distillation is more rapidly proceeded with. The advantage of a damp season over a dry one consists in a greater yield of oil in the former, when about 8 to 9 okes or 22 to 24 lbs. of the blossoms are required to produce one miscal or 1½ drachm, whilst in the latter 14 to 16 okes or 38 to 44 lbs. of the flowers will barely suffice to produce the same quantity.

In low and sheltered localities the rose tree comes to perfection sooner than in high lands, owing to the greater power of the sun than in elevated positions, where harvesting is naturally more backward.

The harvest this year has, on the whole, been more remunerative to cultivators, and the crop, it is said, will yield in quantity some 500,000 miscals, or about 93,750 ounces of otto or attar of rose, and is valued at about £70,000; but as the weather throughout last spring was moist, distillation was profuse, consequently it is less strong than last year's produce. The best quality of otto varies in price from 17 to 18 piastres the miscal, or from 15*s.* 4*d.* to 16*s.* 10*d.* per ounce; whilst inferior qualities realize from 14 to 15 piastres the miscal, or 13*s.* 1*d.* to 14*s.* the ounce.

The mode adopted for testing the purity of the different qualities of these oils is to put the essence into flasks, which are afterwards immersed in water at a temperature of 63° to 68° F., when if the quality be good it will freeze; this oil is preferred to all others as being of the purest kind. These oils will also greatly differ in quality, according to the nature of the soil. A stony, sandy ground, impregnated with oxide of iron, is said to favour the growth of the plant, and produces oil of the very best quality; while hard, unmixed land will only yield oil of an inferior kind, which will not freeze at 52° F.

Manufacturers also frequently adulterate these oils by an admixture of a substance likewise produced by them from certain kinds of grasses.

Otto of rose is mostly exported to Germany, and buyers and agents from that country annually resort to this province, and make extensive purchases for firms to the amount of upwards of 61,800 ounces, the remainder finding ready markets in the East and Constantinople.

The principal localities where this valuable article is manufactured are in the districts of Kizanlik, Karlowo, Kalofer, Eski-Saara, Jeni-Saara, Tschirpan, and Philipopoli, on the southern slopes of the Balkan mountains, the first-named places being chiefly renowned for their extensive plantations of roses of the most esteemed varieties, viz., the damask rose, sempervirens, and musk rose.

The Pharmaceutical Journal.

SATURDAY, NOVEMBER 29, 1873.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square,*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE ADULTERATION ACT IN ITS RELATION TO DRUGGISTS.

Now that attention is being so much directed to the subject of Adulteration it may be useful if we refer to the opinion which has been frequently expressed in this Journal that the Adulteration Act was likely to become a source of unnecessary annoyance to chemists and druggists. Hitherto, with the exception of the citrate of magnesia case, there has however been little immediate cause for uneasiness on this score; but, as we are informed that several prosecutions of druggists are about to be instituted for the alleged sale of adulterated drugs, there can be no doubt that much anxiety will soon be felt throughout the trade, and it is probable that many will experience the inconvenience and detriment always attendant on a prosecution even when it fails to terminate in conviction.

We think, therefore, that attention should be seriously directed to this danger, and that individually every possible means should be taken to prevent such results. As regards the case of palpable misnomers, we refer our readers especially to the advice offered by Mr. SANDFORD in the letter we publish this week and to the unmistakable tendency of the opinion given by the ATTORNEY-GENERAL and Mr. POLAND in the "Citrate of Magnesia" case.

Over and above this we should urge our readers to institute for themselves systematic examinations of their drugs and chemicals, with the object of ascertaining their quality and purity. Such a course, generally adopted, would contribute towards affording apprentices and assistants that scientific knowledge of their business which it is essential they should give evidence of possessing when they present themselves for examination, and it would conduce much to lessen the number of failures we now have to report from time to time.

We would also strenuously urge the impropriety of relying upon the plea that articles are sold as obtained from wholesale houses or manufacturers, as an extenuation of any deficiency in quality or actual adulteration. Apart from the undignified character of such a defence in a general way, it must be borne in mind that in the case of the grocers magistrates have refused to listen to it, and it may readily be imagined that disinclination to admit such a line of defence would be even more decided in the case of pharmacists who claim to be recognized as the possessors of scientific qualifications.

Even as a matter of expediency, therefore, it is undesirable to adopt such a course, and if it be necessary to illustrate the danger attending it, we could not do better than refer to the 24th section of the Pharmacy Act, which provides that the Act for Preventing the Adulteration of Articles of Food or Drink shall extend to all articles usually taken or sold as medicines, and that every adulteration of any such article shall be deemed an admixture injurious to health; and that any person registered under that Act who sells any such article adulterated shall, unless the contrary be proved, be deemed to have knowledge of such adulteration.

A very brief consideration of the scope of this section will, we believe, be sufficient to convince everyone of the necessity of exercising caution as to the character and purity of the drugs they sell, and of the obligations it imposes in regard to the interests of the public, and to self-protection on the part of the trade.

Some tendency has been manifested in various quarters to move for a repeal of the Adulteration Act, but with such stringent legislative enactments already in force as regards chemists and druggists in the Pharmacy Act, we cannot think there will be any disposition to support such a movement, which, if successful would only facilitate the sale of inferior and adulterated drugs outside the trade, and augment the competition of this kind which they now complain of with too much reason.

PROFESSIONAL REMUNERATION.

IN these days of high prices, increasing general prosperity, and luxurious living, it is not surprising that the medical press should discuss the subject of professional fees. Pharmacy is so intimately associated with the practice of medicine, that whatsoever affects the interests of the doctor, tells more or less on those of the dispenser.

Remembering with a sigh the days when patients swallowed their daily draughts as regularly as they took their meals, we sympathise with the hard-working physician who points to RADCLIFFE'S days, when the prices paid for the necessaries of life were but a fraction of what they have now become; RADCLIFFE consoled himself at the loss of five thousand guineas by saying, that he would be recouped by going up and down an equal number of pairs of stairs, and his neighbour, Dr. GIBBONS, received £1000 per annum from the overflow of patients who were unable to gain admission to the great physician of that time.

There can be no manner of doubt as to the great disproportion between the purchasable value of a guinea now and in the time of Queen ANNE; and if, in the 19th century, this sum be regarded as a comparatively small amount for a physician to receive in his quiet consulting room, how insignificant does the

five shillings fee of the general practitioner appear, especially when we remember that he has to include in his charge nsually either a bottle of mixture, or pills, or both.

It is suggested, that consultation fees shall be increased, at all events, by the leading physicians in large practice to two or three guineas, according to circumstances, and that one fee should cover one consultation only. The latter stipulation is insisted on to prevent injury to the general practitioner, and the degradation of consulting practice. Further, that greater circumspection ought to be exercised as to the class of persons to whom gratuitous advice is given.

It may be doubtful, perhaps, if any benefit would accrue directly to the pharmaceutical chemist or chemist and druggist should these or any other like propositions be adopted by the physician, but should this principle be carried out by all classes of practitioners we think it highly probable that an important indirect gain will result to all engaged in pharmacy. To us it may be a matter of little moment whether the physician receive two guineas or one at a consultation, but the case is otherwise when the general practitioner can obtain a distinct fee of ten or even five shillings for each visit. Will he not under such circumstances be disposed to discontinue the practice of dispensing?

By many, if not the majority, of medical men engaged in active practice, the compounding of medicines is regarded as irksome and objectionable, if not in some respects degrading, and we feel confident that they would gladly welcome such an alteration of fees and professional relations with their patients as would enable them to abandon the custom. During the past few years there have not been wanting signs of the desire of some sections of the profession to sever the connection between medicine and pharmacy; and if an amended scale of fees be agreed upon we may anticipate that this feeling will become general.

Meanwhile we may contemplate the possibility of increased fees to prescribers with a sense of satisfaction and prepare the way for the auspicious times which have been foreshadowed, by discouraging all encroachments on the province of the medical man, and seeking to cultivate with him, without sacrificing our independence, those friendly relations which will conduce most materially to the honour and advantage of the art of healing as well as pharmacy.

THE PROPOSED UNIVERSAL PHARMACOPŒIA.

The question of the introduction of an International Pharmacopœia was discussed at the Third International Medical Congress recently held in Vienna, when the following resolutions were agreed to:—

I. *a*. That the Third International Medical Congress recognizes the necessity for an International Pharmacopœia. *b*. That it should contain the most important and generally accepted medicines, and the more necessary excipients and correctives, together with a precise scientific description and precise declaration of their qualities; that for the text the Latin language should be used; that for denoting proportionate quantities for the compound medicines the decimal system should be used.

II. The Congress recommends that in future the metric system should be used by the prescriber.

III. The Congress entrusts the office bearers of the Fourth International Congress with the organization of an international commission for the Pharmacopœia.

WORKING MEN'S COLLEGE NATURAL HISTORY SOCIETY AND FIELD CLUB.

This Society has now been established, under the Presidency of Professor Flowers, F.R.S., five months, and during this period has had fourteen lectures and papers and thirteen field days. It was formed to enable its members, by means of walks, etc., to study practically the sections of the geological strata to be seen about London, and to learn practically the distribution, habits, and structure of the plants and animals which are found in easily accessible localities.

Lectures are delivered every month upon scientific subjects calculated to interest and inform the members, and papers are read by which members record their observations in the several branches of the Natural History Sciences: in this, as well as for special stndy, the Club has the advantage of being able to use valuable microscopes, an excellent museum of geological and other specimens, and a small library for reference, which the executive of the Working Men's College have placed under their care.

The meetings are held in the College Museum, 45, Great Ormond Street, W.C., and the terms of membership may be obtained on application to Mr. John Fotheringham, the Honorary Secretary. A lecture on the "Dead Nettle and its Alliances," by Mr. C. J. Savage, is announced for Tuesday, Dec. 2.

We are informed by the *Athenæum* that, at a sale in Mincing Lane, a few days since, a lot of mossed Crown bark (*Cinchona officinalis*), from the Nilgheri plantations fetched the "prodigious price" of 5*s*. 9*d*. per lb. Altogether 23,646 lbs. of Nilgheri cinchona bark were sold on that occasion, the total sum realized being £3350, or an average of 2*s*. 10*d*. per lb. The same journal states, that the total cost of the introduction of the cinchona into India, including the expenses of Mr. Clements Markham's expeditions to Peru and India, has been £70,000, and that the annual sales now realize a net profit of from £4000 to £5000 per annum.

The Royal Society has this year awarded the Copley medal to Professor Helmholtz, of Berlin. One of the two Royal Medals usually given has been awarded to H. E. Roscoe, F.R.S., Professor of Chemistry in Owens College, Manchester, and the other to Dr. Allman, Professor of Biology in the University of Edinburgh.

Mr. C. R. C. Tichborne, Ph.D., F.C.S., has been appointed Professor of Chemistry in the Carmichael School of Medicine (Richmond Hospital), Dublin.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

November 19th, 20th, and 21st, 1873.

Present—Messrs. Allchin, Barnes, Carteighe, Corder, Cracknell, Davenport, Gale, Hills, Linford, Martindale, Schweitzer, Southall, and Umney.

MAJOR EXAMINATION.

Four candidates were examined. *One* failed. The following *three* passed, and were declared duly qualified to be registered as Pharmaceutical Chemists :—

*Bird, Matthew Mitchell .....King's Lynn.
Wood, Alexander .....Brentford.
Gardner, James Richard .....Devonport.

MINOR EXAMINATION.

Seventy-seven candidates were examined. *Thirty-eight* failed. The following *thirty-nine* passed, and were declared duly qualified to be registered as Chemists and Druggists :—

*Spencer, James Hampson .....Manchester.
*Strongitharm, William George Birmingham.
Princep, Philip .....Uppingham.
Marlow, Frederick William.....Coventry.
Balchin, Edwin Samuel .....Devizes.
Higginson, Alfred..... .....Manchester.
Stamford, Frederick .....St. Austell.
Equal. Macaulay, Joseph John .....Manchester.
Equal. Wright, Conrad William .....Tewkesbury.
New, Thomas Cheney .....Evesham.
Hucklebridge, James Marwood London.
Equal. Swinbank, John.....Heighington.
Equal. White, Robert .....Durham.
Watson, Joseph Henry .....Halifax.
Jarvis, Abraham .....Kingsbridge.
Ellis, Thomas Wokes .....Hull.
Bradwall, John Heald .....Sheffield Moor.
Jones, Walter .....Carmarthen.
Lewis, Samuel Edward.....Liverpool.
Morris, Thomas Henry Vaughan Dorchester.
Equal. Evans, John ....Bishop's Road, W.
Equal. Equal. Smith, William .....Norwich.
Equal. Equal. Williams, Richard .....St. Clear's.
Equal. Masters, Henry James.....Bath.
Equal. Sawden, Alfred..... .....Filey.
Purse, Alfred Dodds .....Sunderland.
Hayton, John William..... ...Wigton.
Equal. Crang, Walter .....Bath.
Equal. Harrison, James ....Sunderland.
Griffiths, Griffith .....Barmouth.
Hindson, James Alfred .. ..Hull.
Maxey, John Thomas .....Wisbeach.
Equal. Compton, Arthur .....Reigate.
Equal. Hall, Henry Stacey ..... Doncaster.
James, Joseph .....Hanley.
Sutcliffe, Edward West .....London.
Brooks, Charles.....Wandsworth Road.
Fisher, Sidney .....Wolverhampton.
Casely, Thomas.....Liverpool.

The above names are arranged in order of merit.

PRELIMINARY EXAMINATION.

A certificate of the Apothecaries' Hall of Ireland was accepted from

McDermott, Philip .....Bermondsey

in lieu of the Society's examination.

* Passed with Honours.

Provincial Transactions.

NORTHAMPTON PHARMACEUTICAL ASSOCIATION.

At a special meeting held in the College Street Room, on November 12, 1873, Mr. A. J. Lance read a paper on Light, describing the corpuscular and undulatory theories, the solar spectrum, the chemical and heat rays, the effect light has upon vegetative life, how by its agency plants form chlorophyll gums, oils, etc., the effect produced upon animals by the deprivation of light, and the practical application of the power possessed by chemical rays in photography. The discussion was taken up with much interest.

An adjourned meeting was held on November 19 ; Mr. H. J. Masters in the chair.

The Secretary, Mr. Druce, read the minutes, and said Mr. Osborne had given them a very ingenious apparatus for operating with sulphuretted hydrogen.

Mr. Masters trusted the members would show their appreciation of "the really excellent programme of classes," by coming as early and as frequently as possible to those classes.

Mr. Masters delivered a very interesting and instructive paper on Iron, giving its history, how it is found in nature, meteoric iron, and the different ores and their composition. Having noticed the ancient use of iron, the speaker instanced the Forest of Dean, in which the iron was worked by the Danes, but in such a wasteful manner that the refuse furnished sufficient work for twenty blast furnaces during many years. He then described the blast furnace, the smelting and puddling processes, the Bessemer process, the difference between wrought and cast iron and steel. Having alluded to the works going on in their own neighbourhood, where the ferrous carbonate was worked, and to the strength and ductility of a mixture of that and the Welsh argillaceous ore, he concluded by explaining the manner in which iron was rolled, welded, turned, converted into steel, and to the multifarious uses to which it was put.

The lecture was copiously illustrated by some handsome specimens kindly lent by Samuel Sharp, Esq., F.S.A., of Dallington Hall, which included Brown Hematite $Fe_4H_6O_9$, Red Hematite Fe_2O_3, Iron Sand from Africa containing 93 per cent. of metallic iron, Specular Iron Ore Fe_2O_3, Bog Iron, and the Northamptonshire Ore $FeCO_3$; also some handsome Pyrites FeS_2, containing belemnites, ammonites, and other fossils. One very fine specimen exhibited showing a most beautiful radiating section.

Messrs. Harrison and Clayton also sent samples of pig iron, cast and wrought iron, turnings and filings, crude and polished steel. J. W. Wood, Esq., lent iron ores, fossiliferous pyrites and selenite (sulphate of lime) from the Northamptonshire beds ; and Mr. Druce, native metallic iron from trap rock, and cubical iron pyrites from the slate in Westmoreland and Carnarvonshire.

A vote of thanks was proposed by Mr. Wallis to Mr. Masters, and which, with one to S. Sharp, Esq., and the other exhibitors, having been most cordially passed, the meeting terminated, the lateness of the hour precluding discussion.

BRISTOL PHARMACEUTICAL ASSOCIATION.

The second general meeting of the present session was held at the Bristol Museum and Library, on Friday, Nov. 14, 1873, Mr. G. F. Schacht, President, in the chair. Mr. Louis Siebold, of Manchester, delivered a lecture on "Volumetric Analysis," of which the following is an abstract :—

VOLUMETRIC ANALYSIS.

BY LOUIS SIEBOLD.

After commencing with a few general observations on quantitative analysis and the comparative merits of

the ponderal and volumetric methods of determination, the lecturer pointed out that it could not be his intention to explain all the numerous instances of volumetric testing, but that he would confine himself to the illustration of a small number of instructive and very useful instances of that kind, calculated to show their practical value, and to convince the students of pharmacy that quantitative analytical operations do not present such difficulties as many suppose.

Having shown and described the various instruments used for volumetric estimations, he proceeded to show the determination of chlorine in chloride of sodium by means of a standard solution of nitrate of silver. To mark the end of the reaction, a few drops of a strong solution of yellow chromate of potassium were added to the solution of NaCl before applying the test. The nitrate of silver then added gradually from the burette produced a white precipitate of AgCl, and the first drop used in excess after the complete precipitation of Cl caused the mixture to turn red from the formation of Ag_2CrO_4. The use of K_2CrO_4 for the end reaction requires that the solutions must be neutral.

The application of a standard solution of $AgNO_3$ for determining the strength of hydrocyanic acid was explained next. The HCN used for the experiment is mixed with sufficient solution of NaHO to produce distinct alkaline reaction, and to this mixture, containing NaCy, the silver solution is added drop by drop until a permanent white precipitate of AgCy is formed. At first, a soluble double salt, $NaAgCy_2$, is formed, thus :—

$$AgNO_3 + 2NaCy = NaNO_3 + NaAgCy_2.$$

This action proceeds until one half the Cy contained in the HCN is used up; the next drop of solution of $AgNO_3$ causes the formation of a permanent precipitate,

$$NaAgCy_2 + AgNO_3 = NaNO_3 + 2AgCy.$$

To make the end of the reaction more distinct it is useful to add some solution of NaCl after the addition of NaHO to the HCN. The permanent precipitate forming then is AgCl, which shows more distinctly than the AgCy.

Mr. Siebold then explained how a standard solution of $AgNO_3$ might be used for the determination of K and Na in a mixture of their chlorides, or of others of their salts convertible into chlorides. The dry chlorides of K and Na must be weighed, then dissolved in water, and the chlorine estimated by $AgNO_3$, with the aid of K_2CrO_4, as above. Now, if m were to represent the weight of the two chlorides, and n the quantity of Cl found by volumetric analysis, and if we call the quantity of KCl x, and the quantity of NaCl y, we need only remember that one part of KCl contains 0·4756 Cl, and that one part of NaCl contains 0·6066 Cl, in order to get the two following equations :—

$$x + y = m.$$
$$0{\cdot}4756\,x + 0{\cdot}6066y = n.$$

From which the values of x and y or the quantities of KCl and NaCl may be easily calculated.

In a similar way, the standard solution of $AgNO_3$ might be used for the analysis of a mixture of KCl and KI, or of KI and KBr, showing the extent to which KI may be adulterated with KBr or KCl.

From this the lecturer turned to the determination of iron in ferrous solutions by permanganate of potassium, showing this as an instance in which the substance to be determined was not precipitated, and in which the end of the reaction was indicated by a change of colour in the solution. A solution of ferrous sulphate, acidulated by H_2SO_4, was used, and the solution of $KMnO_4$ added drop by drop as long as the colour of the latter still disappeared. After all the ferrous sulphate had been completely converted into ferric sulphate, a single drop more of the permanganate sufficed to impart a purplish tint to the mixture.

$$10feSO_4 + 8H_2SO_4 + 2KMnO_4 = 5fe_2(SO_4)_3 + 2MnSO_4 + K_2SO_4 + 8H_2O.$$

Mr. Siebold said he much preferred the permanganate to the red chromate recommended in the B.P. as being more exact and easier for recognizing the end of the reaction. The B.P. process was explained by the following equations :—

$$6feSO_4 + K_2Cr_2O_7 + 7H_2SO_4 = 3fe_2(SO_4)_3 + K_2SO_4 + Cr_2(SO_4)_3 + 7H_2O.$$

Owing to the formation of $Cr_2(SO_4)_3$ the mixture assumes a green colour, and as soon as a drop of the mixture ceases to turn blue with a drop of a solution of ferrocyanide of potassium (united with it on a plate by means of a glass rod) the experiment is finished.

The next determination performed by the lecturer was that of the strength of sulphurous acid by a standard solution of iodine (a solution of I and KI in water). The H_2SO_3 is mixed with a little thin starch paste, and the iodine solution then added until a permanent blue colour is produced. At first the iodine does not act on the starch, as in converting the sulphurous acid into sulphuric acid, it forms hydriodic acid which has no action on starch, but as soon as this process is completed the further addition of iodine produces the deep blue iodide of starch.

$$H_2SO_3 + 2I + H_2O = H_2SO_4 + 2HI.$$

The change from colourless to blue was brought about by a single drop of the solution of iodine.

The estimation of available chlorine in chlorinated lime formed the subject of the next experiment. The lecturer explained that the entire quantity of chlorine contained in that preparation is liberated by mineral acids, provided that its two constituents, calcium hypochlorite $CaCl_2O_2$ and calcium chloride $CaCl_2$, are present in equivalent proportions, as is generally the case.

$$CaCl_2O_2 + CaCl_2 + 4HCl = 2CaCl_2 + 2H_2O + 4Cl, \text{ or}$$
$$CaCl_2O_2 + CaCl_2 + 2H_2SO_4 = 2CaSO_4 + 2H_2O + 4Cl.$$

A weighed quantity of chlorinated lime was then dissolved, mixed solution of KI in excess and the mixture acidified with HCl.

The available chlorine present would thus liberate its equivalent amount of iodine, forming KCl and I and the quantity of free iodine was now determined by means of a standard solution of sodium hyposulphite $NO_2S_2O_3$ which was added drop by drop until the solution became colourless, showing that the free iodine had been completely converted into NaI.

$$2Na_2S_2O_3 + 2I = Na_2S_4O_6 + 2NaI.$$

One molecular weight of $Na_2S_2O_3$ thus indicates one atomatic weight of iodine, liberated by one atomatic weight of available chlorine contained in the chlorinated lime.

Penot's method of estimating the quantity of Cl in chlorinated lime was also mentioned. It is based on the fact that arsenious acid in alkaline solution is converted into arsenic acid by chlorine.

$$H_3AsO_3 + 2Cl + H_2O = H_3AsO_4 + 2HCl.$$

The arsenious acid with the requisite quantity of Na_2CO_3 is dissolved in water so as to obtain a solution of known strength which is added from a burette drop by drop to the solution of a weighed quantity of chlorinated lime until a drop of the mixture placed on a piece of iodized starch paper ceases to turn the latter blue, showing that all the Cl has been consumed for converting the H_3AsO_3 into H_3AsO_4.

An experimental illustration was then given of the estimation of silver, and particularly of small quantities of that metal, by means of a standard solution of iodide of starch, whose strength was previously ascertained by a standard solution of $AgNO_3$.

The quantity of silver present in a solution of $AgNO_3$ was now determined by mixing the latter with some precipitated calcium carbonate, and then adding the standard solution of iodide of starch. Iodide of silver being thus

formed, the deep-blue test solution could not impart any colour to the mixture before all the Ag had been precipitated as AgI, but this being accomplished, the further addition of iodide of starch turned the mixture greenish blue. The $CaCO_3$ was required to prevent the formation of free HNO_3.

Mr. Siebold strongly recommended this method for determining the amount of silver in coins, and in alloys of silver with copper generally :—0·5 gramme of the alloy is to be dissolved in $AgNO_3$; sufficient water added to make up 100 c.c., and the quantity of silver estimated in 5 c.c. of this solution by mixing with $CaCO_3$, and adding the standard solution of iodide of starch.

Having thus shown a number of instances of volumetric testing, in which the end of the reaction is recognized by a visible change of colour, or by the formation of a permanent precipitate, the lecturer then alluded to cases in which repeated filtrations were necessary in order to see whether complete precipitation of a substance had taken place or not, and as an instance of this kind he selected the determination of phosphoric acid in phosphates by means of a standard solution of ferric chloride. A solution containing sodium phosphate was mixed with a solution of sodium acetate and some acetic acid, and the fe_2Cl_6 added from a burette. After all the phosphoric acid is precipitated in the shape of white ferric phosphate, the filtrate would form a blue precipitate on the addition of ferrocyanide of potassium. The latter can only be added to the filtrate, and not to the unfiltered liquid, as the precipitated ferric phosphate would also turn blue with the K_4FeCy_6, but in order to avoid great loss in filtering, and to be able to filter and test a single drop at a time, a piece of paper is soaked in a solution of K_4FeCy_6, spread upon a china slab or plate, and drops of the liquid under examination are brought by means of a glass rod on small pieces of doubled filtering paper placed upon the paper saturated with ferrocyanide. The ferric phosphate will thus be left on the small pieces of doubled filtering paper, whilst a clear liquid will pass through and produce a blue spot on the ferrocyanide paper as soon as fe_2Cl_6 has been used in excess. A second determination may be needed to assure a perfectly accurate result. The action of the Fe_2Cl_3 was explained by the following equation :—

$$Fe_2Cl_6 + 2Na_2HPO_4 + 2NaC_2H_3O_2 = Fe_2(PO_4)_2 + 6NaCl + 2HC_2H_3O_2.$$

Mr. Siebold thought that the experiments which he had the pleasure of performing would convince all students present that quantitative analyses by the volumetric methods were quite within their reach, and if fairly studied and practised would enable them not only to test the strength of the various chemical preparations used in pharmacy, but also to test the correctness of the many new volumetric methods proposed and published in the journals, and to render good service to science by assisting in this important process of sifting. He had even known students succeed in discovering new analytical methods, and this might be more generally the case if they (the students) would devote themselves with greater energy to the practical and theoretical study of chemical science.

The lecturer concluded his remarks by expressing a hope that by the end of this memorable century the records of its scientific labours would include the names of many who are now students of pharmacy.

HALIFAX CHEMISTS AND DRUGGISTS' ASSOCIATION.

A meeting of the above Society took place on Friday, Nov. 21, Mr. Jessop, President, in the chair. After the minutes of last meeting had been confirmed, the President brought under the notice of the meeting the recent conviction under the Adulteration Act. While he thought that a change of label, as had been suggested, would place members of the trade in safety, yet there were so many drugs and preparations in the same category as citrate of magnesia, and they were at the mercy of wholesale druggists to so large an extent, that he thought it was important to discuss the subject, and he would be glad to hear the opinion of members with respect to it. Eventually, on the motion of Mr. James Farr, seconded by Mr. Blade, the following resolution was carried unanimously, viz. :—

> "That, as regards the recent conviction, and penalty of £10, for an alleged infringement of the Adulteration Act, against a London druggist, for the sale of the so-called citrate of magnesia, this meeting is of opinion that the said conviction was unjust, and the penalty excessive, and is further of opinion that it should be the duty of the Pharmaceutical Council, representing the trade, to take such steps for the future as may be deemed advisable, to prevent so flagrant a decision, with respect to the sale of drugs, being given; and failing this, to endeavour to obtain an amendment of the said Act."

The Honorary Secretary then read the balance sheet of the finances, showing a surplus in favour of the Society of £5 3*s*. 6*d*. After arranging for future meetings, and appointing Mr. Hebden as a delegate to represent the body at the annual dinner of a kindred society, Mr. Farr moved, and Mr. Brierley seconded, the following resolution :—

> "That a photographic album be purchased for the reception of the *cartes de visite* of members and of eminent pharmaceutical chemists, and that Messrs. Brook and Hebden be appointed to collect and arrange the same."

Mr. J. B. Brierley then gave notice that he would call the attention of the members at the next meeting to the desirability of supporting and assisting any member who may be prosecuted under the provisions of the Adulteration Act, subject to certain rules and regulations, a copy of which shall be sent to each member prior to the meeting.

Proceedings of Scientific Societies.

PHILADELPHIA COLLEGE OF PHARMACY.

A pharmaceutical meeting in connection with this College was held on Tuesday, October 21, under the presidency of Mr. Dillwyn Parrish.

Mr. Clemmons Parrish having tendered his resignation as Registrar, Mr. Joseph P. Remington was elected to succeed him in that office.

Adulterated Oil of Gaultheria.

Dr. W. H. Pile called attention to a sample of adulterated oil of gaultheria, which seems now to be pressing on the United States' market. The adulterating substance he found to be chloroform, and the means adopted for detecting the fraud were, first, by taking the specific gravity, and, secondly, noting the boiling-point. The specific gravity of true oil of gaultheria is 1·18, whilst that of the sample in question was 1·24. The boiling-point of the true oil is 400° F., whilst the adulterated oil boiled actively at 200° F. By shaking the adulterated oil in a test-tube, after slightly warming, the odour of chloroform is distinctly apparent. He ascertained that this impurity existed in the oil in the proportion of 1 part of chloroform to 4 parts of oil, and his mode of arriving at the quantitative estimation consisted in mixing certain proportions of chloroform and oil together until he obtained the same specific gravity as the adulterated sample had.

Mr. Charles Bullock stated that he had met with two cans of the oil, which he thought probably belonged to the same lot as that mentioned by Dr. Pile, and he exhibited a very neat and convenient little apparatus for detecting and separating the mixed liquids by fractional distillation.

It consisted of a small glass flask, into which the oil was poured; a bulb-like stopper, having a tubulure at the top, which had a rather long tube leading from it at a similar angle to that usually seen in alembics, and a thermometer, which passed through the tubulure and into the bulb of the stopper. If heat be now applied to the flask, the temperature of the vapour which fills the bulb, and is being condensed, can easily be read off. By this method Mr. Bullock was able to separate the chloroform from the oil, and he also found that it contained a very large portion of oil of sassafras. The manner in which the oil had been made seemed to have been: Take 4 or 5 lbs. oil of sassafras, 1 lb. oil of gaultheria, and chloroform sufficient quantity to bring up the specific gravity to the right point.

Professor Maisch, speaking of oil of gaultheria adulterated with oil of sassafras, said that when oil so adulterated is treated in the cold with commercial nitric acid, a deep red resinous mass separates, whilst the pure oil of gaultheria is not coloured by it.

Mr. Charles Bullock reported that, having some suspicions that the heavy lubricating coal oils were used for the purposes of adulteration, he took the specific gravity of one of the most dense in the market, and found it to be only ·883; he regarded them on this account unfit for the purpose.

Pareira Brava.

Professor Maisch exhibited three samples of Pareira Brava, two of which differed from the kind usually seen in commerce of late years, and a sample of the real Pareira, which has been proved by Mr. Daniel Hanbury to be produced by *Chondodendron tomentosum*. The three spurious Pareiras, all of which were mentioned in Mr. Hanbury's paper, were the usual commercial variety, with the layers of wood in more or less excentric layers. a sample of a bright yellow colour internally, with the wood developed almost altogether in one direction, and a sample nearly tasteless, the wood of which is in more concentric layers. The sources of these three kinds are unknown, but all are derived from plants of the order Menispermaceæ.

Spurious Quinine.

Mr. Gaillard spoke of having received a sample of what purported to be French quinine, from a friend in the South, who had been offered the article at a very low price, and had sent him a portion to ascertain why it could be sold so low. It proved to be the old fraud—muriate of cinchonine.

This fraud was brought before the American Pharmaceutical Association at Richmond by Professor Maisch, when Dr. Squibb said that some of the quinine manufacturers were in part responsible for it, as they disposed indiscriminately of the large quantities of cinchonine salts obtained in their operations. This has led to a disclaimer in the *Circular of the Philadelphia Drug Exchange*, which was read to the meeting by Professor Maisch, to the following effect:—

"We take occasion to say that, so far as *American* manufacturers of sulphate of quinine are concerned (1), they do not dispose of the cinchonine salts indiscriminately to any who apply for them, but only to regular customers who pay for them; and (2), so far from being responsible for this attempt to defraud the people, they purposely avoid handling *muriate of cinchonine*—they do not make the article.

"We consider that this statement is eminently due to our friends who make sulphate of quinine here, for they have not only declined making, but refuse to deal in, the article of *muriate of cinchonine*, on account of its close resemblance to *sulphate of quinine*.

"*Muriate of cinchonine* is largely sold in *Europe*, but not in this country, so far as sulphate of quinine manufacturers are interested."

It was suggested that advantage might be taken of the condition of affairs to ascertain what virtues muriate of cinchonine possesses as an antiperiodic.

Diluted Phosphoric Acid.

Mr. Joseph P. Remington introduced the subject of Diluted Phosphoric Acid, and gave the results of an experiment based on a fact mentioned to him by Professor Maisch, in which it was shown that diluted phosphoric acid, made from the phosphorus direct, according to the U. S. Pharmacopœia, would make a clear solution when mixed with an equal quantity of tincture of chloride of iron, whilst that made from the glacial phosphoric acid produced a precipitate when similarly mixed.

Professor Maisch stated that it required repeated treatment with nitric acid in the manner laid down in the second formula of the U. S. Pharmacopœia, in order to convert thoroughly the monobasic into the tribasic variety.

CHEMICAL SOCIETY.

Thursday, 20th November, 1873. Dr. Odling, F.R.S., President, in the chair. The names of visitors having been announced, and the minutes of the previous meeting read and confirmed, a paper, "On the Co-efficient of Expansion of Carbon Disulphide," by J. B. Hannay, was read by the Secretary. Dr. Russell then communicated his researches "On the Action of Hydrogen on Silver Nitrate," giving an account of the precipitation of metallic silver in the crystalline state by means of hydrogen. There were also a "Note on the Action of Zinc Chloride on Codeine," by Dr. C. R. A. Wright; "On the Chemical Properties of Ammoniated Ammonia Nitrate," by E. Divers, M.D.; and "On the Analysis of a Meteoric Stone, and the Detection of Vanadium in it," by R. Apjohn. The meeting was finally adjourned until Thursday, 4th December.

Parliamentary and Law Proceedings.

Prosecutions under the Adulteration Act.

The Alleged Presence of Iron Filings in Tea.

At the Birmingham Police Court, on Thursday, November 20, before Mr. Kynnersley, the hearing of summonses against several grocers for selling adulterated tea was resumed. In one case several scientific men were called upon to give evidence as to the alleged presence of iron filings in a sample.

John Smith was charged with selling a quarter of a pound of black tea that had been adulterated. Mr. Young prosecuted and Mr. Rowlands was for the defence.

Evidence having been given as to the purchase of the tea, Dr. Hill said he received a sample of tea marked 52 from Mr. Woolley. He first of all inspected it with his eye. He saw that it was adulterated with particles of matter which were not tea. They were broken up masses of leaves and stones, more or less irregular in shape, bound together by some adhesive material. He observed on looking at the tea that it was faced with plumbago; such a facing was very easily discovered with the naked eye. He was not aware that plumbago was injurious to health. He next incinerated five grammes. The ash weighed 11·74 per cent. of the tea, or 5·4 per cent. above the normal weight of tea ash. He tested the ash with the magnet, and found it largely attractive. He separated the attractive particles from the ash, and dissolved them in hydrochloric acid, when he obtained a solution of iron, and estimated the quantity of iron by means of a solution of bichromate of potash of known strength. The weight was determined by volumetric analysis. The particles consisted partly of metallic iron, and partly of a crystalline iron mineral. He was able to say they were metal because they effervesced under the hydrochloric acid. He tried the particles with ferrocyanide, and ferricyanide of potassium and found indications of iron. He came to the conclusion that it was iron first when it effervesced under the acid. Carbon would not effervesce; carbonate

would. Carbonate of lime would effervesce, but not in the same way as the iron. The lime would effervesce much quicker than the iron. Common oxide, in connection with some carbonate, would cause effervescence. He would not say the particles were iron filings only because they adhered to the maguet. It was highly improbable that particles of matter drawn up by the magnet from the dry tea would contain carbonate. Peroxide was found in the ash of genuine teas. He did not think it would come from the pans in which the tea was dried; he thought it would be taken up by the plant from the earth in its vital processes. He felt sure that the tea was not dried on red-hot iron pans. He did not find pieces of quartz in the particles that adhered to the magnet. If iron filings were filed off malleable iron they would be malleable, if off cast iron they would not. He had not a sufficient quantity of them to test whether they were malleable or not. There was no doubt that iron-filings would grate between two pieces of glass if rubbed; they would not be pulverized. Magnetic iron would decompose bichloride of mercury; magnetic oxide would not. Metallic iron would precipitate copper, when treated with sulphate of copper. That was a capital test of the presence of metallic iron, but it was not an incontestable test, because other things would throw down copper. Zinc would do so. He was aware that there was a large quantity of magnetic oxide in the earth, but he did not think that it would adhere to the leaves of the tea when they were growing. He believed that pure tea might be bought for 16*d.* a pound. He thought the leaves gathered from the tea plant within a foot of the ground would not be splashed with dirt from the rain. The genuine tea in such a case would be as liable to become splashed as the adulterated tea. He found the sand in these teas rolled up in the leaves. If sand was thrown into a chest of tea in bulk it would be liable to fall to the bottom of the chest, but some of the leaves would retain pellets. He believed that in this tea the sand had been put in in two ways, by being rolled up in the leaves and by being put into it in bulk. He found lye tea in every one of the samples in regard to which action had been taken. The supposition that such large particles of quartz sand as he found adhered to the tea-leaves by being splashed up by rain, or when blown upon by the wind, was an absurdity. The percentage of sand and silica in this tea was 4·74 above the normal quantity.

Mr. Wentworth Lascelles Scott said he received a sample of tea on 16th September. He first tried it with the magnet. A few small particles adhered. These he mixed with the tea, and then weighed 100 grains of tea from the sample, and tried them with the magnet a second time. Out of the 100 grains he got magnetic particles weighing 0·341, by means of the magnet. Next he burned off at a low temperature anything there might be of an organic character about the particles. The weight of the remainder amounted to 0·57. This residue was very magnetic. In his opinion, the magnetic particles contained no portion of metallic iron whatsoever, but were some magnetic form of combined iron.

Mr. Kynnersley: The question was asked the other day whether burning would not convert the iron into oxide.

Witness said it would convert into oxide only superficially. It would continue to be magnetic in a great measure. There would be a portion of iron unoxidized inside the outer crust of oxidized iron and retaining its metallic character. He examined the particles with a microscope, and was confident that they were distinct from iron filings. They presented no marks of tools, such as iron-filings did. They had no torn appearance or "pulled-bready" look which iron filings had. Some of these particles when magnified looked like ordinary pebbles—some of them presenting a smooth, rounded, water-worn surface, others presenting a flattened, cindery appearance, like iron scales, and a third variety presented the appearance of perfect octahedral crystals. He had frequently observed the octahedral form amongst particles of magnetic oxide. He had examined several magnetic minerals and sands with the microscope, and found similar appearances to those presented by the particles from the tea. He tried the tea with bichloride of mercury, and next with sulphate of copper, without any result. This showed him that they were not iron filings. With dilute hydrochloric acid there was no effervescence, but he had taken the precaution to damp the particles first of all with pure water, in order to divest them of any little adherent air bubbles that might rise up when the particles were put into the acid, and be mistaken for effervescence. Iron filings when rubbed in an agate mortar threw off a bright lustre. They were more or less malleable, whether from cast or wrought iron, provided the pressure was sufficient. On the contrary, magnetic oxide or iron, from whatever source derived, was capable of being ground into a fine powder, and did not give any metallic or bright-looking lustre streak. Iron filings were incapable of being ground to powder in that way. Rubbed between surfaces of plate glass, iron filings would be carried along the glass without cutting the glass, or being themselves broken up, whereas magnetite or magnetic oxide of iron would themselves grind, and in many instances, more especially where they were in a crystalline form, such as those small octahedral crystals, they would cut the glass and scratch it. He could reduce the magnetic particles which he found in the tea to a powder, by grinding them between pieces of unglazed porcelain. It was almost impossible to gather vegetables without magnetic oxide. To do so, the weather would have to be extremely favourable. He had found larger particles of sand on several kinds of leaves—strawberry leaves, beech leaves, etc.—than those produced by Dr. Hill.

Mr. William Phillips Horn said he received a sample of tea from one of defendants' shop assistants on the 14th instant. He found magnetic particles in it. He took three samples of 100 grains each, and burned them. The ash weighed in each case respectively 9·738, 9·339, and 8·438, giving a mean of 9·171. The amount of magnetic particles present was 1·130, 1·000, and 1·312; mean, 1·147. Upon treating the remaining ash, which was silica, with hydrochloric acid to dissolve any earthy matter, the results were—2·471, 2·671, and 1·840; mean, 2·327. It was a most difficult thing to get three samples of tea alike, even from the same bulk, and this accounted for the differences in his results. He believed the magnetic particles were derived in part from the iron pans in which the tea was treated; and were partly attached to the leaves mechanically, being derived from the soil in which the tea grew. He had tried the particles in a steel mortar, and they became powder, whereas iron filings, when tried in the same way, became flattened iron plates. He had tried several other tests, all of which led him to the result that there was no metallic iron in the tea, except in combination, and in the shape of magnetic oxide.

The Court adjourned till the next day.

On the following day—

Mr. Alfred Bird, chemist, said he received a sample of tea from one of Mr. Smith's shop assistants. He burned 100 grains, and found the ash to be 10 grains. He washed the ash, when it lost 4 grains. The remaining 6 grains showed 0·22 magnetic oxide of iron, silica 1 grain, leaving a net residue of 4·78 of earthy matter. When tried with hydrochloric acid the 0·22 magnetic oxide threw off no hydrogen gas, nor was there any effervescence. He also tried the sulphate of copper test, and no copper was precipitated. He tried some rusty iron filings with the sulphate of copper, and they precipitated copper. He believed the magnetic oxide in the tea had been wafted upon the leaves when the tea was growing, and had been collected along with the tea. He believed it was possible for magnetic oxide to become attached to the leaves in the course of their vegetation. The amount of silica in the ash of a great many plants

which he had examined was from 3 to 7 per cent. Senna contained about 6 per cent. Although the difference between his result and that of Dr. Hill in regard to magnetic oxide was as 0·22 and 1·46, the samples might be taken from the same bulk. He believed that if twenty persons were to take samples of tea from the same chest, the analysis of three of them would not agree.

Dr. Wrightson said he had analysed a sample of tea brought to him by one of Mr. Smith's assistants. He took 50 grammes of the leaves and mixed them in cold water, in which he allowed them to remain for three days. This allowed the sandy matter to subside. Having decanted the tea leaves, he weighed the residual matter—the dirt—and found it to be 1·15 per cent. On examining this with his eye and a glass, he observed quartz, talc, and apparently some ferruginous particles, and also a portion of coaly matter or ash—a heterogeneous mixture, in fact, such as he should not have expected to be used as an adulterant. He next examined a second portion of the sample with the microscope, and did not discover any metallic particles. From a ¼lb. of tea he extracted 15½ grains, or about 1 per cent., of magnetic particles, which were readily soluble in not very dilute hydrochloric acid. He tested the magnetic particles first by mixing them with a small quantity of nitric acid in a tube—adding a little sulphuric acid. The absence of smell or appearance of brown fumes showed the absence of metal. Secondly, he took a little of the substance, and placed it in a dish. He put hydrochloric acid upon it, and warmed the mixture. The substance dissolved readily, without the slightest evolution of gas, and in the solution he detected iron in the state of protoxide by means of red prussiate of potash. Peroxide was discovered in it by yellow prussiate. That the peroxide and protoxide were chemically combined in the substance was proved by its being magnetic. The substance was therefore magnetic oxide of iron without any metallic iron. This showed that there were no iron filings present. Witness thought that magnetic oxide was the last thing in the world that a Chinaman would use to adulterate tea. He incinerated a portion of the tea, and found the ash to weigh 8 per cent. of the tea. Upon analysing the ash, he found it contained 19·6 per cent. of silica, 9 of phosphoric acid, 7 of lime, 4·58 of magnesia, and 5·65 of peroxide. There was about 40 per cent. of potash and soda also in the ash, and the remaining 15 parts were made up of sulphuric acid, chlorine, traces of manganese, and other things. All these were proper constituents of the tea ash, with the exception of a little excess of sand or silica—perhaps to the extent of 3 or 4 per cent. The analyses of plants varied very considerably according to the character of the soil in which the plants grew—whether sandy, loamy, or alluvial; so did the character of the ash. The older the plant the greater the amount of ash. There was no more sand in the tea than he could conceive to be accounted for by natural or accidental causes.

Mr. Martin Murphy said he had received a sample of tea from Mr. Smith. He did not notice any plumbago facing upon the tea. He had put a portion of it into water, and let it stand until the earthy matter fell to the bottom. Out of 50 grammes of tea he got 0·9 gramme of sediment, which he dried. He found oxide of iron or rust in the sediment, but no metallic iron. He explained other tests which he applied, showing that there was no metallic iron present.

Mr. W. Phillips Horn was called. Witness said that since the previous day he had examined his sample of tea very minutely for lye tea. He found a number of spherical masses in the tea, and produced twenty-five of them. (Those produced were pretty similar to those brought forward by Dr. Hill.) He found fifty of these masses altogether, in about half-a-pound of tea. He examined twenty-five of them. His opinion was that they were not the so-called lye tea. The greater part of them consisted of whole leaves, and the remaining portion consisted apparently of burnt or charred leaves. He found sandy and earthy matter and magnetic oxide of iron in them, the magnetic oxide being taken from the charred leaves. The amount of sand and iron filings alleged by Dr. Hill to be put into the masses of lye tea was certainly not present in these spherical masses which he found. He did not find any gum or starch in the masses.

Formal evidence was given to show that the tea supplied to the various chemists by the defence was from the same source as that supplied to Mr. Woolley.

Mr. Rowlands then addressed the Bench for the defence. It appeared to him that there were three questions raised in the case—first, whether this article was sold as unadulterated; second, whether it was adulterated; and third, what were the adulterants? With regard to the first question, to constitute the sale of an article as unadulterated there must be an express warranty that the article was not adulterated. As for the second question, the charge that the tea was adulterated with sand and earthy matter, and iron filings, he reviewed the evidence at some length, and said he was firmly convinced that there was no metallic iron in the tea.

Rebutting evidence was then produced by the prosecution, a protest on behalf of the defendant being overruled.

Dr. James Campbell Brown, borough analyst of Liverpool, said he received a sample of tea from Dr. Hill, and analysed it. He came to the conclusion that it was adulterated for two reasons; first, because it contained pellets of spurious tea, such as he had heard called lye tea in court, and on account of the total increase of weight of the tea especially by means of mineral matter. Aided by a lens he found pieces of caper tea, which appeared to be blackleaded like a grate. He also picked out pellets of spurious tea. He called it spurious tea because when boiling water was poured upon it instead of the leaves unrolling like tea-leaves, they became disintegrated, and were found to consist chiefly of sand and small stones joined to little bits of organic matter—tea-dust, he believed. The whole was cemented together. He picked out of the tea some small stones; some of them were so large as one-tenth of an inch. They were composed of a white rock, probably quartz, but were blackened on the surface like a black-leaded grate. By means of the magnet he picked out portions of what looked like broken up lye tea, and which consisted of mineral particles adhering to the tea-dust. The majority of these particles were not magnetic, although they were attracted by the magnet. He believed that the majority of the particles attracted by the magnet were pieces of chopped or crushed iron ore; some were metallic iron. He washed the particles carefully, so as to remove carbonate of lime, etc., from the iron particles. He put a portion of the washed particles into diluted sulphuric acid, and a second portion into diluted hydrochloric acid. In both cases he saw at first no effervescence—not for the first half minute or so. Had there been carbonate of lime present the effervescence would have been immediate. He watched the test-tubes, and noticed that in a short time the iron, which had been rather passive at first, began to dissolve in both cases. Small bubbles of gas began to rise, and continued to be evolved from some of the particles for many minutes. He tested the substance further by means of permanganate of potash, which was rendered colourless by the hydrogen gas evolved from the iron while under the acid. He burned some of the tea, and found the total ash, including all the mineral particles, to be 13·4 per cent. He had analysed tea which was practically free from impurities. He had examined such pure tea sold at prices from 1*s.* 2*d.* upwards. The maximum of ash in unadulterated tea was 6 per cent., inclusive of accidental dust. He believed that the tea in the present case had been designedly adulterated. He would not swear that it was plumbago with which the tea was faced. The pellets handed into the Court were not, in his opinion, leaves scorched up. There was nothing adhesive in

scorched leaves. He considered that iron ore was more objectionable in the tea than iron filings.

Dr. Arthur Hill Hassall was then called, and examined by Mr. Kynnersley: Witness read the results of his analysis of sample 52 sent to him by Dr. Hill. It was a black tea, with leaf much broken. It was highly magnetic, containing nearly 6 per cent. of "lye" tea. The ash of the whole tea amounted to 12·54 per cent.; the ash of the lye tea to 20·3 per cent. The former contained 4·07 parts of matter which consisted chiefly of sand and stony particles, and 0·83 parts of iron over and above the amount of iron found in genuine teas. There was separated by means of the magnet 1·64 per cent. magnetic iron; the matter in the tea amounted to 10·01; the extractive matter to 30·27; and theine to 1·50 per cent. One or two leaves not tea were detected. The result of the analysis showed that the tea was adulterated with lye tea, sand, and magnetic iron. It was so highly magnetic that it adhered very freely to the magnet. It was impossible that the large quantity of foreign matter contained in this tea could have been introduced into it through any allowable accident. The lye tea was a specially fabricated article, and could only have been introduced by design. The mineral matter present could not have consisted of mere ordinary dirt and soil, into the composition of which a great many other things enter. The iron found in soils was chiefly in a state of ferrugo or peroxide, the quantity of magnetic oxide being very small in comparison to it.

Mr. Kynnersley: You have heard all the evidence of both sides of the case; do you still remain in the same opinion as when you wrote that paper you have read?

Witness: Yes; but I think I had better add something which will come out in other ways. I have no desire to keep anything in the back ground. In my first report I mentioned freely the words "iron filings." That circumstance occurred in this way. We have seen constantly in analyses of tea in the papers "magnetic tea" and "iron filing tea." I accepted that fact as a fact that this tea which was magnetic owed its magnetic properties to iron filings without question. No question arose in my mind until the hearing of the cases, when I was present on the last occasion. On my return home, of course, I felt it necessary to investigate for myself that matter, and the conclusion at which I arrived was that these magnetic particles consisted, in the main, of magnetic oxide of iron. I say "in the main," because there is a little reservation founded on the following circumstances. I tried this hydrochloric test with some magnetic matter which I extracted from sample 45. I took care to cleanse the particles thoroughly by means of liquor potassa before applying the test.

Mr. Rowland said he did not wish to interfere with the doctor, but this was what he did in another case.

Dr. Hassall: I want to show you what steps I took. I mentioned in my former examination that I had not performed the hydrochloric test. Subsequently, I did so in several instances. In the case of sample 45, I obtained an effervescence, after having taken great precautions. In sample 50 I tried the reduction of the copper by placing some of this magnetic matter in a solution of sulphate of copper. I got a small reduction, and that was placed in a filter to get rid of a portion of the copper. The particles in the filter were dissolved in the droppings of nitric acid, and then ammonia itself was applied. In two instances I got a slight discoloration. With regard to this present sample—No. 52—I performed the same experiment, that is to say, for the effervescence and reduction, and I got no result.

The Clerk: You have arrived at the conclusion that the particles are magnetic oxide partly?

Witness: Yes; that is in accordance with the experiments shown by the witnesses for the defence.

To Mr. Kynnersley: He could not account for the presence of so much oxide as he found in this sample by any natural causes, or by the ordinary preparation of tea.

To Mr. Rowlands: He thought it was something more than an oxide in degree. These magnetic particles had a very appreciable size, and corresponded with the description given by Dr. Brown as to their being broken up ore. He had not analysed China soil, but he certainly should not expect to find in 100 parts of it more than 23 parts of magnetic oxide. In the present case he should certainly not describe the particles found as iron filings. Asked to describe lye tea pellets in the sample in question, he said he would not say the leaves in them were not tea leaves, as the sample was too small to make a minute analysis. Lye tea consisted usually of tea-dust and sand, made up into little pellets or masses, with some adhesive material. The pellets were faced in imitation of black tea or green tea, as the case might be. He had no opportunity of examining what the adhesive matter in the present case was. Damp disintegrated the pellets. He could not think that the pellets would be made in the process of drying or manufacturing the good tea, because of the broken leaf and large proportion of inorganic matter they contained. It was a well-known fact that lye tea was constantly found in tea, and he preferred to accept the theory that it had been put in in this case. He did not find that because tea was cheap it contained sand.

This concluded the evidence in the case, which was then adjourned till Wednesday, when the decision will be given.

Is Rowland's Odonto a Patent Medicine?

At the Wandsworth Police Court Mr. Joseph Delayen, a hairdresser at Wimbledon, appeared on Tuesday, Nov. 24, to answer an adjourned summons for selling a box of Rowland's Odonto toothpowder without a licence. The question was whether toothpowder was a medicament. On the first hearing of the summons Mr. Bridge expressed an opinion that it was no more a medicament than a piece of soap which was used for washing purposes, but he adjourned the summons for a month, in order that the supervisor of Excise might communicate with the Board of Inland Revenue on the subject of taking a case or not. Mr. Dwilly now pointed out that the Act mentioned toothpowder. Mr. Bridge said he had not noticed this before. The defendant's son wished to know whether Rowland's Odonto was mentioned in the Act. Mr. Bridge said it was not. Probably it was not known at the time the Act was passed. The Act included all things of a similar nature to those mentioned in it, and therefore he must convict the defendant. The fine, however, would be the lowest he could impose—£5.—*Times*.

Review.

A Manual of Botany. By Robert Bentley, F.L.S., M.R.C.S. London: Churchill and Co.

As fresh means of acquiring knowledge increase, our study of plants can no longer be merely "a culling of simples," and considering the progress which has been made not only in horticulture generally, but also in all that pertains to systematic as well as structural botany, any work which shows an advance will be received with pleasure by all those who have taken up this branch of scientific pursuit. We most heartily welcome this third edition of a work which has already stood the test of more than twelve years' trial, and stands so high as a text book amongst students. It has been well observed "that so much depends on the art of putting things:" this holds especially true in the work before us, and although hard words will intrude, yet as a whole this work must be considered as "put" in as simple a manner, and taking into consideration the magnitude of the subject, in as concise a form as possible. We could have wished that a little more had been written on the morphology of plants, a subject which is now engrossing the thoughts and attention not only of botanists but also of almost all thinking men—a subject which in time bids fair to solve problems

hitherto baffling our utmost endeavours to determine. Although fossil botany may be considered foreign to the subject, yet it is so intimately connected with it that we think Balfour was right in setting aside a chapter to it in his manual, and we could have wished that Mr. Bentley had done so in his present edition.

The enlarged type in the present work is a great improvement, making it much more readable. The illustrations have been considerably increased in number; a step has also been taken in the right direction in placing cells and cell structure at the end of the work; the dreary routine of tissues has often frightened the young beginner at the outset. In learning botany an early application should be made to the practical examination of flowers, leaving the structural portion as much as possible to the latter part of the course. As a whole we can fully recommend this work to all those who, either from love of nature or from dire necessity, have taken up this pursuit; a pursuit, by the way, which once fairly appreciated will be more and more followed, not only from duty, but from its own intrinsic merits.

BOOK RECEIVED.

QUANTITATIVE CHEMICAL ANALYSIS. By Dr. C. REMIGIUS FRESENIUS. Sixth Edition. (Reprinted from the Fourth Edition). Translated from the Fifth German Edition. By A. VACHER. London: J. and A. Churchhill. 1873. From the Publishers.

Obituary.

Notice has been received of the death of the following:—

On the 17th November, 1873, Mr. Samuel Booth, Pharmaceutical Chemist, of East Greenwich. Mr. Booth had been a Member of the Pharmaceutical Society since 1865.

On the 19th November, 1873, Mr. James Margetson, Chemist and Druggist, of Old Market Street, Bristol. Mr. Margetson was a Member of the Pharmaceutical Society.

On the 6th September, 1873, Mr. Aaron Whitfield, Chemist and Druggist, of Biggar, N.B.

Notes and Queries.

[369.] AQUARIUMS.—The aquarium should have a layer of fine sand covered with shingle at the bottom, in this the weeds should be planted. The best for this purpose are *Valisneria spiralis*, *Anacharis* and *Chara vulgaris*. A few water snails should also be put in; the best are *Planorbis*, *Paludina*, and *Amphibia glutinosa*. These may all be otained at the Bedford Conservatories, Covent Garden Market, for a small sum. One plant and two or three snails should be used for each gallon of water put into the aquarium.—*F. G.*

[370.] HOMINY.—A correspondent in a recent Journal, whose initials I cannot quote, not having the Journal before me at this moment, asks what is hominy? In reply, allow me to inform your correspondent that hominy is a name given in America to a kind of meal prepared from Indian corn or maize (*Zea Mays*, L.). There appears to be several sorts of different degrees of fineness, some almost as fine as ordinary "corn flour" and others composed apparently of the finely broken but not pulverized grains.—JOHN R. JACKSON, Museum, Kew.

[370.] HOMINY.—If *J. T. H.* will write to Messrs. Horsnail and Catchpool, Liverpool Road, London, N., they will supply him with American hominy meal, and can no doubt tell him how to cook it. I believe it is made into a kind of pudding.—*F. G.*

A similar answer has been received from Mr. Wm. Bradley.

[371.] MORPHIA SOLUTION FOR HYPODERMIC INJECTION.—By using meconic, instead of acetic acid, Mr. H. J. Davies will be able to prepare a neutral and stable solution of the strength desired, or much stronger. A neutral meconate of morphia is pre-eminently adapted for hypodermic treatment.—T. and H. SMITH, Edinburgh.

[373.] BROWN BOOT-TOP LIQUID.—

Saffron.	15 grains.
Boiling Water . . .	2 ounces.

Infuse and strain. Add

Tinct. of Rhubarb . .	1½ ounce.

Concentrated Infusion of ditto to make up 4 ounces. —*F. G.*

CITRATE OF MAGNESIA (Citras Magnesicus).—$Mg_3C_6H_5O_7$, $7H_2O$. The following extract respecting the neutral citrate indicated by the above formula is taken from Ferrand's *Aide Mémoire de Pharmacie*:—

"It is prepared by saturating a solution of citric acid with magnesia and evaporating. But when thus obtained it soon loses its solubility in water, so that if required for medicinal use it should not be prepared until wanted, or else the following plan should be adopted:—

Citric Acid, in crystals	200
Calcined Magnesia	29

"Fuse the acid in its water of crystallization by means of a water-bath, and incorporate the magnesia carefully. The mixture, which is at first pasty, solidifies, and is pulverized and preserved (*Dorvault*). This citrate is very soluble, and its solution is permanent when eight or ten times its weight of water is employed. The 29 parts of calcined magnesia may be replaced by 64 parts of carbonate of magnesia; the carbonic acid is driven off and there remains a pulverulent mass resembling bicarbonate of soda. Thus prepared the citrate is insipid, and it requires the acid to be augmented by 4 parts to give it an agreeable acidity.

"This salt is a gentle purgative, without disagreeable taste, and is taken by the most difficult patients without repugnance. It is employed especially under the form of 'limonades sèches' or 'limonades liquides.'

REMOVAL OF NITROGEN FROM ALKALOIDS.—Bocke states (*Deut. chem. Ges. Ber.*, vi., 488) that by distilling quinine with zinc and zinc sodium a distillate free from nitrogen and resembling cumin oil in odour may be obtained, sodium cyanide being left in residue. Previously to this statement, Weidel had been reported (*Ann. Chem. u. Pharm.*, clxvii., 88) to have split up cinchonine ($C_{20}H_{24}N_2O$) by oxidation into two nitrogenous products, one of which was a well-crystallized acid, which yielded its nitrogen to nascent hydrogen to form ammonia, leaving a crystalline tribasic acid resembling the vegetable acids in general character. The other nitrogenous product has not yet been examined. The results appear to indicate that cinchonine is composed of a C_{11} and C_9 group; the examined acid being obtained from the former.

DETECTION OF ARSENIC IN COLOURED PAPERS.—Hager saturates the paper with a solution of nitre in a mixture of alcohol and water, and after drying burns it upon a plate. The ashes are then boiled with water and a few drops of potash solution, the liquor filtered, acidulated with sulphuric acid and permanganate until this is no longer decolorized with heat. The cold filtered solution is then introduced into a small flask with a strip of zinc and a few drops of sulphuric acid, and at the orifice are held two bands of paper, one impregnated with nitrate of silver, the other with acetate of lead. The latter is used only to establish the absence of sulphur; if arsenic be present the silver paper blackens immediately.

Citrate of Magnesia.

Sir,—I have watched with some interest the remarks and letters published in the Pharmaceutical and other journals on the recent conviction of Mr. McDermott under the Adulteration Act. In the main, I find the general opinion to be that he was unjustly convicted, because, although the article he sold assuredly was not citrate of magnesia as its label purported, there was no fraud intended or committed either by Mr. McDermott or the manufacturer, inasmuch as it was the article known both by the public and the profession under that name. If that which we call unwritten law be not sufficient exoneration, there is in the sixth edition of Squire's 'Companion to the British Pharmacopœia' of 1867, p. 235, this foot-note to "Sodæ Citro-tartras Effervescens":—

"*Fr. Limonade sèche au Citrate de Magnésie. New preparation; vulgo, Granular Effervescent Citrate of Magnesia.*"*

There is one extraordinary exception to this fair judgment on the case in the *Medical Press and Circular* of Nov. 19th, in the opening of an article, p. 461, headed "Fraud in Drugs," but as the editor expressly contradicts himself at p. 463, in another article entitled "The Adulteration Act," I need not remark further on that.

My object in writing is to urge my brethren, on this most fitting opportunity, to abolish once for all a discreditable misnomer. I may be told that our shops are full of misnomers. Yesterday I was asked, "What is your dragon's blood? Who killed the dragon?" To-morrow I may be examined on crab's eyes and hartshorn. The thing seems absurd, but I take it there is a great difference between using a name handed down to us by the ancients for a simple substance and launching a compound preparation under a false name on the world in these days of advanced chemical knowledge and pharmaceutical honesty—the granular effervescent powders are scarce fifteen years old.

I remember that when the names of carbonate and subcarbonate of potash were exchanged for bicarbonate and carbonate, it was thought the public would never buy them under the new terms; but we find no difficulty now, and I believe there would be no greater difficulty with these granular preparations.

I know my desire to see this change effected is shared by the best pharmacists in the kingdom, and I would venture to remind all that it is our only means of safety so long as the Adulteration Act exists. Without going into the question of what observation might fairly have been expected to accompany Dr. Muter's report in guidance of the magistrate, I venture to say that no analyst would have pronounced the powder handed to him to be citrate of magnesia, and in confirmation of my opinion that we shall not be safe in selling it under this false name I give you, from a circular just received from Mr. Bishop, an extract which he quotes from Her Majesty's Attorney-General and Mr. Poland.

They advise that in the sale of citrate of magnesia to a customer, "*care should be taken to inform such customer that the article sold is not pure citrate of magnesia, but is the preparation called 'Granular Effervescent Citrate of Magnesia'*"; and that even if it be sold with Bishop's label on the bottles, the customer "*should be asked whether he requires the preparation called Granular Effervescent Citrate of Magnesia, which is, in fact, not Citrate of Magnesia.*" Those who have to retail these articles will appreciate the difficulty of putting such questions, and making such remarks, better than the learned gentlemen who declare them to be necessary always.

Sir, I find no fault with Mr. Bishop for endeavouring to protect that which is doubtless a valuable property; but we have a higher duty to perform, from which I trust we shall not shrink, and I have the greater hope that we shall not, because in performing it we shall remove a blot from pharmacy, and undoubtedly ensure our own safety. I enclose two labels which I have adopted; one for the Pharmacopœia preparation, the other for the magnesian compound.

George W. Sandford.

Citro-Tartrate of Soda,
Of the British Pharmacopœia;
Commonly known as
CITRATE OF MAGNESIA.

Effervescent Saline Aperient;
Commonly known as
CITRATE OF MAGNESIA.

Sir,—Does Mr. Alfred Bishop consider that the presence of a certainly very small percentage of magnesia (probably existing as sulphate and in that case not citrate of magnesia at all) can justify him or anybody else in ignoring an overwhelming proportion of other ingredients, upon the presence of which the properties of the preparation depend? But, I observe that he does not lay claim to its being "citrate of magnesia" but "granular effervescent citrate of magnesia."

Now, with all due deference to him, I apprehend that by adding two adjectives to express properties pertaining to a substance, you in no way deny that it is really what it pretends to be; granular effervescent citrate of magnesia cannot (or ought not to) be the less citrate of magnesia in that it possesses granular and effervescent properties.

Mr. Alfred Bishop may reply that it is impossible to make a true granular effervescent citrate of magnesia. That may be so; I have never tried to do it; but it was not impossible for him to call the preparation by its proper name in the first instance. Of course, as he says, it is now too late, and I have known cases parallel to his, in which an initial departure from strict veracity has borne consequences impossible to foresee.

It is only charitable to suppose that he did not contemplate the possibility of a tradesman being fined for selling an article under a name the vendor never gave to it and which he had no power to alter; yet this is the way in which our hands are tied, and for which we have to suffer.

But, surely it cannot mend matters to call in the aid of a thing of fogs, fictions, and mysteries like English law, which its own professors do not pretend to understand and can only offer an opinion on, in order to solve a question quite capable of apprehension by anyone possessing some knowledge of chemistry and a fair share of common sense.

The distinction between "citrate of magnesia" and "granular effervescent citrate of magnesia" is well worthy of the Attorney-General, Mr. Poland, *et id genus omne*, but such subtleties are not quite satisfactory to the non-legal mind of a layman like myself.

If instead of the eleven paragraphs contained in his statutory declaration, Mr. Bishop could have made only two as under, namely, that:

1. Magnesia formed an *essential* part of the preparation and was present in an important quantity, not as sulphate but as citrate;

2. That it was really a citrate and not a compound containing tartaric acid,

it would have sufficed; but, Sir, in that case no statutory declaration would have been necessary.

H. C. W.

---

* Mr. Sandford's quotation is quite correct as such; but it involves an error committed by Mr. Squire in describing the Limonade sèche au citrate de magnésie of the French Codex as a preparation corresponding to our effervescent citro-tartrate of soda, as will be evident from the following formula:—

Limonade sèche au citrate de magnésie.

Pr.	Magnésie calcinée	6,50
	Hydrocarb. de magnésie . .	6
	Acide citrique	30
	Sucre blanc	60
	Alcoolature de citron . . .	1

Pulv. grossièrement ensemble le sucre et l'acide; mélangez les autres subst.; enfermez dans un flacon à large ouverture.

En bouchant la bouteille où l'on fait la dissolution, et maintenant le bouchon à l'aide d'une ficelle, on a une limonade gazeuse.—Les doses ci-dessus représentent 50 gr. de citrate de magnésie. (Cod.).—Ed. Pharm. Journ.

Sir,—The recent "National Chamber of Trade" Conference furnished proof to an onlooker of the helplessness of the ordinary London druggist. Accustomed as he is to have everything "managed" for him, he is a sheep without shepherd when deserted by his guardians. It is otherwise with his brethren in little provincial towns, where business does not tie them to the counter all day long and a good bit of the night; they are able to take their part in local affairs—frequently a leading one—which is due to the superior intelligence and education among Pedlingtonites, and spare time enables the country man to read more widely and solidly, and so expand his mind with general and classic literature.

The object of this letter is, not to advocate the remedy, viz., the short-hour movement, with its concomitant opportunities, but it is most important that the Council should not construe the apathy of the trade (for the "effervescent" affair is already going flat) into an excuse for their own inaction, having allowed themselves to be placed in position to watch over the interests of pharmaceutists, and furnished with every requisite means for conducting influential corporate resistence to injustice.

They have allowed a dangerous precedent to pass unchallenged, and though every one is resigning himself to the fools' paradise of hoping himself will not be "dropped on," it is certain that others will be so, and shortly, too; then there will be another panic, and so that will have to be done with a bad grace which might have earned the gratitude of their constituency. If they persist in doing nothing there is only one alternative that I can think of (until next election)—Is there not plenty of administrative ability among the wholesale firms?—and they are not the least interested in this matter.

The resolutions at the Chamber of Commerce met with the support they deserved, the wonder is that only three individuals seemed to see the incongruity of *chemists* pleading to be excused from the penalties for impurity that have been inflicted (with such general approval by the public) on grocers and milkmen. They would be more suspicious than ever of physic. The desperation of the "resolvers" must have been extreme to wring out an appeal to "Dr. Redwood, in the corner," to help them, *i.e.*, to repeal the Act which provides him a little salary. This is *too* much even for a public officer's self-denial.

We have seen how an analyst can disregard his private interests, however considerable, when public duty runs counter to it; but it is scarcely part of such a one's duty to try to repeal the Adulteration Act; it requires an Irishman to commit such a suicidal blunder. The victim on whose account these proceedings were undertaken voted with the gentleman who moved that the meeting be adjourned *sine die!* Did he construe it into "never say die?" He is evidently game for a fight, defiantly keeps the mag. eit. conspicuously in his window. By-the-way, it *is* an orthodox pharmacy, notwithstanding the uncongenial neighbourhood, and should teach a lesson to more pretentious shops that compete with fancy bazaars. And that most disagreeable sort of Job's comforter, the "Candid Friend," in speaking of the "unknown neighbourhood" (of Bermondsey) might be reminded that Shakespere immortalizes the "tanners of Bermondsey," in words which will survive when the Prince Regent is unknown to history.

Again, if the inspectors of South London are more active there than those of the West-End, it is unreasonable to insinuate that he who selected Mr. McDermott is afraid to "inspect" the great men of the west; they are (fortunately for them) out of the zealous one's district. Doubtless, the selection was purely chance; it would hardly be thought so if well-known shops were picked out.

Many points remain to be touched on, but this is too long already; so I leave the subject in worthier hands than

J. P. C.

Nov. 20th, 1873.

A Provincial on the "Citrate" Question.

There are four points on which it is imperatively necessary there should be a distinct understanding throughout the whole "drug trade" regarding the article sold under the name "Gran. Eff. Cit. Magnes.", and the position it occupies amongst other articles designated in a similar manner. Those points are—first, its composition; second, its analysis; third, its name; fourth, its sale.

First, its composition. Every chemist is fully aware how it was first brought into existence, and every chemist is or ought to be fully aware that its supposed composition as at first made public has not been adhered to. Even to those tradesmen so unequal to the requirements of the profession as not to be able to analyse, the well-known fact that an article bearing the name can be bought at less than half the price at which the first manufactured was sold, affords sufficient information. There are few, however, aware of how the article is manufactured so as to sell at an extraordinarily low price, and at the same time bearing sufficient resemblance to the "genuine" and far more valuable kind, as to entitle it to the original name.

Moreover, the Bermondsey case can only mislead retail purchasers on this very point.

Ask a "wholesale" representative the reason why such cheap preparations of the citrate can be manufactured, and he will generally say that "larger quantities of sugar are used." A chemist accustomed to analyse his samples, however, knows better; the true reason being that tartaric is generally substituted for citric. But even this reason only reaches to a certain extent.

Forms have frequently been given for its manufacture differing materially from each other in quantities and qualities, though not in principle. Now invariably in the forms for the common kinds the ordinary magnesian sulphate enters very largely.

Dried epsom salts, it is well known, possess a great avidity for moisture. It is also well known that the commoner kinds of effervescing citrate attract moisture a great deal more rapidly than those higher priced.

Putting these facts together, and weighing them in connexion with the character of Bermondsey sample as given by analysis, the probability is that the purchaser got full value for his money and a comparatively good article into the bargain.

For, if magnesia was not found in it, and I presume there is no reason for doubting the analyst's accuracy, then there must have been employed in its manufacture chemicals of higher value than the magnesium sulphate. Possibly, however, as magnesia was not found there, sodium sulphate had been used. That, however, is almost as expensive as the former, at least the difference, except in especial instances, would not make it worth while to substitute one for the other, when the gain by so doing would be counterbalanced by the loss of prestige in the entire omission of magnesia from the article sold. But again, I believe the analyst's certificate does not say that he found sulphuric, therefore it is quite evident that the Bermondsey sample could not have been of the very commonest kind. Also in the face of this it is quite within possibility to believe that if the analyst had found only the slightest quantity of magnesia, he would have given a more satisfactory certificate. This, however, I repeat is only a possible eventuality. Although seeing the results of analysis lately placed before the public, it is deserving of notice by people whose commercial prosperity and commercial morality are at stake.

Second, analysis. An exact quantitative process is needed by the chemist in very few cases. The quantitative indication afforded by the qualitative method being generally sufficient for all ordinary purposes. What he actually requires is the knowledge of two or three tests that will give him an idea of the adulterating constituents, if any. For this the usual qualitative processes in analytical practice will answer. Barium chloride and hydrochloric acid for sulphate, and sodium phosphate in ammoniated solution for magnesia. Absence of citric acid by calcium chloride, alcohol, hydrochloric acid and ammonia. This is Fresenius' teaching, which the writer has found more satisfactory than that of others.

However, should there be a necessity for a somewhat accurate quantitative analysis, more especially for the determination of the magnesia, then for the separation of the alkali precipitation with potassium antimoniate will succeed pretty accurately, and the further employment of the qualitative method quantitatively will suffice. Of course the whole process is only indicated very roughly here.

Third, name. None of the names suggested as substitutes for the original one will answer to the nature of the article. Besides, if any of them actually represented, that is chemically, the nature of the compound, they are all decidedly objectionable because of their being very cumbersome.

Previous experience has proved it certain that whatever name be adopted that name will eventually get into common use only if it be short and pointed. Who, therefore, will

ever ask for "granular effervescent citro-tartrate of soda with magnesia"?

But the compound is not what this title indicates. According to none of the forms published will the article formerly sold as the "citrate" be found chemically analogous to what this title properly describes, neither as sold, nor after being dissolved. In the former case it is not a citro-tartrate of sodium with magnesia; in the latter case it is not in a "granular effervescent" condition.

Still more, in either case where is the sugar taken accoun of?

The condition to be observed in searching for "a name" is that the name must be in accordance with the substance.

Probably, all things considered, the label that would come nearest to a true designation of the article, that would not cause doubts to arise in the minds of purchasers, and that would settle the question once for all, both with competent and incompetent analysts, would be

Compound
CITRATE OF MAGNESIA,
Formerly called Effervescing Citrate of Magnesia.

There is no actual necessity, however, for the latter part.

Fourth, sale. After the previous remarks very little requires to be written on this point. However, as it is not very probable a quantitative analysis of what is sold as the "effervescing citrate of magnesia" will be made in the interest of the "Adulteration" Act, in consequence of the indefinite nature of the composition, when "genuine," and in the want of a recognized definite formula for its preparation it is useless to enter into the legal question. Still, this can be safely put on record, according to the received notion of its constitution, any article containing citric acid and magnesia, only in moderate proportions, with sugar, and in mechanical combination, is fully entitled to be considered as an "effervescing citrate of magnesia." Therefore, despite the "Food and Adulteration Act" the unprincipled tradesman and manufacturer can escape its penalties with impunity.

E. D.

[*** We cannot agree with the opinion expressed in the concluding paragraph of our correspondent's letter. So far as we are able to speak as regards a proprietary article, we should say the composition of the article sold as "citrate of magnesia" is the same now that it was when that article was first introduced. Both as regards magnesia and citric acid, it is a case of misnomer; but though it must be admitted that the article sold under the name of "citrate of magnesia" is not correctly represented by that name, still we fail to recognize any circumstances which justify the opinion that the sale of this article under the familiar name it has acquired—wrongly, it must be granted—should be treated as a case of adulteration for the purposes of the Act.—ED. PH. JOURN.]

Sir,—As unusual interest appears to be taken by your correspondents on the late conviction of Mr. McDermott for the sale of so-called "citrate of magnesia," and as all unite in condemning the Adulteration Act as applicable to the sale of drugs, etc., may I call your attention to the facts?

The summons was originally taken out under the second section of the Adulteration Act of 1872, but at the hearing was amended by the magistrate, and the conviction took place under sec. 24 of the Pharmacy Act (Amendment) of 1868.

The Adulteration Acts are without doubt very faulty, but if amendment be necessary in respect to this case attention should be turned to the Act, of which I believe your Society were the promoters.

Though absent through illness from the court, I believe you will find my statement perfectly correct.

THOS. PAYNE, *Sec.*

The Anti-Adulteration Association, Limited.
Offices—Adelphi Chambers,
6, John Street, Adelphi, Strand, W.C.,
Nov. 24th. 1873.

[*** Mr. Payne is in error in supposing the Pharmaceutical Society in any way promoted the Adulteration Act. The only action taken by the Council in reference to that Act was in obtaining an amendment of the Bill by the introduction of the third section, so as to restrict the application of the Act to those only who sell a drug knowing it to have been mixed with any other substance, with intent fraudulently to increase its weight or bulk (*see* PHARM. JOURN. iii., 129).

We think also that Mr. Payne is wrong in stating that the conviction of Mr. McDermott took place under sec. 24 of the Pharmacy Act, 1868—at least, we have never seen the case so reported.—ED. PHARM. JOURN.]

Sir,—There has been much correspondence on the citrate of magnesia case, but there are two important points which I have not seen noticed.

As you report the case on p. 376, a parcel of cit. magnesia was bought at the same time that a prescription was dispensed. There appear to have been two distinct transactions. But the magistrate, in his remarks, speaks as if he thought the citrate was used in the prescription.

Surely this is an essential point, and if the circumstances were what your short report implies, the penalty inflicted was decided under a wrong impression, and therefore the case is far from a decisive one.

But it is stated on p. 373 that Mr. McDermott is not a chemist and druggist. Was he not, therefore, liable to a penalty for dispensing a prescription? If so, in this case, although justice seems to have been blind, she was by accident just.

W. SYMONS.

Barnstaple, 24th Nov., 1873.

[*** We took some pains at the time the report was published to clear up the question as to the prescription and the simple sale of 4 oz. "citrate of magnesia," but could not do so satisfactorily, though we inclined to the opinion that the case was one of ordinary retail sale. Since then, however, we have learned, on the authority of Mr. McDermott himself, that the 4 oz. of effervescent citro-tartrate of soda were supplied by him to meet the terms of a prescription, written in the usual manner, ordering—

Magnes. citratis effervescentis . . . . . ℥iv

with directions in Latin how this was to be taken.—ED. PH. JOURN.]

WHO'S PHILIP?

Sir,—I think I can tell Mr. Greenish who Philip is, and where he is to be found; but I very much fear that if I were to divulge the secret of his whereabouts, I should bring a nest of hornets about my ears. He must be satisfied to know that he is not be found this side of the Edgware Road.

Mr. Greenish's excellent letter opens up so wide a field for discussion that I almost hesitate to encroach on your space, and fear that I shall lay myself open to the charge of having an attack of "*Cacoëthes Scribendi.*"

The prescription he alludes to was evidently intended to be sent to a particular chemist, and I imagine the prescriber would scarcely consider any chemist was justified in questioning his right to get his formulæ dispensed wherever he might choose. My impression is that whenever an invalid consults a medical man, the doctor's first duty is to his patient (after himself.) I have no doubt it is to his interest to send his prescription to his own particular chemist, and most probably he thinks that it is to his patient's interest also, but is it just to the general body of pharmacists? Most of us can trace the loss of old and valued customers to the fact of a new physician being called in who insists on the medicines being procured from a particular establishment; and, as a rule, patients readily fall in with what their medical adviser desires. I know however of one very notable exception, in the person of an old baronet, who does me the honour to bring me his prescriptions when he is in town. He tells me that whenever he consults a medical man, and he is told to go to one particular pharmacy for the medicine ordered, he says: "That is the very shop I shall *not* go to; why am I to leave my own chemist to go to a man I know nothing of?" When he is told that the particular remedy prescribed can only be procured at the establishment recommended, his answer is: "Then my own chemist may send and get it for me."

A medical man is perfectly justified when a patient *asks* him to recommend a good chemist in naming the man in whom he himself has confidence; in the case of strangers coming up from the country this is indeed very advisable, and most of us have to thank some kind medical friend for such

recommendation, but it is the impertinent interference with the established relationship of a chemist and his customers that is so much to be reprehended. When a doctor is called in to attend a family, before he advises them to change the chemist, let him ascertain that the man (who has probably been employed for years and years, and that with every satisfaction) is not a reliable man, and that he does not supply good drugs, and then is the time to put in his friend.

Another phase of the subject presents itself to me. The legion of new preparations continually introduced is rapidly getting an abominable nuisance. As a rule, they are also made the excuse for sending the prescription to a particular establishment. Where one is a reliable and valuable chemical or pharmaceutical product, ninety-nine are but senseless varieties of recognized Pharmacopœia preparations. How much valuable time is wasted, and that not unfrequently at the busiest time of the day, in running about to find out where they are to be procured! To provincial and suburban chemists the nuisance must be simply intolerable, and the expense of sending to London and elsewhere for these things must surely be a great item in their current expenditure. If medical men, when they order these preparations, would but put the name and address of the chemist who prepares them against the acticle ordered, it would save much time and trouble. I well recollect when the late Dr. Marshall Hall prescribed his "Pilula aloes diluta," since introduced into the London Pharmacopœia under the name of "Pilula aloes cum Sapone," he went to the expense of having the formula printed on a small gummed label, which he invariably affixed to the prescription when he ordered this particular pill. In these days of keen competition one can scarcely expect from brother pharmacists so much consideration as the publication of their formulæ; it would be too much on the "*Sic Vos non Vobis*" principle, but I think a doctor ought to do so when he gets a guinea for his prescription, and I most earnestly hope that when my friend Mr. Greenish next gets an order for some "Pil. Philip." he will find that Dr. Marshall Hall's sensible little plan has been adopted.

"'Tis a consummation
Devoutly to be wished."

JOHN TAYLOR.

13, *Baker Street, Portman Square, W.*
Nov. 22nd, 1873.

Sir,—The letter of Mr. Greenish in the last issue of the Journal is well worthy the notice of the trade. The grievance to which he draws attention, though happily less prevalent now than it was some years ago, still retains a not inconsiderable vitality in many provincial towns, and is productive of much inconvenience to the patient and the chemist, the latter not unfrequently suffering in reputation as well as pocket. So far as the ethics of the matter are concerned, it is to my mind at least somewhat questionable honesty for a medical man to tender in return for a fee a prescription which is of no service, but at some particular establishment, thus serving his own interest only, and treating with indifference that of his patient, who pays with the tacit understanding that he will receive, *not* a cipher, the key of which is in the possession of some privileged individual, but a prescription, clear and intelligible, which can be dispensed without let or hindrance in any part of the kingdom to which in the ordinary course of business or pleasure he may have occasion to remove. Now as most of us are supporters of the principle of free trade, the question arises, How is this monopoly to be broken through? and to this end I, for one, think Mr. Greenish has touched the right key-note in his determination to publish every such case that comes under his notice. I would therefore suggest that this plan be adopted, wherever practicable, by chemists at large. I venture to predict that it would yield results of a most salutary kind, and go very far towards completing the downfall of a system that is manifestly unjust in its operation and pernicious in its results. Trusting that the subject will not be shelved until some practical good is accomplished, I am, etc.,

G. MASSON, Ph. Chemist.

Mere Street, Diss, Norfolk.
Nov. 24th, 1873.

Sir,—Mr. Greenish's pertinent question in last week's issue will provoke, I have no doubt, some few replies. As, some few years since, "Philip" came frequently under my notice, I venture so throw some light on the difficulty experienced by Mr. Greenish. "Philip" is the putative production of a well-known practitioner in "Tyburnia," and is one of many brethren filling important places in that gentleman's private compilation, some of whom, notably, "Linim. Scorpio.," "Embroc Camphor. Co.," "Tinct. Sumbuli Co.," Mist. Calumbæ. Eff.," bidding defiance to prescriptive limits, are occasionally met with, straying from their native region.

Descending from a respectable and well-tried family, "Philip's" actual composition is (or was):—

Hydrarg. Submur . . . . gr. j.
Pil. Hydrarg. . . . . gr. iij.
Pro Pil. j.

And, judging from his therapeutic effect, I can easily understand his "derivative" was assumed for a twofold purpose, viz., commercially, to perplex the uninitiated; and professionally, to convince the sceptical.

Who will say he has failed in either respect?

ROBERT A. JOHNSON.

45, *Westbourne Grove, Nov. 26th*, 1873.

"*An Apprentice.*"—The object of an apprenticeship is to enable the apprentice to acquire a thorough practical knowledge of his business, and he is bound to perform whatever duties may be required of him in pursuance of that object. For further details we must refer you to the terms of your indentures.

A. P. S.—Duncan's preparation is still sold and dispensed by some houses of good repute, and is the one strictly entitled to the name. We should use it whenever chloric ether is ordered.

W. W.—First convert the calomel into perchloride, and then into ammoniated mercury in the usual way.

St. Mungo, W. B. (*Egham*), 2 *Alpha*, are referred to the rule respecting anonymous communications.

"*Gareloch.*"—(1) The substance mentioned is not included in Schedule A. of the Pharmacy Act, 1868. (2) The necessity for a patent medicine licence would depend upon whether it is represented in any way as a remedy for the cure or relief of disease.

A. P. S.—Any medicine that is a secret preparation, said to be prepared *only* by a particular person, or which is recommended on the label or in any other way as a remedy for the cure or relief of any disorder, is liable to the stamp duty, and the vendor must take out a patent medicine licence.

Leeds Chemists' Association.—The report of the meeting, kindly furnished to us by the honorary secretaty, Mr. J. W. Longley, did not reach us until after the Journal had been made up for press, but will appear in our next number.

COMMUNICATIONS, LETTERS, etc., have been received from Professor Balfour, Messrs. Baker, Robinson, Ingham, Lunn, C. Crook, W. Bradley, J. Leay, Johnson, Dolomites, Cymru, Euxesis, E. J. P., K., H. C. W., A. E. M.

A NEW SOLVENT OF PHOSPHORUS; ITS PREPARATION AND PHARMACEUTICAL USE.

BY A. W. GERRARD,

Dispenser and Teacher of Pharmacy to the University College Hospital.

The principal known and most generally adopted solvents of phosphorus for pharmaceutical purposes are bisulphide of carbon, chloroform, ether, alcohol, oil of almonds, oil of theobroma, and mutton suet.

The power of these bodies to dissolve this element varies from any proportion to less than half per cent.; the most powerful being bisulphide of carbon, the least, alcohol.

Most of the above solutions of phosphorus, when dispensed, are of an unsatisfactory and unstable character. Those which are fluid and miscible with water in the presence of mucilage—the manner in which it is usually prescribed—are rapidly decomposed and become inert; they are likewise nauseous and objectionable to the patient in an extreme degree. The solid forms are but little better and are exceedingly troublesome to manipulate.

Bisulphide of carbon has been recommended by Mr. Proctor, of Newcastle, as a means of dispensing phosphorus in the pill form, and it answers the purpose very well, with the exception that the pills retain a compound smell of phosphorus and bisulphide of carbon, which is repulsive in the utmost degree.

The new substance which I propose to add this evening to the list of solvents of phosphorus is resin, that body described in the Pharmacopœia as the "residue of the distillation of the turpentine." This substance suggested itself to me amongst others as a probable solvent, and the result of my experiments upon it is that I have found it capable of dissolving four or more per cent. of phosphorus; the limit of its solubility is a question for further experiment.

I would call this substance phosphoretted resin. The method of preparing it is thus:—Take a strong wide-mouthed well-stoppered bottle and weigh it, then melt a quantity of resin sufficient to fill the bottle; let the bottle be warmed, then pour in the resin to nearly but not quite fill the bottle, reweigh, and for every ninety-six parts of resin take four of phosphorus. Now observe that the resin is in a fluid state; if so, add the phosphorus, and fix the stopper tightly. Place in a sand-bath previously warmed, and apply heat to 200° C. or 392° F.; digest at this temperature, and shake frequently until the phosphorus is dissolved.

The kind of resin to be used in this preparation is the black translucent variety, known in commerce as rosin, not that pale yellowish kind usually met with in chemists' shops, unless it has previously been deprived of its water, of which it contains a varying amount, sometimes ten per cent.

In conducting the process, it is necessary to observe the following precautions:—In adding the phosphorus, if possible let it be in one piece, and take care that the resin is previously in a fluid condition, as then the phosphorus readily sinks below the surface, and is covered by the resin; otherwise, if the phosphorus were in small pieces and the resin semi-fluid, the phosphorus would rest on the half-hot resin, and speedily take fire; but by observing the above precautions, this accident may be prevented.

A bottle full of the preparation should be made at a time, as I find there is great risk of accident (having had one myself) if the vessel is only partly filled. The phosphorus is also volatilized, and deposited in the upper portion of the bottle.

Keep a thermometer in the sand-bath during the process, and maintain the temperature between 200 and 210 C. At higher temperatures the resin boils, and the heat is liable to change the phosphorus to the red amorphous state.

When the prepared resin has cooled it is difficult to remove it unless the bottle be broken; the method I have adopted is to draw it from the bottle, when partly cooled, under hot water.

It is a pharmaceutical process which, like many others, requires care and attention to ensure success, but whatever difficulties may arise, to a practical person a remedy will suggest itself.

I will here mention a curious change which takes place if this phosphoretted resin be reheated. When it reaches a certain temperature it becomes of a whitish cream colour throughout, if the temperature be raised still higher it again becomes transparent; this phenomenon does not occur in the cooling. It is probably due to the influence of molecular change.

The formula I would suggest for its exhibition is the following:—

Take of—

Phosphoretted Resin, 4 per cent. .	25 grains.
Powdered White Sugar	75 „
Tincture of Tolu, a sufficient quantity.	

Pulverize the resin, mix with the sugar, and form into a mass with tincture of tolu,—eight to ten drops are sufficient; then divide into twenty pills, each pill will contain one-twentieth of a grain. This forms a mass of an excellent consistence, and pills made therefrom retain their form and present an elegant appearance without the addition of any coating; they have but a faint odour of phosphorus, and that may be completely removed by the addition of oil of peppermint.

The experience gained from the administration of these pills in the in- and out-patients' departments of the hospital to which I am attached proves that the theurapeutic properties of the phosphorus are in no way injured or modified by this combination, but that it is fully equal to any that had been previously used.

In conclusion, I consider the advantages of this preparation to be that it is inoffensive to the tastes of the patient, definite and reliable for the prescriber, ready and convenient to the dispenser, and I believe judging from its nature it has unlimited keeping powers.

[*The discussion on this paper is printed at p.* 451.]

NOTE RESPECTING GLYCERINE OF GALLIC ACID.

BY SAMUEL GALE.

It is well known that glycerine has the property of dissolving most salts in greater proportion than water.

It also exerts a power on certain salts (as ferric chloride) in preventing their precipitation by the alkalies.

It combines with certain organic and inorganic acids to form definite compounds, as with sulphuric and phosphoric acids.

Most of the salts when dissolved in glycerine will bear dilution, even if much less soluble in water.

In the Pharmacopœia the authors have given us some very useful preparations of glycerine, and it is to one of these I wish to draw attention for a minute.

When the glycerine of gallic acid is diluted with an equal bulk of water (after a short time) the gallic acid crystallizes out, and there appears a solid mass.

[*The discussion on this paper is printed at p.* 451.]

BITTER WINE OF IRON.*

BY CHAS. L. MITCHELL.

This preparation, so much in demand amongst practitioners in the United States at the present time, is, when rightly made, a most elegant tonic and stimulant. As often sold, however, it is of an inky colour and taste, and quite repulsive to the patient. Taking advantage of the property which the hydrated sesquioxide of iron possesses of removing the tannic acid from the different vegetable astringents and tonics, I have succeeded in making a preparation which is handsome, efficient, and pleasant to the taste. The formula is as follows :—

Grd. Cinchona Calisaya	192 grs.
,, Gentian Root	128 ,,
Soluble Citrate of Iron	192 ,,
Sherry Wine	13 f. ozs.
Brandy	1 f. oz.
Alcohol	1 fl. ,,
Oil of Orange	12 minims.
Sugar	2 ozs.
Solution of Tersulphate of Iron . .	2 f. ozs.
Water of Ammonia	q. s.

Dissolve the oil of orange in the alcohol, and mix with the sherry wine and brandy. With this menstruum percolate the ground drugs, recovering 15 f. ozs. tincture by pouring on water. Dilute the iron solution with twice its bulk of water, and add ammonia until in slight excess. Wash the precipitate until the washings are tasteless, and drain thoroughly. Mix this precipitate with the percolated tincture, and allow to stand, shaking frequently, until a portion filtered off has a light yellow colour and does not blacken with tincture of chloride of iron. Then filter, dissolve the citrate of iron and the sugar, and bring up the measure with a little water to 16 f. ozs.

Each fluid ounce contains 12 grs. cinchona calisaya, 8 grs. gentian root, and 12 grs. of soluble citrate of iron.

THE PRODUCTION OF METHYLAMINES FROM ACETONE.†

BY C. VINCENT.

The author, having noticed the presence of methylamine, dimethylamine, and trimethylamine in methylic alcohol, was induced to investigate the conditions under which those bodies were formed. He found that they were not produced directly in the carbonization of wood, but that the ammonia which is first formed, and which accompanies the lighter products, gives successively methylamine, dimethylamine, and trimethylamine, according as it is a longer or shorter time in contact with these matters under such conditions. He therefore tried to ascertain what was the reaction which gave rise to the various methylamines during the distillation of the alkaline methylic alcohol. With this object, he placed pure methylic alcohol and aqueous solution of ammonia together in a flask furnished with Liebig's condenser, which he heated first in a water-bath, and then in a closed vessel to 100° C. After twenty-four hours, however, he was in neither case able to detect a trace of methylamine.

* *American Journal of Pharmacy*, Nov., p. 483.

† *Comptes Rendus*, vol. lxxvii., p. 898.

As crude methylic alcohol contains considerable quantities of acetone, the author thought that the ammonia reacting on that body might engender successively the various methylamines and aldehyd, according to the following equations :—

$$C_3H_6O + NH_3 = C_2H_4O + NH_2(CH_3)$$
$$C_3H_6O + NH_2(CH_3) = C_2H_4O + NH(CH_3)_2$$
$$C_3H_6O + NH(CH_3)_2 = C_2H_4O + N(CH_3)_3.$$

He therefore placed acetone and aqueous solution of ammonia in a flask heated by a water-bath, and connected with a Liebig's condenser. At the end of twelve hours the liquid was saturated with oxalic acid, and evaporated to dryness in a water-bath. The residue treated with absolute alcohol gave a solution which was evaporated to dryness to drive off the alcohol. The matter so obtained, treated with a boiling solution of potash, disengaged a gas which was dissolved in water.

This solution was strongly alkaline, and when boiled gave off an inflammable gas that burned with a yellowish flame. It precipitated the salts of cadmium white, and the precipitate was insoluble in an excess of the reagent. By these characters it was recognized as methylamine.

The presence of aldehyd in the products of the action of ammonia upon acetone was manifested by saturating with acetic acid the first product of the rectification, and passing through it a current of sulphuretted hydrogen ; sulphydrate of hydride of sulphacetyl was formed, the odour of which is characteristic.

It may be concluded from these reactions, that the methylamines met with in methylic alcohol have their origin in the action of ammonia upon acetone during the repeated distillations to which crude methylic alcohol is necessarily submitted in order to purify it. Similarly the simultaneous formation of aldehyd in this reaction explains the presence of that product in methylic alcohol.

QUANTITATIVE ESTIMATION OF EMETINE, ACONITINE, AND NICOTINE.*

BY O. ZINOFFSKY.

To estimate emetine, the author treats 15 grams of powdered ipecacuanha with sufficient 85 per cent. alcohol, to which a few drops of sulphuric acid have been added, to measure altogether 150 cubic centimetres. This is filtered, and 100 cubic centimetres are taken, from which the alcohol is removed by distillation ; to the residue is added a titrated solution of iodo-hydrargyrate of potassium, until a portion of it is no longer rendered turbid by that reagent after filtration. The number of cubic centimetres of the solution of iodo-hydrargyrate required, multiplied by 0·0189, or one ten-thousandth of an equivalent of emetine, gives the quantity of emetine contained in ten grams of the root. The normal solution of emetine is prepared by mixing aqueous solutions of 13·546 grams of bichloride of mercury and 49·8 grams of iodide of potassium, and completing to one litre with water. One cubic centimetre of this solution precipitates one ten-thousandth or one twenty-thousandth of an equivalent of alkaloid. Ipecacuanha wine can be estimated in the same way.

Aconitine is treated in a similar manner; but the number of cubic centimetres of solution of iodo-hydrargyrate of potassium required to precipitate the alkaloid is multiplied by 0·02665, or one twenty-thousandth of an equivalent.

In order to estimate nicotine, 15 grams of tobacco are digested for 24 hours with a sufficiency of 85 per cent. alcohol, to which fifteen drops of sulphuric acid have been added, to bring the volume up to 150 cubic centimetres. Fifty cubic centimetres of this solution are filtered and evaporated, and the solution of iodo-hydrargyrate of potassium added to the residue. The number of cubic centimetres required, multiplied by 0·00405, or one ten-thousandth of an equivalent of nicotine, gives the quantity of alkaloid contained in five grams of the tobacco.

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE ADULTERATION ACT IN ITS RELATION TO DRUGGISTS.

THE report we publish this week of the proceedings at Westminster Police Court last Saturday will no doubt be read with much interest, and it is so full that there is no need to recapitulate the details here.

The case will serve to illustrate the possible oppressive application of the Adulteration Act, and to demonstrate the want of some proper means of regulating the action of the local authorities with whom rests the obligation of carrying out the provisions of the Act. Such bodies are very generally in the same state of disability indicated by Mr. ROGERS, who, representing the Westminster Board of Works, said that the position they were placed in was that they scarcely knew what they were to do.

Under these circumstances, it is not surprising that uninformed excess of zeal should, as we have already had occasion to point out, run riot in promoting prosecutions for which there is no kind of foundation in fact.

It is in this way that dangerous and expensive experimental prosecutions are instituted, with no other results than those of wasting public money, harassing tradesmen, and possibly damaging their credit, as well as wasting their time. No wonder, then, that the magistrate should have expressed himself in such strongly condemnatory terms in regard to the course taken by the Westminster Board of Works; and we trust that his decision will have a wholesome influence in preventing the perpetration of such abuses in the future.

Out readers may congratulate themselves that the result of these prosecutions has turned out in the way it has, when they consider the perils with which even a sound defence is surrounded in a court of law, whenever the questions at issue are of a scientific nature. Anyone who reads through our report of the case now referred to will readily perceive that both the magistrate and the lawyers acting for the several parties were under great difficulties in endeavouring to comprehend the real merits of the case. The principal witness for the prosecution was throughout his evidence at cross purposes with his cross-examiner as to the several scientific details which it was necesary to deal with, and, although no exception can be taken to the evidence he gave as an analyst merely, it was quite apparent that he laboured under serious misapprehensions, arising from a want of practical pharmaceutical experience. On no other foundation could he have formed the opinion that the sale of sweet spirit of nitre was an infringement of the Adulteration Act, or even of the Pharmacy Act, which is so much more stringent in its provisions as regards registered chemists and druggists. We venture to think that had he known that sweet spirit of nitre was an old established and popular remedy, and a preparation distinct from the spirit of nitrous ether of the British Pharmacopœia, we should never have heard of the prosecutions which received such signal defeat last Saturday.

In passing, we may note that the trial of this case incidentally brought out some points of importance, and among these the opinion expressed by Mr. ARNOLD that the provisions of the Adulteration Act relating to drugs do not in any way apply to pharmaceutical preparations or compounded medicines. So likewise the fact is worth noticing that though the Pharmacopœia is the authority by which pharmacists are to be guided in the compounding of medicines ordered by physicians, that work is not to be regarded as operating in any way as a restriction of trade or manufacturing industry in respect of preparations required for other purposes than those contemplated by its prescriptions.

We are glad to find that the medical journals generally acknowledge the impropriety of these prosecutions. The *British Medical Journal* regards them as being equally as ill-judged and oppressive as the recent prosecution for the sale of "citrate of magnesia." It rejoices in their failure, and adds that, while proceedings so harsh and ill-founded are quite contrary to the public interest, they can only tend to bring a useful Act into public odium.

The *Medical Times and Gazette* says that at a time when adulteration is being carried on to a large extent in articles of every day use, it would be better to look out for cases of some utility to the public to be exposed, rather than to raise a legal question as to the manufacture of an officinal preparation which by the most liberal stretching cannot after all be called actual adulteration.

In a like spirit the *Medical Press and Circular* considers that a great mistake was made at Westminster in dragging several respectable pharmacists and a qualified medical practitioner before the magistrate on a charge of selling adulterated spirit of nitre, when it appeared from the evidence that those persons sold as spirit of nitre an article known by that name for more than a century.

The *Lancet*, while admitting that it was rather harsh to make the charge of adulteration at all, is at the same time somewhat incorrect in its remarks on this case. In the first place, it is negatively incorrect in omitting to state that the "unfortunate" attempt to obtain a conviction was directed against a medical practitioner as well as against "a number of druggists." The case actually tried was that of a surgeon, although of course we do not think that fact affects the merits or demerits of the case. Secondly, it is positively incorrect in stating that the prosecution was instituted "for selling 'adulterated' sweet spirit of nitre," inasmuch as the adulteration alleged was that of spiritus ætheris nitrosi, B.P., it being contended that the sale of sweet spirit of nitre—another thing entirely—constituted an offence under the Adulteration Act. Again, the well-known fact of the instability of spiritus ætheris nitrosi was not urged as an "excuse" for selling the old-fashioned preparation; the demand for the latter, not only by the public, but also by medical men, being the sole reason for doing so. We doubt whether that demand will be materially influenced by the information to the public, now volunteered by the *Lancet*, to the effect that sweet spirit of nitre "possesses absolutely no value whatever."

An opinion is also expressed by the *Lancet* that it is very desirable the motives of the Westminster authorities, and of their analyst, Dr. DUPRÉ, should not be misrepresented as it is assumed they have been by the reports in the papers. We have not as yet seen any such misrepresentation, and if we may take the statement of Mr. ROGERS the solicitor for the Board of Works, this body seems to have had no motives; but merely to have proceeded on the analyst's certificate as a matter of obligation. As regards Dr. DUPRÉ, we imagine he would not desire to be credited with "motives" at all. They would certainly be very inconsistent with the function of the analyst, and we have his own distinct assurance that he had nothing to do with the institution of these proceedings.

But while we express satisfaction at the issue of the spirit of nitre case, we must guard ourselves against being supposed to have any tendency towards defending practices that are really objectionable, either as regards the quality of drugs and pharmaceutical preparations or otherwise. It has always been the policy of the Pharmaceutical Society to discountenance anything of that kind, and to promote to the utmost the sale of genuine articles, and it is only by pursuing such a course that pharmacists can hope to secure the recognition and public confidence which appertain to their calling. It is from such a feeling that we have thought it our duty to suggest in regard to the "citrate of magnesia" question the advisability of abandoning the use of the misnomer which has been so long current. That Mr. BISHOP, as the manufacturer of a proprietary article, should seek to continue the name he has hitherto used, is very intelligible, and though we cannot give concurrence to the reasons he assigns for so doing, we prefer leaving the discussion of this point to himself and those correspondents whose letters he replies to this week.

Our argument for the abandonment of the term is urged from the point of view of the interest of pharmacy, and we hold that in this light it would even be better to resign the trade in this article to the grocers than to incur the possible prejudice arising from the use of so palpable a misnomer as "citrate of magnesia."

While speaking of this subject we must take the opportunity of expressing our dissent from the opinions expressed in Mr. GILES' letter. To those who know him it will not be a novelty to find him taking a chivalrous part; but the suggestion he puts forward as to the late case of conviction for the sale of "citrate of magnesia" seems to us impracticable, inasmuch as the defendant in that case was not a registered chemist and druggist, and it would be as reasonable for the trade to take up the defence of any grocer fined in like manner under the Adulteration Act.

A NEW catalogue of the books contained in the library of the Pharmaceutical Society is now ready for distribution. On the motion of Mr. SANDFORD, it was resolved by the Council at its meeting, on Wednesday last, that a copy of this catalogue should be supplied to every Member of the Society and Associate in Business who makes an application for one. It is desirable that such applications should be made as soon as possible to the SECRETARY, in order that an estimate may be made as to the number that will be required.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL,

Wednesday, December 3rd, 1873.

MR. THOMAS HYDE HILLS, PRESIDENT.

MR. ALEXANDER BOTTLE, VICE-PRESIDENT.

Present—Messrs. Atherton, Baynes, Betty, Brown, Frazer, Greenish, Hampson, Mackay, Owen, Radley, Robbins, Sandford, Savage, Schacht, Shaw, Stoddart, Sutton, Urwick, and Williams.

The minutes of the previous meeting were read and confirmed.

NEW BYE-LAWS.

The SECRETARY read a letter to the effect that the amended Bye-Laws had been received and approved by the Privy Council.

ELECTION OF EXAMINERS.

In accordance with the new Bye-Laws, sec. 10, cl. 2, the Council then proceeded to appoint examiners for the year beginning January, 1874.

The VICE-PRESIDENT suggested that only twelve examiners should be elected on the present occasion, although under the new Bye-Law they had power to elect fourteen; the matter not having appeared on the agenda, and members not being prepared with names.

The present examiners were thereupon formally re-elected by ballot.

Seven members of the present Scotch Board were also re-elected. One examiner having retired, Mr. Mackay stated that the North British Branch were not at that moment prepared with another name.

ELECTIONS.

PHARMACEUTICAL CHEMIST.

Sant, George .....Woodstock.

ASSOCIATES.

The following having passed the Minor Examination were elected Associates of the Society :—

Balchin, Edward Samuel.....Devizes.
Compton, Arthur .....Reigate.
Evans, John .....Bishop's Road, W.
Hucklebridge, James Marwood.London.
Johnstone, Thomas Francis.....Dumfries.
Masters, Henry James.....Bath.
Maxey, John Thomas .....Wisbeach.
Morris, Thomas Henry Vaughan.Dorchester.
Princep, Philip .....Uppingham.
Smith, Charles .....Sleaford.
Williams, Richard.....St. Clears.
Wright, Conrad William.....Tewkesbury.

LOAN OF SPECIMENS.

Mr. SCHACHT, as President of the Bristol Pharmaceutical Association, had been requested to ask permission for the collection made by Dr. Porter Smith in the Museum to be sent down, in order to illustrate a lecture which Dr. Porter Smith had kindly offered to give. The specimens were not such as would be likely to be injured by carriage, and of course the Society would be put to no expense.

The PRESIDENT said he was quite sure the Council would authorize him to give the requisite permission; they were always desirous of aiding the cause of education in any way.

Mr. SANDFORD preferred a somewhat similar request on the part of Mr. Claypole of York Town, Blackwater, for certain chemical and electrical apparatus to illustrate a lecture on water.

This request also was acceded to.

FINANCE.

The report of this Committee was read and confirmed, and sundry accounts ordered to be paid.

Benevolent Fund.

The Committee of this Fund recommended a grant of £10 to the widow of the member to whom a grant had been recommended last month, but who had died before the grant could be made. Also a grant of £20 to the widow of a member in straitened circumstances who was desirous of emigrating. These grants were now made by the Council, as also a grant of £10 to the widow of a member into whose case inquiries had been made by Mr. Atherton, but too late for consideration by the Committee.

Report of Special Benevolent Fund Committee.

The Committee appointed to consider what means could be adopted for increasing the income and usefulness of the Benevolent Fund, presented a report recommending that a letter asking for further donations be forwarded to every chemist and druggist whose name was on the register, and also that in future every subscriber of 5*s.* should be entitled to one vote, and so on in proportion, one vote for every 5*s.* subscribed.

Mr. Williams thought it worthy of consideration whether a circular should be issued, or whether an advertisement in the Journal would not be sufficient.

Mr. Robbins suggested that the consideration of this report should be deferred to another meeting. He thought if the Committee discussed the matter a little further some still better method might be adopted.

Mr. Brown moved

"That the consideration of the report and recommendations of the Special Committee be postponed."

He thought it had been arrived at a little hastily. He also took the opportunity of correcting a misapprehension either on his part or on the part of Mr. Robbins, in expressing himself at a former meeting. He certainly understood that Mr. Robbins advocated the purchase of annuities with the invested capital of the fund, and against that he entered his strongest protest. Since then, however, he had arrived at a more definite idea of the course Mr. Robbins would advocate. They had hitherto confined the granting of annuities to the amount of interest on their invested capital, but after considerable thought on the matter he had arrived at the conclusion that they might fairly take a further step, and proceed at least to consider, if not to resolve, upon granting two classes of annuities, the first class payable out of the interest of the accumulated funds invested, and a second class payable out of the annual subscriptions. He believed when the Committee came to consider the means that should be adopted to increase the annual subscriptions this might be found more effectual than any other which could be adopted. It was very desirable, of course, that every case should be relieved, and he believed that was done, but clearly it would be very desirable if they could have a larger number of deserving and necessitous persons in receipt of small annual incomes from the Society. He believed the time had now arrived when, having nearly £14,000 invested, they might grant some annuities out of the annual income, and although they might not be so absolutely secure as those paid out of the invested funds, still he believed they would be found sufficiently secure, and would be the greatest encouragement to increased subscriptions on the part of the members. He therefore hoped the matter would be again remitted to the Committee.

Mr. Betty seconded the motion.

Mr. Baynes supported the views of Mr. Brown, and proposed that that gentleman's name be added to the Committee.

The resolution was unanimously adopted, and Mr. Brown's name was added to the Committee.

Library, Museum and Laboratory.

The report of this Committee was read, stating the arrangements which were being made for lighting and furnishing the Library, etc., and also with regard to the custody of the specimens and apparatus belonging to the Society.

The Committee also recommended the purchase of the following books for the Library:—

Drury's 'Useful Plants of India;' Wanklyn's 'Milk Analysis;' Tyndall's 'Six Lectures on Light;' Babington's 'Flora of Cambridgeshire,' and Brewer's 'Flora of Surrey.'

It was reported that 42 pupils were at present at work in the Laboratory; 20 attending the botanical lectures, and 32 those on chemistry and pharmacy.

The report and recommendation were received and adopted.

Parliamentary.

The following letter from the solicitor was read with respect to the mode of carrying on the business of a deceased chemist and druggist:—

[Copy.]

"3, East India Avenue,
Leadenhall Street, London, E.C.,
"*October* 20*th*, 1873.

"Elias Bremridge, Esq.

"Dear Sir,—

"We advise, as requested, upon the three questions submitted to us by a member of the Council at the Committee Meeting, those questions being:—

"'1. Can the trustees of a deceased chemist and druggist carry on business in the name of the late proprietor only, or must the names of the trustees, or the words "Trustees of the late," etc., appear on the sign, prescription envelopes, labels, etc.?

"'2. If a P.C. or M.P.S. by subscription, can the title be used either with or without "subscription"?

"'3. If a P.C. by examination, can the words "Pharm. Chemist" be affixed?'

"The whole law on the subject of question No. 1 is contained in the Pharmacy Act, 1868, and the exception in favour of executors, administrators, or trustees is limited to that created by the words in section 16:—

"'And upon the decease of any pharmaceutical chemist or chemist and druggist actually in business at the time of his death, it shall be lawful for any executor, administrator, or trustee of the estate of such pharmaceutical chemist or chemist and druggist to continue such business if, and so long only as, such business shall be *bonâ fide* conducted by a duly qualified assistant.'

"We regard the exception as one to be construed strictly, and as enabling 'executors, administrators, and trustees' only to continue a business actually conducted by the deceased at the time of his death, and so to continue it only so long as they are doing so in the capacity of 'executors, administrators, or trustees'—that is to say, for the benefit of the deceased's estate, and not for their individual benefit.

"The continuance of the business will not be in exercise of any personal qualification in the 'executors, administrators, or trustees,' and will not confer upon them any degree of qualification to carry on business on their own account, or open any new business as 'executors, administrators, or trustees,' and the exception in the Act of Parliament will not delay the erasure of the deceased's name from the register, or entitle the 'executors, administrators, or trustees' to be placed upon the register, and it follows, as we consider, that the proper style for the conduct of a business under the exception is—

The { Executors, Administrators, or Trustees } of A. B. { Pharmaceutical Chemist, or Chemist and Druggist. } deceased.

"With regard to the sales of poisons under clause 17 of the Pharmacy Act, 1868, we consider that the intention of the Act of Parliament is that there shall be a personal responsibility to the purchasers and the public, and that

the 'executors, administrators, or trustees' continuing the business are the persons or 'sellers' liable to the purchasers and the public for the fulfilment of the conditions imposed by clause 17, and therefore that it will be the proper and safe course that on every sale of a poison the conditions of section 17 shall be complied with by the full names of the 'executors, administrators, or trustees,' with the address at which the business is conducted, being placed on the label used for the poison, in addition to, and before the above suggested style of the business.

"Regarding the questions Nos. 2 and 3, we consider that there are not any pharmaceutical chemists 'by subscription,' or any pharmaceutical chemists 'by examination,' and that all pharmaceutical chemists are such by one qualification, namely, that of being on a common register, and not otherwise, so that the words 'by subscription,' or 'by examination,' applied to a pharmaceutical chemist or chemist and druggist, are words of misdescription. The words 'by subscription' we have never seen in use. 'By seniority' would appear to be the more accurate expression, if either could be accurate.

"We suggest for consideration whether it is desirable for the Society to encourage the use of the words 'by subscription,' 'by seniority,' or 'by examination,' or other words whereby the public may be led to regard the great body of pharmaceutical chemists as subdivided, and so also with regard to the more numerous body of chemists and druggists.

"We are, dear sir,

"Yours truly,

"FLUX AND CO."

Mr. SAVAGE said the letter they had heard, was very important in connection with the question of the widow of a chemist and druggist, carrying on business. It appeared that the trustees had power, so long as they were trustees, to do so. But no matter how soon the trusts expired, the widow could no longer carry on the business. Now, that seemed an anomaly, and he thought it ought to have been so arranged that with a properly qualified assistant, the widow should have had power to carry on the business. It was quite certain that trustees were not in ordinary cases pharmaceutical chemists; they might be totally ignorant of the business, and still they had the privilege of carrying it on as long as they were trustees, and he thought the widow should have the same advantage.

Mr. STODDART thought this was a very serious question; suppose, for instance, a man died, leaving a widow and children. Of course he ought to make a will, and to appoint his wife sole executrix, or to appoint an executor; but supposing that any accident took place, in point of law the person would be asked, are you on the register? The question was, who was to be on the register.

Mr. FLUX said that on the death of any pharmaceutical chemist, or chemist and druggist, his name would be expunged from the register, and in respect of the business there would be no name on the register. The executors or trustees carrying on the business, must carry it on by reference to the register which was in existence at the date of the death of the deceased; they would point to that register and say we are carrying on a business which was carried on by that gentleman at the date of his decease. But neither the dead man, nor the living man could be on any present register.

Mr. STODDART said there was the difficulty.

Mr. FLUX: There is no provision for putting executors on the register. If any mistake is made, a civil action must be brought against the person who actually committed the mistake, that is to say, the executors; and if the executors take upon themselves a responsibility of that kind, it is just the same as in the case of debts. If an executor carries on a business, he is personally responsible in respect of every purchase made by him; it is a personal debt, although he may indemnify himself against it out of the estate of the deceased. So with regard to any liability to an action for damages, he would be personally responsible, because the carrying on is a personal act, although he might in respect of it be entitled to indemnity out of the estate of the deceased. The executors carry it on by force and virtue of a right which they acquire through the deceased consequent on his having had a personal right at the time of his decease.

Mr. SAVAGE said if the widow were left without any trustees, he supposed the business must necessarily be sold.

Mr. FLUX: That is not so, because she would be entitled to letters of administration as the widow, and so long as she carried on the business *quâ* administratrix she would be protected by force of the Act of Parliament. But from the moment that she ceased to carry it on *quâ* administratrix, and by any means became possessed of the business as her personal property, and thenceforward carried it on for her personal benefit, she would infringe the law.

Mr. SAVAGE said that seemed about the same thing.

Mr. FLUX: It is not the same thing, for although the law gives the widow a right to administration, it is only for the purpose of administration. If the deceased left children she is trustee of the business to the extent of two-thirds for the children. She has first to pay all the debts, and until that is done she is trustee for the creditors. From the moment that the debts are paid she is then trustee for the children, if there are any, to the extent of two-thirds. If there are no children, then she is trustee of a moiety for the next-of-kin. Then a day would come when she ceased to hold that position of trustee, but that day would only come by force of some act of her own terminating the position, or by force of some act of the children, or the other next-of-kin which brought about a settlement of the accounts, and thus terminated the administration by force of some contract then entered into, not by force of being the widow; the business then would change hands, and if by the change of hands she in her own capacity becomes the proprietress of the business she commits a breach of law.

Mr. OWEN: Is there any limit of time?

Mr. FLUX: No; it is a question of fact to be determined in every instance. I have known trusts continue for half a century.

Mr. SAVAGE: Suppose a man dies intestate?

Mr. FLUX: Then the widow is the first person entitled to administration.

Mr. BOTTLE asked whether clause 1 in the Act would override clause 16, the first stating that no person, not on the register, could carry on business; and clause 16 stating that nothing hereinbefore contained should extend to the executor of the deceased registered pharmaceutical chemist or chemist and druggist.

Mr. FLUX said that neither clause must be taken to override the other, but they were to be taken and read together. If read together they become consistent.

Mr. GREENISH said he thought they were not yet all quite clear with regard to the case of a widow, and it was very important they should be; for instance he should like to know whether—supposing anything happened to him, and he left his business to his wife for the support of the younger children—could she carry on the business, not being on the register?

Mr. FLUX: Certainly, so long as she does so in execution of the trusts of your will; but at the moment when she puts into her own pocket all the profit so made, and takes out of her pocket all the losses she may sustain, at that time she begins to break the law.

Mr. BROWN said this was a most interesting question to gentlemen who were married. Supposing he made a will simply leaving everything to his widow, and leaving her sole executrix. If he left no children she would have no trust to fulfil and therefore he presumed she could not carry on the business after his decease.

Mr. FLUX said he was clearly of opinion that Mr. Brown's widow would be in no better position than

another man's sister. Still in the abstract case put by Mr. Brown there would be a period during which the widow clearly would carry on the business *quâ* executrix, because she must have time to look around her, and see that all the debts were discharged. And even though she feel conscious that there was ample to pay her debts, yet as her first duty was to pay the debts of the deceased, no lawyer would hold, until that was done, and a fair period had been allowed for the purpose, that there was any breach of the law.

Mr. GREENISH said a man might have some children grown up, and some very young, who required a good deal to be spent on their education. Could his widow carry on the business for the education of those children?

Mr. FLUX: Certainly, because although every mother is bound, as every parent is, to maintain her offspring so long as that offspring requires maintaining, that being a distinct personal obligation created by the law of the land, and therefore if a widow is left with the business, as a widow or otherwise not distinctly charged with the trusts of maintaining the children, she is not a trustee, but a beneficiary; still, if the will said: I leave to her that business upon trust, that so long as any child of mine is an infant he shall share in the proceeds to a certain extent, or upon trust that the widow shall maintain that child, then there is an active trust, and the widow could carry it on *quâ* trustee, for the purposes of the trust, and the trust would be capable of being enforced.

Mr. BAYNES said he believed this matter had arisen out of certain questions which he had brought before the Parliamentary Committee, arising out of a case actually present to his own mind. He himself had no doubt of the power to leave trustees to carry on the business for the benefit of children, and the question put by him was in what form that business should be carried on. As he understood the answer was that it should be carried on in the names of the trustees. But beyond that there was this difficulty: that if the names of two or three, or more trustees appeared it would undoubtedly damage the business; with that however they had nothing to do, but simply to obey the law. In the particular case to which he referred he had suggested that the business should be carried on in the name of the deceased proprietor, only until this question could be settled. He understood now that that would not be legal, but that it must be carried on in the name of the trustees. He apprehended however in all cases there must be a duly qualified assistant to conduct the business.

Mr. FLUX: Certainly.

Mr. MACKAY said he had listened very attentively to all that had been said, and if he understood the matter thoroughly it was this, that the law had provided a certain mode of procedure in the event of a man dying leaving a trust to put the widow in a proper position; but supposing he died leaving a widow without children, and no deed of any kind, nothing except law gave her the power of administering to his effects, those effects consisting chiefly of the druggist's business. Was he right in understanding that that widow might for a time retain the business whilst she looked around her with a view to determining the best means of disposing of it; but that certainly she could not continue to carry on the business even with a qualified person?

Mr. FLUX said to the general question he should answer affirmatively, as he thought the lady would not carry on the business *quâ* widow, but that *quâ* widow she would exercise the right given to her by law by taking out letters of administration, and then *quâ* administratrix carry on the business for the purpose of the administration.

Mr. BROWN said whilst they were informed that a widow could carry on the business so long as she had trusts to fulfil, and that trust might exist for a definite period, there was no obligation to wind up the affairs of the trust within any specific time. He would put this case:—Supposing a widow left the absolute possession of the business (no trust to fulfil, except to take out letters of administration and to wind up the affairs in connection with the business), could she carry it on for any time beyond that necessary to wind up the affairs, get in the assets, and turn the business into cash?

Mr. FLUX: No.

Mr. BROWN asked if, supposing a man left no family, it would be sufficient to constitute a trust if he left a provision in his will that the trust should be to pay a guinea to the Pharmaceutical Society for 20 years, could the widow carry on that business in order to execute such a trust?

Mr. FLUX: I would ask you not to put me to a clear definition of a trust, because trusts are very multifarious, and it is impossible to say what does constitute in strictness a trust. There is a limitation with regard to trusts fixed by what is called the *Thellusson Act*, that is to say, that a trust can only continue for the life or lives of a person or persons in being, and twenty-one years afterwards; that is to say, during the life of any person existing at the date of the decease, and sufficiently long for that person to come of age. That, I believe, is quite sufficient for conducting the business of a chemist. You would meet the matter generally by making a will and associating another trustee with the widow. But then I apprehend trustees generally look a little to this, and do not like to incur personal liabilities. Most gentlemen who are trustees look forward with some anxiety to the day when their trusts shall end, because so long as they continue they are under a personal liability. However, any gentleman may be quite sure that so long as he can get a trustee, not a beneficiary, to *bonâ fide* carry on the business as his trustee, so long it can be continued.

Mr. BROWN: Then in the case of a widow left sole executrix with no trusts to fulfil, she would not be allowed to carry on the business for any definite period.

Mr. FLUX: No; but there would be no disposition on the part of anybody to strain the law against her. Allow me to add that it is an old saying with lawyers that hard cases make bad laws, and that though it might be desirable to extend mercy to widows, yet the general principle is for the benefit of chemists and druggists in general—that is to say, that no person shall by force of being appointed executor or administrator carry on a business for his or her personal benefit. That would give rise to no end of evasion of the law; and with respect to any hardship, it is no harder for chemists and druggists than for any other persons who have to get their daily bread by their personal qualifications. If you look to medical men, clergymen, or lawyers, in all these cases the personal qualification dies with these persons, and there is no such merciful provision in their case as is contained in the Pharmacy Act.

Mr. MACKAY said the whole might be summed up in this, that they could not remedy what they felt to be rather unfair without making a change in what it was quite evident was a very imperfect Act of Parliament.

Mr. GREENISH asked if it were the case that, supposing he left a wife sole executrix, with no children to educate until they attained the age of twenty-one years, must she then dispose of the business which might be her only means of support.

Mr. FLUX: Certainly, there is no difference between a widow and any other relation you might leave, your child or your grand-grandchild. In fact, if you once start with the personal exception there would be no limit to it. It might extend to uncles, cousins, and all other relations. Therefore, it stops short, and on the death of the deceased person all personal qualification ceases. From that moment no qualification exists except a representative one, and at the moment when that representative qualification ceases there is none at all.

Another letter from the Solicitor was read, with relation to the Adulteration of Food and Drugs Act, and the following resolution was unanimously carried:—

"That the Solicitor being present to advise the Council on a question of law, this Council do now resolve

itself into a committee for the purpose of communicating with him."

After a somewhat lengthy discussion in committee the Council meeting was resumed, and the following resolution was passed unanimously :—

"That the recent action of the analysts under the Adulteration of Food, Drink, and Drugs Act be referred to the Parliamentary Committee for consideration, and that they be instructed to watch any future proceedings."

PROVINCIAL EDUCATION.

The report of this Committee was read recommending that a grant of £15 be made to the Sheffield Pharmaceutical and Chemical Association. The report and recommendation were adopted.

SPECIAL.

The report of the "Special Committee appointed to consider the proposals of the Board of Examiners, in reference to the Preliminary and Prize Examinations, and the Jacob Bell Memorial Scholarships," was read, which stated that the Committee had came to the conclusion to recommend a reduction in the number of centres, and a list of towns was appended at which they proposed the Preliminary examinations should be held. Also that persons should be specially appointed to superintend the examinations who should be called "superintendents," and should receive a fee of one guinea for each examination ; such persons to be appointed by the Council. Also that a special room, suitable for the purpose, should be hired for each examination. The Committee also adopted the recommendation of the examiners with regard to the examination for the Pereira Medal and the Prize of Books ; but they recommended that the Jacob Bell Memorial Scholarships should be competed for in the country. They did not object to the recommendation of the examiners that medical Latin should be discontinued after 1874. Lastly, the Committee desired, if their recommendations should be adopted, that the subject should be again referred to them for consideration of the details.

Mr. HAMPSON said he supposed by adopting the report they would not be prevented from adding to the prescribed number of places, of which a list had been read.

Mr. SANDFORD said certainly not. They simply said that for the present the centres should be so-and-so.

Mr. WILLIAMS moved, and Mr. SANDFORD seconded :—

"That the report of the Special Committee appointed to consider the proposals of the Board of Examiners in reference to the Preliminary and Prize examinations, and the Jacob Bell Memorial Scholarships, be received and adopted, and that the matter be again referred to the Committee for arrangement of the details and to report to the Council at the January meeting."

Mr. FRAZER said he was very unwilling to trespass on the time of the Council again, but he felt so strongly on this question that he was obliged to do so, and he must propose an amendment as follows :—

"That believing it to be inexpedient and unwise to reduce the number of centres for conducting the Preliminary examinations, this Council whilst accepting the arrangements, recommended by the Special Committee, for holding the Bell and other Prize Examinations, are of opinion that the change in the method of conducting the preliminary examinations suggested by the Board of Examiners, and recommended by the Committee in their report, ought not to be adopted until it be shown that the regulations for the same, when duly given effect to, are insufficient to meet the necessities of the case."

His reason for bringing forward this amendment was the difficulty which had been experienced all over the country in getting assistants. He had been told that this was peculiar to Scotland, but since he had been in London that day he had received evidence that it had extended even there, and he knew that all over England the same thing was true. He maintained that this restriction of the number of centres would be a great step in the same direction, for the class of persons from whom their apprentices were taken could not afford to go these distances. He also objected to it as being a restriction on the mode in which they should carry on their trade. As he had already stated, he considered they were the custodians of the existing trade, and it was not for them to throw any obstacle in the way of its being carried on. He believed this to be a serious step in the wrong direction, which would bring about a reaction which all would regret. Besides that, it was indirectly, or rather directly censuring the local secretaries, whereas he maintained that up to the last there had not been any evidence brought before the Council to warrant such charges. They had heard of some cases being mentioned in committee, but the parties concerned, the local secretaries, had had no information from the Council, and were really condemned unheard. Further than that, he considered that the Board of Examiners were in a great measure answerable for the irregularities through having, no doubt out of kindness, not insisted upon the strict carrying out of the regulations which were made. He objected to these constant and revolutionary changes, and held that this was the most serious blunder the Council had committed since he entered it, and therefore he trusted the Council would refuse to accept it. He ventured to say most distinctly that they would have to get a class of men inferior to the present, unless another Act was brought in to compel them to conduct their business with men who had passed the examinations. He could assure the Council that at the present moment many gentlemen were conducting the business with porters, instead of getting apprentices. Whatever might be the ultimate prospect of the business, for the present he thought the proposed change would act injuriously on their constituents.

Mr. WILLIAMS thought it was a little irregular to hear the amendment moved before the mover of the resolution had had an opportunity of speaking to it, which he would now ask leave to do. They were really now acting under the advice of the Board of Examiners, and they would be taking a great responsibility if, when a certain course was recommended, evidence having been given to prove that that was a good course, they were to stand in the way of carrying it out. He thought they were bound to pay great attention to every suggestion made by the Examiners, and at any rate not to do anything to prevent them doing their work in an efficient and proper manner. Of course, under the present condition of things, where there were so many centres for examination, many of the superintendents who were appointed found it a great hardship to have to attend to them. The idea therefore had been entertained of reducing the number of the centres, and the Board of Examiners suggested that about thirty should be fixed upon, but the Committee had suggested about sixty, but they were not limited to that number. It would be most advantageous if they could afford to pay a small fee for the superintendence, and they would then be able to speak more authoritatively to the superintendents, and keep them to the strict performance of their duties. The idea was not to make these examinations more stringent or difficult, but simply that they should be fairly conducted, so that each candidate should stand upon an equal footing. Mr. Frazer's objection really seemed to be to examinations altogether, not to this or that system, and no doubt having any examination at all was disadvantageous in Scotland, and perhaps also in England, as far as regarded the getting of apprentices, but they had no option in that matter ; they were under an Act of Parliament. They were bound to examine, and to see that the examination was reasonable and just to all.

Mr. SANDFORD, in seconding the motion, said he need scarcely give his reasons at any length, having so often stated them. Mr. Frazer said no evidence had been laid

before the Council of the necessity for a change, but he admitted it had been brought before the Committee, and he therefore admitted its existence, although it had not been made public. For his own part he should have thought it better if these examinations were got rid of altogether, and in this view he was supported by a letter then on the table from Mr. Randall, of Southampton, who suggested that they should be handed over, as were those of the Science and Art Department, to examiners specially appointed. He had seen one of the examiners of Apothecaries' Hall, who told him that they continued these examinations, but instead of conducting them themselves appointed three masters of arts to do it. He thought men of that class would really be much better examiners for lads just coming from school than their own board. They did not want any technical knowledge, but simply proof that a boy was sufficiently educated to take advantage of the opportunity he would have of learning his business, without having to spend the time of his apprenticeship in learning the Latin grammar and such things. He was very glad to accept the compromise which had been suggested, and had prepared a map on which forty or fifty centres had been marked, which the Committee had since extended to about sixty-three; other important alterations in the regulations had also been made; one being that the examinations should no longer be held at the houses of the superintendents, but in rooms hired for the purpose. Another was that in each centre there should be two persons authorized to superintend, not both to be employed at the same time, but in the event of one being unable to attend, then the other should be called upon to act. There were many things in the regulations which must be made more stringent and explicit; he should be very sorry to see candidates sent back simply from some informality on the part of the superintendents. According to the proposed arrangements no young man would have to go more than about twenty-five miles to be examined, and if they could not do that, the next thing would be that they would have to send examiners round the country to every village where a boy resided who wanted to be a chemist and druggist. He did not think the change would tend to keep out educated men or bring in uneducated men, but, on the contrary, would tend to bring in a better educated class of men, and would ultimately much improve the business. He hoped therefore the proposition would be accepted.

Mr. URWICK seconded Mr. Frazer's amendment, though he was sorry to differ from gentlemen who had given so much consideration to this subject. Still he felt it a duty to oppose taking from the country a privilege which they had hitherto possessed and making a change which he saw no necessity for. He distinctly understood from Mr. Carteighe that he did not advocate a change up to that time in the Preliminary examination, and until some faults or failures were placed before them to demand a change, he thought it was a false step to take. He maintained that the local secretaries, as a body, had conducted these examinations as well as they were conducted in that house. It had been said that sometimes they had to leave the candidates in a room whilst they were filling up their papers, but he had seen the same thing occur in Bloomsbury Square. He agreed that the secretaries ought to be paid, and then they could be more justly required to attend to their duties, but he objected to any kind of centralization, and thought the more secretaries they had the stronger would be the ramification of the Society throughout the country, and the more intimate the tie which united them to London. It was said that the list of centres might be changed, and at the present time examinations were not held in all the towns where there are secretaries, and therefore he saw no necessity for the change. Besides this, the new system would very probably create jealousy amongst the secretaries who were omitted, and who perhaps had done as well in the past as those who were to be continued.

Mr. SCHACHT felt it necessary not to give a silent vote on this matter, lest it should be considered he had changed his views upon it. As far as the question of principle was concerned, his opinion remained the same as before. The principle alluded to by the last speaker consisted in centralization *versus* diffusion; but they were not adopting any principle of centralization, as a few facts and figures would show. According to the existing principle, they had about three hundred centres at which examinations were conducted, and that to a certain extent required persons to travel, for they did not all live in the towns where the examinations were held. According to the proposed scheme, there would be sixty-three centres, and there was also a provision that the Council might add any others as it was found necessary. It was therefore only an extension, or rather a contraction of the present system. Now, he found that out of the three hundred centres, taking the average of the last twelve examinations, there were twenty-four centres at which there was an average of three persons and upwards attending per examination; forty-six at which there were two individuals and upwards; ninety-four at which there was only one; fifty-nine at which there was about half a person for examination; seventy-nine even less than that, and thirty-two in which there was no examination held at all. Then when they came to meet the demand in any way at all, and to improve the existing state of things,—and he must conclude it to have been made out that faults had been committed, partly due to an imperfect system,—it was necessary to frame good regulations, which was a comparatively easy task, and next to see that they were enforced, which was not so easy, when you come to deal with three hundred centres. It could only be done by placing superintendents over them, who would be in some degree responsible to the Council. Now if a fee of only £1 1*s.* were to be paid to three hundred individuals four times a year that would be a very serious charge, and putting that beside the fact that in many cases they had gentlemen presiding over one candidate, they could not but arrive at the conclusion that it was a wise thing to diminish the number of centres, and so secure a more efficient superintendence on the part of those which remained, remunerating the person placed in charge. They did not advocate centralization, but simply lessening the number of centres which at present existed, and it must be remembered that all further details were to be considered by the Committee, for it was evident the scheme was as yet by no means perfect. For instance, he saw no reason why the regulations should not be printed at the head of the papers on which the candidates had to write, informing them that unless these regulations were fulfilled, their work would not be accepted. With regard to the Jacob Bell Memorial Scholarships, he rejoiced to find that the Committee had agreed to allow this to remain, at any rate, for the present, without change, thinking, no doubt, that if the proposed alteration in the mode of conducting the examination were adopted, the objections to it would cease. He therefore thought, on the whole, that by meeting the suggestions of the examiners, they would be serving the object which they all wished to serve, the perfect fairness and *bona fides* of the examination, and that the provinces also would find they really had their rights preserved.

Mr. MACKAY also supported the scheme recommended by the Committee for the reasons which had been already given. He went on to make some objections in detail to the scheme as at present constituted with regard to the Scotch centres, but on the understanding that this would be reconsidered by the Committee, said he would not make any motion on the subject. He felt very strongly the importance of the suggestion that the examinations should be conducted in rooms hired for the purpose, and not on the premises of the superintendent, knowing that in some cases the examinations had taken place in rooms quite unfit for the purpose.

Mr. Shaw also expressed his cordial approval of the resolution.

Mr. Radley also supported it, but suggested that some improvements might be made in the details.

Mr. Brown said he should support the resolution, on the understanding that the list of centres read was not strictly adhered to, without further consideration.

Mr. Williams remarked that it had been suggested, that in some cases there should be double, or rather alternate centres, where there were two large towns pretty near together, holding the examinations alternately at the one and the other.

Mr. Robbins thought that a very good suggestion.

The Vice-President said he felt himself somewhat in an anomalous position on this question, having had the honour of taking the chair at the Committee which recommended this scheme to the Council, and then having to express his dissent from the conclusions they had arrived at. Still he felt it his duty to exercise his own private judgment, and the conclusion he had come to was, that it was inexpedient and unwise to make the change now proposed. He grounded this on the fact that the day was fast approaching when they would be compelled to abandon these Preliminary examinations, and hand them over to other societies. He felt that before many years were past the certificates of the universities, of the College of Preceptors, and of other examining bodies, would be accepted rather than their own. And so far as his own county was concerned this arrangement was actually forced upon them almost by the present scheme. The Committee, on his recommendation, had selected Canterbury as the centre of the county, and no better place could be selected, but the local examinations of the universities were held in Dover, Ramsgate, Blackheath, and he believed also in Tunbridge Wells; therefore it would be far easier for lads to go to those places than to come to their own centre at Canterbury. He also felt that much of the complaint made against the conduct of the examinations by the local secretaries arose from the action of the officials in London, the local secretaries not being properly informed as to what was required of them, and in some cases more being required than there was any necessity for. For instance, he thought it quite uncalled for to require the initials of the superintendent to all the papers of the candidates, when he had already certified that a certain thing had been done in his presence, and had sealed up all the papers himself, and forwarded them. He doubted very much if the local secretaries whose services were proposed to be retained had conducted the examinations any better than the two hundred and sixty who were rejected, and feeling that in a short time they must make another change, he asked them to seriously consider whether it was not better to leave matters as they were at present.

The amendment was then put and lost, the voting being as follows :—

For—Messrs. Baynes, Bottle, Frazer, and Urwick.

Against—Messrs. Betty, Hampson, Hills, Mackay, Radley, Robbins, Sandford, Sutton, and Williams.

Messrs. Brown, Greenish, and Owen were present but did not vote.

The original motion was then put and carried, the voting being as follows :—

For—Messrs. Betty, Hampson, Hills, Mackay, Robbins, Sandford, Sutton, and Williams.

Against—Messrs. Baynes, Bottle, Frazer, and Urwick.

Messrs. Brown, Greenish, Owen, and Radley were present but did not vote.

Library.

Mr. Sandford proposed the following resolution, of which he had given notice :—

"That, in order to render the advantages of the Library of this institution more accessible to members of the Society residing in the country, the Librarian be authorized to pay the carriage one way of books borrowed by country members and associates in business, and to charge the same to the Society.

"That the period during which books may be retained by country members and associates in business be extended to three weeks.

"That a catalogue of the Library be sent to each member of the Society and associate in business."

He said it had been suggested to him by a country member, and he thought it would be only just and proper, that country members should have every possible facility afforded them for enjoying the advantages of the Library. He found from the Librarian that only thirty-eight persons in the country applied during last year for books, and only twenty-one of those made two applications. If the applications did not increase the expense would be very trifling indeed, but he would be glad to see it much greater, for he thought that by encouraging this kind of thing they would only be putting the Library to a proper purpose.

Mr. Mackay thought the suggestion a very good one, but doubted the desirability of sending a catalogue to every member, which he thought would be putting the Society to a great deal of unnecessary expense. In very many instances they would only be treated as waste paper; and he would, therefore, suggest that the catalogue should only be sent to those who applied for it.

Mr. Greenish seconded the motion. He said that the Library Committee were adding most valuable books to the Library every month, and he thought that every facility should be afforded to country members to procure what books they required.

Mr. Sutton also approved of the proposal, saying that gentlemen in the country found great difficulty in procuring technical books for reference without purchasing them, which was very expensive. He also suggested that it might be well if country members were allowed more than one book at a time.

Mr. Sandford thought these details might be left to the Committee.

Mr. Brown doubted the desirability of paying the carriage of the books one way, though he thoroughly agreed in the principle of giving every facility for lending the books in the Library to all the members.

The motion was then put and carried unanimously, the last Clause having been altered as follows :—

"That a catalogue of the Library be sent to each member of the Society and associate in business *on application*."

PHARMACEUTICAL MEETING.

Wednesday, December 3, 1873.

Mr. Thomas Hyde Hills, President, in the Chair.

The minutes of the previous meeting having been read, the following donations to the Library and Museum were announced, and the thanks of the Society were awarded to the respective donors :—

'Medico-Chirurgical Transactions,' vol. 56, from the Royal Medical and Chirurgical Society; 'Principles and Practice of Medical Jurisprudence,' 2nd edition, from Dr. A. S. Taylor; Fresh specimens of *Eucalyptus globulus*, in blossom, from Mr. J. Fuller, of Cannes, France, late of Ealing; a new powder-folder, from Messrs. Lynch and Co.

The Eucalyptus Globulus.

Professor Bentley drew attention to a remarkably fine specimen of the *Eucalyptus globulus*, a plant which was at present exciting a great deal of interest. He said that a great many statements had been made with reference to

its medicinal properties, some of which were doubtless exaggerated, as was generally the case when any new substances were introduced; but he believed there could be no doubt, so far as extensive trials were concerned that it would be a useful antiperiodic. Whether as a tree it might be as serviceable as it had been stated to be in promoting the healthiness of a district would of course admit of considerable doubt. It was impossible to say at present whether the stories told in regard to it were fabulous, or whether there was in them a certain amount of truth mixed up with fiction. The whole genus from which the plant was got was an interesting one. It was not only used as a febrifuge, but any one holding up the leaves to the light would see that they were filled with transparent dots, and it was in those dots that the eucalyptus oil was contained, and this oil was largely imported and used extensively in perfumery. This and other species of the same genus also yielded Botany Bay kino, which was used as a substitute for ordinary kino. The plants of this genus were natives of Australia. Independently of its uses, the plant was interesting botanically, as giving an illustration of a particular kind of calyx that was rarely seen. The top of the calyx came off like a little cup, similar to what took place in the fruit of the henbane, which opened in this manner, instead of opening as most fruits did from above downwards, or from below upwards. A similar opening also occurred in the case of the common eschscholtzia of the garden, the yellow flower introduced some years ago from California. Another peculiarity in the flowers of the species of this genus was the absence of a corolla.

Mr. HANBURY remarked, that the eucalyptus tree was not only said to cure fever, but was more remarkable in that it rendered localities that were feverish habitable. He received a letter a few weeks ago from a botanist in the south of France, giving a marvellous account of the advantage it had been in the low-lying districts around the Mediterranean and especially Algeria, and stating that the marsh fevers had entirely disappeared from some localities. The tree grew with extraordinary rapidity. The timber seemed to be extremely durable when buried in the ground, and would therefore probably be useful for railway sleepers.

Professor REDWOOD would like to hear from Mr. Hanbury whether he thought it possible that a tree could have any influence, in malarious districts, in destroying marsh fever. A friend of his had told him quite recently that where these trees were grown they produced an effect in drying the air. Was it not more likely that the effect should arise from the diffusion of a large quantity of essential oil contained in the foliage.

The PRESIDENT suggested whether it might not be from the oxygen it gave off. Nothing was a better preventative of fever than pure oxygen.

Mr. HANBURY asked why the eucalyptus should give off more oxygen than any other tree. His information with regard to the beneficial effects of this plant came from M. Naudin, living in the south of France, who was a member of the Institute, and one of the most eminent of French botanists. He (Mr. Hanbury) showed M. Naudin's letter a few weeks ago to Dr. Weddell, who said that the tree acted like a great sponge, and drew the moisture out of the ground. With regard to there being a diffusion of essential oil, that was a much more puzzling question. It had not yet been solved how these essential oils were locked up in the vessels of plants. Persons might pass over ground covered with odorous trees like these and not perceive the faintest smell, and it was not until the plant was bruised that there was any diffusion of the oil.

Mr. PRESTON corroborated what Mr. Hanbury had said as to the effect of the eucalyptus tree in clearing the air from malaria, and said that a gentleman had written to the newspapers suggesting its introduction at Ashantee and along the Gold Coast. Those who spoke with considerable experience of the tree were of opinion that the effect mentioned was produced by the enormous roots it threw out, which drained the ground. He did not understand that it took the water from the atmosphere so much as drained the soil.

POWDER-FOLDER.

Mr. UMNEY said that he had been requested to bring before the notice of the meeting a new powder-folder, introduced by Messrs. Lynch and Co., of Aldersgate Street, E.C. One point in which it varied and had great advantages over the ordinary folder was that instead of being adjusted by a thumb-screw, one of the supports could be fitted into either of a series of grooves, by which the instrument could be reset exactly to any desired length. Another point also worthy of notice was that each of the grooves was numbered, so that at any time a dispenser could register the number by which a powder was folded in his prescription book.

GLYCERINE OF GALLIC ACID.

A note respecting Glycerine of Gallic Acid was read by Mr. Gale, which is printed on p. 441, and gave rise to the following discussion:—

Mr. M. CARTEIGHE said it had been shown that these solutions in glycerine were really best combined in medicine when mixed with water. Mr. Brady alluded to this subject at the Bradford Conference. It was now a well known fact that if a greatly astringent effect were required, it was far better to take glycerine of tannin, and mix it with water, than to take the original strong solution in glycerine. So far as he could understand from practitioners in medicine, these solutions had not proved so satisfactory as they could have wished, due to the fact not generally known, that they required to be mixed with water before use. In cases of serious hæmorrhage, crystals of perchloride of iron had been dissolved in glycerine, and applied to the affected part without useful effect; but when the solution in glycerine was diluted with water, and applied to the part, it was at once effective.

Mr. MARTINDALE said he had sometimes noticed a similar occurrence to that mentioned by Mr. Gale with glycerine and gallic acid alone, the gallic acid crystallizing out of the glycerine when the temperature was much below normal.

Mr. CANDY said he had noticed in the case of carbolic acid in glycerine that the glycerine seemed to neutralize the carbolic acid. Certainly a solution in water was more caustic than when the carbolic acid was dissolved in glycerine.

Professor REDWOOD asked Mr. Gale whether he had made any experiment to indicate what the proportion of water would be.

Mr. GALE said that three times the quantity of water separated the crystals. He had tried the experiment with arsenious, boracic, and benzoic acids, and he found that benzoic acid acted in a similar manner, but the others did not.

GAS FURNACE.

Professor REDWOOD said he had been requested by Mr. Fletcher, of Warrington, to bring to the notice of the Society a gas furnace, which was well adapted for pharmaceutical purposes. The object of the furnace was to enable the operator to regulate the heat, so that it could be very slight or very intense, diffused over a large surface or concentrated, as might be required. It was an inexpensive gas furnace, which admitted of a number of useful applications. Mr. Fletcher seemed to imagine that it answered the purpose even of a drying closet, on a small scale.

A NEW SOLVENT FOR PHOSPHORUS.

A paper by Mr. A. W. Gerrard, describing "A New Solvent for Phosphorus; its Preparation and Pharmaceutical Use" was next, and gave rise to the following discussion. The paper is printed on p. 441.

The PRESIDENT said they were much obliged to Mr.

Gerrard for bringing this subject forward. It was very difficult to manipulate phosphorus for medicinal use. Mr. Gerrard had not only the advantage of making this preparation, but of hearing what medical men said, and they seemed to approve of it.

Mr. GERRARD added that he had asked medical men what was their experience of its therapeutical effects, and they had told him that it was equal to anything that had been previously dispensed.

Mr. GREENISH mentioned that Mr. Gerrard had put into his hands some of the phosphoretted resin a day or two before, upon which he had made several experiments, with the object of obtaining from it a preparation in a liquid form; he found that, mixed with mucilage, it gave a deposit after a time. If the resin were dissolved in chloroform, and the proportion of spirit required to make it spirit of chloroform added, a more satisfactory result was obtained. A little orange-flower water mixed with the solution concealed the taste of the phosphorus. He should prefer some method of sending out phosphorus in mixture rather than in pills. Mr. Greenish asked Mr. Gerrard whether his attention had been directed to a phosphorus pill which had been brought out, and which appeared to be prepared from some kind of resin.

Mr. GERRARD said that he had experimented on samples of the pills to which he supposed Mr. Greenish referred. He had placed one of them, as well as a pill prepared according to his own formula, to digest in a ten per cent. solution of hydrochloric acid. The latter, as might be expected from the quantity of sugar it contained, commenced to dissolve immediately, but the former was quite unacted upon at the end of twenty-four hours.

Mr. MARTINDALE thought Mr. Gerrard's form of making the preparation would be very useful. There were two or three preparations of phosphorus before the public at the present time worthy of note, especially those phosphorus pearls which contained about $\frac{1}{30}$ grain of phosphorus, and were coated with gelatine. These seemed to be most agreeable to the patient, because they had no smell of phosphorus at all, and they were, as a rule, very efficacious. It had been stated by a writer in the *Practitioner* that one grain of phosphorus was soluble in three fluid drachms of alcohol; this was true, so long as heat was applied, but when the alcohol became cold, it deposited nearly the whole of it—at least three-fourths were deposited. Such statements about its solubility would make the dose very different from what might be expected.

Professor ATTFIELD asked in what state the phosphorus existed in the resin—whether Mr. Gerrard had made any experiments with the view of getting the phosphorus back—whether the phosphorus was in a state of solution, or whether chemically combined? These were points which must be therapeutically as well as chemically interesting. As some present had inquired for a fluid preparation containing phosphorus it might be worth the while of those who were interested in these researches to try those bodies which were produced when phosphoric anhydride was made to act on the aldehydes found in many essential oils. A sort of resin and phosphoretted oil was said to be obtained in that way which would no doubt be soluble in alcohol, and which might be made into emulsion.

Mr. GERRARD thought that phosphorus was objectionable in the form of a mixture which would not keep after being made a day or two. Under the changes of composition a patient might on the third day take a dose not more than one-tenth part of that of the first day. If a little of the resin were taken and rubbed between the fingers it would be found that the phosphorus was evolved. He was inclined to think that if treated with alcohol, the alcohol would remove the resin, and the phosphorus would separate.

Mr. BLAND said, he had had an opportunity of examining one of the pills made by Mr. Gerrard, although he did not know exactly how long it had been made; but having burnt it, it was quite evident that the phosphorus existed in the pills in an uncombined state. He should judge, however, that it was rather a mechanical mixture than a chemical solution.

Mr. WILLIAMS said that what medical men wanted and were seeking for was phosphorus in the active state, or lower condition of oxidation. He had made large quantities of hypophosphites, and had lately turned his attention to phosphites. He had been gratified in discovering solid phosphorous acid, and had now got it in crystals, and a beautiful body it was. It was probably the terhydride of phosphoric acid, and he believed the phosphites would prove valuable salts for the use of the medical man, because the phosphorus was contained in the half oxidized or probably more active condition.

Mr. GREENISH said he forgot to mention that one tablespoonful of such a mixture as he had prepared and submitted to the meeting contained about one-twentieth of a grain, which should be a dose. He rubbed down some of the resin, and examined it under the strongest power of a microscope, and there were no indications of the presence of undissolved phosphorus.

A vote of thanks was given to Mr. Gerrard for his paper.

ADULTERATED DRUGS.

Mr. UMNEY said: I should like to call the attention of this meeting, and also of the whole trade, to a most important matter, which presented itself to me with additional force upon reading an article in the PHARMACEUTICAL JOURNAL, Nov. 8th, by Mr. E. A. Cook, entitled "Some Practices of the Trade which it would benefit the Profession to abandon." I cannot endorse all Mr. Cook there states, for from my own experience I know that, at any rate, as far as London is concerned, the same state of things does not wholly exist as he has described at Liverpool. *Still*, I do believe, and I say so with regret, that at the present time *undue value* is attached to the price at which drugs, chemicals, or pharmaceutical preparations can be purchased, rather than to their degree of purity when judged by the British Pharmacopœia or other standard works. Upon citrate of iron and quinine, instanced by Mr. Cook, there can be but one opinion. When made of any other strength than that of the British Pharmacopœia, it can only be with one object in view, and can only be called by one name—*deception*. I will not say that all manufacturers deceive their customers; *on the contrary*, some who are forced into the sale of such preparations by the demand from the trade affix labels stating the strength. But is it to be supposed that when the salt passes into the hands of the public that the same is represented to the consumer? Surely the time has now come, when manufacturers should decline to make, and druggists refuse to purchase this and any preparation which is its parallel. With opium, jalap, etc., instanced by Mr. Cook, I am afraid there is greater difficulty. A very simple method, however, and one which would at once strike at the very root of the evil, would be the appointment of an inspector of drugs in *bond*. We should then hear little of opium without alkaloid, and jalap with 2 per cent of resin.

Mr. HANBURY asked whether the jalap which was now being imported in such prodigious quantities, and which appeared to be unusually large and fine, was commonly defective in resin.

Mr. UMNEY believed that some of the jalap lately imported was of the finest quality, as far as resin was concerned, ever imported into the country. He had seen some of the tubercules containing probably 12 per cent.; they were however either imperfectly dried or slightly water-damaged.

Mr. WILLIAMS remarked that this was a most important question. It was perfectly notorious that these things were made of various strengths and qualities, according to price, and the ethical question was whether it was permissible for the manufacturer to do so, provided always he used genuine articles and stated distinctly on the label what the strength was. His opinion was that the manufacturer was perfectly justified in doing that; but if, as

Mr. Umney had hinted, the label might be removed that was no fraud on the part of the manufacturer, but of the person who removed it. If manufacturers were convinced that it was wrong to make a lower quality article they would cease to do it, but in the present state of the trade there was little chance of their doing it. As an individual he should be glad to give up the manufacture of lower qualities of citrate of iron and quinine, but at present he did not see his way to adopting that course. Only that morning he received from the country an offer for the lower qualities of citrate of iron, amorphus quinine, and strychnia, to be labelled *pure* citrate of iron, quinine, and strychnia, but his firm had refused to entertain the offer. The question of putting on a false label was one that he could not think of entertaining.

Professor ATTFIELD thought the suggestion of Mr. Umney, that there should be appointed an inspector of drugs in bond, was most important. During the past few months he had been pained to find that chemists and druggists in this country, after 25 years of public effort to improve the character of drugs, should be liable to be brought up in a common police court for selling adulterated articles. They had been trying by means of combination in this Society, and in other ways, to produce a right state of feeling amongst pharmacists with regard to the purity of drugs. This Society had scarcely ever held a meeting in which some paper or proposition had not been brought forward regarding some better method of manufacturing an article which had seemed to be weak in active principle, or some process by which possible adulterations might be exposed. Within the last ten years the British Pharmaceutical Conference, numbering about 2000 gentlemen, had united themselves under a certain code of rules, one of which was to "maintain uncompromisingly the principle of purity in medicines;" and after all this effort to produce pure medicines it seemed hard that they were liable to be prosecuted indiscriminately for adulteration. From what had recently taken place it was possible they would no longer be under that ban. It had been ruled, or at least a strong opinion had been given by an important personage, that druggists were scarcely liable under the Adulteration Act, except for drugs, and drugs had been held to be simple dry raw materials. But however that might be—and he would not then further allude to that matter—it was just in regard to raw material that pharmacists had the minimum of control. It was true pressure could be put upon the producers of articles abroad, but that was a slow process. If, however, an inspector of drugs in bond existed there would be a guarantee to the manufacturer or manipulator of these raw materials that the articles which might come into his hands were at least what the heads of the profession in this country through their Pharmacopœia had indicated that the respective substances should be.

Professor REDWOOD said it was desirable that these proceedings should not be reported to the effect that anything that had recently passed would exonerate chemists and druggists from the application of the Adulteration Act in reference to other substances than drugs. Every gentleman who would take the pains to look at the Pharmacy Act would see that every pharmacist was liable under the Adulteration Act, and that all the pains and penalties of that Act applied to him, if he sold any article of any description used in medicine that was found to be adulterated. The law was as clear as it was possible for any law to be, but the attention of the magistrate the other day was not directed to that particular point. Dr. Attfield had referred to the exertions which had been made for a long series of years to improve the state of pharmacy in this country, especially with regard to the supply of pure drugs, and it appeared to him (Dr. Redwood) that in proportion mainly as these objects could be efficiently carried out, the body of pharmaceutical chemists would rise in the estimation of the medical profession first, and ultimately in that of the public at large. They therefore saw the importance of attention being directed to this subject, and he felt grateful to Mr. Umney for having brought it under the attention of the meeting. He agreed to a great extent with Mr. Williams, in considering that they must not attempt to shackle the manufacturer too much in the production of various substances used in medicines—substances varying in composition and in the mode of production from those which were generally recognized by the names under which they were sold. But in reference to such an article, for instance, as sweet spirit of nitre, which had been used for ages and for various purposes by the public, he thought that some variation of the strength and quality might be excused to a large extent. But there were medicines which were far more important. He looked upon citrate of iron and quinine as a sort of sheet anchor to the physician, and he would class it almost with laudanum and prussic acid. The pharmacist ought to know exactly what the composition was, for as much evil might result from the use of a great variety of preparations of that description, all sold under the name of citrate of iron and quinine, as from tincture of opium being sold of all possible strengths.

Mr. GREENISH said that the importers of drugs were not the only sinners, for a few days ago he received a letter from abroad stating that large quantities of muriate of cinchonine had been sent out there in ounce bottles, labelled as quinine.

Mr. PRESTON thought it was only education that would bring about that higher state of feeling in the mind of men, which would ultimately lead them not to manufacture or sell articles of an inferior description. Professor Redwood had referred to the Adulteration Act, but one of the questions they wanted to have settled was what adulteration was. As spirit of nitre had been referred to, he might say that the question which lately arose was whether the spirit of nitre which was sold, and which was actually made according to the British Pharmacopœia, was an adulterated article or not, because it did not stand the test laid down in the British Pharmacopœia. That question was not brought before the magistrate. He (Mr. Preston) contended that even if it did not stand the test there was no adulteration. There was no doubt whatever that in this trade, as in others, there were frequently subterfuges, which could not be recognized as right by right-minded men. He should be glad if the Pharmaceutical Society would take up this question, and if it were possible to get an inspector of drugs in bond appointed, he believed it would be exceedingly desirable; at the same time there were great difficulties in the way. As Mr. Gladstone had pointed out, there was great difficulty even in appointing an inspector for the inspection of tea.

The PRESIDENT reminded the meeting that the Council had not forgotten this important subject, which had been before them that day in committee, and was referred to the Parliamentary Committee.

Mr. UMNEY said that the spirit of nitrous ether of the British Pharmacopœia could be made so as to stand the chloride of calcium test there given. By using the proportions prescribed in the British Pharmacopœia, and operating upon the quantity therein mentioned, a product could be obtained which would answer the Pharmacopœia test in every way. But when operating upon a large scale it was somewhat different. It was very difficult to condense all the nitrous ether, and the specified proportion of 10 per cent. was not present in the product if all the spirit ordered were added. But it would be remembered that the Pharmacopœia directions were very elastic on this point, namely, to mix "two pints of the rectified spirit, or as much as will make the product correspond to the tests of specific gravity and percentage of ether separated by the chloride of calcium." He had found that, if instead of adding the whole of the spirit (two pints) he had added it in proportion of one pint fifteen ounces, he could obtain, even when manufacturing large quantities, a product that would answer to the tests. He had also found that by redistilling the spirit of nitrous ether from an acid carbonated alkali, a beautiful colour

less product, was obtained, while a coloured residue was left behind the nature of which he had not yet investigated.

The PRESIDENT thought it was the most unstable and unsatisfactory preparation with which they had to deal.

Mr. PRESTON said his point was that it would not keep, and not that it could not be made according to the Pharmacopœia. He could produce evidence to prove that nitrous ether gradually lost its strength, and if kept in a bottle which was opened from time to time the nitrous ether would almost entirely disappear.

The PRESIDENT said that since this question had come before the magistrate he had consulted two physicians, fellows of the College, and one of them said it was the most unsatisfactory thing he ever had to deal with. It did not answer the purpose for which it was supposed to be given, and he would much rather give the spirit of chloroform, which answered very much better, and was a definite compound. He (the President) asked him whether he would give that opinion in evidence before a court of law in case it was wanted, and he said he would rather not, preferring that that should be done by one older than himself. He (the President) then went to another fellow of the College of Physicians and a member of the Medical Council, and he told him the same, and that he was ready to give testimony to that effect at any time, and that he never prescribed it. But so long as the public would have it, it was important to make it in the best possible way.

The PRESIDENT announced that the next meeting will be held on February 4th.

Parliamentary and Law Proceedings.

BLOOMSBURY COUNTY COURT,
December 4th, 1873,
Before G. L. Russell, Esq., Judge.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN *v.* PLANT.

The defendant was sued for a penalty of Five pounds incurred by him under the 15th section of the Pharmacy Act, 1868, in selling or keeping open shop for the retailing, dispensing, or compounding poisons, or a poison, not being duly registered.

Mr. Flux represented the plantiffs.

The defendant did not appear.

The Register was produced, and it was shown that the defendant's name did not appear therein.

Mr. Ward, clerk to Messrs. Flux and Co., proved that on the 12th day of August last he attended at the defendant's shop, No. 1, Frankfort Terrace, Harrow Road, and presented a prescription for a compound in which hydrocyanic acid was an ingredient, that the prescription was dispensed by the defendant's assistant in the defendant's presence, and that he paid 1*s.* 6*d.* for it, and on the following morning delivered the bottle containing the medicine to Dr. Redwood at the house of the Pharmaceutical Society.

Dr. Theophilus Redwood, Professor of Chemistry to the Pharmaceutical Society, proved that he received the bottle (which he produced) as deposed to by the former witness, and that he analysed a portion of its contents and found the same to contain hydrocyanic acid, namely, prussic acid—a poison in the schedule to the Pharmacy Act, 1868.

The judge gave a verdict for the £5 penalty, with costs, including attorney's fee and cost of witnesses.

PROSECUTION UNDER THE ADULTERATION ACT.

ALLEGED ADULTERATION OF SPIRIT OF NITROUS ETHER.

Westminster Police Court.

On Saturday, the 29th November, a surgeon and several chemists and druggists were summoned before Mr. Arnold under the Adulteration Act, charged with selling adulterated spirit of nitrous ether. The proceedings seemed to excite a considerable amount of interest, the small and inconvenient court being densely crowded during the hearing.

The summons against Mr. W. S. Saxby came first in order, but that gentleman was not in attendance at the moment.

Mr. Rogers, who appeared for the District Board of Works, said he had some other summonses, and he might therefore proceed with the next.

Mr. E. Draper said he believed there was some little misunderstanding with regard to some of these summonses. He was instructed in one case, and he understood that Mr. Poland was also instructed to appear for some of the defendants. He believed Mr. Poland was desirous that the case should be postponed, on account of his being engaged at Bow Street on behalf of the Government.

Mr. Arnold said he would go on with any case that was ready.

Mr. St. John Wontner said he was quite ready to go on with the case against Mr. Fenton.

Mr. Flux: I have been instructed on behalf of the Pharmaceutical Society of Great Britain to attend and watch these cases. They appear to involve an important question of principle, and if you will permit me, in due course, I think I can show upon the Acts of Parliament that, as regards the proceedings in this case——

Mr. Arnold: Do you appear for either of the parties?

Mr. Flux: No, sir, I appear for the Pharmaceutical Society to watch the cases.

Mr. Arnold: You may watch if you like, but you will have no right to address me.

Mr. Flux: I could only do so by the indulgence of your Honour.

Mr. Arnold: I could not do that. I cannot hear you; you have no *locus standi* at all.

The summons against Mr. George Fenton, a surgeon keeping a druggist's shop in Great Smith Street, Westminster, was then proceeded with.

Mr. Arnold: What section is this under?

Mr. Rogers: This will be under the second and third sections of the Adulteration Act.

Mr. Wontner: We are not summoned under the third.

Mr. Rogers: It is under the second section. I appear on behalf of the Board of Works in this case. The article was purchased by Mr. Williams, the Inspector, on the 12th of November, 1873. I will call the Inspector at once, and he will state the facts of the case to you.

Mr. Draper: I have to make an application in one of these cases to your worship which seems to me of very great importance. There are four summonses for precisely the same alleged offence. It might happen that after three of the cases have been tried, and the defendants convicted, Mr. Poland's acuteness might bring out a point on which we might all have got off, and I should therefore ask your worship if one case is to be adjourned for Mr. Poland's attendance, that ours may be adjourned also.

Mr. Arnold: I have not adjourned any case yet.

Mr. Draper: I understood there was a case adjourned.

Mr. Arnold: No. Mr. Saxby's case was called, but the party is not here, and I am taking another case. The summons is not adjourned.

Mr. Owen Williams was then sworn and examined by Mr. Rogers as follows:—

You are one of the Inspectors appointed by the Board under the Adulteration of Food and Drugs Act?—Yes.

Did you on the 12th November, 1873, purchase of Mr. Fenton, of Smith Street, some sweet spirits of nitre?—I did.

What did you ask for?—I went into the shop——

Mr. Arnold: What shop?—Into Mr. Fenton's shop, 28, Great Smith Street.

What sort of a shop is it?—A chemist and druggist's shop.

Mr. Rogers: What did you ask for?—I asked for four ounces of sweet spirits of nitre.

State to the magistrate what followed.—It was handed over to me, and then I told the assistant——

Mr. Wontner: What was handed to you? Show us what was handed.—The spirits of nitre was handed to me; at least, it was put into a bottle.

Mr. Arnold: Is spirits of nitre and sweet spirits of nitre the same thing?—I believe so.

Mr. Wontner: It is spirit of nitrous ether, according to the summons.

Mr. Arnold: The summons says spirit of nitrous ether. I do not know whether that is the same thing or not; do you know?

Mr. Rogers: Dr. Dupré will be able to give you further information as to the identity of the articles.

Mr. Arnold: You asked for sweet spirits of nitre, and it was handed to you in a bottle.

Mr. Rogers: What did you say?—When I received it, I told the assistant to give my compliments to Mr. Fenton, and say I had procured this for the purpose of having it analysed, and I mentioned my name.

Did he say anything to you?—He said he believed it was pure; he had every faith in it, that they had it from a first-rate maker.

What did you do with it when you received it?—I took it over to the office. This was the day before I had to send it over to Dr. Dupré.

Mr. Arnold: Where is the office?—Exactly opposite the office of the Board of Works. I put that label on.

You placed that label on the bottle?—Yes. I am not certain. I believe there is a label underneath this, but to prevent the name being known to Dr. Dupré, I put our own label on.

Mr. Rogers: To conceal the name of the person from whom you bought it?—Yes. I am not certain, but I think there is a label under it.

Did you take that to Dr. Dupré?—I locked it up until the following day.

Mr. Arnold: This rather looks as if another label had been removed.—I believe there is another label under that.

I do not think there is any other label under.—I will not be certain about that.

Mr. Rogers: Did you take it to the analyst?—I locked it up, and the following morning I gave the bottle to the analyst. He took a portion from the bottle.

Did you see him?—Yes. After he had taken what he wanted, he sealed it up, and initialled it. I have had it in my possession ever since.

Mr. Rogers: You took that in the same condition to the analyst in which you received it from Mr. Fenton?—Yes.

Was it marked in any way?—Marked No. 1.

Mr. Arnold: That is on your label?—Yes.

Mr. Rogers: Did you see it?—That was marked No. 1 in my presence.

Did you receive a certificate from Dr. Dupré?—I did; it was sent me.

Mr. Arnold: How did you receive it?—I received it from the inspector of St. Margaret's, Knightsbridge. He was ordered to go to Dr. Dupré's and he brought the whole of the reports.

Mr. Rogers: He is another inspector appointed by the Board. Dr. Dupré always signs his certificates in the presence of one of the inspectors. This is the one who attended Dr. Dupré when he signed the certificate.

Mr. Arnold: The certificate is made evidence, is it?

Mr. Rogers: It has been held by Mr. Woolrych that the certificate is not evidence where the Board is the prosecuting party. In cases where the private individual purchases an article, in that case the certificate is evidence, but where the Board is the prosecuting party, there the certificate is not evidence, and the analyst must be called as a witness to prove it.

Mr. Wontner: There is nothing in the Act of Parliament to prove that.

Mr. Rogers: I am only stating what has been held by the court here. You will find it referred to in the 9th section.

Mr. Arnold: I suppose Mr. Woolrych thinks the whole of that clause ought to be read together, that it applies only to the case where a private purchaser has an article analysed.

Mr. Rogers: That is Mr. Woolryeh's opinion, and therefore Dr. Dupré is in attendance to-day.

Mr. Wontner: We should have subpœned him if you had not.

Mr. Arnold: I suppose this man is a purchaser, is he not?

Mr. Rogers: No doubt.

Mr. Arnold: He has not said so.

Mr. Rogers: I asked the question of Mr. Williams, Did he purchase? He said he asked for 4 oz. of spirits of nitre, which he purchased.

Mr. Arnold: I have not got down that he said he paid for it.

The Witness: I paid for it.

Mr. Rogers: What did you pay?—I paid 1*s.* 4*d.* for the nitre and a penny for the bottle.

After obtaining the certificate you applied for the summons?—Yes.

Cross-Examined by Mr. Wontner.

You went by Dr. Dupré's instructions?—I did.

Did you ask for the sweet spirits of nitre?—I asked for sweet nitre, I believe.

Mr. Arnold: You said before you asked for sweet spirits of nitre.

Mr. Wontner: I should like to know which it was?—I will not be certain whether it was sweet spirits of nitre or whether it was sweet nitre; it is one and the same thing.

Whatever you asked for, or, at any rate, whatever was given to you, was given to you in the bottle you have there?—Yes.

Let me look at the bottle [handed to the learned gentleman]. It says "sweet nitre" on the label. Whose writing is that?—That is mine.

You covered the label over that was on it. Do you remember what was written on the label?—Mr. Fenton's name was there—that was the reason I removed it, and "sweet nitre" was written on it.

Sweet nitre, or sweet spirits of nitre?—I believe it was sweet nitre, I wrote it exactly as it was there.

Mr. Arnold: You copied it?—Yes.

Mr. Wontner: Not spirit of nitrous ether?—No, spirits of nitre, that was what I asked for.

How long was it before you sealed up the bottle?—Immediately afterwards, not ten minutes after I left Mr. Fenton's shop.

Do you mean immediately after you left the shop, or immediately after the analyst took some out?—I sealed it up at the office.

That is opposite defendant's shop?—Yes.

Mr. Arnold: I must say you are not very exact. You never said you sealed the bottle until after you had given Dr. Dupré a portion of it?—I took it to the office and sealed it up.

You did not say so?—But I did.

What you said was, that you locked it up, that the next morning you took it to the analyst, and gave him the bottle to take a portion from it, and then he sealed it up.—I sealed it up.

When did you seal it up?—At the office.

Before you locked it up?—Yes.

You never stated that before?—It was in the presence of one of the clerks.

Mr. Wontner: Why did you not seal it up in the presence of the assistant who served it to you?—In the presence of the assistant!

Is not it usual under the Act?—The assistant could have done that himself.

Is it not usual that a person in your position should

seal up the article in the presence of the party who is to be charged with adulteration?—If they require it.

Not unless they state their requirements, you would not do it of your own accord?—If I thought there was any doubt about it I should decidedly.

You personally know nothing about the merits of this case?—No, I merely handed it over to the analyst.

(*Dr. Dupré sworn. Examined by Mr. Rogers.*)

Your name is August Dupré, and you are the analyst appointed by the Board of Works, under the Adulteration of Food Act?—I am.

Did you on the 13th of November, 1873, receive from Owen Williams, the inspector, a sample of spirits of nitre?

Mr. Wontner:—What did he receive?—You call it spirits of nitre, but we are summoned for spirit of nitrous ether.

Mr. Rogers: Well, spirit of nitrous ether, then.

Mr. Wontner: It is not that which was sold to him.

Dr. Dupré: I believe I received it on the 14th, if I am not mistaken.

Mr. Arnold: On the 14th, was it?

Mr. Rogers: Yes, sir, on the 14th.

Mr. Arnold: Mr. Williams certainly said he bought it on the 12th, and on the following morning handed it to Dr. Dupré.

Mr. Rogers: That was my mistake, sir.

Mr. Arnold: It is what Mr. Williams said, at any rate.

Mr. Rogers: It is in the certificate of the analyst as being received on the 14th. There must be a mistake somewhere, either in Dr. Dupré's certificate or Mr. Williams'.

Mr. Arnold: Do you recollect the day of the week?—It would be on my certificate; I cannot now remember.

Do you recollect the day of the week when you received it?—It is some weeks ago now. I believe it was on the Thursday—I really do not remember. But here in the certificate it is the 14th.

Mr. Wontner: The date really is not material. There is a very much larger question involved in this than a matter of date.

Mr. Arnold: Just so; only it is just as well to be accurate.

Mr. Rogers: What took place next?—He handed to me this bottle, with the label on it, which is on at present. I put on my initials, and the date, November 14th, is on the bottle.

Mr. Arnold: That is the 14th, is it?—Yes, it is the 14th.

That is in your writing?—Yes, I took out a part of it to analyse. I then put a label over the cork with my initials on, and tied it over, and then Mr. Williams sealed it in my presence as it is at present.

Mr. Rogers: Did you analyse that portion?—I analysed it and wrote out a certificate.

Is that your certificate? [Handing a document to the witness.]—That is my certificate.

What was the result?—The result was that it was considerably adulterated with spirit—ordinary spirit—and to a slight extent also with water.

Cross-Examined by Mr. Wontner.

To what extent was it adulterated with water, Dr. Dupré?—Well, I think about 10 per cent.

Ten per cent?—Something like that; it is not possible to say within——

Does your certificate state that?

Mr. Arnold: I thought you said it was not evidence.

Mr. Rogers: No, but I bring it in as evidence by Dr. Dupré,

Mr. Arnold: If it is not evidence it does not become more evidence by his producing it.

Mr. Rogers: Dr. Dupré is here, and I have also handed up his certificate.

Mr. Arnold: If he is here he should state *viva voce* what is the amount. If it has been held that it is not evidence, it cannot be evidence at all.

Mr. Rogers: Dr. Dupré will be able to state that exactly.

Mr. Arnold: 10 per cent. of water; but he says it is not possible to say exactly.

Mr. Wontner: Give me the certificate please. Did you make a note at the time of your analysis?—Certainly.

Have you the note with you?—No.

Why not?—I did not think it necessary.

Did the note state how much water there was?—The note only gives the result of the analysis.

I suppose the result of the analysis would be to give the relative quantities?—No, it simply states the facts.

Do you mean that the note would simply give what is placed in the summons, and what is put upon the certificate, that it is largely adulterated with spirit, and to a small extent with water?—Neither.

It does not state that?—No.

Does it state the relative quantities of water and of spirit, and the relative quantity of nitrous ether?—No, it simply gives the analysis.

Mr. Arnold: Did you not state the relative quantities of ordinary spirit and of water?—No.

You, Dr. Dupré, are not a doctor of medicine?—No.

Are you a pharmaceutical chemist?—No.

You are a pure chemist?—Yes.

Have you an English degree?—No; a German degree.

Tell me the quantity of water you found. Was that in excess of the quantity you would expect to find from evaporation after the spirit had been kept for four or five months?—Certainly.

It was?—Yes. At least, I am assuming it was moderately well kept. I cannot answer if a man leaves the bottle for six months perfectly open, or puts it into a dish or anything of that kind. I am assuming that it is moderately well kept.

Mr. Arnold: In a bottle?—Yes.

Mr. Wontner: The idea, then, that you formed was that water had been added?—Yes.

That this was not the result of evaporation, but that water had been added to it?—Decidedly.

You cannot tell me in what quantity?—No, not exactly.

You will not pledge yourself that there was more than 5 per cent.?—Well, I should say, yes.

Would you pledge yourself positively to that, that there was more than 5 per cent.?—As I said before, assuming that it was moderately well kept, there was more than 5 per cent.—there was 10.

Mr. Arnold: Whether it was well kept or ill kept, it would not make any difference in what you found?—No, but it makes a difference in my interpretation of it.

What you are asked is, whether you will pledge yourself that there was more than 5 per cent. of water?—I pledge myself there was 10 per cent.

Mr. Wontner: You said you could not tell exactly.—I said I did not know that 10 per cent. was added.

Mr. Arnold: I understood you to say that you thought there was 10 per cent. of water, but it was not possible to give it so exactly?—There may be 11. But allow me to explain. The difference is, I cannot pledge myself that 10 per cent. was added, but I will pledge myself that 10 per cent. was present.

Mr. Wontner: You mean that 10 per cent. was the minimum. I should like to know how much it is. I do not much care, if you will tell me?—It is not really possible to pledge oneself.

Is it possible to say there was more than 5 per cent.?—Yes.

Well, if we run up the scale, you will be able to stop me?—If you will allow me to look——

Can you tell me what was the specific gravity of the whole?—Certainly. The specific gravity of the whole was ·867.

Will you pledge yourself professionally to the fact of its being more than ·853 ?—Certainly.

Would ·850 be about proper ?—·845 would be the proper specific gravity.

It is the Pharmacopœia you go by ?—Yes.

I may as well ask you is the Pharmacopœia the standard by which you go ?—Certainly.

And is it by the Pharmacopœia that you alleged this to be an adulteration ?—Yes.

You took that as your standard in judging what this should be ?—Yes.

I presume when you say the Pharmacopœia you mean the British Pharmacopœia, not the London ?—Yes, the British.

Not the Edinburgh ?—No, the British.

You know that there are London Pharmacopœias ?—Yes.

And Pharmacopœias of Dublin and of Edinburgh ?—Yes.

Do you know that the London Pharmacopœia existed long before the British Pharmacopœia had any existence at all ?—Certainly.

And that the British Pharmacopœia, the first one, was in 1867 or 1864 ?—I do not know.

There are two—1864 and 1867. I may take it that your contention, and the contention of the Board is that if the article in question is not made up in accordance with the Pharmacopœia that is an adulteration; is that it ?—Decidedly.

Mr. Arnold : That is according to the British ?—Yes.

Mr. Wontner : Can you tell me what the temperature was ?

Mr. Arnold : I have not got down what the adulteration with ordinary spirit was, yet.

Mr. Wontner : I will take this gentleman through it presently. That is the cardinal point in the case, as your worship will see presently. Just another step first. Do you call this a drug ?—Yes.

It is a liquid ?—It is a liquid.

Do you call it a drug ?—Yes.

Did you personally take the specific gravity of this ?—It was done.

Did you do it ?—I did not do it.

Then you do not know at what temperature it was done ?—Yes, I looked at the temperature myself.

You were not there, were you ?—Oh yes, I was.

You did not take it yourself, but you saw the temperature ?—Yes.

Did you give instructions to the inspector what to ask for ?—I did.

What did you tell him to ask for ?—I wrote it down on paper.

You remember what you wrote ?—Yes—*Spiritus ætheris nitrosi.*

Did you tell him what verbally to ask for ?—I do not suppose he would understand that. No.

Did you tell him to ask for sweet spirit of nitre ?—I did not see Mr. Williams at all.

Mr. Arnold : Did you tell him what to ask for or did you write it down ?—I wrote down what he was to ask for.

Who did you give it to ?—To Mr. Hughes.

Did you tell Mr. Williams to ask for sweet spirit of nitre ?—No, I did not.

You have heard of sweet spirit of nitre ?—Certainly.

Mr. Arnold : Is the paper here, or is it destroyed ?

Mr. Wontner : Mr. Hughes, have you got it ?

Mr. Hughes : I have not got it here. I do not know that I have it at all now.

Mr. Arnold : What you wrote down was not sweet spirit of nitre ?—The one is only the name of the Pharmacopœia, the other is the popular name. It is exactly the same thing.

You did not write down the words sweet spirit of nitre ?—No.

What did you write it in—Latin ?—Yes, in Latin.

Mr. Wontner : You say that is spirit of nitrous ether, and sweet spirit of nitre is the popular name ?—Yes. It has four or five names, these are two of them.

Mr. Arnold : Is spirit of nitrous ether and sweet spirit of nitre the same thing ?—Yes.

Mr. Wontner : That is what you say ?—That is what I say.

You found no mention of sweet spirit of nitre in the Pharmacopœia ? –[Referring to a book.] No.

You are obliged to look, apparently ?—No.

What is it called in the Pharmacopœia ?—It is called spiritus ætheris nitrosi—spirit of nitrous ether.

That I take it is not at all sweet, is it ?—Which ?

The spirits of nitrous ether ?—Oh yes ! If freshly prepared it would be slightly sweet.

As compounded according to this formula ?—Yes.

Is there not a quantity of copper in it ?—No.

And acid ?—No.

No copper or acid ?—No.

Do you really mean that ?—I really mean that.

To begin with the spirit of nitrous ether ; as compounded, it is not a drug that you can handle, but it is made by distillation, is it not, by distilling various compounds ?—Yes, it is prepared or manufactured.

Do you know, or is it that you as a pure chemist do not know, how it is compounded ?—Certainly I do, I should be sorry to be ignorant of it.

You do know ?—Certainly I do ; I not only do know, but I have manufactured it myself.

What are the ingredients in the distillation of it ?—You mean after it has been distilled ?

It has no existence before ?—Before it is distilled it is made this way. A mixture of sulphuric acid, and nitric acid, and spirit of wine.

Mr. Arnold : I thought you said there was no acid ?—This is only to begin with ; if you will please to wait you will see there is none in it.

Mr. Wontner : And copper ?—If you will wait a moment——

But I thought you stopped.

Mr. Arnold : You mix sulphuric acid, and nitric acid, and spirit of wine. That is what you call ordinary spirit, is it not ?—Yes.

Mr. Wontner : And what else ?—Then you introduce it into a retort, and fine copper wire is added.

There is copper, then ?—It is a mixture ; you distil it over a gentle heat ; I forget the exact temperature, but it is in there.

You forget the temperature ? I mean you need not turn to the Pharmacopœia. You should have your knowledge ready, not get it up here.—That is such a minor point. That has nothing to do with the matter at all.

That is a minor point, is it ?—Quite, except that it should be a slight heat.

This particular nitrous ether that you analysed, what has been added to that ?—I did not analyse the nitrous ether ; what I analysed was the spirit of nitrous ether.

What has been added to that ?—It has been adulterated with alcohol—with spirit of wine.

Before or after it became spirit of nitrous ether ?—That I cannot tell.

What ?—No.

What ! a public analyst cannot tell whether it was before or after ? Do not you know that the whole composition would be altered if it were added after ?—No ; I cannot tell that.

Mr. Arnold : Before or after what ?

Mr. Wontner : Before or after it became spirit of nitrous ether.

The Witness : Would you allow me to finish the mode of manufacture ? This mixture is distilled at a gentle heat, and the distillate is a strong solution of nitrous ether in spirit, or very strong nitrous ether. This is then examined, to see how much nitrous ether it contains—to see how strong it is.

You are telling us what you do ?—In the preparation.

What the Pharmacopœia says?—I am telling you the manufacture of spirit of nitrous ether.

You are telling us what the Pharmacopœia says. Is that so? Is it your own experience, or is it what the Pharmacopœia tells you?—Of course I have prepared it according to what is the best mode. After that, spirit is added to bring it down to the proper strength.

Mr. Arnold: Rather, to bring it down to the proper weakness?—Well, yes.

Mr. Wontner: You would hardly endeavour to bring it down to the proper weakness by adding spirit of wine, would you?—Certainly.

Is that a heavier or a lighter body, this spirit of nitrous ether?—Well, spirit of nitrous ether is very nearly the same specific gravity; it is a very little heavier than the spirit of wine.

Mr. Arnold: The ether?—Yes.

Mr. Wontner: So that you would not increase the weight by adding spirit of wine?—Certainly you would.

Of course, if you make ½ lb. into 1 lb. you increase the weight?—Water is also lighter than alcohol, but if we add alcohol to water, we do increase the weight.

You have told us already that spirits of nitrous ether is heavier than spirit of wine?—Slightly heavier.

So that to make a given quantity only, if you put more spirit of wine in, that would not increase the gravity, would it?—It would diminish the gravity.

So that if this has been adulterated, as you say, by the addition of spirit of wine, that is lessening the gravity instead of increasing it?—It is lessening the gravity of the first product.

Lessening the gravity instead of increasing it?—Of the first product.

I suppose if you went on adding *ad infinitum*, comparatively it would get smaller and smaller?—Certainly.

So that the adulteration you complain of is not an adulteration under the Act of fraudulently increasing the weight?—Certainly.

What! by adding a lighter spirit?—Of course.

Just to clear that up, as to the value of spirit of wine of the proper proof, is that dearer or cheaper than spirits of nitrous ether?—It ought to be cheaper.

Is it? Do not you know as a fact that they are exactly the same price, or that if anything, spirit of wine is rather dearer?—No, I beg your pardon, I think it is rather cheaper.

Will you pledge your professional experience to that fact, because I have evidence here?—That has nothing whatever to do with the question.

Mr. Arnold: I do not know. It has this to do with it—what motive the chemist would have to put a dearer ingredient into it?—If you will allow me I can explain that.

Mr. Arnold: You had better answer the question first?—I am not a retail dealer; I do not know.

Mr. Wontner: You do not know?—I only know that the wholesale houses sell spirit of nitrous ether for 3*s*. per lb., and no spirit of wine here is sold at 3*s*. per lb.

Mr. Wontner: Do you know the firm of Messrs. Herrings, who supplied this?—I have heard of them.

Do you know of any other firm superior to them in the country as people of respectability, and for the genuineness of their wares?—I do not.

You believe there are none? Do you know as matter of common knowledge that they have been established ever since the first or second year of the century?—I do not know.

You have not taken the trouble to inquire?—No, I did not know even where the articles came from.

In your analysis of this article do you find that sulphuric acid is wanting?—Sulphuric acid has no business to be present at all.

Do you find in your analysis of this that the sulphuric acid that you mentioned and the copper are wanting in the preparation?—You do not seem to understand the process, therefore it is difficult to explain.

I do understand the process—No, I beg your pardon, you do not.

I do understand your process, but you do not understand ours—The sulphuric acid remains all the time in the retort, and does not go into the product.

Mr. Arnold: Then there was no sulphuric acid in this sample?—Certainly not, at least I mean no appreciable amount.

Mr. Arnold: I shall have to go through a course of chemistry, I am afraid, in order to understand this case.

Mr. Wontner: I do not think you will, sir; you will understand it presently.

With respect to the formula, or whatever you call it, in the Pharmacopœia, did that first appear in 1864 or 1867?—I do not know.

Have you examined any of the London Pharmacopœias before that date?—No, I have not.

Do you know that the preparation up to the date of that formula, in 1864 or 1867, was completely different?—Yes, I know that. I may as well save you trouble by saying I take my stand on this. [Holding up the British Pharmacopœia.]

I know you do. Do you know that in the old Pharmacopœias down to 1864 there was the distillation of spirit of wine, nitric acid, and nothing else?—I do not know. I know that was a process. I know that was one of the processes.

Mr. Arnold: With no sulphuric acid and no copper.

Mr. Wontner: No sulphuric acid and no copper. Do you know from your own personal experience, taking it back as far as it will go, and from experience acquired by study that that was a mode of preparation that has been used for centuries?—Well, I do not know.

Of course not; but as far as your own personal knowledge goes prior to 1864, do not you know that as far as you personally can tell, as far as you remember, that was so?—I really cannot tell. I believe it was first made originally something like two centuries ago.

You say that in the Pharmacopœias before 1864 it is so set out as one of the means of preparation?—I do not know that.

You said so just now?—I beg your pardon; I did not say that.

I understood you to say so.—No.

You have not looked at these Pharmacopœias before?—No.

Mr. Arnold: I thought you said it was in some of the old formulas?—Yes, it used to be a preparation, but whether it was in any of these Pharmacopœias I do not know.

Mr. Wontner: Whether according to the British Pharmacopœia or not, are you aware that the preparation you condemn is found at least in the proportion of ten to one as compared with the preparation given by the British Pharmacopœia?—I do not know that.

Before taking these proceedings did not you think it well to inquire?—Inquire about what?

Inquire as to the ordinary mode of making this and the ordinary preparation that was sold.—No. I did not think it necessary.

Will you say that it is not so?—I will not say.

Will you say that this preparation which you condemn is not sold generally to the profession and to the public in the proportion of ten to one of the preparation in the Pharmacopœia that you take your stand by?—I am not aware of that.

However, you are aware, I suppose, that this preparation which you condemn, is very largely sold?—I am aware that nearly every specimen of spirit of nitrous ether that is bought in London is adulterated—that I am aware of.

Is what you call adulterated. But is it adulterated in the same way as you allege this to be adulterated?—In a similar way.

Have the preparations which you have examined been

similar to this?—Some of them are better and some are worse.

But are they all prepared in the same way?—That I have no means of telling.

As far as you can judge, is it so?—I do not know.

Let me help you. In the particular spirit of nitrous ether that the Pharmacopœia provides for is there a yellowish colour?—Yes.

Is there a strong scent?—Well, it smells.

Is there a want of the sweetness which you find in this which you have been analysing?—I do not know that I have ever tasted it.

Mr. Arnold: You have never had a cold?—Tasting is no evidence. I never go by taste, because tastes differ.

Mr. Wontner: Tastes differ, and the public tastes differ a great deal. Do not you know that the public tastes differ from yours so much that they prefer that which you condemn to that which you hold up, buying it in the proportion of ten to one? Do not you know that the public tastes differ so much as that?—I do not know that.

All you know is, that tastes differ, and your taste is the Pharmacopœia; you will not have anything else?—Exactly.

From the examination you have made, have you, as a pure chemist, the smallest doubt that the difference between your standard and that which you condemn is the omission from the still of the sulphuric acid and the copper; do not you know that?—No, I do not know that.

Instead of that, an addition of spirit of wine?—I take it——

Yes or no?—No.

You do not know that?—No.

Then your powers of chemical analysis are not sufficiently strong to enable you to find that out; is that so?—I will not say it would not, but I have not directed any attention to it.

You found it was not similar, but you have not endeavoured to find out in what way it differs?—Oh yes. I found that out; it is considerably less strong; it is adulterated. However the adulteration is perpetrated, it is immaterial; it is badly manufactured.

I thought we had got over that. We have got your 9 or 10 per cent. of water. Then, with the exception of the water, there is nothing to make it heavier so as to adulterate it, nothing to make it heavier, so that the article would sell better, and be more profitable?—I confess I do not understand this reasoning.

There is nothing at all that I can see difficult to understand.—It seems to me very difficult, because milk is heavier than water, and we all know that milk is very largely adulterated with water.

Mr. Arnold: Milk is a natural production, and you can easily find whether it is adulterated or not; but when you have a manufactured article it is very difficult to say.—It should be a manufactured article, according to a certain standard, if it be sold by a chemist.

This you say is adulterated because it is not made according to the Pharmacopœia?—It is not the strength of the Pharmacopœia.

Mr. Wontner: That really is the case.

Mr. Arnold: The Act does not say that drugs shall be sold as they are made up in the Pharmacopœia.

Mr. Wontner: Not at all.

The Witness: I always understood that a chemist who sells a drug is supposed to sell it according to the official standard.

Mr. Arnold: That may be; but that is not what the Act says. If I went and bought ground rhubarb, and was sold ground rhubarb mixed with sand, that would be adulterated; but in this Act I do not know whether there is anything which requires that the drugs are to be made up according to the Pharmacopœia.

The Witness: As long as they reach the strength.

Mr. Arnold: These observations ought to be addressed rather to Mr. Rogers, because it is a legal point.

Mr. Rogers: I can find nothing in the Act with reference to it.

Mr. Arnold: Is there anything in the Apothecaries Act?

Mr. Rogers: Your worship refers to the Pharmacy Act.

Mr. Wontner: I have the Pharmacy Act here.

Mr. Rogers: There is nothing there about it.

Mr. Arnold: Where the article is a natural production, such as milk, and many other things you might mention, one at once knows how they might be adulterated by adding extraneous substances to them, but it is very difficult to say when it is a compound, unless there is something binding that it shall be made up according to the Pharmacopœia. I do not know how one can say it is adulterated. Is there anything in these articles—in this sample which you have got which renders it unwholesome or prejudicial?

The Witness: No, I will not say that, except negatively.

Mr. Arnold: I do not wish to stop the case on that point, but it has occurred to me it is a very difficult question, unless there is an Act of Parliament or unless there is some obligation which says that all drugs shall be made up according to a certain standard.

Mr. Rogers: I am not aware that there is anything.

Mr. Arnold: The same difficulty might arise in the question of bread.

Mr. Flux: It was on this point I was specially desirous of assisting the court, if the court will permit me to do so. I would call your worship's attention to the 15th section of the Pharmacy Act as bearing on this point.

Mr. Arnold: Thank you. As *amicus curiæ* I shall be much obliged to you.

Mr. Flux: It is the 15th section of the Act of 1868 which points out the specific remedy for adulteration or errors in the matter.

Mr. Arnold: I do not wish to stop the case on that point, but I feel great difficulty about it.

Mr. Wontner: Dr. Dupré, let me understand you. Do I understand you to say that the adulteration is before this becomes spirit of nitrous ether, or whilst the preparation of spirit of nitrous ether is going on?

Mr. Arnold: He said he could not say whether it was before or not.

The Witness: I have no means of telling that.

Mr. Wontner: There is no such thing as spirit of nitrous ether until after the process of distillation which you have described has gone on?—No.

So that if the failure were before, the adulteration would be before the thing was made; if it is a failure, to put something in, if there be an adulteration, it would be before the thing is made?—Yes.

The drug has no existence—you call it a drug—until after distillation?—No.

So that if I am correct in putting the difference between your specimen and the other specimen as the absence of copper and sulphuric acid from the one, and their presence in the other, the adulteration you would charge would be the omission to put them in during the distillation? Is that so?—No, there is no sulphuric acid or copper in any specimen.

We already have it from you.—I did not say after the distillation copper and sulphuric acid appear.

I suppose they are put in for some purpose?—No, I beg your pardon, it would be an absurdity for me to tell you that copper or sulphuric acid are in the distillate.

Are they put in for nothing?—Oh no, certainly not.

I suppose if they are put in for some object that object makes itself shown when the compound is arrived at?—But they remain, after having done their work, uncombined with the spirit. They have no business whatever in the finished article; they remain behind in the retort.

Mr. Arnold: Do they have any effect?—They promote the action.

Mr. Wontner: In point of fact they bring out the nitrous ether more strongly than if they are left out. Is that so?—Yes.

That is the effect—they bring out the ether more strongly?—Yes, but they are not in.

And the nitrous ether is that which has the very strong flavour?—Yes.

And which gives a high colour?—Yes.

The nitrous ether and the spirit of wine, as we learnt from you, have the same specific gravity?—You did not learn that from me.

I thought you told us you would not say?—No, I stated distinctly that pure spirit of nitrous ether is rather more.

We were about a quarter of an hour trying to get at it, and you pledged yourself at last to nothing.—I beg your pardon, I most distinctly contradict that.

You said a little lighter, I think?—Yes.

Mr. Arnold: The spirit of wine is lighter than spirit of nitrous ether?—Yes.

Mr. Wontner: I was going to ask you, but the magistrate forestalled me; can you tell me any law which forbids the making of this preparation?—I cannot.

Mr. Arnold: There is a penalty for making up any medicine (it does not say "drugs" in the Act) excepting according to the formula in the British Pharmacopœia.

Mr. Flux: You observe, that is a penalty to be sued for in a civil action at the instanec of the Pharmaceutical Society.

Mr. Arnold: It also goes on to say that shall not interfere with any other penalty.

Mr. Flux: But there is not any other.

Mr. Wontner: That of course has nothing whatever to do with this case. We are not summoned here under the Pharmacy Act, nor if we were summoned under that section should we be within it. We have nothing whatever to do with the making up of medicine. This is simply selling a genuine compound. It is not pretended that is made up after the formula of the Pharmacopœia. We do not allege that at all; on the contrary, what we do allege is, that we are in no way bound by the Pharmacopœia. If the public taste is for such as we manufacture, in opposition to the Pharmacopœia, we fling the Pharmacopœia to the winds, and make what there is a trade for, and not what there is no trade for. I want to learn from this gentleman if he can tell me anything to prevent us from doing it?—No, I cannot tell you any law. I am not a lawyer.

You have told me you made an analysis: can you tell me how much nitrous ether this did contain, what proportion? (The witness looked at a piece of paper.) Is that what you made at the time?—This is a copy.

I object to your copy; put that in your pocket if you please. From your recollection can you tell me how much nitrous ether it contained?—I have just seen the copy, it contained ·36 per cent.

The rest is spirit of wine?—The rest is chiefly spirit of wine.

I do not very well understand it; will you kindly explain it again?—Explain what?

How much nitrous ether it contains?—·36 per cent., rather more than one-third per cent., $3\frac{1}{2}$ in 1000, or 36 in 10,000.

How do you estimate it?—Well, am I bound to answer that?

Mr. Arnold: Yes.—I have no objection at all; only it seems to me that some of the gentlemen here are rather ignorant how to do it.

Mr. Wontner: We are anxious to see you do it.—I shall be very happy.

Then they will learn.—I shall be very happy to teach them, if they will allow me. It is done very easily. You take a small glass flask, a small vessel of thin glass; into that is put a small amount of hydrate of potash. You then weigh in a given quantity of the sweet spirit of nitre; you cork up well, and let stand for twenty-four hours. At the end of that time all the nitrous ether has been converted into nitrite of potassium. You carefully evaporate the excess of spirit, dilute with water, acidify with sulphuric acid, and with a standard solution of permanganate you estimate the nitrite.

Mr. Arnold: I dare say Mr. Wontner follows you, but I do not.

Mr. Wontner: I confess I do not understand it, but I do not think it will affect the legal question much. Do you know the pharmaceutical test?—The test is that if spirits of nitrous ether is mixed with twice its volume of a saturated solution of chloride of calcium, you separate 2 per cent. of its volume of nitrous ether.

Did you test by that process. But you did not test at all yourself, your assistant did it?—I did that myself.

And your assistant did all the rest?—My assistant only took the specific gravity; he put the bottle on the balance, and I stood by to see that it was done correctly. I checked it.

I should like to know, Dr. Dupré, whether it was by your advice these proceedings were taken?—I have nothing to do with these proceedings.

Was it by your advice?—No, I have no advice to give.

Did you give no advice to the local authorities?—No.

Did not you suggest it?—I! No.

Did not you go before the board?—I do not suggest. What I do is simply to analyse the specimens brought to me, and give the inspector a certificate, I have nothing further to do. I know not where it comes from. I do not know what is to be done with it; all I do is to give my certificate.

There are sundry questions I should like to ask you with reference to the medicinal properties, but you are not a doctor of medicine?—No.

You would not appreciate it, you would not be able to tell me the medicinal qualities of spirit of nitrous ether?—No; I do not believe anybody can tell you.

Or of the spirit of wine?—The spirit of nitrous ether has been so shamefully adulterated all the time that no medical man in London could be able to tell you what would be the action if he had the real article, because he has not for many years obtained it.

Mr. Arnold: That is pleasant for those who take sweet spirit of nitre.

(The court adjourned for a short time.)

Mr. Wontner: Is there a property, Dr. Dupré, in the spirit of nitrous ether after it is produced which is known as aldehyde?—Yes, there is; but it is not exactly a property, it is a substance.

Do you know the medicinal properties of aldehyde?—I do not. As far as I am aware, it is not used medicinally.

Are you aware it is a very moot point whether of the spirit of nitrous ether the aldehyde is not really the active ingredient?—As I stated before, I think there are very few, if any, medical men who know the real properties because they never had the article.

Very few know what are the real properties of this compound; but do you know as a matter of professional knowledge that it is a moot point whether it is not the aldehyde that has the virtue?—I never heard that before.

Have you never heard that before?—No.

Have you never heard that it was a point much discussed?—No.

But you say as a fact, that it is not clearly ascertained what is the most active ingredient?—No, I beg your pardon, I did not say that.

I thought you did say so?—No, what I said was that it is not known what are the exact medicinal properties of the sweet spirit of nitre.

But aldehyde is largely present in it, is it not?—Aldehyde is present.

Is there more aldehyde in this preparation that you condemn, than in that of the Pharmacopœia?—I should say less.

Did you ascertain what quantity there was?—No, I did not; it is only a rough guess.

You left the aldehyde out of the question altogether?—Not quite.

Very nearly; you did not take the proportion of aldehyde?—No, I do not think that can be done, at least not readily.

Now as to this aforesaid aldehyde. You, as a pure chemist, would be eminently capable of telling one this. Is aldehyde a property that very rapidly decomposes?—No, certainly not; it is neither a property, nor does it decompose readily.

Does aldehyde, whether it is a property or not——?—If you wish me to give correct answers, you should ask me correct questions.

I dare say, but I am not a scientific man like you; I try to frame my questions as well as I can, and if you understand what I mean, perhaps, you will kindly give me the answer?—No, it is not what chemists called decomposed.

Does it turn into acetic acid?—It absorbs oxygen and becomes acetic acid—vinegar—acid of vinegar.

Is that acid heavier than water?—Yes.

So that the specific gravity of the article would be increased on its becoming acetic acid?—Certainly.

Would not it very readily become acetic acid, if the cork were left out?—Yes, I think tolerably readily.

If exposed to the action of the air in any perceptible degree it would become acetic acid, would it not?—Yes, no doubt.

Take a bottle like this half full, would not the air contained in the upper part of the bottle be sufficient to turn it into acetic acid?—Yes, no doubt, to a certain extent, it depends on the relative quantity of aldehyde that may be in.

And you say there is aldehyde in both these compounds?—Yes.

Sal volatile—have you made that your study, at all, have you analysed that?—Yes, I have.

Is that always made according to the British Pharmacopœia?—As far as I am aware it is scarcely ever made so.

The general trade in that is according to a formula not in accordance with the British Pharmacopœia?—At least the product is not in accordance.

Mr. Arnold: Would you consider sal volatile a drug?—Yes.

You think it is?—Yes, I think so.

Mr. Wontner: Is it as much a drug as this?—I am not here just now to define what a drug is.

But you ought to be prepared, because you summon us for adulterating a drug?—I take it every substance used medicinally may be called a drug.

Suppose you were ordered brandy medicinally, would that be a drug?—Yes, it would.

You have not taken any proceedings yet against the manufacturers of sal volatile?—No.

But that is produced by distillation, is it not?—Yes.

Mr. Arnold: Is there a formula for it in the Pharmacopœia?—Oh yes.

Mr. Wontner: I do not know whether you told me, but at the risk of repetition I will ask you again if you can tell me—I think you did tell me, that medicinally you could not say what were the qualities of spirit of wine as compared with spirit of nitrous ether?—If you were a medical man or a chemist you would know that for years past there has been a discussion going on what is their action.

That is what I want to get at?—There has been a discussion going on for years what is their action.

That is not yet decided?—No.

So that you cannot tell what would be the effect of putting more spirit of wine or more spirit of ether in this preparation?—It is not spirit of ether.

Well nitrous ether. You could not tell what would be the effect of there being an excess of the one over the other, which ever way it is, medicinally?—Well at least I can tell you what is the general supposition.

Whether supposition or not you say it is a point which has been under discussion for a long time, and is not yet settled?—Let me explain. What I stated was this, that it is a point of discussion how spirit of wine acts medicinally. It is another point of discussion how spirit of nitrous ether may act.

How it may act—how it does act?—How it acts, but how the one acts in relation to the other has nothing whatever to do with the question; they are very distinct matters.

Are you the sole analyst in this district?—As far as I am aware.

I mean public analyst?—I am the only analyst appointed by this board.

Dr. Redwood, is he one?

Mr. Rogers: There is only one analyst appointed immediately by the Board of Works for the Westminster District.

Mr. Wontner: For the other districts there are others?—Yes.

This is the first summons taken out?—In what respect?

With respect to an article of this description?—I believe so.

Mr. Arnold: The first summons taken out at all, or do you mean in this district?

Mr. Wontner: I mean with regard to such a kind of substance.

Mr. Arnold: Is this the first summons you know of at all, or the first summons in this district?—I do not know of any other.

Mr. Wontner: This is the first in the country?—I believe so.

It is taken out for the purpose of experiment. I suppose, to see whether it would succeed?—No, for the purpose of putting down what I consider is a shameful adulteration.

Do you seriously mean that?—Quite seriously.

Mr. Arnold: Is it your duty to advise the board.—No.

Is it merely your duty to analyse the matters that are submitted to you?—Yes.

Because when you use such a strong expression as that you consider this to be a shameful adulteration I presume from that that you are the person who advises the authorities as to what are adulterations?—No, I give them my certificate, that is all.

Mr. Wontner: Nothing but the certificate?—The Act directs it. I have no other communication with them at all. I gave them distinct directions to go and get so many samples.

That is not what I am asking. I am asking whether your communication with the board was confined to that certificate, or whether you did not personally recommend these proceedings? Certainly not. I have nothing to do with that at all.

Mr. Rogers: I may tell you, sir, that under the 6th section of the Act, the inspector, on receiving the certificate that the article is adulterated, is bound to prosecute.

Mr. Arnold: If this gentleman was merely called upon to give a certificate, and then uses such a strong expression as that he considers in his opinion it is a shameful adulteration, all I can say is it is a very improper observation for him to have made.

The Witness: I have been here submitted to a considerable amount of cross-examination, which I think in some respects is unnecessary, but if you decide so I am very sorry, and I will retract it if you will allow me.

Mr. Arnold: It is not a proper expression. Seeing that you have used that expression, I should like a definition of what you mean by "shameful adulteration." You say it is not deleterious to health?—No, but it is selling a compound under a false name, it is not the compound which it professes to be.

In what way, if it is not deleterious, and not mischievous in any way, do you consider it a shameful adulteration?—I do not say it is not deleterious to health; All I say is I do not know whether it is so or not.

You said so?—I do not say as a matter of fact it is not.

Mr. Wontner: To carry it further, can you say that this shameful adulteration does not cost quite as much as what you hold up as the standard?—I do not think it does.

Can you say positively, not being a tradesman, that it does not? We have the court full of people who produce it. In their presence, do you say it does not cost quite as much as the article you hold up as the standard?—I should say decidedly not.

What would you say would be the difference?—I do not think I am here to say that. I am not a tradesman; I am not a retail dealer nor a wholesale manufacturer.

You give your opinions, and I wish to test the value of them.

Mr. Arnold: You have voluntcered your opinion, and you are bound to say on what grounds you come to that conclusion.

Mr. Wontner: When you say this is a gross fraud, are you aware that the article is used in almost every hospital and dispensary throughout the country?—I think it is.

I suppose everybody using it, aiding and abetting in this fraud, you would consider to be acting fraudulently too?—Ignorantly.

The medical profession and the chemical profession are all acting ignorantly, and Dr. Dupré is the only wise man, is that it?—Not at all. If you will look into 'Percira,' which I think is the chief standard work on materia medica in the English language, you will find he calls it by almost as strong a name as I do. But I say I have apologized for using that expression, and I think you may fairly consider I have withdrawn it.

I am not saying anything about it; I am asking you as a fact whether it is not used in all the hospitals and dispensaries?—I think it is.

And, as a fact, it is an article which is not sold by the ignorant, but it is sold by medical men and chemists throughout the country—men who are supposed, as far as they can know, to know the properties of it?—They might be supposed to know, but they certainly do not know.

Not as you do, of course?—Not as they ought to.

You see they all have not the opportunity of being brought up in Germany; when we have education here as you have in Germany we shall be better?—I daresay you will.

There is one other question I want to ask, Have you received any samples of this spirit of nitrous ether which you have found in your opinion to be pure?—Yes, I have found it, at least so that I should be sorry to say it was adulterated. I was not sufficiently certain, therefore I cannot say it is adulterated.

Mr. Rogers: You would not give your certificate?—I would not give my certificate as to its being adulterated.

I suppose you could test two ounces as well as any other quantity?—Yes, I could do it by $\frac{1}{10}$th of that.

Mr. Rogers: That is my case.

[*Examined by the Magistrate.*]

I understand you to say you consider this to be adulterated because it is not made up according to the British Pharmacopœia formula?—Yes, because it does not come up to the standard.

Mr. Wontner: I do not know whether you will allow me to ask one question which I omitted.

Mr. Arnold: Perhaps you will let me put a few questions first. You say that you consider every subject that is used medicinally is a drug?—May be considered as a drug.

What do you consider the exact meaning of the word drug—is it synonymous with medicine?—A substance that is used medicinally.

Does not drug rather mean an ingredient or substance which is used for mixing up in medicine?—That is one that is very often so used. It is used by itself, and it is used mixed with others.

Would not you call this medicine?—Well, no.

I do not know whether you are anything of an etymologist, but do not you consider the word "drug" as something cognate with the word "dry"?—I will not say that; preparations would then be all excluded under the Act.

Never mind that. Do not you think the word "drug" means something in the nature of a dry ingredient which is used in making up medicine?—No, I do not.

You do not think that?—No.

You think it means medicine generally?—Substances used medicinally.

A substance used medicinally is a medicine?—Yes.

Is carbonate of soda a drug?—In one aspect it is a drug.

Is it or is it not a drug in your opinion?—If used medicinally, decidedly.

Would you consider soda water a drug?—Well, what is called soda water is very rarely soda water.

But if soda water is merely aërated water without any soda in it, you would not consider that adulterated?—Simply speaking, yes I should.

Then adulteration may consist in the omission as well as in the putting in of things?—Well, of course I am not prepared to give a decided answer to that. That is a difficulty, no doubt.

Mr. Arnold: There has been no case as yet decided on this point, has there?

Mr. Rogers: Not that I am aware of. This is the first case in the Westminster district.

The Witness: Would you allow me to make one statement with regard to this drug? At the beginning of last year I was engaged for the medical department of the Privy Council in examining into the state of the retail drug trade in London, and I was given a list of a number of substances which included spirit of nitrous ether.

Mr. Arnold: I confess I thought the meaning of the word "drug" was an ingredient in a medicine.

Mr. Wontner: It is if you look in Johnson "ingredient used in physic." I was looking last night in several other dictionaries, which gave the same meaning.

The Witness: This, besides being an ingredient used in physic, may be used by itself.

Mr. Arnold: This is a physic, it is made up of different ingredients?—No, because the nitrous ether is the principal.

That is a compound?—Yes, that is a compound. Every substance is a compound, except it is an elementary substance.

Mr. Arnold: In one sense, every substance is a compound if it comes to that, but it is not an artificial compound. Every substance, I suppose, is a compound more or less, but not an artificial compound. Have you any legal comment to offer on that point?

Mr. Rogers: No, I have not.

Mr. Arnold: My strong impression is, that a drug merely means an ingredient from which, with other ingredients, medicine is made up.

The Witness: That is decidedly the case with spirit of nitrous ether.

Mr. Flux: You will find in the Apothecaries Act, 55 Geo. 3rd, c. 194, these words, "Dispensing and vending drugs, medicines, and medicinal compounds," thus by statute drawing a distinction.

Mr. Arnold: Making a distinction between a drug and a medicine. Would you consider that the spirit of nitrous ether is not a medicinal compound?—Certainly it is.

And a drug; you see the legislature has used three different words, a drug, a medicine, and a medicinal compound. Which of these three should you say spirit of nitrous ether is?—I should say it may be under two.

Mr. Arnold: I think not. I think the legislature uses three different expressions.—But the one, and the same substance may be included under two.

How?—Spirit of nitrous ether is used by itself, and then you may consider it as being a medicine, but when it is used to make up a medicine as an ingredient, then it becomes a drug.

Mr. Arnold: It is either a drug or it is not a drug. This is the Apothecaries Act, is it?

Mr. Flux: Yes, sir, and the language of the legislature appears to be consistent with that, in all the intermediate medical legislation.

Mr. Arnold: Another section talks about medicines, "wares, drugs, receipts, distilled water, chemical oils, syrups, conserves, lohochs"—what are those?

Mr. Flux: I believe those are forgotten, or nothing known of them.

Mr. Arnold: There is no evidence laid before me of any medical gentleman as to whether he considers spirit of nitrous ether to be a drug or a medicine.

Mr. Rogers: No, I have not any evidence of that character.

Mr. Arnold: You leave the case as it is?

Mr. Rogers: Yes.

Mr. Arnold: I think the case must go on, but I confess I have a very strong opinion at present upon that point.

Mr. Wontner: There is one question, if you please, upon another point. The learned magistrate has asked you the meaning of the word drug. I should like to ask, what you take to be the meaning of the word adulteration?—Adulteration is the addition of anything which is foreign to the substance, or lowers the quality of the substance.

But clearly an addition—something added?—Well, you cannot back from it; I think so.

Mr. Arnold: I think Mr. Dupré has already said he considered the omission of something might constitute an adulteration.

Mr. Wontner: He said so before, but now he has altered his opinion; it must be an addition, it is perfetly clear.—It is an existing difficulty, and a very important point, which is not so easily decided offhand, because there are many drugs sold where the important thing is left out, and it is a question whether that should be considered an adulteration or not. I believe under the Act it could not be so considered.

Mr. Wontner: You are not a lawyer, you say, neither a doctor nor a lawyer?—Oh, yes, I am a doctor.

A Ph.D., not a doctor of medicine?—That does not matter.

Would you take this to be a correct description of the word from Webster, "To make impure by an admixture of baser materials"?—No, I do not.

You do not think it is the proper description: It must be clearly an addition to an article, which lowers or debases its quality, such as adding sand to sugar.

Mr. Arnold: Or water to milk. If you put a quantity of cream to milk you would not call it adulterating, would you?—I do not know.

Mr. Wontner: What I want to get at really is, that to constitute adulteration there must be an addition, taking the meaning of the word in its ordinary sense, would not you say adulteration means to add something?—I think it does.

In fact the adulteration, if adulteration there were here, was the adulteration before it became this spirit of nitrous ether?—No, it may have been done after.

Would it be nitrous ether until it had gone through the still?—No.

Suppose we show by evidence how this was made, and that nothing has been added since, would you say there was adulteration then?—Yes, I should say so.

What! nothing added? You have told us there must be an addition, you know?—I should say there is something added; there is too much spirit of wine put into the still.

Mr. Arnold: I really cannot take this gentleman's opinion as to the meaning of the word adulteration; it is quite clear what that is. It clearly must mean the addition of some foreign substance.

The witness: But I contend that is an addition.

Mr. Wontner: It is not for you to contend. Technically on that point, I submit the case is bound to fail, and clearly also upon the point which your worship so readily saw, the case must fail also. In the first place it is perfectly clear that this is not a drug. In the second place, it is perfectly clear that the spirit of nitrous ether never had any existence until after the process of distillation had taken place, and the fact of not complying with the British Pharmacopœia by putting in copper and sulphuric acid to assist the action of distillation in more strongly bringing out the nitrous ether is not an adulteration, because the article had no existence until after the distillation was completed. If after distillation something had been done to it, according to the terms of the Act, which rendered it injurious to life or health, then, taking it to be a drug, it would be clearly an infringement of the Act of Parliament. But seeing that before it became spirit of nitrous ether it must go through a process of distillation, and the adulteration, if adulteration there be, would take place while the so-called drug was in the process of making, it is perfectly clear there could be no adulteration, as the summons charges, for selling as unadulterated a certain drug, which was adulterated by spirit of wine, because it did not become spirit of nitrous ether until after the process of distillation. Upon those two points it is perfectly clear that the case must fail.

Mr. Arnold: I have not yet got the amount of the spirit of wine that there is in this; only that it is considerably adulterated with spirit of wine.

Mr. Wontner: I will tell you, sir, directly; I will tell you the process.

Mr. Arnold: Mr. Dupré has not told us that.

Mr. Wontner: I put it to him, and he said he could not possibly tell, but that it was largely adulterated.

Mr. Arnold: Does the Pharmacopœia give the different quantities?

Mr. Wontner: I think it gives the amount of nitrous ether and the amount of spirit of wine. Sir, this case is one of very serious importance; there are several to follow it, and no doubt, if successful, as in the case of other branches of manufacture and trade which come within the Adulteration Act, it is no doubt intended to make a general crusade throughout the country, upon the foundation which a successful conduct of this case would give to the local authorities throughout the country. And when I point out that in the case of the manufacturing druggists who produced this article, it is made by that one firm alone to the extent of tons every year, you will at once see that the issue to be decided is a very large one. In point of fact, the issue is, whether the Board of Works is to be able to impose upon any manufacturer, or class of manufacturers, of either articles of food or articles of medicine any terms they like, and say: We insist on your manufacturing in a certain way, which we prescribe, and in no other way. They hold up to you a book published in 1867—the British Pharmacopœia; they say, we do not charge you with fraud; we do not charge you with selling a spurious article for the purpose of making additional profit; we do not charge you under the terms of the Act with fraudulently increasing the bulk of the article for the purpose of making additional profit, and so committing a robbery on the public. At the same time we cannot say with regard to this particular article whether that which you make or that which we prescribe in the British Pharmacopœia is the best; we cannot say which is the best, but we say as far as we can see that that which you make is not at all injurious to health; and as far as we can tell, it may be just as good a medicine as that which we prescribe. Therefore, looking at the question in its broad light, it must be perfectly clear to you that the Board of Works, and those under the Board of Works, are endeavouring to put an imposition on the general manufacturing public, to insist that they shall only make in accordance with the terms which they prescribe as an authority, namely, the British Pharmacopœia. If that

were the law, and if they could so impose, I am afraid that the growth of medical knowledge in the country would be extremely slow for the future; because if that be a correct view of the law, nothing but what is contained in the British Pharmacopœia could be manufactured at all. If, from superior and advanced knowledge, as time goes on, a better way of manufacturing than is shown by the British Pharmacopœia is discovered as to the manufacture of any article, according to their theory that better process of manufacture cannot be adopted, but they must adhere to the old rule as laid down by the British Pharmacopœia. If such were the law, it must be a most tyrannical one. But such is not the law, I am happy to say. It is perfectly certain, I take it, from what you have already said, that you agree with me in this matter, that such a law has no existence; and if it had it would be a law grossly in restraint of trade, and against the public benefit. Going back to the thirteenth century, pharmaceutical chemists are able to trace this very product which is here to-day condemned. I can take you back and give you the authorities from the time of Lully, in the thirteenth century, to Basil Valentine, the celebrated alchymist, in the fifteenth century. But, coming to more modern times, I can show you by standard works going back to 1746—Pharmacopœias then published—that this very product is recognised. In the way in which it was then made, it is now made, and I have no doubt will continue to be made. I can carry you on by those Pharmacopœias to 1864, when the British Medical Council first took upon themselves to publish a standard work for those who chose to follow it, and show you that after the Pharmacopœia was published in 1864, a fresh edition was published in 1867. In the first British Pharmacopœia in 1864 they published a formula different from that which afterwards came out; that is to say, differing from the old formula which Messrs. Herring make from. They found that that formula would never do; and, therefore, in the one of 1867, they completely altered their formula and adopted the present one. What was the result? The original sweet spirit of nitre, was used as a stimulant, and I suppose if the truth were told, when it is taken, it is rather more as a stimulant than as a medicine. It is a stimulant, pleasing to the palate, pleasing to the smell, and not distasteful to the eye. Its medicinal qualities, as we contend (and there is nothing to show that it is not so) are equally as great as those of the compound of the British Pharmacopœia of 1867. But those who had the editing of the British Pharmacopœia seemed to be of opinion that there should be more nitrous ether in the compound, and therefore, with the view of bringing out the nitrous ether more strongly, copper and sulphuric acid were added in the preparation to that which had been used from time immemorial, namely, nitric acid and spirit of wine. So that really the only difference between the two was that the one was particularly pleasing to the public, pleasant to the taste, pleasant to look at, and pleasant to the smell, whereas by the aid of the copper and sulphuric acid, the powerful smell of the nitrous ether was brought out, which rendered it unpleasant to the smell; the colour was rendered unpleasant by adding a very dark yellow tinge, and a strong bitter taste was imparted by the addition of copper; or, at any rate, by the stronger presence of the nitrous ether. When the Pharmacopœia was published, Messrs. Herring, and not only Messrs. Herring, but all the large manufacturing druggists endeavoured to fall in with views of the publishers of the Pharmacopœia. Accordingly, for the first year, they made large quantities of the new compound as propounded by the British Pharmacopœia. What was the result? The public liked the one, but they did not like the other, and the result was that nearly all they manufactured was returned to them and lay upon their hands. Naturally enough, finding that was so, and finding there was no law in the land to enforce the formula of the British Pharmacopœia upon them, they said it was their business to supply what was wanted. They said the public demanded the old article, and they should have it. Therefore they made not only the new article as propounded by the British Pharmacopœia, but also the old one, in such quantities as it was wanted; the result being that at the present time, for one ton of that which they sell made up according to the British Pharmacopœia, the public demand is for ten of the other. That does not apply only to Messrs. Herring, but to all the wholesale manufacturers. When we come to look at the merits of this case, it really becomes essential to see whether in a pecuniary point of view they are any gainers by this. The learned analyst says it is an adulteration, to put in spirit of wine. As a fact, the best spirit of wine, according to the proper degree of proof, is quite as expensive as spirit of nitrous ether. Therefore, there can be no possible gain to the producer, whereas by putting more ether he increases the specific gravity; he gets a greater weight; so that if he followed out the formula propounded by the British Pharmacopœia, in point of fact, in a pecuniary sense, he would be a gainer, because he would get a greater weight by that than he would by making the old compound, because the spirit of wine being lighter than the spirit of nitrous ether, of course in the proportion in which you add spirit of wine as compared with spirit of nitrous ether, the specific gravity of the compound becomes less, and therefore the manufacturer would have to make more of it in order to arrive at the same value. Really those are the facts of the case. The point lies in a nutshell. I really do not see what there is to be said about it. You hear from the analyst that it is very doubtful what the medicinal properties are. He does not tell you the old compound is not quite as effective as that compounded by the British Pharmacopœia, and there being no possible law to enforce on the trade the formula of the British Pharmacopœia, the case really seems to be at an end. If there were a law to say, you shall make up your medicines and your drugs in accordance with that publication, and they failed to do so, no doubt they would be liable to be summoned for an offence against that law. But to come here and ask you to say that this is an adulteration of a drug under the Adulteration of Food Act, an Act very properly passed for the suppression of fraud by means of the sale of spurious articles, which either are injurious to health, or which have been largely added to, and the bulk increased for the purpose of making a fraudulent profit; to come here and ask you to convict these gentlemen under an Act of that description, teeming with fraud from the very commencement to the end, from the preamble to the last section, is preposterous. The preamble states that the object was to prevent injury to health, and to come here and ask you to convict under that Act upon a summons of this description, when the principal witness himself said that no fraud has been committed, that there is no addition of bulk, but, on the contrary, what they call the adulteration makes the article lighter instead of heavier, and when in addition they admit that they cannot say that it is in any way injurious to health—to come here and ask you to convict under such circumstances, and so make a precedent for the rest of the magistrates in the country acting upon your opinion, is I think on the part of the authorities an unjust proceeding, and I am quite sure you will endorse that view by an adverse decision in this case.

[*Mr. Charles Umney sworn. Examined by Mr. Wontner.*]

Are you a pharmaceutical chemist by examination?—I am.

A Fellow of the Chemical Society and an Examiner of the Pharmaceutical Society of Great Britain?—Yes.

I believe for the last ten years you have been the director of Messrs. Herrings' laboratory, in Aldersgate Street?—I have.

I believe that is one of the largest firms of wholesale

manufacturing chemists and druggists of that description in the country?—It is.

I believe it has been established since 1808?—It has.

Since you have presided over their laboratory, have you been in the habit of selling two kinds of spirit of nitre?—We have.

For nearly ten years?—Yes.

Since the British Pharmacopœia was first published?—Yes.

Two. One of those made according to the formula in the book, and the other made according to the old formula which dates back for centuries?—It has been our custom so to do.

Which is in most request in the trade?—Spirit of nitre as known to the public for some centuries; it first appeared in the London Pharmacopœia in 1746.

Was that the description of spirit of nitre with which you supplied the defendant, Mr. Fenton, in this case?—It was.

Will you kindly describe the process of manufacturing that?—The process of manufacture which is carried on almost daily consists in putting into a still six gallons of spirit of wine, 56 degrees over proof, having a specific gravity of ·838, the strength prescribed by the British Pharmacopœia, and 4 lbs. of nitric acid, also of the strength prescribed by the British Pharmacopœia; then applying steam heat, and slowly distilling until 50 lbs. of distillate be obtained.

Mr. Arnold: The distillate, I suppose, is what is left?—The distillate is the liquid that passes over in the still; it comes over in the form of vapour, and is condensed by cold water in passing through a worm. This quantity of 50 lbs. is about half a pound less in weight (or one per cent. only) than the original spirit employed, when put into the still. We distil it until it is of the specific gravity of ·850. We find that the distillation of 50 lbs. will produce such a specific gravity, or thereabouts.

Mr. Wontner: Is that what, until the British Pharmacopœia appeared, was generally known as sweet spirit of nitre?—It is, and has been known as sweet spirit of nitre for some centuries.

When the British Pharmacopœia was published, did you proceed to manufacture according to the formula given there?—When the first British Pharmacopœia was published, we did so, but afterwards, with other manufacturers, we entirely abandoned the process. I am speaking of the 1864 Pharmacopœia.

What constituted the difference between the methods?—It was ordered to be made from nitrite of soda, a body which it was proved could not be made; therefore it was not likely the spirit of nitre could be made from it.

You first of all dropped the old system, and adopted that of the British Pharmacopœia; you found it was not successful, and reverted to the old one?—We adopted the process of the British Pharmacopœia, 1867, almost entirely, from its publication.

Did you find that the preparation took with the public?—It did not; it was returned in all directions.

Did you then proceed to make in accordance with the old plan?—Not entirely so; we have never abandoned the form of the British Pharmacopœia for those who will have it.

You did revert to the old plan for those who wanted it, selling that of the British Pharmacopœia to those who in their turn wanted it?—Quite so.

In about what proportion do you sell the one to the other?—I should say about nine of the old sweet spirit of nitre to one part of the spirit of nitrous ether of the British Pharmacopœia.

The difference, I believe, in the preparation of the two being the addition of copper and sulphuric acid in the new one, whereas by the old formula, you did not put those?—Quite so; copper and sulphuric acid are added in the retort to assist the formation of nitrous ether.

Mr. Arnold: The old formula omits those things?—Quite so.

Sulphuric acid and copper?—Yes.

That is the only difference?—That is the only difference, save probably in the relative proportions of spirit of wine and nitric acid that might be present.

Mr. Wontner: I take it it is a stimulant?—Undoubtedly.

And in the one way a stimulant pleasant to the taste and smell, and in the other way not so pleasant?—I believe the public so regard it.

Speaking as a pharmaceutical chemist can you tell us whether aldehyde, of which we have heard, is an ingredient in this?—I believe aldehyde is always present more or less in sweet spirit of nitre.

Is it a fact that medical men differ considerably as to what is the active ingredient in this?—I believe it is a very debatable point as to the compound upon which the medicinal properties of spirit of nitre depend—wholly, at any rate.

Whether the spirit of wine, or the nitrous ether, or the aldehyde?—Yes, or both, or all of them.

Mr. Arnold: Mr. Rogers, can you contend after this evidence that the only difference between the spirit of nitre which is manufactured by this gentleman and sold, it appears, by the defendant, consists in the omission of certain things, that that is an adulteration? Can you contend that as a point of law?

Mr. Rogers: No, I do not think I can.

Mr. Arnold: It is quite an end of the case.

Mr. Rogers: You see, sir, exactly the position the board are placed in with reference to this Adulteration of Food Act—we really scarcely know what we are to do.

Mr. Arnold: I should not advise you to attempt these rather expensive experiments.

Mr. Rogers: Certainly not, sir. But I would refer you again to the 6th section, by which, when the certificate is received, the inspector is obliged to lodge a complaint.

Mr. Arnold: It is not done by an individual person; it is the Board of Works, or some other authority, who are setting this on foot. You should exercise a little more caution before instituting proceedings of this kind. In the first place, I entertain, I must say, a very strong opinion upon the question whether this is a drug or not. My strong impression is, that it is not a drug in the proper sense of the word, in the sense in which it is used in the Act of Parliament. On that point, however, I should probably have taken a little time to consider; but I am quite clear on the evidence given by this witness, that the mere fact that certain ingredients are omitted from the compound in the making-up of the distillate cannot be called an adulteration. Do you ask for costs, Mr. Wontner?

Mr. Wontner: If you please.

Mr. Arnold: I think the defendant is entitled to costs.

Mr. Rogers then stated that after what had occurred he should of course withdraw the other summonses.

Mr. Arnold said that would be the best way, if the others turned on the same question. On the application of Mr. Draper he allowed the costs of the defendants in the other cases, except that of Mr. Saxby who was not in court when his name was called.

Mr. Braithwaite said he appeared for Mr. Saxby, and should have been in time, but for being detained by the train.

Mr. Arnold said he could not allow the costs in the case of a defendant who did not answer when called. In the other cases he should allow the costs, because persons had been brought there at great expense and inconvenience, and one summons would have been quite sufficient to try the question.

Notes and Queries.

[375.] COD LIVER OIL EMULSION.—"*Subscriber*" would be thankful for a recipe for making a cod liver oil emulsion that will not separate.

[*** The following formula for a "Cod Liver Oil Mixture," which is stated to have met with much favour in the United States, is quoted from the *Cincinnati Lancet* by the *Medical Record*:—

"Take four fresh eggs; lemon juice, a sufficiency. Place the eggs in a suitable vessel, and pour over them sufficient lemon-juice to cover them, and let the whole remain for twenty-four or forty-eight hours. Then pass the whole through a strainer, and add, with agitation, the following, and in the order given. To the lemon-juice and eggs add an equal volume of honey, cod-liver oil, and brandy or whisky. The whole forms a permanent emulsion, and will keep good during the summer months for a month, and longer in cooler weather. The taste of the oil can be completely covered by the addition of a few drops of oil of wintergreen or oil of bitter almonds. This mixture is pleasant to take, and a valuable therapeutic agent. Glycerine may be substituted for the honey."]

[369]. AQUARIUMS.—The best "grass" for the leech aquarium is the *Vallisneria spiralis*, one of the very few plants that will stand the *forcing* temperature of the shop. A very pretty moss, the *Fontinalis*, also grows well; but there are many pond and ditch plants, as the common Frogbite (*Hydrocharis Morsus Ranæ*), the ubiquitous Chokeweed (*Anacharis alsenastrum*), several of the *Potamogetons*, or even the Duckweed, that look very pretty, do well for a time, and can readily be renewed. Better, however, not start until the spring.—*A. P. B.*

[370.] HOMINY.—In reply to *J. T. H., E. E.* desires to say that "hominy" is maize, or Indian corn, coarsely powdered and boiled in milk for a considerable time over a slow fire, or allowed to macerate in an oven not too highly heated. It is common in Derbyshire—where, however, it is made from new wheat.

[371.] MORPHIA SOLUTION FOR HYPODERMIC INJECTION.—Mr. C. T. Vachell, writing to *Lancet*, recommends the following formula for the preparation of a solution of morphia for subcutaneous injection:—

Acetate of Morphia	1 drachm.
Distilled Water	12 drachms.
Acetic Acid	q. s.

One twelfth of a grain of acetate of morphia would be contained in each minim of the solution.

CASTOR OIL AND GLYCERINE.—A writer in the *Philadelphia Medical Times* states that if castor oil be mixed with an equal quantity of glycerine and one or two drops of oil cinnamon be added the taste of the castor oil is so covered that it can scarcely be recognized.

PRESENCE OF SUGAR AND TARTARIC ACID IN VINE LEAVES.—In a note presented to the French Academy in 1869, M. Petit stated that vine-leaves containted 20 to 30 grams per kilogram of glucose, and a quantity of acid varying from 13 to 16 grams. In further investigating the subject M. Petit has found (*Rép. de Pharmacie*, new series, i., 632) that about one-third of this acid is tartaric acid, which exists in the state of cream of tartar. He has also found that much sugar is present as cane sugar, and in taking special precautions to prevent the conversion of the cane sugar into glucose, he obtained from a kilogram of vine leaves—cane sugar, 15·80 grams; glucose, 17·49 grams. The leaves of the cherry and the peach also contain a mixture of cane sugar and glucose, and from a kilogram of peach leaves he obtained—cane sugar, 33 grams; glucose, 12 grams.

Citrate of Magnesia.

Sir,—Naturally I have read with deep interest the flood of literature on the subject of the article which is, or of the articles which are, somewhat akin to my manufacture, called "Granular Effervescent Citrate of Magnesia," and I have so read with especial interest the letter of Mr. Sandford, and that also of H. C. W. upon one page of our last week's Journal.

I can unhesitatingly follow a suggestion of H. C. W., and say in regard to my manufacture that magnesia forms an essential part of the preparation, and is present in an important quantity. I, with others, consider that during effervescence it becomes a citrate, and I know of my own experience, and you will find the same recorded in the Pharmaceutical Journal, 1868-69, p. 194, that if neutral citrate of magnesia (from which it took its name) be used the preparation soon becomes deteriorated, losing its effervescence and colour.

Regarding Mr. Sandford's suggestions, to the purport that I have, from motives not commendable, launched a compound preparation under a false name, I would point to the necessity which existed for a name to that which was admittedly a new compound preparation, and to the experience of mankind regarding names. It next was necessary that the name of anything animate or inanimate should define the elements of its composition. All that is wanted in a name is that it should distinguish one thing from another. My belief was, and is, that the name adopted by me did distinguish the article from other compounds, and did not, in fact, mislead, and although I might have adopted another designation, and probably should have done so had I foreseen the *harsh* language recently used, I must respectfully disclaim having been actuated by any other than proper motives in my choice of a name.

As for the safety of gentlemen who may sell my article by its proper name, I may point to the opinion of the Attorney-General, Sir Henry James, M.P., and Mr. Poland, as conclusive.

Alfred Bishop.

Dec, 4th, 1873.

"What's in a Name?"—(Old England, 1573.) "£10 Penalty and Costs."—(Young England, 1873.)

Sir,—The explanation of the McDermott case in last week's Journal (p. 439) makes it still more serious. It now appears that this notorious penalty was inflicted upon the accused for misapprehending the meaning of an inexact expression written in a dead language. But did he misapprehend? This depends upon the intent of the writer, and he should have been made to state that upon oath, which, I think, would have been fatal to the prosecution.

If such questions as this come within the scope of the Adulteration Act, no one is safe.

It happened to me to-day in the ordinary course of business to receive a prescription on which was ordered 4oz. effervescing citrate magnesia, to be taken according to directions to be inscribed upon the bottle. Notwithstanding the notoriety of Mr. McDermott's conviction, the usual granular effervescent from Mr. Bishop's manufactory was supplied. What else could be done? Our usual printed label was attached in addition to the written directions as a special precaution consequent upon the publicity given to the late prosecution, but this does not affect the properties of the preparation *supplied as "Effervescing Citrate of Magnesia."*

I write therefore to support the appeal to the Council of the Pharmaceutical Society for intervention. It is intolerable that the whole trade should be subject to convictions under the Adulteration Act for discharging their duties intelligently, simply because a manufacturer has given an objectionable name to a popular article, which name has been adopted by the public and the medical profession, and only protested against by ourselves.

The conviction against Mr. McDermott was a gross miscarriage of justice which ought not to pass unchallenged;

leaving every member of the trade liable to similar annoyance at the instigation of anyone possessing the necessary qualification of unscrupulous malevolence.

RICHARD W. GILES.

Sir,—Mr. Bishop having acted on the President's persuasion, and procured for the Pharmaceutical Society the highest legal opinion as concerning *his own* article, let us hope to see the equivocating attempts to "ring the changes" on mag. cit. labels now give place to a broader view of the whole subject.

'Tis poor fencing to think only of guarding from the cut we've already received. Suppose the next should be on a new tack—*e.g.*, why not "Turkey" Rhubarb as well as "Wallsend" Coals? But I won't (like gentlemen at the Bloomsbury and Brighton Opening Meetings) suggest subjects to the analysts. "Sufficient unto the day," etc.

The guiding principle to be kept in mind seems to be not merely the old *caveat emptor*. The *vendor* must take care that the buyer is not deceived as to the nature or quality of the medicine or food purchased.

J. P. C.

W. B. R. writes to say in reference to the citrate of magnesia question, that he has been in the habit of using the following label, and that it seems to do very well:—"Granular Effervescent Saline, hitherto popularly called Citrate of Magnesia."

LOCAL SECRETARIES AND THEIR DUTIES.

Sir,—It affords me much gratification to have an opportunity, whilst endorsing Mr. Rimmington's expressions contained in the Journal of Nov. 22nd, of publishing my experience of local secretaryship, which certainly is an *honourable distinction!*

In the summer of 1870 it became my duty to report to the Council the fact of a person having, by illegal means, caused his name to appear on the register of chemists and druggists, and from that time till the following summer I was engaged in procuring evidence in support of my charge, and in defence of a writ of mandamus, filed by defendant in the Court of Queen's Bench, against the Council for having erased his name; in each case we (the Society) succeeded. It is needless to say how very delightful is the task of an "informer," raking up evidence against a neighbour—in a small town especially so. Well, after twelve months' trouble, the natural odium and loss of time, not one word of thanks did the Council think proper to accord me.

By this time you no doubt think, sir, "It's nice to be a local secretary;" it is so "honourable" and remunerative. I certainly second Mr. Rimmington's suggestion, "that they be elected for two years only, and not eligible for re-election;" we shall then see how the "new brooms" sweep our register of the incongruous matter contained therein at present.

CYMRU.

Sir,—That some change in the mode of appointing the local secretaries is not only desirable, but much needed, few pharmacists, I think, will question. The local secretary of the Pharmaceutical Society should be the centre of pharmaceutical life of the district in which he lives. This is not always the case; there are gentlemen who have held the appointment for a long series of years, and have done little more than collect the annual subscriptions, and perhaps occasionally answer a communication from the Secretary at Bloomsbury Square. It may be that the members themselves are at fault. The Secretary may have tried to bring them together on some occasion requiring unity of action in matters affecting the welfare of the trade, and after anticipating a full meeting, found that his remarks had to be addressed to a solitary individual and any number of empty benches. It is possible a change of officer might bring about better results the next time. I would go further than Mr. Rimmington in suggesting a change, and propose that every local secretary be instructed to call a meeting annually to elect his successor, and that the retiring secretary be ineligible for re-election. If the members were anxious to keep one in office who had served them well, they would take all the more interest in securing his appointment the next year. An objection to this plan would be that some gentleman would propose his friend to fill the office, and to oppose his election might be thought to display a hostile feeling towards him, and so the post would be filled alternately by two gentlemen. But this might be avoided if (as at present) the names of all the eligible members in the district were proposed for election, and the votes taken by ballot. Then, as figures are not so easily recognized as handwriting each name might be designated by a number and the number used on the voting paper instead of writing the name of the person in whose favour the vote was to be recorded.

R.

Nov. 26th, 1873.

EDINBURGH EXAMINATIONS.

Sir,—No one, through the medium of your columns, has attempted to solve Mr. Williams' problem as to how "the candidates in Edinburgh were much more successful than in London."

The London students had better take this rebuke to themselves, and apply themselves more thoroughly to their object.

The reasons for their repeated failures are very intelligible. Many go up from the provinces to the metropolis, and finding themselves for the first time in so great a city, fritter away their time, instead of using the few months in study, and when they do begin to study it is nothing more or less than "cram."

Now in Edinburgh and Glasgow there are classes in the evening, presided over by the University professors, which are always attended by the students at least two sessions before presenting themselves. And masters, with few exceptions, are too much interested in the welfare of their assistants not to give them every facility for studying, by granting time and giving a week or two's holiday to be spent at the Society's rooms, exclusively.

In Scotland we have no "expeditious and economic schools." All are *bonâ fide* students.

Lastly, Scotchmen, as a rule, are better educated than Englishmen. This is proverbial.

K.

Edinburgh, Nov. 22nd, 1873.

THE REMUNERATION OF ASSISTANTS.

Sir,—I have read with interest the letter of Mr. Haynes, in the PHARMACEUTICAL JOURNAL, and fully endorse all he has said relative to the great disadvantages of country students.

I am an assistant in a small country village, where I never have the opportunity of dispensing a physician's prescription, and where the chief trade consists of retailing commercial more than pharmaceutical articles.

As I am very anxious to pass the Minor (having had the good fortune to succeed in the Preliminary), and to set up in business for myself, I have every reason to be discouraged, inasmuch as I cannot afford either the time or the money to undergo a course of study in London, and there being no facilities here for attending lectures, seeing specimens, or engaging in experimental chemistry.

There are hundreds in a like situation, and I maintain that they have just cause to view their future in anything but *couleur de rose* light.

I know several young men who have forsaken the profession altogether, their circumstances not enabling them to prosecute their studies with any speedy chances of a successful termination, other trades holding out greater advantages in a pecuniary point of view.

CHEMICUS.

Sir,—In this week's Journal I see a letter headed "Chemists' Assistants' Association." But the writer of it very soon leaves his text, and launches out on another subject. Now, an association of that class is very much wanted in our midst, and I should be very glad if some gentleman of standing would take it under hand. I quite agree with "Minor Associate" when he says that plenty of young men would be found ready to enrol themselves as members of the association.

In every other walk in life we find the people banding together, and what is the result? Better remuneration for their labour. Not that I believe in strikes or anything of that kind, but I believe if such an association were convened, and then the case was properly represented by the heads of this association to employers, we should get wha

we want, viz., better remuneration and shorter hours. And when that happy day arrives, the Pharmaceutical Society may expect, and have a right to expect, those who present themselves to be better prepared for the ordeal of examination.

EUXESIS.

Osmeston, Nov. 22nd, 1873.

DRUGGISTS' CHARGES.

Sir,—The following advertisement is taken from the *Western Press* of Saturday, November 15th, 1873 :—

"Prescriptions faithfully and carefully dispensed, by duly qualified persons, with best drugs, at from 20 to 100 per cent. below the usual charges, at the Genuine Drug and Chemical Store, ————. ————, Proprietor."

Some of the younger members of our Society are so tender as to feel insulted by dispensing charges being cut down ; but uniformity of prices is impossible ; and whilst some chemists conceal their charges, others will advertise them. And, as regards the public, some will go to cheap shops, and others will avoid them ; so that chemists really need not be jealous of each other, and I am inclined to apply the same remark to co-operative stores.

I would strongly recommend the young chemist not to neglect his small retail customers who bring in ready money ; and, with respect to dispensing charges, if the young beginner charges *high* his customers will prefer the older establishments, and if he charges *low* they will doubt the quality of the medicines.

"Be thou as chaste as ice, as pure as snow, thou shalt not escape calumny."

JOSEPH LEAY.

Chilcompton, Bath, Nov. 24th, 1873.

The Report of the Special Committee respecting Examinations.—We are requested by Mr. Frazer to publish the following in reference to the amendment which he moved to the adoption of the above report (see p. 448) :—

"As it must appear very anomalous to your readers that I should have spoken to my amendment before Mr. Williams had spoken to the motion itself, I think a word of explanation is needed in vindication of my position :—Before the report was given in at all I had consulted Mr. Sandford as to the form in which I should word my amendment to the motion that I expected him to move. When Mr. Sandford, as I clearly understood, twice over, most distinctly said he "had no motion to propose"—that he had merely to give in the report of the Committee—when Mr. Sandford afterwards did this and had sat down, no one rising, and the Chairman, as it seemed to me, putting the report before the Council for its adoption, I saw no course open to me but to rise and propose the amendment. I need not say that I was in the hands of the Chairman and of Messrs. Williams and Sandford, and would at once have given way to them had they signified that such was their wish. As it is, the loss was all on my side—the gain on theirs. They replied to me instead of my replying to them, and they very properly took all the advantage that this position gave them."

"*A Molecule.*"—(1) The figures you refer to are in the first instance obtained by quantitative analysis. (2) In reply to this question we should recommend you not to attempt to commit the formulæ to memory, but rather to study the facts and principles upon which they are based. When these are understood your difficulties in respect to formulæ will have disappeared. As you seem to possess Attfield's 'Chemistry,' read carefully the chapter on the "General Principles of Chemical Philosophy."

W. Smith.—Probably your object would be best attained by redistillation of the spirit, either alone, or with a little carbonate of soda.

W. J. P.—The only trustworthy method for the detection of such an adulteration would be a microscopic examination by a person familiar with the appearance of this and other starches under the microscope.

W. F. C.—Our opinion upon this point has been already expressed in vol. ii., p. 540. To obtain an authoritative decision we should recommend you to apply to the Inland Revenue Commissioners at Somerset House.

J. Young.—The specific gravities corresponding with the several degrees of Baumé's hydrometer, as determined by different authorities, certainly exhibit discrepancies, slight indeed, but not very easy to account for. Thus the determinations made by Delezennes are all lower than those of Francœur, though the two were made at the same temperature, viz., 12·5° C., and Gilpin's numbers for 15° C. are intermediate between the two. Another set of numbers, for 55° F. = 12·8° C. is given by Graham in his 'Elements.' We do not know where he got them from. The numbers given in the article "Alcoholometry," in 'Watts' Dictionary,' vol. i., pp. 84-86, are Gilpin's ; those in the article "Hydrometer" (vol. iii., p. 210), written by Jevons, are Francœur's. We give a short table, giving the specific gravities, at intervals of 5° Baumé, according to the several authorities above quoted. The specific gravities, according to Delezennes and Francœur, for each degree Baumé, from 10° to 60°, are given in the article "Aräometer," in the 'Händworterbuch, 2te Auflage, ii., Band. Absh. 1, p. 180.

Degs. Baumé.	Specific Gravities, According to :			
	Gilpin.	Delezennes.	Francœur.	Graham's 'Chemistry,' 1st. ed., p.
	At 15⅝° C. = 60° F.	At 12·5° C. = 54·5° F.	At 12° C. = 54·5° F.	At 55° F.
10°	1·0000	1·0000	1·0000	1·000
15°	0·9666	0·9654	0·9669	0·963
20°	·9343	·9333	·9359	·928
25°	·9044	·9033	·9068	·897
30°	·8773	·8751	·8795	·867
35°	·8526	·8486	·8538	·842
40°	·8272	·8236	·8295	·817

A new determination of the values of Baumé degrees has lately been made, apparently with great care, by Berthelot, Coulier, and d'Almeida ; but the results are not yet published. A sketch of the method is given in the *Comptes Rendus*, for Nov. 3 (No. 18), p. 970.

"*Alpha.*"—What were formerly juleps in the Guy's Hospital Pharmacopœia are now called mixtures. The Julep. Amm. Sesquicarb. is now called "Mist. Ammoniæ. The formula is :—

Take of
- Carbonate of Ammonia . . . 40 gr.
- Treacle . . . . . 4 fluid-drachms.
- Compound Tincture of Lavard . 4 fluid-drachms.
- Peppermint Water . . . . . 11 fluid-ounces.

Julepum cinnamomi is not in the present edition ; it is probably an old form which has been expunged, and our correspondent may perhaps obtain it by writing to Mr. Stocker, the apothecary. The Pharmacopœia is printed by Ash and Flint, London Bridge, S.E.

E. E. will find that two formulæ for brilliantine are given in vol. i., p. 457.

T. Lunn.—There is a chapter on the examination of urine (illustrated by microscopical drawings) in Attfield's 'Chemistry' (Van Voorst), and another in Bowman's 'Medical Chemistry' (Churchill).

"*Syrupus.*"—(1) The new regulations for the Jacob Bell Memorial Scholarships are now in force, and will apply to the next award. (2) The amount of knowledge of elementary chemistry required would, we suppose, provided the candidate wished to carry off the Scholarship, be such as, *ceteris paribus*, would enable him to surpass the other competitors.

"*Patchouli.*"—Mr. Leonard M. Gill, the manager of *The Country*, a journal of rural pursuits, writes to inform us that the article on "Patchouli" in our issue of November 8 was copied from his paper, without acknowledgement, by the *Journal of Applied Science*, whence we took the article, and he requests us to give the credit of its first production to *The Country*.

☞ In consequence of the great length to which the reports of the Society's Transactions and of the Legal Proceedings extend,—necessitating eight extra pages,—the publication of several reports of provincial meetings at Edinburgh, Leeds, Liverpool, Dublin, etc., is unavoidable deferred.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Mee, Young, Armstrong, Illingworth, Clarke, Hayes, Berry, Mumbray, Safford, Tibbs, Harrison, Longley, C. B., "Heathen Chinee," "Inquirer," "Hater of Injustice," Sec. Midland Chemists Association.

AMMONIO-CITRATE OF IRON.

BY CHARLES UMNEY.

The variation in appearance of ammonio-citrate of iron, as met with in trade, must have been noticed by every observant pharmacist.

Since the time of its introduction into medicine by Beral, now about thirty years since, most manufacturers have adopted, notwithstanding the various officinal formulæ that have been published, one or other of the following methods for its production :—

(α) By dissolving metallic iron (nails) in a solution of citric acid by the aid of heat to the complete saturation of the acid.

(β) By adding hydrated ferric oxide to citric acid dissolved in about twice its weight of water, assisting its solution by the heat of a water-bath until the oxide is no longer dissolved, and is visibly in excess.

Solution of ammonia in both cases being added after filtration, to produce the double salt. By either method the result is very similar, the amount of anhydrous ferric oxide resulting from a calcination of the salt with free exposure to air from 30 to 31 per cent., and the appearance of the scaled product nearly or quite identical.

A review of the various formulæ that have been published in the London and British Pharmacopœias will serve not only to show the relative amounts of ferric oxide directed to be added to the citric acid, but also to indicate (when the examination of commercial specimens is brought forward) that obsolete processes are followed by manufacturers.

As this iron salt is almost universally used, it will be interesting at the same time, to note the formulæ of the French Codex and the United States' and German Pharmacopœias.

London Pharmacopœia, 1851. *(First officinal.)*

Sulphate of Iron	12 ozs. (Troy).
Carbonate of Soda	12½ ozs.
Citric Acid	6 ozs.
Solution Ammonia (·960)	9 fl. ozs.

British Pharmacopœia, 1864.

Solution of Persulphate of Iron (1·441)	8 fl. ozs.
Citric Acid	5 ozs. (Avoir.).
Sol. Ammonia (·960)	14 fl. ozs.

British Pharmacopœia, 1867.

Solution of Persulphate of Iron (1·441)	8 fl. ozs.
Citric Acid	4 ozs. (Avoir.).
Sol. Ammonia (·959)	19½ fl. ozs.

United States' Pharmacopœia, 1873.

Citric Acid	5 oz. 360 grains (Troy).
Sol. Persulphate of Iron (1·320)	16 fl. ozs.
Sol. Ammonia (·960)	20 fl. ozs.

French Codex, 1866.

Acid Citric	100 parts.
Hydrated Peroxide of Iron	q. s.
Sol. Ammonia	18 parts.

Add such a quantity of hydrated ferric oxide as will correspond to 53 parts of anhydrous oxide iron.

Pharmacopœa Germanica, 1872.

Citric Acid	2 parts.
Oxide of Iron	q. s.
Then add Citric Acid	1 part.
Sol. Ammon.	q. s. to saturation.

The following table, deduced from these formulæ, will show at a glance the relative amounts of anhydrous ferric oxide to the same amount of citric acid :—

	Citric Acid.	Ferric Oxide.	
Lond. Pharm., 1851	100 parts	57·3	Added as ferrous salt.
Brit. Pharm., 1864	,,	33·4	Added as ferric salt.
,, 1871	,,	41·8	,,
U.S. ,, 1873	,,	40·0	,,
French Codex	,,	53·0	,,
Pharm. Ger., 1872	,,	?	,,

The London and British Pharmacopœias describe the amount of ferric oxide resulting from incineration with free exposure to air, but the Codex and German and American Pharmacopœias do not state the amount of ferric oxide perfect specimens of their respective salts should contain.

Pharm. Lond.,	1851	34	per cent. Fe_2O_3
Brit. Pharm.,	1864	26·5	,,
,, ,,	1867	27·0	,,
U.S. ,,	1873	?	,,
French Codex		?	,,
Pharm. German.,	1872	?	,,

Most of the recent formulæ have one feature in common, viz., the complete saturation of the acid by the oxide of iron, but the quantities ordered by each work with this object in view are very disproportionate.

The British Pharmacopœia, 1867, says, "*dissolve the citric acid in eight ounces of distilled water, and having applied the heat of a water-bath, add the oxide of iron, and stir them together until the whole, or nearly the whole, of the oxide has dissolved.*"

It is presumed that complete saturation is intended by the expression "*until nearly the whole of the oxide has dissolved*," and that the amount of oxide produced by the precipitation of the persulphate of iron ordered is in slight excess of the quantity required for such saturation.

Be this as it may, upon referring to the Codex we find an amount of hydrated oxide ordered which shall be equal to 53 parts of anhydrous oxide, whereas the British Pharmacopœia, 1867, orders an equivalent of 42 parts only.

Practically I have found that the French Codex formula is much more like the basis of ammonio-citrate of iron of the best makers than is the British Pharm. formula, although fifty parts (half its weight) would more accurately represent the amount of ferric oxide (added as hydrated oxide) required to saturate 100 parts of citric acid than would *fifty-three* parts, as named by the Codex.

A comparison of the formulæ of the British Pharmacopœias of 1864 and 1867, as to the amount of ferric oxide added to the acid, and the amount stated to be left by calcination is most conflicting ; for instance, the 1864 Pharmacopœia shows that for 33·4 parts ferric oxide to 100 citric acid, as much as 26·5 per cent. is left upon calcination, whereas that of 1867 indicates that from 41·8 parts added to the same amount of citric acid, 27 per cent. is left by calcination.

The mean of three analyses of ammonio-citrate of iron (B.P. 1867) gave ferric oxide by calcination 27·4 per cent., proving the accuracy of the present officinal test and the fallacy of the 1864 Pharmacopœia.

Of course it may so happen that the British Pharmacopœia does not intend that the acid shall be saturated with oxide, and has merely framed its formula with other objects in view.

If it were so contemplated I think a great improvement in the formula would have been made if a salt had been recognized that would have scaled easily, and represented the best specimens as met with in trade.

An examination of the ammonio-citrate of the leading London manufacturers indicates that at the present time uniformity is the exception rather than the rule; that the British Pharmacopœia scales are not to be met with; that the preparation of the London Pharmacopœia, or a modification of it is still used; and that the *complete saturation* process is in some cases followed.

London Pharmacopœia, 1851 .	34·0	(determined).
British Pharmacopœia, 1867 . .	27·4	,,
Manufacturing Proccss (saturation)	30·7	,,
Trade Specimens . . . (1.)	26·0	
,, ... (2.)	24·1	
,, ... (3.)	30·1	
,, ... (4.)	30·0	
,, ... (5.)	33·4	
,, ... (6.)	33·3	
,, ... (7.)	29·4	

As uniformity in all substances used in medicine is of vital importance I would suggest that at the earliest convenient date the use of ferric oxide sufficient to the complete saturation of the acid by the aid of a water-bath heat be recognized, and that the formula of the British Pharmacopœia be amended by substituting *nine and a half fluid ounces* of the persulphate of iron solution for the present quantity of eight fluid ounces, or as much hydrated ferric oxide to one hundred parts of citric acid as shall be equivalent to fifty parts (49·6) of anhydrous ferric oxide.

Laboratory, 40, *Aldersgate Street, E.C.*

THE VERIFICATION OF BAUME'S AREOMETER.*

BY MM. BERTHELOT, COULIER, AND D'ALMEIDA.

The areometers of Baumé, as supplied by the manufacturers, being rarely accordant with each other, the authors were requested to draw up a report, indicating the proper methods for verifying these instruments. The following is an abstract from this memoir :—

§ I. *Definition given by Baumé of the fixed points of his Areometer.*—The following is the text taken from the last edition of Baume's '*Eléments de Pharmacie*' published during his lifetime (8th edit., vol. i., p. 341) :—"Take an ordinary glass hydrometer, and mark zero at the place where it ceases to sink below the surface of pure water; this will form the first term. For the second term prepare a saline solution by dissolving 15 pounds of very dry and very pure marine salt in 85 pounds of water; this will give 100 pounds of the solution. Plunge the instrument into this liquor, and when it ceases to sink mark the place on the tube as 15°, which will be the second term. Divide the interval between these two terms into equal portions, which will form degrees. The interval so graduated will serve as a standard for dividing in the same manner the lower part of the tube. All these operations ought to be conducted in a cellar, and it is necessary to leave the liquid sufficiently long to acquire the proper temperature, which is ten degrees (Réaumur) above freezing, or 12·5° C."

Such are the instructions of Baumé himself, and all instruments made in conformity with them will be in accordance with each other. The authors consider that the introduction of any change in these directions for the construction and verification of Baumé's areometer must be arbitrary.

§ II. *Density of the Standard Solution and Tables.*—The point of departure in all the operations for constructing or verifying Baumé's areometer is the preparation of the standard saline solution, and the determination of the weight of a litre of that solution. For the preparation of the saline solution the authors weighed fifteen parts of pure and carefully dried marine salt, and eighty-five parts of distilled water, and introduced them into a flask, when solution was effected with certain precautions. The determination of the weight of a litre was made by the flask method, and found to be 1110·57 grams. This number expresses the weight of a litre of salt and water at a temperature of 12·5° C., weighed in air with brass weights under a pressure of 760 millimetres, which conditions correspond with the definition and mode of operation adopted by Baumé. From this number, and that which represents the weight of a litre of water at the same temperature, the following table is calculated :—

*Table indicating the Relation of the Degrees of Baumé's Areometer with the Weight of a Litre of Liquid weighed in Air, under a Pressure of 760 Millimetres, and at the Temperature of 12·5° C.**

(The table can be used at 15° C., and all neighbouring temperatures.)

Degrees	Weight of Litre.	Degrees	Weight of Litre.	Degrees	Weight of Litre.
0	998·404	26	1210	51	1520·5
1	1005	27	1220	52	1536
2	1012	28	1230	53	1552·5
3	1019	29	1240·5	54	1569
4	1026	30	1251	55	1586
5	1033	31	1262	56	1603
6	1040	32	1272·5	57	1620
7	1047·5	33	1283	58	1638
8	1055	34	1295	59	1656·5
9	1063	35	1306	60	1675
10	1070·5	36	1318	61	1694
11	1078	37	1330	62	1714
12	1086	38	1342	63	1734
13	1094	39	1354	64	1754·5
14	1102	40	1366	65	1775
15	1110·57	41	1379	66	1797
16	1119	42	1392	67	1819
17	1127·5	43	1405	68	1841·5
18	1136	44	1418·5	69	1865
19	1145	45	1432·5	70	1889
20	1154	46	1446·5	71	1914
21	1163	47	1460·5	72	1938
22	1172	48	1475	73	1964
23	1181·5	49	1490	74	1990
24	1191	50	1505	75	2017
25	1200·5				

This table may be used not only for liquids at a temperature of 12·5° C., but also at temperatures up to 15° C., or a little higher, since up to that point the dilatation of the areometer may be neglected. It must be remembered however that when at a certain temperature—14° C. for example—the instrument sinks into the liquid to a fixed point, the table indicates the weight in air of a litre of this liquid, measured at the same temperature of 14° C.

§ III. *Verification of the Areometer.*—For this object two methods may be adopted, which are equally good.

(1) Commence by ascertaining that in distilled water, at + 12·5° C., the areometer marks zero. Then determine the weight in air of litres of liquids of different densities, such as more or less concentrated solutions of marine salt, sulphate of zinc, syrups, glycerine, sulphuric acid, etc. When the weight of a litre of one of these liquids has been taken, the vessel being filled at a given temperature, about 12·5° C., the areometer should be plunged into the liquid while at the same temperature.

* Abstracted from *Répertoire de Pharmacie*, vol. i., p. 621.

* This table does not agree with that given in the preliminary notices of the Codex of 1866. For instance, the Codex gives for 30° the density 1261, and the above table gives 1251. We think this later table will be preferred, because of the scrupulous care with which it has been drawn up.—*Ed. Rep. Pharm.*

The areometer ought then to indicate the degree corresponding with the previous table. The important point is that the temperature of the liquid when the litre is weighed should be exactly the same as when the areometer is placed in it.

When it is wished to verify the whole of the scale it is desirable to use such solutions as would represent the weights intermediary between 1000 and 2000 grams. But when the areometer is only required for one particular purpose, such as the testing of glycerines, it is only such weights as correspond with those of the glycerines met with in commerce that it is necessary to verify with care, and this may easily be done by means of the preceding table.

The second method of verification necessitates the employment of a good balance, which by means of a hook, string, and some small pulleys can be raised and lowered at will. Beneath one of the scales (A) is attached a very fine silken thread or hair about 12 or 15 centimetres long; at the lower end of this thread a small piece of soft wax, the size of a pin's head, is affixed, to which the areometer can be stuck. In the other scale (B) is placed a sufficient counterpoise to balance certain weights in (A), and to bring the needle of the balance to zero when the areometer is immersed as far as zero in water at 12·5° C. This counterpoise must be left in (B) during all the subsequent verifications. The areometer is then weighed in air, and its weight exactly noted. It is next placed in distilled water at 12·5° C., when it ought to indicate zero exactly. The vessel containing the water and the areometer is then placed under the pan (A) of the balance, and the thread is stuck to the stem of the areometer. Weights are removed successively from the pan (A) equal to the weight of the areometer multiplied by 0·03367, 0·06733, etc., as given in the following table, and when the needle of the balance is at zero, which is attained by raising the balance, the areometer should indicate the degrees which are placed opposite these numbers :—

Degrees indicated.	Numbers by which the weight of the areometer is to be multiplied.	Degrees indicated.	Number by which the weight of the areometer is to be multiplied.
5	0·03367	45	0·30300
10	0·06733	50	0·33666
15	0·10100	55	0·37033
20	0·13467	60	0·40400
25	0·16833	65	0·43766
30	0·20200	70	0·47133
35	0·23566	75	0·50500
40	0·26933		

If, for example, it were wished to verify the 25th degree of an areometer, of which the weight in air is 57·3 grams, this latter figure must be multiplied by 0·16832, and an equal weight to the product—9·645 grams—removed from the scale pan (A). Then, if the balance be raised until the indicator is at zero, the areometer should indicate 25 degrees, provided it be plunged into water at the temperature of 12·5° C.

The areometer should be well moistened several degrees above the level of immersion, and in reading this level a uniform method should be followed, which should be the same as that adopted in graduating the tube.

The remainder of the report is taken up with a description of the precautions taken by the authors to secure exactitude in their experiments.

SOLUBILITY OF ISINGLASS IN WATER.*

BY C. CARROLL MEYER.

The author took one hundred grains each of American ribbon, American sheet, Russian and Prussian (?) isinglass and treated them separately, first with f℥viii of water to soften them; then f℥viii more of water was added and boiled, until all soluble matter was extracted, then filtered, and the following table will show the solubility of the different kinds experimented with :—

Isinglass.	Quantity used.	Soluble.	Insoluble
American strip .	100 grs.	70 grs.	30 grs.
,, sheet	100 ,,	82 ,,	18 ,,
Russian . . .	100 ,,	88 ,,	12 ,,
Prussian . . .	100 ,,	80 ,,	20 ,,

From the foregoing experiments it will be seen that the Russian is the most soluble and the American strip the least soluble.

The bladder of a hake fish, weighing ℥xv, was washed with water to remove salt, and boiled with sufficient water until all soluble matter was obtained, then filtered, and found to contain ℥i of insoluble matter.

As aqueous solutions are prone to decompose, experiments were made to see if anything would arrest decomposition, and glycerine was found to answer very well in the proportion of one part glycerine to fifteen parts solution of isinglass. Solutions to which glycerine was added kept sweet and were quite palatable, while those to which no glycerine had been added soon decomposed, and became quite offensive to both taste and smell.

* From the *American Journal of Pharmacy*.

INDIAN HOSPITALS AND DISPENSARIES.

Bad water and bad drainage are in India the sources of pestilences which periodically carry off large numbers. Except in cholera years, fever claims more victims than all the other diseases and accidents put together. The number of deaths from fever alone in 1871 is computed at about one and a half million. Cholera has also been bad in some parts, but small pox has steadily declined since vaccination has been attended to. The passion for pilgrimages is another great source of mortality; hosts of pilgrims starting, but few returning. No less than 14,529 deaths from snake bites were reported in 1869; and Dr. Fayrer, who has made the subject his special study, estimates the annual mortality from snake bites to exceed 20,000. Deaths from wild beasts are very numerous. In the 'East India Progress and Condition Report' for 1871–72, from which these particulars are taken, a single tigress is spoken of as killing during three years no less than 108 persons. The Government offers rewards for their destruction, but without avail, partly owing to the natives looking on a "man-eating tiger" as an incarnate and spiteful deity which should not be interfered with, and partly from the wish of some to spare them as game.

The Government, however, is not inactive in these matters, and the sanitation of the towns receives careful attention. Sanitaria for the troops have been established in many places in the Hills. Quinine is looked upon as the only real remedy for fever; the people believe in it and are very anxious to obtain it, and the Government desires that the alkaloids shall be prepared at so low a rate as to be within the reach of all.

In all the large towns there are richly endowed and well regulated hospitals, partly supported by the Government and partly by private subscriptions. Numerous dispensaries also are established throughout the country on a "grant-in-aid" system, the town furnishing a building and guaranteeing a certain subscription, and the Government providing and paying for the necessary medical staff. In the North West Provinces there are 90 civil hospitals and 41 dispensaries. In Bengal there are 160 dispensaries, and certain medicines are distributed over the country and supplied to villages, so as to be sold at cost price. The medical students are first trained at

the dispensaries and then complete their course at the Agra College. At Bareli and Naini women are taught medicine and surgery, and some have already commenced practice. In the Panjab there are 110 hospitals and dispensaries, being in the proportion of 1 to every 160,000 inhabitants. The Mayo Hospital connected with the Lahor Medical School was opened in 1872, and has accommodation for 114 patients. In Oudh there are 26 Government dispensaries and 1 private one. In the Central Provinces there are 92 dispensaries, the Government furnishing the medical staff to 76 of them. In Bombay there are 121 dispensaries, 30 of which are attached to civil hospitals, 60 charitable, 1 self-supporting, and 30 wholly supported by Government. In some districts the *Hukims*, or native doctors, are made use of in epidemics after receiving elementary instruction, the Government paying them and supplying medicines. Many of the *Hukims* have sent their sons to medical schools for regular training.

SUNDERLAND CHEMISTS' ASSOCIATION.

ANNUAL DINNER.

The annual banquet of the Sunderland Chemists' Association was held on Wednesday evening, December 3, at the Palatine Hotel, and proved in every respect an enjoyable and successful one. Alderman Thompson, the president of the Society, occupied the chair. Mr. H. Thompson discharged the duties of vice-chairman. After the usual loyal and local toasts had been honoured—

Mr. Sharp, in proposing "The Medical Profession," said he was glad to see so many medical gentlemen present, and he hoped their intimacy would continue to increase. The professions of chemist and surgeon, as they were all aware, were most intimately connected, and no doubt each had done something to develop the other since the days when the physician prescribed toads, eels, serpents' tongues, and other abominable things. There was no doubt that medicine had advanced in proportion to the discoveries made in chemistry, and the time was coming when the people would act on the philosophy of "prevention is better than cure." As greater attention was paid to sanitary arrangements and the laws of health, the less would be required of doctor and drugs. In this conviction he might state that he was pleased they had got an efficient medical officer in Dr. Yeld, who would look well after the sanitary state of the town. Mr. Sharp next alluded to the question of medical men dispensing, and concluded by hoping that the time was not far off when the doctor would merely prescribe, and allow the chemists to have their legitimate work of dispensing.

Dr. Horan replied, and dwelt on the progress made in pharmacy, and, in alluding to the question of general practitioners dispensing, said they should, if possible, give it up. Nothing, he remarked, was more arduous, after a hard day's work, than for a medical man to have to prepare medicines, but when the members of the profession gave up this work, they would, of course, expect chemists to cease prescribing.

Dr. Yeld next proposed "The Sunderland Chemists' Association," coupled with the name of Mr. J. J. Nicholson, its secretary. He said that the subject of sanitary reform had been alluded to, and he might state that for many years past there had been a great many lives sacrificed entirely in consequence of inattention to sanitary arrangements. He believed that as they lessened the mortality of a town they at the same time diminished the burden on the rates. A great many cases had been brought before his notice which showed the necessity of taking energetic action in cases where the disease was of a contagious nature. He thought many of them had little idea of the miserable and wretched state which many poor people were in in that town. In the course of a few months he expected to be able to effect a considerable improvement in the sanitary state of the town. Dr. Yeld then referred to the subject of the toast, and said that although the chemists in the town were not numerically strong they were a thoroughly educated body of men, and he only wished they would devote a little more time to the scientific branch of their profession. The chemist could be of very great service he thought to medical men, for unless the general practitioner was well posted up in his chemistry, he was apt to prescribe drugs which were not compatible with each other, and would therefore counteract the effects of each other. He sincerely hoped the junior members would dive deeply into their science, and do all they could to advance it.

Mr. J. J. Nicholson briefly replied, and said the number present indicated that the profession of the chemist was advancing in this town. He hoped that the suggestions Dr. Yeld had made would be attended to, and that many of their members would take a deeper interest in their meetings and discussions. This was one of the great means by which they could not only advance their own interests, but the interest of the science which they all professed to love. There were many gentlemen who, when behind the counter, would say you ought to do so and so, but never came forward themselves. He hoped that the younger members of the profession at least would be inspired by what they had heard that night to renew their exertions in their studies.

Mr. Harrison Thompson, the vice-chairman, then proposed the health of the president, and said that Alderman Thompson was not only admired by his fellow-chemists, but by all who knew him, for his kind and benevolent disposition. He had been the very life of the Society, and had spared neither trouble nor expense in keeping it together. On all important occasions when their interests were at stake, he was first at the meeting and last to leave. They were deeply indebted to Alderman Thompson, and he hoped he might long be spared to preside over their meetings.

After returning thanks, the Chairman said he had only one object in view in relation to their Association, and that was to promote its success, and thereby improve the status of its members. Referring to his own career in the profession, he said he had attained his position through industry and perseverance, and he hoped he would not be the last chemist who would occupy the post of chief magistrate of the town. The young members of the profession had now a splendid chance to gain scientific knowledge in chemistry, and he hoped some enthusiasm had been that evening kindled in them, and they would go forward with the intention of mastering the science. In a short time he believed that the chemists would cease to deal in little things, and become solely compounders of medicine. After again thanking them for their kindness, he resumed his seat amid much applause.

Dr. Potts, who said he was the guest of Alderman Thompson, proposed "The Pharmaceutical Society," and pointed out that formerly the most dangerous drugs were compounded by men who had had no chemical education at all, but now—thanks to the Pharmaceutical Society—things are changed, and drugs were only dispensed by skilled men.

Mr. Sharp briefly replied, and then Mr. Turnbull proposed "The Visitors." Mr. Harkness, in responding, showed what chemistry had been able to do in the somewhat rough business of making steel and iron. By the aid of the scientific intellect, Bessemer steel was now made direct from pig iron, and through the aid of another chemist, Ratliff,—who was equal to Bessemer—malleable iron was now made direct from the raw material. These operations of course were not in their line, but if the young chemists connected with the Association had any love of their science, they would devote all their spare time to study and research.

The Pharmaceutical Journal.

SATURDAY, DECEMBER 13, 1873.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square,*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE POSITION OF TRUSTEES UNDER THE PHARMACY ACT.

WHAT is the nature of the provision which a registered chemist and druggist can make for the carrying on of his business after his decease, without contravening the terms of the Pharmacy Act? This is a question that has frequently been asked with considerable anxiety by chemists and druggists, and frequently replied to. The additional elucidation of the problem, however, by the Solicitor of the Pharmaceutical Society, at the last meeting of the Council, and the points raised in the subsequent discussion, are of such importance that no apology is needed for recounting them here. The subject has been previously referred to in these columns more than once, and it is with satisfaction that we note that although it has now been discussed in greater detail, the opinion of the Solicitor is in strict accordance with that which we had ventured to express.

The subject naturally divides itself under three heads: (1.) Who can carry on the business of a deceased registered chemist and druggist? (2.) Under what conditions can such a business be carried on? (3.) How long can such a business be carried on? Taking the report of the discussion printed in last week's Journal for our basis, we shall endeavour to answer these queries succinctly in the order in which they are here set down.

(1.) *Who can carry on the business of a deceased chemist and druggist?* The Pharmacy Act is sufficiently explicit upon this point. It says (sec. 16), "Upon the decease of any pharmaceutical chemist, or chemist and druggist, actually in business at the time of his death, it shall be lawful for *any executor, administrator, or trustee* of the estate of such pharmaceutical chemist, or chemist and druggist, to continue such business." What constitutes a trust, and consequently a trustee, is a question for a lawyer and not for us to decide. It is evident, however, that this part of the section is very elastic, and although it would be a great misfortune if such trusts were very extensively created, their validity would be determined by rules of law of wider application than the Pharmacy Act. The case put by Mr. GREENISH probably illustrates the class of trusts which it would be sought most frequently to create. He asked, if a registered chemist and druggist left his business to his wife to be carried on for the support and education of his children, whether she, not being on the register, could carry it on. Mr. FLUX's reply to this question was explicitly affirmative, with this important proviso,—that there should be an active trust to that effect. He pointed out that by the law of the land these were duties which naturally devolved upon the parent, and that if a widow were left with a business not distinctly charged with the trust of maintaining her children, she was a beneficiary, and not a trustee. This answer will apply to a great number of cases which would only be variations of the foregoing one.

In the event of a registered chemist and druggist dying intestate, his widow, if he leave one and if she choose to act, or his next of kin, can take out letters of administration, and as administratrix may carry on the business. It is important to notice that here it is by virtue of being administratrix, and not through any relationship, that the power to carry on the business accrues, and that a widow, as a widow, stands on exactly the same footing as the children, sisters, mother, or any other relative, none of whom can acquire any right to carry on the business as legatees.

(2.) *Under what conditions can such a business be carried on?* The key to the answer to this question is to be found in the fact that the qualification to carry on the business of a chemist and druggist is now a personal one. Acquired personally by passing a certain examination, it cannot be transferred by its possessor to another person during life, neither can it be transmitted to his successor after death. In this it resembles that of other callings in which examination is the test of qualification, such as the clerical, legal, and medical professions, though for these latter obviously there could be no such provision even as is found in the Pharmacy Act. But on the death of a registered chemist and druggist his name is at once removed from the register, and no other is substituted for it; the question therefore naturally arises, what is the proper style for carrying on such a business? The answer given by the legal advisers of the Society is to the effect that, since the continuance of the business will not be in exercise of any personal qualification in the executors, administrators, or trustees, and will not confer upon them any degree of qualification to carry on business on their own account, or open any new business, the proper style for the conduct of such a business would be—

The { Executors, Administrators, or Trustees. } of A. B. { Pharmaceutical Chemist, or Chemist and Druggist. } deceased

Also, that as it is the intention of the Pharmacy Act that there shall be a personal responsibility to purchasers and the public for the fulfilment of the conditions imposed by clause 17, "the full names of the executors, administrators, or trustees, with the address at which the business is conducted," should, in every

sale of poison, be "placed on the label used for the poison—in addition to, and before the above-suggested style of business." Another condition imposed by the Pharmacy Act is, that the business shall be conducted by an assistant who is a pharmaceutical chemist, or a registered chemist and druggist.

The foregoing are conditions arising out of the Pharmacy Act itself, but of course, beyond these there is the usual responsibility of trustees in respect of debts, actions for damages arising from mistakes, etc., which probably would have a tendency to induce trustees to terminate their trusts as soon as practicable.

(3.) *How long can such a business be carried on?* The answer to this question is, So long as the trust exists and no longer. When the purposes for which the trust was created are accomplished the right to carry on the business by the trustees as representatives of the deceased immediately ceases. In the case of a person administering to an estate,—for instance, a widow,—so long as she carried on the business as an administratrix she would be protected by the Act of Parliament. A certain amount of time would be required to wind up the affairs of the estate, such as the collection and payment of debts, etc., and so long she would stand in the position of a trustee of the estate. But as soon as by force of her own act, or that of the next of kin, a settlement of the accounts takes place and the administration of the estate is terminated, the business would pass from her hands as trustee, and could no longer be legally carried on by herself or any other unregistered person. No person by virtue of having been appointed an administrator or executor could carry on a business for his or her personal benefit.

In thus laying before our readers what appear to be the principal provisions of the Pharmacy Act in relation to this important subject, we have avoided expressing any opinion as to their fairness or unfairness. We know that it has been asserted that the effect is sometimes very harsh, and is the result of an imperfect Act. Still we think it cannot be denied that the reading upon which the foregoing opinions are based, namely, that the qualification to carry on the business of a chemist and druggist is a personal one, which dies with the person acquiring it, is strictly in accordance with the whole spirit and tenor of the Pharmacy Act. We also think it evident that if exception were made in favour of any relative, it would be impossible to establish a limit that would not be harsh to those outside it, and the door would be at once opened to numberless evasions of the Act all over the country.

THE REGISTERS FOR 1874.

THE time has now arrived when, in compliance with the provisions of the Pharmacy Act, 1868, the Registrar has to prepare for publication the registers of Pharmaceutical Chemists and Chemists and Druggists for the year of 1874. We have frequently pointed out the importance to the Pharmaceutical body, collectively and individually, that the greatest possible correctness should be secured for every entry upon these Registers. On the one hand it is indispensable that the judicial authorities, who may be called upon to base their decisions upon the Registers, should find them trustworthy; on the other there is the fact, that absence of a person's name from the Register, is by itself evidence that it has no right to be there, and even an inaccuracy in the entry might involve the person referred to in considerable trouble to prove his claim. To assist in maintaining this desirable accuracy, the Registrar requests us to ask every member of the trade who may be aware of any rectifications in the Registers that have become necessary, in consequence of deaths, removals, or other causes, to send information respecting them *at once* to him at 17, Bloomsbury Square, London.

WE have much pleasure in announcing the safe arrival in India of MR. C. H. WOOD, F.C.S., who was recently appointed Quinologist of the Sikkim Cinchona plantations. MR. WOOD was known to most of our readers as a scientific chemist, and more recently as the able Editor of the 'Year Book of Pharmacy.' MR. WOOD sailed from Southampton on the 28th of August, and after a pleasant voyage arrived safely at Calcutta on the 8th of October, where he remained a guest of DR. HENDERSON, the Superintendent of the Botanic Gardens for about a week. The remaining part of his journey from Calcutta to Rungbee, near Darjeeling, where the plantations are situated, must have been very trying to one accustomed to English modes of conveyance, for owing to the extremely hilly nature of the country, and the badness of the vehicles, the rate of progress did not in some parts exceed a mile an hour. MR. WOOD has now been in his new home nearly two months, and he and his family are now enjoying excellent health. He describes the vegetation and general scenery as magnificent, and the climate all that could be desired. We are sure that all who knew MR. WOOD will unite with us in wishing him a continuance of good health, and success in his new undertaking.

Mr. C. R. MARKHAM, C.B., whose highly succesful labours in the introduction of the Chinchonæ into India are so well known, is about to bring out a memoir of the Lady ANA DE OSORIO, Countess of CHINCHON and Vice-Queen of PERU, A.D. 1629-39, the lady who first introduced the quinine barks into Europe. The book will be in small 4to, printed on laid paper and illustrated with coats of arms, maps, views of the castle and town of Chinchon, some in colours, and will contain a full history of the COUNTESS's family, and the story of her cure and of the introduction and distribution of the bark by her in Europe. The book will also contain a plea for the correct spelling of the genus, viz., *Chinchona*, instead of *Cinchona;* "cinchon" meaning a policeman's belt, and the alteration thus defeats LINNÆUS'S wish to honour the memory of the lady. The book will be published by Messrs. TRÜBNER and Co., and the price to subscribers will be one guinea.

Provincial Transactions.

PHARMACEUTICAL SOCIETY, EDINBURGH.

(North British Branch.)

The first meeting for Session 1873–74 was held in the Society's Rooms, St. Giles Street, on Thursday evening, November 27, at half-past eight. Mr. J. R. Young, President, in the chair. There was a full attendance.

The President gave the following introductory address :—

"When, a few days before the last election, it was intimated to me by Mr. Baildon that the Vice-President preferred in the meantime to retain his present position, and that the Council was desirous, if possible, that my friend and partner, Mr. Brown, should occupy the chair during this year, I promised to do everything in my power to aid in carrying out the proposal. Mr. Brown had been complaining for some time, had gone on a visit to the south of England, and accordingly I wrote him expressing the pleasure it would give us all if he would allow himself to be nominated. Mr. Brown promptly replied, thanking all for the kindly feeling evinced towards him, but regretting that the state of his health was such that he must at present decline. It was in these circumstances, and just on the eve of election, that I was requested to allow myself to be put in nomination. I was not dreaming in the least of such a proposal, having already occupied the chair on two previous occasions; and having no particular views to expound, or mission to accomplish, I felt disposed rather to linger on the memories of the past; but, from the want of sufficient firmness to say "no" decidedly, unlike some friends whom I could easily name, here you find me again for one year. And while I thank you all sincerely for the honour which has been done me, I do hope you will oblige me and gratify the Council by being present as often as possible at the meetings which may be held during the session, more especially at those when we are favoured with addresses from such friends as the Council may be able from time to time to secure. A very little reflection enabled me to perceive the difficulties connected with the position which I had thus somewhat hastily undertaken. I felt that I was succeeding one who from the institution of the Society had been one of its most valued members in this district; who was well versed in its history; who had been most serviceable in negotiating various matters of immense importance to this Branch; who was from experience very familiar with all the duties devolving on any one occupying the chair; who had the confidence of the Society in a very marked degree; and who had discharged the duties of its President during the meetings of the Pharmaceutical Conference in Edinburgh and at other seasons in such a way as to earn the gratitude and admiration of his constituents. Permit me just to say in passing how deeply we sympathize with Mr. Baildon and his family in their sore bereavement, and how earnestly we hope that the soothing influence of time may gradually enable them to recover from the sudden and severe shock which they have had to sustain. It was at a time when Mr. Baildon was President of this Branch of the Society that Professor Christison was kind enough to deliver an address at one of its scientific meetings. In that address the learned Professor sketched very graphically the contrast between this country and the continent in regard to the position which each occupied in the science of pharmacy as it presented itself to his mind during his period of study at Paris and at London; and alive to the steps which had been taken in connection with the formation of the Pharmaceutical Society, he looked forward with much hope to the younger pharmacists as being likely to raise the profession from that dead level to which in this country it had all but sunk. There were in the opinion of the Professor "three cardinal means always within reach" for the attainment of such an object, and these he comprehended in the brief advice, "extend, educate, and purify." Twenty years have nearly passed away since this laconic advice was given, and it may not be amiss now for a very few minutes to consider whether any or what progress has been made in any of these directions. Now I am sure that no one at all acquainted with the Pharmaceutical Society will venture to affirm that a great work has not been accomplished through its instrumentality. Its aim has been from the day of its institution to form into one solid phalanx the previously disunited units of the profession, to break down existing barriers through having friendly intercourse with one another, and by using all legitimate means for extending its influence, make it, what it really has become, one of the institutions of the country, recognized by the Government and the legislature, and every year its usefulness becoming more apparent to the general community. This state of things has arisen in great measure from the position which the Society has all along held in reference to the importance of education. So long as there was no compulsory examination, the Society did everything in its power to stimulate those connected with the profession to place themselves under its wing, and that they were not unsuccessful is proved by the many bright names which in various parts of the country now shine as stars in the pharmaceutical firmament, and which anyone interested in the science can readily point out. Now, however, none can enter its ranks without examination, and, so far as these have yet gone, I think on the whole the examinations are fair, but quite as stringent, as in the meantime they ought to be. Here, in Scotland, we have had, and are likely to have, even greater advantages than heretofore in the matter of education, but as many parents, more especially in our manufacturing towns, throw off their children as apprentices at or about the age of fourteen, it does not appear to me desirable that so long as we must draw our apprentices from that class, that the examination papers for the "Preliminary" should exceed the capacity of the average of boys of that age. It is certainly most desirable that the manner of conducting these Preliminary examinations should be beyond the taint of suspicion, and as rumours have been floating about of late that in consequence of it may be the want of suitable accommodation, or of proper surveillance, there have been occasional cases of supposed collusion amongst the candidates, I do think it is imperative on the part of the Society to use all the means in its power to prevent even the possibility of such an occurrence, and this, in my opinion, can only be done by having a sufficient number of local centres throughout the country, at which places rooms apart from places of business should for the time being be secured, and during the examination the local secretary of the district should attend, and be paid a proper fee for such attendance. I am well aware of the amount of work which our local secretaries have so long, so efficiently, and so ungrudgingly discharged, in the interests of the Society, but now that it has reached a point that its funds are sufficient, I think it is only an act of justice and fair commercial dealing that such an arrangement as has been indicated should be honestly carried out. I dislike the idea of handing over these examinations to other parties, and equally so that of confining them exclusively to London and Edinburgh, and very much for the reasons given in the very able letter of the late president, Mr. Haselden, which appeared in a recent number of the Journal. As regards the scientific examinations no great difficulty should be felt by our young men in mastering them, but it would tend very much to their convenience, and without lessening the value of the examination, if the system as at first introduced, or at any rate some modification of the present, was adopted by which, in the event of failure on a first attempt, the candidate should be told where he is deficient, and have credit given him for the subject or subjects in which he may have passed, thus giving him a measure of encouragement, and leaving him to concentrate his energies for a succeeding

examination on those subjects in which he is defective. It must always be borne in mind that the scientific acquirements of our young men are mostly attained during the period of their apprenticeship, when hard at work from morn till night, and that it is scarcely fair to place them on a level with the students of medicine, who for three or four years devote themselves exclusively to their studies. With all or many of these little matters still under consideration I think it will be admitted that, on the whole, we have made progress, and that the pharmacists of the present day are in advance of the past in so far as that there exists a very general feeling that everyone who now enters the business should be something more than a mere trader in the articles in which he deals; that he is now more fitted by his training to examine the goods received into stock; that he is interested in their history, qualities, and medical properties, and in many cases possessing the ability and having the inclination to make minute investigations regarding them. He is now much more alive to the responsibilities under which he labours: he watches with jealous care the manufactures of the various compounds in his laboratory: he becomes truly the handmaid of the medical attendant who, confiding in the purity of his preparations and the accuracy with which they are dispensed, engages in his arduous work with the conviction that in so far as the medicine prescribed can be effectual for the relief of his patient, every precaution has been taken, and his minutest instructions fully carried out. Unfortunately the purification specially recommended by Professor Christison is in many cases still wanting: the sale of quack medicines is rife as ever throughout the country, and so long as existing regulations continue regarding them it is not easy to see how any change can be effected. The most worthless nostrum, if sufficiently advertised, is sure to sell, and the day seems yet a long way off when the pharmaceutical chemist will be at liberty to take up such a position as will enable him to dispense altogether with their sale. Counter practice also prevails to a considerable extent in certain districts of the country; but for this the chemists are not wholly to blame. In some districts it would be impossible for a chemist to live did he not to some extent indulge in such a course, and in addition add to his stock many articles of a heterogeneous kind, the sale of which he would gladly, in other circumstances, avoid. Hucksters, it is true, are not now allowed to add to their stores paregoric, laudanum, and such like medicines, nor are they permitted to dispense prescriptions as in days gone by, but the evil is that, in most cases, the medical men in country towns dispense the prescriptions, and the huckster has very much the entire sale of castor oil, tincture of rhubarb, and medicines of a similar nature. I have no doubt that some remedy will ultimately be found for this state of things. Within my recollection an entire change has taken place in Edinburgh in regard to dispensing by medical men. I can remember when the leading medical men had well-appointed surgeries, each with a full staff of apprentices, for preparing their patients' medicines. Now, no such thing exists; even the youngest city practitioner shrinks from the idea of such a course, and as a consequence counter practice is discountenanced, and the result is pleasing and beneficial to all parties. You are all aware of the decision which was recently given under the Adulteration of Food Act, in reference to the sale of what has hitherto been called "effervescent citrate of magnesia," and of the excitement occasioned thereby throughout the trade. Such a decision points to a far higher condition of professional responsibility than we have yet dreamt of, and if such remains unchallenged and unaltered, will necessarily render it imperative on us all to examine very specially not only the quality, but also to weigh well the very name of every article admitted into our several places of business. Considerable discussion has taken place in reference to the course which should be adopted in dealing with this article in future. Mr. Bishop has taken high legal opinion, and announces his intention of retaining the name as it is, so far as his preparation is concerned, and as it does contain magnesia, the want of which in the article as supplied by Mr. McDermott led to the conviction, it seems to follow that all other manufacturers must in future introduce magnesia into their preparation. As the compound is not a citrate of magnesia a change of name, as suggested, would in my opinion have been the right course to adopt, but as Mr. Bishop's manufacture is well known to the public, is really an agreeable and refreshing beverage, and will continue to be advertised extensively, as heretofore, other manufacturers will be obliged to conform or leave Mr. Bishop to enjoy the full benefit of his invention. In connection with this it is well to observe that a meeting of chemists and druggists in London has been held under the auspices of the National Chamber of Trade, for the purpose of considering this very case, at which resolutions were moved and carried, that the judgment was contrary to equity, and that Parliament be petitioned to repeal that portion of the Act which relates to drugs and chemicals. This seems to me the right course to pursue, and I hope every encouragement will be given to the committee which was appointed to carry out the resolutions, so that it may proceed vigorously. During the recess the cabinet with specimens for the use of candidates for the scientific examinations has been carefully refitted. It contains specimens, and good ones too, of all the substances on which a candidate is examined, excepting the fresh botanical specimens. The cabinet will be open for inspection at such times as the Secretary will name hereafter. Ample provision has, as usual, been made for attendance on special terms by our young men at the classes of various lecturers on different branches of study, and in addition for the convenience of those who have not leisure during the day, Mr. Melville has opened classes in the evening for instruction in botany, materia medica, chemistry, and pharmacy; but of course it must depend on the number who join these latter, whether or not they will be continued. Many very interesting specimens have been added during the past year to the museum, and I have the pleasure to-night of presenting to the Society from my partner, Mr. Brown, a number of volumes which will tend very much to enhance the value of the library as one of reference. Mr. Brown was for a considerable period the convener of the library committee, and the members of that committee know well the zeal and enthusiasm with which he has all along advocated the importance of an extensive library. Many of us at times have thought his views a little Utopian, but he has proved by his valuable donation how sincerely he holds them, and how willing he is to help in having them carried out. From the experience acquired during the time we have occupied our present premises it is very evident that more efficient provision must be had before the full benefit we anticipated can be obtained; but from the interest taken in the welfare of the North British Branch by the parent society, and their determination to maintain it in a position commensurate with its connection, I have no doubt that everything will be arranged so as to secure the comfort and instruction of all who frequent the rooms."

At the close of the address Mr. John Mackay made a few remarks on some of the subjects alluded to by the President. He made special reference to the citrate of magnesia case, and to the movement in connection with it which had been taken in London at the recent meeting of the National Chamber of Trade, and thought chemists and druggists might fairly consider whether they should agitate for a repeal of that portion of the Act embodied in the Adulteration of Food Act which relates to interference with drugs and chemicals; stating that if some effort of this kind was not made, there was the prospect of constant annoyance in regard to many things in daily use in every pharmacy. He concluded by moving a vote of thanks to Mr. Young for his able and interesting address, which was carried by acclamation.

The Secretary then proceeded to draw the attention of the meeting to the handsome contribution of books by Mr. D. R. Brown (of Messrs. Macfarlan and Co.) to the library of the Branch of the Society in Edinburgh. The volumes numbered 209, and being on the table would speak for themselves. Not only were there several valuable scientific works of reference among them, but their good condition and the handsome binding of most of the volumes would commend them as being well suited to grace the shelves of the library. He proposed a very cordial vote of thanks to Mr. Brown for this present to the Society. This was unanimously and with acclamation carried.

The following is a list of the volumes presented to the library of the North British Branch of the Society in Edinburgh by Mr. D. R. Brown :—'Philosophical Transactions,' 18 vols.; 'Edinburgh Philosophical Journal,' 14 vols; 'Edinburgh New Philosophical Journal,' 50 vols.; 'Report of British Association,' 17 vols.; 'Cicero,' 10 vols.; 'Edinburgh New Philosophical Journal,' new series (1864), 19 vols.; 'Braithwaite's Retrospect of Medicine,' (1869), 59 vols.; 'Paris Universal Exhibition Catalogue, British Section,' 1 vol.; 'Scoresby's Magnetical Investigations,' 2 vols.; 'Metcalfe's Caloric,' 2 vols.; 'Catalogue of Library of R. C. P. and R. M. S.,' 1 vol.; 'German Pharmacopœa' (1872), 1 vol.; 'Lucretius, de Rerum Natura,' 3 vols.; 'Murray's Chemistry' (1806), 4 vols.; 'Duncan's Edinburgh Dispensatory' (1st Edition), 1 vol.; 'Duncan's Edinburgh Dispensatory (12th edition), 1 vol.; 'Lewis's Dispensatory (1781), 1 vol.; 'Complete English Dispensatory' (incomplete), 1 vol.; 'Berzelius, Treatise on Chemistry' (1839), 3 vols.; 'Haydn's Dictionary of Science,' 1 vol.—in all, 209 volumes.

In addition to Mr. Brown's presentation, the Secretary had further to announce the following donations to the library :—

From Messrs. Macfarlan and Co., North Bridge: 'Renodæus, Medicinal Dispensatory' (London, 1657); 'Pharmacopœia Medico-Chymica,' 1662; 'Dalei Pharmacologia' (London, 1737), 2 copies; 'Zwelferi Pharmacopœia,' 1672; 'Pharmacopœa Parisiensis' (Paris, 1738); 'Pharmacopée Universelle (Paris, 1738); 'Pharmaceutical Times,' vol i., 1847. From Messrs. Frazer and Green, 'Druggists' Price and Stock Book. The 'Pharmacist,' from the Chicago College of Pharmacy. Catalogue of Books in 17, Bloomsbury Square, belonging to the Society in London. 'Transactions' of the Chemical and Royal Societies in London for the current year, from Mr. John Mackay. For the Museum: Galls on English Oak, from Professor Maclagan; and a piece of Lignaloe (*Amyris Tecomaca*), Mexico, from Professor Archer of the Museum of Science and Art.

The Secretary then made the following announcement to the meeting.

The Secretary begged to draw special attention to the fact that the President of the Society in London, Mr. Hills, had in the most kind, generous, and liberal manner, given funded property, yielding £5 per annum, to the North British Branch, for the following purpose, viz., that of presenting books to the young man who stood highest in marks at each Minor examination in Edinburgh. It has therefore been arranged that as there are at present four examinations each year, £1 will be devoted at each meeting to be spent as indicated by the donor. If applications for examination become so numerous as to call the board together *five* times a year instead of *four*, then there will always be sufficient funds to continue the prizes. One word as to the application of the sum. It is Mr. Hills' expressed desire that the successful candidate be allowed to name the books he would like, but it must be distinctly understood that as the prize is to be given for the purpose of aiding the successful Minor to prepare for the Major examination, so the books named must be in connection with his forward studies, and therefore pertain to chemistry, botany, or pharmacy. No literary volumes will be allowed to be selected, as the main feature in the gift would be thus destroyed. The first application of the grant falls to be made at the January Examination, and the prize adjudged by the board of the examiners, when the numbers and marks of the candidates have been summed up and obtained. The Secretary then proposed that the meeting should award a very hearty vote of thanks to Mr. Hills for his liberal and handsome gift to the North British Branch of the Society; that the same be entered in the minutes, and conveyed in writing to Mr. Hills.

This proposal was met with acclamation, and the thanks of the North British Branch was cordially and unanimously passed to Mr. Hills.

Mr. Gilmour, Vice-President, then gave a very interesting lecture on the Polariscope, which he illustrated with the oxy-hydrogen light, numerous diagrams, and a great many very beautiful illustrations upon the screen. The crystallization of some of the substances was very interesting and striking, particularly that of santonin and tartaric acid. All the experiments were eminently successful, and at the close a hearty vote of thanks proposed by the Chairman was unanimously and enthusiastically carried.

The meeting then adjourned.

LEEDS CHEMISTS' ASSOCIATION.

The Annual Meeting of this Society was held on Wednesday evening, Nov. 12th, at the Trevelyan Hotel. Tea and coffee, with refreshments, were provided. About 120 persons sat down to an excellent repast; after which the business of the Society was proceeded with by the Hon. Secretary (Mr. J. W. Longley) reading the report and minutes of last meeting.

Mr. Freshfield Reynolds (the President) then delivered the following address :—

"I have to crave your kind indulgence, whilst in obedience to the time-honoured English custom of speech-making, I venture to address a few remarks to you this evening. But a few weeks ago it had never crossed my mind for an instant that I should be asked to become the President (for the ensuing year) of the Leeds Chemists' Association, under whose auspices we meet here to-night. I can honestly say that it is by no desire of my own that this position is not filled by some one of those older, abler, and better-known gentlemen who sit around me. I wish very much, both for your sakes and mine, that one of these had the opportunity of providing for you (now that we have taken thought for the wants of the body) an intellectual repast, fertile in imagination, and full of brilliant thoughts, such as the accomplished Mr. Schacht entertained the members of a similar association with, at Bristol only the other day. But, gentlemen, the banquet was for the sunny South this year; you must be content with only a few crumbs. The attitude which we, the chemists of Leeds, have assumed towards each other to-night, by meeting in this social manner, puts me in mind of a fact or two dwelt upon by Professor Williamson, in his recent inaugural address to the British Association, at Bradford. Speaking of the atomic theory, he reminded his audience that under favourable conditions, the molecules, or clusters of atoms of which matter is made up, are always acting and reacting upon their neighbours. If the adjacent molecules are of distinct natures (or, so to speak, of different nationalities), then a blending of races takes place, and new compounds are formed, having often distinctive characteristics and new powers. But if the molecules are all of one kind, then in the absence of alien or hostile ones, they proceed to act upon one another. One is tempted to pause and ask whether this law which works so silently in nature, is one and the same with that which actuates the untamed and savage tribes of American Indians, or of Central Africa? The former doubtless would rather scalp, and the latter rather devour, a white man or molecule, than one of his own kind; but failing a white man, I fear a friendly molecule would fare no better.

But is there not a wide difference between the all-wise law of the Creator as exhibited in the atomic process of nature, and that law (or rather absence of law) which rules the human passions of the savage? If we consider for a moment, we shall perceive that the design of the savage is solely *destructive;* whilst the design of nature is at once *destructive* and *constructive.* And may it not be that this very action which is constantly at work between neighbourly molecules, and which at first sight appears to be of a hostile character, is only part of a beautiful arrangement, by which stagnation or indolence of matter is prevented? But perhaps some of you will be saying, what on earth has this to do with our social meeting? Allow me to explain, gentlemen. We, the chemists of Leeds, are, if you please, molecules of the same genus. May I venture (for the sake of elaborating the idea) to assign the name of "Composing Atoms" to our associates present? Now, in a general way, we may regard the public as hostile molecules, upon whom, under our various *aliases* of Rhubarb, Aloes, Calomel, and Co., we are accustomed to act and react. But in the absence of these alien molecules let us act in a friendly spirit upon one another. I hope we shall all be refreshed by the process, and be the better friends when we part. Reverting again to Professor Williamson's address, it is cheering to find from so high an authority that, amidst the vast and rapid changes through which the science of chemistry has continued to pass of late years, there is at least one great discovery of a past generation which still, in his opinion, remains to be a truth. Let me tell you in his own words what he said about the great Dalton's "atomic theory." He says, speaking of a time when Dalton had ceased from his labours: 'The father of the atomic theory was no more; and the little infant had no chance of life, unless from its own sterling merits it were found useful in the work still going on. What, then, was the result? Did it perish, like an ephemeral creation of human fancy? Or did it survive and gain strength by the inquiries of those who questioned nature and knew how to read her answers? Although anticipating my answer to these questions, you will probably be surprised to hear the actual result which I have to record—a result so wonderful that the more I think of it the more I marvel at it.' Speaking of subsequent discoveries, he goes on to say:—'Not only did these various theories contain nothing at variance with the "atomic theory;" they were found to be natural and necessary developments of it, and to serve for its application to a variety of phenomena which were unknown to its founder.' The Professor also pointed out how the further development of this beautiful atomic theory has explained to us the mysteries of *Isomeric Compounds.* I well remember in my early apprentice days that an older fellow apprentice persisted in affirming that essence of lemon and turpentine were one and the same thing. Now, I think I did not doubt his word (for he whose gentle spirit has since been borne to a more peaceful world was incapable of telling a falsehood), but I am sure I did doubt whether the *ignorance* of the science of chemistry was not more wonderful than its *knowledge.* So much for the evidence of one's senses. But now the mystery of isomerics is explained, and bodies externally differing, but containing precisely the same number of molecules of the same families, are known only to differ by the manner in which those molecules are arranged. To a fuller understanding of this important fact, I believe we are indebted for many recently invented chemical bodies. It seems probable, also, that the artificial building up of substances like the vegetable alkaloids will be accomplished by the application of the knowledge of their exact composition, which this theory has furnished. This, you know, is a day when 'trades'-unions' flourish, and we are met here to-night somewhat in the character of a trades'-union. There is, however, one feature in which ours differs from most others, and which should commend it to the gratitude of a not over appreciative or generous public; thus, whilst colliery owners combine to keep the price of coal at what to many must be almost famine prices, in order that they may fill their pockets with a daily profit almost equal in amount to the average annual returns of a chemist and druggist's business; whilst butchers and farmers combine to place that ancient staff of an Englishman's life, roast beef, beyond the means of genteel poverty; whilst even the vendors of the sky-blue liquids hitherto known in our large towns by the generic term 'milk,' are forgetting their former petty jealousies and their little scandals, about Mrs. Cunning's stealthy visits to the cow with the iron tail, and Mr. Cheet-'em-well's belief that the daily consumption of even milk and water is unwholesome without the addition of say Cret. Ppt.,—I say even these much-abused members of society are uniting against their common enemy the "Adulteration Act," and they too demand a higher price for our children's staff of life,—and, lastly, whilst the main object of unions of every description of paid labour, down even to the agriculturist, is to enhance and force up the price of that labour; hitherto the aim of our Association has been to give the public better value for its money. For if we except this one annual social gathering, our chief energies are spent in endeavouring to give increased technical educational advantages to those who will make the future pharmacists of England. I venture to say that this being the principal object of our existence as an Association, we have a high and noble calling, however imperfectly and humbly it may have been followed hitherto. Some of us may feel that we are not able to do much by our own hands or heads to further the movement, but let us remember that our own noble town hall is built up of individual stones; the foliage but lately so beautiful in our matchless public park was made up of single leaves; and the very water composing its extensive lakes once existed as tiny dew or rain drops; so let us all make a fresh resolve that in the future our Association shall be a noble structure, because it shall be built up by, and composed of, the best efforts of every single member. In commending to you, gentlemen, who are our associates, the means of acquiring scientific information which are offered by Mr. Ward's chemistry classes, and Mr. Abbott's materia medica lectures, I believe it is not too much to say, that no provincial society enjoys the advantage of the educational services of abler or more conscientious teachers. The fees, moreover, for these courses are exceedingly small, and I hope that you will encourage those gentlemen by crowding their class rooms during the present session. The early closing movement has, I am glad to say, made considerable progress, even amongst the members of our trade, and I trust it is also very generally acknowledged by employers that they are bound not only in their own interest, but in absolute duty to their apprentices, to make way for them to avail themselves of such opportunities for technical instruction as I have referred to. And I maintain that, the examinations of the Pharmaceutical Society (at least so far as the Preliminary and Minor are concerned) being now made compulsory by Act of Parliament, no master can overlook his responsibility in this matter without doing a positive injustice to his pupils. Into the vexed question of educational centralization, or de-centralization, pharmaceutically considered, it is not my intention to enter; you are doubtless aware that a much abler brain than mine has already guided the pen on behalf of the interests of provincial chemists. I have the greatest sympathy with those to whom science is a hard mistress, and the pursuit of her mysterious depths no fondly wooed love; to whom, in fact, the systematic study of chemistry and botany is akin to constitutional Gregory's Mixture. I have a belief that the greatest difficulty these have to overcome is very much in the mastering of the first principles of science, the foundation upon which the superstructure is to be reared. There must of necessity be a good deal of drudgery in this where the bent of the mind does not lie in the direction required. My advice to all young men who feel this to b their case, is, to begin

their arduous work as early in life as possible ; by so doing they may perhaps soon overcome the dislike to uncongenial study, and having conquered the rudiments, find a real pleasure in the further pursuit of science. The recent sitting of the Pharmaceutical Conference at Bradford may possibly form the subject matter of one of our monthly meetings ; but there is just one question which occupied its attention, to which I will briefly call your notice. It is a question of considerable importance to the trade at large, namely, 'What is the duty of the dispenser when an unusual or excessive dose is prescribed?' The practical issue of the discussion was the adoption of a resolution to the following effect :—

> 'That this Conference having duly considered proposals for the use of special signs to mark unusual doses in prescriptions, and the great advantages to be derived from them, considers that the bracketed initial letters of the prescriber's signature, written immediately after the unusual dose, is the best method for the purpose. The Conference also urges upon medical men the importance of the prescriber's full name and address being written on all prescriptions to facilitate communication between the prescriber and dispenser. The Conference likewise considers it desirable for the dispenser to retain all prescriptions in which initialled unusual doses are presented.'

It was left with the officers to circulate the resolutions among the profession in the manner they thought most desirable. In the wisdom of this course I think you will all unite. Should the suggestion be adopted by the medical profession generally, dispensers will be relieved from much occasional perplexity. I need hardly point out the extreme undesirability of discussing, on a *quasi*-public occasion like the present, our personal experiences in relation to the clerical errors of prescribers. Of the smart controversy arising out of the well-known Ramsgate case, but little need be said, except that, had the precaution now proposed been in vogue, all the unseemly squabble might have been prevented. In dismissing the subject, I will venture to affirm that there never was a time when the medical profession, as a whole, was more cordially disposed towards pharmacists ; and the way for us to maintain this desirable state of things is, to act in all cases of difficulty or doubt (where immediate access to the prescriber is impossible) according to the dictates of experience and common sense. Turning to another subject of trade interest, I may remind you that the past few years have witnessed the rapid development of what is popularly termed the "co-operative," or "mutual supply" system, by means of which private families are enabled to obtain goods of almost every description at a small percentage above manufacturers' prices. I have some doubts whether the political economists who first advocated the establishment of this system ever intended it to apply to the general wants of society as a whole. At all events, I think it was originally designed to enable the then, perhaps, underpaid working classes to purchase the necessaries of life on equally advantageous terms with their wealthier neighbours, who were larger consumers than themselves. And so long as the plan is confined to such an object, it appears reasonable enough ; but when the principle is strained to admit of co-operative societies being formed amongst the rich and well-to-do classes, it becomes vicious in its character, and utterly inconsistent with true political and social economy. As Englishmen, we are justly proud of our past and present national prosperity, and of the general harmony and contentment which reign amongst us : is it boasting to say that this enviable condition of things is largely and principally due to the sterling character of England's trading citizens? Napoleon might call us a "nation of shopkeepers" in derision, but I say, gentlemen, he unconsciously pointed to a great truth, namely, that the energy, the shrewd common sense, the methodical habits, and the steady application of purpose acquired in the active business of the shop, has played no mean part in the chapter of England's success. What, then, is the bearing of all this? Carry out this new-fangled system to its logical conclusion, extend its ramifications throughout the kingdom, establish its stores in every town and village, and what then ? Why, simply the annihilation of the retail trader. The great industry of the middle classes is swept away, and we must all sink to the dull level of the artizan or labourer, or else swell the already over-crowded ranks of official or professional life. Our own trade is, by its very nature, somewhat sheltered from the worst attacks of this pernicious system. The question of 'personal confidence' enters so largely into the relations existing between pharmacists and the public that the co-operative store cannot easily undertake our functions and responsibilities. This argument, however, applies mainly to the dispensing of medicines. We are all aware that the majority of chemists depend more for their livelihood upon the miscellaneous wants of their customers than upon 'dispensing' *pur et simple*. Now it is quite evident that in the large branch of retail business embraced by the patent medicine catalogues, as well as in the domains of aërated waters, perfumery, and what are called 'druggists' sundries,' there is little to hinder the co-operative store from stepping in and robbing us of our legitimate trade. Can anything be done to prevent such a result from coming about ? Nothing can be done with 'the public' (because 'the public' is human nature in its least responsible aspect) unless you frighten it. Let a bishop be poisoned in a co-operative establishment, and then the favourable moment may have arrived. It appears, then, that we must endeavour to make it as difficult as possible for these societies to obtain our class of commodities at wholesale prices. This may be difficult, but something may be done if associations like our own, as well as individual members of the trade, would take the matter up, and, in a respectful but firm circular, address all wholesale houses, and also manufacturers, remonstrating against the practice of supplying societies which are ruining their best friends, namely, the retail traders. If, after this, any houses be found countenancing the practice, then the laws of self-preservation will naturally come into action, and retail traders must *combine*, and become their own 'wholesalers.' There is yet another, and even less agreeable phase of the subject, as illustrated by the defection of members of our own ranks. If a pharmacist so far abandons his *esprit de corps* as to sell himself and his pharmacy to the enemy, no words of mine, I am sure, can express the contempt with which you and I regard the traitor. I trust our Association is far too honourable to contain such an one. I now propose to draw your attention to a subject of great importance to all of us, namely, the bearing of the 'Adulteration of Food, Drink, and Drugs Act' upon the business of a chemist and druggist. Doubtless most of the gentlemen now present are aware that a London tradesman was fined £10, under the operation of the Act alluded to, for selling an article labelled 'Effervescing Citrate of Magnesia,' but which contained no magnesia at all. This is so far as I know the first prosecution for the adulteration of a drug, under the new Act ; and it not unnaturally makes one desirous of knowing how far we are amenable to it. I have very carefully gone through the whole legislation on the subject of adulteration, subsequent to, and including the Act of 1860. I will therefore in the first place endeavour to convey to you a clear idea of how the law stands, so far as it affects us. 'The Adulteration of Food and Drink Act' passed in 1860, was confined to the *sale* of adulterated articles 'in fraud of Her Majesty's subjects, and to the great hurt of their health,' etc. By a special clause in this Act, 'drugs and articles commonly used as medicines' were exempted from its operation. But I believe it has been generally overlooked that, by the xxiv. clause of the 'Pharmacy Act of 1868,' 'all articles taken or sold as medicines' are brought under the Adulteration Act of 1860. The clause runs thus :—'The provisions of the Act of the 23rd and 24th of Victoria, chapter 84, intituled "An Act for preventing the adulte-

ration of Articles of Food or Drink" shall extend to all articles usually taken or sold as medicines, and every adulteration of any such article shall be deemed an admixture injurious to health ; and any person registered under this Act who sells any such article adulterated shall, unless the contrary be proved, be deemed to have knowledge of such adulteration.' By this clause, be it observed, the Adulteration Act is made to apply *more stringently* to drugs than even to articles of food and drink. Firstly, because it *assumes* (unless proved to the contrary) the guilty knowledge on the part of the seller ; and secondly because *all* adulteration or admixture of drugs or medicines is to be considered injurious to health. The Act of 1860 proving very much a dead letter, another was passed in August, 1872, intituled 'An Act to amend the Law for the Prevention of Adulteration of Food and Drink, and of Drugs.' Now the 4th clause of the new Act says that, 'The Pharmacy Act, 1868, and the Adulteration Act of 1860 shall be deemed to be incorporated with this Act.' It is most important to observe, that, by the incorporation of the Pharmacy Act, 1868, we may be brought into grave difficulties under the 15th clause of the said Act. And I desire the more forcibly to draw attention to this because, in the printed copies of the Act which I have seen, the *marginal heading* or *summary* does not give one any idea of the true nature of the clause. The marginal note runs thus :— 'Protection of titles, and restrictions on sale of poisons ;' and yet, gentlemen, the most important part of the whole clause is contained in these words, 'or who shall *compound* any medicines of the British Pharmacopœia except according to the formularies of the said Pharmacopœia shall for every such offence be liable to pay a penalty of five pounds.' It may be this word *compounding* was only intended to apply to the dispensing of the prescriptions of qualified medical practitioners ; but I shall be able to show that it is by no means safe to rest satisfied with such an interpretation of the word ; indeed, I believe any chemist might be made to suffer a penalty, under the Adulteration Act, for selling to a retail customer an ounce of any compound, for which there is a formula in the British Pharmacopœia, which has not been prepared strictly according to that formula. Hence any pharmacist having his own private recipe for 'Spirit of Sal Volatile,' Quinine Wine, or, say Soap Liniment, is, literally speaking, prevented under a penalty of £5 from ever retailing the same. I think, however, there is a loop-hole out of this dilemma to be found in the 16th clause of the Pharmacy Act, 1868, which specially exempts 'the making or dealing in patent medicines' from its own operation. I think there is nothing to hinder a person putting up *any rubbish*, and labelling it 'Smith's Tincture of Rhubarb,' so long as it bears the 'respectable' Patent Medicine Stamp. But to return to the Adulteration Act of 1872— its first, second, and third clauses run thus :—

'1st. Every person who shall wilfully admix, and every person who shall order any other person or persons to admix, with any article of food and drink, any injurious or poisonous ingredient or material, to adulterate the same for sale ; and every person who shall wilfully admix, and every person who shall order any other person or persons to admix, any ingredient or material with any drug, to adulterate the same for sale, shall for the first offence forfeit and pay a penalty not exceeding £50, together with the cost attending such conviction ; and for the second offence shall be guilty of a misdemeanour, and be imprisoned for a period not exceeding six calendar months, with hard labour.

'2nd. Every person who shall sell any article of food or drink, with which, to the knowledge of such person any ingredient or material, injurious to the health of persons eating or drinking such article, has been mixed ; and every person who shall sell as *unadulterated* any article of food and drink or any drug which is adulterated, shall for every such offence forfeit and pay a penalty not exceeding £20,' etc., etc.

'3rd. Any person who shall sell any article of food or drink or any drug, *knowing* the same to have been mixed with any other substance, with intent fraudulently to increase its weight or bulk, and who shall not declare such admixture to any purchaser thereof before delivering the same, and no other, shall be deemed to have sold an adulterated article of food or drink, or drugs, as the case may be, under this Act.' Now, I would like to ask any common-sensed Englishman (not being a lawyer) if there is not running through all these clauses the clearest and most unmistakable evidence that the penalties of the Act were only intended to apply to wilful, known, or fraudulent adulteration ? But alas ! for plain English, when a lawyer is the interpreter ; for, Mr. Justice Blackburn (who has the reputation of being a sound one), in deciding a case sent for appeal to the Court of Queen's Bench, said, 'It is difficult to say what the 3rd section means, but I am clearly of opinion that it is not necessary to prove a guilty knowledge on the part of the seller' ! If this is not driving a coach and four through an Act of Parliament I don't know what is ! In the PHARMACEUTICAL JOURNAL of a recent date (November 8th) we have ample testimony from the lips of the President of the Pharmaceutical Society, Mr. Hills, of Mr. Sandford, and also of Mr. Haselden, that the qualifying words, knowingly, fraudulently, and wilfully, were introduced by the Marquis of Salisbury, with the concurrence of Lord Granville, at their special request, and with the express purpose of modifying, and of making more just the penal operation of the Act. One word more respecting the citrate of magnesia question, and I will leave the whole question in your hands. I am not sorry that it is now necessary for us to abandon an ill-chosen and misleading name for an elegant and popular preparation ; and that henceforth we may clear ourselves from the stigma of sailing under false colours and adopt a form of label which will at least be *honest*, if not scientifically accurate. We have not yet followed the example of some kindred associations in inviting ladies to attend our annual gatherings, and as they are absent this evening, perhaps we may the more freely speak of their possible future connection with the calling of pharmaceutical chemist or chemist and druggist. The question has more than once I think been debated in the Council of the Pharmaceutical Society, at present with a decision adverse to the ladies, as to whether they should be admitted to its examinations. I may here observe that I am by no means at present a convert to the 'women's rights' programme in its most pronounced form ; but we must pay some regard to the signs of the times, and be prepared for what is not unlikely to come about in the larger domain of national politics. It may be remembered as not without precedent, that what a government (with a large majority at its back) had refused to grant to a small section of its supporters, another government (with a very small majority) has been constrained to yield to its *opponents*. Such a thing *may* happen again. And in the event of the political franchise being granted to women, I anticipate that, in smaller matters, decisions favourable to their claims would speedily follow. Putting on one side, therefore, any question of good taste in the matter, and the desirability or otherwise of ladies having to attend to the miscellaneous wants (not always of a delicate character) of a chemist's customers, I warn you, gentlemen, who are students, that at no very distant date, you may have to compete for honours with the gentler, but by no means always mentally inferior sex. And now, in conclusion, I will venture to address a few more remarks especially to *you*. You are not ignorant of the increased and increasing competition in all branches of commerce ; thus the difficulty of making a living and of providing for the families which I hope some day you will be the happy possessors of is augmented. Then, this is not an age of 'physic.' Medical practice is more rational, if less favourable to the chemists' interest, than formerly ; prices which in most branches of industry are

steadily advancing, do not follow the same rule with us; and again it is possible the co-operative system may become a serious rival in the future. What then should you do? Quit the business, says some one! By all means if you like,—but will you find things much better elsewhere? Your truest course is to use all the facilities for obtaining scientific knowledge within your reach; store up in your minds all the information thus obtained; learn to apply it to the requirements of the age in which we live, and then you will have a stock-in-trade which no co-operative store can supply, and few competitors of any kind will be found to undersell you. The greatest king the world ever saw, when he was told to ask of the Great Head of the universe whatsoever he would, asked neither silver nor gold, neither great possessions nor great power, but he asked that which was of higher intrinsic value than these, and yet at the same time was the pass-key to them all,—He asked for 'Wisdom and Knowledge.'"

After a few remarks by Mr. W. Smeeton on the Adulteration Act, he said the system of co-operation, no doubt required well looking into before a decision was arrived at. He believed it first originated with some clerks at the General Post Office buying a chest of tea. One way he looked at co-operation was this:—Suppose there is a village of 1000 inhabitants, and there is one grocer to the whole number of inhabitants, and that he turned over say a £1000 a year, and when all expenses were paid he cleared £100. Well, so far, so good; but somebody said, "Let us club together and see if we cannot manage better than that." So they form a co-operative store, and the result is that the £100 has to be divided among the 999 members, which leaves them about 2*s.* per head, perhaps not so much, because there will be the extra expenses of a manager for the business, and the profits no doubt will not be so large, for, generally speaking, a man can manage his business better than a paid servant. Then, of course, we see the poor grocer ruined, who perhaps has a large family; and the only advantage that is derived by the inhabitants is that of being a shilling or so richer at the end of the year.

Mr. E. Brown fully endorsed the remarks of Mr. Smeeton respecting co-operation. One topic of the address just read he should like to say a word about, and that was the Preliminary examination. After a few words of good advice to those who were preparing for the examinations,

Mr. Abbott and Mr. E. Yewdall both spoke very warmly on the subject of adulteration, and urged the necessity of the trade binding themselves together, and getting better prices for the articles sold by them.

Mr. R. Reynolds said that as a public body they had a right to criticize the Act. The question of citrate of magnesia would no doubt require an alteration of labels; but it was to be hoped the injustice would be righted, and that that was an isolated case. In the country they had many advantages over co-operation which they had not in London, for there, there was no doubt, the various trades had suffered bitterly during the last few years, and the most cruel injury had been done them. Everything should be done that could be done to bring the influence of the Association to bear to protect themselves and try and avert the evil, or modify the degree to which the evil might extend.

Mr. Barclay (Messrs. Southall, Son, and Dymond) said it gave him great pleasure to meet the chemists of Leeds, and to propose the vote of thanks to Mr. Reynolds. He was also glad to see such a number of young men assembled together, and to hear from the report, that there was an increase in the number of associates. He should like to mention a word in reference to the co-operative stores. He did not think there was much to be feared on that ground. Liverpool had passed through the ordeal with fear and trembling, and the co-operative stores had come to an untimely end. He then briefly referred to the Adulteration Act, and advised the raising of prices, because there were greater expenses to bear, better education to provide, higher rents to pay, and larger wholesale prices to give. He had very great pleasure in proposing a vote of thanks to Mr. F. Reynolds for his able address.

Mr. Jefferson seconded the vote, after which Mr. F. Reynolds briefly returned thanks, and introduced Mr. Davis of Harrogate, who then read an abstract of a paper entitled:—

Monthly Analytical Examinations of the Harrogate Spas, 1872.

I have been requested by my friend, Mr. Reynolds, to occupy your attention on this occasion for a few minutes with an abstract of a paper by myself, recently published in the *Journal of the Chemical Society*, entitled "Monthly Analytical Examinations of the Harrogate Spas, 1872."

I feel somewhat diffident in bringing before you a matter which can hardly be classed as belonging to the domain of pharmacy. Nevertheless, I hope it may be of some little interest to you.

Anyone who has compared the tables of analyses of a mineral water, which has been submitted to repeated analytical investigation at considerable intervals, must have been struck with the discrepancies, and the conclusion usually arrived at is that the greater accuracy with which these examinations are now conducted detects constituents which analysts in former years with their imperfect methods have failed to find.

There is no doubt some degree of reason in this, but there are many remarkable discrepancies which do not admit of this ready explanation; the variations in many cases take place in the spring themselves. In the year 1872 I submitted to analysis, at monthly intervals, the water of two of the most important spas in Harrogate; the springs selected were the old sulphur well and the chloride of iron spa.

Quoting from my paper, "In making these analyses great care was taken to ensure accurate results; a sufficiency of the standard solutions was prepared in the first instance, and the same apparatus was used throughout. The determinations of the chlorine and the total residue obtained were calculated for the gallon from the specific gravities, and the temperatures were carefully noted, so that the results might furnish exact and trustworthy data with regard to these important springs."

First, as regards the old sulphur well:—

The temperature of the water in the well varied only six degrees throughout the year; from 46° in February and March to 52° in July, August, and September.

The following quantities are given for the gallon:—

The results in September furnished the largest proportion of hydrosulphide of sodium, viz., 17 grains; the smallest proportion observed was in March, viz., 15·13 grains; the quantities of chloride and total residue fluctuated, but not in corresponding proportion. The December analysis gave 625·52 grains of chlorine, while in May the amount was 603·91. The largest total residue was in November, viz., 1067·1 grains, while in June the quantity was 1028·43 grains.

In the early part of 1866, I had the honour of reading before you a paper giving the history of the chloride of iron spa, in which I had tabulated all the recorded analyses of the water of this remarkable spring. When first obtained, by boring in 1819, the water was free from ferrous chloride. Repeated analyses, extending over a period of thirty-five years, proved that it has been subject to considerable fluctuations in the amount of saline constituents. An analysis made by Dr. Hofmann in 1854 exhibits it as containing only 285 grains in the gallon; including ferrous carbonate, 4·6 grains.

From that date no analytical examination appears to have been made for eleven years, and, in the interval, this spa had almost fallen into disuse. In the spring of 1865 it was first discovered that some remarkable change had

taken place in the water, and an analysis subsequently made by Dr. Muspratt and Dr. W. Allen Miller in the same year first announced the presence of ferrous chloride in considerable quantity in this spa. At the present time not only is the quantity of ferrous chloride more than double, but the total solid constituents have considerably increased. In 1865 the water contained 14·49 grains of ferrous chloride in the gallon; the average of 1872 gives 30·57 grains. The solid constituents in 1865 were 465·47 grains in the gallon, while the average of 1872 was 540·97 grains.

The largest proportion of ferrous chloride was in January, namely, 34·5 grains; the smallest in April, 28·97 grains; of ferrous carbonate, 11·84 in January, while August exhibited 9·73. The largest quantity of chlorine was in June, viz., 346·69 grains; December gave the smallest, 329·53.

The total residue in April was 557·09 grains, while in February the proportion was 517·89.

Underlying these fluctuations, if I may so express it, other and more important changes in the course of years are gradually taking place. In 1854 Professor Hofmann analysed most of the Harrogate spas, and in all of them found sulphate of lime present in varying proportions.

In 1866 the waters, with one or two exceptions, were free from sulphate, while salts of barium and strontium had made their appearance. These changes, doubtless inherent to all mineral waters, are not at all surprising if we consider that one of those I am more particularly interested in, the old sulphur well, brings to the surface 17½ tons of saline constituents per annum. This must of necesssity exhaust the strata through which the water passes, however far and deep the ramifications of the spring may extend. The rainfall throughout the district will sensibly affect the yield. In addition, the geological changes which are slowly and imperceptibly taking place in the crust of the earth, producing upheavals and dislocations of strata will also have the effect of modifying the character of mineral waters.

After a cordial vote of thanks had been presented to Mr. Davis for his interesting paper, proposed by Mr. S. Taylor, seconded by Mr. T. B. Stead, the meeting terminated, a very agreeable evening having been passed.

LIVERPOOL CHEMISTS' ASSOCIATION.

The fourth general meeting of this association was held at the Royal Institution, on Thursday, November 20th, Dr. Charles Symes, President, in the chair.

The attendance was again remarkably good, fully showing that the popularity of this association is on the increase. Messrs. Wm. Jones, John Brook, and Thomas H. Morris, were elected members, and Mr. John Griffiths an associate of this association. The following donations were announced:—*The Pharmaceutical Journal*, *The American Chemist*, *The New York Druggists' Circular*, and the 'Proceedings of the Liverpool Geological Society,' and addition of 'Lectures on Pharmacy,' by Barnard S. Procter, to the Library.

On behalf of Mr. Delf, who was unavoidably absent, Dr. Symes presented the association museum with a fine specimen of magnesite, from which large quantities of sulphate of magnesia are now produced. Formerly the carbonic acid for preparing bicarbonate of potash and soda was obtained almost entirely by decomposing carbonate of lime with sulphuric acid, a large amount of useless sulphate of lime resulting therefrom. Now in obtaining the carbonic acid from magnesite (which is composed chiefly of carbonate of magnesia, with some carbonate of lime), not only the dried product but the lye product also is available. If the crude article contains 50 per cent. carbonate of lime, it is then known as dolomite.

Mr. Alfred E. Tanner made some very interesting remarks on American drugs, explaining their properties and mode of preparation. He also exhibited a new American drug mill, which he thought very useful for many purposes, and advised the members who were chemists and druggists to give it a little of their attention.

Dr. Symes then said he thought good results would ensue if a proposition which the Hon. Sec. (Jas. T. Armstrong) had brought forward, were carried out, viz., that there should be an exhibition at every meeting of any new drug or preparation, or any new discovery, that had come before the members, and that he was glad so many things were that night upon the table. He felt quite sure that everyone would be benefited by the proposition, and he hoped that the members would bring forward many things of interest.

A lecture on Adulteration was announced to be delivered by Mr. Martin Murphy, F.C.S., but the Hon. Sec. read part of two letters he had received from that gentleman saying that he had been called to Birmingham on professional business, and therefore could not be present.

The President said he regretted the unavoidable absence of Mr. Murphy on the present occasion, and hoped to have his paper for another evening, He continued—the subject of that paper, "Adulteration," has become such an important one, that delay is dangerous; and without in any way anticipating Mr. Murphy's remarks, which would probably be of a more technical nature, it was very desirable that that association should at once consider the matter from a trade point of view, and if possible disarm the enemy. Whilst the Adulteration Act *appeared* as a measure intended to deal with fraud, men who conducted their business with integrity looked at it as something calculated to do good rather than otherwise, and did not fear any mischievous results to themselves from a thing so distant; but when it is found that its administration, or rather, he should say, its mal-administration, practised the very fraud it purported to suppress; when it is found that inspectors and analysts have so little legitimate work to do that they pounced on the innocent; when it is found that the justice which should be exercised in such cases is so grossly adulterated with injustice that there remains scarcely a trace of the genuine article in it; when we find this law to be but a whitened sepulchre, with something worse than rottenness within; then, gentlemen, it is surely time for the trade of this country to awake to its interests. We are told that the Act will work better by-and-bye, when our magistrates, etc., become educated to its actual requirements: let me ask how many victims are required to complete this education? That the unjust practices which the Act was ostensibly intended to suppress are actually and flagrantly perpetrated by its promoters, is evinced in the Government receiving duty on adulterated tea and afterwards prosecuting retailers of the same article. A case which comes more within our province, fully illustrating my second remark as to the prosecution of the innocent, is the recent one of Mr. McDermott, charged with selling an article known for some years as *citrate of magnesia*. You are all familiar with the facts of the case. Had a customer, or even the inspector, received a true citrate of magnesia, he would have refused the article; he got exactly what he wanted and what he paid for. As to the citrate containing *not a particle of magnesia*, I presume we cannot question the accuracy of Dr. Muter's analysis, as no other appears to have been made of the same sample. Still we have the errors in the tea cases as precedents for so doing were we so disposed. Dr. Muter tells us that his duties commence with receiving a sealed packet and end with handing in an analysis of its contents. This would imply that he exceeded his duty, as he is reported to have given evidence to the effect that it might have been prejudicial to health. And, finally, we have ignorance of facts put forth as a paltry excuse for the magistrate's decision. Is such an excuse for one moment tenable? I much regret that the usual lethargy which characterizes the operations of the Pharmaceutical Council was again displayed in this instance. It was not a question of the *man*, but the case—a case which affected the

direct interest of every one of their members, and the whole body of chemists and druggists of which it should be the representative. The cold, timorous manner in which the case was handled at the meeting, ended in something worse than abortive measures; for by proposing at this critical moment to alter the popular name of the article in question, they commenced undermining the ground on which we must take our stand and face the enemy.

Mr. Edward Davies then made some excellent remarks on the Act.

Mr. Shaw said, that he had not expected any discussion on the subject of adulteration on that evening, in consequence of the absence of Mr. Murphy, who was to have introduced the matter by reading a paper. He thought the Chairman had been unnecessarily severe in his observations on the conduct of the Council of the Pharmaceutical Society. He might state that the citrate of magnesia case had not been overlooked by the Council, but had been discussed. Speaking for himself personally, he considered it was much preferable that the working of the Adulteration Act should be discussed at the meetings of the various associations throughout the country, as was done at Bloomsbury Square at the evening meeting of the Society, so that when a definite expression of opinion had been obtained, the Council would then be better enabled to carry out the wishes of their constituents. He also observed, that in everything appertaining to the welfare of chemists and druggists, the Council took a warm interest, and he instanced the action taken in reference to the appointment of analysts under the Adulteration Act, when a definite opinion had been obtained, whereby competent chemists and druggists notwithstanding their possessing no *medical* qualification were quite eligible for appointment. However, he supposed that the Council in London, as well as the Council of the Liverpool Chemists' Association, might be considered fair game for an occasional shot. With respect to the Adulteration Act, he thought there was much need for amendment, or greater uniformity in its administration. And the mode of procedure of professional analysts was also open to improvement. In many cases, evidence of a most contradictory character had been given, which tended materially to destroy the value of analytical investigations. With respect to milk, he thought it very desirable that the *minimum* quantity of solids which genuine milk ought to contain should be authoritatively fixed. Dr. Anderson in a recent report stated, "that no fixed standard had been laid down up to which genuine milk must come, but he considered there ought at least to be 11½ per cent. of solid matter, and that he had analysed genuine milk containing as much as 17 per cent. of solids.

Mr. Sharp then spoke, chiefly with reference to the working of the Act.

Mr. Norman Tate, after a few remarks on the question, said, he was sorry the evening was so far advanced, and made a proposition to the effect that "the Council be requested to call another meeting on the subject, and that that one be considered adjourned," which was seconded by Dr. Cook, and carried. Arrangements were therefore been made that Mr. Martin Murphy, F.C.S., should deliver a lecture on "The Adulteration of Food, Drink, and Drugs considered in relation to legal repressive measures; its prevalence, and the means in operation for its detection."

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The third general meeting of the Association was held in Anderson's University, on Wednesday, 26th November, 1873, at 9 p.m., Mr. John Currie, President, in the chair.

The minutes of the previous meeting having been read and confirmed, the Secretary read a note that he had received from the Secretary of the Andersonian Library, in which it was stated that the members of the Glasgow Chemists and Druggists' Association could have the use of the library only on the condition of their joining one of the lecture classes.

The Secretary also read a letter from Mr. McDonald, of the Glasgow Apothecaries' Company, in reference to the case of Mr. Freeland, chemist, Bathgate, asking if the Association would undertake the getting up of a subscription to assist in defraying the expenses connected with his law suit, and that he (Mr. McDonald) would start the subscription in the name of his firm.

It was finally agreed upon that it would not be advisable for the Association to have anything to do with the matter, but that it should just be left to individual members to subscribe if they felt so inclined and were called upon. At the same time, the Chairman thought that it would be a good thing if a defence or protection fund could be established for the benefit of chemists in the west of Scotland,

Dr. Nairn, Glasgow, then delivered an able and very interesting lecture on "The Brain and Nervous System," illustrated by anatomical specimens.

At the close, the lecturer was awarded a most hearty vote of thanks.

It was announced that at the next meeting of the "Assistants' Section" a paper would be read by Mr. John Foster on "Animal Substances used in Medicine."

The meeting then separated.

BIRMINGHAM AND MIDLAND COUNTIES CHEMISTS' ASSOCIATION.

At a meeting of the Birmingham and Midland Counties Chemists' Association, held recently, a long discussion took place on the "citrate of magnesia" question.

A resolution proposed by Mr. Arblaster: "That the words 'citro-tartrate of soda, with magnesia and sugar, formerly known as "citrate of magnesia,"' be adopted for recommendation to the Council of the Pharmaceutical Society as the most suitable label" not finding a seconder was not put to the meeting.

It was then proposed by Mr. Homer: "That the words 'compound effervescing magnesia' be adopted"; this also found no seconder.

It was then proposed by Mr. Willcox and seconded by Mr. Crook: "That the words 'granular effervescing saline, formerly known as "citrate of magnesia,"' be recommended for adoption." This was carried.

It was then resolved that this resolution be forwarded for publication in the Pharmaceutical Journal.

HALIFAX CHEMISTS AND DRUGGISTS' ASSOCIATION.

A meeting of the above body, Mr. Jessop, President, in the chair, was held on Friday, Dec. 5, 1873, to consider the following resolution, viz. :—"That in case of any prosecution arising from the operation of the Adulteration Act with respect to the sale of drugs and chemicals to any of the members of the Halifax Chemists and Druggists' Association, this meeting is of opinion that it would be desirable for this association to support and assist such member by defraying in part or whole the expenses in connection with the defence before the Courts in this town, subject to the following conditions, viz. :—That a full and honest statement of the particulars of the case be laid before the committee, who shall then decide as to whether such case is deserving of the support of the association, and that their decision shall be final."

Mr. Brierley had great pleasure in moving the adoption of the proposal. That something of this kind was absolutely needed was shown by the recent attempt at conviction for the sale of spirits of nitre before the Westminster Police Court, which statement he read from the *Times* newspaper. No one now could feel absolutely safe from prosecution, and the idea was a good one to have an association to confer with and advise as to what course would

be best to adopt should any case arise calling for its support.

Mr. Robert Brook, honorary secretary, in seconding the motion, wished it to be clearly understood that while the Society should extend its support and sympathy to a member, it would not be responsible for the penalty if unfortunately a conviction should ensue. He thought also the action of the Society should be confined as closely as possible to drugs and chemicals. Much had been said about their being at the mercy of the wholesale trade to a large extent. In the 1849 edition of 'Mohr's and Redwood's Practical Pharmacy' the learned doctor had a chapter on drug grinding. He showed how powdered drugs are adulterated with sawdust, from the loss in moisture by drying being greater than the wholesale trade would allow. With the Adulteration Act hanging over their heads, if the system were still adopted, they certainly stood in slippery places.

Mr. Dyer, in supporting the resolution, thought the Society should not draw too sharp a line and confine its action to drugs only, as there were many other articles sold by the trade, such as mustard, pepper, etc., which should as a matter of course be included. The latter part of the resolution however left a wide margin for the committee to act upon and decide each case upon its own merits.

The President, in submitting the motion to the meeting for adoption, thought the Society was taking a wise step forward in bringing it before the notice of the trade. He had for some time thought it desirable that there should be a guarantee as to the purity of drugs given by the wholesale houses, and if the same system of per-centage in the drying and powdering of drugs was now in vogue as formerly it became more important than ever. He hoped the wholesale dealers would rise to the importance of the occasion. The resolution was carried unanimously.

ASSOCIATION OF CHEMISTS AND DRUGGISTS OF IRELAND.

A meeting of this Association was held at 44, Molesworth Street, Dublin, on Monday evening, the 1st inst.

The new Vice-President, Charles R. C. Tichborne, Ph.D., F.C.S., etc., was inducted into office by taking the chair on this occasion.

The first subject brought before the meeting was the report from the deputation of this Association which waited upon the Governor and Court of Directors of the Apothecaries' Hall, to confer with them as to what steps should be jointly taken to secure the new Pharmacy Bill (already drafted) being passed through Parliament during the coming session. One of the members reported the result of the interview to the following effect. He said that the deputation from the Society was received with much courtesy by the governor and court of the Apothecaries' Hall; the amendments suggested by the Society were discussed *seriatim*, some were agreed to, and others they thought it would not be advisable to adopt, but the Chemists and Druggists' Society had every reason to be satisfied with the result. It was also agreed that Dr. Leet (Secretary to the Apothecaries' Hall) should write to the Attorney-General, to know if he would receive a joint deputation from the Apothecaries' Hall and Chemists and Druggists' Society, to request his taking the conduct of the Pharmacy Bill through Parliament.

Messrs. Hodgson, Erson, Goodwin, and Hayes were then elected to join with an equal number from the Board of the Apothecaries' Hall to form this deputation.

The next matter brought under notice of the meeting indicates that since the chemists and druggists have determined that they will obtain a Pharmacy Bill for Ireland, they show an equal determination to prove themselves worthy of it, by insisting upon a high standard of education both for themselves, their assistants, and apprentices, and at once applying themselves to this important task.

It appears there has recently been formed, in connection with the Apothecaries' Hall, a course of practical instruction in chemistry, pharmacy and botany, chiefly, through the energy of Mr. Tichborne and his earnest desire for the instruction of young men in these important branches.

The Chemists and Druggists' Society deputed six of its members to attend these classes and report as to their suitability as an elementary educational course for its members. The reports being all of a favourable character it was unanimously agreed to adopt these classes. As a beginning eighteen names were given in to the Secretary of those present who wished to join the classes, and it is confidently expected that before many days there will be three times that number.

The Vice-President at the close of the meeting spoke at some length, giving much good and wholesome advice to the young men on the importance of at once applying themselves to study of a practical and useful nature, and strongly recommending perseverance in what might at first be only a drudgery, but would be much more useful to them in after life than studies of a more pleasing nature. He also recommended a short course of practical lectures from friends who take an interest in the Society, and intimated that he should not be backward in assisting in the filling up this part of the programme.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION.

At the second monthly meeting of the session, held at the rooms of the Association, 37, Blackfriars Street, on Friday evening, Dec. 5th, Mr. W. S. Brown, President, in the chair, a lecture on "Methods of detecting Hydrocyanic Acid and Cyanide of Potassium in poisoning cases" was given by Mr. Louis Siebold. There was a good attendance.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, 4th Dec., 1873. Dr. Frankland, F.R.S., in the chair. When the minutes of the preceding meeting had been read and confirmed, and the nomination and election of Fellows had taken place, a paper entitled "Mineralogical Notices" by Professor Story-Maskelyne and Dr. W. Flight was read by the former, treating of the composition of caledonite and lanarkite. Mr. John Williams then exhibited some fine specimens of crystallized phosphorous acid and metallic phosphites and gave a short account of their reactions. After which, Professor Church made a communication to the Society on the composition of the mineral autunite. Professor Lawrence Smith of the United States, whilst describing a modifica- of the Bunsen gas burner employed by him for heating the crucible in determinations of the alkalies in silicious minerals, gave a short sketch of the process he had devised for that purpose. In the course of the evening, a gas burner by Mr. Fletcher of Warrington was also exhibited.

The meeting was finally adjourned until Thursday, 18th Dec., when the following papers will be read :—

1. "Researches on the Action of the Copper-Zinc Couple on Organic Bodies, No. IV., On Allyl Iodide," by Dr. J. H. Gladstone and Mr. A. Tribe.
2. "On a New Compound of Nickel and Phosphorus," by Dr. R. Schenck.
3. "On the Preparation of 'Standard Trial Plates,' to be used in verifying the Composition of the Coinage," by Mr. W. Chandler Roberts.

CALIFORNIA PHARMACEUTICAL SOCIETY.

The Annual Meeting of the California Pharmaceutical Society was held in San Francisco on Oct. 9th, 1873.

The following officers were elected :—President, John

Calvert ; First Vice, John Newman ; Second Vice, A. L. Lengfeld ; Secretary, J. W. Forbes ; Treasurer, W. J. Bryan ; Board of Directors, John Calvert, W. T. Wenzell, J. G. Steele, J. W. Forbes, H. B. Shaw.

Reports of retiring officers were accepted.

The Secretary of the Board of Pharmacy, Mr. J. G. Steele, presented a report. There have been registered as graduates, 20 ; licentiates, 25 ; practising pharmacists, 81 ; practising assistants, 102—total, 228. The actions which have been brought by the Board against those who failed to comply with the requirements of the Act have been successful in every instance. Mr. J. G. Steele, having resigned the position of secretary, Mr. J. W. Forbes has been elected to fill the vacancy. The affairs of the Society arc in a prospcrous condition, a larger balance remaining on hand than at any previous time.

Parliamentary and Law Proceedings.

The Alleged Adulteration of Tea in Birmingham

On Wednesday, November 26th, Mr. T. C. S. Kynnersley, the stipendiary magistrate at the Birmingham Borough Police Court, gave judgment in the cases of alleged adulteration of tea (see *ante*, p. 433). After noting the technical objections, he recapitulated the history of the cases, and the evidence that had been brought forward. The question whether the iron found in the tea was metallic iron or magnetic oxide he considered to be unimportant, unless its presence in the tea in such large quantities was accounted for. What business had it there at all ? One theory was that it was blown or washed on the plant, and stuck to the leaves, though thcy were as smooth and shining as those of a camellia ; another that it was the scale from the red-hot iron plates on which the tea is dried. Both theories appeared to him wholly insufficient to account for their presence, or for that of the sand. If the soil of China were so rich in iron as to throw up accidentally such an amount of metal it would be worth looking after for smelting purposes. The difference was so great in the quantity of iron and sand and lye tea found by Drs. Hill and Brown, and that found by Messrs. Scott, Bird and Murphy in the sample 52, that he could hardly conceive that their researches had been employed on the same samples of tea. While the experiments of Dr. Hill, and Dr. Brown, and Dr. Hassall were performed on the sample bought by Mr. Woolley's clerk, sealed up at the time, and handed from one to the other, those performed by the chemists called on the part of the defendants were on tea the identity of which with that produced on the part of the prosecution was so vague, that if the casc had been before a jury he doubted whether any judge would have admitted the evidence. Dr. Hassall, having heard the whole of the evidence on both sides, saw no reason to alter the opinion he had formed on the subject of the adulteration of the tea. But he added that since writing his statements he had made further experiments, and come to the conclusion that the iron detected in the tea was not really iron filings, but magnetic oxide and crushed ore. This, however, though it afforded a triumph to Mr. Bird, as to the nature of the substance, by no means altered the case as to the amount of adulteration. Whether it was crushed ore, or iron filings, or magnetic oxide was not of the slightest importance. In pure tea neither the one nor the other is ever found, and its presence cannot be accounted for by any theory of inevitable necessity or mere accident. Upon this evidence how could he hesitate as to the decision to which he must come ? All these substances—iron, sand, and lye tea—to say nothing of plumbago, Prussian blue, etc., were wholly unaccounted for. In one case there was no less than 23·8 per cent. of lye—the ash of the whole tea is 21·83 per cent. (being 15 pcr cent. above that of pure tea), and the ash of lye tea 56·34 per cent. If this were not adulteration what is ? If 5 or 10 or 15 per cent. of foreign substances were not enough to constitute adulteration where was the line to be drawn ? Would an additional 2 or 3, or 5 or 10 pcr cent. be sufficient ? Clearly it was impossiblc to refine to that extent. He had a plain question beforc him—adulterated or not ? and he could not hesitate to say that the whole of the teas, 45, 46, 47, 49, and 52, were adulterated. The next question was—If the tea was adulterated, did the defendants sell it as unadulterated ? Mr. Justice Blackburn says, "The simple fact of selling butter amounts to a representation that it is not adulterated, and the seller must take the trouble to examine his samples, and sce whether they contain lard or not." Mr. Justicc Quain says :—"I think that when a man sells butter across the counter to any one who asks for it, he means to represent that the article which he sells is butter, and not a compound of stearin and palmatin. I think, therefore, that there was a representation that the butter was unadulterated." In the same manner he (Mr. Kynnersley) was obliged to say that when *tea* was asked for, and an article sold, there was a representation that that article was tea, and not a compound of tea, and iron, and quartz, and silica, and plumbago, and Prussian blue, and turmeric. It had been contendcd that when the purchaser asked for tea he meant only the tea of commerce, and that anything which the Chinaman chose to send over as tea must be accepted as such ; which would really amount to this, that no tea could be considered adulterated so long as there was a particle of genuine tea present, unless it could be proved affirmatively that the addition of foreign substances took place in this country and not in China. Of course this would render the Act entirely nugatory as applied to tea. He was very glad to hear that it did not at all follow that because a tea was sold at a low price it was therefore adulterated. On the contrary, Dr. Brown had analysed a perfectly pure and genuine tea which was sold as low as fourteenpence a pound. It appeared that the price depended a great deal upon the season of the year at which the leaves are gathered, and the care bestowed on the drying. He had been told by a gentleman that he had bought in Russia what was called "caravan tea," made from the undeveloped buds at 25*s.* a pound. The leaves gathered in the autumn were said to be used in making the low-priced teas. As purc claret might be had at 12*s.* or 14*s.* a dozen as at 60*s.* or 70*s.*, and he was informed that cider varied in price from 3*d.* a gallon to 1*s.* 3*d.*, all equally pure. But what is the position of the retail dealer if this is *law* ? Simply this, that the effect of this clause of the Act of Parliament is to throw upon them the duty of ascertaining by competent analysis that every article of food which they sell is pure and unadulterated. If they neglect to do this they sell at their peril. The retail dealer had his remedy. He must have an understanding with the general merchant that no article should be considered accepted by him which does not stand the test of analysis, and that anything that proves to be adulterated shall be returned. With this, however, he (Mr. Kynnersley) had nothing to do. It was not his business to justify the law, but to administer it. He had found as a fact that the tea was adulterated, and the Court of Queen's Bench had decided that a person selling it without any qualification sold it as unadulterated. He had, therefore, no option but to declare that the defendant in each case had, by the act of selling, rendered himself liable to a penalty under the second section of the Act. He wished, however, publicly to declare that he had no reason whatever to suppose that in any case the seller was awarc of the existence of any adulteration, that none of the ingredients were injurious to health, and that he believed the addition of the foreign substances to have been made fraudulently by the Chinaman in the manufacture and preparation of the tea, and not in this country ; and therefore it was that he withheld the names of the defendants, and spoke of them only by their numbers. As regards the penalty, he was acting in accordancc with the opinion of other magistrates in thinking that if there was a conviction at all, the penalty should not be less than 20*s.*, and that was the penalty which hc inflicted in each case.

The defendants were ordered to pay the costs—not including, however, those of Dr. Hassall and Mr. Postgate. Upon these the magistrate made no order, thinking they might fairly be considered among the expenses of executing the Act, and be paid out of the Borough Rate.

Poisoning by Essential Oil of Almonds.

An inquest was held in Liverpool on Monday, Dec. 1, respecting the death of a child named Jane Orr, aged six years. It was stated that a man named Robert Williams had taken essential oil of almonds from a bottle standing on the mantelpiece, and which had been obtained for flavouring pastry, and administered some to the deceased and another child. Deceased became sick, and mustard was given to her as an emetic, but she died shortly afterwards.

Dr. D. D. Costine stated that he had made a *post-mortem* examination of the body of the deceased, and found a quantity of essential oil of almonds mixed with the food and mucus in the stomach. The smell of almonds was very strong, and permeated the intestines and liver. The brain was congested from convulsion consequent upon the poison. Death was the result of taking the oil of almonds.

Dr. Brown, borough analyst, said that on the 25th ult. he received a small phial from Dr. Costine, and also a jar containing a child's stomach. Both smelt strongly of oil of bitter almonds. He distilled from the fluid in the stomach oil of bitter almonds, from which he obtained prussic acid. The essence of almonds was improperly, and in his opinion dangerously, used as a flavouring in cookery. The oil was at all times very dangerous, as the strength of it was often very uncertain. The essential oil of almonds was not used as a drug.

When taken into custody Williams said he had given the children three drops in some water, and that he had often taken it himself. He added that he always believed it was essence of cinnamon.

The Coroner observed that the poison had been administered apparently without any motive, but if the jury thought that Williams had administered the poison against the child's wish, then the question arose whether he administered it so incautiously or recklessly as to be responsible in point of law for his actions.

The jury returned a verdict of manslaughter against Robert Williams.

Analysis of Bread.

On Tuesday evening, December 9th, a special meeting of the Shoreditch Vestry was held in the council chamber, Mr. Charles Stevens in the chair, to receive the report of a special committee appointed to investigate certain charges made by Mr. Butler, baker, Pitfield Street, Hoxton, against Dr. Stevenson, the analyst of the parish. Mr. Butler appeared before the Vestry some time ago, and stated that he sent, through a friend, a 2lb. loaf made of the finest flour to the inspector of the parish for analysis, and the certificate returned stated that the bread was not injurious to health, while a second 2lb. loaf in which there was a drachm of alum was certified by Dr. Stevenson as free from adulteration. The report stated that evidence had been given that alum was introduced into the second loaf. It had not been dissolved with water, but sprinkled in the dough, and then introduced into it in layers. A portion of the same loaf was submitted to Dr. Dupré, of the Westminster Hospital, and analyst for the parish of St. James's, Westminster, who reported that it had been adulterated with 0·507 of alum. Dr. Stevenson, in a long letter to the Vestry, said that Dr. Dupré's report confirmed the statement that alum was irregularly and imperfectly mixed in the bread. No chemist was at all times infallible in his operations, and he expressed the hope that the Vestry would not doubt his analytical skill in consequence of what had occurred. Mr. Stead moved that the report be received, and trusted that great caution would be exercised in future by their analyst. The report was at once adopted.—*Times.*

Reviews.

The Druggists' Stock and Price Book. Arranged by Frazer and Green, Pharmaceutical Chemists, Glasgow. London: J. and A. Churchill. 1873.

The Chemists and Druggists' Diary and Pharmaceutical Text-Book. 1874.

Now that the year is drawing to a close many tradesmen are doubtless looking forward with a certain amount of repugnance to the tedious process of stock-taking. We have, therefore, great pleasure in referring to the book recently issued by Messrs. Frazer and Green as one that is well calculated to relieve pharmaceutists from a great deal of the labour usually attending this operation, and to assist them in conducting it in so methodical a manner as to be really effective in securing the object in view. The compilers inform us that the volume was designed and prepared for the press without the remotest idea of publishing it, since it was intended for their own exclusive use, but that they complied with a suggestion made that its publication would be useful to the trade, and have accordingly issued it. We hope that their generosity will be repaid by an ample sale.

The book is divided into three parts, containing lists of the materia medica, furnishings and sundries, and proprietary articles in general use, respectively, and the pages are ruled in columns for stock-taking purposes and for recording the cost and retail price of every article kept in stock. There is also an explanatory note prefixed as to the way in which the book should be used.

The book is characterized by an admirable series of cross references of synonymous names to one heading—and last, though not least, it is clearly printed on good paper.

The nature of the second book on our list, 'The Chemists and Druggists' Diary for 1874,' has been too well foreshadowed by its predecessors to require more than passing mention. In fact, the publishers appear to have taken it for granted that its uses are so obvious and its birthplace so well known that a title-page could be dispensed with—at least there is none in the copy forwarded to us. The text this year consists of a considerable amount of information respecting impurities in drugs and how to detect them, the maximum doses of powerful drugs, abstracts of various Acts of Parliament, and other information specially interesting to chemists and druggists. The "diary," which is interleaved with blotting paper, is followed by a "revenue and expenses account," "quarterly statement," record of drugs purchased, and of pharmaceutical operations. Altogether, the book is one that is capable of being very serviceable to every chemist and druggist.

BOOKS RECEIVED.

Maud Vivian: a Drama; and Poems. By Walter Rew. London: E. Moxon, Son and Co. 1873. From the Author.

On Spectrum Analysis as Applied to Microscopical Observation. By W. T. Suffolk, F.R.M.S. London: J. Browning. 1873. From the Publisher.

The Chemists and Druggists' Diary and Pharmaceutical Text Book, 1874. From the Publishers.

Obituary.

Notice has been received of the death of the following:—

On the 1st of December, Mr. Thomas Hadfield Gloyne Pharmaceutical Chemist, of Dewsbury, died suddenly from heart disease. The deceased gentleman, who was sixty-eight years of age, was dressing himself preparatory to going to his shop when he suddenly fell on the floor, and almost instantly expired. He was the son of a Wesleyan minister, and he had been in business as a chemist and druggist in Dewsbury forty-six years. Mr. Gloyne was one of the founders of the Pharmaceutical Society, and was also Local Secretary for Dewsbury.

On the 15th October, 1873, Mr. Andrew Wylie, Chemist and Druggist, of Stewarton, Ayrshire.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

Citrate of Magnesia.

Sir,—I heartily endorse the opinion expressed by Mr. R. W. Giles, in last week's Journal, that the decision in the "Citrate of Magnesia" case should not be allowed to harden into a precedent, but that every effort should be made to re-open the question whilst it is still fresh, and to have, if possible, a new trial, that the erroneous decision may be reversed.

It is all very well to discuss what better descriptive name should be given to a well-known and popular article, but the serious fact to be kept in view is this: that a severe fine has been inflicted for selling as "citrate of magnesia" the only article generally known by that name, and it matters little whether the sufferer was a registered chemist or not.

I maintain that no chemist would have been justified in sending out any other preparation than one similar to that supplied by Mr. McDermott, unless there had been on the prescription a special indication that some other preparation than that usually known as "Cit. Magnes. Eff." was intended. I frequently receive prescriptions for "Cit. Magnes," the Eff. being generally omitted, and I would no more consider myself justified in sending either the chalky tasting "potential" or "future perfect" citrate containing carbonate, or the neutral or acid citrate, than in giving the nauseous residual salts of the Seidlitz spring, were the prescription for "Pulv. Seidlitz."

The evidence given on the trial appears so extraordinary in the brief report that it is to be desired that opportunity may be given to the analyst on whose evidence the decision seems principally based, to clear himself of the suspicion of "suppressio veri," which may be only the result of the condensation of the report.

The analyst presides over an institution where students are rapidly instructed in subjects relating to pharmacy, including the preparations of the British Pharmacopœia, and it is scarcely conceivable that pupils can be permitted to pass over the sodæ citro-tartras effervescens without being told that this was introduced as the official representative of the effervescing citrate of magnesia of commerce.

There is no trace in the report of this all-important fact having been stated in court; indeed it is scarcely possible to reconcile the magistrate's decision with a knowledge of this. Was this explanation omitted, and if so, why?

The analyst is also represented as saying that the preparation in question "might be injurious if mixed in other medicines when citrate of magnesia was prescribed," but what does he mean by citrate of magnesia? Then as to the intention of the prescriber, it is curious to find that after a month's discussion we are still in the dark as to what was really meant.

Let us then by all means have the case re-opened, either by action taken by the Council of the Pharmaceutical Society, which would be the preferable course, or by a special committee of the trade.

If we do not get this question of names and things properly settled, we may find ourselves heavily mulcted, because our "cold cream" does not contain a particle of cream, and because analysts may be unable to discover the proportion of precious metal in golden ointment.

Alexander Kinninmont.

69, *S. Portland Street, Glasgow,*
Dec. 10, 1873.

Sir,—In reference to the letter of Mr. Bishop in your last number, I wish to point out that the statement that "magnesia forms an essential part of the preparation, and is present in an important quantity," does not strictly represent the fact, so far at least as regards the past. The amount of magnesia in this preparation has seldom exceeded 1 per cent., and that has been present in the state of sulphate. Neither the amount of the magnesia, nor the condition in which it exists, nor the chemical probabilities as to the effect produced during solution, justify the adoption of the name "citrate of magnesia" to distinguish the preparation referred to from others, for it fails to conform with the very sound principle enunciated by Mr. Bishop that "the name of anything animate or inanimate should define the elements of its composition."

If Mr. Bishop had acted on that wise principle in the outset there would have been no occasion for such harsh language as has recently been used to the prejudice of pharmaceutists. Mr. Bishop would not have had occasion to seek succour from legal subtleties, and individual chemists and druggists throughout the country would have been spared the anxiety attendant on the prospect of having to go to a police-court at the instance of meddlesome and officious analysts, to prove that in supplying their customers with the particular article they desired to have, although asked for under an erroneous name, they have not rendered themselves liable to a charge of having acted "in fraud of Her Majesty's subjects and to the great hurt of their health and danger to their lives."

X. Y. Z.

Sir,—Are not we making too much of a bugbear of this matter? Would not the course have been to have applied to a judge for a reversal of the sentence, or formed a deputation to Government for the same purpose? Properly explained, either must have seen the injustice of the case, and could not have refused the application, but the multitude of your correspondents seem to be racking their ingenuity for a new name, when, I think, the question might be finally settled, if dealt with boldly.

Frederick Tibbs.

Dec. 3, 1873.

Sir,—In reference to Mr. Payne's letter on p. 439, respecting the Act under which Mr. McDermott was convicted, in answer to an application to the Clerk at the Southwark Police Court I have been informed that the proceedings were taken under the Adulteration of Food Act 1872, and that no amendment was made in the summons.

I therefore understand the conviction to be for an offence against the Adulteration Act.

F. P.

3*rd December*, 1873.

Sir,—So many different names have been proposed and adopted that confusion and difficulty are sure to be experienced, especially by retailers and their customers. The name which I would suggest is "Citrated Magnesia," or "Granular Effervescing Citrated Magnesia." It is highly desirable that a common name be adopted, and it appears to me that the one I suggest would retain a resemblance to the old sufficient to prevent any serious doubt in the minds of purchasers, would for all business purposes sufficiently indicate the character of the article, while it would convey no idea of definite chemical composition, and would protect dealers from prosecution, always assuming that the article sold contained citric acid and magnesia, which the citrated magnesia I manufacture really does.

George Smith.

112, *Renfield Street, Glasgow, Dec.* 6*th*, 1873.

Who will be the Next Victim of an Experimental Prosecution?
Who Will Help Him?

Sir,—Most of your readers will, I think, feel that a great anxiety is added to the many they already have, in the possibility that any or every customer is on the look-out to entangle them in the meshes of a prosecution.

Amongst us there are some honest folk who are content that their daily lot shall be one of work and self-denial, if haply by these means and God's blessing they may in their old age be free from the necessity of appealing for help to the Committee of the Benevolent Fund, or, dying, leave their widow or orphans not utterly destitute. These, and many of our poorer brethren, may, as you say of the spirit of nitre prosecution, "congratulate themselves that the result of these prosecutions has turned out in the way it has," but "when they consider the perils with which even a sound defence is surrounded in a court of law, whenever the questions at issue are of a scientific nature," must feel a sinking at heart lest they should be the next victims selected for an "expensive experimental prosecution."

With your leave, therefore, I beg to offer the following suggestions for the formation of a fund, the first and

primary object of which shall be to provide legal assistance in all deserving cases.

1st. That any pharmaceutical chemist or chemist and druggist who shall be able to satisfy the trustees of the fund for the time being (or any person authorized by them) that the practice or sale for which he is subjected to prosecution is unobjectionable shall be supplied at the expense of the fund with every legal assistance necessary for the conduct of the defence.

2nd. That the fund shall be invested by the trustees in such manner as by them shall be deemed best, and that at the end of every year the interest for the past year, less expenses incurred as aforesaid, shall be handed to the Committee of the Benevolent Fund, to be by them applied in aid of annuities or grants.

3rd. That the trustees of this fund shall be the gentlemen who for the time being are the Committee of the Benevolent Fund.

It seems to me that an ill-conducted defence may lead to an honest deserving man being (so to speak) improperly convicted, and from that to loss of business, and to want.

From this possibility (an ill-conducted defence) it is not our large establishments or wealthy members that are likely to suffer; neither are they likely to apply to the trustees for assistance.

I take it, then, a fund of this kind would confer the following benefits:—

It would ensure an efficient defence in all deserving cases.

It would relieve us, as individuals, from all pecuniary anxiety, as long as we did what was honest in the sight of all men.

It would, by taking up the defence of a case, have no doubt a very considerable effect in favour of the defendant on the mind of the magistrate or judge before whom the prosecution was instituted.

Lastly, after relieving from the dread of loss or want, its yearly income would be spent in the alleviation of want.

If any of your readers are pleased to consider an object of this kind a worthy one, I shall be happy to add my mite to theirs, or, to say something more definite, if forty-nine others will join me in the like amount I will give a subscription of £10.

M. E. T.

The Adulteration Act.

Sir,—As the Adulteration Act is being carried out in such a peculiar manner, would it not be well to insert in the Journal a word of caution to those chemists who are vendors of the cheap aërated waters. In many cases the so-called soda and potash waters do not contain any alkali; the lemonade is acidulated with acid. sulph.; while the ginger-beer is a solution of tartrate of soda, flavoured with tinct. capsici.

In either case I presume the vendors render themselves liable under the Act, and should only sell the waters from those makers who will guarantee they are exactly as represented to the public.

R. Knowles.

Anerly Road, Anerly, S.E., Dec. 10, 1873.

What is Sweet Spirit of Nitre?

Sir,—In reference to the recent case of *so-called* adulteration of "spirit of nitrous ether," it seems to me, after reading your report, that one of the most important points was entirely passed over.

The inspector appears to have asked for "Spirit of Nitre" or "Sweet Nitre." I maintain that he *was* served with "Sweet Spirit of Nitre," the popular remedy of that name, made for upwards of two centuries in the same, or nearly the same manner. A formula for it was published in the London Pharmacopœias from the earliest until 1864, when the British Pharmacopœia, intended to unite those of London, Edinburgh, and Dublin, published a formula, and another new one in 1867 for a "Spirit of Nitrous Ether," to take the place of the old preparation. When the public ask for their favourite remedy they desire, expect, and should be served with Sp. Æther. Nitrici, P.L. I see no mention of "Spirit of Nitre" in the B.P., and while I do not think it right to give old names to new preparations, I consider it positively unjust and reprehensible to endcavour to palm off on the public a new and repulsive preparation by giving it the same name, and wishing to *force* it to be sold instead of an agreeable and highly popular domestic remedy.

In short, I maintain that "Spirit of Nitrous Ether" *is not* "Sweet Spirit of Nitre," and I should be glad to have some better opinion on the point.

C. W. A.

Dec. 9th, 1873.

[*** We think our correspondent is in the main correct, and if he will refer to the report of the case in our last number he will find that his view was substantially that adopted by Mr. Wontnor in his defence.—Ed. Pharm. Journ.]

The Library.

Sir,—No doubt the new regulation respecting the issue of books from the Library will be a great convenience to country members, but at the same time it may possibly prove inconvenient to those who use the Library for reference. Recently on two occasions I wished to consult such standard works as the 'Codex' and 'Redwood's Practical Pharmacy,' but was unable to obtain them. If such be the case now what will it be if the circulation of the books increases, as I hope it will, unless steps be taken to provide duplicate copies of all standard works for reference only?

Disappointed.

W. R. M.—We have received your letter offering to supply for a pecuniary consideration the formula asked for in our "Notes and Queries" column, but we must decline to make that department of the Journal a medium for sale and barter.

J. L. D.—Many extraneous substances are frequently introduced into the manufacture of vulcanized india rubber, but we cannot say whether a salt of lead is so used.

"*Chemicus.*"—(1) Yes, sulphocyanides. (2) We are not aware.

J. Young.—The proposed new test has not yet become law, but the former Act was continued for another year at the end of last session.

"*Student.*"—The best way to preserve the colours is to dry the plants as quickly as possible between bibulous paper, changing the sheets every four or six hours.

G. T.—Tinct. Rhei and Tinct. Rhei Co. might be considered synonymous terms, since the Tinct. Rhei, B. P., is a compound tincture; but Dec. Scoparii Co. could not be simple Dec. Scoparii, B. P.

W. B.—We agree with you that there seems to be little or no saffron present in the pills sent, but as your remedy should be with the maker we are unable to make further use of your communication.

J. S.—We believe that legally the arms of the Pharmaceutical Society can be used only by the Council in their corporate capacity.

A. P. B.—The moss sent is the *Fontinalis squarrosa.*

"*Litmus.*"—The cardamoms are added in the Extr. Coloc. Comp. at the end of the process in order that the essential oil, upon which their odour and medicinal properties depend, may not be destroyed by the continuance of heat necessary to bring the mass into the proper consistence for forming pills. Ext. Papaveris.—The spirit is added in order that the albuminous principle (the cause of ferment) may be precipitated and finally removed. Read Proctor's 'Practical Pharmacy,' and refer to the composition of the various drugs you have named as given in Pereira's 'Materia Medica' for information as to other queries.

"*Major Associate.*"—The colouring is probably due to slight oxidation, but we cannot state the precise reason why it occurs in some cases and not in others.

W. Tearle.—In spirit of nitrous ether the quantity of aldehyd bears some relation to the quantity of nitrous ether formed in the process by which the spirit has been prepared. Dr. Dupré stated that the spirit of nitre he examined contained only 0·36 per cent. of nitrous ether. There would not be much aldehyd in such a spirit, and no doubt much less than the spirit of nitrous ether of the B. P. would necessarily contain, although the latter would contain much less than spirit of nitre, P. L., of equal strength with that of the B. P. as regards the ether.

Communications, Letters, etc., have been received from Messrs. G. T. Smith, L. Lunn, G. L. Napier, Matthews (Brighton), F. H. Cumine, H. W. Jones, "Nota Bene," "Dipenser," "Pharm. Chemist by Examination," "Argentine," "Truth," C. W. A.

MR. SORBY ON THE COLOURING MATTERS OF LEAVES.*

BY HENRY POCKLINGTON.†

My last article on the "Microscope in Pharmacy" concluded with an intimation that I should immediately pass to the discussion of the colouring matters of leaves and bark of Eucalyptus, but on revising my notes I found that it would be advisable to defer their publication, until I had an opportunity of carefully working through Mr. Sorby's recent enlargement of our knowledge of the colouring matters of leaves, in order that, where possible, I might identify my colour elements with his, and attach his names to them. Having done this, I think it desirable to state the results of Mr. Sorby's latest researches, so far as they vary from his former conclusions, before proceeding with an account of my own work on Eucalyptus and the Cinchonas. To some extent, indeed, this is necessary, in order that certain technical names may be understood by those who have not access to Mr. Sorby's memoirs.

Mr. Sorby's present paper treats almosts solely of such colouring matters as are soluble in alcohol, bisulphide of carbon, ether, and the fixed oils. The large class soluble also in water, or selectively soluble in water, are little referred to.

The prominent feature of Mr. Sorby's paper is his enlargement of his previous classification of chlorophyll and chlorophyll compounds, of which I have already given an epitome,‡ and the recognition as definite of colour-elements previously only guessed at; and also the employment of photo-analysis in addition to the chemicals previously used. The more important colour-elements soluble otherwise than in water are now these, the actual number of colouring matters being probably many hundreds, or, including those soluble in water, possibly thousands. They are classified in the order of their optical character, commencing with those whose absorption extends nearest to the red.

The first group, as before, is the chlorophyll group, and comprises three entirely distinct substances, soluble in CS_2, but insoluble in water. The whole of these three have hitherto been treated as one substance, and were so charted in my previous paper, although doubts as to the elementary character of the substance were very present in my mind then and long before. They are all characterized by well-marked absorption bands in the red, differing so slightly in position, that a dense solution of the mixture shows only one broad band, and can only be obtained in an isolated form by skilful management, and then only in an approximately pure condition. The three chlorophylls are—blue chlorophyll, yellow chlorophyll, and chloro-fucine. The former, or blue chlorophyll, can best be obtained from olive algæ, and is peculiarly sensitive to the action of acids or alkalies. Its spectrum gives a band nearer the red end of the spectrum than the others, and the two other bands figured in No. 1 of the paper already referred to.§ Yellow chlorophyll has not yet been obtained in a pure state. Mr. Sorby states that the best method of procuring it is to boil *Ulva latissima* first in water and then in spirit. The dark-green solution in alcohol should be agitated with bisulphide of carbon and a few drops of water added, if requisite, to cause nearly all the green colouring matter to be carried down, and nearly all the xanthophyll to remain in solution. On removing this, and agitating the CS_2 with fresh alcohol (methylated of the usual strength) taking care to have a considerable excess of the CS_2 present, a large portion of the yellow chlorophyll and some of the blue are dissolved. Removing this solution to another tube,* adding a little water, and separating the diluted alcohol, the precipitated bisulphide should be evaporated to dryness at a gentle heat. On redissolving in benzole and examining the spectrum of a properly diluted solution, it will be seen, that, besides the bands characteristic of blue chlorophyll, it has a dark narrow band in the red (nearer the blue end than in the blue chlorophyll), and another much broader in the middle of the blue. This is the substance figured in fig 2, on page 61, already referred to. The substance examined and figured was, however, contaminated by an admixture of undecomposed blue chlorophyll, to which the band in the green was due. The band in the orange near D is, I think, due to an undiscovered or unisolated colour element. This yellow chlorophyll may be prepared in an approximately pure condition (contaminated with xanthophyll and chloro-fucine) from dried Eucalyptus leaves and there largely predominates over the blue. In the freshly gathered leaves the balance is rather the other way, but anything like an accurate quantitative analysis is as yet out of the question. Mr. Sorby prepares *Chloro-fucine* from the leaves of *Fucus* and other olive algæ as follows:—The fresh fronds should be crushed in a mortar and slightly dried, so that on adding ordinary spirit of wine too much water may not be present. On agitating with repeated quantities of CS_2 the whole of the blue chlorophyll may be removed, and the alcoholic solution then contains much fuco-xanthine and the chloro-fucine. On adding water and agitating with more bisulphide, both these substances are carried down; and on evaporating the mixed solution the chlorofucine is often partially lost by decomposition in some unknown way. To prepare it free from fuco-xanthine, the above-named alcoholic solution should be diluted with an equal bulk of water, a drop or two of ammonia added, and agitated over and over again with fresh bisulphide, until it subsides to the bottom nearly colourless. By thus adding ammonia the chloro-fucine is retained in the alcohol solution, which is then of a pale green colour, and contains chloro-fucine mixed with a yellow substance soluble in water. This yellow substance deserves prolonged investigation, and may be procured in an approximately pure condition from the young leaves of *Laurus Camphora;* its oxidation changes are of a highly interesting character, and there are many reasons for believing that the wonderful colour changes of the camphor tree leaves (ranging from delicate pink to deep claret red) are nearly entirely due to this nameless substance (as recently shown by me before the Leeds Naturalists' Society). On evaporating this mixture to small bulk at a gentle heat,

* 'Proc. Royal Soc.,' 146, xxi., 1873.

† This may be regarded as, in part, a continuation of my note on "M. Chautard's Classification of Chlorophyll Bands," PHARM. JOURN., 3rd series, vol. iv. p. 61, and as necessary to render my notes on the colouring matters of Eucalyptus and Cinchona understandable.

‡ PHARM. JOURN., 3rd series, vol. iv., p. 61.

§ Rapidly made alcoholic solutions of cinchona leaves contain this in a nearly pure condition.

* An india-rubber suction pipette, with glass tube, is the most convenient instrument for doing this. The bulbous expansion of the tube should be capacious, the tube fine.

loss of alcohol causes impure chloro-fucine to be deposited, and after transferring it to a narrow tube, allowing it to subside, and removing the aqueous solution, almost pure chloro-fucine can be dissolved out by absolute alcohol. Its spectrum gives two dark absorption bands, one between the red and the orange, and another between the orange and yellow. The whole of the green is transmitted, but the whole of the blue cut off, except in very dilute solution, when a broad and obscure band in the blue may be seen by excellent daylight. The xanthophyll group consists of a *series* of five substances, whose spectra differ only in the position of their absorption bands, which are all situate at the blue end of the spectrum. They are all soluble in CS_2, insoluble in water, and more or less selectively soluble in alcohol. They are: Phycoxanthine, with broad bands at 5—6½ of Sorby's scale; Peziza xanthine, 5½—7; orange xanthophyll, 6—7½; xanthophyll, 6½—8; yellow xanthophyll, 7—8½. Frequently several of these xanthophylls co-exist, giving more or less continuous absorption of the blue end of the spectrum, and then isolation is not a very easy matter. They are all more or less sensitive to the band-raising power of solvents, and to the action of light and acids.

Phycoxanthine, Mr. Sorby seems to think, is a derivative of orange xanthophyll, and may be prepared from *Peltigera canina* by a process which I have not space to describe. Peziza xanthine is similarly prepared from *P. aurantia* and some other fungi, and is not, so far as I know, found elsewhere. The three xanthophylls are found everywhere; they may be prepared separately from plants in which they severally exist, but cannot, I think, be separated from each other with any approximation to purity, where they co-exist in equal, or nearly equal proportions. Mr. Sorby gives wall-flowers and *Porphyra vulgaris* as the source of xanthophyll; yellow crysanthemums as the source of yellow xanthophyll, and the orange-coloured antherozoids of *Fucus serratus* as the source of orange xanthophyll. The xanthine and lichno-xanthine groups consist of colouring matters soluble in CS_2, but selectively soluble in alcohol and in methylated alcohol. They are to be prepared in a pure state only from those fungules or lichens in which they severally attain their greatest development, and can only be detected in the higher plants by carefully watching the action of light and reagents on the solution containing them, these solutions having been rendered as approximately pure as possible. The different members all give a more or less complete general absorption of the blue and green to the end of the spectrum, and are as follows:—Fuco-xanthine, the principal colouring matter of Fuci, and already referred to; orange lichno-xanthine, to be obtained from the lichen *Peltigera canina*, growing well exposed to the sun; lichno-xanthine from *Clavaria fusiformis;* and yellow lichno-xanthine, derivable from Parmelia (Physcia) *parietina*.

Two other groups are very briefly discussed. They are the Phycocyan, to which possibly the "yellow substance" of camphor leaves may be referable, and the Phyco-erythine. Both these groups are soluble in water, and are, I think, derivatives of either blue chlorophyll or yellow xanthophyll,* and pass probably into the members of the erythrophyll group. At least, my experiment on the deoxidation of the chlorophylloids and xanthophylloids of the leaves of *Cinchona succirubra* point in this direction, but considerable care must always be taken by those engaged in these researches to avoid errors introduced by what Mr. Sorby calls the band-raising power of solvents, even though these are in all other respects quite neutral and exert no chemical action on the colouring matters.

Mr. Sorby states that he has carefully determined the order in which various liquids thus raise bands and compared it with the order of their specific gravity, and of their dispersive and refractive power, but has hitherto failed to recognize any simple connection between what may be called the band-raising power and any other physical property.* This band-raising power is probably associated with some loading of the molecules of the colouring matter, or some new grouping of them, by the solvents, so that it is hardly accurate to speak of their exerting no chemical action upon them. It is of course no new thing for a substance in changing its state to vary its absorption bands. A well known instance in which this occurs is that of *didymium*, whose absorption bands are subject to numerous modifications, according to the physical state of the earth, whether combined or not; and the character of the light employed, whether common light or the ordinary or extra-ordinary ray of polarized light. (See Roscoe on Spectrum Analysis for a pretty full account of Bunsen's memoir on this subject.) Erbia agrees in part with didymium in these characteristics and they doubtless have a connecting link somewhere with the band-raising power we are considering.

* Probably the former.

THE PHYSIOLOGICAL AND THERAPEUTIC ACTION OF HYDROCHLORATE OF AMYLAMINE.†

BY M. DUJARDIN-BEAUMETZ.

During the author's physiological and therapeutic researches upon trimethylamine, he received a suggestion from M. Wurtz that amylamine would have a more energetic action, and that it was desirable to study its effect upon the system. A *résumé* of the results of the investigation has recently been presented to the French Academy.

The author used the hydrochlorate of amylamine ($C_5H_{14}NCl$), a perfectly definite substance, which crystallizes in colourless scales; the salt was prepared by M. Frederick Wurtz. When solution of hydrochlorate of amylamine was introduced under the skin, phenomena were observed varying according to the dose employed. For example, when a dose of 1 to 5 centigrams was administered to rabbits, there was a marked diminution of the pulse and of the temperature, the pulse in one hour falling from 204 pulsations to 156. The lowering of the temperature was less clear, amounting only to one or two degrees. When, with the same animal, the dose exceeded 5 centigrams, the depressive phenomena of the pulse and temperature gave place to eccentric and varying nervous symptoms, but characterized essentially by tonic and chlonic convulsions, and by staggering movements. These phenomena were much intensified

* He does not, however, seem to have made any comparisons between their thermal relations and this band-raising power, or to have made any attempts to trace a connection between it and their behaviour towards polarized light under the influence of an electric current.

† *Comptes Rendus*, vol. lxxvii., p. 1247.

by a dose of 20 centigrams, and with 30 centigrams became sufficiently severe to cause death. Upon a dog of medium size, the dose of 20 centigrams produced a notable depression of the pulse, which fell from 80 to 64 pulsations, but it was necessary to raise the dose to beyond a gram before the nervous disturbances before spoken of were observed. So that with the preceding animals hydrochlorate of amylamine produced first, in a feeble dose, lowering of the pulse and of the temperature, and in a higher dose convulsions, which promptly brought on death.

With man a dose of 50 centigrams to 1 gram was observed to cause also diminution of the pulse and temperature, amounting to from 10 to 20 pulsations per minute in the space of an hour. These depressive properties of hydrochlorate of amylamine upon the pulse and temperature have been applied in the treatment of fever, particularly of typhoid fever, and in ten cases where this medication was used a manifest lowering of the pulse and temperature was uniformly observed, and the result appeared to be advantageous,. In comparing the physiological action of hydrochlorate of trimethylamine with that of hydrochlorate of amylamine, it appears that the latter, if it does not possess the sedative and calming action upon the nervous system possessed by trimethylamine, at least exercises a much more marked action upon the pulse and temperature, and that its toxic action is much more considerable than that of hydrochlorate of trimethylamine, or that of hydrochlorate of ammonia.

The author proposes to continue his researches upon the compound ammonias, and investigate in the next place the physiological action of propylamine, and compare it with that of amylamine and trimethylamine.

PREPARATION OF CARBOLIZED RESIN CLOTH.*

BY EDWARD LUND, F.R.C.S.

The author having found some difficulty in preparing the antiseptic carbolic gauze recommended by Professor Lister (see PHARM. JOURN. [3] vol iii., p. 41) in the way indicated by him, has sought to modify the process by taking advantage of the property possessed by carbolic acid, and first pointed out by Professor Lister, that it can be combined with resin and resinous matters generally with great facility, and that when so combined nearly all its irritating acrid properties are neutralized, while the resulting compound retains the power of evolving an antiseptic vapour at the temperature of the body. It is well known that to touch the mucous membrane, or even the skin of the lips, with pure carbolic acid, occasions pain and excoriation, but the author found, in experimenting on a mixture of one part of carbolic acid and five parts of resin that all the acridity was destroyed, the acid being still present, but stored up and rendered harmless by the new combination. He, therefore, came to the conclusion that this property allowed of the easy preparation, without the aid of heat, of a valuable application for antiseptic purposes in surgery; all that would be required was the saturation of a very thin calico gauze with a mixture of resin and acid dissolved in methylated spirit, and drying it quickly after pressure had been applied to it. But the compound of resin and acid thus left on the threads of the calico after evaporation was found to be too brittle and adhesive for a wound covering, and therefore to impart flexibility castor oil was added, as being the only accesible fixed oil entirely soluble in spirits of wine. The author finds that some samples of castor oil, in consequence of adulteration, are not entirely soluble in alcohol, but he is content to use an oil that will unite with twice its bulk of rectified spirit. Mr. Lund thus describes the proportion of the ingredients and the preparation of the antiseptic cloth :—

"Carbolic Acid Crystals, melted . .	2 fluid ounces.
Castor Oil	2 ,,
Purified Resin, by weight	16 ounces.
Methylated Spirit	40 fluid ounces.

Mix.

"To dissolve these ingredients easily, we must add them together in a certain order. To the resin, liquefied by heat and removed from the fire, add one-third part of the spirit; when these are well mixed, put in another third of the spirit, in which the oil has been previously dissolved; and, lastly, the acid in the remaining portion of the spirit must be slowly added to complete the mixture. The whole must be agitated until all the constituents are thoroughly incorporated, and afterwards passed through a muslin filter to get rid of any extraneous matters. If this plan be not adopted, the resin will concrete into a mass at the bottom of the vessel, and it will be extremely difficult afterwards to get it perfectly mixed. When thus prepared, the solution is of a dark colour, clear and free from any deposit; and it can be kept unchanged, in a well-corked bottle, for a long time. It is, in fact, a kind of thick varnish. To make the resin cloth, as I term it, for the sake of distinguishing it from the cere-cloth dressing for wounds, which I described in a paper read at the Leeds meeting of the British Medical Association in 1869, it is needful to select a very thin, cheap, porous calico or calico-muslin, known in the trade as 'mulls,' which costs at wholesale price about four shillings per piece of twenty yards. This, divided into strips, each about nine inches wide and six yards long, is reduced to a convenient form for general use. The calico should be unbleached and free from stiffening, and each of the strips should be carefully folded up, so as just to lie flatly in the press, as I am about to explain.

"An ordinary square tincture press may be used to press the cloth, or such a press as is sold for copying letters, to which a tin box has been adapted, so that the plates of the press can work in it; and into this box the folded calico is placed, the solution being poured over each successive layer, so as to wet perfectly every part of it. There should be an aperture at the bottom of the box, with a tap by which the superfluous fluid can be removed, collected, and used a second time. The press being brought into action, the pile of calico should be squeezed as dry as possible, all the fluid drained off, the resin-cloth taken out, laid over a few lines of string in a warm room with a good ventilation; and in an hour or two, when all traces of smell of the methylated spirit have departed, the cloth may be rolled up and kept in tin cases ready for use.

"It is difficult for me to state the exact cost of resin-cloth made by this process, for I have not yet bought the materials for its preparation at such prices as could be had if it were to be manufactured in large quantities; but, allowing for some slight reduction, where six or eight twenty-yard pieces of calico are bought at a time, and the solution made by the gallon, I find it comes to a fraction less than threepence per yard of average width of 44 inches. In using it as a dressing for wounds, I deal with it precisely as I would do with Mr. Lister's antiseptic gauze, for which it must be taken as a cheap and ready substitute. I generally apply ten folds of it over the face of a wound, as in an amputation, and perhaps six folds higher up the limb for some distance, and I cover it with the macintosh hat-lining, so as to distribute the serous discharges through the breadth of the resin-cloth thus covered. I have never found it to irritate the skin in any degree beyond what the oiled silk (protective), liberally used, could control; except once, when, in the hurry of preparing the resin-cloth, I had neglected to dry it thoroughly, and it was applied, still moist with the methylated spirit, the naphtha in it seeming to be the chief cause of the skin irritation. But if this precaution be observed, I believe this resin-cloth will be found a very useful addendum to our means of treating wounds and abcesses on antiseptic principles."

A DISCOURSE ON MOLECULES.*

BY J. CLERK MAXWELL, M.A., F.R.S.,

Professor of Experimental Physics in the University of Cambridge.

(*Continued from page* 405.)

We find that now, as in the days of the earliest physical speculations, all physical researches appear to converge towards the same point, and every inquirer, as he looks forward into the dim region towards which the path of discovery is leading him, sees, each according to his sight, the vision of the same Quest.

One may see the atom as a material point, invested and surrounded by potential forces. Another sees no garment of force, but only the bare and utter hardness of mere impenetrability.

But though many a speculator, as he has seen the vision recede before him into the innermost sanctuary of the inconceivably little, has had to confess that the quest was not for him, and though philosophers in every age have been exhorting each other to direct their minds to some more useful and attainable aim, each generation, from the earliest dawn of science to the present time, has contributed a due proportion of its ablest intellects to the quest of the ultimate atom.

Our business this evening is to describe some researches in molecular science, and in particular to place before you any definite information which has been obtained respecting the molecules themselves. The old atomic theory, as described by Lucretius and revived in modern times, asserts that the molecules of all bodies are in motion, even when the body itself appears to be at rest. These motions of molecules are in the case of solid bodies confined within so narrow a range that even with our best microscopes we cannot detect that they alter their places at all. In liquids and gases, however, the molecules are not confined within any definite limits, but work their way through the whole mass, even when that mass is not disturbed by any visible motion.

This process of diffusion, as it is called, which goes on in gases and liquids and even in some solids, can be subjected to experiment, and forms one of the most convincing proofs of the motion of molecules.

Now the recent progress of molecular science began with the study of the mechanical effect of the impact of these moving molecules when they strike against any solid body. Of course these flying molecules must beat against whatever is placed among them, and the constant succession of these strokes is, according to our theory, the sole cause of what is called the pressure of air and other gases.

This appears to have been first suspected by Daniel Bernoulli, but he had not the means which we now have of verifying the theory. The same theory was afterwards brought forward independently by Lesage, of Geneva, who, however, devoted most of his labour to the explanation of gravitation by the impact of atoms. Then Herapath, in his "Mathematical Physics," published in 1847, made a much more extensive application of the theory to gases, and Dr. Joule, whose absence from our meeting we must all regret, calculated the actual velocity of the molecules of hydrogen.

The further development of the theory is generally supposed to have begun with a paper by Krönig, which does not, however, so far as I can see, contain any improvement on what had gone before. It seems, however, to have drawn the attention of Professor Clausius to the subject, and to him we owe a very large part of what has been since accomplished.

We all know that air or any other gas placed in a vessel presses against the sides of the vessel, and against the surface of any body placed within it. On the kinetic theory this pressure is entirely due to the molecules striking against these surfaces, and thereby communicating to them a series of impulses which follow each other in such rapid succession that they produce an effect which cannot be distinguished from that of a continuous pressure.

If the velocity of the molecules is given, and the number varied, then since each molecule, on an average, strikes the sides of the vessel the same number of times, and with an impulse of the same magnitude, each will contribute an equal share to the whole pressure. The pressure in a vessel of given size is therefore proportional to the number of molecules in it, that is, to the quantity of gas in it.

This is the complete dynamical explanation of the fact discovered by Robert Boyle, that the pressure of air is proportional to its density. It shows also that of different portions of gas forced into a vessel, each produces its own part of the pressure independently of the rest, and this whether these portions be of the same gas or not.

Let us next suppose that the velocity of the molecules is increased. Each molecule will now strike the sides of the vessel a greater number of times in a second, but, besides this, the impulse of each blow will be increased in the same proportion, so that the part of the pressure due to each molecule will vary as the *square* of the velocity. Now the increase of velocity corresponds, on our theory, to a rise of temperature, and in this way we can explain the effect of warming the gas, and also the law discovered by Charles that the proportional expansion of all gases between given temperatures is the same.

The dynamical theory also tells us what will happen if molecules of different masses are allowed to knock about together. The greater masses will go slower than the smaller ones, so that, on an average, every molecule, great or small, will have the same energy of motion.

The proof of this dynamical theorem, in which I claim the priority, has recently been greatly developed and improved by Dr. Ludwig Boltzmann. The most important consequence which flows from it is that a cubic centimetre of every gas at standard temperature and pressure contains the same number of molecules. This is the dynamical explanation of Gay Lussac's law of the equivalent volumes of gases. But we must now descend to particulars, and calculate the actual velocity of a molecule of hydrogen.

A cubic centimetre of hydrogen, at the temperature of melting ice, and at a pressure of one atmosphere, weighs 0·00008954 gramme. We have to find at what rate this small mass must move (whether altogether or in separate molecules makes no difference) so as to produce the observed pressure on the sides of the cubic centimetre. This is the calculation which was first made by Dr. Joule, and the result is 1,859 metres per second. This is what we are accustomed to call a great velocity. It is greater than any velocity obtained in artillery practice. The velocity of other gases is less, as you will see by the table, but in all cases it is very great as compared with that of bullets.

We have now to conceive the molecules of the air in this hall flying about in all directions, at a rate of about seventeen miles in a minute.

If all these molecules were flying in the same direction, they would constitute a wind blowing at the rate of seventeen miles a minute, and the only wind which approaches this velocity is that which proceeds from the mouth of a cannon. How, then, are you and I able to stand here? Only because the molecules happen to be flying in different directions, so that those which strike against our backs enable us to support the storm which is beating against our faces. Indeed, if this molecular bombardment were to cease, even for an instant, our veins would swell, our breath would leave us, and we should, literally, expire.

But it is not only against us or against the walls of the hall that the molecules are striking. Consider the immense number of them, and the fact that they are flying in every possible direction, and you will see that they cannot avoid striking each other. Every time that two molecules come into collision, the paths of both are changed, and they go off in new directions. Thus each molecule is continually getting its course altered, so that

* Lecture delivered before the British Association at Bradford, September 22, 1873.

in spite of its great velocity it may be a long time before it reaches any great distance from the point at which it set out.

I have here a bottle containing ammonia. Ammonia is a gas which you can recognize by its smell. Its molecules have a velocity of six hundred metres per second, so that if their course had not been interrupted by striking against the molecules of air in the hall, every one in the most distant gallery would have smelt ammonia before I was able to pronounce the name of the gas. But instead of this, each molecule of ammonia is so jostled about by the molecules of air, that it is sometimes going one way and sometimes another, and like a hare which is always doubling, though it goes a great pace, it makes very little progress. Nevertheless, the smell of ammonia is now beginning to be perceptible at some distance from the bottle. The gas does diffuse itself through the air, though the process is a slow one, and if we could close up every opening of this hall so as to make it air-tight, and leave everything to itself for some weeks, the ammonia would become uniformly mixed through every part of the air in the hall.

This property of gases, that they diffuse through each other, was first remarked by Priestley. Dalton showed that it takes place quite independently of any chemical action between the inter-diffusing gases. Graham, whose researches were especially directed towards those phenomena which seem to throw light on molecular motions, made a careful study of diffusion, and obtained the first results from which the rate of diffusion can be calculated.

Still more recently the rates of diffusion of gases into each other have been measured with great precision by Professor Loschmidt, of Vienna.

He placed the two gases in two similar vertical tubes, the lighter gas being placed above the heavier, so as to avoid the formation of currents. He then opened a sliding valve, so as to make the two tubes into one, and after leaving the gases to themselves for an hour or so, he shut the valve, and determined how much of each gas had diffused into the other.

As most gases are invisible, I shall exhibit gaseous diffusion to you by means of two gases, ammonia and hydrochloric acid, which, when they meet, form a solid product. The ammonia, being the lighter gas, is placed above the hydrochloric acid, with a stratum of air between, but you will soon see that the gases can diffuse through this stratum of air, and produce a cloud of white smoke when they meet. During the whole of this process no currents or any other visible motion can be detected. Every part of the vessel appears as calm as a jar of undisturbed air.

But, according to our theory, the same kind of motion is going on in calm air as in the inter-diffusing gases, the only difference being that we can trace the molecules from one place to another more easily when they are of a different nature from those through which they are diffusing.

If we wish to form a mental representation of what is going on among the molecules in calm air, we cannot do better than observe a swarm of bees, when every individual bee is flying furiously, first in one direction and then in another, while the swarm, as a whole, either remains at rest, or sails slowly through the air.

In certain seasons swarms of bees are apt to fly off to a great distance, and the owners, in order to identify their property when they find them on other people's ground, sometimes throw handfuls of flour at the swarm. Now let us suppose that the flour thrown at the flying swarm has whitened those bees only which happened to be in the lower half of the swarm, leaving those in the upper half free from flour. If the bees still go on flying hither and thither in an irregular manner, the floury bees will be found in continually increasing proportions in the upper part of the swarm, till they have become equally diffused through every part of it. But the reason of this diffusion is not because the bees were marked with flour, but because they are flying about. The only effect of the marking is to enable us to identify certain bees.

We have no means of marking a select number of molecules of air, so as to trace them after they have become diffused among others, but we may communicate to them some property by which we may obtain evidence of their diffusion.

For instance, if a horizontal stratum of air is moving horizontally, molecules diffusing out of this stratum into those above and below will carry their horizontal motion with them, and so tend to communicate motion to the neighbouring strata, while molecules diffusing out of the neighbouring strata into the moving one will tend to bring it to rest. The action between the strata is somewhat like that of two rough surfaces, one of which slides over the other, rubbing on it. Friction is the name given to this action between solid bodies; in the case of fluids it is called internal friction, or viscosity.

It is, in fact, only another kind of diffusion—a lateral diffusion of momentum, and its amount can be calculated from data derived from observations of the first kind of diffusion, that of matter. The comparative values of the viscosity of different gases were determined by Graham in his researches on the transpiration of gases through long narrow tubes, and their absolute values have been deduced from experiments on the oscillation of discs by Oscar Meyer and myself.

Another way of tracing the diffusion of molecules through calm air is to heat the upper stratum of the air in a vessel, and to observe the rate at which this heat is communicated to the lower strata. This, in fact, is a third kind of diffusion—that of energy, and the rate at which it must take place was calculated from data derived from experiments on viscosity before any direct experiments on the condition of heat had been made. Professor Stefan, of Vienna, has recently, by a very delicate method, succeeded in determining the conductivity of air, and he finds it, as he tells us, in striking agreement with the value predicted by the theory.

All these three kinds of diffusion—the diffusion of matter, of momentum, and of energy—are carried on by the motion of the molecules. The greater the velocity of the molecules and the further they travel before their paths are altered by collision with other molecules, the more rapid will be the diffusion. Now we know already the velocity of the molecules, and therefore, by experiments on diffusion, we can determine how far, on an average, a molecule travels without striking another. Professor Clausius, of Bonn, who first gave us precise ideas about the motion of agitation of molecules, calls this distance the mean path of a molecule. I have calculated, from Professor Loschmidt's diffusion experiments, the mean path of the molecules of four well-known gases. The average distance travelled by a molecule between one collision and another is given in the table. It is a very small distance, quite imperceptible to us even with our best microscopes. Roughly speaking, it is about the tenth part of the length of a wave of light, which you know is a very small quantity. Of course the time spent on so short a path by such swift molecules must be very small. I have calculated the number of collisions which each must undergo in a second. They are given in the table and are reckoned by thousands of millions. No wonder that the travelling power of the swiftest molecule is but small, when its course is completely changed thousands of millions of times in a second.

The three kinds of diffusion also take place in liquids, but the relation between the rates at which they take place is not so simple as in the case of gases. The dynamical theory of liquids is not so well understood as that of gases, but the principal difference between a gas and a liquid seems to be that in a gas each molecule spends the greater part of its time in describing its free path, and is for a very small portion of its time engaged in encounters with other molecules, whereas, in a liquid, the molecule has hardly any free path, and is always in a state of close encounter with other molecules.

Hence in a liquid the diffusion of motion from one

molecule to another takes place much more rapidly than the diffusion of the molecules themselves, for the same reason that it is more expeditious in a dense crowd to pass on a letter from hand to hand than to give it to a special messenger to work his way through the crowd. I have here a jar, the lower part of which contains a solution of copper sulphate, while the upper part contains pure water. It has been standing here since Friday, and you see how little progress the blue liquid has made in diffusing itself through the water above. The rate of diffusion of a solution of sugar has been carefully observed by Voit. Comparing his results with those of Loschmidt on gases, we find that about as much diffusion takes place in a second in gases as requires a day in liquids.

The rate of diffusion of momentum is also slower in liquids than in gases, but by no means in the same proportion. The same amount of motion takes about ten times as long to subside in water as in air, as you will see by what takes place when I stir these two jars, one containing water and the other air. There is still less difference between the rates at which a rise of temperature is propagated through a liquid and through a gas.

In solids the molecules are still in motion, but their motions are confined within very narrow limits. Hence the diffusion of matter does not take place in solid bodies, though that of motion and heat takes place very freely. Nevertheless, certain liquids can diffuse through colloid solids, such as jelly and gum, and hydrogen can make its way through iron and palladium.

We have no time to do more than mention that most wonderful molecular motion which is called electrolysis. Here is an electric current passing through acidulated water, and causing oxygen to appear at one electrode and hydrogen at the other. In the space between, the water is perfectly calm, and yet two opposite currents of oxygen and of hydrogen must be passing through it. The physical theory of this process has been studied by Clausius, who has given reasons for asserting that in ordinary water the molecules are not only moving, but every now and then striking each other with such violence that the oxygen and hydrogen of the molecules part company, and dance about through the crowd, seeking partners which have become dissociated in the same way. In ordinary water these exchanges produce, on the whole, no observable effect, but no sooner does the electromotive force begin to act than it exerts its guiding influence on the unattached molecules, and bends the course of each toward its proper electrode, till the moment when, meeting with an unappropriated molecule of the opposite kind, it enters again into a more or less permanent union with it till it is again dissociated by another shock. Electrolysis, therefore, is a kind of diffusion assisted by electromotive force.

(*To be continued.*)

THE EUCALYPTUS GLOBULUS AS A DISEASE DESTROYING TREE.

In the exhaustive report upon the culture, properties, and uses of the plants of the genus Eucalyptus, presented two years since by M. Wattel to the Paris Société d'Acclimation, a full abstract of which was printed in this Journal,* it was pointed out that one of the most valuable properties claimed for it was its antimiasmatic action when grown in marshy districts. Numerous experiments to test this point have been made in Algeria, and some of the results were recently brought before the French Academy by M. Gimbert.† Numerous cases are cited, amongst others that of a farm twenty miles from Algiers, formerly noted for its pestilential atmosphere. In the spring of 1867, 13,000 eucalyptus trees were planted on the farm, since which time not a single case of fever has occurred there, the immunity commencing the same year, whilst the trees were yet only two or three metres high. The *Gardeners' Chronicle* recalls the fact that a similar virtue has been attributed to the sunflower, and that the sanitary condition of the Washington (U.S.) Observatory, which was situated in a very unhealthy, marshy locality, where fever was rife at certain periods of the year, was much improved after the ground had been annually sown with sunflower. The *Gardeners' Chronicle* also recapitulates some interesting points in connection with this remarkable tree, as follows :—

"The numerous species of eucalyptus, known as gum-trees, iron-barks, or stringy-barks, are among the most characteristic features of Australian and Tasmanian vegetation. Many of them are extremely valuable as timber trees ; others yield a resinous juice, which, when hardened, possesses powerful astringent qualities ; and many are useful in various ways too numerous to mention. Among them all, however, there is none of more general utility or economic importance than *E. globulus*. Even from an ornamental point of view this tree is well worthy of cultivation. The trunk, of which the outer layers of bark detach themselves, as in the Oriental Plane, is smooth and ash-coloured ; the leaves are bluish green, or, when young, often glaucous-white, often from half-a-foot to a foot in length, and the flowers are large and axillary, growing close to the stem, either singly or in clusters of two or three. The tree sometimes attains the height of 200 feet, but often flowers when not above 10 feet high. It is a native of valleys and moist declivities of wooded mountains in various parts of Victoria, as well as of Tasmania. Besides its very great value as a timber tree, this species of eucalyptus, in common with many others, is of importance as a honey-producing tree. The flowers yield a large quantity of honey, and are greatly affected by bees ; at least, such is the case in Australia, where the honey-bee of Europe, introduced there, spread in a few years in a remarkable manner, and soon established itself in the forests, in which the eucalypti form nearly 99 per cent of the vegetation. The leaves, probably from their coriaceous and resinous nature, are singularly proof against the ravages of locusts. This was noticed by M. Ramel in 1865, in a part of Senegal where *E. globulus* had been introduced, when the leaves of all other trees were devoured by the locust, those of *E. globulus* resisted their attacks. It has been proposed to employ the leaves and other portions of the tree in medicine, but Mr. Broughton, the Government chemist of Ootacamund, does not find in either bark or leaves any traces of quinine, which was supposed to enter into their composition. He says :—'Much has lately appeared in the papers and quasi-scientific journals concerning the valuable qualities of the eucalyptus globulus as a febrifuge. In the *Lancet* for April 20, 1872, a notice is given of the uses of this tree medicinally, in which it is stated that all parts are most favourable as a febrifuge medicine, and also that the leaves, when smoked, are most efficacious in allaying pain, calming irritation, and procuring sleep. This article furthermore informs us that Professor Vauquelin obtained an alkaloid from the bark which crystallized like quinine as a sulphate, and which yielded the ordinary reaction of quinine with chlorine, water, and ammonia. I have examined the bark and leaves, and have the honour to state that neither quinine, quinidine, cinchonidine, nor cinchonine is contained in the plant in any proportion.' A French chemist, M. Cloez, has extracted from the leaves an essence analogous to camphor, to which he gives the name eucalyptol. This substance, which possesses the agreeable odour of the plant in the highest degree, seems to exercise upon the system an action similar to that of most other essential oils. Mixed with water, it yields a pleasant rather bitter camphor-like flavour. In Mauritius an infusion of the leaves was administered with some success in malarious fever, the leaves being sold for this purpose at 6*d.* per ounce. Cigars made from the leaves were exhibited in the Paris Exhibition of 1867, and recommended as being very efficient in promoting digestion ; and in the last International Exhibition were some

* PHARM JOURN. [3] vol. iii., p. 23, 43.
† *Comptes Rendus*, vol. lxxii. p. 764.

cigarettes made from the foliage, prepared by a chemist at Melbourne, who urges their employment in bronchial and asthmatic affections.

"In Germany, Italy, and France this plant is credited with the power of removing the sources of fever, and in addition to the case above mentioned we are told of a Dutch landed proprietor who planted some plots of sunflower upon the banks of the Scheldt, near his houses, and whose tenants enjoyed afterwards complete immunity from miasmatic fever, although that disease continues to be prevalent in the neighbourhood. In the swampy regions of the Punjab district the sunflower is grown in some places in large plantations with marked success, its influence tending to remove malaria, and thus benefiting the health of residents in those districts. The Agri-Horticultural Society of the Punjab has taken the matter up, and in a recent report advocates the extension of the cultivation of this plant."

In addition to the above it will be remembered that M. Rabuteau also has examined eucalyptus leaves with the view of ascertaining whether its alleged febrifuge powers are dependent upon the presence of an alkaloid ;* his conclusion, like that of Mr. Broughton, being that no such alkaloid exists in the leaves.

As this tree is now being so freely cultivated, the following information how to grow *Eucalyptus globulus* in England, communicated to the *Medical Times and Gazette* by Mr. V. F. Benett Stanford, of Pyt House, Tisbury, will be read with interest :—

"I have successfully reared from seed two dozen of these trees, and they are now growing well out of doors. I obtained the seed five years ago from South Australia, and forced it in a hot-house ; in one year it was four feet high, and now, in its fifth year, it is growing rapidly in a sheltered position in the park, having attained a height of thirty feet. The first three years the tree must be taken under cover every winter, and the fourth and fifth years should be protected for several feet up with wisps of hay or straw. When the trees are kept indoors in winter, it should be in an orangery or very high greenhouse, with plenty of light and little water."

RELATIONS OF PLANTS AND ANIMALS TO INORGANIC MATTER, AND ON THE INTERACTION OF THE VITAL AND PHYSICAL FORCES.†

BY J. BELL PETTIGREW, M.D., F.R.S., ETC.

In entering upon a great science like physiology it becomes us to take as wide a survey of its several dependencies as is consistent with the knowledge of the epoch in which we live. It has, therefore, appeared to me that it might not be inappropriate on the present occasion *to consider organic beings in relation to inorganic matter, and the forces and affinities which weld, as it were, the organic and inorganic together in living organisms.* This seems necessary in an introductory lecture like the present ; as it is of the utmost importance to familiarize ourselves at the outset not only with the matter from which, but the mode according to which, the several organisms and organs which it is the object of physiology to expound are formed.

The plant lives upon inorganic material, and the animal feeds on the plant or on some other animal nourished by the plant. Directly or indirectly, living organisms are linked to the globe they inhabit. It is impossible to speak of any one of the organic series as apart from the inorganic world, for the obvious reason that the same forces to a great extent enter into the composition of both. The grand scriptural dictum, "Dust thou art, and unto dust thou shalt return," is not more philosophical than it is physiological. It expresses in quaint but vigorous language those peculiar vital, physical, chemical, and other combinations and relations which bind living to dead matter. To trace those combinations and relations from their incipient beginnings in "*brut*," or inorganic matter, through the organic series, is the true province of physiology. In this wider and grander sense, physiology has to do with the universe and those beautiful physical laws which regulate the distribution and motion of matter. It has to do with embryology and the beginnings of life, whether by supposed spontaneous generation or from an accredited parent ; it has to do with anatomy and zoology, regional and histologic ; it has to do with chemistry and the myriad combinations and transformations incessantly going on between living and dead particles in vegetable and animal organisms ; it has to do with physics and mechanics, with mathematics, with electricity, magnetism, heat, light, and a great number of kindred subjects, many of which are still in their infancy.

The relation between the organic and inorganic kingdoms and between the vital, physical, and other forces is of the most intimate description ; and physiology, to be perfect as a science, must be all-embracing—*i.e.*, it must occupy itself not only with living and dead matter, but also with vital, physical, and other force. The ancients, with a boldness and grasp worthy of modern times, regarded physiology as synonymous with the science of nature. With the Grecks, who coined the word, physiology was the λογος, reason or philosophy of φυσις, nature ; that is to say, the generating and generated κοσμος, world or system of the universe. It was, in short, the science of universal nature. In modern times, and especially among the Germans, what was thus expressed by the ancients has come to be expressed by the exactly parallel terms, *natur philosophie*, and *naturwissenschaft* (our natural philosophy).

During the last century the term "physiology" was restricted in its meaning not merely to the science of life and organisation, but more especially to the life and organisation of man. It thus came strictly to denote an all important branch of medical science. During the present century it has been gradually widening its boundaries, and at the present day it holds out the prospect of an indefinable increase. There is now a physiology of man, a physiology of animals, and a physiology of plants. This increase has taken place contemporaneously with the enlargements in the fields of those sciences, such as botany, zoology, and human anatomy, which directly supply its subject matter ; and of those other sciences, such as chemistry, and all the kinetic branches of physics —*e. g.*, electricity, magnetism, heat, optics, etc.—which have become all important aids in the investigation of many of the hitherto altogether mysterious processes of life and organisation. Physiology is consequently emerging from the comparatively confined and isolated position it occupied during the eighteenth century, and entering into a most intimate relation not only with the whole range of the natural sciences, but also with the whole range of the physical sciences ; for with mechanical and dynamical laws, such as leverage and capillary action, it has as intimately to do as with the subtle physical powers of heat and magnetism. Physiology is thus plainly cosmic or universal in its relations and dependencies. From the tendency which the circle of the sciences has to widen, it is impossible to draw a sharp line of demarcation between them. Already the little circles which indicate collateral branches are indenting each other, and the time will assuredly come when all shall merge and blend to form one grand whole. Then, and then only, shall we realize the important fact that all science, like all truth, is one.

Such being the nature of our great subject, it cannot be inappropriate in an introductory lecture to direct your attention very briefly to the cosmic or universal relations and affinities of physiology.

In ancient Greece it was customary to regard all matter as consisting of four elements—viz., earth, air, fire, and water. The elements now, owing to the rapid advance of

* PHARM. JOURN. [3] vol. iii., p. 463.

† An Introductory Lecture to a Course of Physiology. Reprinted from the *Lancet*, Nov. 15.

chemistry and the judicious use of spectrum analysis in the hands of Bunsen and Kirchoff, amount to sixty-five.

Thales believed that the secret of life was to be found in the water; Anaximenes was of opinion it resided in the air; Pythagoras traced it to heat, and Xenophon to the earth. Hippocrates went further, and asserted that φυσις (Nature) presided over and controlled all the actions of the body. According to him, Nature assimilated what was good for the body and rejected what was bad. Plato, still more daring, attributed a soul to man, consisting of three parts—namely, the knowing or cognitive faculty, seated in the head; the passions, placed in the breast; and the appetites, confined to the belly. Aristotle entertained similar views. The soul, in Aristotle's opinion, was the vital energy or power which animated all organic bodies. Thus, with him, there was a vegetative soul for plants, a sentient soul for animals, and a rational soul for man.* Plato and Aristotle, with a weird wisdom, drew a broad line of demarcation between matter, life, and spirit. Democritus and Epicurus, who believed in none of these things, regarded the body as an accidental aggregation of stray particles, variously grouped, and consequently discharging dissimilar functions. In Democritus and Epicurus we behold the materialist of modern times; in Plato and Aristotle the immaterialist.

It is exceedingly interesting and, I will add, exceedingly instructive to trace those ancient doctrines rising gradually from matter to life, and from life to spirit or soul, but I will not tax your patience; suffice it to say, that the ground originally occupied by Plato and Aristotle on the one hand, and by Democritus and Epicurus on the other, is vigorously maintained by two rival schools of modern philosophers. Thus there are those who attribute everything that exists to a spiritual agency, or, what is the same thing, a divine power, while there are others who persistently maintain that the universe and all it contains is due to an accidental assemblage of parts mutually acting and reacting upon each other. Newton and Swedenborg, *e.g.*, support the former view, and Haeckel and Tyndall the latter. These four philosophers equally assume the existence of matter for their systems of the universe, but there is this fundamental difference between them: Newton and Swedenborg attribute the disposal, arrangement, and movements of matter directly to divine interposition and agency; whereas Haeckel and Tyndall refer everything to a power inhering in the matter itself. In other words, Newton and Swedenborg admit that matter, once created and placed in certain conditions, will obey certain laws; they, however, deny that matter can accomplish anything of itself, which is the position defended by Haeckel and Tyndall.

Newton's conception of the universe is very grand. He pictures a mighty chaos, matter without form in the illimitable void. He then represents it as assuming shape and falling into position by the force of gravitation and under divine guidance. The assuming of shape is the origin and order of movement. By motion thus produced the universe becomes gradually perfected; the relative size, distances, and movements of its several parts can be accurately ascertained.† Newton never loses sight of a first cause. Thus, speaking of the formation of the sun and fixed stars, he says: "I do not think (this) explicable by mere natural causes, but I am forced to ascribe it to the council and contrivance of a voluntary agent." Numerous other passages of a like tenor might be cited from this author.*

Swedenborg in like manner, when descanting of gravitation, attributes the disposal of matter to divine agency. He says that nothing can be truly known of the visible world without a knowledge of the invisible, for the visible world is a world only of effects, while the invisible, or spiritual, is a world of causes.†

Haeckel gives a very different and not over-cheering account of the Creation. It is too long to quote on the present occasion, but I may say briefly that he refers not only the origin of the primitive cell, but also that of the young earth, to condensation and rind-formation. He does not recognize a First Cause. He says: "The homogeneous, viscid, plasma substance, which singly and alone formed the bodies of the first organisms, and even at this day quite alone forms them in the case of the *moneres*, or simplest amœbic forms, is analagous to the tenacious and viscid planetary substance which contains the elements and substance of the young earth, as well as of the other glowing world bodies. . . . In both cases the form of the creation happened, not through the capricious interference of a personal Creator, but through the original power of matter fashioning itself. Attraction and repulsion, centripetal force and centrifugal force, condensation and rarefaction of the material particles, are the only creative powers, which at this point lay the foundations of the complicated structure of creation."‡ Thus speaks and writes Haeckel. His system is not more intelligible for having excluded the divine agency. It is principally remarkable for bringing us face to face with the hydra-headed, myriad-handed protoplasm, and with the primitive cell, regarding which we have heard so much in recent times. Haeckel, it will be observed, holds extreme evolutionist views. According to him, matter does everything of itself and for itself.

Tyndall is equally extravagant in his opinions. In the region beyond the microscope limit, he says, the poles of the atoms are arranged—that tendency is given to their powers; so that when the poles and powers have free action, and proper stimulus in a suitable environment, they determine first the germ and afterwards the complete organism.

From the foregoing it will be evident that philosophers are diametrically opposed to each other as to the constitution of the universe: one sect attributing everything to divine agency and to law and order impressed upon all matter, whether living or dead, from the first; the other believing that matter of itself can account for the universe and all it contains. Both sets of philosophers, however—and this is the point with which we as physiologists have to do,—equally believe in matter and force.

(*To be continued.*)

* Strictly speaking. Aristotle held that man, while possessing, in common with the brutes, a ψυχη, possessed also a πνευμα, or rational principle.

† "From the time when Newton discovered, by analysing the motions of the planets on mechanical principles, that every particle of ponderable matter in the universe attracts every other particle with a force varying inversely as the square of the distance, astronomers have been able, in virtue of that one law of gravitation, to calculate with the greatest accuracy the movements of the planets to the remotest part and the most distant future, given only the position, velocity, and mass of each body of our system at any one time."

PALERMO MANNA.

The production and exportation of manna constitutes a very important item in the commerce of Sicily. Much valuable information on this subject was contained in Mr. Hanbury's paper, printed in the Journal (vol. iii., p. 421); but from a recent report on the commerce and navigation of Sicily we learn that during the three years ending in 1871, as many as 7,148 cwts. were exported, of an aggregate value of £45,720, made up as follows:—1869, 2546 cwts.; value, £15,972. 1870, 1564 cwts.; value, £10,220. 1871, 3,038 cwts.: value, £19,528.

Manna is produced chiefly in the Province of Palermo about Cefalù and Geraci, Cinisi, and Capaci. It is shipped principally to France and the northern ports of Italy, whence it is conveyed overland to the North of Europe. England consumes but a small quantity.

The Pharmaceutical Journal.

SATURDAY, DECEMBER 20, 1873.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square,*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ.',*

TEA ADULTERATION.

OUR readers will doubtless be aware that one of the objections urged by the grocers against being subjected to the operation of the Adulteration Act in the case of sophisticated tea, has been the indiscriminate admission of all descriptions and qualities of tea by the Customs. A strenuous effort has been made by the grocery trade to strike at the root of adulteration of tea by means of government inspection. We think the action taken with this object will be of interest to our readers, as it may prove a possible means of paving the way for the adoption of the excellent suggestion made by Mr. UMNEY, at the late evening meeting, that drugs such as opium, scammony, etc., should be submitted to examination while in bond.

There would be little difficulty in proving that the Chinese, English merchants, and the British public have all assisted in bringing about the present state of things, with respect to the adulterated tea imported into this country. The Chinese have manipulated the lowest descriptions of tea so perfectly that it has become possible to palm on the British public tea of good appearance but low quality at comparatively a very high price, if the value is considered. The masses, always craving for something cheap, have patronized this imposture, and by buying these manipulated teas have encouraged the trade. With a reduction in the import duty to sixpence a pound, we have witnessed the importation of green tea loaded with sand and magnetic oxide of iron; "Maloo Mixture," which is nothing but exhausted and old leaves redried and mixed in the drying with offensive substances, which shall be nameless; putrid tea, and tea which has been damaged by sea water. As the duty now imposed bears a small proportion to the actual value of the tea, importers are willing to run the risk of importing teas of the lowest quality, well knowing that as the public taste just now runs in the direction of buying cheap and nasty things, these teas, however bad and unsound, can be sold at a fair profit, either alone or after being mixed with others of a better quality.

This trade had certainly become so gigantic that it was necessary somebody should take the matter in hand, and with great propriety and zeal the Sanitary Authorities of the City of London directed their attention to it. They met and consulted together, and after having discovered a shipment of tea "unfit for human food," they determined to make an example of the importers by taking legal proceedings for the condemnation of the tea. But unfortunately there was no law under which they could act as long as the tea remained in bond, and consequently they at once put themselves in communication with the Government. The Custom's Authorities, under their present laws, could not act in the matter, and we may say that up to last Saturday week the Government authorities took very little interest in the question so long as the duty was paid on the good and bad tea alike. On that day, however, Mr. Stansfeld seems to have become impressed with the arguments of the deputation which waited on him; and when it was proposed that a bill should be introduced into Parliament next session empowering local sanitary authorities connected with food adulteration to inspect the bonded tea warehouses, and place all spurious or adulterated tea under the regulations of the Adulteration of Food Act, he seemed to think that this should be a duty undertaken—if at all—by the Government. We think so too; for it seems to us a monstrous thing that, while tobacco containing the smallest admixture of saccharine or other foreign matter is pounced upon by the Customs and condemned, adulterated tea should be allowed to be imported and cleared for home consumption with impunity so long as the duty is paid.

It will be said that there is a great difference between tobacco and tea, because the great bulk of the former being imported in the unmanufactured state, it is necessary to provide that all which is imported shall be genuine, to enable the Inland Revenue Officers to guard against adulteration during the process of manufacture; whilst in the case of tea—a finished article ready for consumption when the duty is paid—if any of it is adulterated the adulterant is charged with the tea duty.

But we wish to show that as the government can frame laws for the protection of the tobacco revenue, and rigidly enforce them, they can, if so inclined, also frame similar laws for regulating the importation of tea. If we look into the Statute Book we find this was actually done when the tea duty was high, and at the present time it is a penal offence for persons in this country to manufacture certain leaves in imitation of tea. The British public have a right to demand that the duty of inspecting tea in bond shall devolve upon the Government. No local authority can have the facilities at its disposal that the Government officers have. At all the bonded warehouses the tea is always under revenue lock; the Government officers, in constant attendance, know where the tea comes from, the importer, and everything connected with the vessel bringing it. In addition to this, the officers at every port are under the same regulations and control, and, as a matter of course, have constant supervision from the central authorities.

If this proposed duty of inspecting bonded tea

warehouses were given over to the local authorities we are convinced they would be compelled to ask for assistance from the Customs to enable them to keep a watch on tea suspected of being adulterated, which might only be in the warehouse for transhipment; for we apprehend that, however stringent the law might be, it would only include in its provision tea imported for home consumption, and would not interfere with the carrying business of British shipowners. We may further state that the working of the Adulteration Act up to the present time has filled us with alarm. The readers of this Journal will have seen cases brought before the magistrates which ought never to have been taken into court, as well as chemical and microscopical evidence given by some of the analysts which was proved to be not well founded. At every port into which tea is imported we cannot expect to find an analyst who has had a life-long experience of adulterations of every kind, and to judge from some of the appointments lately made under the Adulteration Act, the public analyst may be a person who, with little experience in chemical and microscopical research, as applied to the adulteration of food and drink, would consequently not be competent to perform the duties connected with the inspection of tea in bond. There is another objection to the appointment of local sanitary authorities for this duty on account of the expenses connected with such inspection having to be borne by the borough or county rates, but chiefly by the former, and, consequently, the cost of the inspection would fall upon a small section only of the community. If the duty were undertaken by the Government the cost would be national, and all those paying taxes would then have to contribute. On the score, therefore, of justice, efficiency, and equity, this duty of tea inspection if done at all should be undertaken by the Government. It is evident from the numerous prosecutions of tea dealers in different parts of the country the matter cannot rest where it is. These traders may, in many instances, be regarded as innocent of any intentional fraud, and yet they are punished for selling an adulterated article on which the Government have been paid the duty as tea. Though we cannot adopt the opinion that they have no means of finding out whether the tea they vend contains exhausted leaves or is faced with Prussian blue or other pigments, and are more disposed to agree with Mr. KINNERSLEY* in thinking the effect of the Act is to throw upon retail dealers the duty of ascertaining by competent analysis that every article they sell is pure and unadulterated—still we can only regard that as an additional reason why the Government should perform its part in preventing the introduction of an adulterated article upon which duty is charged.

If the Government obtain powers to examine tea in bond, and condemn all found adulterated or unfit for human food, we are sure the Chinese will very speedily discontinue their present practice of sophisticating teas for the English market, and we shall, without doubt, soon have tea on our market, perhaps a little higher in price, but certainly much better in quality than that which is now sent into consumption. The evil has been of long duration, but stringent measures are only required to bring the tea trade once again into a healthy state.

OPIUM TRADE IN INDIA.

IN the 'East India and Progress and Condition Report' for 1871-72 some interesting notes are given on this subject.

The cultivation of opium in India is still increasing. At present there are 560,000 acres in Bengal and 608 in Bombay under cultivation, and Government has appointed an agent to watch the growth and to study blights or deteriorations in the plant, which requires high cultivation and careful manuring.

All the opium is bought up by Government which thus has the monopoly of sale. There are two opium agencies for this purpose, one at Patna, and another at Ghazipur, where the Government officers buy opium from the cultivators at a rate to meet the market. Malwa opium is grown within the territory of native states, and is there free of any duty. To guard against the advantage it would gain in the market when pitted against the highly taxed opium of the Government, it is only allowed to be exported from Bombay, and is there subjected to such a high duty as to make its price equal to the other.

The exports of opium during 1871-72 amounted to 93,364 chests, valued at £13,365,288; of this quantity Bengal contributed 49,455 chests, and Bombay 43,909 chests, and the net revenue to the Government amounted to £7,657,213. This large revenue was due to the high price, and to the small payments made to the cultivators owing to the shortness of the crops. The price per chest in Bengal was £139, leaving a net profit of £90, the price being £26 higher than the average of the preceding year. The short crop was owing to a peculiar blight in 1871, and dry winds in 1872.

ROYAL INSTITUTION ARRANGEMENTS FOR 1873-4.

WE have just received from the Secretary of the Royal Institution the programme for the coming session. It comprises the following probable arrangements for the Friday evening meetings before Easter:—

Jan. 16th. Professor Tyndall, D.C.L., LL.D., F.R.S.:—"The Acoustic Transparency and Opacity of the Atmosphere."

Jan. 23rd. Professor Sylvester, M.A., F.R.S.:—"Recent Discoveries in Mechanical Conversion of Motion."

Jan. 30th. Sir Julius Benedict :—"Weber and his Times."

Feb. 6th. Alfred H. Garrod, Esq. :—"The Heart and the Sphygmograph."

Feb. 13th. Dr. Doran, F.S.A. :—"The Opponents of Shakespeare."

Feb. 20th. Vernon Heath, Esq. :—"The Autotype and other Photographic Processes and Discoveries."

Feb. 27th. Francis Galton, Esq, F.R.S. :—"Men of Science, their Nature and Nurture."

March 6th. Sir Samuel W. Baker, M.A. :—"Suppression of the Slave Trade of the White Nile."

March 13th. Dr. C. R. A. Wright, F.C.S:—"The Chemical Changes accompanying the Smelting of Iron in Blast Furnaces."

March 20th. Dr. W. B. Carpenter, F.R.S.:—"The Temperature of the Atlantic."

March 27th. Professor A. C. Ramsay, LL.D., F.R.S.:—"The Physical History of the Rhine."

The following are the Lecture arrangements for 1873-74 :—

Professor Tyndall, D.C.L., LL.D , F.R.S.—Six Christmas lectures (adapted to a juvenile auditory), on the "Motion and Sensation of Sound," on Dec. 27th (Saturday), 30th, 1873 ; Jan. 1st, 3rd, 6th, 8th, 1874.

Professor Rutherford, M.D., F.R.S.E.—Five lectures on "Respiration." On Tuesdays, Jan 13th to Feb. 10th.

Professor Tyndall, D.C.L., LL.D., F.R.S.—Six lectures on "The Physical Properties of Gases and Liquids." On Tuesdays, Feb. 17th to March 24th.

Professor P. M. Duncan, F.R.S.—Six lectures on "Paleontology, with Reference to Extinct Animals and the Physical Geography of their Time." On Thursdays, Jan. 15th to Feb. 19th.

Professor W. C. Williamson, F.R.S.—Five lectures on "Cryptogamic Vegetation." On Thursdays, Feb. 26th to March 26th.

Professor G. Croom Robertson.—Four lectures on "Kant." On Saturdays, Jan. 17th, 24th, 31st, and Feb. 7th.

R. Bosworth Smith, Esq., M.A.—Four lectures on "Mohammed and Mohammedism." On Saturdays, Feb. 14th, 21st, 28th, and March 7th.

Charles Thomas Newton, Esq., M.A.—Three lectures on "Ephesus." On Saturdays, March 14th, 21st, and 28th.

Professor Rutherford will give six lectures on "The Nervous System" after Easter.

THE REPRINT OF THE PHARMACOPŒIA.

We are enabled to state that the reprint of the Pharmacopœia is being rapidly proceeded with, and that it, together with the Addendum, containing the requisite additions, may be expected to be published in a few weeks.

On Monday last a case of raw meat, preserved in Buenos Ayres in April last (as certified under consular seal) was publicly opened at the warehouse of Messrs. Culverwell, Brooks, and Cotton, Saint Mary Axe, City, in the presence of a large number of persons interested in the subject of meat preservation. Notwithstanding the time that had elapsed since its preservation, the meat appeared to be perfectly sweet and fresh.

According to consular returns, the total quantity of cinchona bark shipped from Saint Martha during the year 1872, amounted to 2,758,991 lbs., being a considerable decrease on that exported in the previous year, when it amounted to 3,415,149 lbs.

Provincial Transactions.

BRIGHTON ASSOCIATION OF PHARMACY.

At a meeting of the Brighton Association of Pharmacy, at the room in North Street, Mr. W. D. Savage, President in the chair, Mr. W. H. Smith, of the Sussex County Hospital, in a short paper on "Opium and its Preparations," showed those present how Messrs. Deane and Brady had rendered the study of the microscopic characters of the opium alkaloids not only interesting, but very instructive and useful, to both the physician and the pharmacist. If a solution of opium like the tinct. opii of the B. P. was made with weak spirit, all the alkaloids would be dissolved, and such a solution would very well represent the medicinal properties of the drug from which it was produced. But all the alkaloids had not the same action when taken internally as medicines, and this fact had caused the invention of various solutions, from some of which certain alkaloids were excluded, while others consisted of solutions of only one or two alkaloids. A microscopic examination of such liquids would often exhibit their principal active ingredients. Mr. Smith had made a great number of slides of tincture of opium, but in every case he had only been able to recognize a very few of the crystals. He thought that the bases must be in combination with some acid, which was very easily separated, for he found that preparations which had been made by more elaborate processes gave much better crystals. He was unable to find any crystals in the tinct. opii which polarised so well as his specimens of narcotine, but he had observed that large crystals of narcotine did not give such strong colours as the small ones did. He was struck with the similar appearance presented by a slide of tinct. opii and a badly prepared slide of sulphate of morphine. Were the principal salts present in opium sulphates ? and would the lime present in common water separate the sulphuric acid from such combinations ? If so, he could easily understand why such preparations as liq. opii sed. yielded more definite crystals. One preparation (Jeremy's opiate) yielded only two kinds of well formed crystals, which he believed to be codeine and morphine.

The Chairman complimented Mr. Smith on his preparing a very excellent *résumé* of an important subject, and a vote of thanks having been heartily accorded, Mr. Smith exhibited a number of alkaloids and preparations, the President and Mr. Ettles kindly assisting with their microscopes, and towards the end of the meeting they exhibited various other objects of interest. The meeting concluded with a vote of thanks to the Chairman.

HULL CHEMISTS ASSOCIATION.

ANNUAL DINNER.

The members and friends of this Association celebrated their annual dinner on Tuesday evening, December 9th, at the Cross Keys Hotel, when about forty gentlemen assembled under the presidency of Mr. Anthony Smith. The vice-chairs were filled by Messrs. F. Earle and J. Beal. After the loyal toasts,

The President proposed the "Healths of the Mayor and Corporation of Hull," coupling with it the Mayor of Hull (Mr. Alderman Seaton), who was present.

The Mayor, after replying to the toast in his official capacity, alluded to the objects of the association whose anniversary they were met to celebrate. He had before him a report which accompanied the invitation to him to be present, and he was exceedingly pleased at the progress which the Association had made. He noted particularly the attention which had been given to the botanical class, and he only regretted that circumstances had prevented the prize which was given by the president being competed for. He could only say as the Mayor, and as an old chemist, that should there be no prize offered this year

for the botanical class, he should be happy to give one to the student the Association might recommend. Referring to an allusion in the report to the advisability of the earlier closing of their places of business, which, if carried out, would necessarily do away with Parliamentary interference, he said he thought the matter lay a great deal in their own hands. With mutual reciprocity and good feeling, added to a kind forbearance and forethought by the public generally, they would achieve their great object. He looked upon the continual interference by the Legislature in matters concerning business as a subject of extreme vexatiousness, and he could not help thinking, when reading the paragraph of that memorable Bath letter which Mr. Disraeli wrote when he spoke of "business harrass," that if there was one business harrassed more than another, it was really the business of a chemist and druggist. Only the other day an unfortunate chemist was fined for selling (what he had sold for years) citrate of magnesia, because of some informality in the designation, and because it did not contain magnesia. It had passed current amongst people under that name just as Schweppe's lemonade, or Day and Martin's blacking, though neither firm contained a Day, nor a Martin, nor a Schweppe. So there had been a tirade against sweet spirits of nitre, and he could not help thinking a poor druggist would be perplexed when a customer asked for drugs by the ordinary names of paregoric, Friar's balsam, or pilcocia, by which names people had been accustomed to ask for them from childhood. He might receive a visit from the inspector, who would at once institute an analysis to prove that the compound known as Friar's balsam was not the compound understood by the name of tincture of Benjamin of the present day. These things were so vexatious and harrassing that he hoped Government would see the necessity of leaving things of that kind alone. It was never intended that such microscopic matters should be gone into, when they could not be prejudicial to either life or health. As an old chemist, it gave him peculiar pleasure in being present as chief magistrate, and meeting many of his old friends holding together, with Mr. Anthony Smith as their president, and also to have the opportunity of congratulating them upon being presided over by so able a gentleman. He asked them to drink the "Health of their worthy President," and coupled with the toast "Success to the Hull Chemists' Association."

Mr. Anthony Smith said he little thought he should have been called upon by his fellow tradesmen to continue in office for another term. There was not the slightest doubt that the Adulteration Act would be a bone of contention, not only between the chemists, but every other class of trades, and the authorities who were appointed to look after them. It was unnecessary for him to say that in Hull there would be no violation of that Act; still he believed that at present it was working so badly that the big fish slipped through the net, while the little ones were caught. If Government would prosecute the manufacturer instead of the retail trader, the Act would work well. But they, as an Association, were bound to watch the working of this Act, and so to protect themselves. If they did so, no doubt they should find, to use a Hibernian metaphor, that the man who dared to tread on the registered palctot of the Chemists' Association would get a crack on the head with a shillalegh.

Mr. Bordass proposed the "Healths of the Vice-President, Secretary, Treasurer, and the Committee."

Mr. F. Earle, in responding as the Vice-President of the Association, thought they must all see the necessity of unity, and one means of effecting this was a more studious attention to the matters which their worthy Mayor had spoken about. The tendency of the present day was to put a considerable amount of oppression on the chemists, and he denounced the Adulteration Act as an insult to their intelligence and honesty. His feeling was that the measure referred to would have to be repealed; and if the Hull Chemists' Association would only move in the matter, and obtain the assistance of other kindred societies, they would succeed in getting it erased from the statute-book.

Mr. C. B. Bell replied as the Hon. Secretary and Treasurer of the Association. This was the sixth time he had had the honour of responding to that toast, and it was a great pleasure to him to think they had so often unanimously elected him to that honourable position. During the past year the Shop Hours' Regulation Bill had occupied the attention of the Committee, and the benefit of such associations as this, spread throughout the length and breadth of England, was shown by the fact that that obnoxious measure had been rejected. That bill would have affected very injuriously the retail trade of the chemists and druggists of the country, and it was with very great pleasure that they received the information that it had been withdrawn. During the next session in all probability petitions would be presented to Parliament in opposition to the Adulteration Act, and it would require the energy and watchfulness of every member of the trade to get the oppressive clauses of that bill expunged. He was glad to inform them that the balance-sheet this year was even more satisfactory than that of the preceding year, for after defraying all expenses there remained a balance in hand of £3 4*s.* 8½*d.* This must be gratifying to the members, as it was specially so to himself, considering that in the preceding year they had a deficit of £2.

Mr. Oldham, in responding for the Committee, said there were many things they ought to attend to, and if they only looked ahead and met more frequently it would be conducive of great benefit to themselves and likewise to all the members of the trade in this town, who did not meet with them as members of this Society. He thought they were hardly sufficiently alive to their own interests, their meetings were not always well attended, and their President and Secretary were not supported as they ought to be. He was glad to see so many members of the trade present, and only hoped that when they met at the next general meeting they would have an accesion to the number of their members.

Alderman Chapman next proposed the "Medical Profession."

Dr. J. H. Gibson observed that in replying to this toast at meetings of this Association he had, like Paganini, always to play upon one string, namely, the relationship between the chemists and the medical profession. He had told them previously how they could carry on those relationships amicably and harmoniously; and he was sure if they all put their shoulders to the wheel it could be done. He, like many of those present, was thoroughly tired of, and disgusted at, the idea of dispensing his own prescriptions; he had been annoyed and disgusted at it for many years; and he had even gone so far as to say that if a dozen others would join him he would not dispense any more medicine. This was done in Liverpool, Manchester, and by the Scotch in Edinburgh, and also in a great measure in Leeds, Bath, Bristol, and other places; and he did not see why it could not be done in Hull. He was sure it would relieve the medical men of a great amount of labour, and of some responsibility. He was very much pleased that this Association had for one of its objects a higher system of education. He believed the chemists had to undergo examinations in materia medica, in botany, and in chemistry. He did not care how strict these examinations were; the stricter the better, because the sooner would the medical profession have confidence in them, and give up that abominable mode of dispensing their own prescriptions. Chemistry was of essential assistance to the practice of medicine. He had only to call to their mind the invention of chloroform. A chemist, and not a medical man, invented it; and though Sir John Simpson led the way in utilizing it, yet the world would never cease to be indebted to the chemist who had given to them the greatest boon of the age (he excepted none) in medicine. So of another medicine —hydrate of chloral—with its wonderful hypnotic

power. They were also indebted to the chemists for the alkaloids. Therefore, he considered the more highly educated the chemist and druggist became, the more rapid would be the advances in chemistry—that was, in special chemistry as it bore upon the art and practice of medicine. He did not mean it as an insult when he said he looked upon them as stokers. The medical men were the engine-drivers, driving a mighty engine. As the practical engine-driver had nothing to do with the construction of his engine, so in the case with the art of medicine. The practitioner had to make use of it in the study of its anatomy, pathology, and physiology, and everything that related to it. They looked to the chemists for the fuel. Now, much had been said about the Adulteration Act, and he must say he was a little at variance with previous speakers on this point. He wished to touch upon it as delicately as possible, but he said it was sinful—outrageous—that medical men should be supplied with adulterated drugs. If they took the trouble to analyse they knew adulterations did exist, and he maintained it was the duty of the chemist to put himself in such a position that if the wholesale chemist or manufacturer placed in his hands an adulterated article he should be able to detect that adulteration. He sincerely sympathized with them in the course which this and other associations had taken. The prosecutors had gone to the wrong people; and not only so, they had not seized upon the proper objects of adulteration. Adulteration did exist; they all knew it did. He read in the *Lancet* the case of a man at Houndsditch who declared that such were the commercial prices of articles kept by the chemists and druggists that they could not afford not to adulterate them. If a man stood up in a vestry meeting and said such a thing as that, they were bound to believe there was something in it. It was a thing that ought to be detected, and, if it existed, ought to be put a stop to. Many drugs were capable of adulteration. For instance, the tinctures made according to the old Pharmacopœia; he thought they should be made according to the British Pharmacopœia. Then, again, East India rhubarb was often sold for Turkey rhubarb; cinchonine was mixed with quinine. Now the medical men wanted a good article. It was not much they prescribed, and they were willing to pay a good price. Therefore, he maintained the Adulteration Act was good in theory, and though it might want amendment it should not be expunged from our legislative enactments. Experience would show that it required revising, and perhaps re-modelling; but he believed if it were properly re-modelled and put in force it would be a great boon to the people of this country. Soon in that town they would have to appoint a public analyst, and he hoped there would be found some amongst that association who would feel themselves competent to take such a position.

Mr. A. Pickering proposed "The Pharmaceutical Society of Great Britain," in doing which he said he had called in question many of the proceedings in connection with that body, and he contended they had not done their duty in accordance with the charter granted them for the extension of pharmaceutical education. The first clause of that charter stated that the Society was incorporated for the express purpose of promoting pharmacy and chemistry, in especial relation to the trade in which they were engaged. But when he found that they possessed an income exceeding £10,000 a year, and that during the past year they had, in the fulness of their hearts, only granted the sum of £10 for the advancement of provincial pharmaceutical education, he must say he could not accord to them any great amount of anxiety to promote the welfare of the pharmaceutical chemists of the country. He did not begrudge a farthing that had been spent for the extension of the School of Pharmacy in Bloomsbury Square; but he did think that, whilst investing in the three per cent. consols two or three thousands a year, and granting only £10 for the spread of pharmaceutical education in the provinces, they had failed in their duty. At the same time he was not prepared to say they had done nothing to advance the interest of pharmacy and chemistry. He believed they had been, and would continue to be, a power for good; but it was within their power to be instrumental in doing more good than they had done hitherto. He referred to the case tried only a few days ago at Westminster, in which the magistrate and lawyers were totally devoid of scientific education, and it was only when Mr. Umney, the manager of Messrs. Herring and Co's laboratory in Aldersgate Street, as well as one of the examiners of the Pharmaceutical Society, was called in, that they could arrive at any solution of the difficulty. Dr. Dupré, the analyst of the Westminster Board, wrote on a piece of paper "4 oz. *spiritus ætheris nitrosi*," and gave it to a policeman, who took it to a medical man keeping an open shop, and asked for 4 oz. of sweet nitre, as the old people were in the habit of calling it. Dr. Dupré's assistant analysed it, and pronounced it deficient in nitrous ether; and on information being furnished to the Board, summonses were issued not only against this unfortunate medical man, but also against several chemists in London. What was the result? The Court got into a glorious muddle, and it was only when Mr. Umney was called in, and explained the difference between the spirit of nitrous ether of the British Pharmacopœia and the sweet spirit of nitre of the London Pharmacopœia, that the judge was able to understand the question brought before him. Had the British Pharmacopœia of 1864 been prepared by practical men, they never would have been so foolish as to stake their reputation by giving a formula for the preparation of spirit of nitrous ether from nitrite of soda, when they knew such a thing could not exist. He would say that the spirit of nitric ether of the London Pharmacopœia was a preparation which had given satisfaction to the public and the profession, whereas the spirit of nitrous ether of the British Pharmacopœia of 1867 was an unchemical preparation, that it would not keep, that it was liable to decompose in a very short time, that it was unsatisfactory in its character and effects. It was unsatisfactory for the chemist as well as for the medical man. He maintained that the committee which the College of Physicians employed in preparing their Pharmacopœia should comprise practical pharmacists as well as scientific chemists. He was not surprised that judges gave such extraordinary verdicts as that returned in McDermott's case, who was fined £10 for selling an article known by the public as citrate of magnesia. Had the judge in that case possessed chemical knowledge, or had the assistance of a man like Mr. Umney to explain its composition, he never would have given so unjust a decision. A great deal of unjust and untruthful clamour had been raised in the country by the prosecutions undertaken under the Adulterations of Food and Drugs Act, and by the untruthful articles which had appeared in some of the medical journals. As a member of the trade for forty years, he solemnly pledged his honour, and staked his reputation there, and denied that there was an organized system of adulteration in the country. A pharmaceutical chemist would scorn to send to a patient any drug that was not strictly and faithfully in accordance with a prescription.

Mr. C. B. Bell regretted the absence of Mr. James Baynes, who, had he been present, would, as a member of the Council of the Pharmaceutical Society, have been enabled to reply to the remarks of the last speaker. He agreed that the funds of that Society had not been invested to the best advantage. With regard to education, the Council of the Society had a difficult and laborious task, and if this were remembered, they would not be so free to stigmatise them as they frequently did. Certain members of the Council had reflected on the conduct of the local secretaries as being lax. With regard to Hull, he might say that during the eighteen months he had held that position—and he was sure he could speak for Mr. Earle, who had preceded him—he had discharged the duties to the best of his ability, and he believed to the satisfaction of the Pharmaceutical Society. He com-

plained of the tardiness of the Society in forwarding the printed instructions connected with the examinations, and contended there was not the slightest ground for imputation against Hull.

The chairman proposed the "Healths of the Lecturers," alluding to the great assistance rendered by Mr. Niven in the botanical class, and by Mr. Parson in materia medica.

Mr. Niven and Mr. Parson acknowledged the compliment, and after a few other toasts the company separated.

SOCIETY OF ARTS.

On the Energies of the Imponderables, with especial reference to the Measurement and Utilization of them.*

BY THE REV. ARTHUR RIGG, M.A.

Lecture VI.

The Energy of Light, especially with reference to the Measurement and Utilization of it.

The energy of light is all-pervading. Wherever life is there this energy is. Darkness, or absence of light, is another name for death. That our knowledge of the mode in which this energy acts is "cabined, cribbed, confined," there can be no doubt. It has however, an extended influence; indeed, there is reason to infer that it has an actual active kinetic power which may be described as enormous, even when separated from its usual allies, heat and actinism. The very small area of explored light-land only serves to assure us by its embarrassment of rich energies that in respect to light there are not only as great, but even greater developments to be made, than have yet taken place in any of the "imponderables."

The animal, vegetable, and mineral kingdoms; solid, liquid, and gaseous matter, each, in some form or other, admits of the energetic action of what passes under the general name of light. Such universal consent to the power of light, which recent science-investigations seem now, for the first time in the history of the human race, to be making known, is rendering a spontaneous but somewhat unconscious and undesigned testimony to the truths of Scripture. In the first chapter of the book of Genesis, and at the third verse, we read that the very first act of creation is light—"Let there be light." It must be admitted as singular, very singular indeed, that that old book—the Bible—about which some men cavil, should have had written in it of events occuring, say, 6,000 years ago (six million years ago, if you please), that which science-investigation of the last 50 or 100 years has only made clear to all who read. Strange that this, "offspring of Heaven first born," without which no life can even now be sustained in healthy vigour, should have been formed in the fullness of energy before revelation asserts that life was. The strangeness ceases when the religious faith in inspiration enters.

Before this lecture is closed the conclusions and illustrations, if successful, will prove that, whilst this energy is less comprehended, and, if possible, more perplexingly mysterious than even the energy of affinity, it is nevertheless one whose presence is for vigorous action. Even the conducting power of bodies for electricity have within the last few months been shown to be so connected as to be influenced by light.

It is not in my power to produce the experiment, but it may be stated that if a small bar of selenium—say two inches long, and one eighth of an inch diameter—have its ends electrically connected with a galvanometer, then the speck moves as light shines upon or is excluded from the bar.

The sources of this energy are the sun, the stars, and meteors, which in some way unknown to us, setting aside the theory of luminous heat consequent upon atmospheric friction, are self-luminous.

There is no similar self-luminosity on earth. If it be wished to obtain light from other and accessible sources it is done by extraneous agencies. Heat caused either by affinity, electricity, or mechanical means, or by a concentration of the energies of some self-luminous source, is the way by which we usually produce light.

This process of production by concentration from self-luminous sources, although generally adopted, is very unpromising as a means for ascertaining the energies of such source-produced light. For this reason—as the light passes through or is reflected from the bodies employed in the concentrating operation, the extent or degree in which this energy may have been expended in chemical or physical work within or upon the concentrating body cannot be ascertained. Hence the remaining work—be it represented chemically or mechanically—is all that is left for investigation. It represents but the balance of the account. Now as a coin so small as one shilling may represent the balance of two accounts, neither of which reaches one pound, so the same coin may represent a balance of accounts reaching many thousand pounds. Clearly, then, from this remaining work no inference can be drawn respecting the total of the energies involved in the production of such a balance.

The energy of light varies with the source from which it originates. In some respects, viz., as regards heat and light, properly so called, the energetic elements in what we call the electric light are more similar to those in the sun than any from other lights within our means of artificial production; in another respect, viz., chemism, or actinism, the energy of that from the combustion of magnesium is nearer to solar light than is the electric.

There are two lights which seem to have in themselves no traces of an energy producing effects on any of our appliances. They are the result of some unknown and as yet unappreciated energy. These are lights due to phosphorescence and fluorescence.

The decay of what was once possessed of the energy of vitality is a condition manifesting phosphorescence, a state in which light is without much (if any) heat. Whether the light on being given out is the result of some new operation of what was once called the vital principle, or whether it is a consequence of some elements of affinity approximating in character to those we call combustion, is an unsolved problem. Friction and the passage from a formless state to the state of crystal frequently cause a phosphorescent light to be emitted.

Phosphorescence is a name also given to a mode of obtaining light which seems to depend upon the property that certain bodies possess of rapidly concentrating within themselves the light they may receive from being exposed in the neighbourhood of a luminous body, and then emitting this absorbed light gradually. Probably the light stored up in a few seconds is not emitted in less than minutes.

Diamonds and other substances shine in the dark for a short time, after exposure to intense light. This shining of certain crystals, in the absence of light, probably led to the opinion that such crystals were living beings, petrified by light in the hands of men. Certain flowers, especially those with bright *yellow* petals, sometimes emit a sudden flashing light a little after sunset; also, some plants growing in mines emit light from their whole surface. Certain preparations continue to emit this light so intensely and continuously as to be used as night lights—not for illuminating rooms, but for such purposes as reading the hands of a watch.

There are in this box a series of tubes which, doubtless, appear to all of you, at the present time, perfectly white. If, however, we allow an intense light to shine upon them they are seen to possess a phosphorescence that will last for some time—from ten minutes to half-an-hour, as the case may be. This magnesium lamp shall be lighted, and

* Cantor Lecture, delivered March 10, 1873; reprinted from the *Journal of the Society of Arts*.

the tubes exposed to its rays for a short time, and you will see, not only the simple phosphorescence, but different colours which the contents of each tube assume.

Fluorescence is a peculiar appearance consequent upon placing some substances in certain positions with respect to light. This may be illustrated by the action of light upon sulphate of quinine. In this bottle is what appears as pure colourless water; it is a very weak solution of sulphate of quinine. If looked at in the presence of light rich in actinic rays, a change in the appearance is observed. A piece of magnesium ribbon is now lighted. In certain angular positions a beautiful azure blue may be noticed; this blue is a consequence of those phenomena called fluorescent. These, phosphorescence and fluorescence, are two characteristics of the energy of light, of which all we know is that we can render no account of the causes of them, unless the theoretical explanation be accepted that the two may be classed as one—by regarding them as consequences of an alteration in certain wave lengths in portions of the entire beam of light. From the previous statements it may be inferred that the measurements of the energies of light are not yet accomplished; also, that two lights, which to the eyes do not differ much in intensity, or in what some might call power, yet may show very different energies. It must be borne in mind that here, as in electricity, intensity is not energy; there may be great intensity and little energy.

The great source of light is the sun, and whatever may be the speculations of science, either as to the cause of that light, or as to the mode in which it is propagated from the sun and received at the earth, they do not concern us at present. What we are concerned with is, how are the energies of the light thus received, and of such artificial lights as are utilized, to be measured?

A reference to the diagram of the spectrum may explain what is manifested by an analysis of solar light. Observe, there is shown in this spectrum heat, light, and actinism, or chemism, as it is sometimes called. The spectrum visible to us is the part thereon coloured, containing the usual prismatic colours: red, orange, yellow, green, blue, indigo, and violet; therefore, the light, properly so called, and which is utilized by human eyes for vision, extends from the letter A to the letter H and no further, and any energy consequent upon the state which occurs before the letter A, and any energy consequent upon the state beyond the letter H, is not the energy of light properly so called. Now, to the left of the letter A, extending over a space which bears a proportion to light, about half as long again as light, is a space containing the energy due to heat. To our right, beyond the letter H, extending to a distance longer than that of light, we have a space in which photographers and chemists delight. Chemists can get nothing out of this dark end to our left, except heat, and chemists and photographers get nothing out of that dark end to our right except chemical action. The intensity of heat lies here, just before we reach light at all; and the intensity of chemical action lies there, just after we get beyond the light. No scientific investigation has yet detached the energy of light and its intensity from these two energies with which it is associated. At this line, marked D on the diagram, it will be noticed that those curves, indicating heat and actinism, die out. The one seems to be passing into the other. At D is what mathematicians might name a "cusp"—a zero on the scale similar to that zero in the arithmetical tables which may be said to mark the turn between counting by integers to the left, and by decimals to the right. At D is this dead blank for heat and actinism, and yet it is there the energy of light really lies. Before the end of the lecture something more should be said about the energy of light at this particular point. Amongst these three constituents of a solar beam—heat, light, and actinism—there are several marked and extraordinary differences, yet we call them all "light." For instance, heat causes bodies to expand, but heat fails to make an impression upon the retina. Professor Tyndall, some years ago, put his eye into the focus of a heat beam where platinum was melted, and it produced no impression upon the eye. In his account of the experiment he says he did it, but he does not advise anybody else to do it—a piece of advice likely to be more generally accepted than advice usually is. This shows that heat fails to make an impression upon the retina. Heat also fails to produce any photographic result; heat can be conducted along metals, and heat can cause organic and inorganic bodies to expand.

Light, properly so called, possesses these qualities. It makes an impression upon the retina, it effects changes in organic bodies, and probably (in some way mysterious to us) in inorganic bodies also. Light does not possess these qualities—it cannot be conducted by metals, it cannot cause bodies to expand. Now, as to actinism or chemism, it possesses these qualities—it produces photographic results and chemical changes in organic as well as in inorganic bodies. It does not possess these qualities—it fails in making an impression on the retina, it cannot be conducted by metals, and it cannot cause bodies to expand. Hence there seem to be properties in each portion of the spectrum which do not exist in the other; therefore in the comprehensive term—light—there are three distinct elements, and it is really an error to write them under the one name light. Great would be the social misunderstandings if, because wheat, barley, and oats, are all called corn, or grasses, these general terms were as constantly applied to them as the term light is to phenomena with which it is associated, but not connected.

There is also another form in which the energy of light is presented, *i.e.*, in its penetrative power.

For lamps and lighthouses this penetrative power is all important. Certain substances in combustion are possessed of this power in a much higher degree than other substances. It is not, however, only in the material burnt, but further in the mode of burning, that this penetrative power is manifested. The same substances under different conditions manifest very different energies in the emission of light to a distance.

Even the ordinary paraffin lamps—how very inferior in illuminating power some are to others. The utilization of the energy in the one and only way in which it can be utilized without waste is well illustrated in the various constructions for the burning of different hydrocarbons, to which time forbids further reference. Many present are aware of the different schemes now before the public for obtaining both light and heat from the combustion of the hydrocarbons.

But it is not in liquids only that this difference exists. Even the same quantities of gas—*i.e.*, of a suitable gas—one containing such an element as carbon under different circumstances, yield lights of marvellously different penetrative power.

(To be continued.)

Parliamentary and Law Proceedings.

Prosecution Under the Adulteration Act. Alleged Adulteration of Meal.

At the Greenock Police Court, on Dec. 13, a grocer was charged under the Adulteration Act with selling oatmeal adulterated with barley meal. The case was adjourned for a week, to give the defendant an opportunity of having a portion of the sample analysed by another analyst.

The Masters and Servants Act.

At the Guildhall Police Court, on Wednesday, Dec. 17, Mr. Holmes Keall, a chemist and druggist of Maida-vale, was summoned by Mr. James Crisp, of No. 4, Cheapside, chemist and druggist, his former employer, for breach of contract under the Masters and Servants Act.

Mr. Poland appeared for the complainant, and Mr. H. N. Christmas for the defendant.

Mr. Keall had been an assistant to Mr. Crisp for about

two years on the usual terms of a month's notice, his salary being £60 per annum with board and lodging. On the 9th September the defendant asked leave to go out for a short time, and received permission from Mr. Crisp to do so. It appeared that his object in going out was to purchase a business at Maida-vale, which he succeeded in doing. When he returned, he told Mr. Crisp what he had done, and asked to be allowed to leave forthwith. Mr. Crisp refused to allow him to do so, but said he would let him go as soon as he could get another assistant in his place. The defendant told him that he could not stay, as he had to take possession of the business the next night; but he offered to give up one month's salary to terminate the engagement, in lieu of one month's notice. Mr. Crisp declined that offer, and threatened proceedings against him if he left without the month's notice. He did eave without that notice, and twice afterwards applied for the salary due to him from the 30th of June to the 9th of September, less £5, for one month's notice. The money was not paid, and on the 29th November Mr. Keall took out a summons in the County Court against Mr. Crisp for the amount, and on the 10th of December Mr. Crisp obtained this summons against the defendant. The County Court summons would not be heard until the 22nd instant. Mr. Crisp deposed that the custom was a month's notice on either side, unless mutually arranged to waive all such rights; and Mr. Keall stated that either party could terminate the engagement at a moment's notice on giving the other side a month's wages.

Mr. Christmas took a legal objection to the summons under the third section of the Act, which said, "Nothing in this Act shall apply to any contract of service other than a contract within the meaning of the enactments described in the first schedule to this Act;" and there was nothing in that schedule which mentioned chemists' assistants. They did not come under the head of artificer or labourer, but were in the position of clerks, to whom this Act did not apply.

Mr. Poland contended that although a skilled man, in the shop he was only an ordinary shopman, and as such he contended that the Act did apply to him under the head "servant," although that term did not apply to domestic servants and clerks.

Sir Thomas White said he had given the greatest consideration to the case in consequence of its importance, and he had come to the conclusion that there was no doubt the defendant did not come within the Masters and Servants Act, and he must therefore dismiss the summons; at the same time he had no doubt that the defendant had acted very improperly to his master.

Mr. Poland said he would ask that the judgment of the court might be respited for a week to give him time to consult his client as to whether he would ask for a case for the superior court, so as to obtain a definition as to who really was a servant under the Masters and Servants Act.

Sir Thomas White said it was a most important question, and he would give every facility for taking the opinion of a superior court. He would therefore adjourn the case for a week, when if the plaintiff decided not to have a case stated the summons would be dismissed.—*Daily News.*

Reviews.

MILK ANALYSIS; a Practical Treatise on Milk and its derivatives, Cream, Butter, and Cheese: by ALFRED WANKLYN, M.R.C.S.

An excellent little treatise as welcome to the chemical public as was the 'Water Analysis,' published by the same author (jointly with the late Mr. Chapman) some years ago; equally clear and straightforward in its statements, and also, like that treatise, everywhere bearing the marks of extensive experience in the subject on hand, but, at the same time, equally dogmatic and dictatorial. In the book before us, in fact, the author simply "lays down the law," without looking to the right hand or to the left. But, after all, perhaps we ought not to find fault with him for that: the author's colleagues will look in the book for nothing but *Mr. Wanklyn's* methods and *his* way of interpreting results, while the general Demos of "chemists" are all the better to have it simply told them what they have to do. Now let us pass to reviewing.

What we inhabitants of large cities buy and drink as "milk"—as everybody knows—is, in general, not what it pretends to be, but consists largely of water, mixed with more or less of what would be real cows' milk, if it had not been previously skimmed. Other adulterations, as our author states as the result of his extensive experience, scarcely ever occur. They would either not pay or be too easily detected. Thus all that the milk analyst, as a rule, has to do is to find out the relative quantity of cream taken away and the amount of water added by the salesman when he mixed the article. But here we at once meet with a difficulty: what *is* the composition of "*normal*" milk? The author's answer is: Cows' milk is a mixture of—we all know what—constituents, the relative proportions of which vary only within very narrow limits. "The milk of an animal has probably very much the same constancy of composition as the blood of the animal." Now that is putting it rather strongly, and, even if considerably toned down, would be contrary to what other authorities give as *their* experience. But be it as it may, the only correct way of interpreting the results of a milk analysis is first of all to ascertain the average composition of true cows' milk of the respective district, then to take such average milk as one's standard, and, for the "milk" under examination, to ascertain the weight of fat that would have to be added to, and the weight of water that would have to be eliminated from it, in order to bring it up to the ideal standard.

To determine these quantities we must evidently ascertain the relative quantities of at least two of the constituents, say of fat and sugar, or fat and casein, or fat and "solids not fat." Supposing, for a moment, the solid constituent of milk (*i.e.* the sum total of what is not water) was a complex of constant composition, and the practice of "skimming" did not prevail, then the amount of water added might, perhaps, be ascertained, with a sufficient degree of accuracy, by means of a good hydrometer. But, unfortunately, skimming *is* practised along with watering, so that, in commercial milk at any rate, the ratio of fat to "solids not fat" is eminently variable, and of these two constituents the first diminishes while the second increases the density. Hence the "lactometer," although it is extensively used, is a treacherous instrument, says our author, and we think he is right. Regarding another instrument, which pretends to determine the percentage of fat in a milk from its relative opacity, the author says he has no experience. We happen to be in a position to supply some information on this point. According to our experience, which is founded upon a series of comparative determinations of fat in different milks, by means of the instrument in question on the one hand, and exact chemical means on the other, the apparatus is absolutely useless. The "*cremometer*" (a graduated cylinder in which the milk is allowed to stand until the cream has gone up, the volume of which is then read off) would *prima facie* appear to be of some value, but according to Mr. Wanklyn is, like the "lactometer," at best, a "treacherous guide."*

In short: A reliable analysis of milk can be effected only by *chemical* methods. A full analysis, however, is not necessary; it suffices to determine the fat and total

* Possibly the indications of the cremometer might be rendered more constant by saturating the milk with sulphate of soda before setting it aside; at any rate, the cream would then separate out more completely.

solids, or at most these and the milk-sugar, casein, and salts.

For all these determinations the author gives short, elegant, and easy methods, which, according to his experience, lead to exact or at any rate constant results; and he describes these methods with such admirable clearness, that any person who has the slightest experience in quantitative work should be able to execute them.

For the determination of the total solids, the author simply evaporates 5 c.c. of the milk to apparent dryness in a platinum dish over a water-bath, exposes the residue to the heat of the bath for a definite number of hours (found by experience to suffice for the complete expulsion of the water) and weighs the residue. The customary addition of sand or plaster of paris, according to Mr. Wanklyn's experience, is a needless complication of the process. To determine the fat, the solids from a somewhat larger known volume of the milk are treated with ether; the ether is expelled by evaporation, and the remaining fat dried and weighed. From what the ether left, alcohol extracts the sugar, leaving the "casein" (*i.e.*, the sum total of nitrogeneous constituents) and the salts, which are first weighed jointly, whereupon the salts are obtained for themselves by incineration and weighed. The well-known titrimetric method of determining sugar by ascertaining the quantity of cupric oxide which it is capable of reducing to cuprous oxide, finds no favour with our author. We venture to think that if he would only take the trouble of making himself familiar with this method he would be sure to adopt it. For the determination of the "casein" Mr. Wanklyn has quite a peculiar process, which, if we understand him rightly, he considers quite as good as the direct gravimetric method:—He distils the milk with *largely diluted* permanganate and alkali, determines in the distillate the ammonia formed, colorimetrically, by means of Nessler's reagent, and from the results—and by means of constants empirically determined by him—calculates the quantity sought.

The fat and "solids not fat," according to the author, are the safest elements for the calculation of the fat skimmed off (as cream), and water added, to what served to make 100 c.c. of the "milk analysed," supposing the maker to have started with "standard milk." To make things easy the author gives the necessary formulæ, and explains them so clearly that even a person who has no knowledge of algebra is able to see through and work them. Speaking of these formulæ, we will direct the attention of the author to the fact that his way of grouping together the several terms of an arithmetical expression—though quite correct—is contrary to usage, and apt to lead to mis-reading. Thus, for instance, the formula at the head of the last column in the table on page 42 would be improved by transforming it from

$$100 - \frac{100}{9{\cdot}3}\,a + \frac{3{\cdot}2}{9{\cdot}3}\,a - b \text{ into}$$

$$100 - b - \frac{a}{9{\cdot}3}\,(100 - 3{\cdot}2).$$

This formula, by the way, is mis-printed on page 40.

After the division on milk there follow shorter chapters on cream, butter, and cheese. Regarding these we should like to say a few words, but prefer here to close, the more willingly as, no doubt, all those of our readers who take an interest in the subject will possess themselves of a book which at present is, and for some time will be, *the* book on the branch of applied analysis it treats of.

Waste Products and Undeveloped Substances: A Synopsis of Progress made in their Economic Utilization during the last Quarter of a Century at Home and Abroad. By P. L. Simmonds. London: R. Hardwicke. 1873.

The aphorism of Lord Palmerston, that dirt is but matter in a wrong place will well bear extension, so as to include "waste," and no small portion of recent chemical investigation has been devoted to the task of putting such errant matter into a right place. Probably in no other twenty-five years of the world's history has so much of this kind of work been accomplished as during the last quarter of a century, and in no country more than in Great Britain. The subject is one to which the author is known to have paid considerable attention, he having read two or three papers before the Society of Arts, and published a former volume on Waste. When, therefore, it was decided by the authorities of the Vienna International Exhibition to set apart a special section where each exhibiting country might show what advancement it had made in this direction since the year 1851, it was only natural that the British Commission should invite Mr. Simmonds to form a representative collection for this country, and it is just as natural—according to modern custom—that a book should be the outcome of his work.

But we heartily wish the book had been a better one. Even the author's modest estimate of himself—surely too modest if it be true that hints and suggestions formerly thrown out by him "have led to the establishment of many great and profitable industries"—as but a "gatherer and disposer of other men's goods," which he endeavours to "classify and arrange systematically," is one that would hardly find a basis in the present work. Wealth of material is certainly present, but arrangement and critical supervision, in our opinion, are not. Some facts are stated, and restated more than once, yet not with the effect of impressing them upon the reader's mind, but rather of bewildering him; for they are so surrounded with a sea of verbiage, that

"Apparent rari nantes in gurgite vasto."

"Prevention is better than cure"; and the economy of unsoiled paper is surely as much a duty as the utilization of that which has been stained by printer's ink.

To illustrate our meaning, we may remark that at the commencement of the volume appears what the Archduke Regnier had to say upon the general subject of waste, followed by extracts from Lyon Playfair, the *Commercial Bulletin*, the *Times*, the *Telegraph*, the *Saturday Review*, etc., each quotation made with a special object, doubtless, but not being confined to the illustration of that particular point they involve frequent repetition. As to the arrangement, the division "Animal Wastes," commences with offal, including bones; passes to the economic uses of dead animals, horse-flesh as food, etc.; next to waste in the silk manufacture; waste hair; and then comes back to the utilization of blood, bladders, guts, etc. (surely offal); next to leather clippings, and then to bones again, past woollen rags, to silk waste again.

Much of this results from the freedom with which the author appropriates "other men's goods;" collation and condensation of these extracts would have multiplied their value. But when the author speaks for himself he occasionally makes astonishing statements. "So long as bones are a substitute for lime in agriculture, and it is cheaper to dissolve or grind them than to quarry limestone, crush it, and carry it to the land, so long only will they be thus used" (p. 11), and "Cod-liver oil and chloral hydrate are on the wane" (p. 74) are statements that have surprised us; whilst "tartaric acid of potash," "saponification with sulphuric acid," "sulphate," and "bisulphate of carbon," and "a most beautiful white carbonate of potash of great strength" are terms that one does not meet very often.

But, though quarrelling with the style, we do not despise the matter of the book, nor would we wish to mislead the reader as to its value. It contains an immense variety of information upon various products, sometimes outside even the wide range of the title; information, too, that is not to be met with in many places. It would be useless to give one division preference over the others, but that which relates to waste products of the fisheries is very suggestive. The following extract gives an account of a new source of lamp-black of which few probably of our readers have heard:—

"A few years ago a party of gentlemen started what they intended to be an oil-well, near Cumberland, Maryland. They soon, however, were disappointed in their expectation, for instead of striking oil, they came upon a gas-chamber. A short time afterwards the emitting gas was accidentally set on fire, and continued to burn for a period of two years. About a year ago Mr. Haworth, a gentleman from Boston, having heard of the burning well, went to Cumberland, tested the quality of the gas, and was satisfied that he could put into operation a scheme or plan of his own for the manufacture of carbon (lamp-black) from the gas. Accordingly, the well was leased or purchased, and a patent obtained for the manufacture, according to the plan of Mr. Haworth. A building was constructed and the manufacture commenced. There are now in operation six hundred and sixty burners, each burner consuming eight cubic feet per hour. The gas is allowed to burn against soapstone plates, on which the carbon is deposited in the form of soot. By a very neat mechanical arrangement, the soot is scraped off and deposited in large tin boxes about three feet long, a foot and a half wide, and a foot and a half deep; scrapers are passed along the soapstone plates every twenty minutes, and the boxes are filled on their fourth passage. A large building is now in course of construction, twice the size of the present one, which will have in use thirteen hundred and twenty eight-feet gas-burners. The present consumption of gas amounts to about one-twelfth of the whole quantity escaping from the well. When the new building is completed, and the burners put in operation, the total consumption of gas, by the burners of both buildings, will be one-fourth of the whole. The carbon is used for the manufacture of ink."

Obituary.

Notice has been received of the death of the following:—

On the 8th December, 1873, from disease of the heart, Mr. W. Christopher, Pharmaceutical Chemist, of Crickhowell, Brecknockshire, aged 56 years. Mr. Christopher was one of the Founders of the Pharmaceutical Society, and formerly acted as its Local Secretary.

On the 11th December, 1873, Mr. James Atkinson, Chemist and Druggist, of Norton, near Malton, Yorkshire.

On the 13th December, 1873, at Canterbury, Mr. John Thomas Linford, aged 82 years. Mr. Linford was in business in Canterbury from 1819 to 1842, and afterwards in London, with his son, from 1859 to 1864.

Notes and Queries.

[376.] PILL COATINGS.—Can any reader kindly favour me with the best mode of varnishing pills, and also of preparing the opaque white coating so much in use now.—NOTA BENE.

[**** See some remarks upon this subject which occur in a paper by Mr. Haselden, PHARM. JOURN. (3), vol. ii., p. 467.—ED. PH. J.]

[377.] OBSCURE FORMULÆ.—Can any correspondent inform me where I shall find the formulæ of any of the following:—"*Tinct. Testæ*," "*Pil. Aloes Glacial*," "*Gutt. Buchu*," "*Pil. Philippi*." They have come under my notice within a few weeks' time in a chemist's establishment in London. I cannot find them in any Pharmacopœia, and therefore can only conclude that they are written by some of the noted London quacks. They have, however, fallen into the hands of very respectable people, and I am anxious to know where to find the formulæ of them, and other such preparations, if they are published anywhere, or if known generally to London chemists.—AN M. P. S. FROM THE COUNTRY.

[**** If these formulæ be all not of the "Philippic" order, perhaps some of our readers may be able to give the information asked for.—ED. PH. J.]

QUININE PILL MASS.—M. Berquier of Provins publishes (*Répertoire de Pharmacie*, N.S., i. 630) the following formula for a quinine pill mass:—

Sulphate of Quinine	30 grams.
Pulverized Gum	5 „
Pure Glycerine	10 „

Suspend the gum in the glycerine, then incorporate the sulphate of quinine, rubbing the ingredients well together in a mortar. A white mass of good pilular consistence is thus produced, which may be divided and rolled as wanted. The mass should weigh exactly 45 grams, or one-and-a-half times the weight of the sulphate of quinine employed, so that it is easy to calculate any desired quantity. Thebaic extract, or any other substance, may be readily introduced. Pills prepared thus are small, and do not harden so as to become more or less insoluble in the stomach. The mass may be kept indefinitely, and if at length it should lose a little of its malleability, a few strokes of the pestle will soften it without any addition.

ADULTERATION OF LYCOPODIUM.—M. Paul Cazeneuve states (*Répertoire de Pharmacie*, N.S., i. 630) that he has been supplied with a quantity of pine pollen in the place of lycopodium. Having had his suspicions aroused by the yellower colour, and smaller degree of mobility and fineness, he examined it under the microscope, and recognized in it the characters given as those of pollen of conifers, and especially of pine pollen, this latter being always constituted by two lateral cells near to a central cell, which is ruptured by the pollenic contents for fecundation. How this pollen is collected is matter for conjecture, but it may be obtained at a lower price than lycopodium, and M. Cazeneuve thinks it to be a substance worthy of further investigation. He has found that in the rolling of pills and plasters and the healing of chaps, etc., it presents the same advantages as lycopodium. It is nearly neutral; the tegumentary membrane has the cellulose nature of other pollens; it contains a little resinous matter, and the pine odour is faintly perceptible in a large quantity. The proportion of mineral matter is very small. One gram of pollen, dried in a water-bath gave, when incinerated, 45 milligrams of white ash, composed of phosphates of potash and lime, and traces of sulphates and chlorides.

LIQUEFACTION OF GASES BY MEANS OF CHARCOAL.—M. Melsens describes (*Comptes Rendus*, lxxvii. 781) a method by which gases may be readily liquefied for the illustration of lectures. Charcoal placed in the longer branch of a tube bent like a siphon is saturated with dry chlorine; the charcoal will thus absorb about its own weight of chlorine. The longer branch, containing the charcoal, is to be heated in a water-bath, at 100° C.; if the shorter branch be then plunged into a freezing mixture, a considerable quantity of chlorine leaves the charcoal and reassumes the gaseous state, but under the influence of the pressure which is developed is liquefied in the short cool branch of the tube. When the tube is removed from the water-bath the liquid chlorine enters spontaneously into ebullition, and is again condensed by the charcoal, while the shorter branch is covered with a kind of rime. A repetition of these phenomena may be caused indefinitely. The author has in this manner obtained several cubic centimetres of pure liquid chlorine, and he has also succeeded in liquefying, with a temperature not exceeding 100° C., ammonia, sulphurous acid, sulphydric acid, hydrobromic acid, chloride of ethyl, and cyanogen.

The Position of a Widow under the Pharmacy Act.

Sir,—The present discussion on the above subject is not only an interesting, but a highly important one. There is a matter which illustrates the absurdity of the present law and which I greatly wonder has not been alluded to.

I understand Mr. Flux's exposition of the law to be this. If I leave my business to my widow for her support and sole benefit she would not be allowed to continue it as my widow, even with the aid of a duly qualified assistant. And yet, during my lifetime, the law will allow me to open a hundred shops anywhere, in a hundred different towns if I choose, and carry them all on with the aid of *non-qualified men*. Residing in Manchester, the law will allow me to open a branch establishment in Birmingham, and place it under the superintendence of a raw apprentice, who may dispense and sell poisons to any extent without let or hindrance, if only the business is my own *bonâ fide* property, and the apprentice my own *bonâ fide* servant. I am not sure that I should be compelled even to put my own name over the door.

I submit that, in view of these facts, the case of the widow is hard in the extreme, and the law absurd in the extreme.

J. T. Slugg.

Manchester, Dec. 13th, 1873.

"Pharmaceutical Chemist by Examination."

Sir,—Will you permit me a word of comment on that portion of Messrs. Flux's letter, published in the Journal for Dec. 6, which relates to the use of the title "Pharmaceutical Chemist (by examination)."

Why should this distinction, corresponding, as it does, to a real and actual difference, be branded as a misdescription?

If it be permitted to an M.D. (Lond.) so to distinguish himself from the graduate, in the same degree, of some less eminent seat of learning, why should it be forbidden to draw the line between those pharmaceutical chemists who have, and those who have not, passed the ordeal of examination.

Amongst the motives which impel a man to present himself for the Major Examination, one of the most reasonable and natural is, that by passing it he may establish a surer claim to the confidence of his customers; but if no means exist for readily acquainting them of the fact, this aim is totally defeated.

Some more compendious expression may, I admit, be substituted, with advantage, for the present clumsy expedient; but while the need for maintaining a high standard of pharmaceutical knowledge is so strong and so widely felt, it must be unwise to weaken, in the least degree, the incentives to its attainment.

A Pharmaceutical Chemist (by examination).

Local Secretaries and Preliminary Examination.

Sir,—The question of Local Secretaries generally or individually, whether they perform their duties conscientiously and well, is a matter apparently resting with themselves; but, in my opinion, they do not all carry out the strict letter of the law—indeed, it would be a wonderful brotherhood if such were the case. The Preliminary Examination seems to be a source for continual correspondence and fraternal commiseration. That there are so many failures in the Minor Examination every month, I am led to believe is due to a great extent to the Preliminary being passed, or got through, through incoherent supervision, or "cram," I truly hope those local secretaries who have done their duty to the Society and candidates will not feel my remarks as touching them; but still, I know there are stray sheep here and there who require shepherding up, and whose consciences want pricking occasionally. There are many of our local secretaries who have sons, one of which, at any rate, we hope to see join the pharmaceutical profession, also a friend or customer may have a son anxious to join our ranks, I think, with all due deference to most of our worthy local secretaries' strict sense of duty, their paternal, or amicable feeling may in these cases sometimes overcome duty.

These are merely objections which could be raised to one party being left alone to watch the interests of the Pharmaceutical Society, and to do the candidate justice. It may be out of place for me to propose anything, but still, I am entitled to an opinion, and I most decidedly think that the following, put in the form of a proposition, would remedy the present unsatisfactory manner of conducting the Preliminary Examination in the Provinces:—

1st. That a special secretary be appointed for each county, and that secretary to reside in the central or chief town in such county, and that he be called the county secretary.

2nd. That any Pharmaceutical Chemist or Member of the Society residing in such town shall be eligible to be elected such county secretary, and that he shall be voted for by the local secretaries.

3rd. That all candidates for the Preliminary Examination shall attend such town at such an hour as the Board of Examiners shall think fit, for the purpose of answering such questions as are put before them, in writing, etc.

4th. That the Examination shall be under the supervision of the county secretary and three or more of the local secretaries, who shall be summoned to attend by the Board of Examiners, and that their (the local secretaries') expenses shall be paid by the Society.

This would, I think, facilitate a fair and impartial return from the country, which is impossible under the present circumstances. It would prevent the unseating of local secretaries, they would have further honour in being called upon to vote for a county secretary, and by occasionally meeting a few brothers at the examinations; it would also prevent the candidates being at the expense of attending 17, Bloomsbury Square, which has, I believe, been proposed.

I ask again, the forgiveness of those who may feel my remarks as irreverent, which is far from my intention.

Relwof.

Lincolnshire, Dec. 15th, 1873.

"Citrate of Magnesia."

Sir,—I have read with interest the voluminous correspondence which has appeared in the Journal regarding the proposed re-baptism of the so-called citrate of magnesia. It is certainly highly desirable that some suitable name should be speedily and uniformly adopted. The name Effervescing Powder, suggested by you in a leader on the subject, is to my mind the simplest and most practical that has yet been offered. It is sufficiently descriptive, and answers every purpose. I would, however, restrict the term to the present official preparation, the so-called citro-tartrate of soda, and apply the name Effervescent Powder with Magnesia, to Bishop's preparation, and the preparations of other makers which contain magnesia. Or, if the different manufacturers would in future prepare it with a certain percentage, say 5 or 10, of the true citrate, it could then be honestly and correctly termed, Effervescent Powder with Citrate of Magnesia; or, perhaps, better, Effervescent Powder of Citrate of Magnesia; for would it not then be closely analogous to some other preparations in the Pharmacopœia? Syrupus Ferri Phosphatis, for example. For Effervescent Powder would bear the same relation to Effervescent Powder of Citrate of Magnesia, as Syrupus does to Syrupus Ferri Phosphatis, and other syrups. But bringing it into close relationship with the present official preparation, would necessitate its introduction into the Pharmacopœia; the proposed appendix no doubt could afford it the necessary space. The advantage attaching to the above titles would be that we could also include the entire host of satellites that revolve around "Magnesiæ Cit."

We should then have a list something like the following:—

Pulvis Effervescens.
Pulvis Effervescens cum Magnesiæ Citrate
vel
Pulvis Effervescens Magnesiæ Citratis.
Pulvis Effervescens Ferri et Quiniæ Citratis.
Pulvis Effervescens Ferri Carbonatis, etc., etc.

These could be rendered definite in strength by making them official, in each case a certain percentage of the name.

giving ingredient being added to the ingredients of Pulvis Effervescens. The labels for the public use might be Effervescent Powder of Citrate of Magnesia (formerly known as Citrate of Magnesia.) This preparation contains ... p.c. of the true Citrate of Magnesia.

THE ADULTERATION MUDDLE.

Sir,—The lamentable want of discretion displayed by the officials entrusted with the working of the Adulteration Act in the selection of cases for prosecution has hitherto greatly impeded its intended operations. Why should persons totally ignorant of trade and its customs be appointed detectors of adulterations?

Mr. Owen Williams, the Inspector of the Board of Trade, may be an excellent detective officer, and Dr. August Dupré, the Analyst of the Westminster Board of Works, a very skilled manipulator, but if either of these well-intentioned zealots had been a pharmaceutical chemist, such a mare's nest as the nitrous ether prosecutions would not have been taken into court.

Let a properly qualified man, of course not actually engaged in business, such as a pharmaceutical chemist or a chemist and druggist who has himself managed or superintended a well conducted business for a number of years, be appointed to inspect the members of his own profession. A grocer might in the same way be appointed to inspect grocers, and so on. Then we might hope to see real delinquents called out and ticketed, instead of respectable tradesmen being harrassed in a manner never intended by the legislature.

FREDERICK PARSONS.

Leicester, Dec. 16th, 1873.

DRUG AND CHEMICAL TESTING.

Sir,—You call attention in an editorial article of Nov. 28th, to the importance of pharmaceutists testing the drugs and chemicals they use. That drugs and chemicals should be tested is highly important, not only to insure the public from fraud, but also for the safety of the pharmaceutist, who is liable to be prosecuted for selling impure drugs, even though they be adulterated previous to his purchase of them and without his knowledge. How this testing is to be done each pharmaceutist must decide for himself. One man may find time to test his chemicals and drugs—another may not.

The British Pharmacopœia gives characters and tests for nearly all the articles contained in it, but in more than one instance these do not afford conclusive proof of the genuineness of an article. Take, for example, gum scammony: according to the British Pharmacopœia it should yield from 80 to 90 per cent. of resin soluble in ether. Suppose a sample should be examined and found to yield 80 per cent. of resin, does it follow that this soluble resin consists entirely of scammony resin? Certainly not. I have only just examined a sample of scammony which is largely adulterated with guaiacum. I am aware of the fact that guaiacum resin is not relatively so soluble as scammony resin, and that a sample very largely adulterated would in all probability yield less than 80 per cent. to ether, but this does not alter the case, or show that scammony need not be tested further than the Pharmacopœia instructs. If a chemist were summoned for selling scammony adulterated with guaiacum, it would not, I think, acquit him of the offence to plead that the sample answered the B.P. tests, and yielded 80 per cent. to ether. As such a sample might exist, it behoves every chemist to see that his scammony is not adulterated even in a slight degree with guaiacum. Again, yellow cinchona bark may be tested according to the instructions given in the Pharmacopœia, and a residue obtained which weighs more than two grains, and the bark considered to be of good quality, at the same time such a bark, such a residue, containing *not a trace of quinine*, the pharmaceutist being misled in this case by the positive statement made in the Pharmacopœia that the residue obtained by the ether process "consists of nearly pure quinia."

These illustrations serve to show the importance of all available knowledge being brought to bear on the subject of drug and chemical testing, and that the Pharmacopœia be not taken as an exclusive guide. It may be said, in defence of the Pharmacopœia, that it is not intended to be, among other things, a manual of technical analysis. Perhaps not, but if it gives tests at all, then such tests should be conclusive ones.

An "appendix" is mooted to the British Pharmacopœia; and may not further and more conclusive tests appropriately find a place there?

H. WILLIAMS JONES.

REMUNERATION OF ASSISTANTS.

Sir,—Under the heading of "Remuneration of Assistants" appears a letter from "Chemicus," who was evidently in a hypochondriacal condition when he penned his communication, as it is full of despair; no ray of hope cheers him in his somewhat exceptional position.

All I know of him is, he occupies a situation as "an assistant in a small country village," and has more to do with commercial than pharmaceutical transactions; consequently a physician's prescription is seldom, or, as he says, never seen.

From his statements he is master of the Preliminary, and is anxious to pass the Minor, but he is discouraged because he cannot afford either time or money to prosecute his studies in London; there is no association existing near him; specimens he has not; nor opportunities to pursue chemical research. And he winds up with almost the determination to allow the thin barrier of the Minor to debar him from entering in business for himself, which is his ambition.

Such is his case; and what a deplorable, yet by no means an exceptional one! His impression as regards the Minor is, that it is necessary to undergo a course of lectures and study in London prior to presenting himself to the examiners; which is a great delusion, as anyone with application can do better in the country, having no enticing allurements. His lack of specimens must surely be through his not applying to the wholesale drug-houses; and, by making an effort, there is no reason why he should not conduct the necessary experiments in chemistry.

Instead of meditating upon his situation, let him shake off his despondency and work for the object he has in view with earnestness and zeal, coupled with a resolute determination, which will culminate in victory; at the same time dispense with "anxiety," as he will satisfy the examiners much better without its presence.

A. J. R.

J. E. Saunders.—In consequence of the contraction which takes place, although 60 volumes of water are added to 100 of spirit, the product will only measure 156 volumes.

W. W.—You will find an answer to your question in any work on chemistry.

P. H. M.—A table showing the composition of various so-called "fruit essences" will be found in the PHARM. JOURN., 2nd. ser., vol. viii., p. 467.

Edinburgh Examinations.—We have received a letter from "*Honour Bright,*" disputing the correctness of an explanation recently given (*ante* p. 467) of the reason why students do not pass their examinations in London as well as in Edinburgh. He says "no university professor presides over any class in the evening that would be of any avail to us," and considers the statement that masters in Edinburgh, with few exceptions, allow their assistants a week or two's holiday to spend in the Society's rooms exclusively, to be grossly misleading. The explanation suggested by "*Honour Bright*" is, that "Scotchmen are not so sure as Englishmen and read more," and, therefore, are better prepared and pass.

Erratum.—A. P. B.—The moss sent was *Fontinalis squamosa*, not *squarrosa*, as printed last week.

G. and T.—We are not acquainted with Dr. Dusart's formula, but formulæ for Syr. Calcis Lacto-Phosphatis have been given in the PHARMACEUTICAL JOURNAL, and the 'Year Book of Pharmacy.'

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Bell, Prof. Axel Key (Stockholm), Mr. Barnby, Mr. Guest, Mr. Saunders, Dr. Symes, Mr. Wilson, Mr. Pitman, Mr. Kinninmont, R. D. M., "Civilian," "Apis."

AN EXAMINATION OF SOME SAMPLES OF HYDROCYANIC ACID.*

BY A. TOWERZEY.

Some little time since, at the suggestion of Mr. Schacht, I submitted to a careful examination the hydrocyanic acid we were then using in his dispensary. As we half suspected, it proved to be distinctly below the standard strength.

The necessity of being very accurate, compelled me to make repeated experiments; and anxious for a variety of samples I applied to several chemists in the neighbourhood, who very kindly acceded to my requests, and gave me the opportunity of more extended experience.

The results I am thus able to show will perhaps be interesting to the association, although I am well aware that this subject has frequently been treated by more competent observers. I may especially call to your recollection a communication by Dr. Tilden, published in the PHARMACEUTICAL JOURNAL of July 29th, 1871; also a paper read by Mr. Abraham before the Liverpool Chemists' Association on the 8th of May, 1873; and likewise Mr. Siebold's report on the "Purity of Commercial Specimens of Officinal Acids," which will be found amongst the transactions of the last meeting of the Pharmaceutical Conference; and I trust these gentlemen will forgive my saying that my results tend to corroborate theirs.

It is not necessary to say one word here concerning the preparation of hydrocyanic acid; indeed, the exact process does not seem to be of much importance, provided the solution contains 2 per cent. of real acid.

The Pharmacopœia gives two tests for estimating its strength. The cyanogen may either be precipitated and weighed as dry cyanide of silver or tested volumetrically with a standard solution of nitrate of silver. This latter was the method we preferred to adopt, and, in practice, found it convenient to employ a nitrate of silver solution of such strength that 40 c.c. would show 1 per cent. in 4 grammes of sample. (I say *we*, because throughout these experiments I was kindly assisted by Mr. Schacht.)

Briefly then, we dissolved 3·15 grammes of dried nitrate of silver in one litre of distilled water; 4 grammes of each sample were carefully weighed in a balance capable of turning to one-tenth of a milligramme, with all the expedition possible (a most important matter), and mixed with rather more than sufficient solution of caustic potash to convert all the HCN into KCN; our silver solution, contained in a burette, was then run in until the last drop produced a permanent faint opalescence in the liquid after stirring. The number of c.c. of silver solution required to produce this effect divided by 40 gave at once the percentage.

Our experiments, conducted I may say, with every precaution to avoid error, and repeated more than once, indeed, several times in every case, upon twelve samples of hydrocyanic acid, gave the following average results:—

So-called B.P. Acid.

No. 1	1·92.
„ 2	1·52.
„ 3	1·36.
„ 4	1·32.
„ 5	1·262.
No. 6	1·22.
„ 7	1·165.
„ 8	1·16.
„ 9	0·26.

Acid of "Scheele's" strength.

„ 10	3·62.
„ 11	4·02.
„ 12	1·3.

The history, as far as we know, of these samples will serve to show how unfortunately unstable is this important remedy, and to indicate the necessity for special care in its management.

No. 1 was obtained from a wholesale house of deservedly good reputation, and examined *directly it arrived*.

Nos. 4 and 6 were samples of the same acid examined in the one case when the bottle was first opened, and in the other when the contents had suffered from the frequent removal of the stopper incidental to the dispensary.

Nos. 3 and 5 were kindly sent me by a friend, who appended the following remarks:—No. 3 "from a 40 oz. bottle, from which over 35 ozs. have been from time to time removed." No. 5. "First removal from a 40 oz. bottle, which has been in stock several months, during which time, however, the stopper had not been withdrawn." "Both samples have been carefully preserved in bottles encased in blue paper, and kept in a cupboard in a cool underground cellar."

Nos. 2, 7, 8, and 9 were portions of the contents of dispensing bottles kindly given me by friends who share with us the desire for a more perfect preparation.

Of the three samples of "Scheele's acid,"

No. 10 had been in stock for several months, during which time the stopper had been frequently removed.

No. 11 was a fresh sample, obtained expressly for examination, and

No. 12 was an acid of unknown birth. Its owner regarded it as a curiosity, and, like most curiosities, it is only fit to be kept on a shelf.

Here, then, gentlemen, are nine samples of hydrocyanic acid, B.P., taken from various sources, and representing very fairly, I should say, the condition in which this medicine is generally met with.

It will be seen at a glance that no two samples are alike, and all, with one exception, considerably below the standard. That such should be the case must be regarded as a matter of grave importance: and the question so frequently asked before I ask once again—Can this variation in so important a remedy be obviated? There is no doubt it arises chiefly from the extreme volatility of the substance itself. This was brought home to us most convincingly during the conduct of our experiments. HCy is much more volatile than water, hence the slightest exposure does something to weaken the sample. I feel bound therefore to answer that I fear nothing can entirely prevent this unfortunate variation in commercial hydrocyanic acid. But I think at the same time that more may be done than is always done to limit this variation and I hazard the opinion that a difference so great as that here shown ought not to exist in any neighbourhood.

In the management of this chemical it is of the utmost importance that every chemist should test for himself the strength of his solution; without so doing he can know absolutely nothing of the real strength of the article sent him. But starting with

* Read at a meeting of the Bristol Pharmaceutical Association, December 12, 1873.

an acid of full strength and keeping it under the most favourable circumstances, he may then have fair reason to expect success in his endeavours to render this powerful agent something like a reliable remedy in the hands of the medical man.

The method we have recently adopted is to purchase acid of Scheele's strength and reduce it to 2 per cent. Mixing some ten or twelve ounces at a time we keep this quantity in well-fitting stopped bottles (1 oz. capacity) protected from the light and in a cool place. One ounce only is brought into the dispensary at a time, and *is renewed every fortnight* provided it lasts so long. This insures a frequent supply of fresh stock. Whether this plan will answer all our expectations I am not yet able to say; still, after all, this is but an endeavour to make the best of a bad job. The object to be sought for is, I venture to think, some other cyanide that may be proved to be equal to the cyanide of hydrogen in medicinal value and superior to it in chemical constancy. The most promising substance we have yet examined is the double cyanide of zinc and potassium. It is a perfectly definite crystalline body, having the composition, $K_2Zn''Cy_4$. The crystals contain no water, and are so stable that they may be even fused without change. In its solution, moreover, the cyanogen appears to be very securely fixed as the following experiment may serve to show. A sample containing (by calculation) 2 per cent. of cyanogen, was tested and found to yield exactly 2 per cent. A pint of air was then driven through the solution in small bubbles, and being again tested, it was found to be of precisely the same strength. A sample of B.P. acid was then treated, with this result—that whereas in the first case it was shown to be of exactly 2 per cent., after the transmission of the pint of air its percentage was reduced to 1·7. But although the cyanogen in this double cyanide is non-volatile, and to that extent more constant than in hydrocyanic acid, yet it is easily evolved by even the weakest acids, such, for instance, as may be presumed to exist in the stomach. In point of fact, hydrocyanic acid itself would be produced directly the remedy was swallowed. The crystals are prepared very easily by dissolving cyanide of zinc in aqueous solution of cyanide of potassium, in the proportion of one equivalent of the former to two of the latter; upon evaporation this yields beautiful octahedral crystals.

A solution corresponding with the strength of the B. P. acid is made with 2 grammes of the salt, and 42·82 grammes of water.

As to the medicinal value of this solution, I am, of course, not able to speak, but I scarcely think it could in any great degree differ from that of hydrocyanic acid.

OBSERVATIONS ON THE ACTION AND USES OF CROTON-CHLORAL HYDRATE.*

BY OSCAR LIEBREICH, M.D.

Professor of Materia Medica in the University of Berlin.

I have the honour of directing attention to a new remedy, which serves to corroborate the theory I have propounded with respect to the action of hydrate of chloral.

When chlorine gas acts on aldehyde, croton-chloral is formed, as has been demonstrated by Dr. Krämer and Dr. Tinner. In order to avoid a mistake which is apt to be caused by the name, I must here remark that this body possesses no relation whatever to croton oil, although its chemical constitution proves it to be the chlorated aldehyde of crotonic acid. Croton-chloral differs in its outward appearance from hydrate of chloral by its being dissolved with difficulty in water, and by its crystallizing in small glittering tablets. Its action, though similar to that of hydrate of chloral, differs widely from the latter with regard to its physiological effects. Four grams, or a drachm, of this substance, dissolved in water, and introduced into the stomach, produce in the course of from fifteen to twenty minutes a deep sleep, accompanied by anæsthesis of the head. Whilst the eyeball has lost its irritability, and the nervus trigeminus shows no reaction whatever on being irritated, the tone of the muscles remains unaltered.

I have experimented with this remedy on maniacs during an attack of mania. They remained quietly sitting on their chairs in a deep sleep, their pulse and respiration being unchanged for two whole hours together. If anæsthesis had reached so high a degree in consequence of the application of hydrate of chloral, the patients would have dropped from their chairs, and both their pulse and respiration would have been considerably retarded. I have seen croton-chloral acting in the same way on healthy individuals. In some cases of tic douloureux, the remarkable phenomenon is exhibited that pain ceases before sleep sets in. I am sorry to say, however, that this remedy acts only as a palliative in this dreadful disease. I nevertheless prefer its action to that of morphia, because it has effects as good as the latter remedy, without being so detrimental to the constitution in general. I have never observed any unfavourable effects of croton-chloral on the stomach or any other organ, although I have made frequent experiments with it.

The indications for the use of this remedy are to be found—1. In cases where hydrate of chloral is inapplicable on account of heart disease; 2. In cases of neuralgia in the district of the nervus trigeminus; 3. In cases where very large doses of chloral are necessary to produce sleep. I there recommend the addition of croton-chloral to hydrate of chloral.

Whilst examining the difference between the action of hydrate of chloral and that of croton-chloral, I have discovered the remarkable fact that it is not the first, but the second product of decomposition of the latter substance which is brought into action, on account of the first being too rapidly destroyed. Croton-chloral, when subjected to the influence of an alkali, first forms allyl-chloroform, a trichlorated body, which is rapidly decomposed into a bichlorated substance called bichlor-allylene. Now, both chloroform and trichlorated substances act, as I have shown, in their first stage upon the brain, in the second on the spinal cord, and in the third on the heart. The retardation of respiration is to be explained by the agency of these substances on the last-mentioned organ. Bichlorated substances act differently, as is proved by bichloride of ethylene. Even if the circulation of the blood in an animal have been stopped by this latter agent for one minute, life may be restored by artificial respiration, which is impossible whenever trichlorated substances have produced this effect, in which case the muscles of the heart remain paralysed. Well, in animals poisoned by croton-chloral to such a degree that both circulation and respiration are stopped entirely artificial respiration is able to restore the action of the heart immediately, and the life of the animal may thus be saved. Bichlor-allylene, inhaled by the lungs, produces the same effect on animals as croton-chloral. We thus see these bichlorated substances acting on the brain, spinal cord, and medulla oblongata, but not on the heart, which explains the fact that both respiration and circulation remain unaltered in man by a medicinal dose. It is a highly interesting fact, however, that under favourable conditions, we still are able to produce in animals the effects of the first product of decomposition of croton-chloral—*i.e.*, of the trichlorated sub-

* From the *British Medical Journal*, Dec. 20.

stance, or of allyl-chloroform. In order to observe these effects it is necessary to introduce immense doses of croton-chloral into the body, when paralysis of the heart actually does ensue.

A DISCOURSE ON MOLECULES.*

BY J. CLERK MAXWELL, M.A., F.R.S.

Professor of Experimental Physics in the University of Cambridge.

(*Concluded from page* 494.)

Another branch of molecular science is that which relates to the exchange of molecules between a liquid and a gas. It includes the theory of evaporation and condensation, in which the gas in question is the vapour of the liquid, and also the theory of the absorption of a gas by a liquid of a different substance. The researches of Dr. Andrews on the relations between the liquid and the gaseous state have shown us that, though the statements in our elementary text-books may be so neatly expressed as to appear almost self-evident, their true interpretation may involve some principle so profound that, till the right man has laid hold of it, no one ever suspects that anything is left to be discovered.

These, then, are some of the fields from which the data of molecular science are gathered. We may divide the ultimate results into three ranks, according to the completeness of our knowledge of them. To the first rank belong the relative masses of the molecules of different gases, and their velocities in metres per second. These data are obtained from experiments on the pressure and density of gases, and are known to a high degree of precision.

In the second rank we must place the relative size of the molecules of different gases, the length of their mean paths, and the number of collisions in a second. These quantities are deduced from experiments on the three kinds of diffusion. Their received values must be regarded as rough approximations till the methods of experimenting are greatly improved.

There is another set of quantities which we must place in the third rank, because our knowledge of them is neither precise, as in the first rank, nor approximate, as in the second, but is only as yet of the nature of a probable conjecture. These are :—The absolute mass of a molecule, its absolute diameter, and the number of molecules in a cubic centimetre. We know the relative masses of different molecules with great accuracy, and we know their relative diameters approximately. From these we can deduce the relative densities of the molecules themselves. So far we are on firm ground.

The great resistance of liquids to compression makes it probable that their molecules must be at about the same distance from each other as that at which two molecules of the same substance in the gaseous form act on each other during an encounter. This conjecture has been put to the test by Lorenz Meyer, who has compared the densities of different liquids with the calculated relative densities of the molecules of their vapours, and has found a remarkable correspondence between them.

Now Loschmidt had deduced from the dynamical theory the following remarkable proportion :—As the volume of a gas is to the combined volume of all the molecules contained in it, so is the mean path of a molecule to one-eighth of the diameter of a molecule.

Assuming that the volume of the substance, when reduced to the liquid form, is not much greater than the combined volume of the molecules, we obtain from this proportion the diameter of a molecule. In this way Loschmidt, in 1865, made the first estimate of the diameter of a molecule. Independently of him and of each other, Mr. Stoney in 1868, and Sir W. Thomson in 1870, published results of a similar kind, those of Thomson being deduced not only in this way, but from considerations derived from the thickness of soap bubbles, and from the electric properties of metals.

According to the table, which I have calculated from Loschmidt's data, the size of the molecules of hydrogen is such that about two millions of them in a row would occupy a millimetre, and a million million million millions of them would weigh between four and five grammes.

In a cubic centimetre of any gas at standard pressure and temperature there are about nineteen million million million molecules. All these numbers of the third rank are, I need not tell you, to be regarded as at present conjectural. In order to warrant us in putting any confidence in numbers obtained in this way, we should have to compare together a greater number of independent data than we have as yet obtained, and to show that they lead to consistent results.

Thus far we have been considering molecular science as an inquiry into natural phenomena. But though the professed aim of all scientific work is to unravel the secrets of nature, it has another effect not less valuable on the mind of the worker. It leaves him in possession of methods which nothing but scientific work could have led him to invent, and it places him in a position from which many regions of nature, besides that which he has been studying, appear under a new aspect.

The study of molecules has developed a method of its own, and it has also opened up new views of nature.

When Lucretius wishes us to form a mental representation of the motion of atoms, he tells us to look at a sunbeam shining through a darkened room (the same instrument of research by which Dr. Tyndall makes visible to us the dust we breathe), and to observe the motes which chase each other in all directions through it. This motion of the visible motes, he tells us, is but a result of the far more complicated motion of the invisible atoms which knock the motes about. In his dream of nature, as Tennyson tells us, he

> "Saw the flaring atom-streams
> And torrents of her myriad universe,
> Ruining along the illimitable inane,
> Fly on to clash together again, and make
> Another and another frame of things
> For ever."

And it is no wonder that he should have attempted to burst the bonds of fate by making his atoms deviate from their courses at quite uncertain times and places, thus attributing to them a kind of irrational free will, which on his materialistic theory is the only explanation of that power of voluntary action of which we ourselves are conscious.

As long as we have to deal with only two molecules, and have all the data given us, we can calculate the result of their encounter, but when we have to deal with millions of molecules, each of which has millions of encounters in a second, the complexity of the problem seems to shut out all hope of a legitimate solution.

The modern atomists have therefore adopted a method which is, I believe, new in the department of mathematical physics, though it has long been in use in the section of statistics. When the working members of section F get hold of a report of the census or any other document containing the numerical data of economic and social science, they begin by distributing the whole population into groups, according to age, income-tax, education, religious belief, or criminal convictions. The number of individuals is far too great to allow of their tracing the history of each separately, so that in order to reduce their labour within human limits they concentrate their attention on a small number of artificial groups. The varying number of individuals in each group, and not the varying state of each individual, is the primary datum from which they work.

This, of course, is not the only method of studying human nature. We may observe the conduct of individual men and compare it with that conduct which their

* Lecture delivered before the British Association at Bradford, September 22, 1873.

previous character and their present circumstances, according to the best existing theory, would lead us to expect. Those who practise this method endeavour to improve their knowledge of the elements of human nature in much the same way as an astronomer corrects the elements of a planet by comparing its actual position with that deduced from the received elements. The study of human nature by parents and schoolmasters, by historians and statesmen, is therefore to be distinguished from that carried on by registrars and tabulators, and by those statesmen who put their faith in figures. The one may be called the historical and the other the statistical method.

The equations of dynamics completely express the law of the historical method as applied to matter, but the application of these equations implies a perfect knowledge of all the data. But the smallest portion of matter which we can subject to experiment consists of millions of molecules, not one of which ever becomes individually sensible to us. We cannot, therefore, ascertain the actual motion of any one of these molecules, so that we are obliged to abandon the strict historical method, and to adopt the statistical method of dealing with large groups of molecules.

The data of the statistical method as applied to molecular science are the sums of large numbers of molecular quantities. In studying the relations between quantities of this kind, we meet with a new kind of regularity, the regularity of averages, which we can depend upon quite sufficiently for all practical purposes, but which can make no claim to that character of absolute precision which belongs to the laws of abstract dynamics.

Thus molecular science teaches us that our experiments can never give us anything more than statistical information, and that no law deduced from them can pretend to absolute precision. But when we pass from the contemplation of our experiments to that of the molecules themselves, we leave the world of chance and change, and enter a region where everything is certain and immutable.

The molecules are conformed to a constant type with a precision which is not to be found in the sensible properties of the bodies which they constitute. In the first place, the mass of each individual molecule, and all its other properties, are absolutely unalterable. In the second place, the properties of all molecules of the same kind are absolutely identical.

Let us consider the properties of two kinds of molecules, those of oxygen and those of hydrogen.

We can procure specimens of oxygen from very different sources—from the air, from water, from rocks of every geological epoch. The history of these specimens has been very different, and if, during thousands of years, difference of circumstances could produce difference of properties, these specimens of oxygen would show it.

In like manner, we may procure hydrogen from water, from coal, or, as Graham did, from meteoric iron. Take two litres of any specimen of hydrogen, it will combine with exactly one litre of any specimen of oxygen, and will form exactly two litres of the vapour of water.

Now if, during the whole previous history of either specimen, whether imprisoned in the rocks, flowing in the sea, or careering through unknown regions with the meteorites, any modification of the molecules had taken place, these relations would no longer be preserved.

But we have another and an entirely different method of comparing the properties of molecules. The molecule, though indestructible, is not a hard rigid body, but is capable of internal movements, and when these are excited it emits rays, the wave-length of which is a measure of the time of vibration of the molecule.

By means of the spectroscope the wave lengths of different kinds of light may be compared to within one ten-thousandth part. In this way it has been ascertained, not only that molecules taken from every specimen of hydrogen in our laboratories have the same set of periods of vibration, but that light, having the same set of periods of vibration, is emitted from the sun and from the fixed stars.

We are thus assured that molecules of the same nature as those of our hydrogen exist in those distant regions, or at least did exist when the light by which we see them was emitted.

From a comparison of the dimensions of the buildings of the Egyptians with those of the Greeks, it appears that they have a common measure. Hence, even if no ancient author had recorded the fact that the two nations employed the same cubit as a standard of length, we might prove it from the buildings themselves. We should also be justified in asserting that at some time or other a material standard of length must have been carried from one country to the other, or that both countries had obtained their standards from a common source.

But in the heavens we discover by their light, and by their light alone, stars so distant from each other that no material thing can ever have passed from one to another, and yet this light, which is to us the sole evidence of the existence of these distant worlds, tells us also that each of them is built up of molecules of the same kinds as those which we find on earth. A molecule of hydrogen, for example, whether in Sirius or in Arcturus, executes its vibrations in precisely the same time.

Each molecule, therefore, throughout the universe, bears impressed on it the stamp of a metric system as distinctly as does the metre of the Archives at Paris, or the double royal cubit of the Temple of Karnac.

No theory of evolution can be formed to account for the similarity of molecules, for evolution necessarily implies continuous change, and the molecule is incapable of growth or decay, of generation or destruction.

None of the processes of Nature, since the time when Nature began, have produced the slightest difference in the properties of any molecule. We are therefore unable to ascribe either the existence of the molecules or the identity of their properties to the operation of any of the causes which we call natural.

On the other hand, the exact equality of each molecule to all others of the same kind gives it, as Sir John Herschel has well said, the essential character of a manufactured article, and precludes the idea of its being eternal and self existent.

Thus we have been led, along a strictly scientific path, very near to the point at which Science must stop. Not that Science is debarred from studying the internal mechanism of a molecule which she cannot take to pieces, any more than from investigating an organism which she cannot put together. But in tracing back the history of matter Science is arrested when she assures herself, on the one hand, that the molecule has been made, and on the other, that it has not been made by any of the processes we call natural.

Science is incompetent to reason upon the creation of matter itself out of nothing. We have reached the utmost limit of our thinking faculties when we have admitted that because matter cannot be eternal and self-existent it must have been created.

It is only when we contemplate, not matter in itself, but the form in which it actually exists, that our mind finds something on which it can lay hold.

That matter, as such, should have certain fundamental properties—that it should exist in space and be capable of motion, that its motion should be persistent, and so on, are truths which may, for anything we know, be of the kind which metaphysicians call necessary. We may use our knowledge of such truths for purposes of deduction, but we have no data for speculating as to their origin.

But that there should be exactly so much matter and no more in every molecule of hydrogen is a fact of a very different order. We have here a particular distribution of matter—a *collocation*—to use the expression of Dr. Chalmers, of things which we have no difficulty in imagining to have been arranged otherwise.

The form and dimensions of the orbits of the planets,

for instance, are not determined by any law of nature, but depend upon a particular collocation of matter. The same is the case with respect to the size of the earth, from which the standard of what is called the metrical system has been derived. But these astronomical and terrestrial magnitudes are far inferior in scientific importance to that most fundamental of all standards which forms the base of the molecular system. Natural causes, as we know, are at work, which tend to modify, if they do not at length destroy, all the arrangements and dimensions of the earth and the whole solar system. But though in the course of ages catastrophes have occurred and may yet occur in the heavens, though ancient systems may be dissolved and new systems evolved out of their ruins, the molecules out of which these systems are built—the foundation stones of the material universe—remain unbroken and unworn. They continue this day as they were created—perfect in number and measure and weight, and from the ineffaceable characters impressed on them we may learn that those aspirations after accuracy in measurement, truth in statement, and justice in action, which we reckon among our noblest attributes as men, are ours because they are essential constituents of the image of Him who in the beginning created, not only the heaven and the earth, but the materials of which heaven and earth consist.

Table of Molecular Data.

		Hydrogen.	Oxygen	Carbonic oxide.	Carbonic acid.
	Mass of molecule (hydrogen = 1)	1	16	14	22

VOLUMETRIC ESTIMATION OF BISMUTH.*

BY MM. BUISSON AND FERRAY.

The method of volumetric estimation of bismuth proposed by the authors is based upon its complete precipitation by iodic acid from an acetic solution. The iodate of bismuth is a white anhydrous powder, corresponding with the formula Bi_2O_3, $3IO_5$, insoluble in water and in acids. Not a trace of it is dissolved by free acetic acid. This method is applicable to the estimation of all the compounds into which bismuth enters, but the authors employ it principally in the estimation of the bismuth contained in the subnitrate, which compound they have found to be adulterated on a large scale.

Commercial subnitrate of bismuth being frequently mixed with the oxychloride, it is important to be able to estimate separately the quantity of subnitrate contained in the salt. This is accomplished by treating with acetic acid, which does not dissolve the oxychloride, and besides allows of the dilution of the liquid without fear of partial precipitation of the bismuth by the water.

The examination of subnitrate of bismuth is effected by dissolving 50 centigrams of the salt in a few drops of nitric acid, and diluting slightly with water; the solution is then saturated with bicarbonate of soda until the appearance of a slight permanent precipitate; the precipitate is re-dissolved by excess of acetic acid, so as to prevent the partial precipitation of the bismuth by the water. The solution is then heated to ebullition and filtered to separate iron and oxychloride of bismuth that may be present. To the filtered liquor 25 cubic centimetres of iodic acid are added, and water to make up 250 cubic centimetres. It is then well shaken and after standing a few minutes it is poured upon a dry filter. To 100 cubic centimetres of the clear liquor are added dilute sulphuric acid and iodide of potassium, in order to decompose the unemployed iodic acid and to re-dissolve the iodine set free, which point is readily observed when grey pellicles of iodine no longer float on the surface. The reaction is represented by the following equation:—

$$IO_5 + 5KI + 5SO_3 = 5SO_3KO + 6I.$$

Into the liquor containing the iodine is poured, by means of a burette, graduated to tenths of a cubic centimetre, solution of hyposulphite of soda until the yellow tint of the iodine has disappeared. The difference between the titration when operating upon iodic acid alone and upon iodic acid from which a known weight of pure bismuth has been precipitated allows of a calculation of the amount of bismuth contained in the compound examined. In testing the subnitrate the authors find it preferable to express the result as metallic bismuth rather than as subnitrate, in consequence of the true composition of that body being yet unknown. According to their experiments they believe it to contain 0·6894 of bismuth.

Lead or baryta present in the compound under analysis should be eliminated as sulphate; tin and antimony as stannic and antimonic acids by previous treatment with nitric acid.

The re-agents employed should be free from chlorides, as the oxychloride of bismuth which would be formed in contact with water is insoluble in acetic acid, and would cause a loss. The iodide of potassium should be free from iodate and the solution used should be a saturated one. The titrated solution of iodic acid is prepared by dissolving 30 grams of crystallized iodic acid in one litre of distilled water, and titrating the solution with pure bismuth. The solution of hyposulphite of soda is of suitable concentration when it is necessary to employ 30 or 40 cubic centimetres to oxidize the iodine set free by 10 cubic centimetres of iodic acid.

THE FLUID EXTRACT OF IPECACUANHA OF THE UNITED STATES' PHARMACOPŒIA.*

BY RICHARD V. MATTISON.

Some dissatisfaction having been experienced with the above officinal fluid extract in consequence of its thick and inelegant appearance, the author instituted a series of experiments in accordance with suggestions of Professor Maisch, which resulted in the selection of the following formula:—

Take eighty troy-ounces of carefully selected ipecac root, grind to appropriate powder, and, after moistening thoroughly, pack firmly in a cylindrical glass percolator, allow to stand four days as directed, then using the officinal menstruum, allow percolation to proceed slowly until the root is exhausted. To the percolate add ten fluid-ounces of glycerin, and evaporate at a temperature not exceeding 140° Fahr. (if the temperature is allowed to rise higher a gelatinous mass will result) until reduced to the measure of fifty-five fluid ounces. Transfer this to a moistened filter and allow to drain. To the soft mass

* *American Journal of Pharmacy*, vol. xlv., p. 481.

remaining upon the filter, consisting of the peculiar substance usually called resin (though not so, properly speaking) water is added by means of a spritz, and the whole thoroughly washed until the filtrate measures sixty fluid-ounces. This causes a reprecipitation of the resinous substance which necessitates the refiltration of the filtrate. To this second filtrate twenty fluid-ounces of glycerin is added, and the whole well mixed.

This furnishes an extract containing in each pint two fluid-ounces less of glycerin than the officinal preparation, limpid, perfectly transparent, and one that can be mixed with syrup without turbidity, and in this respect will, Mr. Mattison thinks, meet the approval of all lovers of elegant pharmacy.

RELATIONS OF PLANTS AND ANIMALS TO INORGANIC MATTER, AND ON THE INTERACTION OF THE VITAL AND PHYSICAL FORCES.*

(*Continued from p.* 496).

BY J. BELL PETTIGREW, M.D., F.R.S., ETC.

At the very threshold of physiology we have to do with the so-called proximate principles of the body—*i.e.*, the substances which enter into its composition. We have also to do with the vital, chemical, and physical forces which aggregate and work up the proximate principles into a consistent living whole.

The proximate principles have been divided into the *inorganic*, comprising such substances as water, chloride of sodium, chloride of potassium, carbonate of potassa, phosphate and carbonate of lime, etc.; and the *organic*, under which may be enumerated starch, sugar, fats, fibrin, albumen, casein, pepsine, etc. The inorganic substances are found both within and without the body; the organic substances being confined to it.

The organic substances are, so to speak, manufactured from the inorganic by plants and animals. A plant to live must be supplied with soil, with water, and air. The soil contains saline matters, to which are generally added decomposing substances, which furnish carbonic acid and ammonia. The water furnishes oxygen and hydrogen in chemical combination; and the air oxygen and nitrogen, and small but important quantities of carbonic acid and ammonia. The plant is thus supplied with water, salts, carbonic acid, and ammonia. But the plant can disintegrate the carbonic acid and appropriate its carbon, which it can subsequently build up with oxygen and hydrogen into sugar, oil, and starch; or it can combine carbon, hydrogen, oxygen, and nitrogen to form those peculiar nitrogenous substances recently known as protoplasm. The sun lends its aid to the plant in these transformations; in fact, the heat of the sun enables the plant to separate the oxygen from the carbon and the nitrogen from the hydrogen in the formation of sugar, oil, and starch. The heat of the sun is, marvellous to relate, not lost in the process. It is stored up in the newly-formed sugar, oil, and starch; and may be reconverted into heat either by burning in the animal body or in an open fire. The heat thus obtained can, when collected, be made to perform a definite amount of mechanical work. The physical and vital forces are correlated and interact.† Sugar, oil, and starch are manufactured by a vital chemistry, and, when once produced, are appropriated, with other substances, as food by the herbivora, and subsequently by the carnivora and omnivora. By vital, chemical, physical, and other forces, the inorganic material of the outer world is incorporated in the organic or inner world of the individual.

The animal, built up, as it were, indirectly from the inorganic and directly from the organic kingdoms by means of the plant, reverses the operations of the latter. It returns to the inorganic world the substances abstracted from it by the plant. Thus the animal takes the complex bodies produced by the plant and oxidizes or burns them. It restores the carbon of these bodies to the atmosphere chiefly in the form of carbonic acid, the hydrogen as water, and the nitrogen with the remainder of the carbon as urea, to the soil.

While these transformations are going on in the animal body the tissues are being built up and conserved, secretions formed, and work done. This work may be either mechanical or mental, or both. The animate and inanimate kingdoms plainly interact. The plant lays the inorganic world under contribution, and the animal lays the vegetable world under contribution; but the animal in due time restores to the inorganic or mineral kingdom, in undiminished quantity, the substances abstracted from it by the plant. In like manner the energy displayed by the animal is to be regarded as the sum of the potential energy stored up in chemical compounds; and this, in turn, is restored to the outer world as heat, which, like the matter, is undiminished in quantity. There is therefore a cycle of force and a cycle of matter in living beings. "Animals, like machines, can only move and accomplish work by being continuously supplied with fuel (that is to say, food) and air containing oxygen; both give off, again, this material in a burnt state, and at the same time produce heat and work. All investigation, thus far, respecting the amount of heat which an animal produces when at rest is in no way at variance with the assumption that this heat exactly corresponds to the equivalent, expressed as work, of the forces of chemical affinity then in action. As regards the work done by plants, a source of power in every way sufficient exists in the solar rays which they require for the increase of the organic matter of their structures."*

It would be quite out of place to refer to the great physical law of the conservation of energy on the present occasion were it not for the fact that the law applies also to physiology. This law resolves itself into three parts—viz., the conservation of energy, the transformation of energy, and the dissipation of energy. We have examples of the conservation of energy in physiology wherever we have mechanical or physical adaptations† which produce a maximum of work with a minimum of power. We have examples of the transformation of energy in the muscles moving the bones, or the heart the blood; and we have examples of the dissipation of energy in the friction accompanying the movements of both bones and blood. In all the vital, physical, and chemical actions and reactions the law plays a prominent part. To take an example: A skilful blacksmith can hammer a piece of cold iron until it becomes red-hot, and the iron so heated can be employed in raising steam and driving a steam engine; but the muscles of the smith's arm are fed by animal matter, that again by vegetable matter, and lastly this by inorganic matter.‡ Similar results might be obtained direct from the inorganic world without the intervention of the smith's arm. Thus the heat in the universe causes water to evaporate, water evaporating is

* An Introductory Lecture to a Course of Physiology. Reprinted from the *Lancet*, Nov. 15.

† "The life of men, animals, and plants could not continue if the sun had lost its high temperature, and with it its light."

* 'Popular Scientific Lectures,' by Helmholtz (1873), pp. 383, 384,

† "There is hardly a natural process to be found which is not accompanied by mechanical actions, or from which mechanical work may not be derived—heat, electricity, magnetism, light, chemical forces, all stand in manifold relation to mechanical processes. . . . While the steam-engine develops for us mechanical work out of heat, we can conversely generate heat by mechanical forces."

‡ "A certain portion of force disappears from the sunlight, while combustible substances are generated and accumulated in plants, and we can assume it as very probable that the former is the cause of the latter. . . . . The immense wealth of ever-changing, meteorological, climatic, geological, and organic processes of our earth are almost wholly preserved in action by the light and heat-giving rays of the sun. . . . In the series of natural processes there is no circuit to be found by which mechanical force can be gained without a corresponding consumption."

steam, but steam collected and confined propels the steam-engine.

The interaction of the physical, chemical, and vital forces is thus expressed by Helmholtz: "If a certain quantity of mechanical work is lost, there is obtained an equivalent quantity of heat, or, instead of this, of chemical force; and, conversely, when heat is lost, we gain an equivalent quantity of chemical or mechanical force; and, again, when chemical force disappears, an equivalent of heat or work: so that in all these interchanges between various inorganic natural forces working force may indeed disappear in one form, but then it reappears in exactly equivalent quantity in some other form. . . . . The universe possesses, once for all, a store of force which is not altered by any change of phenomena, can neither be increased nor diminished, and which maintains any change which takes place on it. . . . The force of falling water can only flow down from the hills when rain and snow bring it to them. To furnish these we must have aqueous vapour in the atmosphere, which can only be effected by the aid of heat, and this heat comes from the sun. The steam-engine needs the fuel which the vegetable life yields, whether it be the still life of the surrounding vegetation or the extinct life which has produced the immense coal deposits in the depths of the earth. The forces of man and animals must be restored by nourishment; all nourishment comes ultimately from the vegetable kingdom, and leads us back to the same source. . . . We are thrown back upon the meteorological processes in the earth's atmosphere, on the life of plants in general, and on the sun."* It would appear from this that living force can generate the same amount of work as that expended in its production.

From what has been stated, it will be evident that physiology is veering more and more round to chemistry and physics, and particularly the latter. The physiologist has at present to deal with the distribution of matter and force, not only in the individual, but also in the universe. It no longer suffices to say the muscles move the bones. The explanation now required is, What substances constitute and what forces actuate the sarcous elements?—for these we know move the muscles. In like manner we are not satisfied with the statement that a certain animal lives: the rising generation asks, Does the animal live by direct descent from a parent, or is it descended from a long line of ancestors dating back to the primeval mud of Haeckel? In other words, is each animal distinct and perfect from the first, or is each animal up to man himself an evolution from lower to higher forms, each improving upon its predecessor? These questions are difficult of solution, difficult even of comprehension, but they confront the physiologist of modern times. Herbert Spencer, one of the most advanced thinkers of the present day, avers "that the chasm between the inorganic and organic is being filled up, and that organisms are *highly differentiated portions* of the matter forming the earth's crust and its gaseous envelope." In like manner, Huxley, also in the vanguard of science, states that "protoplasm can originate only in that into which it dies—the elements—the carbon, hydrogen, oxygen, and nitrogen—of which it is found to consist. Hydrogen with oxygen forms water; carbon with oxygen, carbonic acid; and hydrogen with nitrogen, ammonia. Similarly, water, carbonic acid, and ammonia form, in union, protoplasm. . . . Protoplasm, then, is but an aggregate of physical materials, exhibiting in combination—only as was to be expected—new properties. . . . . All vital action whatever, intellectual included, is but the result of the molecular forces of the protoplasm which displays it."† Protoplasm, according to Huxley, is the formal basis of life. It is the clay of the potter, which, bake and paint it as he will, remains clay, separated by artifice, and not by nature, from the commonest brick or sun-dried clod. Thus it becomes clear that all living powers are cognate, and that all living forms are fundamentally of one character. Huxley regards protoplasm as identical in composition and uniformly diffused in plants and animals—*i.e.*, not contained in cells. In this he differs from the German histologists, who still regard the cell as the precursor and parent of protoplasm. With them, "there is as yet no matter of life; there are still cells of life." Huxley claims for protoplasm a threefold unity—a unity of faculty, a unity of form, and a unity of substance. Each of these positions has been disputed, and properly; for how, say Huxley's opponents, can there be unity of substance if the elements carbon, oxygen, hydrogen, and nitrogen, which constitute the protoplasm, are combined in varying quantity in different kinds of protoplasm? If there is not unity of substance there cannot be unity of form, and if there is neither unity of substance nor of form there cannot possibly be unity of function. The unity of substance of protoplasm depends for its proof mainly upon ultimate organic analysis. Ultimate organic analysis, however, teaches next to nothing in such cases. "Ozone is not antozone, nor is oxygen either, though in chemical constitution all are alike." Further, some protoplasm, in addition to carbon, oxygen, hydrogen, and nitrogen, contains a certain proportion of sulphur; and the Germans have shown that the cells which produce protoplasm contain in some cases glycogen, in others cholesterine, in others protagon, and in others myosin.*

Analogous in many respects to the protoplasm of Huxley is the bioplasm of Beale. This, as its name implies, is also an elementary life stuff. It is undifferentiated, and in this respect is identical with protoplasm. Beale and Huxley differ as to the mode of production of their elementary life stuffs. Beale affirms that they are the product of the *vital* forces, *per se*;† Huxley of the

* Helmholtz, op. cit.

† Huxley as epitomized by J. Hutchison Stirling, LL.D., to whose able critique on "Protoplasm" the reader is referred.

* According to Stricker, protoplasm varies almost infinitely in consistence, in shape, in structure, and in function. In some cases it is fluid, in others semifluid, in others firm and resisting. Occasionally it is club-shaped, bottle-shaped, spindle-shaped, branched, prismatic, polyhedral, etc. One kind produces fat, another pepsine, another pigment. There is a protoplasm for each of the tissues—nerve, bone, brain, muscle, etc. There is, further, a protoplasm for the several kinds of plants and animals, each producing its own kind.

† His words are: "Force (*i.e.*, physical force) is actually opposed to construction, and before anything is built up the tendencies of force must be overcome by *formative agency* or power. . . . The *vital power* transcends altogether physical forces; for it controls, guides, directs, arranges; while the latter *are controlled, are guided, are directed*, etc." ('Life Theories and Religious Thought,' 1871, pp. 40 and 42.) In proof of the foregoing, Beale states that a tree grows against gravitation. This is quite true; but it is equally true that in such cases the physical forces of capillarity, osmosis, chemical affinity, etc., as I endeavoured to show in my 'Lectures on the Circulation,' are largely employed. The vital forces may override or bridle certain physical forces while they act in conjunction with others. In like manner nature may override or bridle one or more of the physical forces by employing stronger physical ones; but the physical forces subdued, or inoperative for the time being, are not on this account destroyed. They are ready for use when the proper time arrives. Capillarity and osmosis (purely physical forces) in certain cases overcome gravitation equally with the vital forces; but it does not follow from this that gravitation as a power is extinguished. When gravitation (and this remark applies to all the physical forces) is useful in building up the organism, it is employed by nature in conjunction with the vital forces; and when capillarity, osmosis, etc., are more convenient, they are preferred. The vital and physical forces must be regarded in their totality, nor must the object in view be lost sight of. Natural laws and forces (vital, chemical, and physical) act and react upon each other; and though at

physical ones. Beale attributes all organization to life, as apart from the chemical, physical, and other forces. According to him the bioplasm or germinal matter is the same always and everywhere, and consists of small masses of a structureless, colourless, and transparent viscid substance. Beale claims for his bioplasm or life matter similar properties to that claimed by Huxley for his protoplasm. To both the same objections apply. Beale grounds the homogeneity and identity of his bioplasm on microscopical research, and Huxley, as explained, upon ultimate chemical analysis. Neither, however, is trustworthy. Experience teaches us that the microscope is limited in its powers, and that chemical analysis, instead of simply disintegrating and breaking up a body into its ultimate elements, not unfrequently produces new combinations, and consequently new substances.

The grand fact remains that the germs and seeds of plants and the eggs of animals, apparently homogeneous and identical, invariably produce not only their own kind, but, during the process of evolution, substances which are altogether dissimilar. Even man himself, with his wealth of imagination and thought, is the product of an egg, which to the eye of the microscopist and chemist is, as to its several parts, homogeneous and identical. Yet this egg, with its several portions placed in exactly the same conditions, produces the tender pulp of the brain, the flaccid muscles, the tough tendons, the elastic cartilages, the hard bones, the still harder teeth ; the enamel, a substance nearly as brittle as glass, and, in due time, the several secretions, the major portion of which is composed of water. To these are to be added the external skin, with its hair, nails, etc. ; the internal skin, or mucous membrane, with its numerous glands ; the secreting and excreting organs ; the nerves ; the lymphatics ; and the bloodvessels, with their contained blood, so rich, so complex, so marvellous in composition. These various products, so diverse in form, composition, and function, are, we know, the product of an egg. Shall we be told, or, if told, shall we believe, that this egg is homogeneous and identical in all its parts and particles? Identical these parts may be to the eye of sense, but to the eye of reason they are not so. Matter similarly constituted, similarly disposed, and similarly conditioned—*i.e.*, placed under precisely similar circumstances—behaves in precisely the same manner ; in other words, all the parts are influenced alike. If life had to operate on absolutely identical matter, the living mass would be simply homogeneous—*i.e.*, undifferentiated, and if undifferentiated, it would have no power either to build up a plant or an animal. It is impossible to produce muscle, bone, brain, etc., from matter identical in ultimate composition. In the germ, the seed, the egg, even from the first, there is differentiation. The first embryonic changes are the result of this differentiation. It is this which enables the different parts of the embryo to attract and assimilate different substances and to build up different textures. One embryonic change involves another, and gradually the individual is evolved, each according to its kind. The weaver may not produce a web dissimilar in texture and pattern in the absence of dissimilar elements. He must be supplied with the warp, the woof, and the varied pigment. A queen bee may be formed from an ordinary grub by changing the quantity and quality of its food, but no amount of change in diet can produce from the same grub a dragon-fly or a locust.

(*To be continued.*)

times some are inoperative, they are not annihilated, neither are they opposed when the final effect to be produced is taken into account. Organized structures are built up in accordance with natural laws. Thus their parts and particles consist of substances which naturally have a chemical affinity for each other ; those substances absorb and respire—*i.e.*, take in and give off fluids ; they exhibit for the most part capillary spaces and interspaces in their interior ; they have weight, porosity, elasticity, and various other purely physical properties. In this way, chemical affinity, osmosis, capillarity, gravitation, etc., have free play, and each in turn assists not only in forming and maintaining the body, but also in disintegrating it. The vital forces, if I may be allowed the expression, use and abuse the physical ones. They do not—they cannot—annihilate them. As well may we say the vital forces annihilate matter."

THE PURIFICATION OF CHLOROPHYLL.*

BY F. A. HARSTEN.

Chlorophyll forms with metalic oxides compounds which allow of the isolation of the fatty matters that accompany it. The author has experimented upon the chlorophyll of the ivy (*Hedera Helix*) which, besides being obtainable at all seasons of the year, offers great resistance to the action of light and chemical agents. The leaves are reduced into a pulp with 55° alcohol, and after twelve hours this pulp is expressed and the residue washed with strong alcohol to remove water together with a bitter substance, hederine, and a principle analogous to saponin. The dried mass is then treated with benzine, and, after twenty-four hours, expressed ; the benzine upon being distilled, leaves a brown residue, with a fatty appearance. Three kilograms of leaves yield about 80 grams of this residue. This is boiled for ten minutes with double its weight of water, and one-eighth its weight of soda. The alkaline liquor is allowed to cool and then filtered, when it is of a dark green colour. The addition of chloride or nitrate of sodium to this solution precipitates the fat soap together with the chlorophyll soap. These soaps are washed with a very concentrated solution of the same salt, then dissolved in water, and sulphate of copper added. A powder is thus obtained of a beautiful colour containing a copper soap and chlorophyllate of copper. After washing and drying, this powder is boiled with alcohol, then washed with ether and benzine, which dissolves the copper soap. Finally, the chlorophyllate of copper remaining is suspended in alcohol, and decomposed by sulphuretted hydrogen.

The chlorophyll thus obtained consists of brittle grains of a nearly black green colour. It is insoluble in water, soluble in alcohol and in hydrochloric acid, with a beautiful green colour different from the colour of the leaves, the latter being modified by yellow. This chlorophyll may be considered free from fatty matters, for it is dry and brittle, and when heated it does not give of acrolein.

Chlorophyll also forms combinations with the oxides of silver and lead, but these do not lend themselves readily to its purification.

INFLUENCE OF THE SEASONS UPON THE PRINCIPLES CONTAINED IN PLANTS.†

BY F. A. HARSTEN.

The author illustrates the fact that the extraction of certain principles from plants is influenced by the seasons. Thus in the autumn he failed to obtain chrysophyll from the elm or the *Mercurialis perennis*, both of which yielded it easily in the spring time. Chlorophyll was affected in a similar manner in the autumn, and that before the colour of the leaves was sensibly modified.

The author states that at the time of flowering he has extracted from the *Isopyrum malictroides* two alkaloids, the one amorphous and the other crystallizable. In the autumn the former was found in the root in greater abundance, whilst the latter had completely disappeared. The author presumes that the crystallizable alkaloid is first formed in the plant, and that it is gradually transformed into the amorphous alkaloid. He considers it probable that this remark would apply in other cases ; for instance, that opium required for the extraction of morphine should be collected at a different period to that required for the extraction of narceine or codeine.

The Pharmaceutical Journal.

SATURDAY, DECEMBER 27, 1873.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square,*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

WHAT IS A "PATENT MEDICINE?"

OUR ingenuity and patience have often been sorely taxed upon the receipt of a label carefully framed to go as closely as possible to the meshes of the Medicine Stamp and Licence Acts without becoming entangled therein, accompanied by a question as to whether it would be liable to stamp duty or not. Obviously, it is not within our province to decide such doubtful points, and we have been compelled sometimes to recommend that the problem should be forwarded for solution to the Excise authorities. It would appear that similar experiments have been tried in the United States, but with a result that was probably neither expected nor desired, and with a development of the tax-gathering faculty which Englishmen fondly imagined was a peculiarity of the late CHANCELLOR OF THE EXCHEQUER. The following are the principal points in a controversy that has for the past two or three months roused the indignation of our American *confrères*.

A perplexed supervisor, feeling incompetent to the disentanglement of certain logical knots tied for him by wicked and mischievous hands, passed his troubles on to his chief, Mr. Commissioner DOUGLASS, who quickly undid them by the Gordian method. "It is an opinion very generally entertained," said that gentleman in so many words, "that only such medicinal preparations as are patent and proprietary, or are made or prepared by some private formula, or occult or secret art, are liable to stamp tax, and many revenue officers have too generally acquiesced in the same opinion." He then went on to state that any medicinal article, "whether simple, or compounded by any rule, authority, or formula, published or unpublished," which is put up in style or manner similar to that of patent or proprietary medicines, was liable to stamp tax, and that there need be only a similarity in style, a likeness in the general points.

Such an elastic phrase as "similarity of style" was sufficient to rouse the angry susceptibilities of even the long-suffering race of pharmacists. Colleges met and passed resolutions; deputations visited Washington and interviewed the Commissioner: but to little purpose. That functionary took his stand upon the newly-discovered reading of the Act of Congress, and, staunch in the performance of his duty, was deaf to all such pleas as "interference with trade," "hardship to poor purchasers," etc., but so far showed himself conciliatory as to state his views on the question in a letter which, as it would occupy several columns, with little probable benefit, we may refrain from quoting.

At first it was intended to test the correctness of the Commissioner's ruling by an appeal to the law courts, but it was found that a decision could not be obtained for two or three months, and it has therefore been resolved to appeal to Congress to modify or repeal the obnoxious clause. Since under the new ruling such labels as "Epsom Salts—one dose," "Castor Oil—one dose," on packages previously made up, were, when submitted, said to "both require stamps," we heartily wish our American brethren success in their effort.

THE RELATION BETWEEN ATOMIC WEIGHT AND PHYSIOLOGICAL ACTION.

THE theory put forth some time since by M. RABUTEAU, and endorsed by Dr. FRASER, in his lectures delivered before the Edinburgh College of Physicians,* that the metals are more active physiologically according as their atomic weights are more elevated, has recently been questioned by Dr. JOHN CURNOW, in his Introductory Address delivered before the Medical Society of King's College.† M. RABUTEAU illustrated the assumed law by the examples of sodium, potassium, and thallium, and magnesium, zinc and cadmium. Thus, sodium with an atomic weight of 23 is inert; potassium, 39, is active in moderate doses; while thallium, 204, is a dangerous poison. But Dr. CURNOW points out that lithium—a more manifest member of the alkali group than thallium—is remarkable alike for its activity and its low combining number (7). Again, he compares copper (63·5) with lead (207), mercury (200) with bismuth (207), and arsenic (75) with antimony (122). Dr. CURNOW also disputes the value of the conclusions adopted by Dr. FRASER in the same lectures, that salts of the same base have analogous actions (compare the carbonate of ammonium with the chloride, or the sulphate of sodium with the chloride), and that isomorphous substances produce similar effects (compare the fluoride, bromide, and iodide of potassium; the sulphates of zinc, iron, and magnesia; and the phosphate and arseniate of soda).

CULTIVATION OF VANILLA IN THE ISLAND OF REUNION.

THE cultivation of the vanilla plant has recently become in high favour in the island of Reunion in consequence of the enormous increase in its value, which is stated to have quintupled during the last eighteen months, and to be still increasing. Last year's crop, however, fell short of that of 1871-72, by something like 2000 kilos, while in Mexico, the great rival of Reunion in vanilla, the decline was still greater.

The value of the vanilla exported from Reunion last year, was upwards of £50,000. It is said by the people of Reunion, that the Germans contracted a taste for vanilla in confectionery during their stay in

* PHARM. JOURN. [3], vol. iii., p. 385.
† *Med. Times* and *Gazette*, Nov. 22, p. 599.

France during the late war, and that owing to the great increase in their wealth by the payment of the French indemnity, they are now able to indulge that taste. At any rate, a large portion of the vanilla now grown in this island is exported to Germany, to supply a demand that has sprung up since that time. Unfortunately, the island is devastated by periodical cyclones, which make it very difficult to cultivate successfully a plant like the vanilla, notwithstanding the support and shelter afforded by the trees, or espaliers, on which it is trained. It suffered immensely in the cyclone of 1872, and one that has recently passed over the island has probable seriously compromised this year's crop.

A POISONOUS COMPOSITE PLANT.

Though some of the members of the Composite order are well-known for their acrid properties, few, if any, have hitherto been known of an actually poisonous nature. A case, however, is reported from America of the poisoning of some hogs from eating the leaves of *Rudbeckia laciniata*. The genus is a well-known North American one, consisting of herbaceous plants nearly allied to *Helianthus* or the sun-flowers; the receptacle, however, is cone-shaped, not flat as in the sun-flower. Several species are known in cultivation. *R. laciniata* is not uncommon in herbaceous borders. It is a smooth, branching plant, growing to a height of from six to eight feet, the lower leaves are pinnate, and the upper three or five parted. The ray florets are vertical, in a single series, yellow, and the disc florets are tubular, of a greenish-yellow colour. The plant is common in some parts of Canada and the States. The effect upon hogs after eating the leaves of this plant is said to be a kind of delirium, succeeded in a few hours by death. A correspondent, writing from Oregon to the Department of Agriculture at Washington, says:—"The hog invariably seeks water, and if he reaches it remains in it until he dies. Vomiting and purging often occur, and are considered favourable symptoms. The discharges are green. Milk and lard are the most effective remedies, and always give relief when the animal is discovered in time. A number of cases were named to me where the hogs had passed into an extreme state of delirium, but were relieved in a few hours by pouring a pint of milk and lard mixed down the throat, and restored to complete health without any other treatment. This plant is very plentiful along the creeks in this county, and is among the earliest in the spring to send forth its leaves, which are eagerly eaten by hogs when turned out. It is also the latest green thing that grows in the fall of the year, and is then eaten by hogs. During the summer months they do not eat it, probably for two reasons—the plants are then tall, and not so tender, and there are many other things for them to eat. The plant is used by some people very early in the spring for 'greens,' but all seem careful to avoid using it except when very tender, as it seems to be the general belief that it is poisonous; indeed, cases have been cited wherein the same results followed the use of it by persons as has been observed in the hog, except that none have been fatal."

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

December 17th, 18th, 19th, and 22nd, 1873.

Present (17th and 19th)—Messrs. Allchin, Barnes, Carteighe, Corder, Cracknell, Davenport, Gale, Hills, Linford, Martindale, Schweitzer, Southall, and Umney.

(18th)—Messrs. Allchin, Barnes, Carteighe, Corder, Cracknell, Davenport, Gale, Hills, Martindale, Schweitzer, Southall, and Umney.

(22nd)—Messrs. Allchin, Barnes, Carteighe, Cracknell, Davenport, Gale, Hills, Linford, Martindale, Schweitzer, and Umney.

Dr. Greenhow was present on the 18th, on behalf of the Privy Council.

MAJOR EXAMINATION.

Four candidates were examined, and declared qualified to be registered as Pharmaceutical Chemists:—

	Walton, Major Foulds	Sowerby Bridge.
Equal.	Senior, William Furber	Doncaster.
Equal.	Wenham, George Daniel	King's Lynn.
	Normand, Claude	Hammersmith.

MINOR EXAMINATION.

Ninety-six candidates were examined. *Forty-two* failed. The following *fifty-four* passed, and were declared qualified to be registered as Chemists and Druggists:—

	*Howell, Evan John	Sloane Street, S.W.
	*Luff, Arthur Pearson	Old Brompton.
	*Dutchman, Walter	London.
	*Gilkes, Frederick George	Banbury.
	*Walker, William	Settle.
	Edmondson, William	Morecambe.
	Morton, Henry	London.
	Atkinson, John George	Horncastle.
	Davies, Samuel	Swansea.
	Wilks, Maurice	Leeds.
	Campbell, Henry	Hammersmith.
	Kemble, James	St. Austell.
	Thomson, Robert	Stirling.
	Broomfield, Robert William	Harrogate.
Equal.	Clayton, Charles	Lincoln.
Equal.	Owles, Charles Edward	Bungay.
	Goodacre, John William	Coventry.
	Harris, William	Llandilo.
	Gordelier, William Gibbs	Sittingbourne.
Equal.	Bladon, William George	Cheltenham.
Equal.	Taylor, George	Kendal.
Equal.	Williams, William	Aberffraw.
	Dunnill, George Henry	Sheffield.
Equal.	Clarke, Thomas Edward	Shrewsbury.
Equal.	Umpleby, Samuel Sayer	Harrogate.
	Kiddle, Richard Neller	Lambeth.
	Lloyd, Frederic Wm. Wellington	Rhyl.
	Evans, Thomas Mould	Derby.
Equal.	Hamond, Joseph	Peterborough.
Equal.	Pearson, Charles Frederick	Liverpool.
	Bridges, Ashley Colston	Cleobury Mortimer.
Equal.	Bumpstead, Robert George	Colchester.
Equal.	Davies, Frank Henry	Portsmouth.
	Flint, Charles Bruce	Glasgow.
	Haysworth, William Stone	Preston.
	Case, Perkins William	Trowbridge.
	Limon, Henry James	Burgh-le-marsh.
	Willson, Alfred	Landport.
	Hookes, Robert Thomas	St. Asaph.
	Shaw, Stephen	London.
Equal.	Dobson, George	Egremont.
Equal.	Elkington, Walter T. Woolldridge	Leicester.
Equal.	Hobbs, Thomas Henry Hurle	Wells.
Equal.	Maude, William Robert	York.
	Wakefield, John	Teddington.
	Forth, William Pilcher	Ashford.

* Passed with Honours.

Equal. { Blacklock, John .....Swinton, near Manchester.
Tharle, Charles Albert.....Ventnor.
Thomas, Thomas Francis.....London.

Equal { Capes, John Henry Cooper.....York.
Evans, David.....London.

Whewell, Herbert.....Birmingham.
Barlow, Joseph Alexander .....Rochdale.
Thomas, Frank.....Boston.

The above names are arranged in order of merit.

Provincial Transactions.

BRISTOL PHARMACEUTICAL ASSOCIATION.

The third general meeting of the present session was held at the Bristol Museum and Library, on Friday, Dec. 12th. The President, Mr. G. F. Schacht, in introducing the business of the evening, namely, the "Reading and Discussion of Papers," congratulated the Association on the fact of so many really important communications being forthcoming for the occasion. With such a programme as had been announced, there was little fear that their time would be otherwise than fully and profitably occupied. Without further preface, he would call upon Mr. Giles, whose name was first on the list, for the paper he had kindly promised.

The Official, Commercial, and Authentic Sources of Pareira Brava.

BY R. W. GILES.

Mr. Giles said the object of his paper would be limited to such an illustration of Mr. Daniel Hanbury's recent communication to the Pharmaceutical Journal on the subject of Pareira Brava as would serve to explain the interest which attached to the specimens on the table which he desired to present to the Association as a contribution to its contemplated museum. Mr. Hanbury's paper was extremely valuable and practical. All his researches were thorough, but inevitably they had not always the advantage of possessing so much trade interest as this last. In it he showed conclusively that pharmacists had been the victims of official delusion as to the source of Pareira Brava, since the period when the Pharmacopœia undertook to enlighten them in 1836, and, what was worse, that they had been the victims of commercial miscarriage—whether wilful, negligent, or excusable, he could not say—which had resulted in supplying them, and through them our customers, with an inert production, instead of a drug of old-established, and, he believed, deserved reputation. This was obviously a matter of real and serious importance, and one against which it was exceedingly difficult for a pharmaceutist of ordinary quality to guard. The possibility of such substitutions as had occurred in respect of Pareira Brava, showed the advantage of a good museum of authentic specimens, with their known substitutes; such a museum as they were proud of possessing in Bloomsbury Square, such a one as he hoped might be formed in Bristol. It also taught them to appreciate the value of the investigations which were pursued with so much zeal by pharmacologists like Mr. Hanbury. He was sure that most of them had remarked the suspicious variations of character in the Pareira Brava which they had obtained from time to time in the ordinary course of trade. It had never seemed to be twice alike. He had noticed these differences with great mistrust, and had not known how to help himself. Mr. Hanbury had explored these occult phenomena, and had not only distinguished between the various *soi-disant* Pareira Bravas, which they might perhaps have done for themselves, but had patiently mined amongst the MS. records of past generations, and had distinguished and brought to light the identity of the original Pareira Brava, which was brought to the knowledge of European medicine in the 17th century, and had held its place with more or less favour to the present day. These investigations assured them that the suspected samples of recent years had in fact been spurious, and the preparations made from them with much pains entirely worthless; but it was satisfactory to know that the drug now in the market was genuine, although it certainly was *not* the product of *Cissampelos Pareira* which the Pharmacopœia required pharmacists to use. Thus it followed that they were liable to penalties under the Adulteration Act for every prescription dispensed intelligently, and guilty of an offence against the public health if they adhered to the official directions, being one of many instances in which they were charged with the obligations of a profession while subject to the annoyances of a trade. They were worried with the trades and harassed with the professions. He would now present to their notice the specimens to which the foregoing remarks referred, viz.:—

1st. *Cissampelos Pareira.*—Given by all the Pharmacopœias from 1836 as the source of officinal Pareira Brava. This specimen was some of the drug referred to by Mr. Hanbury as coming from Jamaica; it was also found in Brazil and elsewhere. They had probably never seen any commercial samples of Pareira Brava bearing any resemblance to this.

2nd. *Chondodendron tomentosum* (Brazil).—Real Pareira Brava, identical with the drug introduced into Europe about the year 1688. (An enlarged section of the stem of *Chondodendron* was represented on a diagram.) Of this root Mr. Hanbury writes: "I strongly advocate returning to the use of *Chondodendron*, which is the drug on which the reputation of Pareira Brava was originally founded." Speaking also of spurious pareira which had occupied the market in past years, but was neither derived from *Chondodendron* or *Cissampelos*, he says: "It should be rigidly excluded from pharmaceutical use." Before, however, gentlemen went home and committed their stock of spurious pareira to the flames, as they would of course do, he had to ask the favour that they would kindly reserve some good typical specimens to add to their museum series of "false pareira." He had, unfortunately, not been able to secure any for that evening's meeting. In concluding that slight, but he hoped not altogether unintersting communication, he could not refrain from expressing disapproval of the laxity which had perpetuated in four Pharmacopœias, from 1836 to 1867, an official error apparently so easy of correction as the ascription of Pareira Brava to the *Cissampelos Pareira*, to which it bears not the least resemblance. It would be better to give no "*unde derivata*" at all, than one which was calculated to increase confusion and to sanction mistakes; and it was painful to think that some youth of ingenuous countenance, who, with becoming diffidence had confessed his ignorance of the origin of Pareira Brava, may have been ruthlessly plucked by his examiners for not repeating the fallacious fiction that it was derived from *Cissampelos Pareira!* (He dedicated that observation with much respect to all whom it might concern.) Let us hope, now that Pharmacy was fairly established in the joint compilation of its own text-book, that those errors might be weeded out. With Dr. Redwood to advise as to the processes, they had every reason to feel confidence that they would be kept up to the advancing course of pharmacy. Could we see the animal and vegetable materia medica placed under the direction of Mr. Hanbury, we might feel equally satisfied as to their thorough revision.

The President expressed the obligations of the Association to Mr. Giles for the interesting paper he had just read to them, and for the excellent specimens which he had kindly promised to contribute to their local museum. He had frequently heard disappointment expressed by medical men with the action of the Pareira Brava preparations, attributable, no doubt, to the worthless substitutes that had been shown to have been in use. Great credit was due to Mr. Daniel Hanbury for his painstaking in-

vestigation of this subject, from which they might reasonably expect the most satisfactory results. And they would agree with him that Mr. Giles was entitled also to their best thanks, for having brought the matter directly under their notice in so complete and instructive a manner.

Mr. Stoddart had also noticed the marked variation in the Pareira Brava preparations sent out by different wholesale houses, and had experienced considerable perplexity on that account. He knew of an instance in which a London firm who had supplied a preparation made from the true variety, had had it returned as unsatisfactory. Referring to the specimens shown by Mr. Giles, he took occasion to draw the attention of the students present to a simple but most reliable method of distinguishing between roots and stems—sometimes not an easy thing to do. With the aid of an ordinary lens, lichen might almost invariably be detected on stems which grew above ground, whereas these were never found upon underground roots. If they would bear this fact in mind, they would find it greatly assist them in the event of their being examined upon the point.

Mr. Boucher (Ferris and Co.) asked Mr. Giles if he had determined the relative proportions of extractive matter in the root and the stem.

Mr. Giles said he had not, but the stem was undoubtedly rich in extractive matter. Mr. Hanbury was of opinion that there was no medicinal superiority in the roots over the stems. It would be noticed that the decoction of the *Cissampelos Pareira* on the table, had a pronounced bitter taste, but was wanting in that sweetness resembling the flavour of liquorice, which was present in *Chondodendron*, and had been remarked by Geoffroy in 1741 as characteristic of the Pareira Brava then known.

The President said he had listened to the discussion with very great pleasure. He was glad to know that the *Chondodendron* of Brazil was easily procurable in the market at the present time. He had scarcely ventured to hope that a supply would be so soon forthcoming. He would now call upon Mr. Stoddart, who had kindly undertaken to discourse to them upon adulterated drugs.

Mr. Stoddart said that before proceeding to that subject he would show them a couple of specimens which he intended for the projected materia medica museum. The first was a fine specimen of Cryolite from West Greenland, a nearly pure sample of the double fluoride of sodium and aluminium. The second consisted of some perfectly formed prismatic crystals of Thenardite, or anhydrous sulphate of sodium, collected on the mountains near Tarapaca, in Peru. The latter were most interesting because they illustrated the fact that in that part of the world there is no rainfall.

Note on some Samples of Adulterated Drugs.

Mr. Stoddart then alluded to the unfortunate and unwise prosecutions that had taken place under the Adulteration Act in the matter of citrate of magnesia and sweet spirit of nitre. He said that unfortunately there was no occasion for choosing such doubtful cases. To prove this assertion he placed on the table samples that had been brought before his notice. Among others were opium, largely adulterated with gum senegal; jalap, with linseed meal; cream of tartar, with alum; white precipitate, with gypsum; citric acid, with tartaric acid; and iodide of potassium containing 10 per cent. of iodate. Mr. Stoddart then reverting to the subject of spirit. æther. nit., said he had examined his own stock and also that of some of his neighbours. He found that none of the P.L. preparations showed the slightest sign of an excess of nitrous ether. The specimen prepared according to the process of the British Pharmacopœia showed an excess of ether from 1 to 1½ per cent. This he thought was very fair. The calcium test is a very unreliable one, from two causes; one from variation in the solution of chloride of calcium itself, and the other from the escape of some of the nitrous ether, which, without great care, it is impossible to prevent. If the solution and the P.L. sp. æth. nit. be shaken together in a graduated glass tube, little action is seen. If, however, the B.P. sp. æth. nit. be used, considerable effervescence takes place, with some amount of pressure upon the thumb or stopper, as the case may be. He thought that to affirm sp. æther. nit. P.B. was not sweet nitre was in reality a kind of quibble. Doubtless the old process for making sweet nitre was by the distillation of nitric acid and spirit of wine, produeing a solution of nitrous ether; but when a proposed better process was used for the production of the same spirituous mixture, he did not think it was untrue to say it was also sweet nitre. The remarks made by many that they could not sell the B.P. article surprised him. Ever since the appearance of the 1867 Pharmacopœia he had sold the sp. æth. nit. of that edition, and in no instance had ever heard of any eomplaint, not even when a teetotaller drank it as a harmless (?) stimulant, instead of the P.L. compound to which he had previously been accustomed. He was rather surprised at Mr. Umney's evidence in favour of the defendant when he said, *he used the process of the London Pharmacopœia, and distilled over nearly the whole of the spirit, according to the directions of the* 1746 *edition*, and ignored all succeeding ones which ordered a less amount of distillate, and which was the article generally understood when any one ordered sweet spirit of nitre without meaning the B.P. article. In his opinion it was rather rash to say that such a preparation was equally worthless with a very much stronger solution of nitrous ether. He could not quite endorse the opinion that sp. vini. rect., containing 10 per eent. of nitrous ether in solution, had no different effect from simple spirit. Medical men no doubt found it so when their prescriptions were made up from the antique formula of 1746.

The President thanked Mr. Stoddart, on behalf of the society, for the valuable mineralogical specimens. They undoubtedly were of more than ordinary interest, and would be an important acquisition to the museum collection which they hoped soon to possess.

Mr. Giles, alluding to the presence of iodate in the sample of iodide of potassium shown by Mr. Stoddart, said that it could not be considered a fraudulent adulteration, but it was evidence of reprehensible neglect in the process of manufacture. Iodate of potash is formed conjointly with the iodide, but it should have been subsequently reduced by ignition, as directed in the Pharmacopœia.

Mr. Charles Townsend (Ferris and Co.) said that some time since they had offered to them, at eight shillings per pound, at a time when opium was quoted at twenty-one shillings, an article to all appearance—internally as well as externally—of remarkably good quality, but which, on examination, was found to contain less than 3 per cent. of morphia. He believed it was commercially known by the name of "pudding." It was adulterated with some gum, and presented a much better appearance than the sample shown by Mr. Stoddart. No doubt a market had been found for it, but he need not say that his firm had not yielded to the tempting inducement.

Mr. Boucher (Ferris and Co.) said that he had found it to contain even less than 2 per cent. of morphia. Tragacanth was the gum with which it was adulterated, and so perfect was the intermixture that no suspicion would be aroused by its appearance, but immediately any attempt at manipulation was made, the fraud was discernible, for it was found impossible to deal with the substance in the ordinary way.

Dr. Tilden—who was cordially applauded on rising—said that he should consider the presence of 10 per cent. of iodate in iodide of potassium a most serious matter, likely indeed to produce poisonous effects, inasmuch as iodine would be liberated on the mixture of iodate and iodide coming into contact with the acids supposed to exist in the stomach. Alluding to the sp. æther nit. controversy, he said that previous to the publication of the

1864 Pharmacopœia, Professor Redwood, himself, and others, had made a number of experiments in connection with sweet spirit of nitre. He considered that the Pharmacopœia test was a most unsatisfactory one, and he believed that for practical purposes the best way would be to treat with a standardized weak solution of caustic potash, and observe the amount neutralized. This method was found to answer very well for estimating the amount of compound ethers in wines, etc. Probably the best of all methods would be to heat with liquid ammonia, and measure the nitrogen gas evolved; but in practice he was afraid this would be found too complicated and troublesome, and, therefore, not likely to be generally employed.

Percolation.

BY R. W. GILES.

Mr. Giles proposed a modification of the usual process of percolation, which he found more convenient and equally efficient. The plan recommended was to moisten the powdered ingredients with, say, half their weight of the spirituous menstruum, so as to allow of their swelling before packing in the percolator—then pack them very tightly, and follow with remaining spirit and displace with water. He found this process more expeditious and more easily conducted than any other, especially with reference to the facility with which the spirituous solvent could be displaced by water without mixing. The apparatus used was simply an inverted wide-mouthed bottle without a bottom, the mouth being covered on the inside by a perforated strainer.

Mr. Towerzey wished to know if Mr. Giles had found it necessary to use any sand.

Mr. Giles: Neither sand nor anything else.

The President remarked that one advantage of Mr. Giles' method was the remarkable simplicity of the apparatus employed.

Mr. Towerzey then read a paper on

"Results of an Examination of some Samples of Hydrocyanic Acid."

[This paper will be found *in extenso* at p. 509.]

The President observed that he felt he must say but little as to the merits of the paper they had just heard, as to some extent he was answerable for the conclusion arrived at. He might, however, be permitted to say that it had given him great pleasure to assist Mr. Towerzey. He had found him throughout moved by the best possible spirit of fair inquiry, always scrupulously careful in performing his experiments, and perfectly content with his results. That hydrocyanic acid was an extremely volatile substance, and on that account absolutely certain of variation in strength, had been abundantly shown in the course of their investigations; for, despite the use of every possible precaution, they had, in successive testings of the same sample, found a gradual diminution in the quantity of acid indicated.

Mr. Boucher said that they were much indebted to Mr. Towerzey for the facts which he had brought before them. It would be a great boon to pharmacists, as well as to prescribers and their patients, if some more stable preparation could be devised; for besides the tendency to lose its HCN on the slightest exposure to air, as shown by Mr. Towerzey, its liability to decomposition on being kept, when perfectly pure and without the addition of other acid, was equally annoying. He had found in his experience that if the percentage of acid was large, rapid diminution of strength took place, and on the other hand a weak solution seemed to undergo decomposition more readily.

Dr. Tilden said he had listened with great pleasure to Mr. Towerzey's observations. Possibly the double cyanide of zinc and potassium would form a good substitute for the fickle acid now used. The crystals exhibited were certainly of beautiful structure, well formed, and apparently stable; but he doubted if the medical profession would be easily induced to prescribe a new preparation, the present one having been for so long a period universally employed. With regard to the remarks of the last speaker, he could not corroborate from his own experience the statement he had made as to the decomposition of a weak acid when pure. This decomposition might be explained, perhaps, by the well-known fact that water was capable of dissolving out a sufficient quantity of the alkali present in glass to acquire a distinctly alkaline reaction, and he believed the alkaline cyanides to be extremely unstable in solution. To obviate this tendency manufacturers were in the habit of adding a small quantity of some mineral acid; he believed sulphuric acid was chiefly used for the purpose as it did not clash with the Pharmacopœial tests. Believing that the changes of strength observed were, however, attributable to volatilization rather than to decomposition of the hydrocyanic acid, his suggestion was that experiments should be made with a much weaker acid—one, say, of ·2 per cent.—equivalent to one-tenth of the present strength, with the addition of the requisite quantity of hydrochloric acid.

Mr. Boucher observed that it had been shown by recent observation that hydrocyanic acid in a state of purity would decompose when kept for a short time in bottles of any description.

Mr. Giles thought that hydrocyanic acid must be accepted as presenting certain difficulties which it was their business to reduce to a minimum by appropriate precautions. If the necessity for these precautions was kept in mind, he thought the difficulties were not such as would cause serious embarassment to themselves or disappointment to the medical profession. Similar difficulties met them in other articles, for example, in stale stock generally, and in infusions and decoctions particularly, and perhaps it was well that they should have their attention directed to these considerations, where it might be that they were most vulnerable, for there were possibly those who would keep a drug until it became bad, who would not willingly buy a bad drug. In looking at the diagram before them they had to remember that it was not simply a case of *not falling below 2 per cent., for it was even worse to be above it*; and in a volatile preparation like hydrocyanic acid, it was inevitable that stock in use should be constantly somewhat below the official standard; for if up to it to-day it would be short of it to-morrow. They were not told expressly whose were those local samples numbered on the diagram respectively Nos. 2, 3, etc., and they would each naturally believe that No. 2 was their own. He should certainly assume it to be *his*, and would proceed to tell them by what arrangements he was enabled to maintain such a creditable specimen. He did not adhere to the high moral and religious formulary of purchasing two strengths of hydrocyanic acid, in order that they might keep each other in countenance, while they lost strength. He thought the best plan was to keep stock of one strength only, and to convert this into the lower official strength from day to day, as required for actual service. By this means it was quite possible to maintain a sufficiently close approximation to the standard for practical ends, and he recommended this method because he did not think there was much prospect of so popular a remedy as the liquid acid being soon supplanted by a more permanent cyanogen compound.

Mr. Stoddart alluded to the old-fashioned practice of sending out hydrocyanic acid in blue glass bottles, which was, he said, about the worst colour that possibly could be chosen, inasmuch as it most readily admitted the chemical rays of light, and so induced the very results it was intended to obviate.

The President having congratulated Mr. Towerzey upon the animated discussion his paper had excited, the proceedings terminated.

GLASGOW CHEMISTS' ASSOCIATION.

(Assistants' Section.)

The Third General Meeting of Assistants' Section of Chemists' Association was held in Anderson's University, on Wednesday, 10th December, 1873, at 9 p.m. Mr. John Hunter, President, in the chair.

The meeting being constituted, the minutes of last meeting were read and approved of.

Mr. John Foster then read a paper on "Animal Substances, as used in Medicine and the Arts." In it he described the origin, history, and uses of the various substances, and touched more especially on the several adulterations to which they were liable, and the best methods of detecting them. At the close, Mr. Foster was awarded a hearty vote of thanks for his able and instructive paper. At the previous meeting Mr. John Hunter gave a paper on "Modern Relations of Organic and Inorganic Chemistry," the object of which was to show that, as researches deepened, many substances for which we had now to rely on uncertain natural sources would be supplied from our chemical works.

These papers were two of a series written for prizes, which, by the generosity of a Glasgow chemist, the Association has been able to offer.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

On Thursday evening, Dec. 11th, a lecture was delivered before the members of the above Association, at their Rooms, Halford Street, by F. T. Mott, Esq., F.G.S. Mr. T. H. Lloyd took the chair, and there was a large attendance, many of the members having brought friends with them.

The Chairman having briefly introduced the lecturer, Mr. Mott delivered a most exhaustive and lucid address on "The Natural Orders of Plants," confining himself, after a few preliminary remarks, to the description of the principal characteristics of thirteen natural orders most commonly met with in this country. Among these were the natural orders Ranunculaceæ, Rosaceæ, Caryophyllaceæ, Umbelliferæ, Compositæ, Cruciferæ, Leguminosæ, Rubiaceæ, Campanulaceæ, and Scrophulariaceæ.

The difficulties attending the classification of plants owing to the singular relationships and similarities which plants of different natural orders sometimes bear to one another were then referred to, and the members were strongly advised to follow out the directions given in some standard work by careful practical study.

A large amount of interesting information was condensed into a lecture of an hour and a quarter, and the audience thoroughly testified to their interest in it by the great attention which was paid throughout and by the intelligent questions which were put to the lecturer at the conclusion.

Mr. Mott indeed thoroughly popularized a subject which is eminently distasteful to many minds, and exhibited the science of botany not as a dry collection of facts and names, but in the aspect of an instructive and delightful study.

A very hearty vote of thanks was accorded to the lecturer for the enjoyable evening he had afforded, and for the interest which he took in the welfare of the Association, and Mr. Mott, in replying, promised at some future time to repeat his kind services.

A vote of thanks to the Chairman closed the proceedings.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, 18th December, 1873. Dr. Odling, F.R.S., President, in the chair. The customary business of the Society having been completed, a paper "On the Preparation of Standard Trial-Plates, to be used in Verifying the Composition of the Coinage." was read by the author, Mr. W. C. Roberts, Chemist of the Royal Mint. After giving a sketch of the variation in composition of the English gold and silver coins from the earliest times, he noticed the various trial plates which had been prepared since 1660, showing that they sometimes varied considerably from the standard of 916·66 parts in 1000 for the gold, and 925·0 for the silver. He then proceeded to describe the process employed and the difficulties to be overcome in the preparation of the new standard trial-plates. These were exhibited at the meeting, and also a magnificent specimen of pure crystallized gold.

The other papers read were "Researches on the Action of the Copper-zinc Couple on Organic Bodies, Part IV.: On Iodide of Allyl," by Dr. J. H. Gladstone, and Mr. A. Tribe, being a continuation of their investigations on this subject. "On Tetranickelous Phosphide," by Dr. R. Schenck. "On Ferrous Anhydrosulphate," by Mr. T. Bolas. The compound, which is crystalline, is precipitated on mixing an aqueous solution of green vitriol with about nine times its volume of concentrated sulphuric acid. The last paper was "On the Hydrochloride of Narceine," by Dr. C. R. A. Wright, after which the meeting was adjourned until Thursday, 15th Jan., 1874, when the following papers will be read :—

"On the Action of Tricloracetyl Chloride on Amines, I. Action on Aniline," by Dr. Tommasi and Mr. R. Meldola.

"Researches on the Action of the Copper-Zinc Couple on Organic Bodies, Part V.: On Ethyl Bromide," by Dr. J. H. Gladstone, and Mr. A. Tribe.

SOCIETY OF ARTS.

On the Energies of the Imponderables, with especial reference to the Measurement and Utilization of them.*

by the rev. arthur rigg, m.a.

Lecture VI.

The Energy of Light, especially with reference to the Measurement and Utilization of it.

(*Continued from page* 503.)

Take a common gas burner; if a short tube having a few holes at the bottom be placed over it and the gas lighted at the top of the tube you have a light which has a certain non-penetrating power. It cannot penetrate far; it has a pale blue lambent flame. Now if the tube be taken off, and the gas lighted at the burner, you have the same quantity of material burning, but with a very different penetrating power. In this case it is evident that the penetrating power depends entirely on the mode in which the apparatus is arranged for combustion of the gas.

From the remarks made it may be inferred that science is yet incompetent to pronounce decidedly, 1st, what or which element or elements in the solar beam, constitute light properly so called; 2nd, even if this be determined positively, yet science is still undecided by what rule, or weight, or measure, the energy of light is to be gauged.

Indeed, this remark may not be an exaggeration—in all probability no two persons see the same degree of light. It may be surmised that no two persons see any portion of the spectrum of the same colour, and, further, it is highly probable that there is no such thing as colour in nature at all. It is likely that colour is a pure impression produced upon the retina of each person's eye by the vibrations of the medium which strike upon it. Hence what we call red, orange, yellow, green, blue, indigo, and violet do not exist actually in the spectrum, but in the eye of the observer, and probably one person will see the red beginning here, and extending thus far, whilst others will see it beginning a little more to the left, and ending a little more to the right, or *vice versa*. Upon that point there is nothing really settled.

* Cantor Lecture, delivered March 10, 1873; reprinted from the *Journal of the Society of Arts*.

As to the first of the foregoing inferences the energy of light is said to be concentrated in the yellow portion of the visible spectrum. If the views of those whose pursuits are photographic are to be received, the perplexities of science are increased. The very name of their art—photography—indicates the writing of or by light alone.

The fact is that photography is not a process dependent upon light as light, but upon that portion of light which is possessed of certain peculiar, and hitherto unexplainable, influences of a chemical character. Photographic chemistry is as yet very partially understood. Were it not that those who think they understand it might be offended, the truth would not be outraged, by saying, that photographic chemistry is not at all understood. And yet no process for estimating the energy of light, as light, has been suggested more hopeful for success than that dependent upon chemical changes ; but these are not those chemical ones to which the photographer appeals. The fact is, that those changes appreciated by the photographer can be produced in inorganic compounds ; what they are can be partially noted, they can be recorded, and that in terms which are but relative (not absolute), and which chemistry alone can measure. The day may not be distant when the energy of light, as light, will be duly and absolutely measured.

Judging from its place in the order of creation, previously named—judging from its influence over the whole world of animal and vegetable existences—judging from such facts as that when light is absent all animal and vegetable life lapses into a species of torpor, or sleep, and on the return of light nature awakes, and resumes its activity and strength, the conclusion is a very legitimate one, that in light—as light—there is great energy. Light opens the eyes, not of animals only, but even of flowers ; hence one of our little English flowers is called "The day's eye." Those who can sleep through noise, and even through heat, are not insensible to the energy of even artificial sources of light, playing, however gently, upon the closed eyelid. Medical men and nurses are well aware how essential light is for the regaining of health and strength by the sick or the infirm. Egypt and Madeira, as sanitaria or convalescent homes for our ailing brothers and sisters, may owe more of their influence to qualities or energies of light, very different from those the photographer esteems, than are usually allotted to them. And it may be permitted to add, that marvellous testimony to some unknown element (be it figurative or be it real) which, whilst pervading all Scripture from Genesis to Revelation, assumes a most marked peculiarity in that expression of St. Paul (Eph. v. 14), "Awake thou that sleepest, and arise from the dead, and Christ shall give thee [marvellous gift] light"—not life, observe, but "light."

Sir H. Davy, in an article on the causes of the colours of organic beings, written about 1790, when Davy was only nineteen years of age, writes—"Nature has catenated together organic beings, and made them mutually dependent on each other for their existence, and all dependent on light. A privation of light would be immediately destructive to organic existence ; vegetation would cease ; the supply of oxygen gas would be immediately cut off from the animals ; the lower strata of the atmosphere would become composed of carbonic acid ; and perception and volition would exist no longer."* Although these views were expressed more than 80 years ago, very little progress has been made in the direction they indicate.

Such considerations as these suggest that he who would truly ascertain and measure the energy of light—that energy upon which all terrestrial life depends—must look to do so in its influence on organized beings ; he must either separate the allied influences, or he must so separately estimate that he can apply his estimate, correcting a general result by a process of common occurrence—viz., the eliminating of all foreign or allied energies, and thus give to science the true energy of true light. He who, with knowledge and patient skill, enters upon this hitherto almost unexplored and yet noble field of investigation and research, will give to the age in which he lives, and transmit to future generations, that which will indeed be a boon to all. Pending the coming of that time when some science investigator, possessed of sufficient knowledge, humility, originality, and skill, shall do for light what Newton, Attwood, and Kater have done for the measuring of the energy of gravity—what Mayer, Joule, and Thompson have done for that of heat—what Haughton has done for that of vitality, and what Siemens, Matthieson, Jenkins, and others have done for electricity—what Davy, Dalton, and others have very partially done for that of affinity, and what Bunsen and Roscoe have done for the chemical energy of light—but what no one has yet done for that of light—properly and exclusively so-called—we must content ourselves with such modes of estimating this energy as are at present known and available.

This energy is supposed to be manifested in the promotion and facilitating of chemical affinities. These affinities (as doubtless some present remember) vary in their character as one or more of the "imponderables" are combined in their promotion. So much is this the case that chemical notation now adds, in reference to certain indicated changes, the words, by heat or electricity, as the case may be. There are, however, certain affinities called forth under the influences of light, which do not show themselves under any other conditions. As, for example, certain of the salts of silver (such as silver combined with chlorine, iodine, or bromine) change their colour and their character, the silver being set free from its combination as a black powder. There is also that power, which plants in the presence of sunlight possess, of changing the carbonic acid gas, which, if allowed to accumulate in the atmosphere, would soon render it unfit to be breathed, into its constituent elements, the plant retaining the carbon and ejecting the oxygen. Priestley, in 1790, that is, at the period when Davy wrote the article from which an extract has been read, a period when, for a short time, men's minds were being directed to this department of scientific research, was the first to show that plants kept the atmosphere pure and healthy, but he could not calculate. His was rather a qualitative and not a quantitative result.

Changes in the colour of salts of silver, through some energy of light, have been observed since the middle of the 16th century. In 1777, Scheele suggested some explanations which, although very imperfect, are as yet the only recognized ones. In the early part of the present century experiments of a similar kind were made at the Royal Institution by Wedgwood and Davy.* The absence of any mode of fixing the impression caused the results to be very evanescent, but the localizing of this peculiar property of light is clearly announced in these words :—"Red rays, or the common sunbeam, passed through red glass, have very little action ; yellow and green are more efficacious, but blue and violet light produce the most decided effect."

The rapid development of the art of photography during the past twenty or thirty years has led enthusiasts in this branch to overlook the purely chemical character of their art, and to attribute the changes with which they deal to a manifestation of the energy of light. Hence scales have been devised which may enable photographers to adopt some kind of a standard. They are not, however, worthy of the name of scales of energy, as they depend upon the power of the eye to appreciate very slight differences in shade. A scale or measure, to be of general use, should be of such a character that a person in one part of the world writing to one in another might refer to some common standard.

* Davy's Works, vol. ii., p. 106.

* *Journal of the Royal Institution* for 1802, p. 170.

There is, however, a process for obtaining a measurement of one element in the energy of light capable of greater accuracy of observation than the photographic one. This also is chemical.

In the lecture on the energy of affinity a brief time was devoted to the peculiar manifestation of affinities under the conditions of the nascent state.

It is apparently a deviation from this form of energy when the two well-known gases, chlorine and hydrogen, are produced and intimately mixed, either in their nascent state or afterwards, in the dark or in the presence of that portion of the solar beam we call red. Under these conditions no rapid union of the gases takes place. Permit the evolution or the mixing of the two gases to be in ordinary light, properly so-called, and an intimate union, or rather an actual chemical combination is a consequence.

If these gases be separately produced and collected in a glass vessel in equal parts, the union and formation of a new chemical compound in this glass vessel follows from exposure to light. If the light, or rather that particular portion of the solar beam to which chemical action is generally attributed, be permitted to act upon the two mixed gases, then the union takes place at a rate determined by the energy of some one or more of these constituent elements of light on which the combination depends. Where in the solar beam these constituents are is a question easily solved.

Every ray, or every portion of a beam of light, is capable of producing union between hydrogen and chlorine; but the combination takes place at very different rates, according to the portion of the beam which acts upon the united gases. The actinic portion will act seven hundred times as rapidly as the heat portion. That is to say, a certain combination will take place under the influence of this portion in one minute, which it will take more than eleven hours to accomplish under the influence of the heat portion. Therefore, by separating the ray of light, we can graduate the rate at which the combination occurs. Here are some glass bulbs, containing chlorine and hydrogen which have never yet been exposed to the light. If one of these be placed under this globe of red glass then the light that passes through it will be the portion of light corresponding to the heat end of the spectrum, and it will take hours to accomplish the perfect union of these two gases. If, however, one be placed under a globe of a blue colour, the light falling upon it will represent that belonging to the actinic portion of the spectrum, and the gases will unite (if the experiment be successful), and explode in about ten seconds.

Whilst recognizing this test and measuring gauge of the chemical brightness of certain lights, it must be borne in mind that it is chemical action and not the energy of light, properly so-called, that is measured. For instance, when the brightness of the sun's disc, as a case of light-brightness, is 520 times that of magnesium wire, the chemical brightness has been found to be not forty times as great.

Here are diagrams of two spectra, one of which is obtained from flint-glass. Now, flint-glass produces an effect which is considered to be due more to the physical property of density than to the elements of which it is chemically formed. Assume this diagram to be a faithful reproduction of the spectrum from flint glass. Now, however similar another glass may be in appearance, yet if it differ in density and constituent elements the distances between certain lines in the spectrum may in some portions be the same, but in others they will differ. If, therefore, light be estimated from the spectral appearance of it after it has passed through any substance, it is clearly subject to the influence of that substance. Again, on another diagram is a series of colours produced by a process called diffraction. This is the apparatus, and this is the mode of producing those colours. At the object-glass end of the telescope there are a number of very fine lines drawn, and if the telescope be directed to a very intense speck of light, such as the reflected sun from a small silvered globe or the bulb of a thermometer, coloured bands are seen, containing the same colours that the flint-glass spectrum shows. But the colours seen under this diffraction arrangement are very different in quantity to those seen under any other arrangement. A diffraction experiment is easily made by each for himself. From that hook a bright reflecting silvered glass globe is suspended, and two or three smaller ones of the same kind. If any one is tired of listening, and feels disposed to go to sleep, they can perform this experiment very easily. Just close your eyes and allow the eyelash to interfere with that speck of light reflected from the globe, and you will probably see colours radiating on both sides. Those are colours due to diffraction, and there are modes by which they can be made to appear much wider apart than by the one now described. Taking the diffraction spectrum, we find that these distances, from D to E, say of the yellow portion of the spectrum, are not of the same length as the corresponding portion in the flint-glass spectrum, and the same with the other portions, so that the proportions are quite altered. This is called the "irrationality" of the spectrum. Line D there becomes the middle of the spectrum instead of being, as it is here, very near to one end. The consequence is, when we talk of there being no heat in this portion of the spectrum, we have really and truly distributed the heat which ought to be condensed in F, G, over that large space, and therefore it shows on a fixed area much less heat than it would do not so distributed. If, now, these apparently unequal halves of the spectrum be examined for heat, it will be found that collecting them into two separate foci, the heat in the one focus is equal to that in the other. Clearly, had these portions been examined over equal areas the heats would not have been equal. Therefore the notion generally entertained of heat being confined solely to one end of the spectrum is not strictly true. That diffraction spectrum explains it, and there are other matters bearing upon it which, if time permit, shall be referred to presently.

(To be continued.)

Reviews.

QUANTITATIVE CHEMICAL ANALYSIS. By T. E. THORPE, Ph.D., F.R.S.E. Professor of Chemistry, Andersonian Institution, Glasgow. Longmans, Green, and Co. 1873.

The 'Text Books of Science' published by Messrs. Longmans and Co., of which series this work is one, are intended to meet the requirements of artizans and students in public schools. But since it is acknowledged that the study of quantitative analysis presupposes sound knowledge, both of theoretical chemistry and of qualitative analysis, there is a great future before us, we think, ere there will be any successful teaching of this branch of chemical science in our public schools; the most to be expected, then, at present in practical chemistry, is the attempt to give instruction in elementary chemical manipulation, and in the outlines of qualitative analysis.

"The aim of this work," in the author's words, "is to teach the principles of quantitative chemical analysis by the aid of examples chosen, partly on account of their practical utility, and partly as affording illustration of the more important quantitative separations." The subjects are arranged under the following heads: (1) The Principles of Quantitative Analysis; (2) Simple Gravimetric Analysis; (3) Volumetric Analysis, solids and liquids; (4) General Analysis; (5) Organic Analysis. The chapters on the principles of analysis and the theory and practice of the balance, are well worth the careful attention of students. Indeed, we do not remember to have seen the article on the balance equalled in a work of this kind. Preliminary details usually given in similar treatises are not wanting, nor, it is to be noted, does the author hesitate to introduce new plans which he considers

to be improvements on the old systems; hence there are many contrivances, mechanical and otherwise, that chemists are continually devising, and which help to perfect the chemistry of analysis. Without further introduction, after the detailed analysis of common salt and cupric sulphate, pearl ash is given for the estimation of potassium and moisture, the student being told to estimate as carbonate the K found from K_2PtCl_6, though, we notice, he is informed that pearl ash contains in addition alkaline sulphates, chlorides, etc. Then follow, Rochelle salt for K and Na; dolomite, for its complete analysis; the indirect estimation of Ba and Ca; glass alloys, etc., finishing the second section. Dr. Thorpe has here introduced the method of CO_2 estimation by absorption in lieu of the one by expulsion and calculating from the loss; also his own methods for nitric acid, lately read before the Chemical Society, based on the re-action ensuing between nitrates and the "Couple" of Dr. Gladstone and Mr. Tribe. The part dealing with volumetric analysis contains but little new, excepting novelties in the graduation of pipettes, and in an ingenious appliance for the estimation of CO_2 in artificially aërated waters. Under the head of general analysis are included schemes for the analysis of refined lead, Fahl ores, wolfram, iron slags, iron for its impurities, phosphates, superphosphates, and the valuation of coal for the manufacture of illuminating gas. For iron ores the excellent acetate of ammonium method is the one described: but sulphur is recommended to be estimated in the acid solution and not by fusion of the ore: and the P_2O_5 is to be determined with ammonic molybdate. Few chemists, however, have as yet been able satisfactorily to work the molybdate method for phosphoric acid. Also many methods are given for estimation of carbon in steels, *e.g.*, Wöhler's, where the metal is directed to be burnt in a stream of oxygen; Weyl's, which consists in dissolving the iron in HCl with the aid of a single element of a Bunsen's battery, no ferric chloride being formed, then, burning the carbon in oxygen as usual in a combustion; also the method of Ullgren, who directs the carbon undissolved by cupric sulphate to be oxidized with CrO_3, and the CO_2 produced to be absorbed in soda-pumice tubes; finally Eggertz's colour test, where the standard is recommended to be made by digesting roasted coffee in dilute spirit. Much space is given to Dr. Frankland's method of water analysis, but with this we are already familiar, from Mr. W. Thorpe's article in Sutton. In the concluding section of organic analysis, it is to be regretted, we think, that only the combustion with oxygen or air is described.

For the most part the methods given are those recognized by the majority of chemists; others there are that require the test of experience, while again some are more select methods of analysis. Dr. Thorpe, we fear, has written beyond the range of those for whom the 'Text Books of Science" are intended, but the work is worthy to be commended to the advanced student in the special science institutions. For the sake of beginners, we should have preferred to have seen in a work bearing this title many more illustrations and explanations, like those given in the analyses of common salt and cupric sulphate, which, while of paramount interest to the young student, would have made the work valuable as a text-book.

PRACTICAL EXAMPLES IN QUANTITATIVE ANALYSIS, forming a Concise Guide to the Analysis of Water, etc. By ERNEST FRANCIS, F.C.S., Demonstrator of Practical Chemistry, Charing Cross Hospital.

Unless for reasons more valid than the contents here warrant, there is but little gain to the student by an increase in the number of works on quantitative analysis. In about sixty pages the author has endeavoured to satisfy the want of the medical student by selecting such "typical examples" as may prove most useful to him. We fail to see that there is any need to recapitulate Wanklyn's method of water analysis, because the recent Sanitary Acts have thrown upon the medical profession the responsibility of examining waters chemically, with a view of ascertaining their potability and freedom from various organic impurities. It is difficult to reconcile the prefatory statement of Mr. Francis that "other examples are given, which the author hopes will furnish such general instructions as will enable the student with a little variation, to apply the examples here given to other cases, which, though differing in detail, are the same in principle," with the fact that amongst the fifteen examples given, exclusive of water analysis, there are three in which we see very little difference, either in detail or in principle, namely, the estimation of solids in water, solids in milk, and solids in urine. The other so-called typical examples include separation of organic from inorganic substances by ignition, casein in milk, uric acid, albumen, and urea in urine, and the estimation of cream, sugar, etc.

Obituary.

Notice has been received of the death of the following:—

On the 17th December, 1873, Mr. Maxwell Low, Chemist and Druggist, of Dumfries, N.B.

Notes and Queries.

[378.] CLEANING OF SILVER LACE.—Will any reader tell me the best mode of cleaning silver lace? I am aware that cyanide of potassium will clean the gold, but it will not touch the silver.—ARGENTUM.

[379.] DEVONSHIRE OILS.—*R. D. M.* asks for a recipe for "Devonshire Oils."

[380.] DATE'S OINTMENT.—"*A Correspondent*" wishes to be supplied with a formula for "Date's Ointment," a preparation for which "Ceratum Calaminæ" is frequently substituted.

[381.] MEDECIN DU ROI.—Do you happen to know the composition of "Médecin du Roi," a popular medicine in Belgium?—W. ENGLAND.

[*** We know of no medicine bearing exactly the above name, but there is a purgative preparation sometimes called "Médecin de Leroy," which is probably the one meant, for which Dorvault gives the following formula:—

	1st Strength.	2nd Strength.	3rd Strength.	4th Strength.
Scammony. . .	48	64	95	125.
Vegetable Turbith	24	32	48	64.
Jalap	190	250	375	500.
Eau-de-Vie (20°)	6000	6000	6000	6000.

Infuse for 12 hours at 50° C., filter and add syrup prepared as follows:—

Senna (Alexandria)	190	250	375	500.
Water	750	1000	1500	1500.

Infuse, filter, and press, then add:—

Brown Sugar . .	1000	1250	1500	1750.

Make a syrup. The second strength is that most commonly used. Dose 1 to 4 spoonfuls daily.

Dorvault adds: "Chacun connait ce rémède, de réputation."—ED. PH. J.]

[382.] DISPENSING.—"*Dispenser*" wishes to know the best method of preparing pills according to the following prescription:—

℞	Zinci Valer.	gr. vii.
	Phosphori Pur. . . .	gr. ½.
	Quiniæ Disulph. . . .	℈ss.
	Codeiæ	gr. iv.

Ft. mass. et divid. in pil. xv.

[*** 12½ grs. phosphoretted resin (see *ante*, p. 441) = half a grain of phosphorus, with the addition of a few drops of tincture of tolu, will make the above into a suitable plastic mass for forming pills, which will not be inconveniently large.—ED. PH. J.]

"Voluntary Assessment."—Benevolent Fund.

Sir,—As this is the season of the year when charitable projects have more consideration than at other times, I wish to make a proposal which I trust will be favourably received, and, if acted upon, be the means of relieving many cases of real distress and suffering. Our business is one which requires a considerable amount of personal attention and many years' application, as a rule, before anything like a competency can be obtained; and, unfortunately in many cases, after several years of toil and close attention, the pharmaceutist has not been able to provide anything against accident, illness, or for his family in case of death. This is the time for the application of the Benevolent Fund, but the amount at disposal *is far too small* for the object, and I think that it may readily be increased, and in such a way as will commend itself to the members of the Society generally. It is simply to make a *voluntary* assessment, and to make the subscription for membership 25*s.* per annum for members, and 12*s.* 6*d.* for associates; it being always understood that 4*s.* in the first case, and 2*s.* in the latter, is a voluntary payment to the Benevolent Fund, and that any who object may pay their guinea and half-guinea respectively, as before. Practically, I think this will yield something like £500 a year in addition to the amount now subscribed, for in making this calculation I have first deducted from the number of members and associates connected with the Society those who already subscribe; these would continue to pay their annual subscriptions. Then I have allowed a discount of 25 per cent. for those who would object to increase their subscription. This would be quite enough, I think, for the assessment would not press on anyone, and the poorer members would be more likely to pay it than others, for they are most interested in the matter naturally. And I would suggest that this amount, notwithstanding the objections raised in the Council against using current income, be annually disbursed amongst the needy applicants. I would have faith enough to elect annuitants for the amount received in response to the first yearly assessments, for I believe we should have an increase of members through the usefulness of the fund, and we may also take it that as the examinations proceed we shall have a constant addition of members and associates, so that the fund through the voluntary assessment would continually be enlarged. I hope this suggestion and appeal will bear good fruit.

Thomas Barclay.

17, *Bull Street, Birmingham.*

Citrate of Magnesia.

Sir,—In common, I suppose, with many other chemists, I have received a printed circular in which Dr. Stevenson Macadam certifies that Bishop's citrate of magnesia contains 1·31 per cent. of magnesia, and that Messrs. Sang and Barker's citrate contains 1·52 per cent of magnesia, and that therefore he (Dr. S. Macadam) is "of opinion that these samples are of excellent quality and are entitled to be regarded as granular effervescent citrate of magnesia."

I should like to ask Dr. Macadam whether Edinburgh chemists as a rule consider that the less a compound contains of the ingredients it is named after the better it is, and how much smaller quantity of magnesia he would consider the citrate should contain to arrive at the climax of perfection?

Self-interest might perhaps be pleaded as an excuse for Mr. Bishop's statement that his compound contained an important quantity of magnesia, but what shall we say to Dr. Stevenson Macadam for having favoured us with such an opinion founded on these percentages.

Perhaps he would oblige the pharmaceutical world with a chemical justification of the well-known proverb "the greater the truth the greater the libel," which may be parodied by "the less citrate of magnesia the more it should be called so." I think Edinburgh and Speck's Fields may now shake hands. *Arcades ambo!*

Dec. 19, 1873.

The Adulteration of Food and Drugs Act.

Sir,—While the recent convictions under the above Act are fresh in our minds I have taken the liberty of making some suggestions on the subject, hoping that they may lead to combined action, with the help and under the guidance of the Council of the Pharmaceutical Society, to get matters upon a better footing as regards prosecutions under this Act.

Some things I desire to call attention to affect retailers generally; others affect more especially chemists keeping open shop. I will take generalities first. The mode in which the articles to be analysed reach the analyst appears open to objection—viz., a stranger may walk into a shop, ask for an article, get it, pay for it, and then simply say—"I have bought this to have it analysed." Away he goes, and the next heard of the affair is that the unfortunate salesman is summoned to appear before the magistrate if the article he has sold be found impure. Here is one thing calling for amendment; when the article bought is stated to be for examination, the seller should be allowed then and there to put *his* seal upon the package, he should be allowed to be present when the package is opened by the analyst, and also be allowed to see the article he has sold analysed if he choose to do so, otherwise what guarantee has he that the article he has sold is not tampered with after it leaves him? I do not think there should be a separate analyst for each town or district, for I should certainly doubt the capabilities of many local analysts who will be appointed, and I think that a local man might be open to local influences; I do not say it would be so, but it might.

I would suggest a central analytical laboratory, with a proper staff of analytical chemists and other officers necessary to the working of the same; it would be far more satisfactory. These men would be beyond the suspicion of partiality and local influence, and if this laboratory were established in London, the chances of incorrect analyses and one-sided certificates would be reduced to a minimum. Again, the local analyst would not have the practice the men employed at a central laboratory would have, and any person who knows anything of the matter knows quite well how necessary is constant practice to enable a man to analyse correctly.

Now as to the manner in which the Act may operate against the interest of the retail chemist especially. It is perfectly right to fine the man who sells sugar and sand, or tea with just a suspicion of chopped birch brooms, or the publican who puts coculus indicus into his porter, and so on, *ad infinitum;*—it is equally right that the chemist who sells cayenne pepper adulterated with red lead, or spirits of nitre with a good dash of "*aqua pumpum,*" (and many other things that could be mentioned) should not be allowed to go unpunished; but I maintain it is most unfair to prosecute a man and to brand him as a fraudulent adulterator because he is found to sell spirits of nitre which is not of the sp. gr. 0·845 (B. P.), or carbonate of soda which will not come up to the B. P. test. This may be an extreme case, not bearing any parallel to the cases in which conviction has been obtained, but the principle is the same, and any one may be prosecuted and punished to-morrow for selling such things as I have mentioned. In the citrate of magnesia case, if I remember rightly, the gentleman who suffered endeavoured to throw the blame upon the wholesale house of whom he purchased, and I think with a great deal of justice; but you, Sir, differed with that view, and held that a chemist should test for himself the quality of the articles supplied to him. I certainly say that every chemist should have sufficient knowledge of analysis to be able to test an article, even if he be unable to make a complete quantitative analysis, and ignorance should be no excuse for selling adulterated drugs; but if a chemist were to test every article that came upon his premises his whole time would be occupied in so doing, and I ask any brother druggist—could he afford to do this or to employ some one to do it for him? Unfortunately the poor retail chemist has to employ his time very differently than in this scientific manner to make both ends meet, and often is not able to keep the wolf from the door. If a chemist is to employ his time in testing drugs and chemicals he must necessarily neglect his retail business, and I fancy the public would not be satisfied if, missing the proprietor of a shop from his accustomed place behind the counter, it were told on inquiry, "that Mr. So-and-so was busily engaged examining his drugs for fear of the consequences of the Adulteration Act."

I think the wholesale dealer should share the responsibility with the retailer. How can the honest grocer afford

to have his cayenne pepper tested each time it comes to him? This is only a solitary article; for you must remember, to be really safe, that every article received by the retailer from the wholesale house should be tested before it is sold to the public. This becomes a really very serious affair, and one, I think, demanding immediate and careful attention, combined with energetic action, for a remedy.

If the act was worked to the fullest extent I think the majority of chemists would stand a very poor chance of being able to continue their business. Take an example—"spot" a man for prosecution; first of all test his sp. æth. nit., not finding it of proper sp. gr. (B.P., this appears the standard)—fine him; then try his sp. am. co., if it does not come up to the B.P. test—fine him; next try his glycerine, find the sp. gr. not 1·25, slightly acid, not quite free from smell, and so on—fine him again. In what estimation do you suppose the public would hold this man if he continued carrying on his business after these repeated attacks? This sort of thing may be done strictly within the letter of the Act, although the unfortunate retailer thus punished may have bought from a good wholesale house, and would utterly scorn the idea of buying adulterated goods or of adulterating them himself.

I know something of the time and attention it requires to test, only in a rough way, and without hesitation I say no man in business (if he has any) can possibly devote the time necessary to test every article he receives from the wholesale houses with whom he deals, and this is the only safe way if the retailer is to be the sole delinquent. Perhaps it may be suggested that the retailer should proceed against the wholesale man who supplied the adulterated articles for the selling of which he (the retailer) was punished. But it is generally admitted how extremely unpleasant a thing it is to be involved in a law suit; particularly so when the chances of obtaining a verdict in one's favour are slightly remote.

However, in conclusion, I would most earnestly appeal to the Council of the Pharmaceutical Society, to all chemists and druggists, and to others having interest in the matter, to set to work at once, and with all the vigour they are capable of exercising, to remedy this most unpleasant, and, perhaps, to many unprofitable, state of things. Do not let the matter drop, hoping the Act will not be pushed to its utmost limits, or that presently it will not be worked so actively as it appears to be just now. Let us combine to bring about an alteration in this obnoxious Act, not the least alteration being in some way to make the wholesale dealers partly responsible. We are quite enough hampered by legislation already without having more burdens to bear.

I think the poor chemist will very soon illustrate the old story of the Frenchman's horse, who, when he was brought to such a state of economical perfection as to live upon a straw a day—died. So with the chemist. When he has been educated, legislated for, examined, fined, and what not—in fact, taught to live upon the "straws" of the trade—he will be found to have died out, his place occupied by a man of another class, more ornamental, but, perhaps, not so useful.

Unfortunately all legislation has been against us. We have had the Pharmacy Act, compelling us to be examined; the Sale of Poisons' Act, to make us register poisons, and to refrain, in some measure, from selling them; and now the Adulteration Act—all very good in their way. Have we had one thing to counterbalance these? No. We are still liable (pharmaceutical chemists excepted) to serve on juries; surgeons are still allowed to dispense their own medicines. The chemist is the poor trader still, with responsibilities as great as a medical man, without his advantages. It is useless to talk of raising the status of the chemist without giving him some advantage.

J.

Homœopathy and the 'British Medical Journal.'

Sir,—Believing you to be "A Lover of Fair Play," I ask space, in the name of truth and justice, for a few remarks on the article headed, "A Dying Faith," reprinted from the *British Medical Journal*, at p. 425 of the Pharmaceutical Journal.

Having looked into homœopathy for some time past with considerable care, and practically tested it in my family for twelve years with the happiest results (several times in critical cases, both as regards myself and others) I am fully able to affirm, without the slightest hesitation or fear of contradiction, that the above-named article, and also that referred to as previously appearing in the same journal, (and which I read when it appeared,) give an entirely distorted and unfair view of the present aspects and past history of homœopathy. The picture there drawn is—I do not say an intentional, but a complete misrepresentation of the facts of the case. In opposition to the Editor of the *British Medical Journal*, I affirm, and am prepared to substantiate the statement by facts and reasoning, that homœopathy never was a "delusion," and is not a "fraud."

The use which the *British Medical Journal* and Dr. G. Johnson make of the so-called cases of "Poisoning by Homœopathic Camphor," clearly reveals the party spirit which has dictated these articles. These cases are apparently quoted as reflecting discredit on homœopathy. They do nothing of the kind. Not one of the persons "poisoned" took the camphor according to the printed directions. These directions are: "Five drops on sugar every 5, 10, or 15 minutes, according to the severity of the symptoms." In another case, "Two or three drops on sugar every 15 minutes; less frequently when relieved." But "Miss T.," instead of taking *five* drops, took *twenty-five*, and in the third case a teaspoonful (!) was positively taken. Suppose a person took a teaspoonful of laudanum instead of 20 drops, then we should have "Allopathic Poisoning by Tincture of Opium," and it would be quite as fair to regard the unpleasant symptoms resulting as reflecting on allopathy, as to regard those arising from this abuse of camphor as reflecting on homœopathy. Just as reasonable in both cases, and quite unreasonable in either. If persons cannot read directions, and follow them, the blame is theirs, not any fault of the system they adopt.

The inferences drawn—or rather the conclusions jumped at by Dr. G. Johnson and the Editor of the *British Medical Journal* in connection with these cases of "poisoning" are as amusing as they are false. We are informed of something called "pseudo-homœopathy." "long known to practitioners in London." Then we are told that "homœopathists have passed from the irrational and ludicrous extreme of infinitesimal dilutions to the dangerous extreme of the greatest possible concentration of active and poisonous drugs." This will, I apprehend, be news to homœopaths. During the twelve years in which I have tested homœopathy, I have come into contact with some half-dozen homœopathic practitioners, and watched their practice, as well as the progress of the system, with the greatest care, but never until I read this article did I hear of "pseudo-homœpathy," or of any such change in practice as Dr. Johnson mentions.* The use of low or high dilutions, etc., is regulated now as always by the nature of the disease, age, and physique of the patient, as any text-book on homœopathy will explain. Some medical men prefer stronger potencies than others, just as some allopaths give larger doses than others. but there is no "recourse," as Dr. Stewart says, "to concentrated tinctures, in order to produce an appreciable effect by very minute doses," since "infinitesimal doses" are absurd. The dose is always "infinitesimal," however concentrated the remedy—that is, it is less than sufficient to produce chemical or physiological action. There is no absurdity however—begging Dr. Stewart's pardon—in infinitesimal doses. They produce plenty of "appreciable" though no *sensible* effects. Has miasmata no power? Dr. Kopp (who was converted to homœopathy unwillingly as the result of his experiments) says his conscience obliges him to acknowledge that "decillionth parts exhibit definite curative power." Cure depends in homœopathy primarily on the law of similars (the only *law* of cure which in my opinion exists, but which the *British Medical Journal* carefully ignores). A bucketful of the wrong medicine will do no good; a drop of the right will relieve at once.

I dare not encroach on your space by referring to the

* There has been no "return in secret to the ancient paths of medicine." This allegation of copying from others, and using more potent remedies than formerly, might be preferred against allopaths with some truth, but not against homœopaths. I have seen a prescription in which tincture of aconite was ordered *alone* in fever by an allopath, evidently a leaf out of homœopathy. Who ever thought of using aconite in fevers until homœopaths recommended it? So of many other medicines I could name. But allopaths freely use the facts and principles of homœopathy, and then abuse the system they get them from. All that the Editor says about the harmful effects of strychnia tincture, etc., reflects no more discredit on homœopathy (if true?) than the camphor cases.

other points to which the article in question alludes, but I may just add that the negative results of analysis, of which the Editor makes a good deal, are satisfactorily disposed of by Mr. Ross in a letter which appeared in a late number of the *Monthly Homœopathic Review*, in reply to the analysis of globules which was copied from the *Practitioner* in a recent number of the PHARMACEUTICAL JOURNAL. The letter was, of course, refused admittance by the *Practitioner*.

As a matter of fact, many homœopathic dilutions *do* give *positive* results when chemically tested, as may be seen in Dr. Granier's 'Conferences on Homœopathy'; but whether they do so or not is no argument against their therapeutic power. The only real test is their efficacy in combating disease, and this is being proved every day and hour.

These attacks on homœopathy are evidently designed to prejudice medical men against the system. I know one allopath who is as disgusted with them as any homœopath could be, and who is giving up the *British Medical Journal* and dissolving his connection with the Association. He is sincerely trying homœopathy, and, I believe with the best results. I am sure no practitioner can honestly test the system without becoming a convert, and that no one could write as the Editor of the *British Medical Journal* does who had really investigated it. There is not a single dispassionate argument throughout either of these articles, which consist of nothing but distorted facts and clap-trap appeals of the most transparent kind. The Editor resorts to the last refuge of the defeated antagonist—a poor trick after all—to slander that which he cannot disprove.

I am no blind partisan either of allopathy or homœopathy. I believe both systems have their value, but that in homœopathy only have we a definite law of cure. All I ask in this, as in everything, is fair and searching inquiry, and gentlemanly treatment of opponents. This, I contend, the Editor of the *British Medical Journal* has not accorded. He has libelled homœopathy as a system, and thereby inculpated the whole body of homœopathists. He is bound either to establish his position, by disproving the homœopathic law of similars, or to retract it, and apologize for having so grossly maligned a truth.

A HATER OF INJUSTICE.

Sir,—The exposure of inconsistency or dishonesty is promotive of good. Homœopathists are human and may deserve to be charged with both; but conscientious men having any claim to be considered either scientific or rational, will be careful not to make these charges without sufficient and satisfactory evidence.

Nothing would be easier than to concoct evidence of the kind produced by the members of the London Clinical Society, to prove that the practitioners of "*rational*" medicine are equally criminal with the homœopathists.

My advice to those gentlemen is, "do not play with edged tools;" and to your readers I would say, "Prove all things and hold fast that which is good."

JOHN P. BERRY, M.R.C.V.S.,
"Registered Chemist."

Northampton, Dec. 3rd, 1873.

HOMŒOPATHS V. HOMŒOPATHY.

Sir,—Originally one of the principal advantages set forth by the advocates of Hahnemann was the immunity to be enjoyed by patients from dangerous overdoses of powerful remedies.

Enthusiastic believers were to be cured by infinitesimal quantities of drugs, hitherto considered of feeble power.

Faith in globules has, however, gradually declined; these apologies for medicine have ceased to perform almost miraculous cures, and are replaced by pilules possessing sensible qualities of dose and flavour, while tinctures of unusual potency supplement their effect. If the old homœopathist strained at a gnat the modern disciple swallows the camel without much effort. I was brought to this conclusion the other day by the following laconic prescription:—

Pot. Brom.	℥ j.
Inf. Gent. C.	ad ℥ vj.

℥ ss. b. d. s.

Had this formula proceeded from an allopathic practitioner of the heroic school it might not have excited remark, but the prescription was accompanied by a bottle bearing the label of a well known homœopathic chemist.

"*A tablespoonful to be taken twice a day.*"

I dispensed the medicine and afterwards heard that it had proved of much benefit in a case of neuralgia, but whether the effect ought to be ascribed to the magic spell of the old dogma "similia similibus" or to a known specific action of the salt must remain an open question.

R. GOODWIN MUMBRAY.

HOMŒOPATHIC (?) PREPARATIONS.

Sir.—Apropos to the article in the Journal, headed "Poisoning by Homœopathic Tincture of Camphor," could you not draw the attention of the public to the unsafe preparations now sold by the homœopathic chemist (?) as tinctures, improperly so called,—they being untinctured by any colouring matter, and so much the more dangerous,—which, if they possess medicinal virtue at all, are necessarily solutions of the alkaloids, as atropia in the tinct. bellad., strychnia in the tinct. nux vom., aconitine, etc., such as it is illegal for any but registered chemists to deal in, and dangerous for any but a medical man to prescribe.

There seems now to be but little difference between the remedies used by the two Schools of Medicine, but there is a vast difference in dispensing for the two; in that the homœopath adds plentifully of that profitable chemical H_2O, whereas the tendency of the regular practitioner is to leave that out altogether, so that the chemist may get as little profit as possible.

E. J. P.

SPONTANEOUS CRACKING OF GLASS VESSELS.

Sir,—There was a discussion some time since in the *Times* on the well-known but singular liability of barometer tubes to crack if they have only been touched on the inside with metal wire.

Last week I stirred a thick watery liquid in a 20oz. measure, which had long been in constant use, with a silver spoon. No liquid differing from the atmospheric temperature had been in the measure for weeks. An hour or so after the measure had been touched by the silver, while standing on a wooden counter with about eight ounces of liquid in it, the bottom of the measure cracked with a considerable noise.

Have any of your readers met with a similar fracture? I have before been surprised to find bottles, pipettes, etc., unaccountably cracked, perhaps from a similar cause. The above measure must have been at least seven years old.

W. SYMONS.

Barnstaple, 24th Nov., 1873.

DRUGGISTS' CHARGES.

Sir,—I think Mr. Leay has nothing to fear from the advertisement he speaks of; for if these "duly qualified" persons really do dispense, etc., at 100 per cent. below the usual charges they must soon "go to the dogs," but if they do not mean what they say, educated business people will think that they are *not* "qualified," and may poison them not meaning it either.

I think they do not know what they are talking about.

T. H. CUMINE.

King's Lynn, Dec. 9th, 1873.

"*Apis.*"—(1) The leaves of the plant mentioned have reticulated venation, which may be seen upon holding one between the eye and a strong light. (2) The table you refer to includes Mg, which is thrown out of solution by the phosphate of ammonia. (3) No; 5·41.

W. England.—(1) The great mullein, according to Thornton's 'Herbal,' is used for colds and diarrhœa. A decoction is made by boiling 2 oz. of the leaves in a quart of water, for 20 minutes. Dose, 6 oz. every three hours. In Dr. Jeannel's 'Formulaire,' there is the following recipe for an infusion—"Mullein, 10 grammes; boiling water, 1 litre. The infusion should be strained, to separate the hairs of the stamen. *Emollient inutile inusité.*" Bentley says it is demulcent and slightly narcotic, and the seeds are used to poison fish. (2) See p. 525.

COMMUNICATIONS, LETTERS, etc., have been received from Symes Armstrong, Pocklington, Gardiner, W. Macnaught, "Enitar," Excelsior, A. A. A.

PHARMACEUTICAL STUDY.*

BY CHARLES SYMES, PH.D.

We are now about to consider briefly the subject of pharmaceutical study; let us do so as fellow students. For I must confess that when looking around on the vast fields of knowledge open before us; when I contemplate what has been done and what remains to be done; when I narrow my view and behold the operations of the sciences forming an essential part or closely allied to pharmacy, and lastly, when I look into what has been accomplished by myself in a life of thirty-three years, I am impressed with the great necessity of plying my every energy, and of becoming a student in earnest.

Some students are necessarily younger in the field than others, and it is to these I would address myself in particular, and offer a few words of advice and encouragement. We always work better and more to a purpose when we have some object in view. It might be well, then, first to consider what is our *object* in study.

Taking the youth just entered on his apprenticeship, he congratulates himself on having done with school and books, and votes study a bore; soon, however, if he has not passed his Preliminary examination (which, by the way, he ought to have done) this stares him in the face as a stubborn reality, but one which should cost him very little effort to pass. After this comes the Minor and Major; again he finds himself amongst text-books, and probably connected with a school, but of a more technical character than the one he has left. It is evident, then, that one object of study is to gain the necessary knowledge for passing the pharmaceutical examinations now incumbent on all. But if this is made the only one, the acquirements will most certainly be superficial. It might be very proper to keep the examination in view whilst you prosecute your studies, and very creditable to pass in honours, but what would you say of a microscope that would show test objects only? There must be a desire to possess knowledge for its own sake, for the pleasure it affords, for the power it gives, for its usefulness in the investigation of intricate subjects beyond the comprehension of the ignorant. Were it not for the pressing necessities of existence, surely such objects were worthy the devotion of half a life-time to study.

Then, most of us have faith in business prosperity; it does not always follow that a man who has passed examinations is necessarily a good business man, or that a man who has not done so is otherwise. Indeed, in times past it has often been the reverse; the ignorant populace have often given the preference to a man of little knowledge and much assurance. But we must bear in mind that the public are becoming better educated, and that elementary chemistry is being taught in most schools; in fact, we often find the youth of fourteen years or the mechanic taxing our abilities to explain their chemical and technical difficulties, and to whom but to the pharmacist have such to go for their solution? It is not necessary that we should invade the territory of the purely scientific chemist; but that a man who undertakes the conduct of a pharmacy should be able to perform minor analyses for medical men and others, and that he should be able to render an intelligent reasoning or explanation in any scientific proposition bearing more or less on his calling, will, I think, be admitted by all. Wherever we find such knowledge, combined with a moderate amount of business tact, there we are sure to find a fair amount of prosperity; there we find pharmacy really elevated, there we find it assuming a professional character, and to such alone can we look as its true representatives.

There are five principal methods or heads under which knowledge is acquired, viz., *Observation*, *Reading*, *Instruction by Lecture*, *Conversation*, and *Meditation*. In its narrowest sense the term study is applied only to the latter of these, but in its broader application it embraces the whole. Let us consider them separately.

Observation is an important part of a pharmacist's education. Shall I say the most important? Yes, for all practical purposes it is so. We occasionally find in our journals letters from dissatisfied apprentices, complaining that they have to dust bottles, etc. For my own part I must say that the short time spent each day in dusting bottles during my apprenticeship was time well spent; in the performance of this duty, which some consider so *infra dig.*, I learned the distinctive characters of the contents of each bottle; the properties which gave an individuality to each; the effects of light on vegetable substances and their preparations; also on some products of the mineral kingdom. I found the pulv. sennæ became bleached, pulv. rhei darkened, and argenti nitras blackened. Then the imperfect stoppering often allowed the effects of atmospheric influence to become apparent; whilst the sodæ sulphas effloresced the potassæ acetas deliquesced, and ferri sulphas lost its grassy green, and became the brown persulphate. Another active agent, time, has many a lesson in store for an observer, and I found the sacred precincts of the pharmacy far from proof against its all pervading influence. Tinctures of cinnamon and kino solidified; liq. antim. tart. became a mass of fungoid growth, and decoct. aloes lost its bitterness.

Doubtless cause and effect were often misplaced, but it was study nevertheless, and grave philosophers have often committed such errors.

Reading.—By this means we become acquainted with the thoughts of others, the accumulated wisdom of ages. It is well that observation and reading should go hand in hand, for by familiarizing ourselves with the thoughts and methods of observation adopted by others we learn to observe more correctly ourselves.

Reading enables us to acquire knowledge which we could not otherwise do; the experimental labour of years is often condensed in a few pages which the student might master in an hour. It is available where but short periods can be devoted to study. One or two facts thoroughly impressed on the mind are worth chapters carelessly read, and it is a fact that those who have but little time at their disposal often render that little more valuable than much possessed by others.

As to the books which should be read by the pharmaceutical student, much depends on the amount of time he can give to study. Make it your law, as steadfast as that of the Medes and Persians, to acquire as *much* knowledge as possible; never ask yourselves *how little* will pass you through your examinations. There are many excellent text books now published which but a few years since had no existence. Fownes' Manual was the student's book on chemistry now superseded by Attfield. Botany was gained in

* Short address delivered at Liverpool Chemists' Association to Students, Dec., 1873.

a somewhat fragmentary manner from Lindley, Balfour, etc.; now Bentley supplies all that can be desired. Pereira and Royle were the books on Materia Medica; the former too voluminous, the latter a most excellent work and one which to my mind leaves nothing to be desired even in the present day. A useful work has been published under this head by Professors Redwood and Bentley. Its arrangement is good, but I am not sufficiently familiar with it to offer an opinion on its merits. In turning over its pages a few days since I observed some statements with regard to doses which scarcely accord with my experience. Chloral hydrate is stated to be given in doses of from 30 grains, whereas from 20 to 25 are more frequently prescribed. On the other hand the dose of bromide of potassium is given as 4 to 10 grains, whereas the average dose is from 20 to 30; sometimes 60 grains are given. But I am digressing. 'Redwood's Pharmacy' is getting out of date, but contains much matter worth perusal: we find it now replaced to some extent by Proctor. I would say then that of the various works at the disposal of the pharmaceutical student, Royle, Attfield, and Bentley stand pre-eminent.

The method I would recommend is—in the first instance read one subject at a time, carefully making notes as you proceed; at the end of your subject study your notes. Then read your various subjects together, *i.e.*, on alternate days; again make notes; each day before prosecuting your study, read over the notes previously made; this you will find a great aid to memory.

From *lectures* and experimental demonstration we acquire knowledge in a pleasant and permanent manner; here the eye lends its aid in imprinting on the memory that which would otherwise be readily erased. I cannot speak too highly of the excellent courses of lectures delivered at Bloomsbury Square. Those who have listened to them will bear me out in their praise. But all cannot go to Bloomsbury Square to study, hence we have provincial Schools of Pharmacy established; we have one in connection with this Association, which, if it in the past has not been so successful as it might have been, we can still hope has a bright future before it. We cannot secure Professors Redwood, Bentley, and Attfield to direct it, but we can offer you lectures by gentlemen thoroughly competent for the proper discharge of the duties they undertake. At present the Chemical Class is but small, yet it is doubly as large as on former occasions; let us hope it will be considerably increased next session. I am sure the students find in Mr. Davies an efficient and painstaking instructor.

In March next we hope to have a course of lectures on botany commenced by a gentleman whose ability none will doubt; and next winter, in addition to these, lectures on pharmacy and materia medica; but you must bear in mind, without a good number of students there can be no success, and it rests mainly with yourselves whether, in a few years, there is established here a School of Pharmacy second to none in the provinces, or whether the effort is given up as useless. This is a serious responsibility—one in which every student in Liverpool participates even though he refuses to acknowledge it. Let us each faithfully discharge our duty and show that we are in earnest in this laudable undertaking.

Conversation.—Under this head comes mutual improvement, and is it too much to hope that the rising generation of pharmacists in Liverpool will yet establish a class amongst themselves on this basis? Aided by a spirit of emulation, this form of study prompts the student to exercise the best of his ability in gaining all the good he can from the sources we have been considering. For my own part I consider the time I spend in converse with professional brethren amongst the most pleasant and profitable hours of my life.

Finally we come to *meditation*, in which we bring together all we have culled from other sources, compare and draw inferences. In meditation we learn to *apply* all the knowledge we possess; by meditation we recall much that would otherwise be forgotten, and originate new thoughts; by thus bringing together the integral parts of what we know we can look at it as a whole and bring the entire power of our minds to bear on any particular subject.

The question of *time* for study is rather a vexed one with you; indeed it is with us all. There is much cause for complaint. The evil originates with and might be terminated by ourselves. Time rolls on and adds years to us. Would that it added wisdom with equal rapidity, enabling us to see that our service should be measured not by its length but by its usefulness.

Such time as you have at your disposal, lose none of it. If your business duties encroach on your evenings you have the mornings at your disposal. I believe in morning study; the mind is fresh from repose and readily impressed; the power of comprehension is clearer and progress is more rapid. If after this before going up for your ordeal you feel it necessary to do a little cramming (and who does not?) take your own notes and from them make an epitome, which do not write on your finger-nails or on the palms of your hands, but deeply imprint on your brain. Throw off timidity and success is yours.

ON THE ADMINISTRATION OF CASTOR OIL.*

BY E. GREGORY.

Castor oil is indisputably nauseous and unpleasant to take, so much so that some patients cannot be induced to swallow it, by any device or on any consideration. At the same time, its qualities are such that in some disturbed states of the system, no other purgative can be substituted with safety. On this account a great deal of ingenuity has been exercised in endeavouring to devise means by which the dose may be swallowed without tasting it. So far as I know, success in this attempt has been only partial, and I fear the difficulties in the way are too great to be entirely overcome. Efforts seem to have been made in three directions; first, to enclose the oil in a tasteless envelope, such as the hard and soft castor oil capsules. To these there seem to be two objections. One, from the number of capsules necessary to be taken for a purgative dose; the other from the fact that most of the makers, in their efforts to reduce the size of the dose, have been tempted to add a foreign ingredient, such as podophyllin, or croton oil, both of which are of so drastic a nature as to make it unwise to give them to a delicate patient. The second class of efforts have been made principally by medical men and nurses, and have consisted in floating the oil on some vehicle, such as tea, coffee, punch, wine, beer, etc., etc. The result is that the patient, in spite of the most careful management, finds some of the oil sticking to his mouth, and sinks back in the bed with the conviction impressed on his mind that oil is abominable stuff. The most successful vehicle of

---

* *Canadian Pharmaceutical Journal*, vol. iii., p. 39.

this kind that has come under my observation is flax-seed tea, well sweetened and flavoured with any agreeable aromatic. If the oil be floated on this, and before the dose is taken the lungs be thoroughly exhausted, so that the whole can be drunk with a deep inspiration, the taste is very little noticed. The third direction in which inventors have exercised their ingenuity in endeavouring to cover up and disguise the unwelcome flavour is by adding various ingredients to the oil, and by making it into an emulsion.

Mr. Herbert G. Rogerson* has given a formula adapted to emulsify most oils and balsams. It certainly makes a very nice looking preparation, having a white pearly lustre, and with the taste and smell of the active ingredients very well disguised. But it is too thick and must be gulped down.

For some twelve or fourteen years past I have used the following formula for a castor oil draught, which has proved very acceptable to adults who could not get down the pure oil. For children it does not answer so well, the dose of necessity being double that of the oil :—

℞

Ol. Ricini, ℥ j.
Mucil. Acaciæ, ℥ ij.
Shake well together, then add
Syr. Simp., ℥ ij.

Shake again, then flavour with spts. menthæ pip., or according to taste, and make up two ounces with water. This mixture can scarcely be called an emulsion, but it mixes well on vigorous shaking. The taste is well disguised; it is thin enough to be easily taken from a wine-glass, and it leaves no oil sticking round the mouth. I have lately obtained still better results from the following formula :—

℞

Ol. Ricini, ℥ j.
,, Anisi, gtt x.
Chloroform, gtt x.
Shake well together, then add
Mucil. Acaciæ, ℥ ss.

Shake well, and make up to two ounces with water. I know not whether this may be considered an infringement on Mr. Copland's patent, but it is a very nice looking and palatable preparation, and does not separate so speedily as the last.

THE PALM OIL TRADE IN OLD CALABAR.

Mr. Consul Livingstone, reporting on the Trade and Commerce of Old Calabar for the year 1872, says, that in all the rivers our agents trade only with the tribes that own the river mouth, and are not oil producers, but merely oil brokers or middlemen. Gladly would the nearest oil producers come and trade direct with the whites, to the advantage of both, and most willingly would some white and many black traders go up to the markets of the oil producers, but the black brokers are strict protectionists, and allow no trade with white or black, except what passes through their own hands, at their own price; and each tribe on river or coast does the same with its next inland neighbour. All are protectionists and have ever been.

Barter is the only medium of trade between white agents and black brokers; but black brokers and oil producers have risen above this rather primitive stage of civilization. The brokers rarely offer trade goods to the producers in exchange for oil. They take the goods to one of the great country fairs and there sell them for native money, and with this money purchase the oil from the producers.

In 1866 sixteen British firms traded in these rivers, and one Dutch. This year, 1872, the number of Liverpool, Bristol, and Glasgow houses is twenty-four, and there are two foreign (Dutch and German). These 26 palm-oil traders have 55 trading establishments in seven rivers, and employ 207 white agents, clerks, mates, etc., 419 black coopers, carpenters, cooks, and stewards from our settlements at Accra, Cape Coast Castle, and Sierra Leone, and 2000 Kroomen from Cape Palmas and other parts of the Kroo coast. Most of the above live in large airy hulks, moored near their cask houses on the beach; a few have houses on shore. For many years the carrying trade was done by sailing ships, and as they remained in the sickly rivers for months, numbers of their men died of fever; but since the two lines of steamships began in 1869, with reduced rates, and five steamers a month, they have secured nearly the whole of the carrying trade, and sailing ships and seamen's deaths have almost disappeared from the principal rivers.

In the days of sailing ships a few wealthy firms had a sort of monopoly of the oil trade, and made large profits; but steam has brought new firms and a keen competition. It has also developed a goodly number of black traders possessed of some education, little capital, and minds satisfied with small profits and quick returns. The price received for oil in England has fallen of late years, while the price paid for it in the rivers has risen to twice and even thrice its former figure.

Many agents are of opinion that the annual oil product of the rivers does not increase; and that while natives take life as easily as they do, and receive such high prices for the oil, the exports are not likely to be much augmented. A large amount of oil is now exported from the west coast direct to foreign countries; and the total exports from the whole coast are undoubtedly increasing to a considerable extent.

The Fernando Po oil crop never exceeds—seldom equals—400 tons a-year. A trustworthy observer who trades in various parts of that island states that, from the number of oil palms he has seen, at least 4000 tons might easily be obtained. But the 25,000 aborigines, or Bubés, do not choose to work beyond 400 tons. Their wants are few—a cheap musket, a little powder and shot, pipes, tobacco, and rum are nearly all. If traders could create new wants, trade might increase; but where is the genius who can create a new want for a Bubé?

On the mainland the oil producers have many more wants, and therefore work harder, *i.e.*, the women and children do; for the men think they have done enough when they climb the palm trees and bring down the masses of palm nuts.

Probably not many of the palm nuts of the countries drained by the oil rivers remain ungathered near the native villages. More oil palms might be planted; there is abundance of room for them in the oil district, though but a mere fringe of the African continent. But natives never plant oil palms, though they plant the palm which produces the best palm wine.

After separating the palm oil from the fibres round the nut, the oil producers used to throw away the nuts, though it was known that the kernels contained a valuable oil. Black brokers would not carry nuts in their canoes for the price received; and agents felt that it would hardly pay to send nuts unbroken to England. Machines for breaking nuts were invented at home, but failed, owing, perhaps, to the different shapes and sizes of the nuts. At length native women and children undertook the business of nut-cracking, and a thriving kernel trade sprang up forthwith. This kernel trade sprang up in Old Calabar early in 1869, and a little sooner in some of the other rivers. A trader, accompanied by a misssionary, visited several oil-producing villages, and urged the people to begin nut-cracking. 1000 tons of kernels were bought that year at 2*s.* a bushel, and in 1871 upwards of 2000 tons at 8*s.* a bushel. But this year—1872—black protection interfered and stopped this new and flourishing native industry. The rapid development of the kernel trade, with the large oil trade, and its pernicious "trust system,'

---

* Pharm. Journ, [3], vol. iii., p. 701.

produced a glut of English goods in the great country fairs, and consequently a heavy fall in prices. When the principal oil brokers went to the country markets and found, to their no small disgust, that, owing to the depreciation of their goods, they had to pay for oil in the markets nearly as much as they received for it in the hulks, they felt that something must be done in order to shut trade goods out of the markets until prices should rise. Now, as the kernel trade was entirely in the hands of poor people, who had neither capital nor credit to become oil brokers, the rich brokers determined to stop the kernel trade. But, having some regard for public opinion, these black protectionists never once hinted that this rapidly growing native industry, so valued by the poor, was crushed for the benefit of the few capitalists. A plausible story was started that the kernel trade was ruining the oil trade—the staple trade of the country—inasmuch as nut-cracking was usurping the place of oil-making. "Do you wish to buy oil *or* kernels?" asked the wily King of the agents; and oil being the response, he announced that the kernel trade was now strictly prohibited.

The statement that the kernel trade injured the oil trade by lessening its amount was evolved from the internal consciousness of the rich brokers. Among the producers the men had still to climb the palm trees, and the women to do nearly all the oil-making work before getting the nuts ready to crack. No African woman in her senses would, after working hard for it, throw away oil worth twice as much as kernels in order to get kernels only, when she could have both oil and kernels.

Many believe that the kernel trade has hurt the oil trade, because they have purchased less oil since the kernel trade began; but this can readily be accounted for by the fact that there are now twenty-six firms in the oil rivers, instead of sixteen, and no increase in the yield of oil. A similar impression was produced in Lagos, and from the same cause, viz., an addition to the number of merchants; but the accurate statistics of that flourishing colony show a steady increase of oil, as well as kernel exports.

CONTAMINATION OF BICHLORIDE OF MERCURY.*

BY M. BULTOT.

Some bichloride of mercury received by the author from a chemical manufacturer was found to be pulverulent and soluble in distilled water in the usual proportions; but in the colourless solution were observed some small yellow insoluble particles. Tested with ether there was a slight rose colouration, and the yellow particles still remained insoluble. Alcohol dissolved the salt with a red colour, which soon became very intense, but the deposit of insoluble matter still remained apparently the same. Chloroform was without action upon it, but the red colour appeared directly alcohol was added. The suspected sublimate was also coloured upon the addition of nitric or hydrochloric acid.

Suspecting the presence of an aniline derivative, M. Bultot added to the red alcoholic solution ammonia, which decolourized it instantaneously, giving at the same time a precipitate of amidochloride of mercury. The filtered colourless liquor again became red upon the addition of hydrochloric acid, yielding a fine crystallization of sal ammoniac. These reactions are easily explained by the fact that the aniline reds are coloured salts of a colourless base rosaniline, and it was this impure base that had caused the alteration in the sublimate. Rosaniline is but slightly soluble in water, insoluble in pure ether, and soluble in alcohol, which it colours red. Acids colour it a crimson red, forming monacid salts, which are decomposed and decolourized by ammonia.

M. Bultot considers the foreign matter causing the contamination was rather the residue of a manufacture than a commercial substance mixed by inadvertence, and that it is probable that the high price of mercury has brought into the market mercurial preparations that have been previously used in the manufacture of aniline colours.

THE DOSES OF THE PHARMACOPŒIA.*

We are enabled to give in another column a short foretaste of what may be expected from the forthcoming addendum of the British Pharmacopœia, which will probably be read with interest, since the Pharmacopœia is the every-day working tool of the medical practitioner. All good workmen are careful as to the quality and form of their tools, although it is said that they are not the best who are the most prone to fall out with them. In an angry little article lately published, Dr. Anstie scolds the Pharmacopœia Committee very violently for presumed shortcomings in the matter of doses. Dr. Anstie has his own ideas of what the posological table of a pharmacopœia ought to be, and he can hardly find language strong enough to express his anger and contempt for those who differ from him. They have been guilty of an "unpardonable blunder," of "extraordinary ignorance or negligence," of "lamentable timidity," of "unaccountable rashness"; they must have been "entirely unfamiliar" with the practical use of drugs; they are "extravagantly wrong"; and their "mischievously misleading" errors have this "unfortunate significance," that they "indicate an ignorance and a carelessness which are very wide-spread in the profession." These are rather strong expressions even from the mouth of this commonly rather impetuous writer; they are especially so if we remember that these ignorant, misleading, and practically uninformed posologists include men bearing the names of Christison, Apjohn, Aquilla Smith, and Quain. If, however, we look to the little fire whence all this smoke proceeds, we see that the particular wrong alleged is, that the Pharmacopœia gives only what may be considered as safe average doses, representing the mean of ordinary practice, without going to either extreme. The compilers of the Pharmacopœia, in departing from the earlier precedent of the London Pharmacopœia, and giving posological indications, met the known and expressed wishes of the profession; but they might easily have incurred very serious risks, and really misled numbers of people, if they had gone to any extreme. The range of doses in the Pharmacopœia does not bind any one; it only affords a certain datum—an indication for the neophyte. More refined or more adventurous therapeutists may give half-ounce doses of tincture of digitalis, or *ounce* doses of succus conii, as Dr. Anstie suggests; but it must remain very doubtful how far such doses can be generally counselled even in extreme cases; and it is far more reasonable, not to say more modest, to assume that, when the compilers of the Pharmacopœia declined to stamp officially with assent doses which might under ordinary circumstances be considered extreme and dangerous, they did so out of the fulness of their knowledge, than that they did so in the vacancy of their ignorance. If they had defined the extreme doses, or had given the whole possible range of administration of every drug, they must have also indicated the special circumstances which justify, or which have been thought to justify, these doses; and, further, they must have proposed safeguards. This would have converted the Pharmacopœia into a treatise on therapeutics. It might almost be advisable, therefore, for this excellent and able critic to reconsider and take back some of his big words. Meantime, as it has been thought advisable to continue to give posological indications in the forthcoming Addendum, we are not sorry to know that the old rule of giving an indication of average doses only, continues to be the guiding principle of pharmacopœial posology.

* From the *British Medical Journal*.

The Pharmaceutical Journal.

SATURDAY, JANUARY 3, 1874.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square,*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ.'*

1873.

THE greetings of the New Year remind us that the time has arrived for taking a retrospect at another twelve months. The history of the past year has been eventful to pharmacists of the present day in many respects, and it will have an important influence upon those of the future ; since, whether for good or evil,—the former we hope and believe,—the Pharmaceutical Society has resolved upon extensive changes with respect to education and examination.

Probably the most important action of the Society during the year has been in reference to education. The alteration in the arrangements of the School was but the realization of a change that had long been contemplated ; but the establishment of the new system is too recent to admit of any inference being yet drawn from its working. The amended regulations as to the examinations, which were finally adopted by the Society at the last anniversary and have subsequently been approved by the Privy Council, do not come into operation until the end of the year now commencing ; but, if we may judge from the large increase in the number of candidates for the qualifying examinations, they appear to have already exercised some influence. Last year the number of candidates for the compulsory qualifying examinations was 656, while this year as many as 913 candidates have presented themselves. It would seem, also, that the somewhat increased stringency which the examinations will have, under the new regulations, has induced some candidates to come up prematurely, for we find that the number of failures was very much larger than in the previous year.

In the Minor examination there have been 820 candidates examined, 776 in London, with 44 per cent. rejected, 44 in Edinburgh, with 43 per cent. rejected. There have been only 93 candidates for the Modified examination, as against 149 in the previous year ; 78 in London and 15 in Edinburgh, with about 26 per cent. rejected at both places. In the Preliminary examination there have been 1291 candidates examined in England, with 48 per cent. rejected, and in Scotland 162, with 41 per cent. rejected.

We think the trade at large may be congratulated upon the sifting of wheat from chaff which the foregoing data indicate as having been the result of the labours of the Board of Examiners, who have thereby earned the gratitude of the whole body. At the same time, the very large proportion of rejected candidates justifies our urging upon masters the importance of fulfilling their obligations towards apprentices by allowing them time for serious methodical study, either during business hours or by closing earlier in the evening, and more especially by instructing them practically in the scientific aspects of the usual routine work of the shop. Those who could and would conscientiously do this might well require from their apprentices an extra year's service with real advantage to both, or they might be recompensed for extra trouble by an equivalent increase in the apprenticeship premium.

Taking the standards to come into force in October next as a basis, it cannot be questioned that any ordinary youth who has passed the Preliminary before being articled, ought at the expiration of his apprenticeship to be able to pass the Minor easily, if he and his employer have done their *duty*. To this end we would urge proprietors of good businesses, and many others well qualified to teach, who now decline the office, to accept the new state of things loyally and take their share in improving the character of our technical education. If from considerations of self-interest those who are competent for this work leave the less qualified to monopolize apprentices, it will be their own class that will suffer *most* in the next generation from the want of competent assistants.

The failures in the examinations may be regarded as due partly to pure ignorance and partly to cram. The latter acts mischievously, inasmuch as country youths are encouraged by the crammers to attempt to gain knowledge which ought to have been acquired during apprenticeship in a few weeks.

Compared with last year, the statistics of the Major examination are rather favourable. In 1872, out of 89 candidates 52, or 58·4 per cent. passed. In 1873 of 83 candidates 54, or 65 per cent., were successful.

Of the total number (1267) who have passed the various examinations 341 have joined the Pharmaceutical Society, either as Members, Associates, or Apprentices. Probably this proportion is much the same as that of former years ; but whether it be an increasing or decreasing ratio it is still painfully small, and demonstrates want of feeling and *élan*, both on the part of the candidates and those who trained them. It is very desirable that the members of the Pharmaceutical Society who are not officers should strive to be as active as the present and past councillors, examiners, and local secretaries have been, and that, in the spirit of the founders, they should work *through* their sons, apprentices, and assistants for the common good. Once obtain an educated united body and it may defy co-operative stores, as well as outcries against dispensing charges, and Adulteration or other Acts will have no terrors for it.

The question of Local Secretaries, their position and duties, is one that has attracted considerable at-

tention, but as the subject is still under discussion we confine ourselves to saying that, since it is very desirable, in the interest of the Society and of the trade generally, that there should be—in every town if possible—throughout the country men ready to represent the Society and capable of carrying out such business as may arise, often at a considerable expenditure of time and labour, it seems only reasonable that some plan should be adopted by which such services might be remunerated.

While preparing the 'Calendar of the Pharmaceutical Society' for 1873, it was discovered that the title of "Major Associate," which for some years had been held by a number of gentlemen who had passed the Major examination, had no legal foundation, and that, by the terms of the Bye-Laws, Associates upon passing that examination had to be removed from the Register of Associates and became eligible as Members. The REGISTRAR had no choice, but was compelled to omit the entire list, containing 149 names, from the Calendar. Some little irritation followed, but it is satisfactory to know that 103 out of the 149 gentlemen have since been elected Members.

A subject which has frequently been mooted in these columns—the manner in which the Funds of the Pharmaceutical Society are invested—was formally brought under review early in the year. At the January meeting of the Council, Mr. URWICK moved that £10,000 of the Society's funds should be invested in freehold land and freehold ground rents. The proposition was seconded by Mr. BAYNES, but after a prolonged discussion, it appeared to be generally felt that no sufficient reason had been given for altering the plan hitherto adopted, and the motion was rejected by a considerable majority.

A little later, when the time arrived for the preparation of the annual Balance-sheet, the Finance Committee expressed a wish to have professional assistance, as the work had become one of considerable responsibility. This was granted, and led to the preparation of a balance-sheet in which the new course was taken of charging each department with its portion of the general expenses, so that an idea might be obtained of the cost of each to the Society. But it would appear that the auditors declined to sign a statement of accounts containing estimated amounts, and it was therefore found necessary to revert to the former system. A proposition by Mr. URWICK, seconded by Mr. BETTY, to publish, in addition, the detailed accounts and estimates that had been prepared was decided upon adversely by the Council as unnecessary, Mr. HASELDEN as PRESIDENT giving the casting vote.

Although the subscriptions to the Benevolent Fund showed for a larger sum in the balance-sheet this year than last, it appeared at first that the Society would have to depart from its custom for several years past by electing only one annuitant instead of two; it was found possible, however, at the last moment to elect two, but this was in consequence of the death of one of the annuitants, not of any sudden and liberal influx to the funds. During the year a legacy of £25 from the late Mr. GEORGE WAUGH was generously increased to £100 by his widow. Still it is felt that this Fund is not so widely supported as it should be. Opinions have been freely expressed that a point has been reached at which the Council may cease to invest any more subscriptions, depending upon the current year's income for the payment of any liabilities that may be incurred for annuities, and that if this were done many who now stand aloof, preferring to distribute their own money in the relief of present necessities, would be induced to contribute to the fund. Acting upon this view Mr. ROBBINS brought the subject before the Council, and a committee was appointed to consider what steps should be taken to increase the amount of subscriptions, as well as the usefulness of the fund. Only at the last meeting of the Council Mr. BROWN expressed his opinion that the time had come when annuities might be granted out of annual income in some way.

There is much reason for congratulation in the fact that, as compared with the numbers engaged in the drug trade throughout the kingdom, there are still so few applicants for relief from the Benevolent Fund. This would seem to show that though we hear frequent complaints of the business being a poor one, it does not, even in its present state, more than any other occupation entail the prospect of having to seek the aid of charitable organizations. Yet it is distressing to find the resources of the fund inadequate to satisfy the actual calls upon it, and that three out of five admittedly deserving applications must be left without the assistance required. We trust that this state of matters will now be remedied, and that by the adoption of some plan to meet the objections to the course hitherto followed in administering the fund, there may no longer be any need to point to the striking disparity between the total number of subscribers and the number of chemists and druggists upon the register.

Early in last year a correspondent, writing from Reading, expressed his surprise that so few subscribed to the Benevolent Fund, and suggested, as Mr. SCHOLEFIELD had previously done, that in future all donations and subscriptions should be expended in granting relief. He considered that by this means many additional subscribers would be obtained, and the same view was taken by Mr. CLARK of Leicester, and others. In regard to this suggestion, it was pointed out by Mr. SANDFORD that according to the existing bye-laws donations to the fund must be invested, and that the granting of annuities must be regulated by the amount of invested capital.

But though grants made on the basis of annual subscriptions can only be contingent, and therefore of less value to the recipient than those secured by the invested capital of the fund, there seems to be a widespread feeling that the action of the fund may be so far extended that there may not in future be any

occasion to reject three out of five candidates, and, to use the words of a correspondent, a "conviction that the fund can and may be made sufficiently strong to meet all legitimate demands."

The effort made to provide a fund for the support and education of the children of JOHN CARGILL BROUGH, late editor of the *Chemist and Druggist*, has been carried to a successful issue, and a sum of nearly £2,000 has been vested in trustees for that purpose.

One question, which at the commencement of the year was certainly a vexed one, appears now to be set at rest, namely, the position to be taken by the Pharmaceutical Society in respect to the admission of women pharmacists. Much misrepresentation, based upon ignorance of the points at issue, has occurred in the public press respecting this matter, and even during the last few weeks the President of an important provincial association evidently laboured under the impression that the Society had refused to admit women to the pharmaceutical examinations, the fact being that there are at present on the register three by virtue of having passed the examinations, and several in the right acquired by being in business before August 1, 1868. What has really been discussed is this:—Shall women be allowed to join the Pharmaceutical Society as Apprentices, Associates, or Members? At the commencement of the session in October, 1872, the Council resolved to rescind a resolution prohibiting the attendance of female students at the professors' lectures in the School of Pharmacy. Shortly afterwards the question naturally arose—were they to be allowed to compete for the sessional prizes in connection with those lectures? In December, and again in January, motions were brought forward in Council by Mr. HAMPSON that ladies should be eligible to compete for the prizes and certificates given at the end of each session. This was met by the objection that only "Registered Apprentices and Students of the Society" were eligible for these honours. When called upon to answer an application from three ladies for election as "Apprentices," in order that they might come within the pale, the Council transferred the responsibility of the decision to the Annual Meeting, which by a considerable majority negatived the proposition. There had been much lively discussion in these columns and some talk of an application to the Court of Queen's Bench for a *mandamus*, but fortunately the decision has produced as little hurt as it would probably have done if given the other way. Still it cannot be too plainly understood that there is nothing to prevent a woman who is qualified from passing the qualifying examinations, and thus acquiring the right to carry on the business of a chemist and druggist.

The Evening Meetings of the Pharmaceutical Society cannot, on the whole, be considered satisfactory. For, although they have not wanted in interest, yet there has been a great dearth of original communications of such value as should be forthcoming at such representative gatherings. Only six evenings in each year are set apart for these meetings, and one of these is always taken up by the Inaugural Address and Distribution of Sessional Prizes; hence it might have been thought that in so wide a field as that covered by the materia medica and chemical and pharmaceutical preparations there would have been sufficient research to require a committee of selection to deal with the superabundant records of results offered for acceptance. Unfortunately, this has not been the case, and the faith shown in the certainty that "something would turn up" could not have been exceeded, even by Mr. MICAWBER. With few exceptions, the time at these meetings has been chiefly occupied with discussion arising upon articles exhibited, or some subject brought forward without previous announcement. Amongst these exceptions, however, were a paper on "Morocco Drugs," contributed in February by Dr. LEARED; one on "A New Basis for Suppositories and Pessaries," by Mr. W. MARTINDALE, and one on "The Mustard of the Pharmacopœia," by Mr. T. GREENISH, contributed in April; some "Pharmaceutical Notes," by Mr. J. B. BARNES, in November; the paper on a "New Solvent of Phosphorus," by Mr. A. W. GERRARD, and a "Note on Glycerine of Gallic Acid," by Mr. S. GALE, read at the last meeting. On two occasions the subject of the Proposed Appendix to the Pharmacopœia was discussed at the suggestion of Professor REDWOOD, and on two other occasions the Adulteration Act was discussed in reference to its relations to pharmaceutists.

During the year the Committee to whose care it is entrusted have spared no expense or pains upon the Library. A considerable alteration and improvement has been effected in the reading-room itself and every suitable book has been placed on the shelves as soon after publication as possible. A very useful and clearly arranged catalogue of the books has been prepared by the LIBRARIAN and printed, copies of which may be had by members upon application. The practice of opening the reading-room from eight until ten on two evenings in each week has been continued, and it is appreciated by some students; but we do not think that the number availing themselves of the privilege is nearly so large as might have been expected in a place like London.

A few months since it was stated in these columns that it was intended to form, in connection with the Museum of the Pharmaceutical Society, a medical herbarium, in which specimens of plants known to be used in popular or scientific medicine, and also of plants that are sometimes substituted for them, should find a place. A request was made that medical gentlemen and pharmacists residing in various parts of the world would assist in making this herbarium as complete as possible. Some assistance has already been promised, and doubtless as the project becomes better known other helpers will come forward. The herbarium now contains between

300 and 400 specimens. During the year, a catalogue of the whole of the specimens in the Museum has been prepared by the CURATOR, which we hope will be printed, and thus rendered more widely available. Separate well-preserved specimens of all the more important indigenous medicinal plants have also been mounted, and are now in daily use by the students.

The meetings of pharmacists, which may now be looked upon as annual, have this year all been interesting and successful. The business of the Annual Meeting of the Pharmaceutical Society, referring principally to the admission of women to membership, and that of the Special General Meeting, referring to the new bye-laws, are spoken of elsewhere. The Dinner at the Crystal Palace and the Conversazione at the South Kensington Museum, were both numerously attended, whilst the Annual Chemists' Ball showed no falling off. The Inaugural Address at the commencement of the session of the School of Pharmacy in October was delivered by Mr. G. W. SANDFORD. Naturally, one of the main topics was the altered conditions under which the Professors recommenced their labours, but it also contained a vigorous assertion to the students of the benefits resulting from thorough and earnest study. The reports of the Professors upon the classes of the previous session were satisfactory, and the distribution of prizes was rendered remarkable by the unprecedented number of honours carried off by one of the Junior Bell Scholars—Mr. SYDNEY PLOWMAN.

The North British Branch of the Pharmaceutical Society has, during the year, made considerable progress towards acquiring the position and appliances to which its representative character in Scotland entitles it. The museum, library, and reading-room in the new premises in St. Giles Street, Edinburgh, had been opened, and a good working code of rules for their regulation had been drawn up. Upon the representation, however, of Mr. J. MACKAY to the Council in London that there was still need for a set of specimens for the examiners, the subject was referred to a committee, with power to make a selection, and arrange for the supply of all that was deemed necessary. A deputation consisting of the PRESIDENT, VICE-PRESIDENT, and SECRETARY of the Pharmaceutical Society was also, in response to an invitation, appointed to visit Edinburgh and inspect the new arrangements, who, on their return, presented a satisfactory report.

In Ireland an attempt has been made to place the unsatisfactory relations of the apothecaries and chemists and druggists towards each other—which have proved incidentally an impediment in the way of the Pharmaceutical Conference visiting Belfast with the British Association—upon a better footing. The first meeting of a "Chemists and Druggists' Society of Ireland," established "with a view to obtain a status similar to that secured by Act of Parliament to England," was held in Dublin in January. The "situation" was illustrated shortly afterwards by a gentleman who was stated to possess the diplomas of the College of Surgeons, England, and the College of Physicians, Edinburgh, but whose name did not appear on the register as an apothecary in Ireland, being fined in two penalties of £20 each for compounding prescriptions. In March a deputation from the newly-formed Society, was appointed to wait upon the Governor and Company of the Apothecaries' Hall, and ascertain their views upon the subject. The Apothecaries' Company met the deputation in a friendly spirit, and suggested the adoption of a Bill drawn up two or three years previously; but it was eventually arranged that the Chemists and Druggists' Association should draft a Bill, and submit it to the Apothecaries' Company. This was done accordingly, and the committee entrusted with the work have recently reported that the Chemists' and Druggists' Association have every reason to be satisfied with the result. If the ATTORNEY-GENERAL should comply with the joint request of the two bodies to introduce this Bill into Parliament next session, it will require, and doubtless receive, the careful consideration of the Council of the Pharmaceutical Society of Great Britain.

The British Pharmaceutical Conference met at Bradford in September, and although the number of members present was not so large as in the preceding year at Brighton, the decrease was no more than might have been expected, through the greater distance of Bradford from London. The papers read were numerous and valuable, but a few of them were not fitted for reading *in extenso*, and would have secured greater interest if short abstracts of them, giving the general results, had been prepared for the occasion. Instead of this, the hearers were overpowered by a multitude of details which but few were competent to deal with, and that not on the spur of the moment. As it is very desirable that nothing approaching to boredom should attach itself to these semi-holiday meetings, the Executive Committee will doubtless consider this point before the next meeting. Up to the present time the Year Book has not made its appearance, although it will probably be published in a few days, but a very full account of the proceedings appeared in this Journal shortly after the meeting. It was resolved that the Conference should next year meet in London, under the presidency of Mr. T. B. GROVES, of Weymouth, and the Council of the Pharmaceutical Society have offered the use of the Society's rooms at Bloomsbury Square for the purposes of the meeting, and have promised to afford every facility for promoting its success. No decision has yet been arrived at respecting the date of the meeting.

Three summonses for breaches of the Pharmacy Act have been heard during the year. In one, where the Pharmaceutical Society prosecuted for the sale of poisons by an unregistered person in Glasgow, it was sought to set up an alleged partnership with a medical

man as a defence, but in the absence of satisfactory corroborative testimony a conviction was obtained; and in another, also taken out by the Society for a similar offence in London, the defendant failed to appear, and was convicted and fined in his absence. The third case was a summons taken out at the instance of a borough coroner against a registered chemist and druggist for selling a strychnine vermin-killer without observing the precautions prescribed in the Pharmacy Act for poisons contained in Part 1 of Schedule A. The magistrate held that an offence had been committed, and inflicted a nominal fine as a warning.

The number of deaths from poisoning recorded in our columns has been below the average. From the date of the publication of a list of poisoning cases in May, 1872, to the end of that year—eight months—41 cases were reported. During the twelve months that are just closing the number has been 38: viz., from aconite, 1; ammonia, 1; arsenic, 2; arsenate of soda, 2; carbolic acid, 4; essence of bitter almonds, 2; hydrate of chloral, 2; laudanum, 6; liquor strychniæ, 1; lotion, 2; medicated oil, 1; morphia, 2; opium, 1; oxalic acid, 1; paregoric, 1; prussic acid, 3; salt of sorrel, 1; spirit of salt, 1; strychnia, 1; vermin killers, 3. It is satisfactory to find that not a single case is attributed to mistake or carelessness on the part of a chemist or druggist. In a case where an assistant to a medical man was tried on a charge of culpable homicide, caused by supplying salt of sorrel in the place of Epsom salts, a verdict of "Not proven" was returned. In one case carbolic acid was administered instead of "senna" by a hospital nurse; and in another it was drunk by a child from a bottle left in a cupboard at a workhouse school. In another hospital prussic acid was dispensed instead of solution of chloral hydrate. One case of poisoning by a lotion and another by solution of ammonia, arose from mistakes on the part of the deceased. It is also worthy of note that since the issue by the Pharmaceutical Council of the notice respecting the conditions under which vermin-killers should be sold, there has been a marked decrease in the number of cases of poisoning by those agents; only 3 cases have been recorded in this Journal during 1873 against 11 in 1872.

The operation of the Adulteration Act has pressed with increased importance upon the attention of pharmacists, not only from the semi-scientific nature of the evidence tendered in many cases, but because of the possibility of this law becoming a source of annoyance and oppression to them. The principal prosecutions under the Act have been recorded in this Journal. Among the cases in which chemists and druggists have been concerned, there have been prosecutions for the sale of quinine adulterated with quinidine, and of mustard adulterated with farina, in which convictions took place; in the charge of adulterating sweet spirit of nitre, which was the most important, the summonses were dismissed. The "citrate of magnesia case," in which a conviction was also obtained, is to be regarded rather as a misapplication of the Act. The proceedings under the Act have fully justified the position taken by the Pharmaceutical Society with respect to the appointment of analysts. Another important prosecution was that by the Excise authorities for an extensive fraud on the revenue laws under the cloak of "perfumed spirit."

During the Parliamentary session several Bills were introduced into the House of Commons presenting features of interest to the pharmacist. Most important of all was the Bill, which was brought in by the Government in February, for the consolidation and amendment of the law relating to juries. It was found with satisfaction that although the tendency of the Bill was to curtail the number of exemptions from jury service, there was an exception in the direction desired by the Pharmaceutical Society, that the exemption at present enjoyed only by pharmaceutical chemists should be extended to all registered chemists and druggists. The Bill was, however, postponed time after time, and ultimately withdrawn at the end of the session. The Shop Hours' Regulation Bill, introduced by Sir JOHN LUBBOCK, was another piece of proposed legislation that attracted considerable attention from chemists and druggists, and in this case generally of an antagonistic character. It was felt that however well intentioned, such a law would be productive of great practical inconvenience. Active opposition to it was organized throughout the country; on the motion of Mr. W. S. BROWN, the Council of the Pharmaceutical Society resolved to oppose the Bill, and the PRESIDENT was authorized to sign a petition against it on behalf of the Society. In face of this opposition, and at the late period of the session, Sir JOHN LUBBOCK found it useless to persevere. A Bill for establishing the metric system of weights and measures after a certain period was again introduced, but it was again unsuccessful, although the advocates of this system may be congratulated upon the valuable report of the proceedings of the International Metric Commission at Paris, an abstract of which appeared in this journal a few months since. A Bill for establishing a registration of the names of the actual members of trading firms, and another for the registration of trade marks, suffered the same unsatisfactory fate, and were withdrawn.

"It's an ill wind that blows nobody good," is a saying that appears likely to receive a fresh application in relation to the subject of unusual doses in prescriptions. An unfortunate occurrence at a well-known seaside resort, where a chemist and druggist refused to dispense an unusually large dose of tincture of digitalis ordered by a prescriber unknown to him and was, therefore, unjustly censured by a coroner's jury as being responsible for the death that followed, attracted the attention of all thoughtful

pharmacists to the unsatisfactory and unsafe circumstances frequently attending the ordering of powerful medicines in doses exceeding those indicated in standard works on posology. It was felt that so long as it was possible to find a medical man who would dogmatically assert that a patient *in extremis* would have recovered had he taken a particular dose, and a member of the medical press that would give colour to such an assertion in the absence of any authoritative rule upon the subject, so long would it be dangerous for a pharmacist to exercise that intelligent caution which his educational training implied. The subject was brought before the Pharmaceutical Conference at Bradford by Mr. R. HAMPSON, in a temperately written paper, and after discussion the subject was referred to a committee to consider. The report of the Committee, which was adopted, recommended that in prescriptions, after any unusual dose, the prescriber's initials, between brackets, should be placed; that with a view to facilitate communication between prescribers and dispensers the prescriber's full name and address should be given on every prescription; and that the dispenser should retain all prescriptions in which initialled unusual doses occur. These recommendations have been recently formally communicated by the Executive of the Conference to the medical profession, and have met with a considerable amount of approval. The *Lancet* accepts the principle of the first two recommendations, and objects to the third, but recognizing the importance of the question, suggests that it should be considered and settled by the College of Physicians, if necessary, after conference with the representatives of the Pharmaceutical Society. The *British Medical Journal* approves of the report as a whole; and the *Medical Times and Gazette*, speaking of the initialling, considers that there "could be no objection to such a rule if it were made universal." So that to this passing cloud there may be a silver lining in the adoption of a rule that will frequently save dispensers much anxiety.

In the first month of the year the fifth of the decennial editions of the United States Pharmacopœia was published, and its merits or failures have been ably discussed by contributors to our pages. We recall here the fact that this pharmacopœia is the work of a committee of delegates appointed by colleges of pharmacy as well as those of medicine, and again we urge the advisability of a similar course being adopted with respect to the British Pharmacopœia. Any attempt to enforce the formulæ and tests of the latter work must be weakened so long as pharmaceutists, who are naturally best acquainted with the practical working of its details, have no opportunity of expressing an authoritative opinion respecting the rules by which they are to be bound. This strange anomaly has just been illustrated. A reprint of the British Pharmacopœia having become necessary it has been resolved by the Medical Council not to make any alteration in the body of the work but to place such additions as may be deemed by it to have become necessary in an appendix. Pharmacists were courteously invited to exercise the privilege of suggesting what preparations should be introduced into their own everyday text-book, and they availed themselves of the opportunity to some extent, but how far their suggestions were accepted and how far declined,—though not for what reason,—they will probably learn for the first time when the book is published, which is expected to be in a few weeks from the present time.

The subject of the proposed Universal Pharmacopœia has been discussed in Paris and Vienna. In the former city, the Society of Pharmacy has reappointed a commission to consider what shall be done, and, if it be thought advisable, to communicate with English pharmacists. In Vienna, the Third International Medical Congress passed resolutions as to the basis upon which such a Pharmacopœia should be constructed, and arranged for the formation of an international commission to which the work should be committed. It may be remarked that the Latin language which is selected for the text is, of the four more extensively used Pharmacopœias, adopted in that of Germany alone; in those of England, France, and the United States the popular tongue being used. The metric system of weights and measures also is chosen, which at present is not adopted in either the Pharmacopœia of Great Britain or that of the United States. Still, if this work is ever to be accomplished, many mutual concessions will have to be made, and certainly these two would appear to be absolutely necessary.

One most satisfactory characteristic of the year is the progress which has been made towards shortening the hours of pharmaceutical labour. Hull, Sunderland, Peterborough, Greenock, and Brighton, and doubtless many other places, have made more or less effort in this direction, and it is to be hoped that the results will be permanent. In the present day, when the tendency in every calling is to shorten the hours of labour, there does not appear to be any valid reason for pharmacists being last in the race, but it is to be feared that the greatest obstacle that lies in their way is that of distrust and jealousy among themselves. While there can be no doubt that the public would exercise the necessary forethought if a proper representation were made to it, still a little unity of purpose and action would considerably heighten its perceptive powers.

One of those hubbubs about the charge for drugs which may be looked for periodically was, early in the year, raised by a writer in the *Globe*, for whose equanimity it was too much to discover that in a first-class dispensing establishment anything more was charged for than the actual drugs used in dispensing a prescription. A raid upon pharmacists and the *Lancet* absent would have been like carrion without flies, and although our contemporary might have been supposed to know more about the merits of the

case than the unknown lay writer, it rushed into the fray with such vulgarity and Donnybrook energy as to make the *Lancet* a mark for the facetiousness of *Punch* and the rebuke of the more staid portion of the medical press. Indeed, so far from overcharge being the rule, our Correspondence columns have several times during the year contained complaints from pharmacists as to the difficulty of providing "things honest in the sight of all men" whilst they have to compete with their "cutting" brethren and co-operative stores.

Another question, intimately associated with that of prices, is the scale of remuneration paid to assistants. In recollection of the repeated assertions as to the scarcity of assistants, some of the statements made respecting salaries offered to examined men have certainly been rather startling; but we fear that both these difficulties must be regulated by the much sneered at law of demand and supply. As to the suggestion which has been frequently made respecting the establishment of a chemists' assistants' association, that is a business which will tax their own energies, for, although employers have proved liberal in providing means of technical education, they can hardly be expected to initiate an organization which they may consider to be directed against their own pockets.

To turn from things political to those of a more technical character. The imperfect state of our knowledge respecting the origin of many articles of the materia medica, which was in the previous year shown in respect to the officinal rhubarb and manna, has received further illustration in the papers on Pareira Brava and Myrrh, by Mr. D. HANBURY, and that on Striated Ipecacuanhas, by Professor PLANCHON. In the paper on Pareira Brava Mr. HANBURY showed that although in the Pharmacopœia that drug is described as the "dried root of *Cissampelos Pareira*," yet the substance usually met with in commerce under that name did not agree with either the root or stem of that plant, but was the product of an undetermined menispermaceous plant; and further, that neither of them was true Pareira Brava, which is the root of *Chondodendron tomentosum*. In the paper on Myrrh, Mr. HANBURY states that although the substance itself has been known to mankind from the remotest period of history, the tree which affords it is almost, perhaps altogether, unknown to botanists. The herbarium specimens represented by EHRENBERG, to have been obtained from trees from which he had also picked very fine myrrh, and described and figured by NEES VON ESENBECK as *Balsamodendron Myrrha*, have proved to be derived from two distinctly different plants. This fact would seem to indicate that this gum resin is furnished by two or three distinct but allied species. The investigations of Professor PLANCHON tend to show that while "striated" ipecacuanha is usually described as the root of *Psychotria emetica*, there are really roots of two entirely different plants met with under that name. One of these ipecacuanhas presents all the characters usually attributed to striated ipecacuanha, but it is not the product of *Psychotria emetica*; the other is the product of that plant, but it does not agree with analyses and descriptions given by various writers on striated ipecacuanha, and notably in the complete absence of starch. The principles laid down in the two valuable lectures of Professor PLANCHON on the study of vegetable materia medica that have been translated for this Journal during the present year could not receive stronger confirmation than in this example and that of Pareira Brava. Another very interesting contribution to the history of ipecacuanha is WEDDEL'S paper on the *Cephaëlis Ipecacuanha* appended to Dr. HENDERSON'S Report on the attempt now being made with every promise of success to acclimatize this plant in India. Professor BAILLON has also questioned the propriety of attributing the balsams of tolu and peru to different species, and advocated a return to the generic and specific name given by LINNÆUS, *Toluifrum balsamum*.

It is also noticeable that from VAN GORKOM'S report some similar confusion appears to have occurred with another important medicinal plant, the cinchona. Although *C. Calisaya* has been in cultivation in Java and India for some years, it was only in 1865 that seeds of the variety *microcarpa*, obtained by Mr. LEDGER, were forwarded from London, and these have produced plants which promise to accord more fully than any yet raised with Mr. MARKHAM'S "glorious Calisaya of the American forests." The bark from these plants is stated to have yielded as much as 9 per cent. of quinine. Notwithstanding mistakes, however, the annual sales of Indian bark are said now to yield a profit of from £4000 to £5000 per annum. Some valuable investigations in respect to cinchona have been recorded during the year. Mr. BROUGHTON has found that the effect of manuring cinchona plants is to increase the total yield of alkaloids (2·81 per cent.), and especially of quinine (4·75 per cent.). Mr. HOWARD reports the total absence of the alkaloids from cinchona leaves; he is of opinion that they do not even commence to be formed there, but that the material for their formation comes from the heart wood of the plant. M. CARLES found that while quinine may exist in all parts of the bark, it is usually present in much larger proportion in the external layers, the proportion diminishing pretty regularly from the exterior to the interior. The locality of cinchonine was not so definitely fixed. An examination of some barks grown in Jamaica gave results which, although small (1·958 per cent. of quinine from *C. succirubra*), appeared satisfactory to Dr. DE VRIJ, considering the recent introduction of the cultivation there. An examination of *C. officinalis* barks from Ootacamund gave in one instance 9·1 per cent. of pure quinine. Dr. DE VRIJ has also described his method of separating the mixed alkaloids. The difficult subject of the estimation of the cinchona

alkaloids has been entrusted by the Paris Society of Pharmacy to a Committee to report upon. A thorough and exhaustive history of the cinchona alkaloids has been published in Germany by O. HESSE, which we propose to present shortly in an English dress. The success of the cinchona acclimatization experiment, although only partial in St. Helena, appears to be sufficiently established in India, Java, Jamaica, and elsewhere ; nevertheless, the quantity exported from Columbia does not appear to decrease. The comparative action of the cinchona alkaloids in combatting fever, and also in resisting putrefaction, have formed matter for two valuable papers.

A contribution to the literature of the oriental aconites by Dr. M. C. COOKE serves to show how little is known as to their botanical origin ; but Mr. GROVES's researches have shown that Bikh root, whatever may be its source, contains the doubted "pseudaconitine." Dr. SQUIBB has suggested a method of testing the value of parcels of aconite. Dr. SQUIBB has also furnished some interesting information respecting aloes. Ammoniacum, which occurred in the list of drugs from Morocco noted by Dr. LEARED, was the subject of a paper by Mr. HANBURY, and also of two others by Mr. JOHN MOSS, in one of which he establishes the absence of sulphur from the Persian and African varieties. Guarana which appears now to have acquired a fair position as a remedy, has been written upon by Mr. HALLAWELL. The Eucalyptus tree, also increasing in importance, has been the subject of several notices, in one of which Mr. BROUGHTON denies that either the bark or leaf contains an alkaloid ; formulæ of preparations of the leaves have also been given. On the other hand, condurango has so completely dropped out of notice as to be a drug in quite another sense. The Indian Simarubae have been described by Mr. A. W. BENNETT, and Mr. POCKLINGTON has continued his valuable papers on the "Use of the Microscope in Pharmacy," dealing this year with the barks of the Pharmacopœia. Mr. BROUGHTON has searched for and failed to find an alkaloid in the bark of the Nim tree, but has described a dark-brown bitter resin, slightly soluble in water, as the active principle. A third alkaloid has been suggested for *Hydrastis Canadensis*. The opium alkaloids have been described by Dr. GUBLER and to close this portion of the list without exhausting it, hyoscyamine has been found by Dr. MERCK to be a liquid alkaloid resembling conia and nicotine. We may say that two more plants—the *Echites scholaris* and the *Garcinia mangostana* –have been added by a Manilla apothecary to the list of those used in medicine ; the "Pituri," an undetermined New South Wales plant, has been mentioned as a stimulant narcotic ; the silphium of the ancients has been identified by OERSTED as the product of a plant which is a congener with that yielding assafœtida, and he proposes to call it *Narthex Silphium* ; Mesquitégum, from the *Prosopis glandulosa* has been used in medicine in America, and the composition of gum Arabic as well as the collection of gum Senegal have been described.

Of plants and substances used or available for the purposes of perfumery, several have been noticed during the year. The *Michelia Champaca* formed the subject of a communication to the North British Branch from Mr. JAMIE, of Singapore ; the "Costus Root" or "Putchuk," used in the East for incense sticks, and the *Liatris odoratissima*, or "wild vanilla," have been described by Mr. JACKSON ; as, also, have patchouli and lavender by other authors. The increased use of true vanilla in Germany, and the curious reason given for it, was recorded only last week. The essential oil known as ylang-ylang is stated by M. GAL to contain an acid apparently identical with benzoic acid, and several oxygenated compounds resembling alcohols, with which probably it forms ethers. The whole subject of perfumes was also dealt with in a paper by Mr. J. PATON.

Probably the chemical preparation which has attracted the greatest amount of attention, certainly that which has given rise to the largest amount of literature during the year has been propylamine, or, more correctly, trimethylamine. A substance under the former of these names, after being introduced into medicine in St. Petersburg, and attracting passing attention in the United States and Italy, fell into disuse until again taken up by Dr. DUJARDIN-BEAUMETZ. Notwithstanding satisfactory reports as to results obtained, it soon became evident that great uncertainty existed as to what the solution used contained, whether propylamine or its isomer trimethylamine, or other compound ammonias, or anything beyond ordinary ammonia. A commission was appointed by the Paris Society of Pharmacy to report on the subject; they identified the substance used under the name of propylamine as trimethylamine, and recommended methods for preparing the solution of more uniform strength, but suggested that the use of the hydrochlorate, which had been prepared as a definite crystallized salt, would be preferable if it gave the same medical results. This plan has been adopted ; but medical men appear yet to be undetermined as to the position this chemical is entitled to take as a remedy. Hydrochlorate of amylamine has also been tested by Dr. BEAUMETZ, and hydrochlorate of propylamine is to be dealt with in its turn. Besides herring brine, several plants, and various decomposing nitrogenous substances from which trimethylamine has been obtained, M. VINCENT has recently reported that the methylamines are produced by the prolonged action of ammonia on acetone during the purification of methylic alcohol. In connection with Dr. BEAUMETZ's experiments, it is interesting to note that early in the year M. RABUTEAU reported to the French Academy that the substitution of the last atom of hydrogen in a salt of trimethylammonium by another molecule of CH_3, converted a comparatively

inactive substance like hydrochlorate of trimethylamine into a powerful poison like iodide of tetramethylammonium. Before leaving the subject of ammonias, we must mention the valuable paper on the rate at which ammonia distils over from weak solutions, by Mr. WANKLYN, and the direct synthesis of ammonia accomplished by Mr. W. F. DONKIN.

Scarcely second in importance as a new chemical remedy stands croton chloral hydrate. Our pages having so recently presented Dr. LIEBREICH'S communication upon this substance, it need only be mentioned here that consequent upon a notice of its action given in the *British Medical Journal* a short time since, a considerable demand for it occurred, which, however, has since diminished. Chloral hydrate—notwithstanding that serious effects have been described as resulting from its continued use—appears to hold its ground, and instances have been given of extraordinary doses administered. Two cases of death from overdose have been recorded during the year, one, singularly enough, of a suicide.

Sulphovinate of soda has come into considerable favour as a gentle purgative, and the changes it was found to undergo led to the publication of a valuable treatise on sulphovinic acid and the sulphovinates, by M. BERTHELOT. Some modifications in the original process for its preparation have been suggested, especially the substitution of the carbonate of baryta by a non-poisonous salt. In the preparation of solutions of magnesia the possibility of using metatartaric acid instead of citric acid has been pointed out by M. LEGER, and there is now a considerable demand in France for metatartaric acid for that purpose. A formula for an effervescing solution of tartrate of sodium has also been given. In connection with the subject of tartaric acid, it has been demonstrated by M. JUNGFLEISCH that it is possible to produce synthetically the varieties possessing rotatory properties, starting from olefiant gas, and without the intervention of any living organism.

The combinations of oleic acid with various metals have been in increasing request, and formulæ for preparing them as well as pure oleic acid, have been forthcoming. The same remark applies to lacto-phosphate of lime, and its preparation as a syrup, or in combination with cod-liver oil.

The comparative solubility of various salts of quinine in water and glycerine was the subject of numerous experiments by M. SCHLAGDENHAUFFEN, and from the published results it appeared that a new salt, the sulphovinate of quinine, was the most soluble. It has, therefore, been thought suitable for hypodermic injection, and has been exhibited in well-defined white crystals at a meeting of the Paris Society. M. SCHLAGDENHAUFFEN also pointed out that tannate of quinine is much more soluble in glycerine than is commonly supposed, and this is corroborated by Mr. BARNES'S note on mixtures containing infusion of roses. We may here refer also to the discussion in our columns respecting the nature of the deposit which forms in tincture of quinine. Another new salt of quinine—the meconate—has been described by Mr. AUSTEN. Meconate of morphia has been recommended by Messrs. T. and H. SMITH as peculiarly well suited for a solution for hypodermic injection. Suggestions have been made for a standard solution of acetate of morphia, and various formulæ have been given for this and similar solutions, but until the method of administering medicines subcutaneously takes a more definite position, pharmacists can hardly hope to have any authoritative formulæ for these preparations.

Preparations of mercury—the mercurous iodide especially—have received unusual attention. M. LEFORT has prepared this unsatisfactory compound by double decomposition, using iodide of potassium and pyrophosphate of soda and mercurous acetate; M. YVON has obtained it in crystals by heating iodine and mercury together in a sealed tube; and Mr. WILLIAMS has suggested an improved method of purifying it as well as of preparing the mercuric iodide. All apprentices who have lost patience and strength in preparing mercurial ointment will thank M. MAGNES-LAHENS for another effort to throw light upon the extinction of mercury in fatty matters. A new preparation, the chloride of mercurethyl, has been the subject of a paper by Professor MAISCH.

Citrate of iron and quinine; and ammonio-citrate of iron, have been dealt with in two valuable papers by Mr. UMNEY. M. GHYSEN has described a new iron preparation which he calls "ferrous mannate;" Mr. BUTLER has published a note on a solution of chloride of iron, and Mr. CREUSE has brought forward a series of new tasteless iron combinations, the nature of which is still under discussion. Nor must M. MEHU'S paper on the tartrates and citrates of iron and their ammoniacal combinations be forgotten.

The notorious uncertainty of strength in solutions of hydrocyanic acid came under the notice of the Pharmaceutical Conference at Bradford, when Mr. GROVES mentioned cyanide of zinc as a salt worthy of attention in this respect. Last week's journal contained a paper on this subject and a suggestion by Mr. TOWERZEY that the cyanide of zinc and potassium would furnish a convenient source of cyanogen. Some interesting results of experiments with cherry laurel water have also been put on record by M. LEGER.

The publication of the new edition of the United States Pharmacopœia, with its numerous fluid extracts, has naturally directed fresh attention to percolation as an operation and to glycerine as a menstruum. The controlling power which glycerine appears capable of exercising over the action of some medicaments—especially astringents—has also been alluded to. Another pharmaceutical operation, the formation of a good emulsion, has furnished a topic for more than one paper. Plaster of paris for suppository moulds, and animal soap, a mixture of stearic and oleic acids, and another of paraffin and theobroma oil, for bases of suppositories, have been recommended by different authors.

Pure stearate of soda has been recommended for the preparation of soap liniment. M. FALIERES thinks that nut oil might play a more important part in pharmacy, and the uses of cherry juice were recounted by Dr. MILLER. Dr. WILKS has spoken of the virtues of copaiba resin. A new formula for liquor bismuthi has been given by M. MEHU. Space will not allow of allusion to all, but amongst the other pharmaceutical novelties described during the year may be mentioned nitrate of zinc as a caustic, a new liniment of glycerate of lime, fluid extract of orange peel, chloroform water, M. LIMOUSIN'S medicated wafers, scales of iodine and blood, iodized tar, carbolized resin cloth, and last but not least, Mr. GERRARD'S phosphoretted resin.

Pepsine—its therapeutic value, and the best modes of preparing and administering it—has been under discussion. Dr. SYMES'S interesting experiments seem to point to Mr. SCHEFFER'S method of preparation as the best and the vinous form of administering it as about the worst. Notwithstanding the doubts recently thrown upon the virtues of this remedy it is probable that much of the disappointment sometimes following its use is due to the uncertain and unsatisfactory way in which it is prepared. Extract of meat has now taken too firm a hold upon the public favour to be much affected by aught said for or against it, but it is noteworthy that perhaps the last production of the late Baron LIEBIG was the defence of this preparation—with which his name will always be associated—that he supplied to our columns last January. Another article of the animal materia medica—cantharides—has been dealt with by Professor MAISCH in his article on Chinese blistering bugs, and the compounds of cantharidin have been described. Mr. POCKLINGTON has examined the colour of the wing cases spectroscopically, and attributed it to chlorophyll, and indulged in ingenious speculations as to the possibility of determining the feeding ground of the insect thereby. Analogous researches to this latter one are those on the chlorophyll bands in the spectrum, by M. CHAUTARD and Mr. POCKLINGTON, and a process for preparing pure chlorophyll has been given by M. HARSTEN.

Many articles on subjects of general scientific interest have appeared in our columns during the year, foremost amongst which must be placed Professor TYNDALL'S lectures on light and Mr. RIGG'S lectures on the measurement of the imponderables, Dr. SPRENGEL'S description of a new method of determining specific gravities, Mr. THORPE'S method of estimating nitric, chloric, and iodic acids, Messrs. GLADSTONE and TRIBE'S new air-battery, and Mr. WILLS' lecture on recent processes for the manufacture of gas for illuminating purposes. Disinfectants, antiseptics, and antiferments have been discussed; an interesting paper on the progress of modern chemical industries has been taken from a foreign source, besides others on the manufacture of potash salts at Stassfurt, and that of bromine in the United States. And to close—but again without exhausting the list—there have been Professor WILLIAMSON'S remarkable address at Bradford, Dr. RUSSELL'S on the colouring matter found in madder, and Professor CLERK MAXWELL'S on "Molecules."

"Of making many books there is no end," and the past year has seen no cessation in the work. Botanists have had Dr. HOOKER'S translation of LE MAOUT and DECAISNE'S splendid work, the concluding volume of DE CANDOLLE'S 'Prodromus,' a fresh edition of DRURY'S 'Useful Plants of India,' and one of BENTLEY'S 'Manual,' besides M. RODIN'S elegant little treatise on the indigenous popular medicinal plants of France, and many others. Chemists have had new editions of FOWNES, VALENTIN, FRESENIUS, and ATTFIELD, and new books from ROSCOE, WAGNER and THORPE. Pharmaceutists have had the new edition of the United States Pharmacopœia, the University College Hospital Pharmacopœia, PROCTOR'S Lectures on Practical Pharmacy, the Year Book, FLUCKIGER'S 'Grundlagen der Pharmaceutischen Waarenkunde,' HOFFMANN'S Manual of Analysis for pharmaceutical chemicals, and FERRAND'S 'Aide-Mémoire de Pharmacie.' Dr. WILSON has published a 'Manual of Hygiene,' and Dr. PARKES a fourth edition of his well-known work on the same subject. And as a relief to the "much study which is a weariness of the flesh" there is Dr. MACLAGAN'S bright and cheerful 'Nugæ Canoræ Medicæ.'

The year has not passed without robbing us of several men whose names are held in reverence by pharmacists. Germany has lost LIEBIG, he who stood head and shoulders above his brethren; France has lost NELATON; America is now grieving over AGASSIZ; and England misses BENCE JONES and CRACE CALVERT. In GEORGE WAUGH and GEORGE DYMOND, men who have done good service to the Pharmaceutical Society at its Council table have passed away, and in JOHN GARLE one who served it faithfully in the examination room.

But we have exceeded the limits originally set for this *résumé*. Numerous as have been the subjects alluded to, many must of necessity be yet unnoticed. We must not, however, omit to express in general terms our obligations for the friendly co-operation and assistance we have received from many quarters in the shape of local news, communication of formulæ etc., answers to queries, and other matters of interest to the trade, either voluntarily supplied or at our request. We appreciate highly the spirit which prompts such efforts to promote the general good, and entertain a hope that it may become much more general, trusting that in time its influence may result in such an increase in the production of original papers on subjects connected with pharmacy that we may cease to appear in this respect at a disadvantage as compared with our continental and transatlantic brethren. It now only remains for us to heartily wish our readers, one and all, a "Happy New Year," and to congratulate them that the prospects of the future appear to have three leading characteristics—better education, increased remuneration, and shorter hours of business.

Transactions of the Pharmaceutical Society.

At a meeting of the Board of Examiners held in London on the 18th of December, 1873, the following Certificates were received in lieu of the Preliminary Examination :—

Certificates of the University of Durham.

Dixon, Richard Dobson .....Sharow.
Naylor, Thomas Hamilton .....Newcastle-on-Tyne.
Taylor, William .....Birmingham.

Certificate of the University of Oxford.

Russon, Henry Albert .....Birmingham.

PHARMACEUTICAL SOCIETY, NORTH BRITISH BRANCH, EDINBURGH.

The second meeting of the present session was held in the Society's Room, St. Giles Street, on Wednesday evening, 24th December, at 8·30., Mr. J. R. Young, President, in the chair.

The following is an abstract of a paper :—

On the Collection and Examination of Potable Waters.

BY DR. STEVENSON MACADAM, F.R.S.E.

The subject of water supply is a very important one, and there are various points regarding the mode of collection and preliminary examination of waters which specially concern pharmaceutical chemists, who may be called upon to take samples for examination, and probably also to give a general opinion as to the purity or impurity of such.

The vessels in which the waters should be placed at the time of collection, and until the chemical examination, ought to be scrupulously clean, and should be washed out twice with the water to be collected before the actual sample is taken. The best vessels for the purpose are Winchester quart bottles, with glass stoppers, but where these cannot be had, then common quart bottles, with fresh corks, may be employed. Stoneware jars are not so suitable, as they are liable to impart certain saline matters to the water, even when they have been carefully cleansed.

In the lifting of the water from the stream or loch, care should be taken not to disturb the banks. A small iron pot, lined with porcelain, and with a wooden handle about five feet in length, will be found very suitable in lifting the water and pouring it into the bottles. If it be desired to lift the water below the surface, say at three or six feet in depth, a galvanized iron cylinder should be used, fitted with tubes and stop-cocks, which can be opened and closed when the cylinder is sunk to the required depth. From greater depths, say 20, 50, 100 or more feet, a galvanized iron cylinder, fitted with valves both below and above, should be quickly lowered with a rope, and thereafter the water may be raised to the surface. In drawing water from a well, the water should be pumped for some time before the sample is taken.

Where the water is taken from a loch or stream, the general nature of the gathering ground should be specially observed. Hill districts as a rule supply purer water than low lying districts. The latter communicate more saline matter and greater hardness upon the water and, as the low grounds are more cultivated, there is more chance of the impregnation of the water by the drainings of highly manured fields. The colour of the water may be observed by lowering a white porcelain plate, or still better, by placing the water in a long glass tube, and looking down through a column of eighteen inches of the water.

The vegetable and animal life in lochs or reservoirs should be noticed. On the banks of all lochs and reservoirs retaining wholesome waters, fresh-water algæ are found attached to the stones, and growing between the stones, whilst distributed through the water during the summer months there are large numbers of "water fleas," principally the *Daphne Pulex* and *Cyclops Quadricornis*. These are very delicate organisms of very minute size, and which can only be seen by looking steadily at a glass full of the water at rest. They can only live in the best natural waters ; are readily killed when any putrifying or sewage matter impregnates the water, or when the liquid is raised to 100° F., or when a little alcohol is added. These vegetable and animal forms are totally different from those found in sewage or impure waters.

The preliminary examination of a natural water may be carried out by the application of the tests for chlorides, viz., argentic nitrate; for sulphates, viz., baric nitrate, and for lime, viz., ammonic oxalate. None of these tests should give more than a faint haziness with the water as collected. When chlorides are abundant they may indicate sewage contamination, and when lime is large the water must be of a hard nature. The organic matter may be of three sources—peaty, marshy, or sewage origin. The first is comparatively harmless, whilst the second, and still more the third sources are positively hurtful.

The action of water upon lead pipes and sheet lead is best determined by enclosing the water in a short length of lead pipe or in a small cistern, and thereafter testing the liquid by dihydric sulphide.

The detailed analysis of a water is necessarily very complex and requires much time and skill.

After some remarks by Dr. Nicol and Mr. Mackay, a vote of thanks was proposed by Mr. Gilmour to Dr. Macadam for his very interesting paper. This was seconded by Mr. Ainslie and carried with acclamation.

The Secretary presented in the name of Professor Douglas Maclagan, the following contributions to the museum :—Maté cup or calabash, used by the natives of Paraguay, for preparing tea ; silver sucking-tube, used in connection with the above ; an oval pocket medicine-case, containing several compartments, used by medical practitioners in Japan.

The Secretary proposed a hearty vote of thanks to Professor Maclagan, which was carried unanimously.

Provincial Transactions.

LEEDS CHEMISTS' ASSOCIATION.

The third monthly meeting of the above Association was held in the Philosophical Hall, Leeds, on Wednesday evening, December 10th, 1873, the President, Mr. F. Reynolds in the chair. Several new members and associates were proposed for election by the honorary secretary (Mr. J. W. Longley), after which a very interesting lecture was delivered by Mr. Louis Siebold, Manchester, on "Fermentations."

Mr. Siebold, in the first place, alluded to the various theories on the action of ferments, showing how difficult it was to explain the numerous different phenomena termed fermentation by any one theory only. He then dwelt on the properties of malt, and its active principle maltine, which he stated to be 200 times stronger in its action upon starch than the article called diastase, which was formerly considered the pure active ingredient in malt. One part of pure maltine would convert 200,000 parts of starch into dextrine and sugar, under suitable conditions. This remarkable and powerful substance was obtained by macerating ground malt with lukewarm water, filtering and precipitating with a solution of tannic acid. Having fully explained the details of saccharine fermentation, the lecturer then proceeded to demonstrate the nature, causes, and results of the alcoholic and lactic fermentations by the description of a series of experiments, showing also that the former hardly ever proceeds without being, to some extent, accompanied by the latter. As well known instances of alcoholic fermentations Mr. Siebold cited the manufacture of beer and spirits, and gave a detailed de-

scription of these important branches of industry, showing it to be the distiller's main object to convert the sugar of the wort as completely as possible into spirit, whereas the brewer does not carry on his fermentation so far, but wishes to retain some of the sugar and dextrine, in order to give flavour and body to his beverage. The lecturer contrasted the English method of brewing with that practised in Bavaria, explaining the main difference to consist in the temperature at which the fermentations are conducted. The English brewer ferments his wort at about 65° F., and finishes it in about a week; the Bavarian brewer requires about six weeks to complete his fermentation which proceeds at a much lower temperature (45° to 50° F.), and in this case, its yeast, instead of separating on the surface, sinks to the bottom and carries down with it every particle of glutinous matter, which, if kept suspended in the beer, would render it so liable to acetification. Bavarian beer, Mr. Siebold said, was richer in body (sugar and dextrine) and in flavour (oil of hops) than the English beer, but the latter was much richer in alcohol. Having given a description of the yeast plant (*Mycoderma cerevisiæ*), and its development, the lecturer next referred to the German and Dutch yeast, as important articles of commerce, of which enormous quantities are used in Yorkshire and Lancashire by bakers, who prefer this pressed yeast to the bitter yeast obtained from the breweries. The fact that this article was imported from Germany and Holland, and not made in this country, had led many people to the erroneous conclusion that, owing to peculiarities in the atmosphere and water, it could not be made here. This idea was quite fallacious, because British distillers might easily skim off yeast from the fermenting wort, wash it by decantation, and press it, and thus obtain an article equal to the best imported. But if they were thus to remove quantities of yeast during the height of fermentation, the produce of spirit would be diminished, and this he could not afford under the present excise laws. In Germany, where the duty on spirit is much less than here, the distiller can relinquish some whiskey in order to obtain a supply of yeast. Either the whiskey is his main product and the yeast merely the by-product, or the reverse is the case. In the latter case in which yeast is the main product, the lactic fermentation is caused to proceed for some time (by keeping the wort at a temperature of between 112° and 95°) before cooling and beginning on the alcoholic fermentation. In this way the product of yeast is increased, but that of spirit is decreased. For this reason the article known as German yeast cannot be profitably manufactured in this country, unless, indeed, a method be found out by which so large a quantity of good active yeast could be obtained from grain, that the distilled liquor could be thrown away, or used for the manufacture of vinegar, instead of distilling spirit from it, and yet a profit realized. The lecturer said he had nearly succeeded in doing this, and showed a lump of yeast of excellent quality made by him in a way which yielded 40 per cent. of yeast from the malt and grain used. This yeast was not of course composed entirely of the *Myeoderma crevisiæ;* but it was equal in strength to the imported article, which generally contained much starch. Mr. Siebold next alluded to fermentations which proceed without the presence or addition of an active ferment provided, and he freely admitted, and quoted experimental proof of the fact that such fermentations are caused by germs floating about in the air, and that air freed from such germs by filtration through cotton wool cannot bring on fermentation in any liquid. The acetic and butyric fermentations, and the action of emulsin upon amygdalin formed the concluding part of the lecture, and were as fully explained as time permitted."

Many questions were asked of Mr. Siebold at the conclusion of his lecture, after which a hearty vote of thanks was accorded him on the motion of Mr. W. Smeeton, seconded by Dr. Heaton.

LIVERPOOL CHEMISTS' ASSOCIATION.

The sixth General Meeting of this Association was held at the Royal Institution, on Thursday evening, the 18th December, 1873; the president, Dr. Charles Symes, in the chair.

Mr. Henry J. Blackbour was elected a member, and Messrs. Arthur C. Jones and Edward E. Rowlands, associates of this Association.

The following donations were announced:—The current numbers of the PHARMACEUTICAL JOURNAL, *The New York Druggists' Circular*, *The Proceedings of the Liverpool Literary and Philosophical Society*, *Journal de Pharmacie et de Chimie*, *Proceedings of the Liverpool Philomatic Society*, and lists of objects ethnological, literary, and antiquarian in the collection of Rev. A. Hume, D.C.L., LL.D.

After the question-box had been opened, and the question contained therein answered, and the miscellaneous communications had been received, Dr. Charles Symes gave an address on "Study."

[This address is printed *in extenso* at p. 529 of the present number.]

Mr. James T. Armstrong, honorary secretary, read a paper on "Pharmaceutical Education."

In the discussion that followed and in which many members took part, it was felt to be very unsatisfactory that so few students were present at the meeting, although 500 circulars had been distributed in the town to the following effect:—"The Council of the Liverpool Chemists' Association are desirous that the subject of pharmaceutical education should not be lost sight of; and for the further consideration of the best means by which they can promote the interests of students in this direction, they have arranged to devote the greater portion of the time at the disposal of the meeting on Thursday evening, December 18th, to the further development of the scheme."

A vote of thanks to Dr. Symes and Mr. James T. Armstrong for their valuable papers brought the meeting to a close.

NORTHAMPTON PHARMACEUTICAL ASSOCIATION.

A special meeting was held on Dec. 19, 1873, Mr. H. J. Masters, President, in the chair. Mr. G. C. Druce, Secretary, having read the minutes, and referred to some specimens of materia medica, presented by Mr. S. N. Maxwell, the President proceeded to read a paper sent by Mr. W. H. Stott (a corresponding member) on Caoutchouc. The botanical sources were first enumerated, and their habitats named, the methods of obtaining it described, and samples of Pará and African rubber containing various impurities, were shown; the chemical composition and the various solvents explained, the powerfully smelling highly refractive bisulphide of carbon being evidently used in the manufacture of some of the articles exhibited. Explanations were then given of the method of purification, and samples of pure caoutchouc pointed out, to illustrate how completely the purification from stones, dirt, etc., had been carried by the process. Various patents connected with the manufacture and methods for preparing hose piping, solid india-rubber bands, etc., were described, and enamelled rubber shown which remained permanently flexible in all ordinary temperatures. Dentist's rubber was also exhibited, and its applications explained; and the almost universal uses of india-rubber further illustrated by horse shoes, watch chains, machine valves, medical and pharmaceutical appliances, etc., etc. Mr. Stott concluded his paper by wishing every success to the Association, and regretted the distance that rendered his attendance impossible.

A hearty vote of thanks was passed to Mr. W. H. Stott, and to Mr. McLauchlan, of Edinburgh, and Mr. Oliver, of Manchester, for loan of specimens to illustrate the paper.

Proceedings of Scientific Societies.

SOCIETY OF ARTS.

On the Energies of the Imponderables, with especial reference to the Measurement and Utilization of them.

BY THE REV. ARTHUR RIGG, M.A.

Lecture VI.

The Energy of Light, especially with reference to the Measurement and Utilization of it.

(*Continued from page* 524.)

That kinetic energy, of a character as important as any found in the other imponderables, exists in light, may be inferred from the fact that if light be extinguished by falling upon such a surface as lamp-black the stoppage of the ray—the consequent absorption of it—produces heat. The motion of the light has been converted into a motion called heat. If, however, the light be stopped by some of the salts of silver, then this motion is converted into chemical changes. The heat and the change are consequences of an energy in light. Nor is it only when influencing different substances that light effects different results. Take, for example, carbon, and note how varied is its behaviour towards light and electricity. When in the form of a diamond, then carbon transmits light and stops electricity; but when in the form of coke, into which the diamond is transformed by heat, then carbon transmits electricity and stops light. No cause has yet been assigned to that which seems almost universally the case, viz., transparent bodies stop electricity; carbon, the metals, and opaque bodies, stop light.

It is a popular opinion that sunlight or sun-brightness extinguishes household fires. May this not be from some hitherto undiscovered energy of solar light, for it is not the heat of the solar beam which thus causes the carbonaceous fuel in our grates to become dim? If the energy of light is to be studied and its value to be estimated and brought within our powers of utilization, it must be done through agencies widely different from those hitherto named. Looking at the order of creation, and watching the behaviour both of the animal and vegetable kingdoms, it seems that through them must be had our knowledge. Allusion has been already made to these. It may be well to investigate more closely the relation of the energy of light to them. No mode of measuring the energy of light in relation to animal life has been suggested, and yet its energy in this respect is more strikingly extraordinary than that of the other imponderables. Take one illustration only. When you knock at the door of a friend's bedroom and receive no answer, how loud, and louder still, becomes the rap ere he awakes. How often are stories told at the breakfast-table of night noises unheard and unheeded by those asleep. Let but a beam of sunlight, or even candle-light, shine on the closed eyelid, and by some mysterious energy on the well-covered retina the sleeper awakes.

The worlds of animal and vegetable life awake and work mainly in consequence of some such hitherto unmeasured energy of light as that now alluded to.

Turn to vegetable life. With respect to this, Professor Helmholtz remarks:—"Take a seed, then look at the tree, and consider from what source has been derived all the material of the tree. Burn the seed, burn the tree, whence comes the different amounts of heat? Chemistry tells us that the heat is produced from carbon, oxygen, and hydrogen; these are derived from carbonic acid and water. Plants cannot obtain these except under the influence of solar light." *

After plants have utilized the light it is not usable again for the same purpose. Take two screens of dark paper with holes in them—say half an inch in diameter—one hole covered with letter paper, the other covered with a green leaf; put pieces of photographic paper behind them, and expose to daylight or magnesium light. Beneath the letter paper is a dark spot—an image of the hole—beneath the leaf is no discolouration. The leaf has utilized the light; the letter-paper has not. The energy of that which passes through the leaf is spent, of that passing through the paper is not spent.

Although in plants a variety of operations take place, which must in some way unknown to us store up a large amount of energy, and although there is to all practical purposes no heat developed, yet we know well that there are thus stored up chemical tensions which give out their true physical value in heat and mechanical work, as the tissues of the plants are destroyed by a process of animal or other combustion. We are as yet quite at a loss to know how the plants do this, or by what elements in light, properly so called, it can be so completely and perfectly done.

Sir John F. W. Herschel, in a paper in the *Philosophical Transactions* for 1842, gives a most interesting account of an extended series of experiments on the action of the solar spectrum on vegetable colours. He operated upon the juices of the leaves, and also upon some of the resinous compounds of plants, and his conclusions have since been confirmed, viz., the action of the solar spectrum is confined to the visible region of it. The chemical or actinic rays act with chief energy upon silver or inorganic compounds, but are, for the most part, powerless upon vegetable colours; so also are the heat rays, or those below the extreme red. Thus Sir J. Herschel, in 1842, separated by a very broad line the luminous portion of the solar beam from the other parts of it. That the energy of the luminous portion of the solar beam is requisite ere plants can exercise their vital functions is well known to all who have made any of the experiments which show the extent to which, under the influence of that energy, plants can effect chemical changes. These changes take place most abundantly in the yellow, or in what our eyes would call the brightest portion of the spectrum.

The energy of this luminous portion may be gathered from experiments made during the last few years by an American. Flowering plants were placed in different colours of the spectrum, and it was soon observed that their action upon carbonic acid gas depended upon the colour of the spectrum. He took a flower, and under the action of a red ray he did not get one cubic inch of gas off, but only 0·33 of an inch. As soon as he submitted that same plant to the orange ray, he got 20 cubic inches, and from the yellow he got 36 inches. But when the same plant was put under green, blue, indigo, or violet, he could not get the plants to act at all in the purification of carbonic acid gas, thereby showing pretty clearly the energy of light in the luminous portion of the spectrum as regards growing plants.

The decomposition, then, of the carbonic acid is effected chiefly by the energy resident in what may be called the yellow rays. It is a somewhat noteworthy coincidence that the eye generally fixes upon the yellow portion of the spectrum as that possessed of the greatest brilliancy; it is also noteworthy that the spectroscope reveals *that* in the atmosphere (viz., sodium) which, on being burnt, always produces a yellow band. It is, to say the least, curious that we cannot get heat by combustion in the air without the production of this yellow light.

It seems, then, that plants and human eyes are most sensitive to the same portion of the solar beam, and this portion is in light properly so-called. May it not be that yellow light is most acceptable to the plant, and most impressive upon us, because carbon is in both cases involved—the retina of the eye being a carbonaceous compound. Had the retina been a salt of silver, the greatest brilliancy would perhaps have seemed to be in the blue rays. This identity in composition between the plant and that part of the animal on which light exercises its chief energy, suggests that in the influence of light on plants (whatever that may be) must be sought the data from which to

* Helmholtz, *Medical Times*, 30th April, 1864, p. 473.

deduce a mechanical rather than a chemical measure of the energy of true light.

The contrast of this energy in its effect upon the metal salts and plants is especially marked as regards time. On the metal salts it may be said to be instantaneous, but on the gums and resins of plants exposure for days and months to clear sunshine is needed to produce any marked action. A patient watching and building up on such scant data as may hitherto have accumulated, will, some day, produce the dynamical equivalent of light.

There is one experiment here which will probably bear out what has been said. You are probably aware that plants, by receiving light, manufacture what we name colour. They manufacture the green material out of which the leaves and the general character of the plant is formed, and that green material is called "chlorophyll." This vessel consists of two beakers with the bottoms cut off, one about an inch and a-half larger than the other. The glass cylinders then left are fixed with marine glue in a wooden ring. The space between them is filled with a solution of chlorophyll, obtained by steeping for forty-eight hours common parsley in any cheap spirit, such as methylated alcohol, and then filtering. It therefore contains the green colouring matter of leaves. This green colouring matter has been made almost exclusively by the yellow portion of light, and not at all by the chemical portion, and, with a view to show this, we must refer to the spectroscope view, namely, that chlorophyll being really manufactured by yellow light, is practically saturated with yellow, and can take up no more. Thus, if a vessel containing a saturated solution of salt had a piece of salt dropped into it, that piece would not dissolve. If, now, there be placed inside this chlorophyll solution anything that produces these other coloured rays, we shall probably find that, whilst sensitive to the one colour, the solution will not be to the other. Here is some lithium, which shall be placed on a little piece of platinum wire and burnt, so causing a beautiful red flame. On putting the flame within the hollow cylinder containing the chlorophyll, you will see the yellow beam alone can pass through the green solution. The green solution having been made with that yellow beam, is thoroughly saturated with it, and can take up no more, but it can take up the other coloured rays, and therefore they do not pass through. In that portion of the flame rising above the green solution, you see the red-coloured flame. Thus, the yellow colour is consequent upon the saturated solution of chlorophyll, and therefore nothing but yellow can come through. The absorption of this yellow portion of the solar spectrum, by the vital energy of the plant and utilizing the same in its composition, might have been inferentially suspected from the fact that leaves become yellow in the autumn, thus restoring in their death what, for want of a better term, we must call "the colour" they had absorbed in their life. The yellow colouring matter of the autmnal leaf is called "xanthophyll." Probably, as "chlorophyll" and "xanthophyll" are more examined and known, so the energy of light may be more appreciated and measured.

This examination of light, properly so-called, has led to another contribution towards an estimate of its energy. That plants grown in the dark are drawn to any crevice through which light enters has long been known. But it has not been so often observed that young plants bend the stems to the indigo portion of the spectrum, *i.e.*, if grown in red, or yellow, or green, they bend in one direction, but if in the violet, then in another direction. They recover the vertical position in darkness. May it not be that the energy in the indigo of the sky produces the vertical character of stem?

Thus light proper produces motion, and so assimilates itself to heat and electricity. The complementary colours of red and green (see the chromatic circle of Newton on diagram) are those which represent the relation of colour between the animal and vegetable kingdoms. Plants reject green and absorb its complementary (red). The blood of animals is red, therefore animals should have green supplied in the fields and in our furniture.

That this energy of light is utilized in vegetation, and that practically we recognize it, may be noted in the ingenious modes by which in our small gardens we try to imitate nature. The nailing of branches on walls—an advance on this in espaliers on lattice woodwork, and the still more recent practice of cutting out the inner branches of orchard apple trees; also training others to hang in umbrella fashion, or the splaying of gooseberry bushes as funnels, all these are devices to permit of the more universal exercise of this unmeasured energy of light.

Light influences the colour of animals and the plumage of birds in tropical climates. In the arctic regions polar bears are white, like vegetables grown out of the influence of light—arctic foxes are white in winter and brown in summer. Fishes inhabiting deep water chiefly are grey, or brown, or black; those living near the surface are of rich and various colours.

That the measurement of the energy of true light should be accomplished by an appeal to its influence on organized matter, and not on inorganic, is a testimony borne by all observations and even suggested by the records of Creation, the earth having been prepared by the creation of light for animal and vegetable life even before they were formed upon it. This measurement has not yet been made.

Parliamentary and Law Proceedings.

The Adulteration of Mustard.

On Wednesday, Dec. 24, Thomas Symth, druggist, 178, Islington, Liverpool, was summoned before Mr. Raffles, under the Pharmacy Act, 1868, and the Adulteration Act, for having sold as unadulterated a quantity of mustard which was adulterated.

Mr. Bremner appeared for the defendant.

Mr. Atkinson, deputy borough solicitor, said this was the first case of its kind, but it was one of some importance to the public. It was a serious thing for druggists to sell anything but pure mustard, as he was told that in many cases where it was prescribed by medical men for poulticing purposes death might ensue if the article was not pure. He, however, wished to say that he did not believe Mr. Smyth had been guilty of the smallest moral fraud, as the article which he had sold for mustard was, in fact, dearer than the genuine article.

Mr. Bremner: And less profitable.

Mr. Atkinson observed that had Mr. Smyth been a grocer he did not think Dr. Browne, the public analyst, would have issued a certificate, but, being a druggist, it was essential in the interests of the medical faculty and the public that the druggists should regard mustard as a drug, unless they stated that it was a condiment. On this occasion the mustard supplied was a very wholesome mixture, and contained a species of farina.

Mr. Raffles: But you mean to say it is wanting in medicinal qualities?

Mr. Atkinson: That is so; as a drug the article is adulterated.

Mr. Bremner: Then the purchaser should ask if it is pure.

Mr. Atkinson said that so satisfied were the prosecution there was no fraud, that he would take the unusual course of asking for only a small penalty.

Mr. Bremner asked that the summons might be withdrawn, as the case would in future be a warning both to the public and the druggists.

John Fitzpatrick, nuisance inspector, proved the purchase of the mustard analysed. The defendant made up the packet in his presence, but put no label on.

Mr. Bremner: Did you ask for mustard only?

Witness: Yes.

Mr. Bremner: Did you say you wanted it for medicinal purposes?

Witness: No; I said nothing about it, but merely asked for mustard.

In answer to a further query, witness said he believed there were four sorts of mustard.

Dr. Browne said he had analysed the mustard purchased by the last witness. He found it adulterated with wheat flour. In the British Pharmacopœia mustard was a drug, and was directed to be made from the seeds of *Sinapis nigra* and *Sinapis alba*, and to be free from farina. If not pure its medicinal effects were lessened.

Mr. Bremner, on the defendant's behalf, did not complain of the summons having been issued, as probably it was advisable that such a summons should be taken out against some druggist for the purpose of raising the question, and also for the purpose of bringing before the public the position in which druggists were under the Act. Persons, no doubt, went to druggists, as such, to buy drugs, but it was a notorious fact that in addition to drugs many druggists sold articles which were in themselves articles of food. He thought that a public officer, when about to perform a public duty, should ask for what he wanted, and not ask a question which certainly bore a double interpretation. If the officer had asked for a pure article to be used as a drug, he would have obtained it.

Mr. Atkinson observed if that had been done, the object of the inspection would have been defeated. They must ask the question in the same terms as would probably be employed by a poor woman who wanted it for a sick child.

Mr. Bremner said that would be just the case in which pure mustard would be asked for.

Mr. Raffles did not think everybody ought to ask for mustard for medicinal purposes when they required it for that purpose, but at the same time thought that when a person went into a druggist's shop and asked for mustard, he was bound to have the pure article. The case was made out, but it was not one where he should inflict a large penalty. The defendant was then fined 5*s.* and costs. —*Liverpool Mercury.*

Notes and Queries.

[379.] DEVONSHIRE OILS.—The following is a receipt frequently used as Pyne's Devonshire Oils in Somerset and Devon :—

M. S. A.

W. Wilkinson, *Manchester.*

[381.] MEDECIN DE LEROY.—Having noticed in last week's Journal an inquiry from Mr. Fingland respecting the composition of "Médecin du Roi," I think with you that he is mistaken in the name, for I have inquired of several pharmaciens here, and they none of them know it. The "Médecin," or as it is more frequently called, "Purgatif de Leroy," of which you have given Dorvault's formula, is frequently sold here and is a very popular purgative.—Atterton Crundall, *Brussels.*

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer ; not necessarily for publication, but as a guarantee of good faith.*

Voluntary Assessment for the Benevolent Fund.

Sir,—I have read Mr. Barclay's letter in the Journal, wherein he proposes a Voluntary Assessment Benevolent Fund, to be set in force by each member and associate of the society making a voluntary payment of 4*s.* and 2*s.* respectively over and above their annual subscription to the Society.

As relief from the Benevolent Fund is open to all alike, I think a scheme in which all unite would be preferable. I therefore suggest a voluntary assessment on the yearly returns of his business by each member of the trade of, say, 1*s.* on every £100 above £300 per annum. By this means I think a very large return would be added to the fund, and each one would be giving as Providence had blessed him.

I think some such scheme as this should meet with favour throughout the trade.

J. K.

Sir,—Some months since you were kind enough to insert a few remarks from me on the desirability of some *unusual* effort being made towards increasing the Benevolent Fund.

The subject, however, seemed too little exciting apparently to attract any attention or awaken any interest at that time.

It has therefore been with feelings of pleasure that I have read the remarks of Mr. Rimmington and others, and am now hopeful that some plan may be adopted.

It is quite useless these letters appearing at detached intervals of time—what we want is decided action of some sort at once.

Were Members or Associates of the Society alone eligible as recipients of relief, there would be no objection, perhaps, to Mr. Barclay's proposal, but if all Registered Chemists and their widows have an equal claim upon the fund, then I consider the method proposed as a very unfair one, and think it will be obvious that the plan previously suggested of an appeal in each city and town, to the members of the trade individually, is the one which should commend itself as the most fair and most reasonable.

One Who Has Known the Drug Trade More Than Thirty Years.

Salt of Sorrel.

Sir,—The 17th section of the Pharmacy Act says : "It shall be unlawful to sell *any* poison, either by wholesale or by retail, unless the box, bottle, vessel, wrapper, or cover in which such poison is contained be distinctly labelled with the name of the article, and the word poison, and with the name and address of the seller of the poison."

Now in this town almost every grocer sells "salt of sorrel," which all druggists (and even the public) know is a poison, and which they can do with impunity, without either name or address, and with great danger to the lives of the subject, because it is not included in the schedules of the poison list.

Surely the list of poisons requires an "over-haul" when this greatly used article is left out.

I also think a few alterations would not come amiss in the list ; for instance, we can sell gallons of laudanum and sol. muriate of morphia by merely putting on a label marked with the name of the article, the word poison, and the name and address of the seller, whereas if we sell six grains of muriate of morphia, we require to put in the poison-book the name and address of the purchaser, purpose for which it is required, etc. Why there should be any difference in the selling of the above, and some other things in the list that I could quote, I really do not know, as the one will kill as well as the other.

H. F.

Helensburgh, N.B., 22nd Dec., 1873.

Test your Opium.

Sir,—Travellers tales are proverbially subject to discount. I have recently discounted two which it may be advantageous to the trade to have repeated.

A month or two ago a pharmacist with whom I had not previously had any dealings led me to believe that he held a few chests of fine Turkey opium, which he could supply at some shillings a pound less than quoted in the wholesale lists, and thus induced me to buy.

A few days afterwards another traveller called, and without any mention of my purchase he quoted opium, and mentioned incidentally that Messrs. Ferris of Bristol, and Messrs. Southall of Birmingham had both recently bought good-looking opium which they found was not fit for medicinal use, and he did not know what had become of the drug which they rejected.

As I said before, I discounted both these stories, but as I habitually test all my opium there was no fear of a bad parcel escaping detection. When the parcel came under examination, I found it was part rough and part smooth, and I thought it a point worth determining whether they were good and bad mixed together to get the bad off hand. (I need hardly mention that I did not obtain the opium from either of the firms mentioned.)

I was surprised to find that *both kinds were bad*, the yield of morphia being *about* 3 *per cent.*, there being a portion of colouring matter which was more than usually difficult to separate.

The opium was of course returned to the pharmacist from whom it came, and the analysis was entered in my notebook, with a memorandum that the dealer was very unwilling to take the parcel back, and thus the matter was gradually passing out of mind till, on receipt of this week's Journal, I find two of the partners in the firm of Ferris and Co. giving their experience of bad opium at a meeting in Bristol, Mr. Townsend saying that he found less than 3 per cent., and Mr. Boucher having found less than 2 per cent. They describe the sample as having a very good appearance, and the discrepancy between their statements agrees with my difficulty in obtaining the precipitate in a condition in which it could legitimately be called morphia. The results of four determinations gave me—

Smooth Opium:

A . . . . . 3·5.
B . . . . . 3.3.

Rough Opium:

A . . . . . 4·0.
B . . . . . 4·1.

But all these contained so much colouring matter, that I estimate the morphia as being under 3 per cent. in each case.

One remarkable feature in this sample of opium, supposing Messrs. Ferris's to be the same as my own, is the great increase in value between the time it left their hands and came into mine.

To them it was quoted 8*s.*, against a market price of 21*s.*, to me it was quoted 24*s.*, market price being 30*s.*

From these two tales let us draw two morals; first, *always test your opium;* second, *never deal with a firm who will hesitate to take back an unsatisfactory article.*

BARNARD S. PROCTOR.

Grey Street, Newcastle, Dec. 26th, 1873.

A Psychological Curiosity.

Sir,—On Sunday last I was disturbed in my afternoon's nap by the following prescription being brought to me to dispense:—

℞

Potass Bicarb. . . . . ℥ iv.
Spir. Æther. Nit.
Syr. Tolu āā . . . . . ℥ iij.
Mist. Camp. . . . . ad ℨ xii.

M.ft. Mist. Take a 12th part every four hours with equal parts of the Acid Mixture—

℞

Acid. Citric. . . . . ℥ iiss.
Aquæ . . . . . ℨ xii.

M. "The Acid Mixture."

When in reply to my customer's question, How much? I answered—five shillings, he stared at me. You can imagine my staring at him in return when he said: "I have the same prescription made up by my medical attendant in the country for *one shilling!*" Convince him it must have been a mistake I could not, as he could show me the bill, etc., and he evidently left with the idea that I was a "rogue," or that his doctor was a "fool."

I might say that half-a-crown is the recognized charge for a twelve-ounce mixture at the West-End; and, although comparisons are odious, why should Sir William Gull charge two guineas for a consultation when a country doctor might only charge two shillings?

Is there no remedy? Can the Pharmaceutical Society do nothing to put a stop to this evil which corrupts the pounds, shillings, and pence of the pharmaceutical chemist?

I enclose my name and address, and beg to subscribe myself.

A. A. A.

Chemists' Assistants' Association.

Sir,—In addition to a Chemists' Assistants' Association, I would propose that a sort of club be formed for the readers of daily papers, and for amusements.

It would, I believe, prove a great boon to many young men of our profession, as it would be the means to a great extent of keeping them from public houses, music halls, and other popular places of resort, all of which we are fully aware have an evil tendency. An association of the kind proposed is becoming more and more necessary every day. I would therefore strongly urge my fellow assistants, for their own benefit, to form one at once, and not allow the project to be nipped in the bud, as has been the case previously.

We have only to look through the list of advertisements in our Journal to form a correct idea of the paltry salaries that are from time to time offered to qualified men; for instance, such as the undermentioned appeared only a short time ago:—

In town; a gentlemanly assistant of good address and obliging manners; must be neat, etc.; produce unexceptional references as to ability and character. Age from 22 to 30. Enormous salary of £40.

All I can say is that we have it in our own hands if we but unite together. Examinations must be passed to qualify us as pharmaceutical chemists; and then our position demands more remuneration for the care and trouble we are expected to exercise to our employers, setting aside the long hours that we have to devote behind the counter.

At present, as regards salaries, our positions are no better than the common labouring man or policeman, if so good. They, I am informed, earn on an average 30*s.* per week, and, in many instances, are only expected to do eight hours' work a day.

Let me, before concluding, remind my fellow-assistants of the old motto, which they no doubt have so often heard:

"Unity is Strength."

TRUTH.

Homœopathic Concentrated Poisons.—We beg to acknowledge the receipt of letters on this subject from Dr. George Johnson and other Correspondents, and regret that we are compelled to postpone their publication until next week.

"*Excelsior.*"—The new bye-law (section 10, clause 16), as approved by the Privy Council, says, "After the 31st day of December, 1874, no person shall be admitted to the Major or Minor examination who shall not have attained the full age of twenty-one years." (2) It would probably prove sufficient, but in studying any subject it is advisable if possible, to consult the works of more than one author. (3) Ganot's 'Physics,' translated by Atkinson, or Deschanel's 'Natural Philosophy,' translated by Everett.

T. Gresty.—The Pharmaceutical Journal would be supplied weekly, post free, for about 5*s.* per quarter by the publishers, Messrs. Churchill, or might be obtained through any bookseller. Members of the Pharmaceutical Society are entitled to it, free of charge. Particulars respecting applications for membership may be had by applying to the Secretary, Mr. Bremridge, 17, Bloomsbury Square.

Hydrocyanic Acid in Coloured Bottles.—We have received a communication from Mr. Ashton supporting Mr. Stoddart's condemnation of blue glass bottles for holding hydrocyanic acid, and saying that yellow glass would be the best as it interrupts all the chemical rays of light.

Communications, Letters, etc., have been received from Messrs. Place, Brown, Abraham, Howard, Ashton, Freeland W. H. Smith, Inquirer.

THE MEDICINAL EXHIBITION OF PHOSPHORUS.

BY A. C. ABRAHAM.

In the PHARMACEUTICAL JOURNAL of December 6th appeared an article by Mr. Gerrard, in which he recommended a method for combining phosphorus with resin for the above purpose.

The process involves the application of a strong heat under circumstances extremely inconvenient and dangerous to the operator, and calculated to deteriorate the product by the oxidation of the phosphorus, and by its conversion into the amorphous form.

To obviate these disadvantages I would propose to use some resin fusible below the boiling-point of water, and also sufficiently heavy to sink in that liquid. Balsam of tolu will be found to answer both these requirements, and by its use the combination can be effected entirely under water. Experiment has shown that four grains of phosphorus are perfectly dissolved by 96 grains of washed tolu, if melted together under water and well stirred.

The preparation so made, when examined microscopically, does not show any particles of undissolved phosphorus, and when seen in the dark and rubbed between the fingers, it gives off a perfectly *equally distributed* light.

This preparation may, therefore, be formed into pills, with every confidence in the equal distribution and activity of the phosphorus.

Liverpool.

THE MICROSCOPE IN PHARMACY.*

BY HENRY POCKLINGTON.

(Continued from Vol. III., p. 992).

EUCALYPTUS GLOBULUS (*Continued*).

The colouring matters of the leaves of the Eucalyptus, although somewhat complicated, are by no means so numerous, or so complex and varied in their distribution in the leaves at different seasons as in many other plants, notably in the Cinchonas. The three chlorophylls (for definition of these terms I must refer the reader to my *résumé* of Mr. Sorby's researches, published in No. 182 of this Journal) are represented, but in quite different proportions. In freshly gathered leaves blue chlorophyll and chloro-fucine are in much greater proportion than in the dried leaves in which the blue chlorophyll appears to be deoxidized into quite another substance, of which the relations are not at present known to me. The chloro-fucine also partially disappears from the dried leaves by changing into a peculiarly yellow amber-coloured substance, much resembling one of the chromules of the bark. The yellow chlorophyll appears to remain unchanged. Of the xanthophylls little can be said. Orange xanthophyll appears to predominate, but nothing approaching an accurate estimation of their† relative proportions can at present be made. The colours of the erythrophyll group do not appear to be present in either the fresh or dried leaves, neither have I succeeded in producing them artificially. Various modifications of the chrysotannic series may be detected by carefully removing as much as possible the other colouring matters from an ethereal solution; they appear to be products of a substance very similar to pyrocatechin in many of its reactions, and susceptible of very various colour changes under the action of oxidizing or reducing agents and of nascent hydrogen, but as to how far the presence with it of a small residuum of blue chlorophyll is essential to the production of these changes I am not at present in a position to say. The other colouring matters present are in small proportion, and so intimately united with those named that their isolation is not, I think, possible, even in an approximately pure condition.

Of the colouring matters of the bark I much prefer saying very little beyond this, that yellow chlorophyll and an unnamed yellow substance are the more important. Many months of careful observation will be necessary before much can be affirmed of the modification the colouring matters of the leaves undergo, before they find their way, as some of them apparently do, to the bark, and what I have hitherto been able to learn will form the subject of a separate notice of the colouring matters of the leaves and bark of *Cinchona succirubra*.

CINCHONÆ CORTEX.—The barks of the cinchonæ now alone remain unnoticed in these articles, and should long occupy us, but Mr. Howard has so thoroughly worked out the subject, that on looking over my own notes I find there is absolutely nothing to say that he has not already said, with the advantage of accurate woodcuts. For the benefit of those who have not access to Mr. Howard's magnificent microscopical illustrations of Pavon's work, or even his various contributions to this Journal, it may perhaps be worth while to give a general outline of the structure of the three barks most commonly met with, and a note or two as to their preparation for microscopical observation.

The red and yellow barks are frequently very difficult of examination, on account of the toughness and distribution of their liber; but good sections may be cut with moderate ease if a small piece of the bark be soaked for a few hours in a strong solution of gelatine, kept just warm enough to be fluid. The gelatine may be removed from the section by immersing them in warm water, or may be allowed to mix with the glycerine or gelatine medium, if these be used. Tolerably good sections may also be cut if the bark be kept in a damp place for a few days, and these are better adapted for examination when it is desired to study the various cell contents than those obtained from a macerated specimen.

Cinchonæ Rubræ Cortex.—The structure of this bark varies very considerably in different specimens, especially, as Mr. Howard has shown, in those of the renewed growth, after previous barking; but the prominent characteristics are numerous well formed and very tough liber cells, in the midst of a very varied parenchymatous series. Occasionally, but in my experience very rarely, spiral or pitted cells may be met with in the middle layers, and various somewhat unusual modifications of the ordinary type of bark structure. These are probably in part occasioned by accidental causes, but may be to some extent characteristic of the plant.

As Mr. Howard has shown, if sections of the bark be boiled for a very short time in solution of caustic potash, and examined under a moderate power of the microscope, numerous crystals may be seen, chiefly distributed in the middle and inner

* I much regret that the continuation of these papers has, from causes beyond my control, been so long delayed.

† The difficulty experienced in procuring an adequate supply of perfectly fresh leaves is a serious obstacle in carrying out these analyses. My thanks are due to Mr. G. W. Fox, of Penjerrick, Falmouth, for the leaves I have examined in a fresh state.

portions of the bark, and Mr. Howard considers these to be undoubted crystals of the alkaloids of the bark. That the crystals may be seen does not admit of a doubt. I have always found them in suitable sections when I have followed his plan of preparing the specimens, but that they are natural crystals of the alkaloids is quite another matter. Very careful examination of the position of the crystals in the cells of my own preparation, and in Mr. West's admirable drawings, lead me to question whether they are not, after all, chiefly due to the reagent employed. I have produced very similar crystals in sections of some other plants, especially of the common garden mint, and I have always referred them to the action of the potash upon some of the active principles of the plant—one of its colour elements, in fact. There is also this to be said, that although very careful examination of various portions of living plants of *C. succirubra* sent me by Mr. Howard shows exceedingly minute crystalline bodies in the cells near the vascular system (in the petioles and stem most abundantly), which are often aggregated by albuminous matters into pseudo-sphœraphides, are very refractive, intensely doubly refractive, and soluble in ether and in dilute sulphuric acid, it is not possible to produce the crystals figured by Mr. Howard in these cells, or, without very great difficulty, in the cells of the living plant at all. On the other hand the position of the crystals as regards the nature of the tissues in which they are most abundant, supports Mr. Howard's view, and his well-known accuracy and familiarity with this subject cause me to express my non-agreement with his conclusion with considerable hesitation. Unfortunately, it is difficult to apply any very crucial test to them whilst they are under observation.

The amorphous alkaloids, described by Mr. Howard, I have repeatedly observed in the barks of commerce, and most abundantly mixed with proteinaceous and other substances in the petiole and young stem of the living plants. These amorphous alkaloids differ much in their position in the plant from most other cell contents. Crystallized substances, resins, and oils are usually contained in special cells, associated more or less intimately with the fibro-vascular system, but these are found only in semi-specialised cells in the parenchymatous tissues, and are, I think, transitional, undergoing modifications as the growth of the plant advances. They are very numerous in the medulla of the petiole, and in the medulla of the growing shoot, but appear much more sparsely distributed in the medulla of the more mature stem, and are there chiefly confined to the sap-containing cells of the subcortical layers.

The outer corky layers of the bark vary little from the usual type of these layers, the parenchyma within them is composed of rather large, irregularly shaped cells, containing various granular substances and cinchona-red mixed with other colouring matters, a little starch, members of the tannin group chiefly localized near the liber and the boundary of the various years growths, and, in semi-special cells, the amorphous alkaloids just named. The liber cells are distributed somewhat irregularly in the liber zone, are long, much consolidated, have successive deposits of hardening matter, easily seen by aid of a high power, and are curiously transversely marked, and somewhat furrowed at times longitudinally. All these characteristics are subject to endless variations.

Cinchonæ Flavæ Cortex—The differences between the structure of this bark and the structure of *C. rubræ cortex* are chiefly differences of degree rather than of kind, and can only be made clear by aid of numerous and accurate drawings. The bark is rather easier of examination, as there is little need for the removal of the colouring matter, which in the case of the red bark renders accurate observation a matter of difficulty. The toughness of the liber and its feeble adhesion to the surrounding tissues are, however, more troublesome than in the other bark, and somewhat longer maceration is needful to enable us to procure good sections.

Cinchonæ Palidæ Cortex.—The above remarks apply with somewhat less force to this bark, the structure of which may be regarded as a small and revised edition of the red bark without its colouring matters. Those who wish to make themselves fully acquainted with the microscopical characteristics of these, as of the other barks, will derive far more benefit from the careful examination of specimens, and the "illustrations," than from bare text descriptions of their structure. I therefore pass to notice rapidly the structure of the few woods of pharmacy.

COMBINATION OF LIME AND GLYCERINE AND ITS PHARMACEUTICAL APPLICATIONS.*

BY P. CARLES.

The recent publication of a note upon this subject† has induced the author to put on record some experiments, the results of which were communicated orally to the Paris Société d'Emulation pour les Sciences Pharmaceutiques in 1871, but have not hitherto been published.

When distilled water is shaken with lime under normal circumstances it only dissolves 1·251 grams per litre; but this proportion is, however, singularly increased by the intervention of neutral bodies, such as the sugars. That glycerine also acts in the same manner was noticed by the author, and gave rise to the following experiments:—

Into a series of flasks of similar capacity were placed constant quantities of 100 grams of distilled water and 20 grams of pure lime, together with varying proportions of glycerine, 0, 50, 100, 200, 400, etc. The flasks were labelled, 1, 2, 3, 4, 5. After agitation of the mixture for some time at a temperature of 18° C. the quantity of lime passed into solution was estimated alkalimetrically, and found to be—

No. 1	1·251
„ 2	1·865
„ 3	2·583
„ 4	4·040
„ 5	6·569

Now if each of these numbers be reduced by 1·251, the coefficient of the solubility of lime in water, it will be found that an addition of 50 parts of glycerine to 1000 of water augments by nearly one-half the solubility of the lime, and that this solubility is doubled by the addition of 100 parts of glycerine per litre. If the proportion of glycerine be raised beyond 200 parts the quantity of lime dissolved is still sensibly increased, but starting from

* *Bulletin de la Société de Pharmacie de Bordeaux*, vol. xiii., p. 294.

† PHARM. JOURN. [3], vol. iv., p. 321.

that figure it is in proportion irregularly inverse to the quantity of glycerine added. It is the author's opinion that the combination of glycerine with lime, which is a true combination very soluble in water, is on the contrary slightly soluble in glycerine itself. Commencing at experiment 5, it communicated to the liquor a latescence more and more opaque, and whilst the undissolved lime was precipitated rapidly or remained upon the filter, the glycero-calcic compound remained for a long time in suspension, or even passed through the paper. In short, the glycerinate of lime is formed in larger proportion as the quantity of glycerine is increased, but being less soluble in the latter than in water remains in suspension.

These solutions appear to the author to be susceptible of the following applications :—

(1) In a chemical point of view, since they remain unaltered during a long time, they might advantageously replace as alkaline liquors the changeable solutions of saccharated lime.

(2) Pharmaceutically, it would allow of the simplification of the preparation of the lime liniment, and yield a superior product. The Codex orders one part of oil of almonds, and nine parts of lime water, to be agitated together, and the separation of the soap which floats on the top. If, in the place of ordinary lime water, equal parts of almond oil and of lime water containing 10 per cent. of glycerine are simply agitated together, a consistent calcareous soap is produced, which, even after several weeks, loses none of its consistence or homogeneity.

(3) Considered therapeutically, the addition of the glycerine, which besides is produced in small quantity in the ordinary process, appears to constitute an excellent adjuvant.

SAFFRON GROWING IN FRANCE.*

The production of saffron is considerable in France, but it is confined to three departments, of which Loiret produces the largest amount and of the best quality. It is a peculiar industry, and little known even in France.

A saffron field is not in full bearing till the end of the second year, and at the end of three years it is exhausted, and, according to the local proverb, the land is then so poisoned that it cannot be used for the same purpose for fifteen or sixteen years more. The average crop of the second and third year is various, from ten to thirty kilogrammes per hectare, or from 9 to 27 lbs. per acre, of dry pistils ; each acre produces about six to seven hundred thousand bulbs, and each bulb two or three flowers. About 30,000 flowers are required to produce two pounds of fresh pistils, which when dried are reduced to one-fifth of that weight ; the pistils are the only productive portion of the flower, the rest is waste.

The labour of picking such enormous quantities of flowers by hand is great, and when the crop is large and labourers scarce, the flowers are carried into the villages and small towns round about, to be picked by women and children at home. In such cases all the world is busy saffron picking ; artisans, shopkeepers, gentlemen, and ladies all assist in the work, the poor working for their own profit, the rich for the benefit of the necessitous. The farmer has to pay from about 10*d.* to 4*s.* a pound for the picking, according to the abundance of the crop.

When the pistils are separated they have to be dried, and this operation is effected by placing about a pound of fresh pistils at a time in a horsehair sieve suspended over a little charcoal furnace. As soon as it is dry the saffron is ready for sale. Commercial travellers generally buy up the saffron, which goes by the name of the most famous district, Gâtincus, principally for Germany, where it is said to be mixed with Spanish saffron and re-sold as a German product.

Saffron requires a peculiar soil, and the land which suits it is worth three to four pounds per acre, or double the rent of ordinary land in the same district ; but the saffron itself sells, on an average, for thirty shillings to two pounds per lb., and when very fine for double those rates ; in very extraordinary years, which, however, occur only once or twice in a century, saffron is worth as much as £8 per lb. Altogether it is an interesting example of agricultural industry.

A REVOLUTION IN THE MANUFACTURE OF CARBONATE OF SODA.*

BY DR. RUDOLPH WAGNER.

Six years ago, when the international jury at the Paris Exposition expressed their opinion upon the state of the soda industry at that time, all the judges, whether practical or theoretical men, believed that Leblanc's process would hold the field for a long time yet. This seemed still more probable since a process had just been introduced for recovering the sulphur from the soda residues. At that time all the soda in use was prepared by this process, excepting a comparatively small amount obtained from Chili saltpetre and cryolite, although there were already tangible indications that soda could be made on a large scale by another method which would be cheaper than Leblanc's process.

The chemical section of the international jury at the Vienna Exposition, under the presidency of Professor A. W. Hofmann, constituted a congress of chemical technology. By its labours during the course of the summer this congress of scientific men was able to authenticate the very important fact that although Leblanc's process might in the future possess some importance for certain branches of the industry, yet in most places another soda process would be introduced in the immediate future, and entirely supersede that of Leblanc. Since the time of the Paris Exposition this new process has grown from a small germ to a strong tree.

The process in question, and which is called by Professor A. W. Hofmann the ammonia process, is not new from either a chemical or scientific point of view. It belongs to the same class of methods as those in which oxide of lead, bicarbonate of magnesia, quick lime, alumina, silicate of alumina, oxide of chromium or fluosilic acid are employed to decompose chloride of sodium and convert it directly into soda or its carbonate. None of these attempts met with a success deserving of notice, although for a century past efforts have been made to render them practically operative. The new process is founded upon a reaction noticed over thirty years ago—that of bicarbonate of ammonia upon a strong solution of common salt. The greater part of the sodium is precipitated as a bicarbonate, while chloride of ammonium remains in solution, from which the ammonia for a second operation is expelled by quick lime. The carbonic acid necessary to convert the ammonia into bicarbonate of ammonia, and thus make the process a continuous one, is obtained by heating the bicarbonate of soda to convert it into the simple carbonate.

The sensation which the ammonia process has created in industrial circles will render a brief history of its development not uninteresting.

So far as I know, Harrison, Dyer, Grey and Hemming were the first to patent the ammonia process in Great Britain in 1838. "Great expectations" were excited by it, but it soon sank into oblivion. Thirty or forty years ago the manufacture of soda was by no means at the head of the great branches of industry ; at that time, too, ammonia was not to be had cheaply and in immense

* From the *Journal of Applied Chemistry.*

quantities, and that branch of machine building which has furnished the necessary apparatus for chemical industries did not exist. Besides this, Anthon, of Prague, in 1840, claimed to have proved that in the ammonia process a very considerable portion of the common salt remained undecomposed.

After a sleep of sixteen years the ammonia process again entered the field. On the 26th of May, 1854, Turck took out a patent in France, and on the 21st of June, the same year, Schlœsing, chemist of the Imperial tobacco factory at Paris, took out a patent for France and Great Britain. The mechanical portion and machinery for Schlœsing's process were designed by Engineer E. Rolland, director of the tobacco factory. In 1855 a company was organized to work this process. An experimental manufactory was started at Puteaux, near Paris, but owing to its situation and arrangements as well as to the salt monopoly, it could not produce soda cheap enough to compete with the other process, and hence, in 1858, the experiment was abandoned. Schlœsing and Rolland were of the opinion that sooner or later the new process must come into use in making soda.

It must here be noticed that in 1858 Professor Heeren, of Hanover, subjected the ammonia process to a very careful test in his laboratory. From his experiments and calculations it was ascertained that this process was better adapted to the manufacture of bicarbonate than of the simple protocarbonate of soda.

To render this sketch more complete and historically true, it must be mentioned that T. Bell, of England, took out a patent October 13, 1857, for a new soda process, which in principle and practice was almost literally the same as that of Dyer.

It was known when the jury was working at Paris in 1867, that essential improvements had been introduced into the ammonia process by the efforts of Margueritte and de Sourdeval, of Paris, and James Young, of Glasgow. A more important fact, however, is that Solvay and Co., of Conillet, in Belgium, actually exhibited at the Paris Exposition carbonate of soda prepared by this new process.

Since that time the ammonia process has been developed and perfected to such an extent, especially by Solvay, Honigmann, and Gerstenhœfer, that as early as February, 1873, Professor A. W. Hofmann, in his introduction to the third group of the catalogue of the Exhibition of the German Empire, was able to make this remark: "At all events, the ammonia process is the only one which threatens to become an important competitor of the now almost exclusively employed process of Leblanc." The Vienna Exposition has since proved the truth of his assertion.

There are now large soda works in England, Hungary, Switzerland, Westphalia, Thuringia and Baden which employ the improved ammonia process, and some of them make fifteen tons of soda per day.

The advantages of the new process over that of Leblanc are very evident, although the details of the process have not yet been made public. The chief advantage consists in the direct conversion of salt into carbonate of soda, and next in the fact that from a saturated brine only the sodium is precipitated, with none of the other metals of the mother liquor. Beside this, the product is absolutely free from all sulphur compounds, the soda is of a high grade, the apparatus and utensils are very simple, there is a great saving of labour and fuel, and no noxious gases and waste products are produced, which is of importance from a sanitary point of view. The only weak point of the ammonia process is the loss of the chlorine, which is converted into worthless chloride of calcium.

The effect which the general introduction of the new soda process will exert upon large chemical industries in general, and especially upon the consumption of sulphur, the manufacture of sulphuric acid, and the price of muriatic acid and chloride of lime, cannot be overlooked.

RELATIONS OF PLANTS AND ANIMALS TO INORGANIC MATTER, AND ON THE INTERACTION OF THE VITAL AND PHYSICAL FORCES.*

(*Concluded from p.* 516).

BY J. BELL PETTIGREW, M.D., F.R.S., ETC.

In making these statements regarding the non-identity of protoplasm, bioplasm, and the several parts of the germ, seed, or egg, I do not mean to affirm that all the tissues enumerated are contained in the original germ, seed, or egg. Only this: that the original germ, seed, or egg is differentiated sufficiently to inaugurate the first series of changes, and that these inaugurate others in constant and rapid succession, until the plant or animal is completed. The first series of changes provides the materials and forces for the second, the second for the third, and so on, according to the degree of differentiation required in each particular organism. It is initial force and matter that are primarily required. Granted this, development in specific directions proceeds as a matter of course.

Chemistry and physics are not the whole of physiology. These sciences can conjure up an automaton, but are absolutely powerless when an ovum is desired. Dumas, a leading authority in modern chemistry, thus limits its province:—"The chemist has never manufactured anything which, near or distant, was susceptible even of the appearance of life. Everything he has made in his laboratory belongs to 'brut' matter; as soon as he approaches life and organization he is powerless." "Organized matter, not capable of being crystallized, but destructible by heat, the only matter which lives or has ever lived—this matter, a subordinating agent of the vegetating power in plants, of the motion and sensation of animals, cannot be produced by chemistry; heat does not give birth to it; light continues to engender it under the influence of living bodies."†

The pretensions of the physicist may be disposed of even more cavalierly.

No machine hitherto devised by human ingenuity at all resembles or can at all compare in efficiency with a living organism when the consumption of material and the amount of work done are taken as the standard of comparison. A man is as far in advance of a steam-engine in this respect as day and light are of night and darkness.‡ If, then, neither the chemist nor physicist, nor both combined, can produce a living organism, or anything even remotely resembling it, we are forced to fall back upon other than the chemical and physical forces, and the only ones we can under the circumstances fall back upon are the vital ones.

Life, there is every reason to believe, is an heirloom bequeathed from parent to offspring—a something superadded to dead matter; and motion in matter devoid of life is an emanation of force from the store of energy residing in the universe. Life, energy, and matter are equally distinct. Matter may be inert, or it may move under the influence of force, physical or vital. The physical and vital forces, however, are not to be confounded. An automaton is not an animal. While the vital and physical forces are independent, they are nevertheless correlated—*i.e.*, the vital forces work in the same direction, and through the physical ones. A living organism builds itself up in accordance with natural laws, and avails itself equally of inorganic matter and physical force. The life supplies only part of the matter and force employed in building up an organism. The life, for example, appropriates and assimilates matter, but in doing this it does not necessarily interfere with capillarity, chemical affinity, gravitation, osmosis or any of those influences or

* An Introductory Lecture to a Course of Physiology. Reprinted from the *Lancet*, Nov. 15.

† Faraday Lecture.

‡ Rumford long ago showed that a much greater quantity of work could be performed by a horse than could be performed by its food when employed as fuel in a steam-engine.

forces which regulate the distribution of matter in time and space. On the contrary, these are the instruments by which it makes itself known and felt. While living matter may and must be contra-distinguished from dead matter, there is no antagonism between them. What lives now dies hereafter, and the dead particles of a disorganized animal and plant may be, and frequently are, resuscitated. This arrangement equally adapts the organic world for the inorganic, and the converse. A living organism is incessantly taking in new and giving off old particles; it is a mysterious highway, along which innumerable organic and inorganic atoms pass in the economy of an individual and in the natural order of events. Hitherto physiologists have been divided into two great classes—the vitalists and physicists. There is reason to believe that neither are wholly in the right, and that the truth lies between the two. It is illogical to infer with Beale that the vital forces are independent of, and altogether opposed to, the physical forces. It is equally illogical to assume with Tyndall that the physical are the only forces in the universe. If the vital forces act upon inorganic matter (and this is admitted), they cannot destroy the forces which actuate that matter as such. This follows because force, like matter, is indestructible. The vital forces transform matter, but do not destroy it. In like manner they modify, but do not destroy, the physical forces with which that matter is indissolubly associated. That the physical forces are not the only ones is evident from this,—that they cannot of themselves, or in the hands of the most expert physicists, produce a living organism.

The vitalists are for the most part panspermists—*i.e.*, they believe that everything that lives is produced from a parent by a germ, seed, or egg.

The physicists, on the contrary, are as a rule heterogenists—*i.e.*, they are of opinion that matter can assume life in the absence of a parent.

The doctrines of panspermism and heterogeny will be most conveniently discussed together.

Heterogeny, otherwise known as "spontaneous generation," is an old doctrine, supposed to have been scientifically interred once and for all by Pasteur. Pouchet, Pentigazzi, Schaffhausen, Bennett, Bastian, Sanderson, and others, however, have of late been busily engaged in exhuming it. Pasteur, as many of you are aware, showed that if certain infusions were placed in flasks having long-drawn-out and bent but unsealed necks, and boiled, they could, if the necks remained intact, be kept for indefinite periods without producing organisms; but if the necks were broken off short and the atmosphere freely admitted, organisms appeared within a few days from the time the necks were broken. This was considered by the panspermists conclusive proof that the air contained germs, and that the organisms which appeared in the infusions within the flasks when the necks were broken off were due, not to spontaneous generation, but to development from pre-existing germs. The heterogenists, while admitting this to be the truth, deny that it is the whole truth. In other words, they give to Pasteur's experiments a different interpretation to that given to them by himself. They affirm that if other and more concentrated solutions than those used by Pasteur be employed, diametrically opposite results to those obtained by him may be produced; and that, in fact, the production of organisms and the peculiar character of the organisms produced is due, *not to germs* conveyed into them by the air, but to the nature of the infusions and organic solutions themselves.*

Pouchet, *e.g.*, states that when three vessels severally charged with urine, cider, and a mixture of both, are exposed side by side, three distinct kinds of organisms are obtained, but that which occurs in the mixed fluid is a hybrid between the other two, deriving its mongrel qualities, *clearly not from the air*, but from the liquid menstruum.*

Bennett, who believes his experiments to be opposed to the atmospheric germ theory, attributes the production or non-production of infusorial animalcules in infusions less to the presence of infusoria, or their germs in the air, than to the physical conditions of that medium—viz., temperature, density, and other physical qualities.†

Sanderson avers that "liquids which contain no particle distinguishable under the highest powers of the microscope can often be proved to possess the property of evolving microzyms (bacteria, etc.) after being boiled in sealed flasks without contact with external media"; and Bastian affirms that when infusions are of a highly fermentable order, and sufficiently strong, infusorial life is evolved even "*in vacuo*."‡

These statements appear very conclusive as against panspermism, or the germ theory; and if the matter had been allowed to rest here many of us doubtless would have felt ourselves constrained to believe in spontaneous generation. Lister, however, who greatly resembles Pasteur in ingenuity, industry, and philosophical acumen, has, it appears to me, fairly turned the tide against the heterogenists. In a paper communicated to the Royal Society of Edinburgh last winter (1873) he showed that many of the forms believed by the heterogenists to be the result of spontaneous generation were neither more nor less than the transitional or developmental forms of certain fungi which could be planted and raised from germs. Lister in fact succeeded not only in planting the minute fungi in question, but, what is more important, he succeeded in tracing them through all their changes from the germ to the bud, from the bud to the perfect plant, and from the perfect plant back again to the bud. The material first operated upon was fresh—*i.e.*, unboiled urine, procured by an antiseptic process in a perfectly uncontaminated condition. This urine was introduced into two wine glasses, supplied with porcelain lids, both of which had been heated far above the boiling point of water, and allowed to cool. When the wine glass with its contained urine was covered with a lid and placed under a glass shade, it remained for months without shadow of change either as regards the development of organisms or putrefaction. When, however, the glass shade and cover were removed, organisms of various kinds, and among them bacteria, soon made their appearance. The material next examined was Pasteur's solution, to which two drops of water from the tap had been added. When this fluid was exposed to the atmosphere, "a deposit which proved to be a minute filamentous fungus, producing abundant spores (conidia) on its branches, made its appearance. These spores, after separation, often produced young plants like the parents; but there were also seen in abundance precisely similar spores, multiplying by pullulation like a torula; and there were also present multitudes of more slender filaments, which were seen to break up into bacteria; while in several instances these filaments were observed springing from spores undistinguishable from those of the fungus."

The view that some filamentous fungi may give origin to both toruloid and bacteric forms (the latter endowed with vital movements) is new to science, and has done

* Wymann, by working with small quantities of infusions in proportion to the size of his flasks, and consequently with relatively greater volumes of calcined air, hardly ever failed to develop organisms in experiments which, in the hands of Pasteur, had produced none.—'Evolution,' p. 7.

* 'Hétérogénie.' Par F. A. Pouchet. Paris, 1859.—'Nouvelles Expériences sur la Génération Spontanée.' Par F. A. Pouchet. Paris, 1864.

† 'The Atmospheric Germ Theory.' By John Hughes Bennett, M.D., *Edin. Med. Jour.*, vol. xiii., pp. 810-33, 1868.

‡ In No. 6 of his experiments, Bastian states that active protamœbæ and ciliated monads were taken from a hermetically sealed flask, which eight weeks previously had been exposed to a temperature of 270°—275° F., and these very organisms were killed afterwards by a temperature of 140° F.

more towards establishing the truth of the germ theory and annihilating that of spontaneous generation than any experiments with which I am acquainted.*

Lister, in his experiments, employed, in addition to the urine and Pasteur's solution referred to, white of egg, milk, turnip infusion, and other substances ; but in every case with a precisely similar result. The importance of Lister's researches cannot be over-estimated. They are exceedingly interesting and instructive in a scientific point of view ; but their scientific value is indefinitely enhanced by the fact that they have for their ultimate aim the relief of suffering humanity.

Spontaneous generation represents one phase of the "theory of evolution." The other is : given a typical plant, or a typical plant and animal, all plants and animals proceed therefrom by infinite permutations, extending over indefinite periods. In other words, the highest plants proceed from the lowest by a series of gradations ; the highest plants and lowest animals merge into each other, and from the lowest animals the highest are ultimately produced. The latter doctrine is partly, but only partly, true. Plants and animals once created, endowed with vital powers and capable of reproducing themselves, may, under varying conditions and within certain limits, alter their several forms, and even their constitutions. I say within certain limits, for the variation is in no case indefinite. A horse remains a horse, and a dog a dog, whatever be the size, shape, and temper of those animals. While a horse and an ass are fruitful, their produce—the mule and hinny—are invariably barren. An animal may not depart from its original type indefinitely, and hope to perpetuate itself. This would introduce endless confusion. In reality, the limits within which reproduction is possible are exceedingly circumscribed, and confined in all cases to specific differences. The generic peculiarities remain always exactly the same under all circumstances. Civilization is based on the capacity for variation within certain limits. Education proceeds on the possible progression of the individual.

The doctrine of evolution has had an unusually able advocate in Darwin, a gentleman whose industry and learning are only equalled by his integrity and courage. Darwin, with infinite ingenuity and quite a plethora of fact, has endeavoured to show that, given one or more fundamental forms, the innumerable tribes of plants and animals may proceed therefrom by natural selection and by infinite permutation in infinite time. In other words, separate acts of creation are not necessary to produce species, and it is just possible not even genera. Darwin's colossal idea does not necessarily clash with that of a creative agency—it simply regards creation as a progressive rather than a finished work.

External conditions, in Darwin's opinion, modify in the fulness of time both plant and animal, and both advance in the scale of being—*i.e.*, plants and animals improve upon their former selves, the fittest always surviving. Darwin's law of the "*survival of the fittest*" affords another illustration of the interaction of the natural forces, for it shows that climatic, geological, and other physical changes modify the form and functions of plants and animals—in other words, modify and alter within certain limits the form and constitution of organic beings.

Darwin's hypothesis has thrown much light upon the complicated questions of natural affinity, the homologies of organs in various animals, and the recurrence in the embryos of the higher animals of structural peculiarities found in the lower ones. It has connected as by a silver thread the various palæontological forms in time and the several faunas and floras in space. It has endeavoured to establish an actual genealogy and consanguinity of organisms. As time advances, fresh links binding apparently irreconcilable types together are found, and in the old geological records of the past the actual transitional forms may be traced.

Few in the present day will doubt that many of the forms regarded by naturalists as distinct species of the same genus were originally derived from the same primitive form ; but the major question is still *sub judice*. It is not yet determined that "all mammals are derived from one original marsupial, all vertebrates from a primitive lancelet, and all plants and animals from the slimy protoplasm of a protiston." If, however, this should be proved at some future period to be the case, it will simply have the effect of reducing the number of separate creations ; it will not obliterate our belief in a great First Cause. It will neither impeach nor impugn the power of the Creator ; still less will it disprove his continued operation through eternal and immutable laws.

Gentlemen,—I fear I have trespassed equally upon your time and patience. The subject however chosen for this my introductory lecture demanded consecutive treatment. I could not consistently treat of the materials and forces employed in the organization of plants and animals, and omit the great modern doctrine of "natural selection." The points which I have endeavoured to illustrate in the course of my observations are these :—

Firstly. That organic and inorganic matter are correlated and interact.

Secondly. That the vital and physical forces are correlated and interact.

Thirdly and lastly. That living organisms cannot be produced from purely inorganic matter by purely physical forces.

* Dr. Bennett states that "no one can carefully watch the mode in which infusoria are developed without being satisfied that they originate from the coalescence of molecules, and not from ova or spores, as has been imagined." This author regards bacteria as simply oleo-albuminous molecular masses, aggregated by physical forces. This view is, of course, diametrically opposed to that of Mr. Lister.—'On the Atmospheric Germ Theory and Origin of Infusoria.' (*Monthly Journal of Medical Science*, March, 1868).

EAST INDIAN PROGRESS.*

According to Act of Parliament, the Secretary of State and Council of India within fourteen days after the 1st of May, have to present to Parliament an account of the state of Indian finances, and "such account shall be accompanied by a statement prepared from detailed reports from each Presidency and District in India, in such form as shall exhibit the moral and material progress and condition of India in each such Presidency."

From 1858 to 1865 these reports were presented in the form in which they arrived from India, without arrangement or condensation, and thus failed to meet the objects of the Act. It was therefore determined to prepare at the India Office a condensed report, based on those received from India. The present report has been confided to the able editorship of Mr. C. R. Markham, C.B., and is everything one could desire.

The substance of the report is distributed under the following headings :—Administration, Finance, Land Revenue, Agriculture, Irrigation, Communications (railways, roads, canals, harbours, etc.), Forests, Minerals, Trade and Manufactures, Condition of the People, Police and Justice, Education, Political, Military, and lastly, Surveys, etc. A general appendix of tables closes the report.

The most useful measure of legislation mentioned in this report is the creation by Lord Mayo, in June, 1871, of a new "department of revenue, agriculture, and commerce." This department has charge of all questions relating to land revenue, settlements, agriculture and horticulture, and Government aids for their improvement, horse and cattle breeding, silks and fibres, forests, commerce, trade and customs, salt, opium, industrial arts, etc.

* 'East India (Progress and Condition). Statement of the Moral and Material Progress and Condition during the year 1871-72.' Ordered by the House of Commons to be printed, April 28th, 1873, pp. xii., 159, with 15 maps.

It also has the charge of census returns, statistics, surveys, geology, meteorology, and such like questions. The want of such a department had long been felt, and questions relating to the trade of the great staple products of agriculture and manufacture, the development of these and the introduction of new products were scattered through many departments, and their solution, as in all such cases, seemed to be the business of nobody, and thus much loss and waste was the result. But better things are hoped for now that the whole matter is under one special department. Under the head of Finance the following interesting figures are given :—The income for 1871-2 amounted to £50,110,215 made up as follows :—Land revenue, £20,000,000 ; opium, £9,000,000 ; salt, nearly £6,000,000 ; from customs, excise and stamps, over £7,000,000 ; the remainder being made up from taxes on various smaller items. With regard to salt, beside the home production obtained from mines and salt lakes, there is a large importation, chiefly from England. The quantity imported last year into Bengal was 5,765,177 cwt. Opium sales met with much higher rates last year than in the preceding. The other custom duties were on imports of cotton goods chiefly, and to a less amount on liquors and metals. The export dues are chiefly on rice, oil seeds, indigo, lac, and cocoanut oil. The exportation of jute, cotton, silk, tea, saltpetre and sugar is free.

The income-tax, as in England, has given rise to much complaint, and though by raising the minimum taxable income to £100 many objections were removed, yet the announcement of its total abolition has given universal satisfaction.

In Bengal the agricultural yield last year was one of abundance, the rain being very plentiful. The jute crop was an extraordinarily good one, but the indigo crops were much injured, In many places indigo has given place to jute, as the latter is the more profitable to cultivate. In the North-West Provinces the spring harvest of 1871 was good, but the autumn crop was bad ; but the improved means of transport lessened the local dearth. In parts of Madras, owing to the failure of the north-east monsoon, there was a drought, which, but for the prompt importation of grain from Cattack, might have resulted in overwhelming distress.

The important bearing meteorology has on agriculture is beginning to be acknowledged by the administration, and a number of stations are now scattered throughout India under the charge of an efficient staff, and some very important observations have been published.

The various agricultural societies of India have done much good, and some receive annual grants from the Government.

There are some interesting remarks on the cultivation of cotton, jute, rhea fibre, and date palm—the latter grown from seeds and cuttings obtained from the Persian Gulf—and also remarks on sericulture. Beside these and other substances attended to in the plains of India, the cultivation of cinchona, tea, and coffee are important agricultural industries on the mountains. Coffee culture commenced in Wynaad in 1840, and in the last year the value of the export alone amounted to £1,383,416. representing 56,889,888 lbs. In Darjilling there are sixty-two tea gardens, with an outturn of 2,665,821 lbs. ; Asam gave 6,257,643 lbs. ; Cachar, 5,406,400 lbs. ; and Silhet, 4,641,659 lbs.

India can produce a much larger quantity than this ; and if it be remembered that Indian teas are beginning to be now regarded with considerable favour, this industry will appear as one of the most promising. The reports on cinchona place the success of that undertaking beyond all doubt, even in a monetary point of view. Cardamoms grow wild in the Western Ghauts, and the yield in the forests of Mysor alone amounted in 1870-71 to 26 tons, valued at £17,000. Last year instructions were given for the demarcation of such tracts of jungle as were favourable for the growth of this spice, and coffee planters are turning their attention to its cultivation. Several cases of ipecacuanha have arrived in Calcutta in good condition, and will be planted in Sikkim. Carolina rice, which we believe was first obtained from Madagascar, is very successful in India, and cochineal insects, obtained from Teneriffe, have been introduced into Mysor, and promise well.

Fish forms one of the chief articles of food, and in some places the only animal food used at all. The native fishermen in this, as in all other cases, have been very destructive, and Dr. Day, to whom the question has been submitted, recommends that nets with meshes below a certain size should not be allowed, that poisoning streams with various narcotics, a custom very prevalent in India, should be put a stop to, and that a "close time" should be introduced. The attention to be bestowed to agriculture becomes more and more necessary on the part of Government, as it seems likely that in time it will become the only employment left to many who now support themselves by manufacturing articles which are fast being ousted from the bazaars by those manufactured in England.

The question of irrigation is one of the most important questions with which the Government has to cope. The rainfall in India is very different in various parts. There are two dry zones with between fifteen and thirty inches of rain, the "Northern Dry Zone" extending from Sind and Kach to the Panjab, forming a belt from 100 to 200 miles broad, including Agra, Delhi, and Lahor ; and a "Southern Dry Zone," extending from a little below Surat to Cape Cormorin, in the centre of the country, at a distance from the two seas. These regions absolutely require irrigation. The next region has a rainfall between thirty and sixty inches, and includes the upper part of the Valley of the Ganges, Central India, and the Eastern Coast. This region also requires irrigation. The next region has a rainfall between sixty and seventy-five inches, and includes the deltas of the Mahanadi and Ganges, and the lower part of the Ganges Valley. Here irrigation is rather a luxury than a necessity except in extraordinary years. Lastly, we have two belts of excessive rainfall of seventy-five inches and above, one in the north extending from the mouth of the Irawadi, along the east coast of the Bay of Bengal, up the Valley of the Brahmaputra, and along the skirts of the Himalaya Mountains ; and the second belt along the west coast of the peninsula, from the sea-shore to the summit of the ghauts. In these, of course, artificial irrigation is unnecessary. Great irrigation canals have been undertaken wherever there is a deficiency of rainfall, and the Government are carrying out such works in a prompt and systematic manner, in order to guard against failure of crops, and thus obviate such fearful famines as the inhabitants of these parts of India have been more than once subjected to. The effect of such works of construction, even in a moral sense, cannot be over-estimated, as cases are not unknown in which wild, unruly cattle-lifters, who followed such a life through the dryness of the soil not allowing of cultivation, have become thrifty, peaceful and industrious. In the rainy districts it is necessary to keep the banks of the rivers in good repair, as the surrounding land is below the level, and has therefore to be guarded against destructive inundation.

Under the head of Forests we have a very good *résumé* of the subject. The objects of the forest department are to supply building, furniture, and fire-wood for home consumption in towns and on railways, and for exportation, and to meet the demand for lac, catechu, caoutchouc, and other forest products. As the conservation of forests is absolutely necessary to protect the land from destruction and to ensure necessary timber supplies, it is not, therefore, or at least should not be, the immediate object of the Government to make forests a profitable speculation or a means of raising a revenue like that obtained from opium. Indeed, any such surplus forest revenue should always be applied to forest improvement where necessary. Still though forestry in India is in its infancy, yet suffi-

cient has been done to prove it a financial success. Beside the cinchona many exotic plants have been introduced, amongst these the Australian eucalyptus and acacia. The training of candidates for forest appointments has yielded good results. Facilities are now offered for studying forestry in Europe, and we have recently had occasion to speak in high terms in this Journal of reports on German and English forests, by Captain Walker and others. Major Beddome has published a 'Flora Sylvatica' and Dr. Brandis is preparing a 'Forest Flora,' both being destined for the guidance of forest officers.

The main system of Indian railways is nearly completed, bringing all the large towns in communication with each other and with the coast. The good effects of this system have already been recognized by the natives, as when there has been a bad harvest in a certain district the prices have not been affected at all, supplies being promptly brought in from surrounding districts. It also has had and will have greater effects in bringing larger quantities of staple articles to market and thus cheapening them. There is a complete telegraphic service along every railway, thus connecting every important place throughout India. Harbours, anchorages, and marine surveys have too engaged much attention, and great improvements have been made.

The mineral wealth of India is practically confined to its coal seams, its salt mines and iron ore. Indian coal has 10 to 30 per cent. of ash, and 52 per cent. of fixed carbon, and as compared with average English coal, with its 2·7 per cent. ash and 68 per cent. fixed carbon, is capable of only doing one-third to two-thirds of the work which an equal weight of the latter would accomplish. The most important coalfield is that known as the Raniganj to the N.W. of Calcutta. In 1868 out of 497,000 tons extracted in India, 493,000 tons was from this mine alone. Its area is from 500 to 600 square miles, and its available contents are roughly estimated by Dr. Oldham as 14,000,000,000 tons. Iron-producing minerals are widely scattered over India, and consist of magnetic and specular iron ores and red hematite in beds, veins of clay iron ores from the coal-bearing strata, and from surface deposits derived from the waste of metamorphic and sedimentary strata and from laterite. In the Salem district of the Madras Presidency the ores occur in immense beds 50 to 100 feet thick, and the outcrop can be traced for miles. On one hill in the same district there are five beds of magnetic iron ore, from 20 to 50 feet thick, and in other parts of India the supply of hematite, clay, and surface deposit iron ore seems inexhaustible. Natives of a very low caste have smelted iron ore from time immemorial, but all the attempts made by the English in manufacturing iron have hitherto utterly failed. In one case, we are told, after £75,000 had been spent in preliminaries, and all obstacles had been overcome, and the enterprise promised well and might have been most successful, the Government suddenly closed the works and offered them for sale, but without success. The matter has again however been taken up. Salt, copper, lead, tin, gold, silver, antimony, cobalt, and petroleum have been found in greater or less abundance, and in some instances worked largely.

The labours of Dr. Oldham and the staff of the Geological Survey are highly spoken of. In the space of twenty-two years, in spite of climate, inaccessibility of districts, and slowness of travel, they have examined an area about four times the size of Great Britain, and have published the results in a series of 'Memoirs,' illustrated with a superb series of figures and descriptions, maps, and plates, and the organic remains, in the *Palæontologia Indica*.

The trade of India is only represented in a small degree by the returns from the great seaports, for the bulk of the productions are consumed in India itself, and the external commerce is only a fraction of the internal trade. The value of the exports for last year was £64,661,940, the chief items being the following:—Coffee, £1,380,409; cotton, £21,272,430; grains, £4,865,748; indigo, £3,705,475; opium, £13,365,228; seeds, £2,728,127; tea, £1,482,185; and wool, £906,699. The value of the imports is stated at £42,657,560, consisting chiefly of cotton-yarn and goods, machinery, railway iron and stores, raw silk and silk goods, wines, etc. One of the most curious and interesting features of Indian trade is the quantity of gold and silver imported and the small amount exported. Thus £11,573,813 represents the imports of last year, and only £1,476,093 the export. Much is used in ornaments, and large quantities are hoarded up. This has been so from time immemorial.

A census return throughout India gives about 260,000,000 as the number of inhabitants, but there is reason to believe it is somewhat higher, from the difficulties in taking a census amongst a people often so mistaking its object as to believe in some instances that the Government intended to blow the surplus population from guns, and a man was known to hide his babies, lest he should be taxed for them! The returns of births and deaths are at present very unreliable. The wages for skilled labour vary from 3*d.* to 2*s.*, and for unskilled, 1½*d.* to 6*d.* per day. As to the morality of the natives, they are said to be singularly temperate as a rule; chaste, honest, peaceful, singularly docile, easily governed, and patient. There is, however, as one might expect amongst so many races, great diversity of temperament and character.

Emigration takes place to a large extent, and the Government take every precaution to protect the Coolies from injustice and false representations.

Under the head of police and justice there is much to interest one. The lawyers get much practice—at least too much for the people's good. Besides the village watchmen, there are 190,000 constables, who have much to do in looking after hereditary thieves. In the N.W. Provinces there are twenty-nine tribes who have for generations devoted part of each year to the profession of cattle-lifting and such like, as a means of gaining an honest living.

Infanticide, especially of girls, from hereditary custom and habit, is very prevalent, but it is gradually lessening as the people begin to be ashamed of it. European vagrants or "mean whites" give much trouble, and great attention is paid to the jails as to their management and sanitation.

There are numerous colleges and schools founded, and taught both by natives as well as Europeans. The missionaries' labours have been of great value in this field; they have always studied well the vernacular languages, and given a great impulse to literary progress, as the report bears testimony.

We cannot help, in closing, noticing the orthography of the proper names. Great efforts have been made to render the spelling of such names more correct; and the system of Dr. Hunter's, based on that of the late Sir Wm. Jones, is officially recognized. But one has to look twice before old faces are recognized in their new dress, such as Burma or Barmah, Rangun, Panjab, Arakan, Asam, Lacknow, and many others. We trust, however, it will be soon permanently settled. Even in the present report we find the same locality spelt as Burma, Burmah, and Barmah, and these are not the only instances. There are many interesting points before us we should like to notice in this report, so unlike what other blue books through which one has to "wade," whereas this is more like a volume of essays, and, together with the admirable map by which each division is illustrated, forms such a summary that the thanks of all who are interested in Indian affairs is due to Mr. Markam for the admirable manner in which he has accomplished his by no means easy task.

COLORATION OF CHLORALHYDRATE BY OIL OF PEPPERMINT.

It is stated by Carl Jehn that if hydrate of chloral be agitated with oil of pepperment, a reddish colour is

soon developed in the mixture, which gradually darkens to cherry-red. The colour is readily soluble in ether, alcohol, and chloroform; boiling does not destroy it; sulphuric acid heightens its intensity, and, if now chloroform be added, a dark, violet tint is produced. The oils of lemon, bergamot, juniper, crisped mint, rosemary, cloves, anise and fennel, do not produce any coloration with chloral hydrate.—*Archiv. d. Pharm.*

SCALE OF MEDICINES AND MEDICAL STORES

ISSUED AND CAUSED TO BE PUBLISHED BY THE BOARD OF TRADE IN PURSUANCE OF THE MERCHANT SHIPPING ACT, 1867.

MEDICAL SCALE FOR MERCHANT SHIPS.

The annexed Scale of Medicines and Medical Stores for Merchant Ships has been issued and caused to be published by the Board of Trade, and is intended to supersede the Scale hitherto in force.

THOMAS GRAY.

Preparations from British Pharmacopœia, 1867. This column is added for the use of Druggists supplying the Medicines indicated.	Names of Medicines, Medicaments, etc.	Proportion for Ships carrying the undermentioned number of Men and Boys (for twelve months). 10 and under.	11 to 20 inclusive.	21 and upwards.
	Alum	1 oz.	2 ozs.	3 ozs.
Copaiba	Balsam of copaiba	4 ozs.	8 „	12 „
	Bicarb. of soda...	8 „	12 „	16 „
*Mist. Sennæ Co.	Black draught	1 pint	2 pints	3 pints.
Lotio Hydrarg. Nigra	Black wash	1 „	2 „	2 „
A mixture containing in each 100 parts not less than 80 parts of Carbolic (or Phenic) and Cresylic Acids, and their Homologues; and not more than 20 parts of water.	†Carbolic acid, liquid	½ gal.	1 gal.	2 gals.
	Or crystal	½ lb.	1 lb.	2 lbs.
	Castor oil	1 lb	2 lbs.	3 lbs.
	†Chloralum or			
	†Chloride of zinc (solution of)	4 pints.	8 pints	16 pints.
Potassæ Tartras Acida	Cream of tartar	2 ozs.	4 ozs.	8 ozs.
	‡Condy's Crimson Fluid ..	½ pint	1 pint	1 pint.
	Epsom salts	3 lbs.	6 lbs.	12 lbs.

ESSENTIAL OILS FROM SICILY.

A large export trade is carried on between Sicily and this country in the essences of bergamot, orange, and lemon. The value of these essences, which are chiefly shipped from Messina, amounted in 1871 to £143,500, out of which England took £97,000. The prices of the essences, owing to the increased demand, have risen enormously since 1869, thus, essence of orange has sprung from 5*s.* the pound in 1869, to 14*s.* in 1871, and essence of lemons rose from 8*s.* to 19*s.* the pound.

A large trade is also done in concentrated lemon juice, which is consumed almost entirely by England, a small quantity only being sent to France and the north of Europe. "It is made and shipped principally at Messina, and the total value of the export in 1869 was about £63,000; in 1870, about £75,000, and in 1871, about £90,000. Owing to the increased demand on the one hand, and the lemon disease on the other, the price has advanced greatly during the last few years. In 1869 it was from £25 to £30 the pipe of 100 imperial gallons; in 1870 it rose to £33,000, and in 1871 to nearly £50 the pipe."

The Pharmaceutical Journal.

SATURDAY, JANUARY 10, 1874.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square,*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

MEDICAL SCALE FOR MERCHANT SHIPS.

The Board of Trade, in the exercise of powers granted to it under the Health Clauses of the Merchant Shipping Act of 1867, has just issued an Amended Scale of Medicines and Medical Stores required to be carried in all foreign-going merchant ships belonging to the United Kingdom. A copy of this Scale will be found in another column, to which we take leave to direct special attention, as many important changes and additions have been made. It is to be observed that Chloralum is now added, and the shipowner is left to choose between this so-called disinfectant and the solution of Chloride of Zinc, one of which must be taken in the medicine chest, in addition to Carbolic Acid and Condy's Fluid, so that, as regards antiseptics, deodorants, and disinfectants, the mind of the ship-captain is likely to be more confused than ever. We are somewhat curious to know whether any attempt to simplify matters on this head will be made in the next edition of the authorized Medical Guide. Great credit was claimed for this Scale of Medicines, when revised in 1867, on the score of simplicity, and it is much to be regretted, on behalf of the non-professional prescribers afloat, that this virtue appears to be now little regarded.

It will be observed that Spirit of Nitrous Ether is now called Sweet Spirit of Nitre, the latter being a more popular and better known designation. Treble instead of double the quantity of Quinine indicated is to be taken to all tropical parts, and a larger quantity of Sulphur is ordered, for, as we presume, purposes of fumigation.

The particulars relative to the scales of medical stores and necessaries set forth that the weights and measures are to be marked in English figures, the words scruple and minim are to be abolished, and the drachm fluid measure is to be divided into forty drops. This plain system of marking weights and measures is, for this special purpose, very important, and we believe that the novel mode of graduating the drachm measure will be found in practice sufficiently accurate, and will certainly simplify the matter to the uninitiated very considerably. Two additional sets of bandages have been added. The triangular bandage was adopted very extensively in the last Franco-German war, and is most useful, but proper directions for its application must of course appear in the Guide. As flannel bandages are wanted for broken ribs, and are specially prescribed for this purpose in the chapter on accidents, it is proper that they should find a place in the chest. We are also reminded that the catheter is to be of gum elastic. Finally, besides desiccated soup, the preserved vegetables carried may be either of the dried or compressed variety, many kinds of both of which are now prepared. We are glad to record a belief that, with the exceptions above-mentioned, the changes and additions made are good and useful, although much still remains to be done in improving the general arrangements of medicine chests. It would be well if the professional advisers of the Board of Trade were called upon to give a report upon this subject, and associated for the purpose with some one of our chemists whose large practical experience would be valuable in such a matter.

It should be remarked that copies of this Amended Scale can be obtained at all mercantile marine offices in London and throughout the kingdom, on application to the superintendents.

SWEET SPIRIT OF NITRE.

WHEN speaking of the opinion recently volunteered by the *Lancet* that sweet spirit of nitre "possesses absolutely no value whatever," we ventured to express a doubt whether the demand for it would be materially influenced by the statement. We are, therefore, not surprised to find that this somewhat superfluous dictum of the *Lancet* has not been accepted as correct by the medical profession. As an indication of this we may mention that Mr. F. H. ALDERSON has written to our contemporary saying that the opinion has astounded him, since, during his student days, Dr. HENRY THOMPSON gave to the students of his class, as one of the questions in the prize competition in materia medica, the mode of preparation and uses of spiritus ætheris nitrici. Moreover, he has always believed the therapeutic effects of nitric ether to be, as NELIGAN states, those of a mildly stimulating diuretic, rendering the action of digitalis, squill, and other diuretics more certain.

Mr. ALDERSON further remarks that if he and others have been mistaken as to the efficacy of the spiritus ætheris nitrici, they may have been prescribing an inert drug, and he is very desirous that this point should be cleared up. He proposes, therefore, that every medical man should have an opportunity of replying to the following questions :—(1) Do you prescribe sp. ætheris nitrici, P. L., or sp. ætheris nitrosi, B. P., or neither? (2) Is sp. ætheris nitrici or sp. ætheris nitrosi in your opinion a drug of any value? (3) What do you consider to be the therapeutical effects of sp. ætheris nitrici or sp. ætheris nitrosi?

We congratulate the *Lancet* upon publishing this contribution to its own stultification.

POISONING BY VINUM COLCHICI.

A REMARKABLE case of poisoning by colchicum wine is reported from Montreal, at least six persons having lost their lives through it. The *Canadian Pharmaceutical Journal,* to which we are indebted

for details, states that a few days before the 27th November, a druggist received from a wholesale house (Messrs. Evans, Mercer and Co.) a bottle containing half a gallon of vinum colchici, but having a sufficient quantity on hand, decided on returning it. On the way, however, it was stolen from the carman to whom it was entrusted, and taken by the thieves to their home in one of the lowest parts of the city of Montreal. There upon examination it was pronounced to be sherry, and was freely supplied to several persons. A boy, to whom a mugful was given, was soon taken ill, and shortly after died. In great consternation medical help was called in, but at the time of writing five other persons,—two men and three women,—had died, and several others were in great danger. The symptoms were those of poisoning by colchicum,—constant vomiting and purging, accompanied by violent abdominal pains. The pulse was weak but rapid, as high as 120 or 130. Consciousness was in general retained almost up to the time of death. It had not yet appeared whether the wine was the *Vinum Colchici*, B. P., prepared from the corms, of which half a drachm is the maximum dose, or the *Vinum Colchici Seminis*, U. S. P., frequently ordered in Canada, of which the maximum dose is two drachms.

THE TRAFFIC IN PERCENTAGES.

The *Canadian Pharmaceutical Journal*, in endorsing the views recently expressed in this Journal respecting the traffic in percentages generally associated in this country with "Philippic formulæ," remarks that in the cities and larger towns of Canada, the percentage system has been largely and openly practised, but is now rapidly falling into disuse. A correspondent writing from Montreal says, that, with two or three exceptions, the leading physicians in that city are pretty well frightened out of the practice, and that if they now accept any pecuniary consideration, it is in the shape of a present at Christmas. This result is attributed to the improved status of pharmacists generally, which has also brought with it an independence of feeling "directly hostile and repugnant to the debasing truckling which characterizes the trade in percentages." Our contemporary is of opinion that "the severance of this self-imposed bond of servility will obliterate the sole remaining sign of medical dominion, erase a most dishonourable blot from the pharmaceutical escutcheon, and remove a cause of ill-feeling which of all others has been a most prolific source of contention." We commend these vigorous contemptuous words to the careful consideration of the few pharmacists who may yet countenance the traffic.

As will be observed by a notice in another part of this Journal, the 'Year Book of Pharmacy' for 1873 is now ready, and it will be issued at once to all members who have paid the current year's subscription. We have been favoured by the Honorary Secretaries with an early copy, and hope to notice the book more fully next week.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL,

Wednesday, January 7th, 1874.

MR. THOMAS HYDE HILLS, PRESIDENT.

MR. ALEXANDER BOTTLE, VICE-PRESIDENT.

Present—Messrs. Atherton, Baynes, Betty, Brown, Greenish, Hampson, Owen, Radley, Robbins, Sandford, Savage, Schacht, Stoddart, Sutton, Urwick, and Williams.

The minutes of the previous meeting were read and confirmed.

Resolved, that the following Pharmaceutical Chemists be elected Members of the Society :—

Bird, Matthew Mitchell .....King's Lynn.
Gibson, Adam .....Leven.
Leake, Thomas Whaplate .....London.
Normand, Claude ..... Shepherd's Bush.
Stewart, James .....Dalkeith.
Gardner, James Richard .....Plymouth.
Troake, Marler Hamilton .....Helston.

Resolved, that the following registered Chemists and Druggists be elected Members of the Society :—

Bowes, Joseph .....Whitehaven.
Hardman, James William .....Leeds.
Harwood, Charles..... .....Folkestone.
Holloway, John.....Wood Green.
Owbridge, Walter Tom.....Kingston-upon-Hull.
Pickburn, George Henry.....Kidsgrove.
Winship, James.....York.
Wylde, George .....Chelsea.

Resolved, that the following, having passed their respective examinations, and being in business on their own account, be elected "Associates in Business" of the Society.

MINOR.

Foster, Harry Pibworth .....Portsea.
Miller, Kenneth .....Pulteney Town, N.B.
Tuck, William James .....Landport.
Williams, Jabez Vivian .....Weymouth.
Williams, William Griffith .....Abergele.

MODIFIED.

Ashton, Alfred .. ..Camden Town.
Clarke, Joseph Adam .....Glasgow.
Greatrex, Henry .....Birmingham.
Jones, Hugh ....St. Asaph.
Kay, John .....Crewe.
Vaughan, William George .....Aberystwith.

Resolved, that the following, having passed their respective Examinations, be elected Associates of the Society :—

MINOR.

Atkinson, John George .....Horncastle.
Barlow, Joseph Alexander .....Rochdale.
Bennett, Henry Charles .....Leigh.
Brown, John Macdonald .....Dunfermline.
Bumpstead, Robert George .....Colchester.
Collins, Thomas Robert .....Leicester.
Dobson, George.....Egremont, Birkenhead.
Fuller, Thomas .....Fallowfield.
Hamond, Joseph .....Peterborough.
Hunt, Freeman William .....London.
Hunter, John Carswell.....Glasgow.
Jones, Walter .....Carmarthen.
Levy, Samuel Edward ... .Liverpool.
Longley, Joseph .....Barnsley.
Luff, Arthur Pearson .....Old Brompton.
Macaulay, Joseph John .....Manchester.
Macmillan, James Laker.....Glasgow.
Pownall, Thomas .....Mold.
Price, James .....Market Drayton.
Read, William .....Havant.

Sawden, Alfred .....Filey.
Smith, Alfred Lambert .....Birmingham.
Stuart, Thomas Peter Anderson Dumfries.
Thomas, Frank .....Boston.
Thompson, Mark Foggett.. .....Thirsk.
White, Robert .....Durham.
Whitlamsmith, Walter.....Uppingham.

MODIFIED.

Banbury, William Walter .....Burford.
Garry, George .....Glasgow.
Lutwyche, Henry John .....London.
Monkhouse, Henry .....Derby.
Wright, John Walter .....Stockport.

Resolved, that the following, having passed the Preliminary Examination, be elected "Apprentices or Students" of the Society :—

Abraham, Alfred Clay .....Liverpool.
Alcock, Frank Harris .....Burslem.
Barrat, Reuben .....Kingston-on-Thames
Biddles, William Byron .....Reading.
Blackwell, Josiah .....St. Austell.
Clower, John.....Nottingham.
Cornish, James Mitchell .....Penzance.
Cridland, Francis Edwd. John..Devizes.
Crook, Herbert .....Gravesend.
Crowden, Samuel Graham .....Buckie.
Cumine, Rupert Henry .....Kingston-on-Thames
Davies, Daniel Rees.....Kilburn.
Davies, John.....Newcastle Emlyn.
Dobson, George Turner .....Holsworthy.
Draper, James William .....Malmesbury.
FitzGerald, John Anthony .....London.
Fowler, George.....London.
Greenough, Hugh Fairhurst ...Manchester.
Grove, Harry Nicholas.....Walsall.
Hall, William.....Portsmouth.
Harmer, James Dorkin .....Kingston-on-Thames.
Haycraft, Henry Robert Howell Glasgow.
Hayton, Peter Bamlett.....Leeds.
Holmes, George.....Sheffield.
Maben, Thomas.....Hawick.
Mitchell, Joe Charles .....Barnsley.
Needham, Francis David.....Dublin.
Northen, Charles .....Thorpe-by-Water.
Ord, Septimus William .....Newcastle-on-Tyne.
Page, Robert Steele .....London.
Parker, John Wortley .....Barnstaple.
Parker, Robert Henry .....Barnstaple.
Powell, John Alfred.....Reading.
Ritson, Fletcher .....Carlisle.
Savery, John Manly.....Loughborough.
Saville, William... .....Leeds.
Sell, William Henry.....Bath.
Smith, Joseph .....Manchester.
Tomlinson, Eldred Edward .....Whitehaven.
Urwick Charles.....London.
Watts, James Orr.....Stafford.
Weston, Benjamin.....Fenton.

Four persons who had neglected to pay their subscriptions within the proper time were restored to their former status on payment of the current year's subscription and a fine, in accordance with the new bye-law.

THE UNIVERSITY OF STRASBOURG.
